The SATA controller supports three levels of software reset, each of which has different impact over the SATA HBA hardware components and AHCI interface registers:

- Software reset (least intrusive)
- Port reset
- HBA reset (most intrusive)

NOTE: It is recommended that user software always starts with the least intrusive reset approach. Software chooses the next most intrusive reset only if the less intrusive reset does not succeed in clearing the condition.

24.8.4.3.2.1 Software Reset

Software reset impacts only the attached to the HBA port SATA peripheral device, without affecting the established communication between physical layers or HBA engine.

To issue a software reset, the user must prepare two H2D register FISs into the emptied command list of the port. The first FIS must have bits SRST = 0b1 and C = 0b0. The first FIS corresponding command header bits C and R are set as follows: C = 0b1 and R = 0b1.The second FIS has bits SRST = 0b0 and C = 0b0. The second FIS corresponding command header bits C and R are set as follows: C = 0b0 and R = 0b0.

However, steps must be taken before issuing the software reset to the peripheral device attached to the port. For details on software reset, see the AHCI specification.

Copyright © 2015–2017, Texas Instruments Incorporated

24.8.4.3.2.2 Port Reset

The port reset (also known as COMRESET) must be applied when the HBA port does not function properly after a software reset is issued to the port. The effect is that the SATA HBA port is reinitialized and communication between the phy layers of both the SATA host and the SATA target device is reestablished.

To trigger a COMRESET sequence on the SATA interface, user software must write 0x1 to the SATA_PxSCTL[3:0]DET bit field. The host receives a COMINIT signal sequence, indicating that the peripheral device has successfully reestablished communication. For more information on port reset, see the AHCI specification (revision 1.1).

NOTE: The port reset (COMRESET) method is the preferred AHCI mechanism for error recovery and should be used instead of the software reset.

24.8.4.3.2.3 HBA Reset

Software can globally reset the SATA controller, if a port reset does not clear the conditions successfully. On HBA reset, all SATA AHCI core interface registers are reset, **excluding those from the hardware initialization domain** - the SATA_PxCLB, SATA_PxCLBU, SATA_PxFB and SATA_PxFBU registers. All state machines that relate to data transfers and queuing return to IDLE state, and the port is reinitialized by sending COMRESET. The global reset is triggered when user software sets the SATA_GHC[0]HR = 0b1 bit. The HBA indicates that global reset is finished, deasserting the SATA_GHC[0]HR bit to 0b0 in hardware. Hence, user software must poll the HR bit to detect this condition. For more information, see the mentioned AHCI standard specification.

24.8.4.4 Power Management

The device SATA host controller subsystem power management can be identified at the following levels:

- SATA controller low power-management features (defined also in the SATA standard specification, revision 2.6)
- Master standby and idle slave protocols established between SATA controller and the device PRCM through a SATA AHCI core wrapper interface (signified as SATAMAC_wrapper instance inside the Section 24.8.6.1, *SATA Controller Instance Summary*).

This section describes the relationships that exist between both levels of SATA Controller power management.

24.8.4.4.1 SATA Specific Power Management

The SATA controller core supports both PARTIAL and SLUMBER low-power states, as described in the SATA standard specification (revision 2.6). These modes allow power savings by powering down part of SATA_PHY and gating off the clocks to the link layer. The port power control module is used to enter and exit these modes, which can have the normal functional clocks gated off.

24.8.4.4.1.1 PARTIAL Power Mode

In the PARTIAL power state, the SATA_PHY component transmits electrical IDLE to the device and the receiver is left on to receive OOB signals. This mode can also be used to support near-end analog loopback, if a device is attached.

24.8.4.4.1.2 Slumber Power Mode

In the SLUMBER power state, the transmitter is completely turned off. This allows for greater power savings but near-end analog loopback cannot be performed and there is a longer latency to exit the mode.

24.8.4.4.1.3 Software Control over Low Power States

The user has manual control over low power states through the SATA_PxCMD [31:28]ICC register bit field. This works if the link is in IDLE state; otherwise, writes to this field are ignored.

Copyright © 2015–2017, Texas Instruments Incorporated

24.8.4.4.1.4 Aggressive Power Management

Low power modes can be initiated by software when there are no pending transactions, but the SATA AHCI core also supports aggressive power management. In this mode, the subsystem automatically initiates the PARTIAL or SLUMBER state when there are no inflight commands. This is useful for power savings, but the price is increased latency if a low-power mode is entered and a transfer request is made. Software enables aggressive link-layer power management by setting the SATA_PxCMD[26]ALPE bit to 0x1. The link aggressive power management state (PARTIAL or SLUMBER) is selected using the SATA_PxCMD[27]ASP bit.

24.8.4.4.2 Master Standby and Slave Idle Management Protocols

The master standby and slave idle protocols are implemented between the PRCM and SATA controller, with mode settings located in the SATAMAC_wrapper register (SATA_SYSCONFIG).

- The standard idle request/acknowledge handshake is associated with the L4_CFG slave port. The default idle mode is smart-idle, as indicated by the power-on reset (POR) value: SATA_SYSCONFIG[3:2]IDLEMODE = 0x2.

NOTE: No other mode is expected to be required in normal operation: no-idle and force-idle are used for debugging only. Because the module is not capable of asynchronous wakeup, the smart-idle/wakeup (IDLEMODE = 0x3) is strictly equivalent to smart-idle.

- The standby/wait handshake is associated with the L3_MAIN master port. Software is responsible to keep the DMA operations and the standby status in sync.

The default standby mode is smart-standby, as indicated by the POR value: SATA_SYSCONFIG[5:4]STANDBYMODE = 0x2. However, the SATA controller hardware does not provide any indication about DMA activity that could be used to drive the standby dynamically (that is, the smart mode): Smart-standby is therefore strictly equivalent to the force-standby mode (that is, the module remains in or goes to permanent standby).

The standby control procedures are therefore software-driven.

To exit standby:

1. Change the standby mode to no-standby by setting SATA_SYSCONFIG[5:4] = 0x1.
2. Optional: Confirm the SATA controller standby status through the PRCM. For more information, see Section 3.6.4.1.4, *Clock Domain Module Attributes*, in Chapter 3, *Power, Reset, and Clock Management*.
3. Only then, enable the controller DMA (AHCI list processor). For more information, see the AHCI specification.

To enter standby:

1. Disable the controller DMA (AHCI list processor). For more information, see the AHCI specification.
2. Ensure all pending transactions have completed. For more information, see the AHCI specification.
3. Change the standby mode to smart-standby (or force-standby) by setting SATA_SYSCONFIG[5:4] = 0x2.

CAUTION

The software is responsible to keep the DMA operations and the standby mode status in sync.

NOTE: Because the standby exit is software driven, it is by definition synchronous: the asynchronous wakeup is never activated, which means that the smart-standby and smart-standby/wakeup are equivalent (as well as force-standby).

Copyright © 2015–2017, Texas Instruments Incorporated

NOTE: For more information on the SATA Controller master standby and slave idle management protocols with the device PRCM , see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

24.8.4.4.3 Clock Gating Synchronization

The bus clock can also be gated off in either the PARTIAL or SLUMBER state, if the software guarantees there is nothing in flight, the clock can be stopped and started without glitches, and the clock can be restarted quickly when activity is initiated from the device side.

The following steps outline the procedure to stop the clock:

1. Put the link in a low power state (either PARTIAL or SLUMBER)
   - SATA MAC link layer can enter low power either manually see Section 24.8.4.4.1.3, *Software Control over Low Power States*) or automatically (see Section 24.8.4.4.1.4, *Aggressive Power Management*)
   - If there is no device attached (making it impossible to enter a low power state), the SATA_SYSCONFIG[16] OVERRIDE0 override bit can be set to 0b1 to stop the interface/functional clock (SATA_FICLK) and save power.
2. Initiate the clock stopping procedure.

CAUTION

If a SATA drive attached to the SATA HBA port has not entered a low power state (PARTIAL or SLUMBER), the user must not set the SATA_SYSCONFIG[16]OVERRIDE0 bit; otherwise, the link layer can be ruined, resulting in indeterminate SATA controller behavior.

Table 24-571. Local Power-Management Features

Feature	Registers	Description
Slave idle modes	SATA_SYSCONFIG [3:2]IDLEMODE bit field	The available modes are: Force-idle, no-idle, and smart-idle wakeup disabled modes are available.
Master standby modes	SATA_SYSCONFIG [5:4]STANDBYMODE bit field	The available modes are: Force-standby, no-standby, smart-standby wakeup disabled
Clock-gate overriding mode	SATA_SYSCONFIG [16]OVERRIDE0 bit field	Clock stopping override function. Should not be applied when attached to port SATA peripheral device has not entered a Low-power mode.

For more information on the L3INIT_L3_GICLK functional clock gating in the device PRCM , refer to Section 3.1.1.1.4, *Clock Domain-Level Clock Management*, in the chapter, *Power, Reset and Clock Management*.

24.8.4.5 Interrupt Requests

This section describes all of the conditions that can generate an interrupt. Each condition is subject to the masking capabilities described in Section 24.8.4.5.4, *Interrupt Condition Control*.

24.8.4.5.1 Interrupt Generation

Both level and pulse interrupts are available. Exercise care when using the pulse interrupt. Because of the synchronization and interrupt aggregation from the internal core, clearing one interrupt as another interrupt occurs can prevent a new pulse from being generated. A new pulse is generated only if the first interrupt is completely cleared (that is, the level interrupt goes away) before the new interrupt event occurs. Thus, an interrupt can occur after the register write is issued to clear the first interrupt but before the interrupt is fully cleared. In this case, a new pulse is not issued and the level interrupt remains asserted. After issuing the write to clear an interrupt, software must read the interrupt status registers to ensure that a new interrupt has not occurred.

Copyright © 2015–2017, Texas Instruments Incorporated

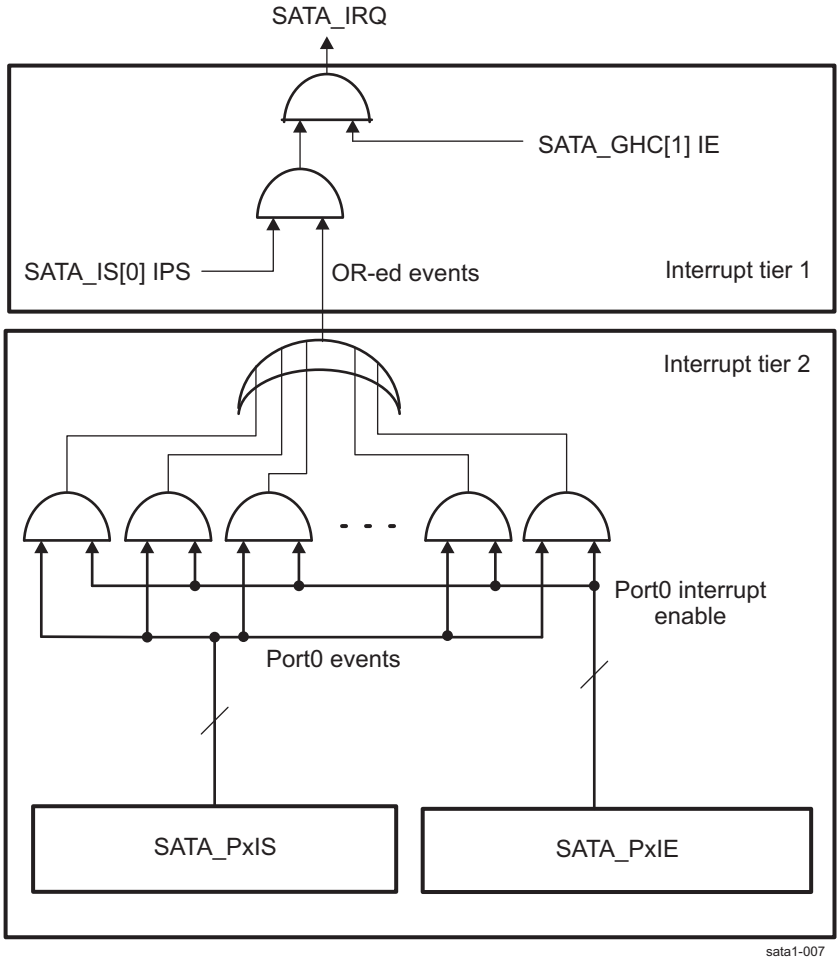
24.8.4.5.2 Levels of Interrupt Control

The AHCI directs that interrupts be indicated in a two-tier structure and thus associated with different HBA ports. Considering the device SATA HBA single-port implementation for the first tier, only the SATA_IS[0] IPS bit should be considered. It indicates if the only port available to the user (HBA port 0) has pending interrupts.

For the second tier, the SATA_PxIS register (where x = 0) indicates which specific interrupt condition(s) occurs to trigger an interrupt on port 0. In most cases, software writes 0x1 (Write One to Clear) to clear these bits, and then writes 0x1 to the SATA_IS [0]IPS bit to clear the interrupt. However, some interrupts in the SATA_PxIS register have alternate methods of being cleared (for details, see Section 24.8.6.2.2, *DWC_ahsata Register Description*). Section 24.8.4.5.3, *Interrupt Events Description*, describes all interrupt generating conditions.

Figure 24-158 shows the SATA controller two-tier interrupt propagation structure. Besides SATA_IS[0], which gates all interrupts at the port 0 level, the tier 1 interrupt is globally gated by the SATA_GHC[1] IE bit.

Figure 24-158. SATA Controller Interrupt Propagation Schema



NOTE: Regardless of the device SATA controller single HBA port implementation, user software must read/write the tier 1 SATA_IS[0] IPS register bit to process interrupts.

Copyright © 2015–2017, Texas Instruments Incorporated

24.8.4.5.3 Interrupt Events Description

This section describes the different events that are reflected in the SATA_PxIS register and that cause SATA_IRQ interrupt generation, if enabled, in the SATA_PxIE register. For more information regarding SATA_IRQ handling at the IRQ CROSSBAR subsystem, see Section 18.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 18, *Control Module*.

24.8.4.5.3.1 Task File Error Status

This event is registered whenever the SATA_PxTFD[7:0] STS bit field is updated by the device and the error bit SATA_PxTFD[0]STS_ERR is set. SATA_PxTFD[7:0] STS is updated when a new register FIS, PIO setup FIS, or set device bits FIS is received from the device.

24.8.4.5.3.2 Host Bus Fatal Error

This event is registered whenever an error is received by the SATA controller internal DMA master port from the configuration slave port.

24.8.4.5.3.3 Interface Fatal Error Status

This event is registered if an error is generated on the interface. The following conditions can cause this:

- SYNC escape during an H2D register or data FIS transmission
- One of the following errors during a data FIS transfer:
  - Protocol (SATA_PSERR[10] ERR_P)
  - CRC (SATA_PSERR[21] DIAG_C)
  - Handshake (SATA_PSERR[22] DIAG_H)
  - SATA_PHY not ready (SATA_PSERR[9] ERR_C)
- Unknown FIS received with a good CRC, but length greater than 64 bytes
- Physical region descriptor (PRD) table byte count of 0

NOTE: This is a fatal error in which the DMA is in an error state until software clears the SATA_PxCMD[0] ST bit or resets the interface with a port or global reset. For more information about software-initiated resets, see Section 24.8.4.3.2, *Software Initiated Resets*.

24.8.4.5.3.4 Interface Non-Fatal Error Status

This event is registered on the following error conditions:

- One or more of the following errors are registered during a non-data FIS transfer:
  - Protocol (SATA_PSERR[10] ERR_P)
  - CRC (SATA_PSERR[21] DIAG_C)
  - Handshake (SATA_PSERR[22] DIAG_H)
  - SATA_PHY not ready (SATA_PSERR[9] ERR_C)
- Command list underflow during a read operation when software builds a command table that has more total bytes than the transaction given to the device

NOTE: The conditions previously described are non-fatal and the SATA host controller continues to operate normally.

24.8.4.5.3.5 Overflow Status

This event is registered if command list overflow is detected during read or write when software builds a command table with fewer total bytes than the transaction given to the device.

Copyright © 2015–2017, Texas Instruments Incorporated

NOTE: This is a fatal error in which the DMA is in an error state until software clears the SATA_PxCMD[0] ST bit or resets the interface with a port or global reset. For more information about software-initiated resets, see Section 24.8.4.3.2, *Software Initiated Resets*.

24.8.4.5.3.6 Incorrect Port Multiplier Status

This event is registered when the SATA controller receives a FIS from a device with a PM field not matching what is expected. The SATA_PxIS[23] IPMS event corresponding bit can be set during device enumeration, but software should ignore it until enumeration is finished.

24.8.4.5.3.7 PHYReady Change Status

This event is registered when the status of PHYReady changes. Its corresponding status bit (SATA_PxIS[22] PRCS) reflects the SATA_PxSERR[16]DIAG_N bit.

24.8.4.5.3.8 Port Connect Change Status

This event is registered when there was a change in the current connect status as reflected by the SATA_PxSERR[26]DIAG_X bit.

24.8.4.5.3.9 Descriptor Processed

This event is registered when a transaction completes. Its corresponding flag (SATA_PxIS[5] DPS) is set whenever a PRD with the I bit set transfers all of its data.

NOTE: The PRD interrupt is an opportunistic interrupt and should not be used to definitely indicate the end of a transfer. Two PRD interrupts can happen close in time so that the second interrupt is missed while the first PRD interrupt is being cleared.

When a PRD entry is exhausted, the HBA can be directed to generate an interrupt through the I bit in the PRD entry (although a PRD is not considered exhausted until all data FISs that transfer data pointed to by that PRD entry is complete). For example, if the data FIS is 8 KiB, and this is covered by three PRD entries, the data is not considered valid at the end of the first or second PRD because the CRC has not been checked, even though the data has been copied to memory or to the device. Therefore, if the I bit is set in the PRD entry, the HBA must hold onto it internally and not set PxIS.DPS until the data FIS is complete and the CRC is correct. Once correct, PxIS.DPS can be set and, if PxIE.DPE and GHC.IE are set, the HBA generates an interrupt.

Conversely, if the PRD entry is 16 KiB and two 8 KiB Data FISS are used to transfer all of the data pointed to by the PRD entry, the PRD interrupt associated with that PRD entry is not signaled until after the second data FIS transfer completes successfully.

24.8.4.5.3.10 Unknown FIS Interrupt

This status event indicates that an unknown FIS is received and copied into system memory.

24.8.4.5.3.11 Set Device Bits Interrupt

This status event indicates that a Set Device Bits FIS is received with the I bit set and copied to system memory.

24.8.4.5.3.12 DMA Setup FIS Interrupt

This status event indicates that a DMA Setup FIS is received with the I bit set and copied into system memory.

Copyright © 2015–2017, Texas Instruments Incorporated

24.8.4.5.3.13 PIO Setup FIS Interrupt

This status event indicates that a PIO Setup FIS with the I bit set is copied into system memory and the data related to that FIS is transferred.

24.8.4.5.3.14 Device to Host Register FIS Interrupt

This status event indicates that a D2H Register FIS is received with the I bit set and copied to system memory.

24.8.4.5.4 Interrupt Condition Control

There are several ways for software to control the conditions causing a non - command completion coalescing **(non-CCC)** SATA_IRQ interrupt assertion. The SATA_GHC[1] IE register bit serves as a global mask. If it is 0x0, all interrupts are masked. If it is 0x1, interrupts not masked by the SATA_IS (all interrupts for port 0) and SATA_PxIE registers can trigger an interrupt. The SATA_PxIE register matches the SATA_PxIS register bit for bit. If the corresponding bit in the SATA_PxIE register is set to 0x1, the interrupt is unmasked. If the corresponding is 0x0, the interrupt is masked off.

Table 24-572 summarizes the SATA controller interrupt status bits and their corresponding interrupt enable bits at the second tier of the SATA controller interrupt generation schema.

Table 24-572. Interrupt Events Summary

Event Status Flag	Interrupt Event Mask	Mapped to Interrupt Output	Brief Interrupt Event Description
SATA_PxIS [30]TFES	SATA_PxIE [30]TFEE	SATA_IRQ	Task File Error
SATA_PxIS [29]HBFS	SATA_PxIE [29]HBFE	SATA_IRQ	Host Bus Fatal Error
SATA_PxIS [27]IFS	SATA_PxIE [27]IFE	SATA_IRQ	Interface Fatal Error
SATA_PxIS [26]INFS	SATA_PxIE [26]INFE	SATA_IRQ	Interface Non-Fatal Error
SATA_PxIS [24]OFS	SATA_PxIE [24]OFE	SATA_IRQ	Overflow
SATA_PxIS [23]IPMS	SATA_PxIE [23]IPME	SATA_IRQ	Incorrect Port Multiplier
SATA_PxIS [22]PRCS	SATA_PxIE [22]PRCE	SATA_IRQ	Phy Ready Change
SATA_PxIS [6]PCS	SATA_PxIE [6]PCE	SATA_IRQ	Port Connect Change
SATA_PxIS [5]DPS	SATA_PxIE [5]DPE	SATA_IRQ	Descriptor Processed
SATA_PxIS [4]UFS	SATA_PxIE [4]UFE	SATA_IRQ	Unknown FIS Received
SATA_PxIS [3]SDBS	SATA_PxIE [3]SDBE	SATA_IRQ	Set Device Bits FIS Received
SATA_PxIS [2]DSS	SATA_PxIE [2]DSE	SATA_IRQ	DMA Setup FIS Received
SATA_PxIS [1]PSS	SATA_PxIE [1]PSE	SATA_IRQ	PIO Setup FIS Received
SATA_PxIS[0]DHRS	SATA_PxIE [0]DHRE	SATA_IRQ	Device to Host Register FIS Received

NOTE: To ensure normal generation of the standard (single-event driven, non-CCC) interrupts described in Table 24-572, the user must ensure that the CCC feature is disabled (that is, the SATA_CCC_CTL[0] EN bit is set to 0x0).

24.8.4.5.5 Command Completion Coalescing Interrupts

The SATA controller supports CCC, which can be thought of as interrupt pacing. Instead of being generated for every command completed, an interrupt can be triggered based on a certain number of commands completed and/or a timer time-out. This significantly reduces the load on the CPU by not allowing software to receive an interrupt every time a command is processed. Software can thus queue many commands or wait for many received FISes and process them as a batch. All CCC functions are controlled by the SATA_CCC_CTL, SATA_CCC_PORTS, and SATA_TIMER1MS registers. Setting

Copyright © 2015–2017, Texas Instruments Incorporated

SATA_CCC_PORTS[0]PRT = 0x1 makes the only available SATA controller HBA port 0 - CCC-aware. The SATA_CCC_CTL register can be used to program CCC logic to trigger an interrupt whenever a certain number of commands are complete and/or a timeout value (as specified by the TV field of SATA_CCC_CTL and SATA_TIMER1MS registers) occurs. For specific programming instructions, see the SATA_CCC_CTL description.

24.8.4.5.5.1 CCC Interrupt Based on Expired Timeout Value

To trigger a CCC interrupt on a port after an elapsed timer value, the following programming sequence must be implemented by user software:

1. Software disables the CCC feature, clearing SATA_CCC_CTL[0] EN to 0b0.
2. Software sets SATA_CCC_PORTS[0] PRT = 0x1 to make HBA port 0 CCC-aware.
3. Software sets SATA_CCC_CTL[15:8] CC = 0x0, which provides that the expired timeout trigger condition is selected.
4. Software defines the 1-ms time-based unit by loading an appropriate number of interface/functional clock cycles into the 20-bit SATA_TIMER1MS[19:0] TIMV bit field. For example, its reset value of 0x186A0 (100 000 x SATA_FICLK cycles) provides that a 1-ms timeout base will be generated if SATA_FICLK = 100 MHz.
5. Software chooses the timeout value as the number of 1-ms intervals through the 16-bit SATA_CCC_CTL[31:16]TV bit field.
6. Software enables the CCC-interrupt feature, asserting SATA_CCC_CTL[0] EN bit to 0b1.

Assertion of bit SATA_CCC_CTL[0] EN to 0x1 is required to start the 1MS TIMER after the above described configuration steps are completed.

NOTE: On CCC event configuration, the CCC feature should be disabled (that is, SATA_CCC_CTL[0] EN should be kept at 0b0).

NOTE: Due to the single SATA controller HBA port integration, the source of the CCC interrupt, if enabled, is always HBA port 0. On a CCC interrupt, the SATA_CCC_CTL[7:3] INT read-only bit changes to 0x0 (its reset value is 0x1) . As a consequence, the STA_IS[0] IPS bit is set to 0x1.

24.8.4.5.5.2 CCC Interrupt Based on Completion Count

If the desired method to receive an interrupt is based on the completion of a certain number of commands, the following settings must be performed:

1. Software disables the CCC feature, clearing SATA_CCC_CTL[0] EN to 0b0.
2. Software sets SATA_CCC_PORTS[0] PRT = 0x1 to make HBA port 0 CCC-aware.
3. Software sets SATA_CCC_CTL[15:8] CC! = 0x0 to the desired number (1–255) of commands to be completed. The CC! = 0x0 provides that the count completion condition is selected.
4. Software enables the CCC-interrupt feature, asserting the SATA_CCC_CTL[0] EN bit to 0b1.

NOTE: On CCC event configuration , the CCC feature should be disabled (that is, SATA_CCC_CTL[0] EN should be kept at 0b0).

NOTE: Due to the single SATA controller HBA port integration, the source of the CCC interrupt, if enabled, is always HBA port 0. On a CCC interrupt, the SATA_CCC_CTL [7:3]INT read-only bit changes to 0x0 (its reset value is 0x1) . As a consequence, the STA_IS[0] IPS bit is set to 0x1.

Copyright © 2015–2017, Texas Instruments Incorporated

24.8.4.6 System Memory FIS Descriptors

The SATA AHCI mode supports a command list of from 1 up to 32 entries (command slots) assigned to HBA port 0, which should be allocated and built into host system memory by user software. After receiving command/data messages from the attached port 0 SATA mass-storage drive, the HBA extracts the FIS Dwords, sorts them out, and stores them into different areas of RX FIS-allocated host system memory.

24.8.4.6.1 Command List Structure Basics

Each command list entry has an associated command header (CH) that takes 32 bytes in host system memory, from which only the first 4 Dwords (16 bytes) are used. The CH contains different fields that detail the direction of transfer (H2D or D2H), type of command (ATA/ATAPI), reset behavior, PM ID, byte count and byte length of the PRD table, etc.

A command list slot CH specifies the base address of the underlying command table and information about the associated command FIS length. The command table in system memory has three main areas:

- A 64-byte command FIS area in which the user loads the command-associated FIS contents
- An ATAPI area in which a 12- or 16-byte ATAPI command is loaded, if specified in the CH (through bit A)
- A PRD table area that allows up to 65535 data descriptor entries

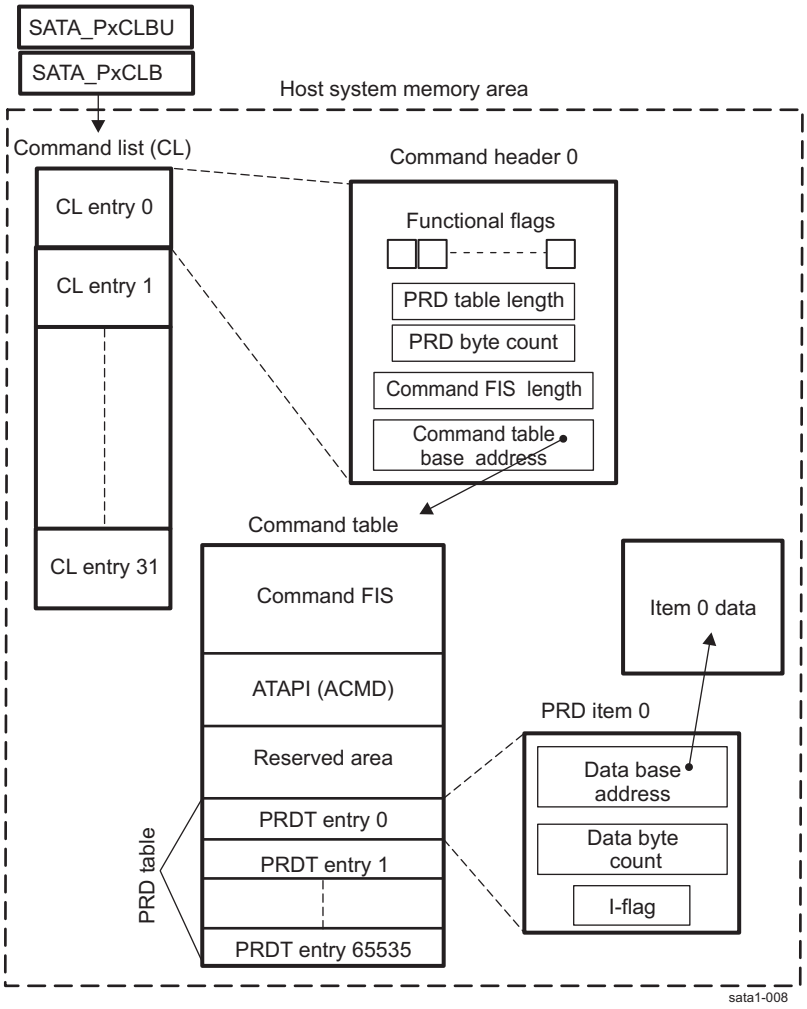
An entry of a PRD table (that is, a scatter/gather list item) specifies descriptor parameters of a data block transfer handled by the HBA port DMA.

Figure 24-159 shows the interrelations between the FIS-related structures that user software must allocate and build into the host system memory.

For details on command and data structures in host system memory, see the AHCI and SATA standard specifications.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 24-159. Command List Descriptor Structures



After allocating the necessary portions for the CL, command slots underlying data descriptors, and received FISs into host system memory, the base addresses of these memory locations must be provided by user software to the HBA through the hardware init domain registers: SATA_PxCLB (command list base address - lower bits), SATA_PxCLBU (command list base address-upper bits), SATA_PxFB (received FISs system memory area base address-lower bits) and SATA_PxFBU (received FISs system memory area base address-upper bits) . Thus, the command and data DMA engines can access the transfer context programming structures.

NOTE: SATA_PxCLBU / SATA_PxFBU registers store the upper half of the native 64-bit AHCI addresses. Because only 36-lower bits of the AHCI 64-bit address bus are integrated in the device, actually only the 4-lower bits within SATA_PxCLBU / SATA_PxFBU are meaningful. **The remaining 28-bits must be always written to '0'-s in the descriptors (SATA_PxCLBU[31:4]=0x0 / SATA_PxFBU[31:4]=0x0) .**
Default value for the SATA_PxCLBU / SATA_PxFBU registers is 0x0, so that a 32-bit SW driver which never accesses them works seamlessly, by accessing only the 32-bit (lower half) addresses which reside in the SATA_PxCLB / SATA_PxFB registers.

24.8.4.6.2 Supported Types of Commands

The following types commands are supported:

- Standard serial ATA nonqueued commands set.

Copyright © 2015–2017, Texas Instruments Incorporated

As opposed to NCQ, these commands are serviced, acknowledged one by one after a successful completion. The nonqueued SATA CL entries can take advantage of the PRD prefetching option indicated by the P flag in the corresponding CH (for more information, see the SATA specification). The ATA legacy commands are not supported by the SATA AHCI core.

- ATAPI commands

  ATAPI commands are supported by the SATA HBA engine. A request for an ATAPI command service is indicated by setting CH bit A to 0b1. The ATAPI command that the user builds into the ATAPI area of the command table can be 12 or 16 bytes in length and is indicated by the PIO Setup FIS sent by the SATA peripheral storage device requesting the ATAPI command. In addition, the SATA controller supports ATAPI active-LED generation (See Section 24.8.4.10, *Activity LED Generation Functionality*).

- NCQ-commands

  NCQ-commands are supported by the SATA controller HBA engine, the execution of which can be greatly facilitated by the CCC interrupt feature (for more information, see Section 24.8.4.5.5, *Command Completion Coalescing Interrupts*). As described in Section 24.8.1.1.2, *Native Command Queuing*, the NCQ commands have FPDMA queued command protocol mechanism, which implies that they are treated in a different way then standard SATA commands. The AHCI interface register set include specific registers, such as SATA_PxSACT, etc., to make the HBA aware of the outstanding NCQ slots in a command list. As opposed to standard nonqueued commands, NCQ commands are acknowledged before their actual completion, which accelerates the CL servicing for NCQ slots. The queue tag of the command requested by the SATA peripheral device is indicated to the HBA port by the TAG field in a DMA Setup FIS that an attached SATA peripheral device sends to the SATA controller host . The HBA then uses the tag value to index the NCQ commands updated by user software in the command list. The NCQ command descriptors are not allowed to use the prefetching option in CH because their order of execution is determined by the SATA target device.

24.8.4.6.3 Received FIS Structures

After stream decoding and primitive removal by the link layer, the validated FIS Dwords are extracted from the RxFIFO buffer by the transport layer DMA, and the original SATA storage drive FIS structures are recovered to a dedicated host system memory space. The DMA stores the received FISs into different memory areas based on FIS type. The unknown FIS reception is legal to HBA, as long as the length of the unknown FIS does not overrun the 64-byte size limit of the FIS descriptors. For details on received FISs memory area organization, see the AHCI and SATA standard specifications.

24.8.4.6.4 FIS Descriptors Summary

The FISs that encapsulate SATA target commands and data contents can be divided into:

- FISs transmitted from the host to an attached SATA peripheral device (H2D FISs)
- FISs sent by an attached SATA peripheral device to the host (D2H FISs)

The H2D FISs are constructed by user software into system memory. he H2D FIS types are:

- H2D Register FIS
- H2D DMA Setup FIS
- H2D Data FIS

The D2H FISs are constructed by the attached SATA peripheral device transport layer. The D2H FIS types are as follows:

- D2H Register FIS
- D2H DMA Setup FIS
- PIO Setup FIS
- DMA Activate FIS
- Set Device Bits FIS
- D2H Data FIS

For details on different type of FIS contents, see the SATA standard specification (revision 2.6).

24.8.4.7 Transport Layer FIS-Based Interactions

24.8.4.7.1 Software Processing of the Port Command List

After user software instantiates the CL structures in host system memory, it must maintain them appropriately. The command list is advanced when the BSY, DRQ, and ERR bits of a serial ATA device task file are cleared, which is communicated through a D2H register FIS to HBA port. The HBA port 0 hardware clears the corresponding to the i-th completed command: SATA_PxCI [i] CI (SATA_PxCI [TAG] CI for NCQ) bit to notify user software that the next command FIS can be advanced into the CL. The software then builds the command slot components: CH fields, command table, and associated PRD data descriptors in system memory. Software asserts the SATA_PxCI[i+1] CI (or SATA_PxCI[TAG] CI bit for an NCQ indicated command) to activate the prepared CL command, which is possible only when SATA_PxCMD[0] ST = 0x1. The nonqueued commands in the CL are processed in ascending order of slots (linear processing). The SATA_PxCMD [12:8]CCS read-only field indicates the CL index of the command currently being issued by the HBA port.

The processing of NCQ command slots invokes additional register update/check steps. Before setting the SATA_PxCI[TAG] CI bit to 0b1 and posting an active NCQ command to the SATA HBA port, software must indicate an NCQ outstanding command at the position defined by the SATA peripheral device queue TAG by setting SATA_PxSACT[TAG] DS = 0x1. After the queued command is posted, the peripheral SATA device sends a Set Device Bits FIS to the HBA port to clear the SATA_PxSACT bits corresponding to the successfully completed NCQ commands.

Command-list processing is initially triggered by software setting SATA_PxCMD[0] ST = 0x1, which requires certain conditions to be satisfied.

NOTE: There are some restrictions to setting SATA_PxCMD[0] ST to 0x1. For more information, see the AHCI specification (revision 1.1).

The SATA controller is capable of command list override (CLO) operation. CLO is activated by setting SATA_PxCMD[3] CLO = 0b1, which is expected only when SATA_PxCMD[0] ST = 0x0 (that is, the command list is not processed by the HBA) to avoid HBA-indeterminate behavior. As a consequence of a CLO operation, the SATA_PxTFD register STS_DRQ and STS_BSY flags are cleared. For example, CLO is necessary when the DRQ and BSY flags cannot be cleared by HBA before issuing a software reset (because of some hang condition). For more information on CLO behavior, see the AHCI standard specification.

24.8.4.7.2 Handling the Received FIS Descriptors

The HBA DMA facilitates the reception of the D2H FISs into host system memory. The reception is enabled by the user setting SATA_PxCMD[4] FRE to 0b1. The software is allowed to change the SATA_PxFB / SATA_PxFBU contents and thus move the FIS reception area to different system memory locations, if SATA_PxCMD[14] FR is cleared, which occurs after software writes SATA_PxCMD[4] FRE = 0b0. In this case, further FIS reception is blocked when the internal RxFIFO becomes full. Before setting SATA_PxCMD[4] FRE to 0x1, the user software must ensure that a valid address is programmed into the SATA_PxFB / SATA_PxFBU registers.

NOTE: The HBA port stores the unknown FISs (up to 64 bytes) in system memory but does not have a specified behavior to indicate an error condition on reception. The unknown FISs must be handled specifically by user software.

24.8.4.8 DMA Port Configuration

The SATA controller handles all data operations on its port with an internal DMA integrated in SATA AHCI core.

The SATA controller DMA transfers all information between system memory and the attached SATA peripheral device, as well as configuration and status FISs. The transmit and receive DMA data paths are independently programmable.

Copyright © 2015–2017, Texas Instruments Incorporated

The burst size in both directions is fixed to 16 Dwords. The DMA issues transactions of this size or smaller (in Dword increments), depending on programmed transaction size.

NOTE: If the programmed transaction size is lower than 16-Dwords (burst size), then the DMA maxes out at transaction size.

The user can also separately program the transaction size for receive and transmit channels by setting the SATA_PxDMACR[7:4] RXTS and SATA_PxDMACR[3:0] TXTS bit fields. The transaction size is the minimum amount of data on which the DMA works. For example, if a FIS comes from the device to the host, the DMA does not begin transferring data into system memory until there is at least SATA_PxDMACR[7:4] RXTS number of Dwords in the receive FIFO. During transmit, the DMA reads data from system memory in SATA_PxDMACR[3:0] TXTS Dword increments to put into the transmit FIFO. Transactions can be broken up into multiple bursts of 16 Dword - size, crossing of a 1-KiB boundary (boundary between 1-KiB address blocks in memory), or end-of-frame. RXFIFO and TXFIFO transaction sizes are limited to maximum half the size of the integrated RXFIFO and TXFIFO buffers. For more information on maximum transaction sizes and RXFIFO/TXFIFO depths, see the SATA_PxDMACR and SATA_PPARAMR descriptions.

24.8.4.9 Port Multiplier Operation

The SATA controller HBA port supports connection to a bunch of maximum 15 devices through a port multiplier (PM). The communication mechanism is based on PM command-based switching.

24.8.4.9.1 Command-Based Switching Mode

In this mode of operation, user software must initiate transfers to different PM ports so that multiple commands are not outstanding to different devices connected to the PM extension ports.

24.8.4.9.1.1 Port Multiplier NCQ and Non-NCQ Commands Generation

The PM port command servicing order depends on the type of commands in the CL:

- Non-queued command generation to PMs

  When processing commands that are non-queued, the HBA executes each command entry in its entirety before moving to the next entry in the command list. The next entry can include a command to a different PM device port. Because the HBA operates in the order of its command list, system software must not fill the list in sequential order with commands to a single device; otherwise, another device might get starved. For more information, see the AHCI standard specification.
- NCQ command generation to PMs

  Because the SATA controller supports command-based switching only, system software must only add NCQ commands to the command list that target a single port behind the PM, wait for the commands to finish (SATA_PxSACT bits all cleared), and then add commands for a different port. For more information, see the AHCI standard specification.

24.8.4.9.2 Port Multiplier Enumeration

To enumerate PM devices, a software reset should be issued by SATA controller to the PM port #0xF (this is a point of connection for the PM or a single endpoint device). The software must prepare two H2D Register FISs into the host system memory for a software reset with the PM-port select (PMP) field set to 0xF. To ensure reliable PM device enumeration, software must also perform a CLO operation. For more information, see the AHCI standard specification.

24.8.4.10 Activity LED Generation Functionality

The HBA port drives the device-level sata1_led signal that is active on the following conditions (see also Table 24-566):

- If (SATA_PxCI [31:0]! = 0x0 or SATA_PxSACT[31:0]! = 0x0) and SATA_PxCMD[24] ATAPI = 0b0 (for active nonATAPI commands indication)
- If (SATA_PxCI [31:0]! = 0x0 or SATA_PxSACT[31:0]! = 0x0) and SATA_PxCMD[24] ATAPI = 0b1 and

Copyright © 2015–2017, Texas Instruments Incorporated

SATA_PxCMD[25] DLAE = 0b1 (for active ATAPI commands indication)

When SATA_PxCI and SATA_PxSACT are cleared to 0x0, the LED on the sata1_led signal-associated pad is driven off.

24.8.4.11 Supported Types of SATA Transfers

SATA controller AHCI mode defines two types of transfers between the host system memory and a SATA peripheral device: DMA and PIO data transfers. Whether the transaction is of a DMA type or PIO type, the HBA fetches and stores data to memory, offloading the CPU. No register is implemented for direct user access to the data port.

PIO transfers specified by PIO Setup FISs are strongly discouraged because of their limited support of error indication. PIO commands use is limited to only few cases in which commands support only PIO mechanism, such as execution of the IDENTIFY DEVICE command and ATAPI command transfers in which the PACKET command is invoked. The SATA controller AHCI mechanism allows multiple DRQ blocks of data per PIO command.

24.8.4.11.1 Supported Higher Level Protocols

The following DMA, PIO, FPDMA-queued, and ATAPI command/data protocols are supported by the SATA controller AHCI engine:

- Standard SATA command-related
  - Nondata command protocol
  - PIO write protocol
  - PIO read protocol
  - DMA write protocol
  - DMA read protocol
- NCQ command-related
  - Write FPDMA-queued protocol
  - Read FPDMA-queued protocol
- ATAPI PACKET command-related
  - PACKET Nondata command protocol
  - PACKET PIO read/write protocol
  - PACKET DMA read/write protocol

24.8.4.12 SATA Controller AHCI Hardware Register Interface

Table 24-573 summarizes the SATA host controller subsystem registers and divides them into functional categories.

Table 24-573. Summary of SATA Host Subsystem Functional Registers

Register	Functional Category	Brief Register Description
SATA_SYSCONFIG	Device-level registers (wrapper of SATA AHCI core)	TI wrapper idle/standby power management configuration register
SATA_CDRLOCK(1)		TI wrapper register which defines default delay of received data valid information.
SATA_IDR	SATA vendor-specific (VS) register	TI high lander identification register

(1) Under normal conditions, the user is supposed to keep this register at its default (power-on-reset) value.

Copyright © 2015–2017, Texas Instruments Incorporated

Table 24-573. Summary of SATA Host Subsystem Functional Registers (continued)

Register	Functional Category	Brief Register Description
SATA_CAP	SATA controller generic registers	SATA HBA capabilities set 1
SATA_CAP2		SATA HBA capabilities set 2
SATA_VS		SATA HBA register showing supported AHCI specification revision
SATA_GPARAM1R		SATA HBA global parameters set 1
SATA_GPARAM2R		SATA HBA global parameters set 2
SATA_GHC		SATA HBA global AHCI settings
SATA_PPARAMR	SATA HBA ports-related registers	SATA HBA port x[2] parameter settings
SATA_PI		Enables SATA HBA port x[2] functionalities
SATA_IS		Enables all SATA HBA port x[2] associated interrupts (first tier of interrupt schema)
SATA_CCC_PORTS		Enables SATA CCC feature for the port x[2]
SATA_CCC_CTL		CCC feature parameters control and status
SATA_TIMER1MS		Time base for 1-ms unit of CCC timeout
SATA_PxCLB	SATA HBA Port Px[2] SATA Specification- defined Functional Registers	CL base address (lower-half of AHCI 64-bit address)
SATA_PxCLBU		CL base address (upper-half of AHCI 64-bit address)[3]
SATA_PxFB		Received FISs base address (lower-half of AHCI 64-bit address)
SATA_PxFBU		Received FISs base address (upper-half of AHCI 64-bit address)[3]
SATA_PxIE		Port x[2] non-CCC interrupt enable
SATA_PxIS		Port x[2] non-CCC interrupt event status
SATA_PxCMD		Port x[2] command register
SATA_PxTFD		Port x[2] task file data register
SATA_PxSIG		Port x[2] associated SATA signature register
SATA_PxSSTS		Port x[2] SStatus SATA register (See the SATA standard specification.)
SATA_PxSCTL		Port x [2]SControl SATA register (See the SATA standard specification.)
SATA_PxSERR		Port x [2]SError SATA register (See the SATA standard specification.)
SATA_PxSACT		Port x[2] SActive SATA register (See SATA standard specification.)
SATA_PxCI		Port x [2]command activation/completion indication register
SATA_PxSNTF		Port x[2] SNotification register (See the SATA standard specification.)
SATA_OOBR		OOB detection counters setup
SATA_PxDMACR	Non-standard Port Px[4] Control register	Port x[4] associated DMA configuration register
SATA_TESTR	SATA HBA BIST related registers	Test/normal mode switching
SATA_BISTAFR		BIST FIS-activate register
SATA_BISTCR		BIST control register
SATA_BISTFCTR		BIST FIS count register
SATA_BISTSR		BIST status register
SATA_BISTDECR		BIST Dword error count register

(2) x = 0, as only SATA HBA port 0 is implemented
(3) Only the 4-lower bits meaningful in the device, the others must be kept at '0'
(4) x = 0, as only SATA HBA port 0 is implemented

24.8.5 SATA Controller Low Level Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the SATA host controller.

NOTE: SATA is not supported on the AM570x family of devices.

24.8.5.1 Global Initialization

24.8.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements to initialize the surrounding modules when the SATA host controller is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the SATA host controller (for more information, see and). Table 24-574 describes the global initialization of surrounding modules.

Table 24-574. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module functional and interface clocks must be enabled (see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*).
Control Module	Module-specific pad muxing and other PHY power configurations must be set in the control module (see Section 18.4.6.1.1, *Pad Configuration Registers* and Section 18.5, *Control Module Register Manual*, in Chapter 18, *Control Module*).
IRQ_CROSSBAR	IRQ_CROSSBAR must be configured to enable the interrupt from the SATA controller (see Section 18.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 18, *Control Module*).
L4_CFG and L3_MAIN interconnects	For more information about the interconnect configuration, see Section 14.2.3.2.1,*L3_MAIN Interconnect Agents* and Section 14.3, *L4 Interconnect*, in Chapter 14, *Interconnect.*

NOTE: The MPU INTC configuration is required when using the interrupt communication mode.

24.8.5.1.2 SATA Controller Global Initialization

24.8.5.1.2.1 Main Sequence SATA Controller Global Initialization

Table 24-575 describes the procedure to initialize the SATA host controller after a POR.

Table 24-575. SATA Controller Global Initialization

Step	Register/Bit Field/Programming Model	Value
Configure the OCP2SCP3 adapter for PLLCTRL_SATA.	See Section 26.1.5, *SATA PHY Subsystem Low - Level Programming Model* in Chapter 26, *Shared PHY Component Subsytems*.	-
Configure the DPLL_SATA.	See Section 26.1.5, *SATA PHY Subsystem Low - Level Programming Model* in Chapter 26, *Shared PHY Component Subsytems*.	-
Configure the SATA_PHY.	See Section 26.1.5, *SATA PHY Subsystem Low - Level Programming Model* in Chapter 26, *Shared PHY Component Subsystems*.	-
Perform all firmware capability writes. (1)	See Section 24.8.5.1.2.2, *SubSequence – Firmware Capability Writes*.	-
Set up all appropriate structures in memory per the AHCI standard specification.	See Section 24.8.4.6, *System Memory FIS Descriptors*. See also the AHCI standard specification.	-

(1) This step has an effect only on hardware initialization.

Copyright © 2015–2017, Texas Instruments Incorporated

Table 24-575. SATA Controller Global Initialization (continued)

Step	Register/Bit Field/Programming Model	Value
Write a valid CL memory base address to the SATA_PxCLB register.	SATA_PxCLB [31:10] CLB	CL Base address (lower-half)
	SATA_PxCLBU [3:0] CLBU	CL Base address (upper-half) Only 4-lower bits meaningful in the device, other must be always written to '0'-s
Write a valid Rx FIS memory base address to the SATA_PxFB register.	SATA_PxFB [31:8] FB	Rx FIS Base address (lower-half)
	SATA_PxFBU [3:0] FBU	Rx FIS Base address (upper-half) Only 4-lower bits meaningful in the device, other must be always written to '0'-s
Issue a software type of reset depending on the error condition.	See Section 24.8.4.3.2, *Software Initiated Resets*.	-
Set the appropriate bits in the SATA_PxCMD register.	See Section 24.8.4.7.1, *Software Processing of the Port Command List*. See also the AHCI standard specification.	-
Program the SATA_PxSCTL register to configure SATA interface capabilities.	See the AHCI standard specification.	-
Program the SATA_PxDMACR register.	See Section 24.8.4.8, *DMA Port Configuration*.	-
Enable the interrupts at port 0.	SATA_IS[0] IPS	0x1
Enable the involved port 0 specific interrupts.	See Section 24.8.4.5.2, *Levels of Interrupt Control*, and Section 24.8.4.5.4, *Interrupt Condition Control*.	-
Enable the FIS reception in the SATA_PxCMD register.	SATA_PxCMD[4] FRE	0x1
Spin up the device (if required).	See the AHCI standard specification and the SATA standard specification.	-

NOTE: The SATA AHCI Controller always manipulates 64-bit memory pointers, and the master interface has 64-bit addresses, but the actual AHCI master interface integration in the device uses ONLY the 36-lower bits. In that case, even though the AHCI support indicates “64-bit” in the SATA_CAP[31] S64A, ONLY the 4-lower bits (SATA_PxCLBU [3:0] / SATA_PxFBU [3:0]) are meaningful in the device.**The upper 28 bits of the address, i.e.** SATA_PxCLBU [31:4] / SATA_PxFBU [31:4] **, must be always SW-programmed to '0'.**

NOTE: Default value of the SATA_PxCLBU / SATA_PxFBU registers is 0x0, so that a 32-bit SW driver which never accesses them works seamlessly, by accessing only the 32-bit (lower half) addresses which reside in the SATA_PxCLB / SATA_PxFB registers.

24.8.5.1.2.2 SubSequence – Firmware Capability Writes

Table 24-576 lists the firmware capability write sequence by which SATA HBA initialization is performed.

NOTE: In the following sequence, SATA controller accesses hardware initialization domain registers that can be written only one time after POR.

Table 24-576. Firmware Capability Writes

Step	Register/Bit Field/Programming Model	Value
Disable the staggered spin-up support feature.(1)	SATA_CAP[27] SSS	0x0

(1) It makes no sense to enable staggered spin-up because only one HBA port is used.

Copyright © 2015–2017, Texas Instruments Incorporated

Table 24-576. Firmware Capability Writes (continued)

Step	Register/Bit Field/Programming Model	Value
Enable the SATA controller port 0.	SATA_PI[0] PI	0x1
Disable the mechanical presence detect feature.(1)	SATA_CAP[28] SMPS	0x0
Disable the external signal-only connector.(1)	SATA_PxCMD[22:21] ESP	0x0
Disable the cold presence detect feature. (1)	SATA_PxCMD[20] CPD	0x0
Disable support for the mechanical presence switch.	SATA_PxCMD[19] MPSP	0x0
Disable the hot-plug-capable port feature.	SATA_PxCMD[18] HPCP	0x0
If PM is attached:		
Set the SATA_PxCMD [17] PMA bit to notify HBA that the PM is attached to HBA port 0.	SATA_PxCMD[17] PMA	0x1
ELSE		
Clear the SATA_PxCMD[17] PMA bit as a notification that a single-target SATA device is attached to port 0.	SATA_PxCMD[17] PMA	0x0

24.8.5.1.3 Issue Command - Main Sequence

The procedure in Table 24-577 prepares a command list entry and issues its corresponding command.

Table 24-577. Prepare and Issue a Command

Step	Register/Bit Field/Programming Model	Value
Build command header and command table into host system memory.	For details, see Section 24.8.4.6.1, *Command List Structure Basics*.	-
Create the command corresponding PRD table.		
Queue the command to the command list.	See Section 24.8.4.7.1, *Software Processing of the Port Command List*.	-
Set the SATA_PxCMD[0] ST bit to direct the DMA to start processing the CL.	SATA_PxCMD[0] ST	0x1(1)
IF a nonNCQ command is issued:		
Set the corresponding SATA_PxCI.CI bit to activate a command already prepared in the i-th slot of the CL .	SATA_PxCI[i] CI	0x-
ELSE		
Indicate the NCQ slot positions through the SATA_PxSACT register. For details on TAG tracking, see Section 24.8.4.7.1.	SATA_PxSACT[TAG] DS	0x-
Set the corresponding SATA_PxCI.CI bit to activate the NCQ command already prepared in the i-th slot of the CL.	SATA_PxCI[TAG] CI	0x-

(1) See the AHCI standard specification for important restrictions when PXCMD[0] ST can be software-asserted to 1.

24.8.5.1.4 Receive FIS—Main Sequence

The procedure in Table 24-578 is used to handle a FIS reception.

Copyright © 2015–2017, Texas Instruments Incorporated

Table 24-578. FIS Reception

Step	Register/Bit Field/Programming Model	Value
Read SATA_PxIS to determine the type of FIS.	For more information, see Section 24.8.4.7.2, *Handling the Received FIS Descriptors*.	-

24.8.6 SATA Controller Register Manual

NOTE: SATA is not supported on the AM570x family of devices.

Table 24-631. SATA_PxIS

Address Offset	0x0000 0110		
Physical Address	0x4A14 0110	**Instance**	DWC_ahsata
Description	Port interrupt status Bits are set by internal conditions and cleared (when possible) by writing 1 to them. Reset on global reset.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CPDS	TFES	HBFS	HBDS	IFS	INFS	RESERVED	OFS	IPMS	PRCS	RESERVED														DMPS	PCS	DPS	UFS	SDBS	DSS	PSS	DHRS

Bits	Field Name	Description	Type	Reset
31	CPDS	Cold port detect status Set when the pX_cp_det input changes its state due to the insertion or removal of a device Valid only if the port supports cold presence detection as indicated by the SATA_PxCMD.CPD bit set to 1. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
30	TFES	Task file error status Set whenever the SATA_PxTFD.STS register is updated by the device and the error bit (bit 0) is set. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
29	HBFS	Host bus fatal error status Set when master (DMA) detects an ERROR response from the slave Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
28	HBDS	Host bus data error status This bit is always cleared to 0. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
27	IFS	Interface fatal error status This bit is set when any of the following conditions is detected: 1) SYNC escape is received from the device during H2D register or data FIS transmission. 2) One or more of the following errors are detected during data FIS transfer: - 10B to 8B Decode Error (SATA_PxSERR.DIAG_B) - Protocol (SATA_PxSERR.ERR_P) - CRC (SATA_PxSERR.DIAG_C) - Handshake (SATA_PxSERR.DIAG_H) - PHY not ready (SATA_PxSERR.ERR_C) 3) Unknown FIS is received with good CRC, but the length exceeds 64 bytes. 4) PRD table byte count is 0. 5) DMA setup FIS is received with a TAG corresponding to inactive (SATA_PxSACT bit is cleared) command slot. Port DMA transitions to a fatal state until the software clears SATA_PxCMD.ST bit or resets the interface by way of port reset or global reset. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
26	INFS	Interface nonfatal error status Set when any of the following conditions is detected: 1) One or more of the following errors are detected during nondata FIS transfer: - 10b to 8b decode error (SATA_PxSERR.DIAG_B) - Protocol (SATA_PxSERR.ERR_P) - CRC (SATA_PxSERR.DIAG_C) - Handshake (SATA_PxSERR.DIAG_H) - PHY not ready (SATA_PxSERR.ERR_C) 2) Command list underflow during read operation (that is, DMA read) when the software builds a command table that has more total bytes than the transaction given to the device. In both cases port operation continues normally. When an error is detected during nondata FIS transmission, this FIS is retransmitted continuously until it succeeds, or until the software times out and resets the interface. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
25	RESERVED		R	0
24	OFS	Overflow status Set when command list overflow is detected during read or write operation when the software builds command table that has fever total bytes than the transaction given to the device. Port DMA transitions to a fatal state until the software clears SATA_PxCMD.ST bit or resets the interface by way of port reset or global reset. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
23	IPMS	Incorrect PM status FIS received from a device in which the PM field did not match what was expected May be set during enumeration of devices on a PM due to the normal PM enumeration process Must be used only after enumeration is complete on the PM Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
22	PRCS	PhyRdy change status Reflects the state of SATA_PxSERR.DIAG_N To clear this bit, clear the SATA_PxSERR.DIAG_N bit to 0. Read 0x1: Internal pX_phy_ready signal changed state Read 0x0: Internal pX_phy_ready signal has not changed state since its last reset.	R	0
21:8	RESERVED		R	0x0000
7	DMPS	Device mechanical presence status Set when the pX_mp_switch input changes its state as a result of a mechanical switch attached to this port opening or closing Valid only when SATA_CAP.SMPS and SATA_PxCMD.MPSP are set Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
6	PCS	Port connect change status This bit reflects the state of the SATA_PxSERR.DIAG_X bit. Cleared only when SATA_PxSERR.DIAG_X is cleared Read 0x1: Change in current connect status Read 0x0: No change in current connect status	R	0
5	DPS	Descriptor processed A PRD with the I bit set has transferred all of its data. Note. This is an opportunistic interrupt and must not be used to definitively indicate the end of a transfer. Two PRD interrupts could occur close enough together that the second interrupt is missed when the first PRD interrupt is cleared. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
4	UFS	Unknown FIS interrupt An unknown FIS was received and has been copied into system memory. Cleared to 0 by the software clearing the SATA_PxSERR.DIAG_F bit to 0. Note: The UFS bit does not directly reflect the SATA_PxSERR.DIAG_F bit. SATA_PxSERR.DIAG_F bit is set immediately when an unknown FIS is detected, whereas the UFS bit is set when that FIS is posted to memory. The software should wait to act on an unknown FIS until the UFS bit is set to 1 or the two bits may become out of sync. Read 0x1: IRQ event active Read 0x0: Event inactive	R	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
3	SDBS	Set device bits interrupt A Set Device Bits FIS is received with the I bit set and copied into system memory. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
2	DSS	DMA setup FIS interrupt A DMA Setup FIS is received with the I bit set and copied into system memory. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
1	PSS	PIO setup FIS interrupt A PIO Setup FIS is received with the I bit set, copied into system memory, and the data related to the FIS is transferred. Note: This bit is set even when the data transfer resulted in an error. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0
0	DHRS	Device to host register FIS interrupt A D2H register FIS is received with the I bit set and copied into system memory. Write 0x0: No action Write 0x1: Clear event Read 0x1: IRQ event active Read 0x0: Event inactive	RW W1toClr	0

ICC				ASP	ALPE	DLAE	ATAPI	APSTE	FBSCP	ESP	CPD	MPSP	HPCP	PMA	CPS	CR	FR	MPSS	CCS					RESERVED			FRE	CLO	POD	SUD	ST

Bits	Field Name	Description	Type	Reset
31:28	ICC	Interface communication control Control of power management states of the interface If the link layer is in the L_IDLE state, writes cause the port to request a transition to a given interface state. If the link layer is not in the L_IDLE state, writes have no effect. When a nonreserved, non-0 (No-Op) value is written, the core performs the action and clears the field back to 0 (Idle) Write 0x0: No-Op Read 0x0: Port is ready to accept a new interface control command, although the transition to the previously selected state might not have occurred yet. 0x1: Active 0x2: PARTIAL. SATA device can reject the request and the interface then remains in its current state. 0x6: SLUMBER. SATA device can reject the request and the interface then remains in its current state.	RW	0x0
27	ASP	Aggressive SLUMBER/PARTIAL 0x0: If SATA_PxCMD.ALPE = 1, the port aggressively enters the PARTIAL state when it clears the SATA_PxCI register and the SATA_PxSACT register is cleared when it clears the SATA_PxSACT register and SATA_PxCI is cleared. 0x1: If SATA_PxCMD.ALPE = 1, the port aggressively enters the SLUMBER state when it clears the SATA_PxCI and the SATA_PxSACT register is cleared or when it clears the SATA_PxSACT register and SATA_PxCI is cleared.	RW	0
26	ALPE	Aggressive link power management enable 0x0: Aggressive power management state transition is disabled. 0x1: Port aggressively enters a lower link power state (PARTIAL or SLUMBER) based on the setting of SATA_PxCMD.ASP.	RW	0
25	DLAE	Drive LED on ATAPI enable 0x0: LED is never enabled. 0x1: Port asserts the pX_act_led output when commands are active and SATA_PxCMD.ATAPI = 1.	RW	0
24	ATAPI	Device is ATAPI Used by the port to determine whether or not to assert pX_act_led output when commands are active. 0x0: Connected device is not an ATAPI. 0x1: Connected device is an ATAPI.	RW	0
23	APSTE	Auto PARTIAL to SLUMBER transition enable 0x0: No automatic transition from PARTIAL to SLUMBER 0x1: Link layer transitions from its PARTIAL power management state to SLUMBER state automatically, whether host software-, port (aggressive)-, or device-initiated.	RW	0
22	FBSCP	FIS-based Switching Capable Port May only be set to ?1? if CAP.SPM = CAP.FBSS = 1 (not the case). Writable once after power up, read-only afterwards. 0x0: port does not support FIS-based switching. 0x1: Port supports Port Multiplier FIS-based switching.	RW	0x0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
21	ESP	External SATA port Writable once after power up, read-only afterward 0x0: Port signal-only connector is not externally accessible. 0x1: Port signal-only connector is externally accessible. SATA_CAP.SXS is also set to 1. Mutually exclusive with SATA_PxCMD.HPCP	RW	0x0
20	CPD	Cold presence detect Writable once after power up, read-only afterward 0x0: Platform does not support cold presence detection on this port. 0x1: Platform supports cold presence detection on this port. SATA_PxCMD.HPCP should be set to 1.	RW	0
19	MPSP	Mechanical presence switch attached to port Writable once after power up, read-only afterward 0x0: Platform does not support a mechanical presence switch on this port. 0x1: Platform supports a mechanical presence switch attached to this port. SATA_PxCMD.HPCP should be set to 1.	RW	0
18	HPCP	Hot plug capable port Writable once after power up, read-only afterward 0x0: Port signal and power connectors are not externally accessible. 0x1: Port signal and power connectors are externally accessible through a joint signal-power connector for blindmate device hot plug.	RW	0
17	PMA	PM attached Software is responsible for detecting the presence of a PM. There is no autodetection. 0x0: No port Multiplier is attached to this Port 0x1: Port Multiplier is attached to this Port	RW	0
16	CPS	Cold presence state Reports whether a device is currently detected on this port as indicated by the pX_cp_det input state (assuming SATA_PxCMD.CPD = 1). Read 0x1: Device detected Read 0x0: No device detected	R	0
15	CR	Command list running For details, see the AHCI state-machine in Section 5.3.2 of the AHCI specification. Read 0x1: Command list DMA engine for this port is running. Read 0x0: Command list is stopped for this port.	R	0
14	FR	FIS receive running For details, see Section 10.3.2 of the AHCI specification. Read 0x1: FIS receive DMA engine for the port is running. Read 0x0: FIS receive DMA engine for the port is stopped.	R	0
13	MPSS	Mechanical presence switch state Reports the state of a mechanical presence switch attached to this port as indicated by the pX_mp_switch input state (assuming SATA_CAP.SMPS = 1 and SATA_PxCMD.MPSP = 1) Cleared to 0 when SATA_CAP.SMPS = 0 Read 0x1: Switch is open. Read 0x0: Switch is closed.	R	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
12:8	CCS	Current command slot This field is valid when SATA_PxCMD.ST is set to 1 and is set to the command slot value of the command currently issued by the port. When SATA_PxCMD.ST transitions from 1 to 0, this field is reset to 0x00. After SATA_PxCMD.ST transitions from 0 to 1, the highest priority slot to issue from next is command slot 0. After the first command is issued, the highest priority slot to issue from next is SATA_PxCMD.CCS + 1. For example, after the port issues its first command, if CCS = 0x00 and SATA_PxCI is set to 0x3, the next command issued is from command slot 1.	R	0x00
7:5	RESERVED		R	0x0
4	FRE	FIS receive enable Must not be set until SATA_PxFB / SATA_PxFBU is programmed with a valid pointer to the FIS receive area Base can be moved after clearing FRE and waiting for FR to clear to 0. 0x0: Received FISes are not accepted by the port, except for the first D2H register FIS after the initialization sequence, and no FISes are posted to the FIS receive area. 0x1: Port can post received FISes into the FIS receive area pointed to by SATA_PxFB and SATA_PxFBU.	RW	0
3	CLO	Command list override Write 0x0: No effect Write 0x1: Request to clear SATA_PxTFD.STS_BSY and SATA_PxTFD.STS_DRQ to 0. Use only immediately prior to setting SATA_PxCMD.ST bit to 1 from a previous value of 0. Any other case results in indeterminate behavior. Read 0x1: Override is active, SATA_PxTFD.STS_BSY and SATA_PxTFD.STS_DRQ are being cleared. Read 0x0: Override is inactive.	RW	0
2	POD	Power-on device Writable if SATA_PxCMD.CPD = 1 (cold presence detection enabled), otherwise read-only -1. 0x0: Disabled 0x1: Port asserts the pX_cp_pod output pin so that it can be used to provide power to a cold-presence detectable port.	RW	0
1	SUD	Spin-up device Writable if SATA_CAP.SSS = 1 (staggered spin-up supported), else read-only 1. Read-only-0 on power-up until SATA_CAP.SSS bit is written with the required value. 0x0: Clearing the bit from 1 to 0 causes no action on the interface. 0x1: On edge-detect from 0 to 1, the port starts a COMRESET initialization sequence to the device.	RW	0
0	ST	Start 0x0: Port does not process the command list. On transition from 1 to 0, the SATA_PxCI register is cleared by the port on transition to an IDLE state. 0x1: Port processes the command list. On transition from 0 to 1, the port starts processing the command list at entry 0. SATA_PxSERR must be cleared prior to setting ST to 1. For important restrictions on when ST can be set to 1, See Section 10.3.1 of the AHCI specification.	RW	0

Table 24-643. SATA_PxSCTL

Address Offset	0x0000 012C		
Physical Address	0x4A14 012C	**Instance**	DWC_ahsata
Description	Port SATA control Control of SATA interface capabilities. Writes to this register result in action taken by the port PHY interface. Reads from the register return the last value written to it. Reset on global reset. Wait for at least seven periods of the slower clock (OCP or parallel serdes clock) between writes, due to the internal clock domain crossing between the transport (OCP) and link (serdes I/F) layers.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

15:12	SPM	Select power management: This field is not used by the AHCI.	R	0x0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
11:8	IPM	Interface power management transitions allowed: Indicates which power states the HBA is allowed to transition to. If an interface power management state is disabled, the HBA is not allowed to initiate that state and the HBA must PMNAK_P any request from the device to enter that state. The two MSBs are always 2'b00 (not writable), as for all unreserved field values. 0x0: No interface power management state restrictions 0x1: Transitions to the PARTIAL state disabled 0x2: Transitions to the SLUMBER state disabled 0x3: Transitions to both PARTIAL and SLUMBER states disabled	RW	0x0
7:4	SPD	Speed allowed: Highest allowable speed of the interface The two MSBs are always 2'b00 (not writable), as for all unreserved field values. 0x0: No speed negotiation restrictions 0x1: Limit speed negotiation to generation 1 communication rate. 0x2: Limit speed negotiation to a rate not greater than generation 2 communication rate.	RW	0x0
3:0	DET	Device detection initialization: Controls the HBA device detection and interface initialization. Can be modified only when SATA_PxCMD.ST = 0. Must have a value of 0x0 when SATA_PxCMD.ST = 1. MSB is always 1'b0 (not writable), as for all unreserved field values. 0x0: No device detection or initialization action requested 0x1: Perform interface communication initialization sequence to establish communication. This is functionally equivalent to a hard reset and results in the interface being reset and communications reinitialized. While this field is 1h, COMRESET is transmitted on the interface. Software must leave the DET field set to 1h for a minimum of 1 ms to ensure that a COMRESET is sent on the interface. 0x4: Disable the serial ATA interface and put PHY in offline mode.	RW	0x0

DS																															

Bits	Field Name	Description	Type	Reset
31:0	DS	Device status: Field is bit-significant. Each bit corresponds to the TAG and command slot of a native queued command, where bit 0 corresponds to TAG 0 and command slot 0. Set by Software prior to issuing a native queued command for a particular command slot. Prior to writing SATA_PxCI[TAG] to 1, software sets DS[TAG] to 1 to indicate that a command with that TAG is outstanding. The device clears bits by sending a set device bits FIS to the port. The port clears bits in this field that are set to 1 in the SActive field of the set device bits FIS. The port only clears bits that correspond to native queued commands completed successfully. Write only when SATA_PxCMD.ST bit is set to 1. Cleared when SATA_PxCMD.ST is written from 1 to 0. Not cleared by a port reset (COMRESET) or a software reset.	RW	0x0000 0000

CI																															

Bits	Field Name	Description	Type	Reset
31:0	CI	Commands issue: Field is bit-significant. Each bit corresponds to a command slot, where bit 0 corresponds to command slot 0. This field is set by software to indicate to the port that a command is built in system memory for a command slot and may be sent to the device. When the port receives a FIS that clears the BSY, DRQ, and ERR bits for the command, it clears the corresponding bit in this register for that command slot. Bits in this field can only be set to 1 by software when SATA_PxCMD.ST is set to 1. Also cleared when SATA_PxCMD.ST is written from 1 to 0 by software.	RW	0x0000 0000

Bits	Field Name	Description	Type	Reset
31:17	RESERVED		R	0x0000
16	OVERRIDE0	Override for clock stopping. Normally the functional clock can be stopped only if the link is put into PARTIAL or SLUMBER power state. However, if there is no device attached (such as in a removable media situation) or the device is not started, the user can stop the functional clocks but not be able to enter a low-power state. In this case, software can set the OVERRIDE bit to 1, removing the requirement for a low-power state WARNING: If there is a device attached, the OVERRIDE bit is used, and the functional clock is stopped when the link is not in a low-power state it ruins the link and causes undetermined behavior. A port reset or full SATASS reset might be required to recover. 0x0: Normal mode 0x1: Override mode	RW	0
15:6	RESERVED		R	0x000
5:4	STANDBYMODE	Configuration of the local initiator-state management mode. By definition, the initiator can generate a read/write transaction as long as it is out of STANDBY state. 0x0: Force-standby mode: Local initiator is unconditionally placed in STANDBY state. Backup mode, for debug only 0x1: No-standby mode: local initiator is unconditionally placed out of STANDBY state. Backup mode, for debug only. 0x2: Smart-standby mode: Local initiator standby status depends on local conditions, that is, the module's functional requirement from the initiator. The IP module does not generate (initiated-related) wakeup events. 0x3: Smart-Standby wakeup-capable mode: Local initiator standby status depends on local conditions, that is, the module's functional requirement from the initiator. The IP module can generate (master related) wakeup events when in STANDBY state. Mode is relevant only if the appropriate IP module mwakeup output is implemented.	RW	0x2
3:2	IDLEMODE	Configuration of the local target state management mode. By definition, the target can handle read/write transaction as long as it is out of IDLE state. 0x0: Force-idle mode: The local target IDLE state follows (acknowledges) the system idle requests unconditionally, that is, regardless of the internal requirements of th e IP module. Backup mode, for debug only. 0x1: No-idle mode: The local target never enters IDLE state. Backup mode, for debug only. 0x2: Smart-idle mode: The local target IDLE state eventually follows (acknowledges) the system idle requests, depending on the internal requirements of the IP module. IP module does not generate (IRQ- or DMA-request-related) wakeup events. 0x3: Smart-idle wakeup-capable mode: The local target IDLE state eventually follows (acknowledges) the system idle requests, depending on the internal requirements of the IP module. IP module can generate (IRQ- or DMA-request-related) wakeup events when in IDLE state. Mode is only relevant if the appropriate IP module swakeup output(s) is (are) implemented.	RW	0x2

24.9 PCIe Controller

This section describes the features and functions of the device Peripheral Component Interconnect Express (PCIe) Controller which provides a high-speed glueless serial interconnect to peripherals utilizing high bandwidth applications.

24.9.1 PCIe Controller Subsystem Overview

The Peripheral Component Interconnect Express (PCIe) module is a multi-lane I/O interconnect that provides low pin-count, high reliability, and high-speed data transfer at rates of up to 5.0 Gbps per lane, per direction, for serial links on backplanes and printed wiring boards. It is a 3-rd Generation I/O Interconnect technology succeeding PCI and ISA bus that is designed to be used as a general-purpose serial I/O interconnect. It is also used as a bridge to other interconnects like SATA, USB2/3.0, GbE MAC, and so forth.

The device instantiates two PCIe subsystems (PCIe_SS1 and PCIe_SS2). The PCIe controller is capable to operate either in Root Complex (RC) or in End Point (EP) PCIe mode. The device PCIe_SS1 controller supports up to two 16-bit data lanes on its PIPE port. The device PCIe_SS2 controller supports only one 16-bit data lane on its PIPE port.

When the PCIe_SS1 controller PIPE port is configured to operate in a single-lane mode, it operates on a single pair of PCIe PHY serializer and deserializer - PCIe1_PHY_TX/PCIe1_PHY_RX. When PCIe_SS1 PIPE is configured to operate in dual-lane mode, it operates on two pairs of PCIe PHY serializer and deserializer - PCIe1_PHY_TX/PCIe1_PHY_RX and USB_PHY_TX/USB_PHY_RX, respectively. The single-lane PCIe_SS2 controller PIPE port (if enabled) can operate only on the USB_PHY_TX/USB_PHY_RX pair. Hereby, if PCIe_SS2 controller is used, the PCIe_SS1 can operate only in a single-lane mode on the PCIe1_PHY_TX/PCIe1_PHY_RX. In addition, PCIe PHY subsystem encompasses a PCIe PCS (physical coding sublayer), a PCIe power management logic, APLL, a DPLL reference clock generator and an APLL clock low-jitter buffer. For more details on PCIe PHY subsystem, please refer to Section 26.4, *PCIe Shared Phy Subsystem*.

- The PCIe Controller implements the transport and link layers of the PCIe interface protocol.
- PCIe PCS (a physical coding sublayer component) converts a 8-bit portion of parallel data over a PCIe lane to a 10-bit parallel data to adapt the process of serialization and deserialization in the TX/RX PHYs to various requirements. At the same time it transforms the transmission rate to maintain the PCIe Gen2 bandwidth (5 Gbps) on both sides (PCIe controller and PHY).
- A multiplexer logic which adds flexibility to connect a PCIe controller hardware mapped PCS logic output to a single (for the single-lane PCIe_SS2 controller) or to a couple (for the 2-lane PCIe_SS1 controller) of PHY ports at a time
- Physical layer (PHY) serializer/deserializer components with associated power control logic, building the so called PMA (physical media attachment) part of the PCIe_PHY transceiver, as follows:
  - PCIe physical port 0 associated serializer (TX) - PCIe1_PHY_TX and deserializer (RX) - PCIe1_PHY_RX
  - USB port associated serializer (TX) - USB_PHY_TX and deserializer (RX) - USB_PHY_RX
- DPLL_PCIe_REF is a DPLL clock source, controlled from the device PRCM, that provides a 100-MHz clock to the PCIe PHY serializer/deserializer components reference clock inputs.
- Both the PCIe_SS1 and PCIe_SS2 share the same APLL (APLLPCIe) which by default multiplies the DPLL_PCIe_REF (typically 100 MHz or 20 MHz) clock to 2.5 GHz.
- The APLLPCIe low-jitter buffer (ACSPCIE) and additional logic takes care to provide the PCIe APLL reference input clock.

Figure 24-160 shows an overview of a device PCIe subsystem with its integrated components.

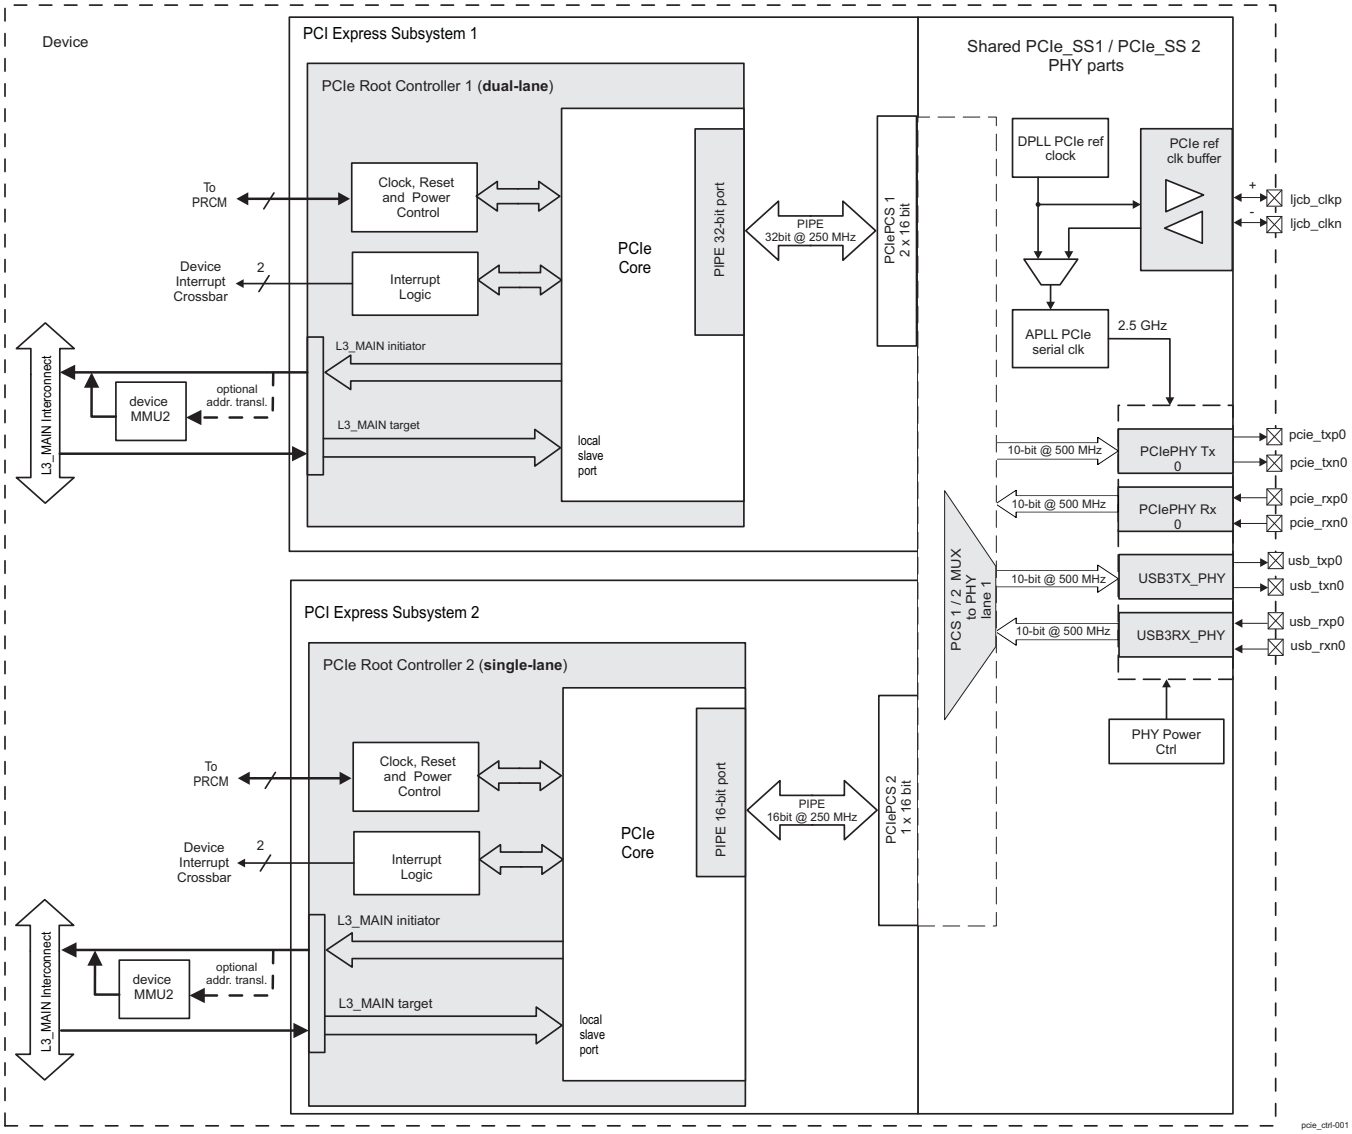
Figure 24-160. PCIe Controller Subsystem Overview



24.9.1.1 PCIe Controllers Key Features

This section describes the features supplied by the PCIe controller modules (including PCIe at device level). The PCIe_SS1 and PCIe_SS2 controllers comply with the following standards:

- PCI Local Bus Specification revision 3.0
- PCI Express Base 3.0 Specification, revision 1.0.

At system level the device supports PCI express interface in the following configurations:

- Each PCIe subsystem controller has support for PCIe Gen2 mode (5.0 Gbps per lane) and Gen1 mode (2.5 Gbps per lane).
- One PCIe (PCIe_SS1) operates as Gen2 2-lanes supporting in either root-complex (RC) or end-point EP.
- Two PCIe (PCIe_SS1 and PCIe_SS2) operates Gen2 1-lane supporting either RC or EP with the possibility of one operating in Gen1 and one in Gen2.
- PCIe_SS1 can be configured to operate in either 2-Lane (dual lane) or 1-Lane (single lane) mode, as follows:

Copyright © 2015–2017, Texas Instruments Incorporated

  - Single Lane - lane 0 mapped to the PCIe port 0 of the device
  - Flexible dual lane configuration - lanes 0 and 1 can be swapped on the two PCIe ports
- PCIe_SS2 can only operate in 1-Lane mode, as follows:
  - Single Lane - lane 0 mapped to the device PCIe port 1

  When PCIe_SS1 is configured to operate in dual-lane mode, PCIe_SS2 is not available.

The main features of a device PCIe controller are:

- 16-bit operation at 250 MHz on PIPE interface (per 16-bit lane)
- One master port on the L3_MAIN supporting 32-bit address and 64-bit data bus.
- PCIe_SS1/PCIe_SS2 master port dedicated MMU (device MMU2) on L3_MAIN path, to which PCIe traffic can be optionally mapped.
- One slave port on the L3_MAIN supporting 29-bit address and 64-bit data bus.
- Maximum outbound payload size of 64 Bytes (the L3 Interconnect PCIe1/2 target ports split bursts of size >64 Bytes to the into multiple 64 Byte bursts)
- Maximum inbound payload size of 256 Bytes (internally converted to 128 Byte - bursts)
- No remote read request size limit: implicit support for 4 KiB-size and greater
- Support of EP legacy mode
- Support of inbound I/O accesses in EP legacy mode
- PIPE interface features fixed-width (16-bit data per lane) and dynamic frequency to switch between PCIe Gen1 and Gen2.
- Ultra-low transmit and receive latency
- Automatic Lane reversal as specified in the PCI Express Base 3.0 Specification, revision 1.0 (transmit and receive)
- Polarity inversion on receive
- Single Virtual Channel (VC0) and Single Traffic Class (TC0)
- Single Function in End point mode
- Automatic credit management
- ECRC generation and checking
- All PCI Device Power Management D-states with the exception of $D3_{cold}$/L2 state
- PCI Express Active State Power Management (ASPM) state L0s and L1 (with exceptions)
- PCI Express Link Power Management states except for L2 state
- PCI Express Advanced Error Reporting (AER)
- PCI Express messages for both transmit and receive
- Filtering for Posted, Non-Posted, and Completion traffic
- Configurable BAR filtering, I/O filtering, configuration filtering and completion lookup/timeout
- Access to configuration space registers and external application memory mapped registers through ECAM mechanism.
- Legacy PCI Interrupts reception (RC) and generation (EP)
- 2× hardware interrupts per PCIe_SS1and PCIe_SS2 controller mapped via the device Interrupt Crossbar (IRQ_CROSSBAR) to multiple device host (MPU, DSP, and so forth) interrupt controllers in the device
- MSIs generation and reception
- PCIe_PHY Loopback in RC mode

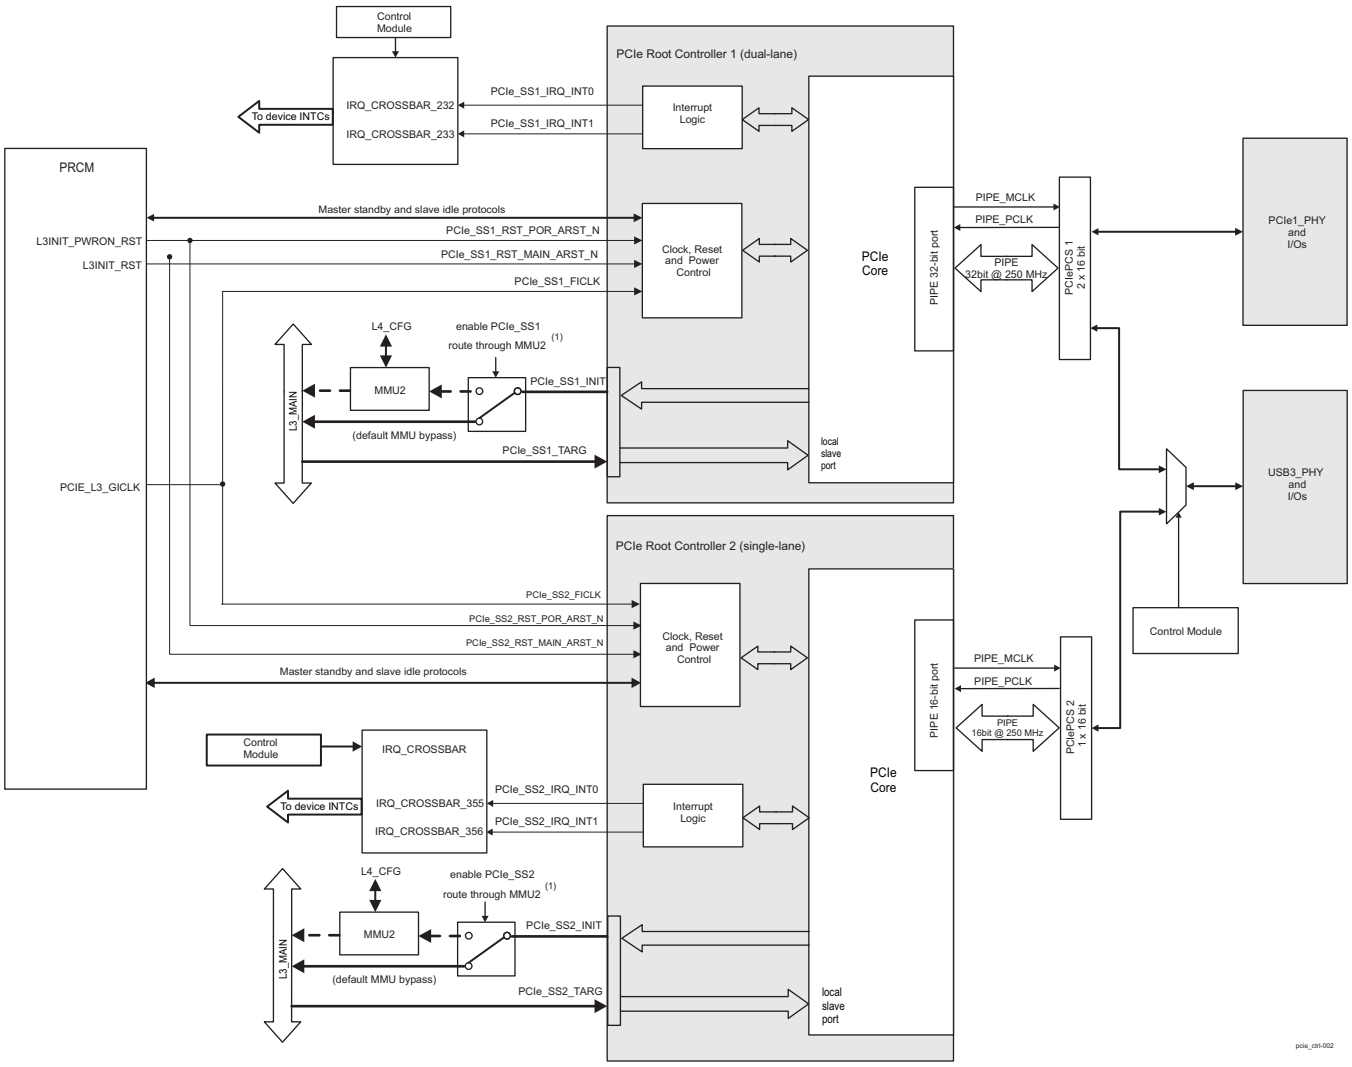
24.9.3 PCIe Controllers Integration

This section describes the PCIe controllers integration in the device, including information about clocks, resets, and hardware requests. Figure 24-161 shows the PCIe controllers integration.

Figure 24-161. PCIe Controllers Integration



NOTE: By default, the traffic from the PCIe_SS1 and PCIe_SS2 controller master (initiator) port - PCIe_SS1_INIT/PCIe_SS2_INIT to the L3_MAIN interconnect, bypasses the device MMU2. Mapping the PCIe traffic from the PCIe master port to MMU2 on the L3_MAIN path is enabled via a bit in the device Core Control Module. For more details, refer to the Section 24.9.4.3.1.1.

PCIe controller integration includes these features:

- A single interface/functional clock (PCIe_SS_FICLK, shared between the master and the slave interfaces)
- A couple of functional clocks:
  - A PCIE controller clock input which receives the PIPE_PCLK generated by the assocaited PCIe PHY PCS logic
  - A PCIE controller clock output PIPE_MCLK which mirrors PIPE_PCLK back to the PCIe PHY PCS component

Copyright © 2015–2017, Texas Instruments Incorporated

- Two hardware non-retention resets - PCIe_SS_RST_POR_ARST_N and PCIe_SS_RST_MAIN_ARST_N by PRCM
- Master standby and slave idle protocols with the power, reset, and clock management (PRCM) module
- Two interrupt request lines (per each PCIe controller):
  - PCIe_SS1_IRQ_INT0/PCIe_SS2_IRQ_INT0 - a main interrupt line
  - PCIe_SS1_IRQ_INT1/PCIe_SS2_IRQ_INT1 - a MSI interrupt line
- No DMA requests generation to surrounding modules
- One 64-bit data/32-bit address master port on the L3_MAIN interconnect (with an option to pass the PCIe initiator traffic to L3_MAIN through device MMU2). For details, refer to the Section 24.9.4.3.
- One 64-bit data/29-bit address slave port on the L3_MAIN interconnect (No MMU included on the slave address path). For details, refer to the Section 24.9.4.3.

For more details on the MMU2 integration in the device, refer to the Section 20.2, *MMU Integration* of the Chapter 20, *Memory Management Units*.

NOTE: For more information about the slave idle protocol and the wakeup request, see Section 3.1.1.1.2, *Module-Level Clock Management* in Chapter 3, *Power, Reset, and Clock Management*.

Table 24-662 through Table 24-664 summarize the integration of the module in the device.

Table 24-662. PCIe Controllers Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
PCIe_SS1	PD_L3INIT	L3_MAIN
PCIe_SS2	PD_L3INIT	L3_MAIN

Table 24-663. PCIe Controllers Clocks and Resets

Clocks				
Module Instance	**Destination Signal Name**	**Source Signal Name**	**Source**	**Description**
PCIe_SS1	PCIe_SS1_FICLK	PCIE_L3_GICLK	PRCM	PCIe_SS1 root controller interface and functional clock (shared between slave and master ports)
PCIe_SS2	PCIe_SS2_FICLK	PCIE_L3_GICLK	PRCM	PCIe_SS2 root controller interface and functional clock (shared between slave and master ports)
Resets				
PCIe_SS1	PCIe_SS1_RST_POR_ARST_N	L3INIT_PWRON_RST	PRCM	A nonretention hardware power-on reset to the PCIe_SS1 controller
	PCIe_SS1_RST_MAIN_ARST_N	L3INIT_RST	PRCM	A nonretention hardware main reset to the PCIe_SS1 controller
PCIe_SS2	PCIe_SS2_RST_POR_ARST_N	L3INIT_PWRON_RST	PRCM	A non-retention hardware power-on reset to the PCIe_SS2 controller
	PCIe_SS2_RST_MAIN_ARST_N	L3INIT_RST	PRCM	A non-retention hardware main reset to the PCIe_SS2 controller

Table 24-664. PCIe Controllers Hardware Requests

Interrupt Requests				
Module Instance	**IRQ Source Name**	**IRQ_CROSSBAR Input**	**Default Mapping**	**Description**
PCIe_SS1	PCIe_SS1_IRQ_INT0	IRQ_CROSSBAR_232	N/A	PCIe_SS1 controller main interrupt request.
	PCIe_SS1_IRQ_INT1	IRQ_CROSSBAR_233	N/A	PCIe_SS1 controller MSI interrupt request.
PCIe_SS2	PCIe_SS2_IRQ_INT0	IRQ_CROSSBAR_355	N/A	PCIe_SS2 controller main interrupt request
	PCIe_SS2_IRQ_INT1	IRQ_CROSSBAR_356	N/A	PCIe_SS2 controller MSI interrupt request.

NOTE: The **Default Mapping** column in Table 24-664, *PCIe Controller Hardware Requests* shows the default mapping of the IRQ sources listed in column **IRQ Source Name** to a certain interrupt line of one of the device interrupt controllers. These IRQ sources can also be mapped to other interrupt lines of each device interrupt controller through the IRQ_CROSSBAR module. For more information about the IRQ_CROSSBAR module, see Section 18.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 18, *Control Module*. For more information about the device interrupt controllers, see Chapter 17, *Interrupt Controllers*.

NOTE: No DMA requests are generated by the PCIe controller to the surrounding modules.

For more details on interrupt request management at the PCIe subsystem local level, refer to the Section 24.9.4.6, *PCIe Controller Interrupt Requests*.

24.9.4 PCIe SS Controller Functional Description

24.9.4.1 PCIe Controller Functional Block Diagram

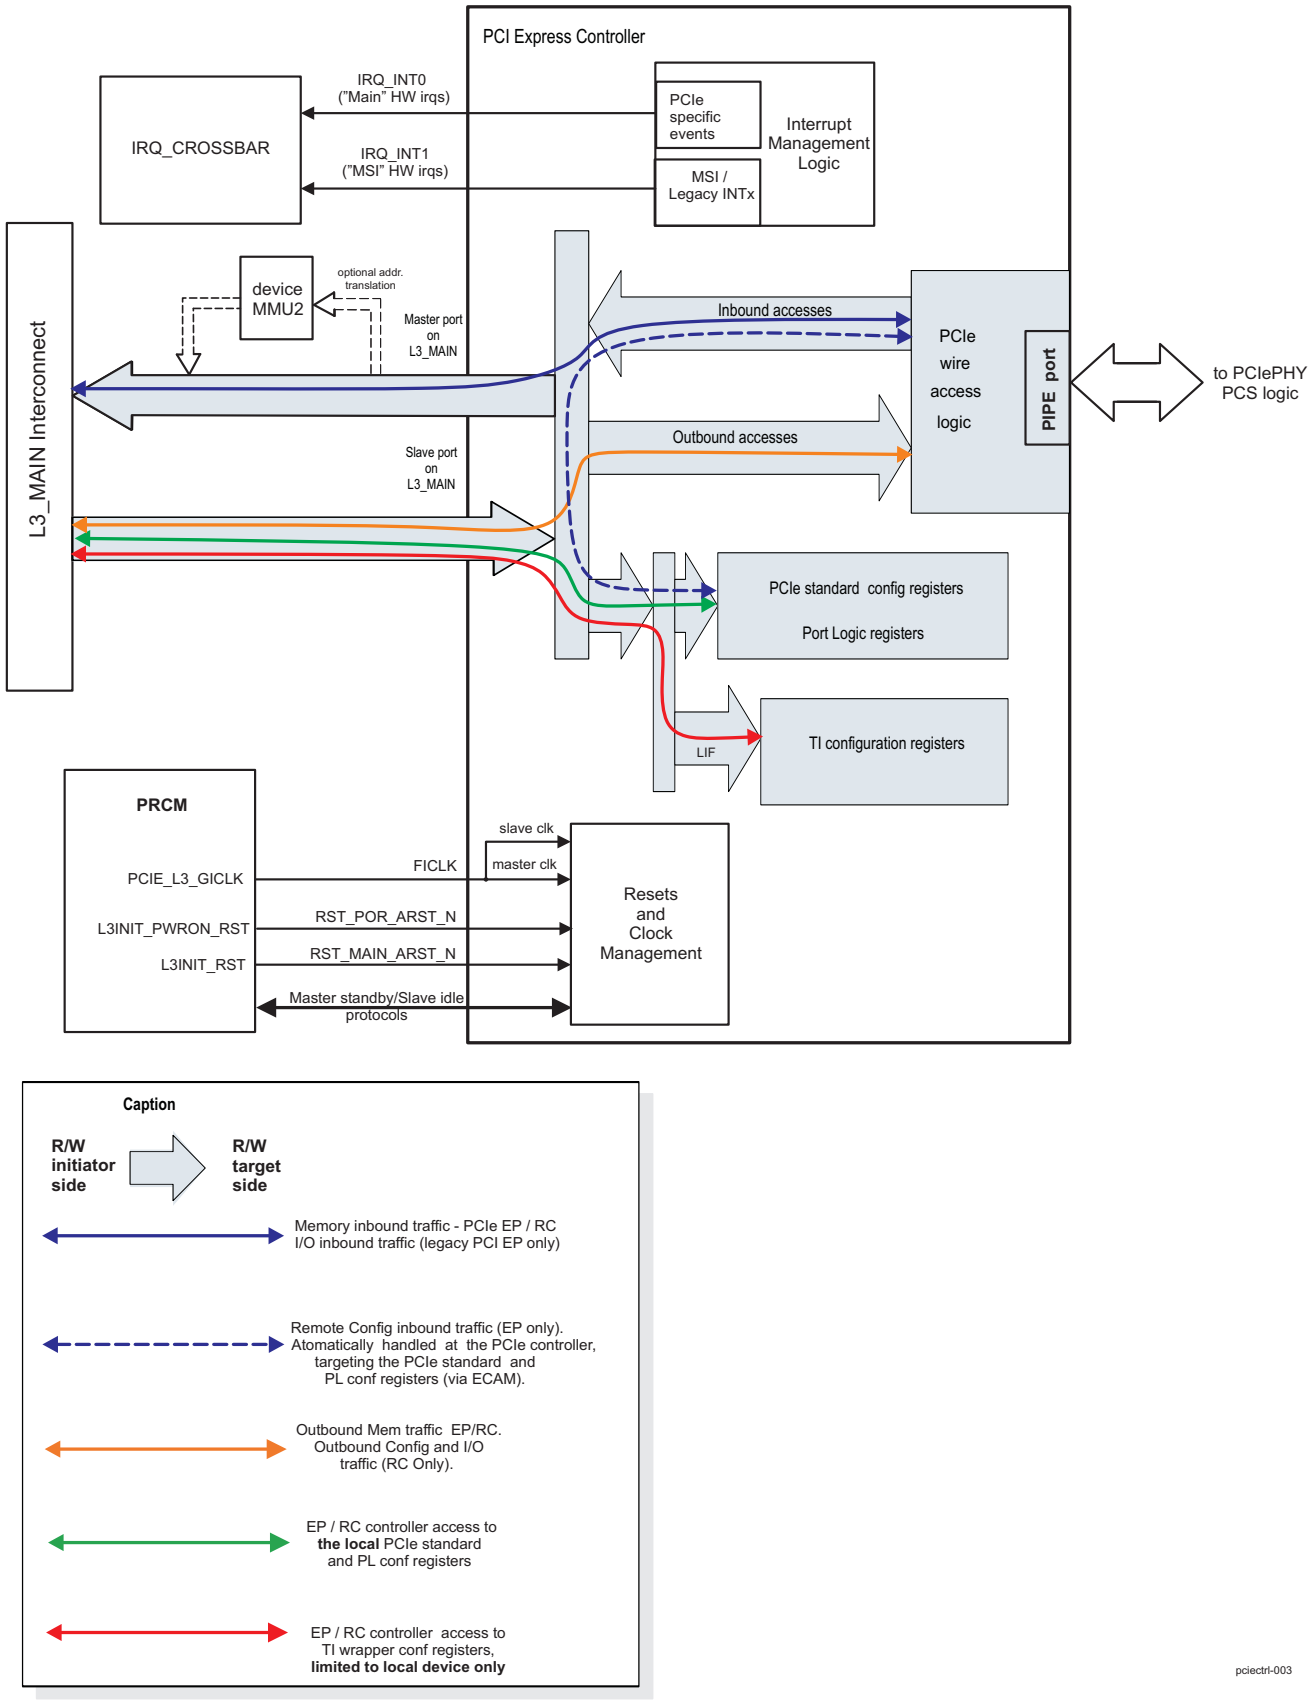
This section describes how the overall PCI express functionality is implemented by the current controller, both as EP and as RC, and how each type of traffic is transmitted and received.

The PCI express interface allows memory-mapped read and write transactions to be performed across different partners of the same PCIe fabric. Locally the device local PCIe system is composed of the PCIe_SS controller itself, device local hosts (such as MPU, DSP, and so forth), device DMAs (EDMA, and so forth) and device system memory (EMIFs SDRAM), connected to the PCIe controller via L3_MAIN interconnect.

Figure 24-162 summarizes the functional components of the PCIe_SS controller, as well as the connectivity between PCIe_SS and other components (MMU2, IRQ_CROSBBAR, PRCM, and so forth) within the device.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 24-162. PCIe Controller Functional Block Diagram



Copyright © 2015–2017, Texas Instruments Incorporated

24.9.4.2 PCIe Traffics

Most of the accesses (Memory-space) are typically flowing straight through the controller, from PCIe bus to L3_MAIN or the other way. However, some transactions are accesses to the PCIe device's configuration registers:

- The source of those accesses is either the local running application, through the PCIe slave port, or a distant PCIe device on the bus, as an inbound transaction from the PCIe wire. Access may or may not be possible depending on the mode of operation (see also transfer descriptions on the Figure 24-162).
- The destination of those accesses is either the PCIe controller core, for the PCIe-standard configuration registers and the non-standard port logic (PL) registers, or the TI wrapper configuration registers accessed over the local interface (LIF).

Figure 24-162 also gives a simplified view of the accesses allowed by device PCIe controller.

On the right hand side of the diagram is the PCIe_PHY (PCS+PMA), itself connected to the PCIe wires. The same structure is expected in the link partner on the other side of the link. Each partner can initiate and complete transactions on the link, using a packet-based protocol. Each lane is a full-duplex serial channel, that is, packets can be exchanged in both directions simultaneously. When more than one lane is used, each packet is transmitted in parallel over all active lanes.

The bidirectional accesses, initiated from components on the PCIe bus (fabric) to/from the device local PCIe subsystem are identified as *Inbound traffic*, while the bidirectional accesses, initiated by device local PCIe system to/from the PCIe bus are identified as *Outbound traffic*.

Note that there are two ways to transmit data from the local PCIe system to a distant PCIe partner:

- **Outbound write accesses**, locally initiated by, for example, a local DMA accessing controller through the PCIe slave port, connected on L3_MAIN, to push data towards a distant PCIe partner.
- **Inbound read accesses**, remotely initiated by, for example, a distant DMA though the PCIe wire, and issued on the PCIe master port, connected on L3_MAIN, to fetch data from the local memory.

Likewise, there are two ways for the local PCIe system to receive data from a distant PCIe partner:

- **Outbound read accesses**, locally initiated by, for example, a local DMA accessing the PCIe slave port, connected on L3_MAIN, to fetch data from a distant PCIe partner.
- **Inbound write accesses**, remotely initiated by, for example, a distant DMA though the PCIe wire, and issued on the PCIe master port towards the local system memory.

NOTE: Inbound PCIe I/O transfers are supported by the PCIe controller only in EP mode (typically for legacy PCI - EPs).

24.9.4.3 PCIe Controller Ports on L3_MAIN Interconnect

The PCIe controller to L3_MAIN connectivity is illustrated, on the left-hand side of the Figure 24-162. Read/write accesses from external PCIe components to the device local system memory on L3_MAIN are performed through the PCIe_SS master (initiator) port - PCIe_SS_INIT. The addresses issued on this port are by default directly routed to the L3_MAIN, but they can be optionally routed to and further translated by the device memory management unit - MMU2 before they reach the L3_MAIN target. For more details on MMU port, refer to Section 24.9.4.3.1.1.

On the other hand, the device local hosts (MPU, DSP, and so forth) initiate accesses to the PCIe controller local registers and PCIe bus remote devices via a PCIe_SS slave (target) port - PCIe_SS_TARG on the L3_MAIN. No MMU is included on the slave path. The slave interface has two uses: manage the local PCIe controller, and carry outbound PCIe traffic, that is initiated locally by PCIe hosts (MPU, DSP, DMAs, and so forth) within the device.

24.9.4.3.1 PCIe Controller Master Port

The PCIe controller master port (using AXI protocol with an adapter to the device L3_MAIN interconnect) has the following key fetures:

- 64-bit data, 32-bit address bus width
- Up to 16 simultaneous outstanding transactions, on up to 16 different IDs (4-bit ID port) total for read

Copyright © 2015–2017, Texas Instruments Incorporated

and write ports together, as follows:

- Posted incoming PCIe transactions are all mapped to AXI ID 0, which ensures that they are executed in order. This includes all high-bandwidth writes, which are memory-type - posted.
- Non-posted incoming PCIe transactions are mapped to AXI ID 1 and above. This includes the high-bandwidth memory-type reads.

- uses the same clock source as the PCIe slave port, but potentially on a different divider ratio
- PCIe master port, does not use a disconnect interface, because unlike the PCIe slave port, it is expected to be always active when the PCIe controller has to initiate a transaction over the device L3_MAIN.
- The PCIe controller maximum inbound payload size is 256 Bytes. The PCIe master port burst maximum length is 16 words (16 x 64-bit data words = 128 Bytes per burst). Hence a 256 Byte inbound data payload is converted by the PCIe master port to 2 max-sized bursts (128 Byte each) towards the device L3_MAIN interconnect PCIe slave port which is 128 Byte-burst compatible.
- Only incremental bursts (INCR) are supported by the PCIe controller master port.
- Non-aligned bursts can be generated - bursts that are not aligned with their own size: a burst-aligned portion of 2^N-bytes aligned burst starts on a byte address multiple of 2^N, that is a byte address with the N LSBs at '0').

The PCIe memory space supports a 64-bit address mode but in the device PCIe controller, the AXI master port address size is restricted to 32 bits.

NOTE: A PCIe controller remains fully functional, and able to receive transactions from , for example, anywhere within the 64-bit PCIe memory space, as long as they are correctly remapped by the inbound address translation unit (ATU) to a 32-bit L3_MAIN space address (device L3_MAIN 4 GiB - memory space). The limitation is that the range addressable by the PCIe master is reduced, and that regions larger than 2^{32} bytes (4GiB) total, cannot be mapped to the AXI master port on L3_MAIN.

24.9.4.3.1.1 PCIe Controller Master Port to MMU Routing

A standalone MMU2 module is included at the system level, primarily for use by the PCIe_SS1 and PCIe_SS2 controller. This provides several benefits including protection of the MPU host memory regions from corruption by PCIe_SS1 and PCIe_SS2 accidental accesses.

PCIe controller initiated (by remote side) traffic can be optionally routed through the MMU2 as controlled by a Control Core Module register bit. The PCIe_SS1 and PCIe_SS2 routing allows these sub-systems to be used to perform transfers.

NOTE: By default, the CTRL_MODULE_CORE instance located CTRL_CORE_CONTROL_IO_1[20] MMU2_DISABLE bit is set to 0b0 and the MMU2 is functionally enabled. Despite this, the PCIe_SS1 and PCIe_SS2 controller traffic still bypasses this MMU.
In order, for PCIe_SS1 and PCIe_SS2 master traffic to be routed through the MMU2, the CTRL_MODULE_CORE bits: CTRL_CORE_SMA_software_7[13] PCIE_SS1_MMU_ROUTE_ENABLE and CTRL_CORE_SMA_software_7[12] PCIE_SS2_MMU_ROUTE_ENABLE, must be set to 0b1 by user software.

Accesses are directed to the MMU2 by the L3_MAIN switch fabric through the use of a 33-rd address bit. For the PCIe_SS1 and PCIe_SS2 master port, the value of the 33rd bit is actually defined by the above mentioned control module CTRL_CORE_SMA_software_7 register bits. For descriptions of the CTRL_CORE_SMA_software_7 register bitfields related to MMU2 route controls, refer to the Section 18.5, *Control Module Register Manual*, in the chapter, *Control Module*.

For more information on device MMU2 functionality and register settings, refer to the Section 20.3, *MMU Functional Description* and Section 20.5, *MMU Register Manual*, in the chapter, *Memory Management Units*, respectively.

Copyright © 2015–2017, Texas Instruments Incorporated

24.9.4.3.2 PCIe Controller Slave Port

The PCIe controller slave port gives access to two internal targets: the local target, to manage the local controller, and the outbound window, which forwards accesses onto the PCIe wire.

The PCIe slave port (using AXI protocol with an adapter to the device L3_MAIN interconnect) has the following key features:

- **64-bit data, 29-bit address** bus width
- Up to 16 simultaneous outstanding transactions, up to 16 different IDs (4-bit ID port).
- Uses the same clock source as the PCIe controller master port, but potentially on a different divider ratio.
- Supports L3_MAIN disconnect protocol
- Exclusive and locked accesses are not supported for read and write port

PCIe Controller slave port purposes are:

- **Configuration and management of the PCIe controller:**
  - This low-bandwidth activity accesses the device PCIe controller local configuration/status registers, the Port Logic registers and the PCIe controller wrapper TI-specific registers.
  - The L3_MAIN base address corresponding to the PCIe_SS1 controller local configuration/status registers (DIF access targets) is 0x5100_0000. For the PCIe_SS2 controller local configuration/status registers (DIF access targets), the L3_MAIN base address is 0x5180_0000.
  - Bursts are not supported when accessing these registers.
- **Outbound PCIe traffic**:
  - This activity can consume the entire bandwidth available on the PCIe wires (up to 1 Gbyte/s in each direction for 2-lane, Gen2 operation), in concurrence with the AXI master ports' operation (that carries inbound PCIe traffic).
  - PCIe controller maximum outbound payload size is 64 Bytes (the L3 Interconnect PCIe1/2 target ports split bursts of size > 64 Bytes to the into multiple 64 Byte bursts). Only bursts of incremental type (INCR) are supported on the PCIe controller slave port.
  - Non-aligned bursts can be generated.
  - All outbound traffic activities are mapped within a device L3_MAIN space region which is 256 MiB in size.
  - For the PCIe_SS1 controller the PCIe outbound window is mapped within range 0x2000_0000 - 0x2FFF_FFFF of the device L3_MAIN memory space. For the PCIe_SS2 controller the PCIe outbound window is mapped within range 0x3000_0000 - 0x3FFF_FFFF (256 MiB) of the device L3_MAIN memory space.

NOTE: The PCIe controller remains fully functional, and able to send transactions to, for example, anywhere within the 64-bit PCIe memory space, with the appropriate remapping of the 28-bit address by the outbound address translation unit (iATU). The limitation is that the total size of addressed PCIe regions (in config, memory, IO spaces) must be less than 2^{28} bytes.

NOTE: Because only incremental burst mode is supported, the PCIe addresses can not be in a cacheable memory space. Subsequently, cache coherence protocol is not involved, and the PCIe controller is not expected to receive coherent PCIe TLPs (NS=0). For safety purpose, the PCIe controller coherent feature must be permanently disabled (and this applies for the device by default) by keeping PCIECTRL_TI_CONF_SYSCONFIG[16] MCOHERENT_EN at value 0b0. In that case, inbound coherent PCIe TLPs (that means with NS=0) proceed normally, but coherence will not be guaranteed by the device.

24.9.4.4 PCIe Controller Reset Management

The PCIe controller has two hardware reset inputs - a hardware **main** and **fundamental** resets which are asynchronous and active low.

Copyright © 2015–2017, Texas Instruments Incorporated

In addition, a number of internal reset conditions can cause some sections of the controller to reset, depending on the power transitions and configuration. All reset conditions and categories are described below.

24.9.4.4.1 PCIe Reset Types and Stickiness

Three types of reset conditions are defined by the PCI standard. Each reset condition listed below falls into one of these categories. The same reset condition can take different types depending on the usecase:

- Cold reset condition: upon device power-up.
- Warm reset condition: does not follow a device power-up.
- Hot reset condition: transmitted over the PCIe link.

A reset including the physical layer (PCIe_PHY) is **called a fundamental reset**. According to the PCI Express Base 3.0 Specification, revision 1.0, it clears the programming registers non-sticky bits, and may clear or may not clear the sticky bits as well, depending on a Vaux power supply. If Vaux integrated in a PCIe subsystem, it is enabled via PM specific sticky bits - PM_CSR[8] PME_EN and DEV_CAS[10] AUXPM_EN register bits.

CAUTION

No Vaux power supply source is defined in hardware for the device integrated PCIe_SS. Subsequently, all PCIe bits defined by the PCIe standard or device specific implementation as "sticky", are reset along with the "non-sticky" bits upon a PCIe fundamental reset assertion. Because it is mandatory to communicate the permanent Vaux absence to the device PCIe EP/RC controller, the EP/RC DEV_CAS[10] AUXPM_EN (or PM_CSR[8] PM_EN) and PCIECTRL_TI_CONF_PM_CTRL [11] AUX_PWR_DET bits have to be always software written ‘0’ during initialization.

A function-level reset (FLR) impacts only one of the EP device’s functions.

NOTE: The device PCIe controller supports only a single function, so it does not support FLR.

24.9.4.4.2 PCIe Reset Conditions

24.9.4.4.2.1 PCIe Main Reset

Main hardware reset: Assertion of the reset signal on the main hardware reset input of the PCIe subsystem unconditionally brings the entire PCIe controller back to its default state. The main HW reset impacts both non-sticky and sticky bits of the PCIe controller.

NOTE: The PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE (RC/EP) bitfield and the remaining TI wrapper configuration registers (PCIe_SS_TI_CONF) are sensitive to main hardware reset only.

24.9.4.4.2.1.1 PCIe Subsystem Cold Main Reset Source

The cold main reset has as a source - the device PRCM L3INIT_PWRON_RST power-on reset. For more information on the PCIe controller hardware reset inputs see Section 24.9.3, *PCIe Controller Integration*).

The L3INIT_PWRON_RST assertion by PRCM resets all PCIe controller registers including the TI wrapper configuration registers (note that the PCIe device type in the PCIECTRL_TI_CONF_DEVICE_TYPE register is reset by default to "Root Complex").

For more information on the PRCM.L3INIT_PWRON_RST hardware reset, refer to Section 3.5.5, *Reset Domains*, in Chapter 3, *Power, Reset, and Clock Management*.

Copyright © 2015–2017, Texas Instruments Incorporated

24.9.4.4.2.1.2 PCIe Subsystem Warm Main Reset Sources

The warm main reset of the PCIe controller is sourced by the device PRCM L3INIT_RST output. For more information on the PCIe controller hardware reset inputs see Section 24.9.3, *PCIe Controller Integration*). For more information on the PRCM.L3INIT_RST hardware reset, refer to Section 3.5.5, *Reset Domains*, in Chapter 3, *Power, Reset, and Clock Management*.

The L3INIT_RST main reset is tiggered from different warm reset sources within the PD_L3INIT power domain (global warm software reset, MPU watchdog reset, and so forth).

Software triggered main reset to PCIe controller : To the above group of PRCM warm main reset sources, there is also a software-triggered reset which can be asserted locally and independently to each of the PCIe_SS1 and PCIe_SS2 in the PD_L3INIT domain. The main software reset is triggered via assertion of bit:

- RM_PCIESS_RSTCTRL[0] RST_LOCAL_PCIE1 for the device PCIe_SS1 controller
- RM_PCIESS_RSTCTRL[1] RST_LOCAL_PCIE2 for the device PCIe_SS2 controller

The software (warm) reset completion triggered through device PRCM is flagged in the *Write-one to Clear* PRCM register:

- RM_PCIESS_RSTST[0] RST_LOCAL_PCIE1 for the device PCIe_SS1 controller
- RM_PCIESS_RSTST[1] RST_LOCAL_PCIE2 for the device PCIe_SS2 controller

The user software running on PCIe controller is supposed to clear the reset status bit upon reset completion event via writing 0b1 to RM_PCIESS_RSTST[0] RST_LOCAL_PCIE1 and RM_PCIESS_RSTST[1] RST_LOCAL_PCIE2 bit in PRCM.

For more details on above PCIe controller software reset bits, refer to theSection 3.11, *PRCM Register Manual*, in the Chapter 3, *Power, Reset and Clock Management*

NOTE: The warm main reset (icluding PCIe subsystem software reset) from PRCM impacts all PCIe core register bits (sticky and non-sticky) and the PCIe TI wrapper configuration registers (PCIe_SS_TI_CONF). Note that the PCIe device type in the PCIECTRL_TI_CONF_DEVICE_TYPE register is reset by default to "Root Complex".

For more details on sticky/non-sticky bits behaviour refer to the PCI Express Base 3.0 Specification, revision 1.0.

24.9.4.4.2.2 PCIe Standard Specific Resets to the PCIe Core Logic

Fundamental hardware reset - This reset impacts all non-sticky PCIe core bits. It is automatically triggered:

- upon a software initiated device type change in the PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE (to RC/EP)
- upon exitting certain low-power modes
- upon PCIe controller's main power supply (Vmain) being powered-up or Vmain detected below a defined threshold by the PCIe RC. This is a cold fundamental reset.

NOTE: All (sticky and non-sticky bits) of the PCIe controller core are reset upon fundamental hardware reset assertion because of Vaux not implemented. Hereby all PCIe core registers have to be re-initialized from scratch after a PCIe fundamental reset.

Hardware fundamental reset operation: The hardware fundamental reset is an input to the PCIe core, to be controlled by the local PCIe software driver. Its impact is conditional: a fundamental reset clears the entire controller (including the PCIe_PHY part), with the following exceptions:

- DEVICE_TYPE register (unconditional) and all other PCIe_SS_TI_CONF registers
- PCIe link PM FSM, if the module is out of "IDLE"

The fundamental reset is applied to PCIe core in the following two cases :

- After reprogramming the device type (to EP or RC) in the PCIECTRL_TI_CONF_DEVICE_TYPE[3:0]

Copyright © 2015–2017, Texas Instruments Incorporated

TYPE bitfield, to latch in the new type and clear the programming registers. Remain out of idle and clear PCIECTRL_TI_CONF_PM_CTRL[11] AUX_PWR_DET to 0 beforehand, in order to reset also the sticky bits.

- L3 exit at initial power-up unless the restart is already initiated by the other side of the link

NOTE: The TYPE value ("EP", "legacy EP" or "RC") has to be read back by software until desired type-value is seen. This insures that the fundamental reset triggered by "TYPE" change has completed successfully. The user software must not change the PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE register value during PCIe core operation.

NOTE: The fundamental hardware reset does not impact the PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE (RC/EP) bitfield and the remaining TI wrapper configuration registers (PCIe_SS_TI_CONF). These can be reset only by a PCIe main reset input assertion.

PCIe link-down reset condition - When the PCIe link has gone down and goes up again, namely transitions from D3cold/L3 back to D0, the PCIe core auto-applies this **internal fundamental reset** and reports it on IRQ event (PCIECTRL_TI_CONF_IRQSTATUS_MAIN[11] LINK_REQ_RST) after link-up.

PCIe hot-reset condition - As defined by the PCIe standard: reset condition propagated in-band (over the PCIe wire) from an upstream port to a downstream port, using the TS1 and TS2 OS (see the PCI Express Base 3.0 Specification, revision 1.0). Requires the link to be already powered and up. The hot reset causes the link to go down and up again, causing a link-down reset condition, and as such is a fundamental reset.

The hot reset sequence can be tracked in the LTSSM by the transition to "hot reset" state, then on to "detect" and the rest of the link-up sequence.

- When RC, a hot reset is generated by writing the bit “Secondary Bus Reset” of the PCIe standard “Bridge Control Register” - BRIDGE_INT [22] SEC_BUS_RST bit .
- When EP, a host reset is automatically processed by the controller hardware.

PCIe soft reset condition - As defined by the PCIe standard: When the D-state of a device is changed from $D3_{hot}$ to D0 by software, namely by the RC doing a remote CFG write to the EP (EP) PM_CSR [1:0] PWR_STATE register, the EP device reacts depending on its DIF CS (local) setting of the no-soft-reset (NSR) bit (EP) PM_CSR [3] NSR:

- If bit NSR=0, the soft reset is applied, and the device transitions to the $D0_{unitialized}$ state (see Figure 24-163). Non-sticky bits are reset.
- If bit NSR=1, the soft reset is inhibited, the device transitions directly to the $D0_{active}$ state (see Figure 24-163), no reset is applied. Full context is retained, including non-sticky bits.

NOTE: The soft reset is a hot reset. The soft reset is not a fundamental reset; that means that it does not reset the PHY, only the programming registers.

24.9.4.5 PCIe Controller Power Management

This section is a brief summary of the supported power modes and power transitions, as well as the consequences (clock gating, power gating, resets, and so forth) on the PCIe controller.

24.9.4.5.1 PCIe Protocol Power Management

The power state of a PCIe controller port is described by four different FSMs, each running at a different level of the protocol, each with its own independent state. The FSMs are covered in Section 24.9.4.5.1.1 through .

Table 24-665summarizes the typical power stable state combinations, namely the combinations of states the controller can settle into, after a number of potential transitions and transient states, and assuming that the lowest power state possible is used.

Copyright © 2015–2017, Texas Instruments Incorporated

The PCIe standard defined optional gating of the reference clock on PCIe_PHY PLL input (and therefore of the PIPE clock) when in L1-state is not supported. As shown in the Table 24-665, the PIPE clock is always running while link is in L1.

Table 24-665. Power States Summary

Device D-state	Link L-state	PHY LTSSM state	PIPE power down	PIPE clock[1]	Vmain	LP_CLK[2] (auxiliary clock)	Slave Idle	Master Standby
D0_uninitialized[3]	LDn	Detect	P1	OFF	don't care	ON	1	1
D0_uninitialized	L0	n/a	P0	ON	ON	ON	0	1
D0_active	L0	L0	P0	ON	ON	ON	0	0/1[4]
D0_active	L0s	L0s	P0s	ON	ON	ON	0	0/1[4]
D0_active	L1	L1	P1	ON	ON	ON	0	0/1[4]
D1	L1	L1	P1	ON	ON	ON	0	1
D2	L1	L1	P1	ON	ON	ON	0	1
D3_hot	L1	L1	P1	ON	ON	ON	0	1
D3_cold	L3	n/a	P2	OFF	OFF	OFF	1	1

(1) The PIPE clock activity, as visible from the PCIe core boundary, implies the activity of the high-speed PLL it is derived from, which implies the activity of the reference clock on the PLL input.
(2) See Section 24.9.4.5.2
(3) Default controller state after reset. Not a real PCIe state.
(4) Master standby value depends on the PCI express application (MSE, ISE, and so forth)

24.9.4.5.1.1 PCIe Device/function power state (D-state)

The function power state machine is the highest-level PM FSM in a PCIe device. The power state control bitfield is part of standard PCIe register bitfield- (EP)PM_CSR/(RC)PM_CSR [1:0] PWR_STATE.

NOTE: A Vaux power source is not tied to the PCIe core, that is why the state D3_cold with Vaux switched-on is unsupported by the PCIe PM FSM.

NOTE: The six available D-states are, by order of decreasing power: D0_uninitialized (default), D0_active, D1, D2, D3_hot, D3_cold. Note that the function power state Cfg field - is only 2 bit, encoding only 4 combinations: D0, D1, D2, D3. The difference between uninitialized and active (D0), and between hot and cold (D3) is implicit.

The eventual (“stable” or “quiescent”) power state of a PCIe link (link state) is determined by the D-state of the downstream device. For the current controller, it means that the D-state determines the link state in EP type mode, but not in RC type mode.

Note also that the device may go through a number of transient link states before entering/after exiting its quiescent link state, so that a device, for example, in D3_hot may be consuming maximum instantaneous power.

D0_uninitialized is the function’s default state, entered after powerup and/or reset. It is used by the RC software to enumerate the function (Cfg transactions). Mem and IO transaction are disabled. It can only be entered though a reset, partial or total. Together with D0_active, it is the highest-power D-state.

D0_active is the function’s active state, where all Memory and I/O transactions take place. By definition, a function transitions from D0_uninitialized to D0_active after the RC software enables Memory and I/O transactions, either as completer ("Cfg" write 0b1 to memory space enable: MSE/IO space enable: ISE) or as requester ("Cfg" write 1 to bus master enable: BME). D0_active can be exited to/entered from D1, D2, or D3_hot by the RC software writing to the function’s (EP)PM_CSR[1:0] PWR_STATE power state. Together with D0_uninitialized, it is the highest-power D-state.

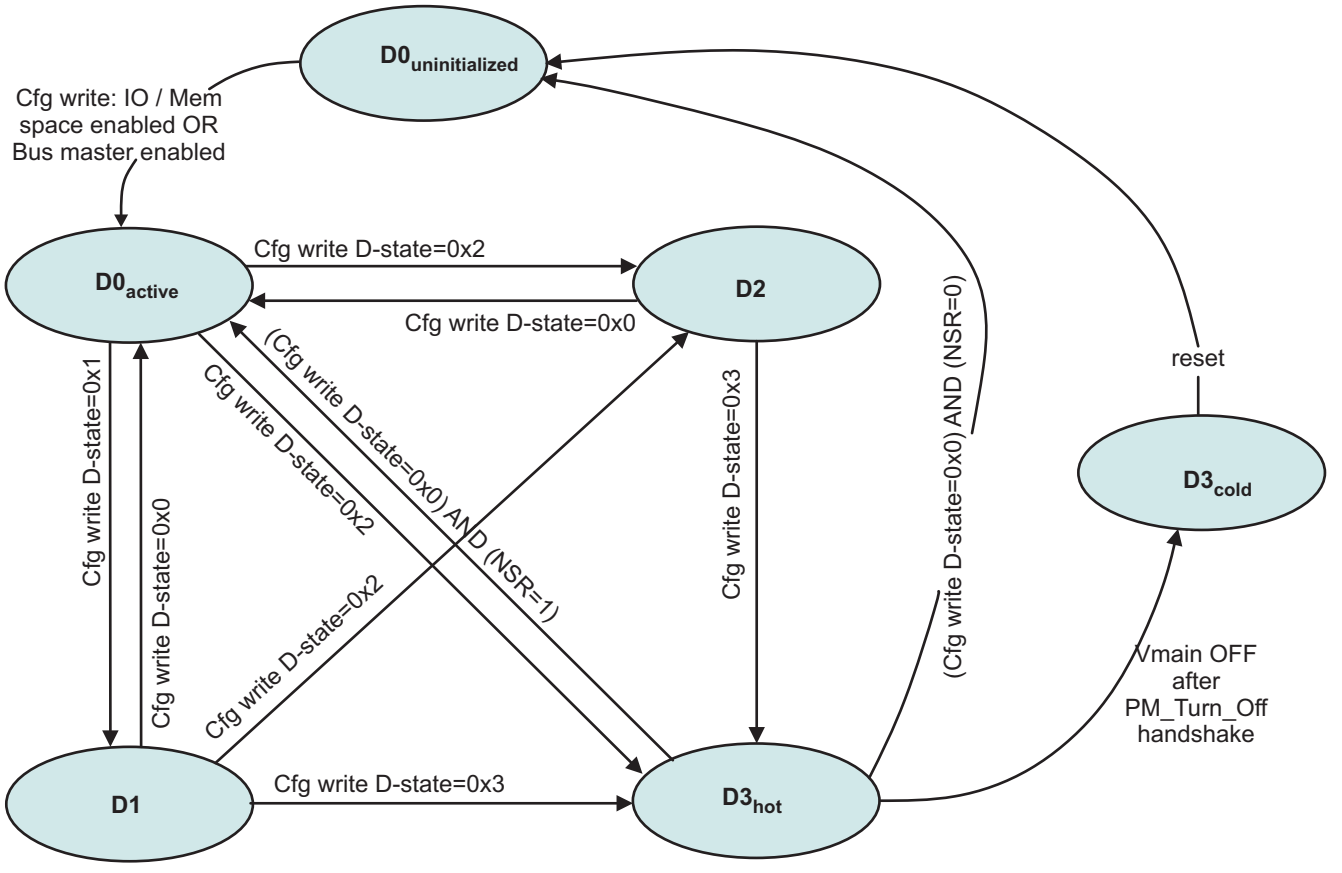
Copyright © 2015–2017, Texas Instruments Incorporated

D1 and D2 are two optional states, with reduced power compared to D0. Both operate the same way, and have the same action on lower-level PM FSM, with D1 expected to have a faster wakeup and D2 a lower power. Both are supported by the current controller. D1 and D2 can be exited to/entered from D0_active, D1, D2, or exited to D3_hot , by the RC software writing to the function's (EP)PM_CSR[1:0] PWR_STATE power state bitfield. The current controller supports D1 and D2 but a fully compliant implementation also depends on the system providing the right combination of HW and software.

D3_hot is a lower-power state (compared to D0, D1, D2). It can be entered from D0_active, D1, or D2 by the RC software writing to the function's (EP)PM_CSR[1:0] PWR_STATE. Transition to D3_hot is typically continued to D3_cold and main power (VMAIN) shutdown. It can also be exited to D0 by the RC writing (0b00) to the (EP)PM_CSR[1:0] PWR_STATE. The state transition to either D0_active or D0_uninitialized depends on the NSR value written in the bit (EP)PM_CSR[3] NSR (No_Soft_Reset bit) of 0b1 (that means - function is not reset) or 0b0 (that means - function is reset, link is restarted and must be reconfigured) respectively.

D3_cold is the lowest-power state, defined by the VMAIN being turned off. It it typically entered from D3_hot as shown in the figure below, but any turn-off request will actually place the function in that state. It can only be exited to D0_uninitialized, by restoring VMAIN and after resetting the function, totally or partially (see link states below).

Figure 24-163. PCIe D-state (function power state) FSM diagram



The Figure 24-163 shows the state transitions in the power state. NSR is the "No_Soft_Reset" bit in the function's (EP)PM_CSR configuration register. NSR advertizes the ability of the device to go into D3_hot while retaining its register settings (when 1), or conversely, the inability to do so and the reset of those setting upon D3_hot exit (when 0).

NSR is read-only to the RC software over Cfg accesses, but it can be set by the EP's local software over DIF (CS access) prior to enumeration. The controller shall apply the NSR to itself accordingly.

Copyright © 2015–2017, Texas Instruments Incorporated

Most function power state transitions are done explicitly by the RC-side software writing into the EP function's (EP)PM_CSR[1:0] PWR_STATE, over the PCIe wire. This is one of the two PM control mechanisms of PCIe, the other one being ASPM. The remaining function power state transitions are caused by resets.

The D-state of a device sets the link power state (L-state) for the PCIe link above. In other words, the L-state of a PCIe link (connecting an upstream device, closer to the RC, and a downstream device, closer to an EP) is set by the downstream device.

24.9.4.5.1.2 PCIe Controller PIPE Powerstate (Powerdown Control)

The PIPE interfaces the MAC, or controller, above PIPE in the protocol hierarchy and the PHY, or transceiver, below PIPE. The current controller implementation has a PIPE interface at its boundary.

CAUTION

The physical layer as defined by the PCIe standard extends into the PCIe MAC layer, to include, for example, the LTSSM, so that "physical layer" and PHY do not coincide, with the latter included in the former.

The PIPE interface has its own power state, driven by the PCIe controller towards PCIe_SS PHY on a 2-bit powerdown signal, depending on the PM state machines above. It has four states: P0, P0s, P1, P2:

- **P0 (pipe_powerdown = 0b00):** active state, for high-speed (HS) data transmission and reception. Used for L0 link state.
- **P0s (pipe_powerdown = 0b01):** active HS receiver, suspended transmitter. Used for L0s link state.
- **P1 (pipe_powerdown = 0b10):** Suspended HS receiver and transmitter, but PIPE clock still running.
- **P2 (pipe_powerdown = 0b11):** Suspended HS receiver and transmitter, PIPE clock stopped - asynchronous mode.

24.9.4.5.2 PCIE Controller Clocks Management

24.9.4.5.2.1 PCIe Clock Domains

The controller has two main clock domains: the L3_MAIN bridge (ports) and the PCIe core.

The L3_MAIN bridge runs on a single clock. That same clock is used to run both the PCIe controller master and slave ports. It can be divided, with independently ratios for master and slave. However, both sides are typically expected to run at the same speed, as both are capable of the same performance.

There is an auxiliary clock - LP_CLK which is a PCIe_SS internal low-power clock, used when pipe clock is stopped. It is assumed to be always available when the module is not idle.

The PCIe core runs on the PIPE clock whenever that clock is provided by the relevant PCIe_PHY. When the PCIe link is in a low-power state and the PIPE clock is not available, the core splits in two sub-domains:

- Most of the core stops
- A small "auxiliary" part of the core (which includes the configuration registers) switches to a low-power clock LP_CLK
- The two subdomains can still be considered synchronous despite their different clocking scheme, since they are either running on the same clock, or one of the subdomain clocks is stopped.

24.9.4.5.2.2 PCIe Controller Idle/Standby Clock Management Interfaces

A PCIe controller has two clock management (CM) interfaces with device PRCM:

- A master port clock management interface based on master standby protocol with the device PRCM
- A slave port clock management interface based on slave idle protocol with the device PRCM

Copyright © 2015–2017, Texas Instruments Incorporated

The PCIe wrapper logic located register PCIECTRL_TI_CONF_SYSCONFIG[3:2] IDLEMODE and PCIECTRL_TI_CONF_SYSCONFIG[5:4] STANDBYMODE bitfields are used to software configure the idle /standby CM behaviour locally for the PCIe_SS controller. The Table 24-666, shows the available CM options.

Table 24-666. Local Power-Management Features

Feature	Registers	Description
Slave idle modes	PCIECTRL_TI_CONF_SYSCONFIG [3:2] IDLEMODE bit field	The available modes are: Force-Idle, No-Idle, wakeup-disabled Smart-Idle and wakeup-capable Smart-Idle.
Master standby modes	PCIECTRL_TI_CONF_SYSCONFIG [5:4] STANDBYMODE bit field	The available modes are: Force-Standby, No-Standby, wakeup-disabled Smart-Standby and wakeup-capable Smart-Standby.

For more information on the PCIeSS functional clock gating in the device PRCM (clock PCIE_L3_GICLK), refer to Section 3.1.1.1.4, *Clock Domain-Level Clock Management*, in the chapter, *Power, Reset and Clock Management*.

The relations between the PCIeSS master (standby)/slave (idle) behaviour to various PCIe protocol link power management features are covered in the Section 24.9.4.5.2.2.1 and Section 24.9.4.5.2.2.2, respectively.

24.9.4.5.2.2.1 PCIe Controller Master Standby Behavior

As a master (initiator) on the device L3_MAIN interconnect, the PCIe controller supports the standby protocol over the standard three signals: mstandby/mwait/mwakeup. The behavior of that interface can be configured in the PCIeSS controller wrapper (PCIe_SS_TI_CONF) register - PCIECTRL_TI_CONF_SYSCONFIG[5:4] STANDBYMODE bitfield.

The standby protocol notifies the local system if inbound PCIe transactions are likely to be routed to the controller's master port.

NOTE: Note that CFG-type transactions are typically not part of the PCIe controller master port transfers: in RC mode they are only outbound, and in EP mode they are processed inside the controller.

Automatic mode (default): most operations are expected to take place in "smart-standby" mode. In that mode, the master standby interface is automatically managed by the PCIe status, featuring (Mstandby = 0) if (D-state=$D0_{active}$ and MSE=1 that is bit (RC) STATUS_COMMAND_REGISTER/(EP) STATUS_COMMAND_REGISTER[1] MEM_SPACE_EN) :

- D-state = D0_active indicates that the link is up, that data can be exchanged. It's also a condition for memory-type transactions to take place.
- The Memory Space Enable bit (RC) STATUS_COMMAND_REGISTER[1] MEM_SPACE_EN, indicating that the RC has enumerated the PCIe fabric and configured the memory space for operation, before EP writing the MSE bit in the local CFG register - (EP) STATUS_COMMAND_REGISTER via DIF CS access.

In automatic (smart-standby) mode, the standby is therefore controlled remotely by the RC software, which sets both the D-state and the MSE.

Note that the master does not go to standby during ASPM (so called active state power management) transitions to L0s or L1 on the link, as it remains in "D0_active" during that time. Although the physical layer is partially or fully stopped during L0s and L1, the short restart time of a few microseconds does not justify a transition to standby by the master. In other words, the master goes or doesn't go to standby after a link layer transition to L1, depending on the cause, if a transition in "D-state" or "ASPM" occured, respectively.

More generally, the link state is not directly correlated to the automatic standby state of the master:

- Master in standby (mstandby=1): link can be in L0 (link startup), L1 (D1, D2, D3hot), L3 (D3cold)
- Master out of standby (mstandby=0): link can be in L0, L0S/L1 (ASPM)

Copyright © 2015–2017, Texas Instruments Incorporated

The "Mstandby" status depends on the possibility of transactions, not on actual transactions. The master may remain out of standby indefinitely without any transaction, and an incoming transaction shall not cause the master to exit standby. The latter is an error case which occurance is prevented in hardware.

The mwait=0 handshake, eventually returned after the mstandby=0 transition, should prevent the master from issuing transactions until the system is ready. However, no back-pressure can actually be applied to the PCIe to prevent inbound accesses after, for example, MSE has been set. It is assumed that there will be sufficient time for the mwait to transition, that is typically for the system to reopen the path to its local memory, before the first inbound transaction is routed to the master.

When the PCIe local controller itself is in RC mode, note that the D-state may remain D0active even after the has gone down. It is therefore advised to use the clearing of the local MSE bit to set the master in standby. Alternatively, the RC can be placed in D3hot mode, or the standby can be forced (to mstandby = 1) by setting the standbymode to “force-standby”. Whatever the method, the RC is aware of the state of the entire PCIe fabric, and is expected to put its master in standby in full knowledge of the situation.

For more information on the PCIe Controller Standby Management Protocol with the device PRCM , see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Manual control, EP type: When incoming transactions are not memory-type (e.g.: IO type), the master is capable of issuing transactions while the automatic out-of-standby conditions above are not met.

NOTE: In the EP, non-memory type transaction cases, it is the user software responsibility to manually force the master out of standby via setting the bit PCIECTRL_TI_CONF_SYSCONFIG[5:4] STANDBYMODE = 0x1, that means - "No-Standby", before the first transaction, and to return it to automatic mode via setting PCIECTRL_TI_CONF_SYSCONFIG[5:4] STANDBYMODE = 0x2, that means - "Smart-Standby" after the last transaction.

For instance, an EP shall have to monitor the ISE (IO space enable) bit and the link status, and set the PCIECTRL_TI_CONF_SYSCONFIG [5:4] STANDBYMODE bitfield accordingly if EP is configured to have an IO BAR.

24.9.4.5.2.2.2 PCIe Controller Slave Idle/Disconnect Behavior

As a target of the device L3_MAIN bus (with target being the PCIe controller slave port on L3_MAIN respectively), the controller supports the "Idle" protocol. The behaviour of that interface can be configured in the PCIeSS controller wrapper register - PCIECTRL_TI_CONF_SYSCONFIG[3:2] IDLEMODE bitfield.

Additionally, the slave port clock management supports a disconnect protocol which is controlled automatically.

The idle transition of the PCIe controller is strictly synchronized to PIPE clock. The PRCM places the PCIe controller to an "Idle state" before PCIePCS generated PIPE clock is stopped due to some reason: g.h. PCIe PHY low power transition with gating local PLL clocks, the APLL_PCIe clock or gating PCIeREF_DPLL clock. The IDLE state is automatically maintained by PRCM during periods in which PIPE clock is stopped.

PCIe controller transitions to IDLE initiated by the system PRCM are strictly synchronized with the PCIe operational state. The PRCM allows the PCIe controller to be brought out of "IDLE" state, only if the generation of the PIPE clock is enabled by configuring the high-frequency PLL (source of the PIPE clock) and the 100 MHz PCIe reference clock scheme (source of the high-frequency clock). For more details on the PCIe PLL and PHY related clocks, refer to the Section 26.4, *PCIe Shared PHY Susbsystem* in the chapter, *Shared PHY Component Subsystems* .

CAUTION

All accesses to the device PCIe controller on its slave port, namely to the local target configuration PL/PCIe standard/wrapper registers or to the PCIe bus, require the PIPE clock to be running. The presence of the PCIe interface clock - PCIE_L3_GICLK is not sufficient to perform such accesses.

Copyright © 2015–2017, Texas Instruments Incorporated

24.9.4.5.2.2.2.1 PCIe Controller Idle Sequence During D3cold/L3 State

When the link of a RC enters L3 mode, the PIPE interface must go to P2 mode for power saving. The PCIe controller maintains the PIPE interface in P1 mode (PIPE clock running) and the internal registers accessible until the system requests entry into "Idle", and only then transition to P2: it is the device PRCM responsibility to Idle the module (PCIECTRL_TI_CONF_SYSCONFIG [3:2] IDLEMODE set to 0x2 - *Smart Idle mode* should be selected), in order to reach a low-power state. Transitioning to "P2", stops the PIPE clock and makes the register inaccessible, which in turn corresponds to an "IDLED" and disconnected from L3_MAIN PCIe slave port.

NOTE: The "L3" state can only be exited when the RC re-enabling the Vmain power supply, and reconfiguring all PCIe registers from scratch: In both EP and RC cases, the system should detect Vmain power assertion, apply a fundamental reset, then bring the module out of "IDLE" and restart the link normally. All registers are reset.

24.9.4.6 PCIe Controller Interrupt Requests

In the rest of this section, and for clarity:

- "**Interrupts**" refer by default to the virtual interrupt lines emulated by the PCIe protocol using either the PCI legacy or PCIe Message-Signaled Interrupts (MSI) methods, and used for non-PCIe purposes by the system.
- "**Hardware interrupts**" refer to the actual interrupt signals coming out of the current PCIe controller, and used to manage various events of the PCIe protocol, including PCI interrupts.

Each PCIe controller has two **hardware interrupt lines** described in Table 24-667 and Table 24-669, which are level-sensitive. PCIe pulse interrupts are unsupported in the device.

The main HW interrupt line - PCIe_SS1_IRQ_INT0/PCIe_SS2_IRQ_INT0 receives all interrupt events related to the control of the PCIe operation, including power management and errors.

The MSI HW interrupt line - PCIe_SS1_IRQ_INT1/PCIe_SS2_IRQ_INT1 receives all interrupt events propagated by a remote EP over the PCIe interface, for specific (non-PCIe) applicative purposes, in conjunction with the PCIe transactions. This includes the legacy interrupts (INTx) as well as the Message Signaled Interrupts (MSI) proper, as defined by the PCIe standard.

NOTE: MSI-X is unsupported by PCIe controller.

The difference between the two hardware interrupt types - "main" and "MSI" is that the main interrupt events are used by the PCIe interface, whereas the MSI interrupt uses the PCIe interface.

NOTE: Incoming MSI events only exist in RC mode when MSI events are received over the PCIe wire. In EP mode, other mechanisms allow controller to generate (transmit) of the same type of interrupt events onto the PCIe bus.

The main interrupt events are further divided into PCI management and error events. The MSI interrupts are divided into legacy and MSI proper. Each of these four categories of events is described in Section 24.9.4.6.1 and Section 24.9.4.6.2.2.

24.9.4.6.1 PCIe Controller Main Hardware Management

24.9.4.6.1.1 PCIe Management Interrupt Events

The events described here trigger the main interrupt line. Each status bit is set to one by a specific PCIe event, and must be cleared by the local SW.

CFG_MSE_EVT: (EP mode) PCIe controller's Memory Space Enable (MSE) config bit has been set by the RC software - written to 1 by a configuration write. This notifies the local EP that incoming memory-type PCIe transactions may now target the local function, over the AXI master port.

Copyright © 2015–2017, Texas Instruments Incorporated

CFG_BME_EVT: (EP mode) PCIe controller's Bus Master Enable (BME) config bit has been set by the RC software - written to 1 by a configuration write. This allows the local EP to initiate (outgoing) PCIe transactions, over the AXI slave's outbound window.

LINK_UP_EVT: Link layer has successfully booted and reached L0active state. Data can be transmitted and received over the PCIe wire.

LINK_REQ_RST: Link-down reset was triggered (by link-down condition). Non-sticky bits have been reset.

PM_PME: (RC mode) PCIe controller has received a power management event PM message on its PCIe downstream port, requesting wakeup.

PME_TO_ACK: (RC mode) PCIe controller has received a Turn-Off Acknowledge PM message on its PCIe downstream port, acknowledging a previously transmitted turnoff message (PME_Turn_Off).

PME_TURN_OFF: (EP mode) PCIe controller has received a Turn-Off PM message on its PCIe upstream port, requesting an acknowledge (PME_TO_Ack) and the transition of the link to L2/L3

24.9.4.6.1.2 PCIe Error Interrupt Events

The events described here trigger the main interrupt line.

ERR_COR: (RC mode) Correctable Error message received on PCIe downstream port.

ERR_NONFATAL: (RC mode) Uncorrectable Error message received on PCIe downstream port.

ERR_FATAL: (RC mode) Fatal Error message received on PCIe downstream port.

ERR_SYS: (RC mode) Either of the three error messages above (correctable, non-fatal, fatal) was reported and enabled in the root control register.

ERR_ECRC: End-to-end CRC error detected.

ERR_AXI: AXI slave error caused by response table overflow. This error is not supposed to happen.

24.9.4.6.1.3 Summary of PCIe Controller Main Hardware Interrupt Events

Table 24-667 describes the events, related to control of the PCIe interface operation itself, including power management, reset and error handling, that trigger the "main" hardware interrupt line.

Table 24-667. PCIe Main Hardware Interrupt Events Summary

Event Status and Clear	Interrupt Enable	Interrupt Disable	Mapping	Description
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[14] CFG_MSE_EVT	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[14] CFG_MSE_EVT_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[14] CFG_MSE_EVT_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	CFG "Memory Space Enable" change event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[13] CFG_BME_EVT	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[13] CFG_BME_EVT_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[13] CFG_BME_EVT_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	CFG "Bus Master Enable" change event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[12] LINK_UP_EVT	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[12] LINK_UP_EVT_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[12] LINK_UP_EVT_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Link-up state change" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[11] LINK_REQ_RST	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[11] LINK_REQ_RST_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[11] LINK_REQ_RST_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Link Request Reset" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[10] PM_PME	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[10] PM_PME_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[10] PM_PME_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Power Management PME message received" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[9] PM_TO_ACK	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[9] PM_TO_ACK_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[9] PM_TO_ACK_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Power Management acknowledge" event

Table 24-667. PCIe Main Hardware Interrupt Events Summary (continued)

Event Status and Clear	Interrupt Enable	Interrupt Disable	Mapping	Description
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[4] ERR_AXI	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[4] ERR_AXI_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[4] ERR_AXI_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"AXI tag lookup fatal error" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[3] ERR_COR	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[3] ERR_CORR_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[3] ERR_CORR_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Correctable Error" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[2] ERR_NONFATAL	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[2] ERR_NONFATAL_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[2] ERR_NONFATAL_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Non-Fatal Error" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[1] ERR_FATAL	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[1] ERR_FATAL_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[1] ERR_FATAL_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"Fatal Error" event
PCIECTRL_TI_CONF_IRQSTATUS_MAIN[0] ERR_SYS	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN[0] ERR_SYS_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MAIN[0] ERR_SYS_EN	PCIe_SS1_IRQ_INT0 PCIe_SS2_IRQ_INT0	"System Error" event

NOTE: While the PCIECTRL_TI_CONF_IRQSTATUS_MAIN register is updated only if corresponding interrupt is enabled in the PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN register, the PCIECTRL_TI_CONF_IRQSTATUS_RAW_MAIN register always provides the Legacy/MSI event status regardless of an interrupt being enabled or disabled in the PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN register.

24.9.4.6.2 PCIe Controller Legacy and MSI Virtual Interrupts Management

The PCIe protocol uses TLPs to create “virtual” interrupt lines across the PCIe fabric. Interrupts do not constitute a separate transaction type like Mem, Cfg, I/O, and so forth, but reuse the existing types.

24.9.4.6.2.1 Legacy PCI Interrupts (INTx)

Legacy PCI interrupts are supported over PCIe by dedicated message codes (posted-write in Msg space) that flag the assertion or deassertion of one of four "virtual" interrupt lines (or pins): INTA, INTB, INTC, INTD. They can only be sent by EPs, and routed to/received by the RC.

PCIe controller supports single-function mode and can send only INTA when configured as EP.

NOTE: Use of legacy PCI interrupt is exclusive with use of MSI (defined in Section 24.9.4.6.2.1.2). MSI should be the preferred method whenever possible.

24.9.4.6.2.1.1 Legacy PCI Interrupt Events Overview

Legacy INTx (with x= A/B/C/D) are interrupt events inherited from PCI, where each was implemented on a physical bus wire. The RC can allocate each line to a given EP function, which is then allowed to assert/deassert that line (and only that line). PCI legacy interrupt events are mapped on the MSI interrupt line of PCIe controller. For more details, refer to Section 24.9.4.6.2.1.2 and Section 24.9.4.6.2.1.3.

The controller HW shall both set and clear the IRQ status bit according to the assert and deassert messages received over the PCIe wire, respectively. In other words, the legacy interrupt status bit do not need to be cleared by the local software after processing.

Typical legacy interrupt service routine (ISR) on the RC-configured PCIe controller is:

- Remote EP function transmits an "assert INTx" message. Value of x (within A/B/C/D) was previously assigned by the RC software using configuration accesses.
- "assert INTx" message is routed up the PCIe topology to the RC (local controller)
- PCIECTRL_TI_CONF_IRQSTATUS_MSI status bit INTx goes to 1
- MSI interrupt line is asserted
- software reads PCIECTRL_TI_CONF_IRQSTATUS_MSI status register. The asserted bit (A,B,C,D)

Copyright © 2015–2017, Texas Instruments Incorporated

allows to determines the EP function that generated the event.

- software accesses this EP function over PCIe to process the interrupt: ad-hoc service routine
- As a result of the processing, remote EP function transmits the “deassert INTx” message
- software clears the PCIECTRL_TI_CONF_IRQSTATUS_MSI status bit INTx to 0.
- MSI interrupt line is deasserted, assuming there is no other asserted event.

24.9.4.6.2.1.2 Legacy PCI Interrupt Transmission (EP mode only)

Writing 0b1 to TI wrapper register PCIECTRL_TI_CONF_INTX_ASSERT[0] ASSERT_F0 bit sends an ASSERT message on the “interrupt pin” specified in the config header space.

Writing 0b1 to TI wrapper register PCIECTRL_TI_CONF_INTX_DEASSERT[0] DEASSERT_F0 bit will send a DEASSERT message on the “interrupt pin” specified in the config header space.

A status of the virtual “interrupt line” is available by reading out either bitfield.

NOTE: This status is just a local record of the last message sent, it is not the result of any feedback from the PCIe fabric, since messages are posted, no response is generated. For that reason, the PCIe protocol does not guarantee the coherence between assertion and deassertion INTx messages, that means that it’s up to the application to ensure that the INTx assertion has been seen by the RC before sending the deassertion, and vice versa.

CAUTION

The operations above should only be used when in EP mode, and will produce undefined results if applied to an RC-configured controller.

24.9.4.6.2.1.3 Legacy PCI Interrupt Reception (RC mode only)

The reception of either of the 8 INTX message codes (ASSERT/DEASSERT of INTA/B/C/D) shall assert/deassert the corresponding HW interrupt event in status register:

- PCIECTRL_TI_CONF_IRQSTATUS_MSI[0] INTA
- PCIECTRL_TI_CONF_IRQSTATUS_MSI[1] INTB
- PCIECTRL_TI_CONF_IRQSTATUS_MSI[2] INTC
- PCIECTRL_TI_CONF_IRQSTATUS_MSI[3] INTD

This implies that the status of an asserted event does not need to be cleared locally (by software writing 1 to the PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI[n] INTx_EN bit, where n=0 to 3 and x=A, B, C, D, respectively) as it is expected to be cleared remotely over PCIe, by the EP function.

NOTE: The RC does not keep track of the INTx requester, even though the information is available in the incoming TLP’s RequesterID: each legacy interrupt is expected to be used by only one EP function, known apriori by the RC.

When messages are posted, there is no response generated by the RC.

INTx messages can only be received (and the corresponding HW interrupts asserted) when in RC mode.

NOTE: The HW interrupts have to be maintained disabled when in EP mode.

24.9.4.6.2.2 PCIe Controller Message Signaled Interrupts (MSI)

Message Signal Interrupts are the preferred option to map interrupt over PCIe. It allows up to 32 interrupts vectors/events to be triggered by each EP function. MSI interrupts are implemented memory-space (posted) writes, 1-DWORD long. They should only be sent by EPs to the RC.

Copyright © 2015–2017, Texas Instruments Incorporated

NOTE: While legacy PCI interrupts are mapped onto PCIe messages (Msg), the Message Signaled Interrupts are mapped onto PCIe memory writes (MWr), not onto messages.

Use of MSI is exclusive with use of legacy PCI interrupts (defined above).

An MSI is a memory (posted) write done by an EP to a mailbox in the RC. The data size is always 32 bit, the address and the data are programmed by the RC during PCIe enumeration, into the EP function's MSI capability descriptor (in the EP function's PCI config space).

Like legacy PCI interrupts, MSI does pass any status information to the RC, other than the interrupt vector (event) itself: the data payload of the write access is used exclusively to identify the interrupt's requester and its vector. The exchange of status information is outside the scope of MSI.

NOTE: Unlike the legacy PCI interrupts, MSI does not emulate an interrupt "level" that is either high or low, gets asserted or deasserted. Each MSI interrupt vector corresponds to a univocal event, that does not get "cleared" later on.

NOTE: The device intergated PCIe controller does not support extended MSI-X message signaled interrupts.

24.9.4.6.2.2.1 PCIe Specific MSI Interrupt Event Overview

MSI are interrupts designed specifically for PCIe, unlike the legacy PCI events seen in the Section 24.9.4.6.2.1. They are mapped on the MSI interrupt line of PCIe controller, using a single status bit in the PCIECTRL_TI_CONF_IRQSTATUS_MSI register. The "MSI controller" decodes and records each received MSI write as a specific "vector" coming from a specific EP function. Each application assigns a dedicated meaning to a given vector. Each function can use up to 32 vectors, as configured by the RC. MSI vectors can only be "asserted" by the EP function, unlike PCI legacy events that can be asserted and deasserted. In other words, the local software has to "clear" the asserted vector before it can be reused.

The PCIECTRL_TI_CONF_IRQSTATUS_MSI status bit MSI must remain set as long as a vector is still set. Once the last vector has been cleared, the MSI bit clears automatically.

See also Section 24.9.4.6.2.2.3.

Typical MSI interrupt service routine on the RC-configured PCIe controller:

- Remote EP function transmits an MSI write, with an address and format previously assigned by the RC software using configuration accesses.
- MSI write access is routed to the RC (local controller)
- Access is identified as an MSI thanks to its unique address, and is routed to the internal "MSI controller" instead of being routed to the AXI master.
- PCIECTRL_TI_CONF_IRQSTATUS_MSI[4] MSI bit goes to 1
- MSI interrupt line is asserted
- software reads PCIECTRL_TI_CONF_IRQSTATUS_MSI status register, and identifies an (unspecified) MSI event, as opposed to a PCI legacy event.
- software accesses the MSI related PL registers, which identifies a given event for a given EP function.
- software accesses this EP function over PCIe to process the interrupt: a dedicated interrupt service routine
- software clears the vector in the MSI PL register
- software clears the PCIECTRL_TI_CONF_IRQSTATUS_MSI status bit to 0, assuming there is no other outstanding event in the MSI queue.
- MSI interrupt line is deasserted, assuming there is no other asserted event.

Copyright © 2015–2017, Texas Instruments Incorporated

24.9.4.6.2.2.2 PCIe Controller MSI Transmission Methods (EP mode)

There are two methods for MSI transmission: hardware and software. MSI transmission applies only to EP configured local PCIe system.

24.9.4.6.2.2.2.1 PCIe Controller MSI transmission, hardware method

The device PCIe controller (EP) transmits an MSI by writing 0b1 to the TI config wrapper register PCIECTRL_TI_CONF_MSI_XMT[0] MSI_REQ_GRANT bit. The other fields indicate function number, TC, vector, for the MSI. The address, data (potentially modulated by the vector) are automatically extracted from the EP function's MSI capability descriptor, previously programmed by the remote RC during enumeration.

For status, PCIECTRL_TI_CONF_MSI_XMT[0] MSI_REQ_GRANT can be polled. The bit remains HIGH (0b1) following a request (write to 0b1) and goes back LOW (0b0) once the MSI transmit request has been granted.

NOTE: Bit PCIECTRL_TI_CONF_MSI_XMT[0] MSI_REQ_GRANT reflects only the PCIe local status, that is a confirmation that the MSI has been transmitted. Since the MSI is a posted write, there is no way for the EP to ensure that it has been correctly received by the RC.

24.9.4.6.2.2.2.2 PCIe Controller MSI transmission, software method

Alternatively, an MSI can also be sent as a SW-composed memory write (MWr). MSI address and data shall be taken from the local EP function's MSI capability descriptor, where they were programmed by the RC at enumeration, along with the "multiple message enabling". If more than one vector is enabled, MSI data can be modulated accordingly. Furthermore, the transaction shall match the mandatory characteristics of an MSI MWr access, as follows :

- Header attribute bits ATTR = 2'b00 (no snoop = 0, relaxed ordering = 0)
- 1 DWORD long
- First byte enable: 0b0000
- Last byte enable: 0b0011 (16 bits of data)

Such a SW-generated MSI can be scheduled at the end of a series of memory transactions (MRd/MWr), with the PCI transaction ordering rules guaranteeing that the MSI will not overtake the other transactions.

24.9.4.6.2.2.3 PCIe Controller MSI Reception (RC mode)

Unlike legacy PCI interrupts, MSI must be configured by the RC in each function before use. Depending on its reception capacities, the RC can enable between 1 and 32 vectors (individual events) per MSI-enabled EP function.

The current RC implementation supports MSI reception for up to 8 different EP functions, with up to the protocol's maximum (32) vectors a piece, all mapped to a single MSI address. MSI reception is handled by the "MSI controller" though non-standard "port logic" (PL) registers (mapped in the PCI config space): For more details see the PCIe controller port logic associated PCIECTRL_PL_MSI_CTRL_x registers in the Section 24.9.7.5.1.

The reception of MSI implicitly requires the MSI mailbox address (in PCI memory space) to be routed to the RC: refer to Section 24.9.4.7, *PCIe Controller Address Spaces and Address Translation* for that. The MSI address (32-bit or 64-bit) is programmed in dedicated PCIe PL registers.

The MSI message data (MWr DWORD) is encoded as follows for the current RC. This encoding shall be used by the RC to configure the remote EP discovered at enumeration.

Table 24-668. MSI Message Data Encoding (RC)

Bit range	Size	Value	Comment
31:16	16	0x0000	Reserved as per PCI standard
15:8	8	0x00	Unused, always zero

Copyright © 2015–2017, Texas Instruments Incorporated

Table 24-668. MSI Message Data Encoding (RC) (continued)

Bit range	Size	Value	Comment
7:5	3	0 to 7	Identifier of EP function in MSI controller (8 possible values)
4:0	5	0 to 31	Interrupt vector for the EP (32 possible values)

An inbound access recognized as MSI is terminated inside the controller, and does not appear on the PCIe controller's master port like other inbound memory writes in the same range.

24.9.4.6.3 PCIe Controller MSI Hardware Interrupt Events

Table 24-669 describes the events, related to non-PCIe interrupts (PCI legacy and PCIe MSI interrupts), which trigger the "MSI" hardware interrupt line.

Table 24-669. MSI Hardware Interrupt Events Summary

Event Status and Clear[1]	Interrupt Enable Bit	Interrupt Disable Bit	Mapping	Description
PCIECTRL_TI_CONF_IRQSTATUS_MSI[0] INTA	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI[0] INTA_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI[0] INTA_EN	PCIe_SS1_IRQ_INT1 PCIe_SS2_IRQ_INT1	Legacy interrupt caused by EP sending inband ASSERT/DEASSERT event on virtually emulated by PCIe pin INTA. Typically set and cleared by the remote EP, without local software intervention.
PCIECTRL_TI_CONF_IRQSTATUS_MSI[1] INTB	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI[1] INTB_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI[1] INTB_EN	PCIe_SS1_IRQ_INT1 PCIe_SS2_IRQ_INT1	
PCIECTRL_TI_CONF_IRQSTATUS_MSI[2] INTC	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI[2] INTC_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI[2] INTC_EN	PCIe_SS1_IRQ_INT1 PCIe_SS2_IRQ_INT1	
PCIECTRL_TI_CONF_IRQSTATUS_MSI[3] INTD	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI[3] INTD_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI[3] INTD_EN	PCIe_SS1_IRQ_INT1 PCIe_SS2_IRQ_INT1	
PCIECTRL_TI_CONF_IRQSTATUS_MSI[4] MSI	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI[4] MSI_EN	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI[4] MSI_EN	PCIe_SS1_IRQ_INT1 PCIe_SS2_IRQ_INT1	MSI interrupt status. It is cleared by clearing all vectors in the MSI controller (PL) registers.

(1) The MSI hardware interrupts have to be maintained disabled when in EP mode.

NOTE: While the PCIECTRL_TI_CONF_IRQSTATUS_MSI register is updated only if corresponding interrupt is enabled in the PCIECTRL_TI_CONF_IRQENABLE_SET_MSI register, the PCIECTRL_TI_CONF_IRQSTATUS_RAW_MSI register always provides the Legacy/MSI event status regardless of an interrupt being enabled or disabled in the PCIECTRL_TI_CONF_IRQENABLE_SET_MSI register.

24.9.4.7 PCIe Controller Address Spaces and Address Translation

The PCIe controller acts as a general-purpose bridge between the device local PCIe system and the PCIe fabric. Both are address-based mappings, and the bridging requires address translation between the different spaces.

The Table 24-670 lists the memory-mapped spaces interconnected by each of the PCIe_SS1 and PCIe_SS2 controllers. For each address space (row), the local PCIe subsystem (including the PCIe core) provides “entry points” (4th column) to inject transactions into the specified space, and ”exit points” (5th column) to receive transactions from the specified space.

Table 24-670. PCIe_SS Address Space Map

Space name	Address width	Size (bytes)	Entry point	Exit point	Comments
Device L3_MAIN memory space visible through PCIe controller's master port	32-bit	4 GiB	iATU IBR output	device system RAM, miscellaneous modules	Accessed over PCIe controller initiator (master) port; Includes the outbound window below.

Copyright © 2015–2017, Texas Instruments Incorporated

Table 24-670. PCIe_SS Address Space Map (continued)

Space name	Address width	Size (bytes)	Entry point	Exit point	Comments
PCIe_SS controller outbound window in device	28-bit	256 MiB	Device CPU hosts (MPU, DSPs, and so forth) of PCIe subsystem on device L3_MAIN interconnect	iATU OBR input	Mapped within PCIe controller target (slave) port, the outbound window is itself remapped within the device L3_MAIN memory space (256 MiB sized region).
PCIe memory space	32-bit/64-bit(1)	4 GiB/16 EiB	ATU OBR output (mem mode)	ATU IBR input (mem mode)	Contains all memory BARs
PCIe I/O space	32-bit	4 GiB	ATU OBR output (I/O mode)	ATU IBR input (I/O mode)	Contains all I/O BARs
PCIe config space (ECAM)	28-bit	256 MiB	ATU OBR output (configuration mode)	Configuration registers inside PCIe controller	Contains the PCIe-standard configuration spaces for EP functions (a 4 KiB- descriptor per function).

(1) Regarding the PCIe address space shared between all devices identified on the PCIe fabric, the local PCIe controller OBR iATU output generates a 32-bit address (it addresses a total of 4 GiB external PCIe space), while the IBR iATU input receives accesses from within a total of 16 ExaBytes of external PCIe space (a 64-bit address).

By definition, an iATU (Address Translation Unit) has an input (the space the access originates from) and an output (the space the access is headed for), with the required address translation taking place in the middle. An iATU inbound region (IBR) routes from PCIe (input) to device L3_MAIN space (output), an iATU outbound region (OBR) routes from the L3_MAIN space (input) to the PCIe (output).

Table 24-671summarizes the action of the different ATU regions. It contains the same information as the table above, organized differently. Note that inbound regions are not required to managed incoming configuration accesses, which are completed automatically by the PCIe controller hardware.

PCIe controller core outbound and inbound ATUs define:

- 16 outbound iATU regions
- 4 inbound iATU regions

Table 24-671. Address Translation Unit Region Access Summary

ATU region direction	ATU region type	Source space	Destination space
Outbound (OBR)	Memory	PCIe controller outbound window	PCIe memory space
Inbound (IBR)	Memory	PCIe memory space	Device PCIe subsystem space
Outbound (OBR)	I/O	PCIe controller outbound window	PCIe I/O space
Inbound (IBR)	I/O	PCIe I/O space	Device PCIe subsystem space
Outbound (OBR)	Configuration	PCIe controller outbound window	PCIe Cfg space

In a read/write access to an iATU outbound region (input), which is mapped in the PCIe controller target's 256 MiB-wide outbound window, do not confuse:

- Physical address accessed in the device L3_MAIN address space - 4 GiB
- Physical address within the PCIe_SS1/PCIe_SS2 controller target (slave) port:
  - PCIe outbound window - Cfg ; Memory and I/O space accessible within (0x2000_0000 - 0x2FFF_FFFF)/(0x3000_0000 - 0x3FFF_FFFF)
  - PCIe controller local configuration/status registers accessible within (0x5100_0000 - 0x517F_FFFF)/(0x5180_0000 - 0x51FF_FFFF)
- Address offset within the outbound window (0 - 256 MiB)

Copyright © 2015–2017, Texas Instruments Incorporated

CAUTION

In the calculation of an ATU outbound region translation, the input is the address offset within the outbound window, ranging from 0x0000_0000 (0 bytes) to 0x0FFF_FFFC (256 MiB – 4 Bytes), they are the third and last address type in the list above.

PCI express is an interconnect that propagates read/write accesses from/to systems beyond the local device PCIe subsystem. The figure below shows such a link, where the transaction initiator (PCIe requester device, on the left) and the transaction target (PCIe completer device, on the right) are two instances of the PCIe controller subsystem, connected over the PCI express fabric (in the middle). The physical routing of the transaction over the PCIe topology (through switches) is implicit and transparent for addresses. A simplified chain of address translation is represented for each PCIe transaction type (Configuration, Memory or IO).

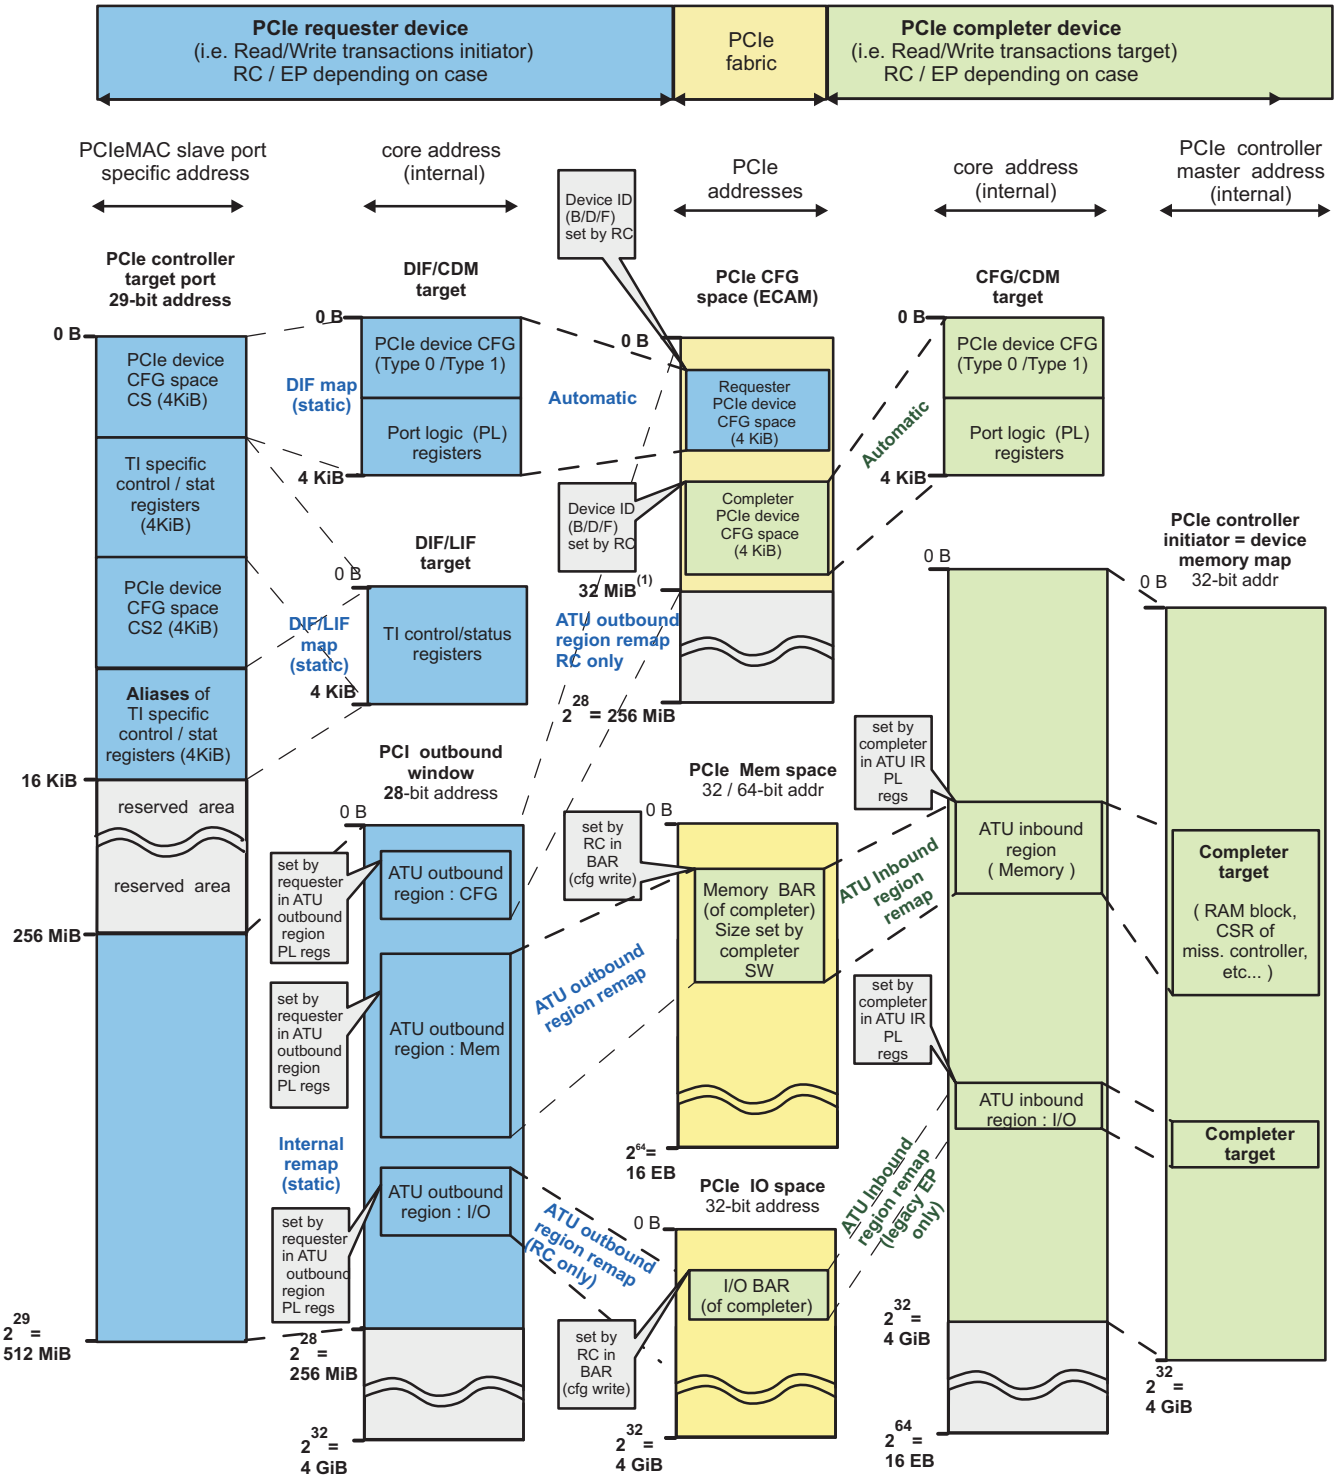
Figure 24-164. PCIe Core to PCIe Core Address Mapping and Translation



Note(1): The EP PCIe CFG space (EP function descriptors) occupies 32 MiB of the whole 256 MiB Outbound window. This because only a single EP function (#0) is implemented out of 8 possible.

pcie_ctrl-004

NOTE: There is a difference between requester/completer and RC/EP relationships, an EP device can be either the requester or the completer in a memory transaction.

24.9.4.8 PCIe Traffic Requesting and Responding

The PCIe wire can carry several types of packet-based traffic. The current chapter details how the current controller can be requester and completer of each type:

- **Requester:** initiates and transmits an outbound request, receives a response if required by (non-posted) request type.
- **Completer:** receives and processes an inbound request, generates and transmits a response if required by (non-posted) request type.

24.9.4.8.1 PCIe Memory-type (Mem) Traffic Management

The bulk of PCIe traffic is expected to take place in the memory (MEM) space, making use of large TLP/large L3_MAIN interface bursts.

Before PCI activity starts, one or several BAR of each device (EP function or RC) shall be initialized in Memory mode, as described in the Section 24.9.4.9.3, *Base Address Registers (BAR) Initialization*.

The following fields shall be set, using (CS) access (they are RO over PCI) :

- BARn[0]= "space decoder" shall be set to 0 = MEM space. This is the default setting for all BAR.
- BARn[2:1] = "type" shall be configured to either 32 or 64-bit. In the latter case, BARn+1 above shall contain the 32-bit upper part of the BAR base address.
- BARn[3] = "prefetchable" (P)

The BAR shall be enabled, using (CS2) access to BARn[0]:

- Write 1: BARn is enabled, can be configured by the RC writing to the MSBits of the BARn base address field.
- Write 0: BARn is disabled: register is read-only and return 0 over PCIe.

As part of the standard enumeration process, the RC then maps all the Memory BARs it finds (while discovering the connected EP functions) into the memory address space (32 or 64-bit address), using Cfg accesses over the PCIe wire. Optionally, the RC can also configure its own two BAR, over the DIF interface.

Once that process is complete, memory requests can take place point-to-point, that means that the requests can be initiated by any device (EP or RC) towards any other device function.

24.9.4.8.1.1 PCIe Memory Requesting

An ATU outbound region can then be programmed to remap the desired parts of the memory space (which correspond to BARs on other devices) into the local controller target's outbound window, accessed through the L3_MAIN slave port.

Alternatively, the iATU can be bypassed, and the outgoing access forwarded to the PCIe wire without address translation. In that *pass-through* mode, the PCIe address is equal to the 28 LSBits of the PCIe controller target address, that is, the address offset within the 256 MiB-wide outbound window. This gives access to the lowest 256 MiB of the PCIe memory space, from 0x0 to 0x0FFF_FFFC.

The forwarded PCIe TLPs shall have the following (hardcoded) header field values:

- TYPE = 0 = MRd/ MWr (Memory read or write)
- EP (poisoned bit) = 0 (not poisoned)
- ATTR (Attributes) = 2b01:
  - ATTR[1] = RO (relaxed ordering) = 0
  - ATTR[0] = NS (no snoop) = 1
- TC (traffic class) = 0

Initiators in the device local PCIe subsystem (typically CPUs or DMA) can then access memory space by initiating read/write accesses on the controller's slave port over L3_MAIN, either to the range of an enabled ATU outbound region, for the translated mode (with all TLP fields configurable), or outside any enabled ATU outbound region, for the pass-through mode (with the TLP fields hardcoded as explained above).

Copyright © 2015–2017, Texas Instruments Incorporated

24.9.4.8.1.2 PCIe Memory Responding

An ATU inbound region can be programmed in BAR matching mode to remap (part or all of) each memory BAR to the controller's inbound window (this means to translate their address to the memory space of the device chip), and issue them on the PCIe controller's master port towards L3_MAIN. BAR matching mode is expected to be the most common method for an EP. In that mode, the ATU can be set up before enumeration - before the BAR's actual range (offset) is configured by the remote RC.

Alternatively, the ATU inbound region can be programmed in address matching mode. In that case, any access routed to the device (EP or RC) and matching the range specified in the ATU is remapped to the controller's inbound window (this means to translate their address to the memory space of the device), and issued on the master port towards L3_MAIN.

Address matching is the preferred method for an RC, which would route any access outside its base/limit range, as defined in its PCIe standard (Type-1) configuration space, and independently of any BAR so that BAR matching is not possible. In that case, only space not already taken up by a BAR can be used. Note the setup of an address matching iATU inbound region can only be done after enumeration, that is, after the RC has discovered and mapped all enabled Memory BAR of all EP functions to their address.

Finally, in case an incoming access does not match any enabled ATU inbound region (BAR or address matching), the transaction is just passed through untranslated, that is, with the address unchanged and the TLP attributes stripped off. This is not expected to be commonly used.

Incoming memory requests (to the local EP's Memory BAR) shall then cause the master port on L3_MAIN to access a given address range of the local system (potentially the entire 32-bit address range).

24.9.4.8.2 PCIe Configuration Type (Cfg) Traffic Management

Configuration (Cfg) traffic is not symmetrical: it can only be requested by the RC, and completed (in the case of PCIe controller) by the EP. It is used by the RC for the enumeration of the fabric: EP, functions, switches.

NOTE: The RC cannot use configuration traffic over the PCIe wire to access its own 4 KiB configuration space. To do that, it uses DIF accesses (CS) with bit PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN = 0b0.

24.9.4.8.2.1 RC Self-configuration (RC Only)

Like any other device on the PCIe fabric, the RC has its own 4-KiB configuration space, where RC local configuration registers are stored.

NOTE: Since the RC configuration registers are programmed by the RC itself, no remote access over the PCIe wire (Cfg TLP) is required. Local DIF accesses (CS) are used instead.

However, some register fields normally defined as read-only by the PCI standard are actually programmable over DIF (see Section 24.9.4.9.2), which may cause a standard software driver to fail. In that case, the CS-writability of those fields has to be disabled by reprogramming the located in the PCIe controller port logic bit PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN to 0b0. Note that this is normally done after CS-writable fields have been configured by the non-standard initialization "firmware", thus making the RC's configuration space PCI compliant.

The Section 24.9.4.8.2.2 and Section 24.9.4.8.2.3 only covers configuration of an EP function by an RC, using actual Configuration TLPs (transport layer packets).

24.9.4.8.2.2 Configuration Requests over PCIe (RC Only)

After coming out of reset, the PCI fabric is enumerated by the RC through configuration (Cfg) transactions to the switches and EP present in the topology. The enumeration process is covered by the PCI and PCIe standards - for more details refer to the PCI Express Base 3.0 Specification, revision 1.0.

Configuration transactions are created by an outbound ATU region set up to translate the PCIe controller slave port accesses into Cfg TLP on the PCIe wire.

Copyright © 2015–2017, Texas Instruments Incorporated

- The L3_MAIN interconnect port (read or write) determines the TLP type (CfgRd/CfgWr)
- The data is passed unchanged from the L3_MAIN interconnect to the PCI world (write) and reciprocally (read)
- The entire PCI configuration space can be mapped as a standard, contiguous block, as specified in the **Enhanced Configuration Access Mechanism (ECAM)**. The ATU maps this 256 MiB block at a programmable base address within the controller slave port's 256 MiB "outbound window", using the ATU "Cfg shift" feature.
- The other parameters are programmed beforehand in the ATU's configuration registers (IATU_*)

The (28-bit) address offset within the 256 MiB ECAM block is the concatenation of :

- **Cfg register address** (Offset[11:0] = 12-bit = 4 KiB configuration space per EP function)
- **Function number** (Offset[14:12] =3 bit = 8 functions per PCIe EP)
- **Device number** (Offset[19:15] = 5 bit = 32 devices per bus, always 0 for PCIe controller itself)
- **Bus number** (Offset[27:20] = 8-bit = 256 busses in the PCIe fabric)
- Total for ECAM: 8 + 5 + 3 + 12 = 28-bit offset, or 256 x 32 x 8 x 4 KiB = 256 MiB

NOTE: The device PCIe controller itself supports only one function in EP mode. On the PCIe fabric, however when in RC mode, the PCIe controller may need to configure up to 8 functions per EP (potentially for all 65536 EPs). Hence the ECAM config. space visible to RC is 256 MiB in size.

A Cfg read access to the Vendor ID register is used by the RC to detect the presence of a function. If that specific read (address 0x000 in the 4-KiB PCI config space) fails with an UR PCIe response (Unsupported Request: no function present), the PCIe controller shall return a correct response to L3_MAIN with data 0xFFFF. This indicates the absence of the function to the application, without triggering an error on L3_MAIN.

24.9.4.8.2.3 Configuration Responding over PCIe (EP Only)

As an EP, the device only expects to receive (and never transmit) configuration transactions, and expects those to be CFG0 and not CFG1.

Incoming Cfg accesses with the appropriate Target ID are automatically routed to the targeted EP function's 4-KiB PCI configuration space, which contains both the PCI standard registers (header, descriptors, extende descriptors, and so forth) and the PL registers. The request read/write complete automatically, with no transaction appearing on the PCIe controller master port. Since Cfg accesses are non-posted, each incoming request shall generate a response.

NOTE: An ATU inbound region is also capable of processing incoming Cfg transactions, and translating them into read/write accesses on the master port towards L3_MAIN. However, this method is not expected to be used, and automatic completion –described above– is expected to be used instead.

24.9.4.8.3 PCIe I/O-type (IO) traffic management

I/O traffic is not symmetrical: it can only be requested by the RC, and responded to by the EP. It is a mostly deprecated feature of PCI, and could be replaced by Memory traffic. However, it is still required by the standard for a PCIe RC. It is supported by the current controller in both RC (requester) and **legacy EP mode (completer)**.

24.9.4.8.3.1 PCIe I/O requesting (RC only)

As part of the standard enumeration process, the RC maps all the I/O BARs it finds (while discovering the connected EP functions) into the 4 GiB I/O address space (32-bit address).

An ATU outbound region shall then be programmed to map a zone of the I/O space into the controller target's outbound window, accessed through the slave port.

Copyright © 2015–2017, Texas Instruments Incorporated

Initiators in the RC host (typically a local CPU) can then access I/O space by initiating (1 DWORD) read/write accesses to the ATU region's range on the controller's slave port on L3_MAIN.

NOTE: There is NO specific hardware mechanism to notify the RC that it is allowed to issue I/O requests, since that configuration decision comes from the RC in the first place.

24.9.4.8.3.2 PCIe IO BAR initialization before enumeration (EP only)

Before PCI enumeration, each BAR can be initialized/enabled individually for IO space, using the DIF access (CS or CS2). The size of an enabled IO BAR (that is, the number of writable bits in the base address) is fixed to 256 bytes, that is, a mask of 0xFF that is, the writable BAR base address range for the RC is BARn[31:8], while BARn[7:0] is read-only.

In (CS) access, the BARn[0] "space decoder" field becomes RW and shall be written to 1 = IO space

In (CS2) access, BARn[0] becomes a write-only BAR enable :

- Write '1': BARn is enabled, can be configured by the RC writing to the MSBits of the BARn base address field.
- Write '0': BARn is disabled: register is read-only and return 0x0 over PCIe.

24.9.4.8.3.3 PCIe I/O responding (PCI legacy EP only)

I/O support is permitted only for the "legacy EP" type, that is, EP's side it is required that PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE has been preliminary set to 0x1 by EP's local software. Before PCI activity starts, one or several BAR of the EP function shall be enabled in I/O mode, to get enumerated by the RC as per the PCI standard.

An iATU (internal address translation unit) inbound region can be programmed in **BAR matching mode** to map the BAR to the controller's inbound window (that is, translate their address to the memory space of the SoC), and issue them on the PCIe master port towards device L3_MAIN.

BAR matching mode is expected to be the most common method for an EP. In that mode, the iATU can be set up before enumeration, that is, before the BAR's actual range (offset) is configured by the remote RC.

Alternatively, the ATU inbound region could be programmed in address matching mode. However, a valid I/O access coming into an EP is necessarily within a BAR, so BAR matching should be used. Additionally, BAR matching can be configured before enumeration, that is, before the RC has mapped the I/O BAR to their actual address.

Incoming I/O requests to the local EP's IO BAR shall then cause the PCIe master port to access a given address range of the local system (potentially the entire 32-bit address range), in 32-bit read/write accesses.

24.9.4.8.4 PCIe Message-type (Msg) traffic management

Most messages are generated and received automatically by logic in the controller HW, and do not require any specific intervention from the user.

The application can transmitted the following power management messages by writing to the TI configuration wrapper instance PCIECTRL_TI_CONF_PM_CTRL register:

- PCIECTRL_TI_CONF_PM_CTRL [0]PME_TURN_OFF: (power management event, turn off) request from RC to turn off, broadcasted downstream.
- PCIECTRL_TI_CONF_PM_CTRL[1] PM_PME: (power management event): request from EP to wake up, routed upstream towards RC.

No dedicated logic exists in the controller to support vendor-defined messages.

The ATU is capable of generating (outgoing) messages, and receiving (incoming) ones, by translating them from read/write accesses on the PCIe controller slave port, or to read/write accesses on the PCIe controller master port, respectively. However, this functionality is not required for standard PCI operation.

Copyright © 2015–2017, Texas Instruments Incorporated

24.9.4.9 PCIe Programming Register Interface

PCI is an memory-mapped, dynamically reconfigurable interconnect protocol, so that the same physical register may be accessed in several different ways. The current chapter targets to describe only the statically-mapped programming registers of the local PCIe controller, accessed over the local AXI slave.

They are composed of:

- **PCIe-standard configuration registers:** by definition accessible over the PCIe wire through the PCIe configuration (and extended configuration - ECAM) space. Those registers are different depending on the selected mode (Type-0: EP or Type1: RC).
- **Port Logic (PL) registers:** non-standard user-accessible registers for additional PCIe functionality. They are also accessible over PCIe wire, in the configuration (ECAM) space.
- **TI-specific control and status registers:** more non-standard registers, accessible only locally. These are associated with the PCIe controller wrapper level functional control and status.

24.9.4.9.1 PCIe Register Access

The Table 24-672 summarizes how the resources of the local controller can be accessed. Note that the rightmost column represent accesses to the PCIe controller hosts system memory.

Table 24-672. Summary of Access Types related to PCIe Controller Local Resources

Access	PCIe standard configuration registers	Port Logic (PL) registers	TI-specific registers	System memory available to PCIe
Local DIF access (over PCIe controller target (slave) port, from device host CPUs and DMAs)	Yes[1] (CS or CS2)	Yes	Yes	No
Remote PCIe config (Cfg) transaction (over PCIe wire)	EP: Yes[1] RC: No[2]	EP: Yes RC: No[2]	No	No
Remote PCIe Memory transaction (over PCIe wire)	No	No	No	Yes (iATU)
Remote PCIe IO transaction (over PCIe wire)	No	No	No	EP: Yes (iATU) RC: No[3]

(1) 1. Read and writes to PCIe standard configuration registers (in PCIe config space, address 0x0 to 0x700) will give different results depending on the access method (DIF CS/CS2, PCIe): see .

(2) 2. PCIe Cfg transactions can only be issued by the RC (to an EP): A RC cannot receive one.

(3) 3. PCIe IO transactions can only be issued by the RC (to an EP): A RC cannot receive one.

24.9.4.9.2 Double Mapping of the PCIe Local Control Registers

Each local programming register is mapped twice inside the controller's local target, with an offset of 0x1000 (4 KiB) between the two mappings.

The "low" mapping is the Data Interface (DIF) chip-select (CS) access. In DIF CS mode, some fields that are read-only (RO) over PCI become writable if PL bit PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN=0b1 (default). This access is used by the local host (e.g. BIOS) for the initialization of the PCI device, prior to PCI protocol startup (LTSSM enable). Fields and registers that are CS-sensitive are labeled (CS) in the Section 24.9.7.

The "high" mapping is the Data Interface (DIF) chip-select-2 (CS2) access. In DIF CS2 mode, some fields that are read-only (RO) over PCI or in DIF CS mode, become writable if PL bitfield PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN=0b1 (default). This access is also used by the local host for further initialization of the PCI device. Fields and registers that are CS2-sensitive are labeled (CS2) in the tables below.

Copyright © 2015–2017, Texas Instruments Incorporated

NOTE: The following important notes on accesses must be considered by user for device PCIe controller:

- If PCIe_SS_PL_CONF instance located bitfield PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN is cleared to 0b0, the "CS and CS2-sensitive" fields become read-only (RO) again, that is, they revert to the behaviour defined in the PCI/PCIe standards.
- The standard PCI configuration registers (header, descriptors, extended descriptors) are the only ones that can change their behaviour in CS and CS2 access.
- The port logic (PL) registers and the PCIe controller wrapper TI configuration registers are not affected by the CS: for those, the two mappings have the same properties, that is, they are perfect aliases
- For an RC, which by definition cannot access its own (locally stored) configuration registers over the PCIe wire, the DIF access is the only alternative. The PCIe controller must present a PCI-standard-compliant type-1 configuration space to the RC software driver, that is, with none of the read-only bits actually writable, as follows:
  - the DIF CS access should be used
  - PL bitfield PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN should be cleared to 0b0 (after a pre-initialization, if required)

24.9.4.9.3 Base Address Registers (BAR) Initialization

The 6 base address registers ((EP) BAR0 through (EP) BAR5) supported in EP mode (Type0), get discovered and configured by the RC during PCI enumeration, as per the PCIe standard. Via the PCIe ECAM (enhanced configuration access) mechanism the **RC** maps a remote EP function's BAR registers in 64-bit PCIe memory space and software run on RC access them as the PCIECTRL_EP_PCIEWIRE_BAR0 through PCIECTRL_EP_PCIEWIRE_BAR5 registers. Note that the configuration space of the RC (Type1 registers) also contains two BARs ((RC) BAR0 and (RC) BAR1), but they are not expected to be used.

Before enumeration, BARs can be initialized by the local software, using DIF access (CS or CS2), to modify the properties seen by the RC at enumeration. The following can be configured in each BAR: enabling, IO or memory type, size (mask width). Even BAR numbers (0,2,4) can also be paired with the BAR number above (1,3,5) to create a single, 64-bit address (memory).

NOTE: If PCIe_SS_PL_CONF instance located register PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN bit is cleared, most BAR fields become read-only again, behaving like in over-the-wire PCI Cfg writes by the RC. Only the BAR base address (MSbits) is still writable. The size/mask, type, and enabling become read-only.

Table 24-673. PCIe Default BAR Configuration

	Enabled[1]	Space[2] BARn[0]	Type[2] BARn[2:1]	Prefetch[2] BARn[3]	Mem Size[1] (M-bit mask)	I/O Size (M-bit mask)
(EP) BAR0	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	1 MiB (20-bit)	256 Bytes (8-bit)
(EP) BAR1	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	64 KiB (16-bit)	256 Bytes (8-bit)
(EP) BAR2	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	1 MiB (20-bit)	256 Bytes (8-bit)
(EP) BAR3	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	64 KiB (16-bit)	256 Bytes (8-bit)
(EP) BAR4	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	4 KiB (12-bit)	256 Bytes (8-bit)
(EP) BAR5	Yes	Memory (0)	32-bit (2'b00)	Yes (1)	64 KiB (16-bit)	256 Bytes (8-bit)

(1) reprogrammable with DIF (CS2) access
(2) reprogrammable with DIF (CS) access

The Table 24-674 and Table 24-675 describe how a memory and IO BAR can be accessed, respectively. A single address of the PCIe config space is accessed for a given BAR, with each line of the table showing a different mode: read vs. write; PCIe Cfg access vs. DIF (CS) access vs. DIF (CS2) access.

"M" is the width of the BAR mask in bits, with 2^M the BAR size in bytes. Bits M and above are writable by the RC over the PCIe wire to set the BAR base address, as follows:

Copyright © 2015–2017, Texas Instruments Incorporated

- The value of M for a Memory BAR varies from 4 (2^4=16 Byte = minimum size) to 32 (2^{32} = 4 GiB for a 32-bit BAR, potentially more for a 64-bit BAR) depending on the BAR and on the configuration.
- The current implementation forces M=8 for an I/O BAR, that is, an IO BAR has a fixed size of 2^8=256 bytes, the maximum allowed by the PCIe protocol.

Table 24-674. BARn Register Access Methods (Mem BAR)

Method	BAR[31:M](1)	BAR[M-1:4]	BAR[3]	BAR[2:1]	BAR[0]
PCI read	Base address readout	Read returns zero	Read out "Prefetchable"	Read out "Type"	Read out 0 "space decoder"(2)
PCI write	Base address write	No effect (masked = R/O)	No effect	No effect	No effect
CS read	Base address readout	Read returns zero (masked)	Read out "Prefetchable"	Read out "Type"	Read out 0 "space decoder"(2)
CS write	Base address write	No effect (masked = R/O)	Write "Prefetchable"	Write "Type"	Write "space decoder"(2)
CS2 read	Base address readout	Read returns zero (masked)	Read out "Prefetchable"	Read out "Type"	Read out 0 "space decoder"(2)
CS2 write	Write 0 to unmask (Sets M)	Write 1 to mask (Sets M)	Write 1	Write 1	Write "BAR enable"

(1) For M=32, the BAR mask is 32-bit wide, the BAR size is 4 GiB and the column disappears.
(2) Space decoder is Memory = 0 in this table.

Table 24-675. BARn Register Access Methods (IO BAR)

Method	BAR[31:8]	BAR[7:2]	BAR[1]	BAR[0]
PCI read	Base address readout	Read returns zero	Read out 0 (reserved bit)	Read out 1 "space decoder"(1)
PCI write	Base address write	No effect (masked = R/O)	No effect	No effect
CS read	Base address readout	Read returns zero (masked)	Read out 0 (reserved bit)	Read out 1 "space decoder"(1)
CS write	Base address write	No effect (masked = R/O)	Write 0 No effect	Write "space decoder"(1)
CS2 read	Base address readout	Read returns zero (masked)	Read out 0 (reserved)	Read out 1 "space decoder"(1)
CS2 write	Write 0. No effect in fixed-sized I/O BAR	Write 1. No effect in fixed-sized I/O BAR	Write 0 No effect	Write "BAR enable"

(1) Space decoder is I/O = 1 in this table.

24.9.5 PCIe Controller Low Level Programming Model

24.9.5.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the PCIe_SS1 and PCIe_SS2 controllers are used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the PCIe_SS (for more information, see PCIe Controllers Integration and PCIe Controllers Environment). Table 24-676 describes the global initialization of the surrounding modules.

Table 24-676. Global Initialization of the PCIe Surrounding Modules

Surrounding Modules	Comments
PRCM	Module functional and interface clocks must be enabled. (See Section 3.6, *Clock Management Functional Description*, in Chapter 3, *Power, Reset, and Clock Management*.)
Control Module	Module configuration must be done in control module. See Section 18.5,*CTRL_MODULE_CORE Registers* and Table 24-661, *PCIe Port Configuration*
(Optional) IRQ_CROSSBAR	Interrupt crossbar configuration must be done to map the interrupts from the PCIe Controllers to a certain device processor INTC via the IRQ_CROSSBAR module. For more details on IRQ_CROSSBAR programming, see Section 18.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 18, *Control Module*.
(Optional) A local INTC	The local interrupt controller must be configured to enable the interrupt once IRQ output is mapped on INTC via the IRQ_CROSSBAR. See Chapter 17, *Interrupt Controllers*.
L4 and L3_MAIN interconnects	For more information about the interconnect configuration, see Section 14.2.3.2.1, *L3_MAIN Interconnect Agents*, and Section 14.3.1, *L4 Interconnect Overview*, in Chapter 14, *Interconnects*.
(Optional) Device MMU2	For more information on the configuration for routing the PCIe_SS1,2 master port traffic through the device MMU2, see Section 24.9.4.3.1.1, as well as Chapter 20, *Memory Management Units*.

NOTE: The interrupt configuration is required when using interrupt communication mode.

24.9.5.2 Main Sequence of PCIe Controllers Initalization

NOTE: This section aims to describe only the basic steps that must be followed by PCIe application software in order for a PCIe RC or EP type device to initialize, establish PCIe connectivity and interact with devices on the PCIe fabric. For this reason, it focuses on settings of the PCIe controllers wrapper registers (and not on PCI/PCIe standard and non-standard (PL) registers), through which PCIe application interacts with PCIe devices.

Table 24-677. Main Sequence PCIe Controller Global Initialization

RC and/or EP Initialization Step[1]	Register/Bit Field/Programming Model	Value
1. Initialize the DPLL_PCIe_REF (clock source, dividers, power dependencies) in PRCM	Refer to Section 26.4.5	
2. Assert a local software main reset to the PCIe_SS1 controllers	PRCM.RM_PCIESS_RSTCTRL[0] RST_LOCAL_PCIE1	0b1
3. Poll main reset completion status for the PCIe_SS1 controllers	PRCM.RM_PCIESS_RSTST[0] RST_LOCAL_PCIE1	=0b1
4. Perform tuning of the PCIe PHY	Refer to Section 26.4.5	
IF: required operation mode for PCIe controller is “RC”	Software Test Condition	
5. Select RC type	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	0x4 (default)
6. Poll to insure a fundamental reset has completed	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	=0x4

(1) Unless a step is not marked as “[EP Only]” or “[RC Only]”, the initialization step should be considered as applicable in both EP and RC modes of PCIe controller.

Table 24-677. Main Sequence PCIe Controller Global Initialization (continued)

RC and/or EP Initialization Step[1]	Register/Bit Field/Programming Model	Value
7. Make sure LTSSM_EN is kept by RC's software at value 0b0	PCIECTRL_TI_CONF_DEVICE_CMD[0] LTSSM_EN	0b0
8. Initialize RC PCIe controller's core registers.	See Table 24-679	
9. Clear the IRQ main status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MAIN[31:0]	0xFFFFFFFF
10. First time enable PCIe main interrupts. Depends on which PCIe protocol events and error events will be handled by application.	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN [14:0]	0x-
11. Clear the IRQ msi status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MSI[31:0]	0xFFFFFFFF
12. [optional step] Enable INTx (x=A,B,C,D) interrupts reception (generated from legacy EPs to RC) but disable MSI interrupts reception at the same time. OR Enable the MSI interrupts reception (MSI interrupts are generated to RC from PCIe EPs only) but disable the INTx interrupts reception at the same time	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI [3:0] INTx_EN	0x-
	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI [4] MSI_EN	0b1
	PCIECTRL_TI_CONF_IRQENABLE_SET_MSI [4] MSI_EN	0b1
	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI [3:0] INTx_EN	0xF
ELSE IF: required operation mode for PCIe controller is "PCIe EP"		
5. Select "PCIe EP" type	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	0x0
6. Poll to insure fundamental reset has completed	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	=0x0
7. Make sure LTSSM_EN is kept by EP's software at value 0b0	PCIECTRL_TI_CONF_DEVICE_CMD[0] LTSSM_EN	0b0
8. Initialize EP PCIe controller's core registers	See Table 24-678	
9. Clear the IRQ main status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MAIN[31:0]	0xFFFFFFFF
10. First time enable –PCIe main interrupts. Depends on which PCIe protocol events and error events will be handled by application.	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN [14:0]	0x-
11. Clear the IRQ msi status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MSI[31:0]	0xFFFFFFFF
12. Disable both INTx (x=A,B,C,D) and MSI interrupts reception.	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI [4:0]	0x1F
ELSE:		
5. Select "PCI Legacy EP " type	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	0x1
6. Poll to insure fundamental reset has completed	PCIECTRL_TI_CONF_DEVICE_TYPE[3:0] TYPE	=0x1
7. Make sure LTSSM_EN is kept by EP's software at value 0b0	PCIECTRL_TI_CONF_DEVICE_CMD[0] LTSSM_EN	0b0
8. Initialize EP controller local registers via DIF CS/CS2 accesses	See Table 24-678	
9. Clear the IRQ main status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MAIN[31:0]	0xFFFFFFFF
10. First time enable PCIe main interrupts. Depends on which PCIe protocol events and error events will be handled by application.	PCIECTRL_TI_CONF_IRQENABLE_SET_MAIN [14:0]	0x-
11. Clear the IRQ main status register in case raw status is not clear (to avoid spurious interrupts)	PCIECTRL_TI_CONF_IRQSTATUS_MSI[31:0]	0xFFFFFFFF
12. Disable both INTx (x=A,B,C,D) and MSI interrupts reception	PCIECTRL_TI_CONF_IRQENABLE_CLR_MSI [4:0]	0x1F
ENDIF		
13. PCIe (RC/EP) controller enables the link. It is supposed that all active EPs attached on the PCIe fabric synchronously enable their LTSSM engine with the RC.	PCIECTRL_TI_CONF_DEVICE_CMD[0] LTSSM_EN	0b1

Copyright © 2015–2017, Texas Instruments Incorporated

Table 24-677. Main Sequence PCIe Controller Global Initialization (continued)

RC and/or EP Initialization Step[1]	Register/Bit Field/Programming Model	Value
14. Local CPU polls until the PCIe Controller link is up (that is, brought into L0- power state)	PCIECTRL_TI_CONF_PHY_CS[16] LINK_UP	=0b1
15. If PCIECTRL_TI_CONF_IRQSTATUS_MAIN[3] LINK_UP_EVT has been enabled in step (10), this means it should be cleared	PCIECTRL_TI_CONF_IRQSTATUS_MAIN[12] LINK_UP_EVT	0b1
16. RC host starts link training sequence, negotiation with EPs, enumeration of the EPs, and initializes the descriptors per each of the discovered EP functions. Example: RC Initializes the MSI message vectors table per each of the EPs. RC maps the EPs global PCIe Memory per each EP function appropriately initializing the BARn registers MSB part.		
17. [RC only] **IF:** an EP is a requester, the RC remotely enables its BME bit via an ECAM access to the EP's command /status register.	PCIe_SS1_EP_CFG_PCIe. PCIECTRL_EP_PCIEWIRE_STATUS_COMMAND_REGISTER[2] BUSMASTER_EN	0b1
18. [RC only] **IF:** an EP is a completer, the RC remotely enables its MSE (for Mem transfers) or ISE bits (for legacy I/O transfers) via an ECAM access to the EP's command/status register.	PCIe_SS1_EP_CFG_PCIe. PCIECTRL_EP_PCIEWIRE_STATUS_COMMAND_REGISTER[1] MEM_SPACE_EN OR PCIe_SS1_EP_CFG_PCIe. PCIECTRL_EP_PCIEWIRE_STATUS_COMMAND_REGISTER[0] IO_SPACE_EN	0b1
19. [EP only] Before EP's application generates a request (that is, requester EP), the EP application must insure that its local BME_EVT status has already been asserted to 0b1 by the RC host controller.	PCIECTRL_TI_CONF_IRQSTATUS_MAIN[13] BME_EVT_MSG OR PCIECTRL_TI_CONF_IRQSTATUS_RAW_MAIN[13] BME_EVT_MSG	=0b1
The EP must locally clear the BME interrupt, writing BME_EVT_MSG flag to 0b1 (Wr1toClr).	Wr1ToClr PCIECTRL_TI_CONF_IRQSTATUS_MAIN[13] BME_EVT_MSG	0b1
20. [RC only] Before RC application initiates a request to an completer EP function with a *Memory type BAR*, the RC must check that EP's MEM_SPACE_EN flag has already been asserted by the RC host. This is done via an ECAM remote access by RC to EP's command/status register. [EP Only] The EP's CPU is notified about remote MEM_SPACE_EN flag assertion in a dedicated bit that can be enabled to generate an interrupt. The interrupt flag is cleared via writing to 0b1 (Wr1ToClr).	PCIe_SS1_EP_CFG_PCIe. PCIECTRL_EP_PCIEWIRE_STATUS_COMMAND_REGISTER[1] MEM_SPACE_EN	=0b1
	The EP application may receive an interrupt (if enabled – see step 10) indicated in the PCIECTRL_TI_CONF_IRQSTATUS_MAIN[14] MSE_EVT_MSG. Or poll this in PCIECTRL_TI_CONF_IRQSTATUS_RAW_MAIN[14] MSE_EVT_MSG.	0b1
20. [RC only] Before RC application initiates a request to a completer EP function with an *I/O type BAR*, the RC must check that EP's IO_SPACE_EN flag has already been asserted by the RC host. This is done via an ECAM remote read access by RC to EP's command/status register.	PCIe_SS1_EP_CFG_PCIe. PCIECTRL_EP_PCIEWIRE_STATUS_COMMAND_REGISTER[0] IO_SPACE_EN	=0b1
[EP Only] Unlike Mem type EPs, there is no interrupt event to notify the EP about its ISE flag being asserted by the RC. So, to be aware of an incoming transaction, I/O legacy EP must poll local IO_SPACE_EN flag until its asserted by RC to 0b1.	PCIECTRL_EP_DBICS_STATUS_COMMAND_REGISTER[0] IO_SPACE_EN	=0b1
[EP Only] 21. IF IO_SPACE_EN bit has been set to '1' for a legacy EP, user must force the legacy EP master port out-of-standby (before first transaction). There is no automatical standby generation for I/O transfers.	PCIECTRL_TI_CONF_SYSCONFIG[5:4] STANDBYMODE	0x1

Table 24-678. Local EP (Type 0) PCIe Standard and Port Logic Registers Initialization Subsequence

8.1 Initialize PCI standard configuration header registers via corresponding DIF CS/CS2 accesses. Example: BAR MASK0 – BAR MASK5 (that must be entirely initialized by the EP, and LSB part of the BAR0 – BAR5 registers)	For more details on these settings, refer to the *PCI Express Base 3.0 Specification, revision 1.0*	
8.2 Initialize the RC PCIe capability registers via corresponding DIF CS/CS2 accesses.	For more details on these settings, refer to the *PCI Express Base 3.0 Specification, revision 1.0*	
8.3 Initialize the RC PCIe Port Logic registers. Example: iATU settings of internal local address ranges, link settings – link powers, timings, and so forth		

Table 24-679. RC (Type 1) PCIe Standard and Port Logic Registers Initialization Subsequence

RC must enable write operation to be able to configure its own PCIe standard and PL registers.	PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN	0b1
8. 1 Initialize RC PCI standard configuration header registers via corresponding DIF CS/CS2 accesses. (Example: RC BAR 0,1 and BAR MASK0,1 registers.)	For more details on these settings, refer to the *PCI Express Base 3.0 Specification, revision 1.0*	
8.2 Initialize the RC PCIe capability registers via corresponding DIF CS/CS2 accesses.	For more details on these settings, refer to the *PCI Express Base 3.0 Specification, revision 1.0*	
8.3 Initialize the RC PCIe Port Logic registers. Example: iATU settings of internal local address ranges, link settings – link power, timings, and so forth Prepare the MSI vectors, Setup of the MSI, others.		
Disable write operation in RC PCIe standard and PL registers.	PCIECTRL_PL_DBI_RO_WR_EN[0] CX_DBI_RO_WR_EN	0b0

NOTE: When the PCIe_SS1 controller is configured to operate in two lane mode, by default lane 0 is mapped to the PCIe1_PHY (device PCIe PHY port 0), and lane 1 is mapped to the USB_PHY (USB PHY port). The PCIe_SS1_TI_CONF wrapper located software control - PCIECTRL_TI_CONF_PHY_CS[0] REVERSE_LANES allows user software to swap mapping of the PCIe_SS1 controller lane 0 and lane 1 on the two device PCIe PHY ports (swapping the RX and TX paths simultaneously with polarity of an individual lane unchanged). Note that the identical control is not functional in the PCIe_SS2_TI_CONF, because the PCIe_SS2 can operate in a single lane mode only, and (if selected) its lane 0 is always mapped to the PCIe PHY port 1 (that is, PCIe2_PHY).

(1) ECAM_Param_Base_Addr = 0x0000_0000 to 0x0FFF_F000

NOTE: The *ECAM_Param_Base_Addr* variable is the 16-bit **base address** (this address is 4 KiB-aligned with value in the range: 0x0000_0000 - 0x0FFF_F000) of the relevant EP function descriptor (relevant EP's function PCIe standard and PL configuration registers) **in a contiguous 256-MiB ECAM space** (0x0000_0000 - 0x0FFF_FFFF). For more information on the PCIe ECAM configuration space mapping mechanism, refer to the section *PCI Express Enhanced Configuration Access Mechanism (ECAM)*, in the *PCI Express Base 3.0 Specification, Revision 1.0*.

For information on the EP's function PL register offsets and descriptions, refer to the Section 24.9.7.5.

24.9.7.2 PCIe_SS_EP_CFG_PCIe Registers

NOTE: This section describes the PCIe EP mode (PCIe type-0) standard configuration registers as they are accessed over PCIe wire logic and not via DIF CS/CS2 accesses. These register names are prefixed with "PCIECTRL_EP_PCIEWIRE".

24.9.7.5 PCIe_SS_PL_CONF Registers

NOTE: The Section 24.9.7.5.1 lists the implementation-specific (that is, not PCIe-standard) “port logic” - PL registers, mapped in the 4-KiB PCIe configuration space along with the PCIe-standard registers already described. Unlike the standard registers, port logic (PL) registers are not affected by the device type (Type-0/EP vs. Type-1/RC).

NOTE: Besides at the (DIF CS space) physical addresses listed in below tables, the PCIe PL configuration registers are also locally accessible (aliased) at the (DIF CS2 space) base address 0x5100_1700 (PCIe_SS1) and 0x5180_1700 (PCIe_SS2), without any difference in PL registers behaviour between CS and CS2 spaces. There is also no difference in PL registers behaviour between PCIe wire remote accesses and local (DIF CS,CS2) accesses.

24.9.7.5.1 PCIe_SS_PL_CONF Register Summary

24.9.7.5.2 PCIe_SS_PL_CONF Register Description

Table 24-864. PCIECTRL_PL_LAT_REL_TIM

Address Offset	0x0000 0000		
Physical Address	0x5100 0700 0x5180 0700	**Instance**	PCIe_SS1_PL_CONF PCIe_SS2_PL_CONF
Description	Ack Latency and Replay Timer Register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REPLAY_TIME_LIMIT																ACK_LATENCY_TIME_LIMIT															

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
31:16	REPLAY_TIME_LIMIT	The replay timer expires when it reaches this limit; The core initiates a replay upon reception of a Nak or when the replay timer expires; The default value depends on number of bytes (NB) per cycle, which is defined by the maximum core base frequency of the device PCIe core, corresponding to 250 MHz for PCIe-Gen2 (5 Gbps) operation. The default is then updated based on the Negotiated Link Width and Max_Payload_Size; Note: If operating at 5 Gb/s, then the rounded-up value of an additional (153/CX_NB) cycles is added, where CX_NB correspond to the number of PCIEPCS 8-bit input symbols per single 16-bit lane, that is, CX_NB=2. This means at 5Gbps, 77 extra cycles should be considered for the replay time limit. This is for additional internal processing for received TLPs and transmitted DLLPs.	RW	0xc0
15:0	ACK_LATENCY_TIME_LIMIT	The Ack/Nak latency timer expires when it reaches this limit; The default value depends on number of bytes (NB) per cycle, which is defined by the maximum core base frequency of the device PCIe core, corresponding to 250 MHz for PCIe-Gen2 (5 Gbps) operation. The default is then updated based on the Negotiated Link Width and Max_Payload_Size. Note: If operating at 5 Gb/s, then the rounded-up value of an additional (51 /CX_NB) cycles is added, where CX_NB correspond to the number of PCIEPCS 8-bit input symbols per single 16-bit lane, that is, CX_NB=2. This means at 5Gbps, 26 extra cycles should be considered for the acknowledge latency time limit. This is for additional internal processing for received TLPs and transmitted DLLPs.	RW	0x40

24.9.7.8 PCIe_SS_TI_CONF Registers

24.9.7.8.1 PCIe_SS_TI_CONF Register Summary

NOTE: Though the PCIe controller wrapper TI configuration registers are also accessible (aliased) at base address 0x5100_3000 (PCIe_SS1) and 0x5180_3000 (PCIe_SS2), the preferable base addresses to access them are the ones used in above table, that is, 0x5100 2000 and 0x5180 2000. These registers are visible only within the device L3_MAIN space.

Table 24-1060. PCIe_SS1_TI_CONF Registers Mapping Summary

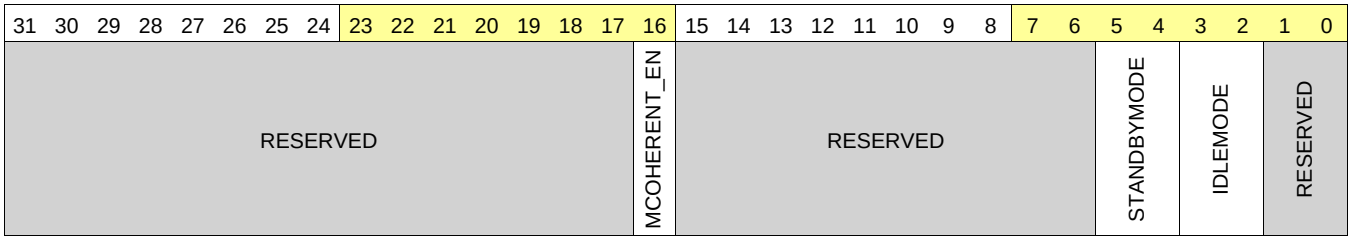
Table 24-1064. PCIECTRL_TI_CONF_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	0x5100 2010 0x5180 2010	**Instance**	PCIe_SS1_TI_CONF PCIe_SS2_TI_CONF
Description	Controls various parameters of the master and slave interfaces.		
Type	RW		

Copyright © 2015–2017, Texas Instruments Incorporated



Bits	Field Name	Description	Type	Reset
31:17	RESERVED		R	0x0
16	MCOHERENT_EN	Allows the no-snoop (NS) attribute of inbound PCIe TLPs to be passed to SoC system bus (AXI) master as a 'coherent' inband flag. 0x0: DIS AXI not coherent 0x1: EN AXI coherent = not(PCIE "NS") that is, cache-coherence is preserved	RW	0x0
15:6	RESERVED		R	0x0
5:4	STANDBYMODE	PM mode of local initiator (master); Initiator may generate read/write transaction as long as it is out of STANDBY state. 0x0: Force-standby mode = Initiator is unconditionally placed in standby state. 0x1: No-standby mode = initiator is unconditionally placed out of standby state. 0x2: Smart-standby mode = initiator's standby state depends on internal conditions, that is, the module's functional requirements. Asynchronous wakeup events cannot be generated. 0x3: Smart-Standby, wakeup-capable mode = initiator's standby state depends on internal conditions, ie the module's functional requirements. Asynchronous wakeup events can be generated.	RW	0x2
3:2	IDLEMODE	PM mode of local target (slave); Target shall be capable of handling read/write transaction as long as it is out of IDLE state. 0x0: Force-idle mode = local target's idle state follows (acknowledges) the system's idle requests unconditionally, regardless of the IP module's internal requirements. 0x1: No-idle mode = local target never enters idle state. 0x2: Smart-idle mode = local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. Module shall not generate (IRQ- or DMA-request-related) wakeup events. 0x3: Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state.	RW	0x2
1:0	RESERVED		R	0x0

24.10 DCAN

This chapter describes the controller area network modules (DCAN) in the device.

24.10.1 DCAN Overview

The Controller Area Network (CAN) is a serial communications protocol which efficiently supports distributed real-time applications. CAN has high immunity to electrical interference and the ability to self-diagnose and repair data errors. In a CAN network, many short messages are broadcast to the entire network, which provides for data consistency in every node of the system.

The device supports two DCAN modules, referred to as DCAN1 and DCAN2, connecting to the CAN network through external (for the device) transceivers. The DCAN modules support bit rates up to 1 Mbit/s and are compliant to the CAN 2.0B protocol specification

Figure 24-165 shows the DCAN1 module highlights.

Figure 24-165. DCAN1 Overview

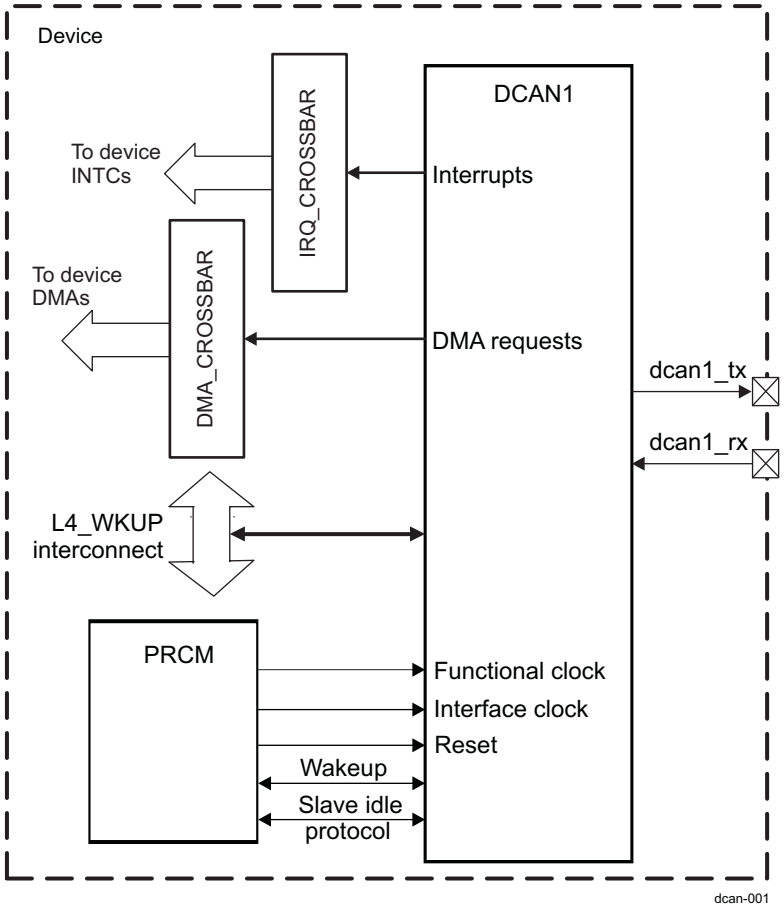

Figure 24-166 shows the DCAN2 module highlights .

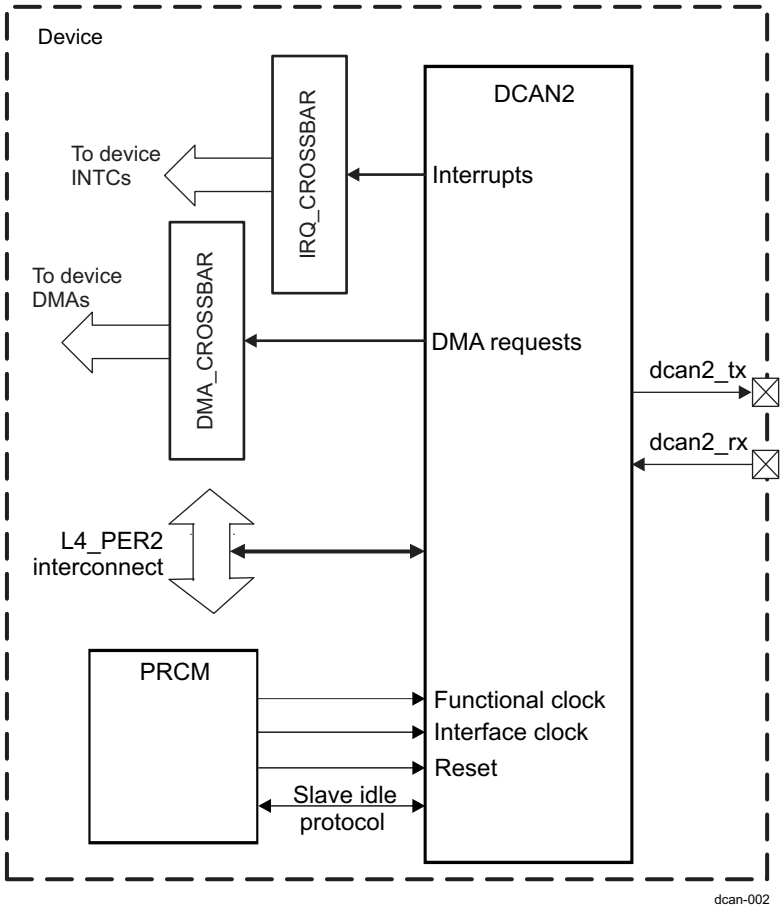
Copyright © 2015–2017, Texas Instruments Incorporated

Figure 24-166. DCAN2 Overview



24.10.1.1 Features

The DCAN module implements the following features:

- Support for CAN protocol version 2.0 part A, B
- Bit rates up to 1 Mbit/s
- 64 message objects in a dedicated message RAM
- Individual identifier mask for each message object
- Programmable FIFO mode for message objects
- Programmable loop-back modes for self-test operation
- Suspend mode for debug support
- Automatic bus on after Bus-Off state by a programmable 32-bit timer
- Message RAM parity check mechanism
- Direct access to message RAM during test mode
- Support for two interrupt lines: Level 0 and Level 1, plus separate parity error interrupt line
- Local power down and wakeup support
- Automatic message RAM initialization
- Support for DMA access

Copyright © 2015–2017, Texas Instruments Incorporated

24.10.2 DCAN Environment

CAN network physical layer consists of two-wire differential bus, usually twisted pair, and provides high level of interference immunity. External CAN transceiver IC is needed to access a CAN bus by the DCAN.

Figure 24-167 shows an overview of a typical DCAN application.

Figure 24-167. DCAN Typical Application

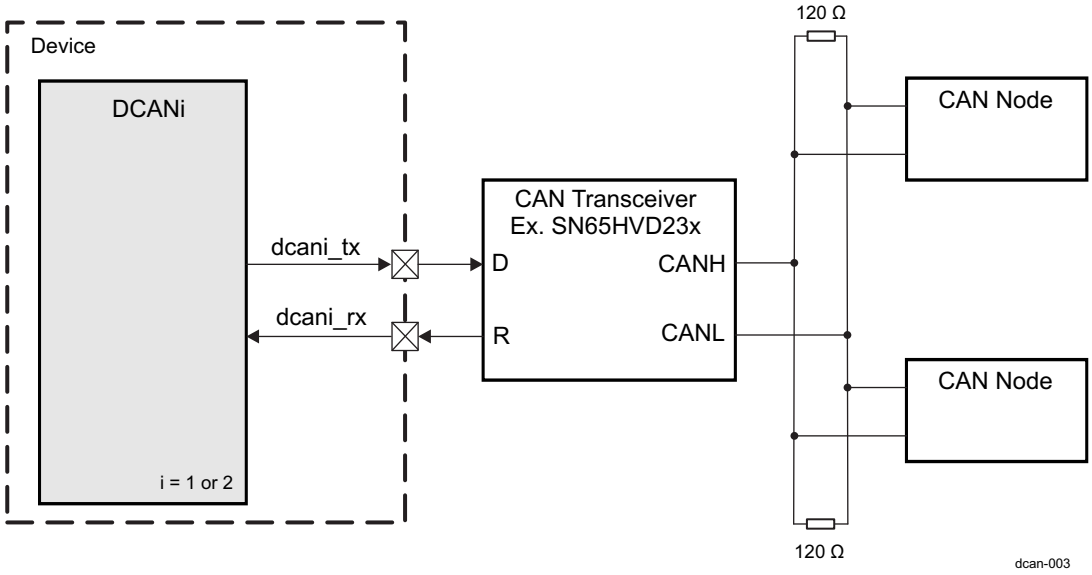


Table 24-1104 describes the external signals of the DCAN1 module.

Table 24-1104. DCAN2 I/O Description

Module Signal	Device Signal	I/O[1]	Description	Value at Reset
CAN_RX	dcan2_rx	I	Serial data input from external CAN tranceiver	HiZ
CAN_TX	dcan2_tx	O	Serial data output to external CAN tranceiver	1

(1) I = Input; O = Output

Table 24-1105 describes the external signals of the DCAN2 module.

Table 24-1105. DCAN1 I/O Description

Module Signal	Device Signal	I/O[1]	Description	Value at Reset
CAN_RX	dcan1_rx	I	Serial data input from external CAN tranceiver	HiZ
CAN_TX	dcan1_tx	O	Serial data output to external CAN tranceiver	1

(1) I = Input; O = Output

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see Section 18.4.6.1.1, *Pad Configuration Registers* of *Chapter 18, Control Module*.

24.10.2.1 CAN Network Basics

- CAN bus is a 2-wire differential bus using NRZ encoding and has two states:
  - Recessive state (logic 1)
  - Dominant state (logic 0)
- The network is multimaster. When two or more nodes attempt to transmit at the same time, a non-destructive arbitration technique guarantees messages are sent in order of priority and no messages are lost
- The message transmission is multicast. Data messages transmitted are identifier based, not address based
- Content of message is labeled by the identifier that is unique throughout the network (for example, rpm, temperature, position, pressure, etc.)
- All nodes on network receive the message and each performs an acceptance test on the identifier. If message is relevant, it is processed, otherwise it is ignored
- The unique identifier also determines the priority of the message (the lower the numerical value of the identifier, the higher the priority is)
- Data is transmitted and received using message frames, consisting of:
  - Arbitration field
  - Control field
  - Data field (0 ÷ 8 bytes)
  - CRC field
  - ACK field.

	DCAN2_IRQ_PARITY	IRQ_CROSSBAR_227	-	Parity error interrupt
DMA Requests				
Module Instance	**Source Signal Name**	**DMA_CROSSBAR Input**	**Default Mapping**	**Description**
DCAN1	DCAN1_DREQ_IF1	DMA_CROSSBAR_158	-	DMA request for IF1 register set
	DCAN1_DREQ_IF2	DMA_CROSSBAR_159	-	DMA request for IF2 register set
	DCAN1_DREQ_IF3	DMA_CROSSBAR_160	-	DMA request for IF3 register set
DCAN2	DCAN2_DREQ_IF1	DMA_CROSSBAR_161	-	DMA request for IF1 register set
	DCAN2_DREQ_IF2	DMA_CROSSBAR_162	-	DMA request for IF2 register set
	DCAN2_DREQ_IF3	DMA_CROSSBAR_163	-	DMA request for IF3 register set

NOTE: DCAN has no default IRQ mappings through the IRQ_CROSSBAR. For DCAN, the IRQ_CROSSBAR module must be configured prior to unmask interrupts in the interrupt controller(s).
For more information about the IRQ_CROSSBAR module, see Section 18.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 18, *Control Module*.
For more information about the device interrupt controllers, see Chapter 17, *Interrupt Controllers*.

NOTE: For more information about the DMA_CROSSBAR module, see Section 18.4.6.5, *DMA_CROSSBAR Module Functional Description*, in Chapter 18, *Control Module*.

NOTE: For the description of the interrupt source, see Section 24.10.4.2, *Interrupt Functionality*.

24.10.4 DCAN Functional Description

The DCAN module performs CAN protocol communication according to ISO 11898-1. The bit rate can be programmed to values up to 1 Mbit/s. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

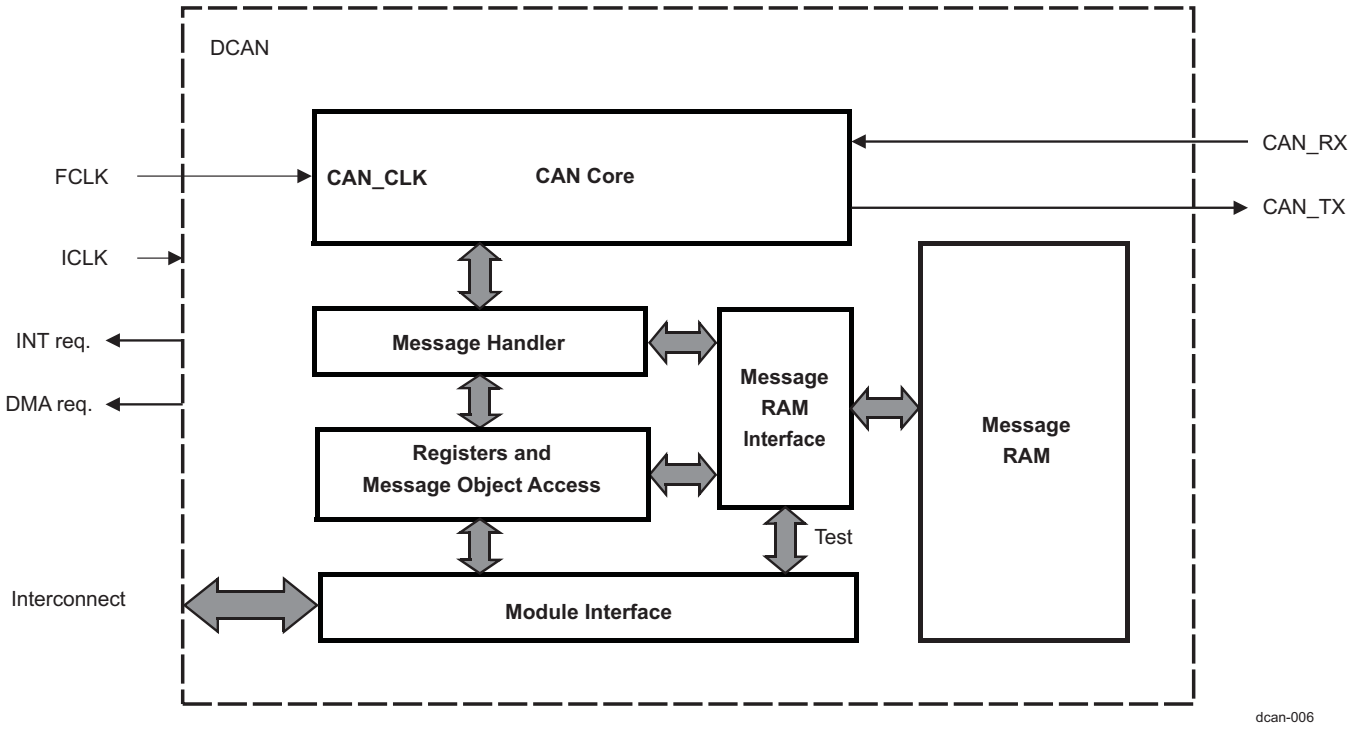
For communication on a CAN network, individual message objects can be configured. The message objects and identifier masks are stored in the message RAM.

All functions concerning the handling of messages are implemented in the message handler. Those functions are acceptance filtering, the transfer of messages between the CAN core and the message RAM, and the handling of transmission requests, as well as the generation of interrupts or DMA requests.

The register set of the DCAN module can be accessed directly via the module interface. These registers are used to control and configure the CAN core and the message handler, and to access the message RAM.

Figure 24-170 shows the DCAN block diagram and its features are described below.

Figure 24-170. DCAN Block Diagram



CAN Core: The CAN core consists of the CAN protocol controller and the Rx/Tx shift register. It handles all ISO 11898-1 protocol functions.

Message Handler: The message handler is a state machine that controls the data transfer between the single-ported message RAM and the CAN core's Rx/Tx shift register. It also handles acceptance filtering and the interrupt/DMA request generation as programmed in the control registers.

Message RAM: The DCAN enables a storage of 64 CAN messages.

Message RAM Interface: Three interface register sets control the MPU read and write accesses to the message RAM. There are two interface registers sets for read and write access, IF1 and IF2, and one interface register set for read access only, IF3. Additional information can be found in Section 24.10.4.8.12, *Reading From a FIFO Buffer*.

The interface registers have the same word-length as the message RAM.

Copyright © 2015–2017, Texas Instruments Incorporated

Registers and Message Object Access: Data consistency is ensured by indirect accesses to the message objects. During normal operation, all software and DMA accesses to the message RAM are done through interface registers. In a dedicated test mode, the message RAM is memory mapped and can be directly accessed by either MPU or DMA.

Module Interface: The DCAN module registers are accessed by the user software through a 32-bit peripheral bus interface.

Clocking: Two clocks are provided to the DCAN module: the peripheral synchronous clock (interface clock [ICLK]) and the peripheral asynchronous clock (functional clock [FCLK]) .

24.10.4.1 Module Clocking Requirements

Two clocks are provided to the DCAN module:

- the peripheral synchronous clock (ICLK) as the general module clock source
- and the peripheral asynchronous clock (FCLK) provided to the CAN core for generating the CAN bit timing.

NOTE: ICLK must always be higher or equal to FCLK, in order to achieve a stable functionality of the DCAN. Here, also the frequency shift of the modulated ICLK has to be considered:

$f_{0,\ ICLK}(OCP) \pm \Delta f_{FM,\ ICLK}(OCP) \geq f_{FCLK}$

For more information on how to configure the relevant clock source registers, see Chapter 3, *PRCM* and the device data manual.

24.10.4.2 Interrupt Functionality

Interrupts can be generated on two interrupt lines: INT0 and INT1. These lines can be enabled by setting the DCAN_CTL[1] IE0 and [17] IE1 bits, respectively. The interrupts are level triggered at the chip level.

The DCAN provides three groups of interrupt sources: message object interrupts, status change interrupts, and error interrupts (see Figure 24-171, *Error and Status Change Interrupts* and Figure 24-172, *Message Objects Interrupts*).

The source of an interrupt can be determined by the interrupt identifiers DCAN_INT[15:0] INT0ID/[23:16] INT1ID. When no interrupt is pending, the register will hold the value zero.

Each interrupt line remains active until the dedicated field in the interrupt register DCAN_INT[15:0] INT0ID/[23:16] INT1ID again reach zero (this means the cause of the interrupt is reset), or until IE0/IE1 are reset.

The value 0x8000 in the INT0ID field indicates that an interrupt is pending because the CAN core has updated (not necessarily changed) the Error and Status register (DCAN_ES). This interrupt has the highest priority. The software can update (reset) the status bits [9] WAKEUPPND, [4] RXOK, [3] TXOK and [2:0] LEC by reading DCAN_ES, but a write access of the software will never generate or reset an interrupt.

Values between 1 and the number of the last message object indicates that the source of the interrupt is one of the message objects, INT0ID resp. INT1ID will point to the pending message interrupt with the highest priority. The Message Object 1 has the highest priority; the last message object has the lowest priority.

An interrupt service routine that reads the message that is the source of the interrupt may read the message and reset the message object's IntPnd at the same time (DCAN_IF1CMD/DCAN_IF2CMD[19] CLRINTPND bit). When IntPnd is cleared, DCAN_INT will point to the next message object with a pending interrupt.

24.10.4.2.1 Message Object Interrupts

Message object interrupts are generated by events from the message objects. They are controlled by the flags IntPnd, TxIE and RxIE that are described in Section 24.10.4.11.1, *Structure of Message Objects*.

Copyright © 2015–2017, Texas Instruments Incorporated

Message object interrupts can be routed to either INT0 or INT1 line, controlled by the interrupt multiplexer registers (DCAN_INTMUX12 to DCAN_INTMUX78).

24.10.4.2.2 Status Change Interrupts

The events WAKEUPPND, RXOK, TXOK and LEC in the error and status register (DCAN_ES) belong to the status change interrupts. The status change interrupt group can be enabled by DCAN_CTL[2] SIE bit.

If SIE is set, a status change interrupt will be generated at each CAN frame, independent of bus errors or valid CAN communication, and also independent of the message RAM configuration.

Status change interrupts can only be routed to interrupt line INT0, which has to be enabled by setting DCAN_CTL[1] IE0 = 1.

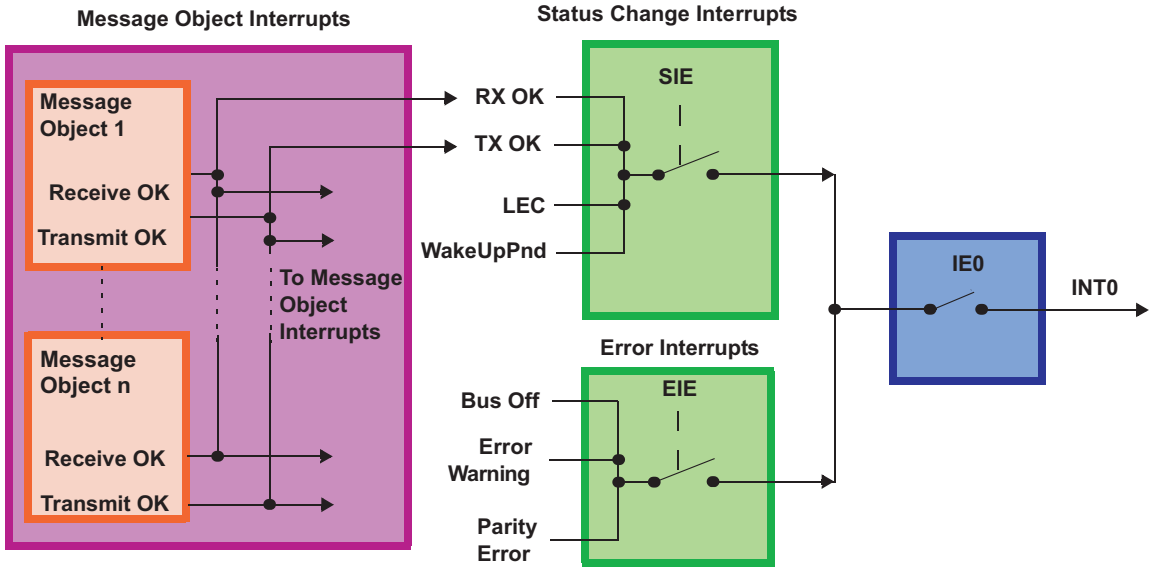
NOTE: Reading DCAN_ES will clear the WAKEUPPND flag. If in global power-down mode, the WAKEUPPND flag is cleared by such a read access before the DCAN module has been waken up by the system, the DCAN may re-assert the WAKEUPPND flag, and a second interrupt may occur.

24.10.4.2.3 Error Interrupts

The events PER, BOFF and EWARN, monitored in the DCAN_ES register belong to the error interrupts. The error interrupt group can be enabled by setting bit DCAN_CTL[3] EIE = 1.

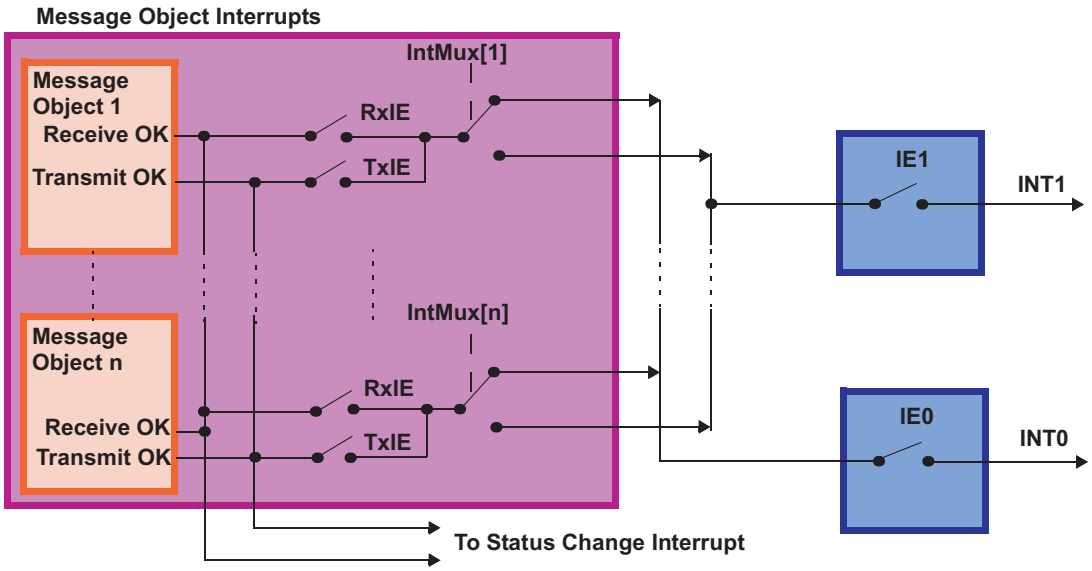
Error interrupts can only be routed to interrupt line INT0, which has to be enabled by setting DCAN_CTL[1] IE0 = 1.

Figure 24-171. Error and Status Change Interrupts



Copyright © 2015–2017, Texas Instruments Incorporated

Figure 24-172. Message Objects Interrupts



24.10.4.3 DMA Functionality

The DCAN provides three DMA request lines, each indicating new data in one of the three interface register sets IF1, IF2 and IF3.

The update of IF1 and IF2 registers will be initiated by a write access to the IF1 respective IF2 Command Registers (DCAN_IF1CMD, DCAN_IF2CMD).

The IF3 registers content can be automatically updated on reception of CAN messages in message objects which are programmed for automatic IF3 update, see Section 24.10.4.10.2, *IF3 Register Set*.

When a DCAN internal IFx (x = 1 to 3) update is complete, a DMA request will be activated and stays active until the first access to one of the relevant IFx registers. The DMA functionality has to be enabled by setting bit [18] DE0/[19] DE1/[20] DE3 in DCAN_CTL.

24.10.4.4 Local Power-Down Mode

The DCAN supports a local power-down mode, which can be controlled within the DCAN registers.

24.10.4.4.1 Entering Local Power-Down Mode

The local power-down mode is requested by setting the DCAN_CTL[24] PDR bit (=1).

The DCAN then finishes all transmit requests of the message objects. When all requests are done, DCAN waits until a bus idle state is recognized. Then it will automatically set the DCAN_CTL[0] INIT bit to prevent any further CAN transfers, and it will also set the DCAN_ES[10] PDA bit. With setting the PDA bit, the DCAN module indicates that the local power-down mode has been entered.

During local power-down mode, the internal clocks of the DCAN module are turned off, but there is a wakeup logic (see Section 24.10.4.4.2, *Wakeup From Local Power Down*) that can be active, if enabled. Also, the actual contents of the control registers can be read back.

NOTE: In local low-power mode, the software must not clear the INIT bit while PDR is set. If there are any messages in the message RAM which are configured as transmit messages and the application resets the INIT bit, these messages may get sent.

24.10.4.4.2 Wakeup From Local Power Down

There are two ways to wake up the DCAN from local power-down mode:

Copyright © 2015–2017, Texas Instruments Incorporated

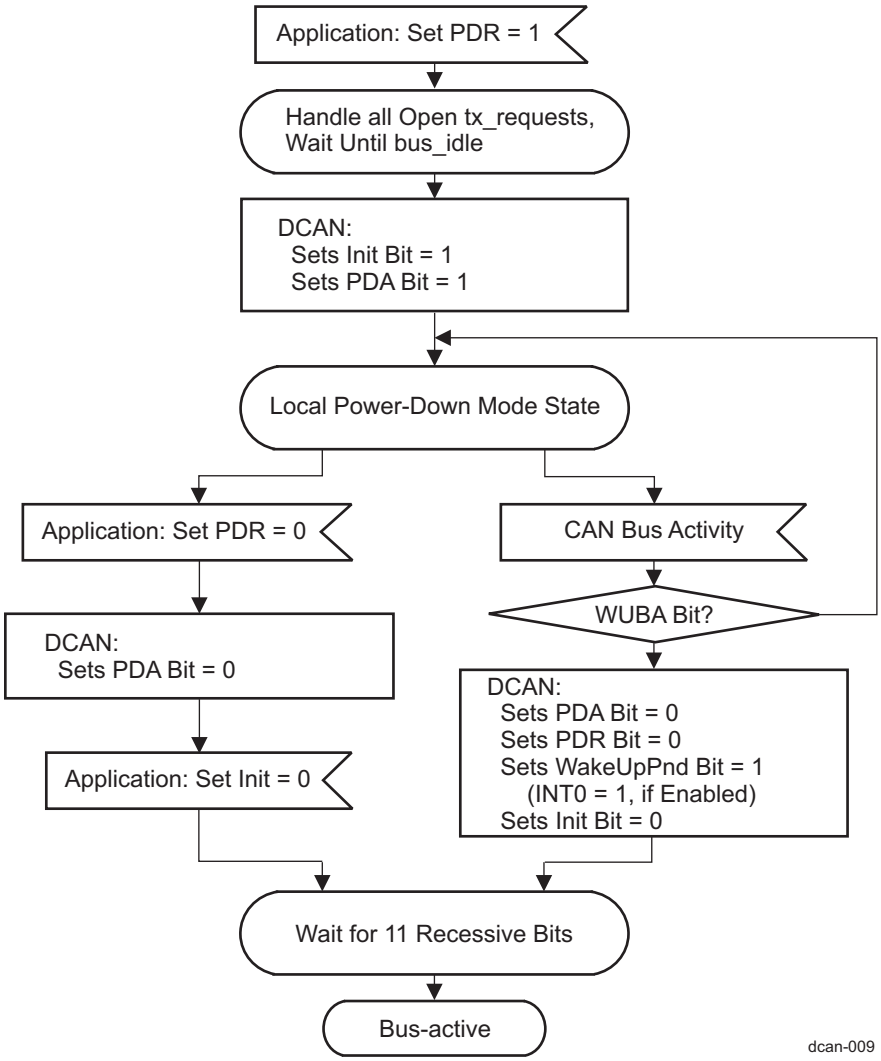
- The application could wake up the DCAN module manually by clearing the DCAN_CTL[24] PDR bit and then clearing the DCAN_CTL[0] INIT.
- Alternatively, a CAN bus activity detection circuit can be activated by setting the wakeup on bus activity bit (DCAN_CTL[25] WUBA). If this circuit is active, on occurrence of a dominant CAN bus level, the DCAN will automatically start the wakeup sequence. It will clear the DCAN_CTL[24] PDR bit and also clear the DCAN_ES[10] PDA bit. The DCAN_ES[10] WAKEUPPND bit will be set. If status interrupts are enabled, also an interrupt will be generated. Finally the DCAN_CTL[0] INIT bit will be cleared.

After the INIT bit has been cleared, the module waits until it detects 11 consecutive recessive bits on the CAN_RX pin and then goes bus-active again.

NOTE: The CAN transceiver circuit has to stay active in order to detect any CAN bus activity while the DCAN is in local power down mode. The first CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power-down and automatic wake-up mode, is lost.

Figure 24-173 shows a flow diagram about entering and leaving local power-down mode.

Figure 24-173. Local Power-Down Mode Flow Diagram



Copyright © 2015–2017, Texas Instruments Incorporated

24.10.4.5 Parity Check Mechanism

The DCAN provides a parity check mechanism to ensure data integrity of message RAM data. For each word (32 bits) in message RAM, one parity bit will be calculated. The formation of the different words is according to the message RAM representation in RDA mode, see Section 24.10.4.11.4, *Message RAM Representation in Direct Access Mode*.

Parity information is stored in the message RAM on write accesses and will be checked against the stored parity bit from message RAM on read accesses.

The Parity check functionality can be enabled or disabled by DCAN_CTL[13:10] PMD bit field.

In case of disabled parity check, the parity bits in message RAM will be left unchanged on write access to data area and no check will be done on read access.

If parity checking is enabled, parity bits will be automatically generated and checked by the DCAN. The parity bits could be read in debug/suspend mode (see Section 24.10.4.11.3, *Message RAM Representation in Debug/Suspend Mode*) or in RDA mode (see Section 24.10.4.11.4, *Message RAM Representation in Direct Access Mode*). However, direct write access to the parity bits is only possible in this two modes with parity check disabled.

A parity bit will be set, if the modulo-2-sum of the data bits is 1. This definition is equivalent to: The parity bit will be set, if the number of 1 bits in the data is odd.

NOTE: DCAN is configured to even parity by the design.

24.10.4.5.1 Behavior on Parity Error

On any read access to message RAM (e.g., during start of a CAN frame transmission), the parity of the message object will be checked. If a parity error is detected, the DCAN_ES[8] PER bit will be set. If error interrupts are enabled, an interrupt would also be generated. In order to avoid the transmission of invalid data over the CAN bus, the MsgVal bit of the message object will be reset to 0.

The message object data can be read by the software, independently of parity errors. Thus, the software has to ensure that the read data is valid, for example, by immediately checking the parity error code register (DCAN_PERR) on parity error interrupt.

NOTE: During RAM initialization, no parity check is done, but if the PMD bit is set, the parity bits will be generated.

24.10.4.5.2 Parity Testing

Testing the parity mechanism can be done by enabling the bit RamDirectAccess (DCAN_TEST[9] RDA) and manually writing the parity bits directly to the dedicated RAM locations. With this, data and parity bits could be checked when reading directly from RAM.

NOTE: If parity check is disabled, the software has to ensure correct parity bit handling in order to prevent parity errors later on when parity check is enabled.

24.10.4.6 Debug/Suspend Mode

The module supports the usage of an external debug unit by providing functions like pausing DCAN activities and making message RAM content accessible via interconnect interface.

Before entering debug/suspend mode, the DCAN will either wait until a started transmission or reception will be finished and bus idle state is recognized, or immediately interrupt a current transmission or reception. This is depending on bit DCAN_CTL[8] IDS in the CAN control register.

Afterwards, the DCAN enters debug/suspend mode, indicated by DCAN_CTL [16] INITDBG flag.

Copyright © 2015–2017, Texas Instruments Incorporated

During debug/suspend mode, all DCAN registers can be accessed. Reading reserved bits will return '0'. Writing to reserved bits will have no effect.

Also, the message RAM will be memory mapped. This allows the external debug unit to read the message RAM. For the memory organization, see Section 24.10.4.11.3, *Message RAM Representation in Debug/Suspend Mode*.

NOTE: During debug/suspend mode, the message RAM cannot be accessed via the IFx register sets.

NOTE: Writing to control registers in debug/suspend mode may influence the CAN state machine and further message handling.

For debug support, the auto clear functionality of the following DCAN registers is disabled:

- DCAN_ES register (clear of status flags by read)
- DCAN_IF1CMD/DCAN_IF2CMD command registers (clear of [14] DMAACTIVE flag by read/write)

24.10.4.7 Configuration of Message Objects Description

The whole message RAM should be configured before the end of the initialization, however it is also possible to change the configuration of message objects during CAN communication.

The CAN software driver must offer subroutines that:

- Transfer a complete message structure into a message object. (Configuration)
- Transfer the data bytes of a message into a message object and set TxRqst and NewDat. (Start a new transmission)
- Get the data bytes of a message from a message object and clear NewDat (and IntPnd). (Read received data)
- Get the complete message from a message object and clear NewDat (and IntPnd). (Read a received message, including identifier, from a message object with UMask = '1')

Parameters of the subroutines are the Message Number and a pointer to a complete message structure or to the data bytes of a message structure.

Two examples of assigning the IFx interface register sets to these subroutines are shown here:

In the first method, the tasks of the application program that may access the module are divided into two groups. Each group is restricted to the use of one of the interface register sets. The tasks of one group may interrupt tasks of the other group, but not of the same group.

In the second method, which may be a special case of the first method, there are only two tasks in the application program that access the module. A Read_Message task that uses IF2 or IF3 to get received messages from the message RAM and a Write_Message task that uses IF1 to write messages to be transmitted (or to be configured) into the message RAM. Both tasks may interrupt each other.

24.10.4.7.1 Configuration of a Transmit Object for Data Frames

Table 24-1109 shows how a transmit object can be initialized.

Table 24-1109. Initialization of a Transmit Object

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	0	appl.	0	appl.	0

Copyright © 2015–2017, Texas Instruments Incorporated

The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of the outgoing message. If an 11-bit identifier (standard frame) is used (Xtd = ‘0’), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored.

The data length and data itself (DLC[3:0] and Data0-7) are given by the application. TxRqst and RmtEn should not be set before the data is valid.

If the TXIE bit is set, the IntPnd bit will be set after a successful transmission of the message object.

If the RmtEn bit is set, a matching received remote frame will cause the TxRqst bit to be set; the remote frame will autonomously be answered by a data frame.

The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask=’1’) to allow groups of remote frames with similar identifiers to set the TxRqst bit. The Dir bit should not be masked. For details, see Section 24.10.4.8.8, *Reception of Remote Frames*.

Identifier masking must be disabled (UMask = ‘0’) if no remote frames are allowed to set the TxRqst bit (RmtEn = ‘0’).

24.10.4.7.2 Configuration of a Transmit Object for Remote Frames

It is not necessary to configure transmit objects for the transmission of remote frames. Setting TxRqst for a receive object causes the transmission of a remote frame with the same identifier as the data rrame for which this receive object is configured.

24.10.4.7.3 Configuration of a Single Receive Object for Data Frames

Table 24-1110 shows how a receive object for data frames can be initialized.

Table 24-1110. Initialization of a single Receive Object for Data Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	0	0	0	appl.	0	0	0	0

The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of accepted received messages. If an 11-bit Identifier (standard frame) is used (Xtd = ‘0’), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a data frame with an 11-bit Identifier is received, ID[17:0] is set to ‘0’.

The data length code (DLC[3:0]) is given by the application. When the message handler stores a data frame in the message object, it will store the received data length code and eight data bytes. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by non specified values.

The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask = ’1’) to allow groups of data frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. If some bits of the mask bits are set to “don’t care,” the corresponding bits of the arbitration register (DCAN_IF1ARB, DCAN_IF2ARB, DCAN_IF3ARB) will be overwritten by the bits of the stored data frame.

If the RxIE bit is set, the IntPnd bit will be set when a received data frame is accepted and stored in the message object.

If the TxRqst bit is set, the transmission of a remote frame with the same identifier as actually stored in the arbitration bits will be triggered. The content of the arbitration bits may change if the mask bits are used (UMask = ’1’) for acceptance filtering.

24.10.4.7.4 Configuration of a Single Receive Object for Remote Frames

Table 24-1111 shows how a receive object for remote frames can be initialized.

Copyright © 2015–2017, Texas Instruments Incorporated

Table 24-1111. Initialization of a Single Receive Object for Remote Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	appl.	0	0	0	0

A receive object for remote frames may be used to monitor remote frames on the CAN bus. The remote frame stored in the receive object will not trigger the transmission of a data frame. Receive objects for remote frames may be expanded to a FIFO buffer (see Section 24.10.4.7.5, *Configuration of a FIFO Buffer*).

UMask must be set to '1.' The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be set to "must-match" or to "don't care," to allow groups of remote frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. For details, see Section 24.10.4.8.8, *Reception of Remote Frames*.

The arbitration bits (ID[28:0] and Xtd bit) may be given by the application. They define the identifier and type of accepted received remote frames. If some bits of the mask bits are set to "don't care," the corresponding bits of the arbitration bits will be overwritten by the bits of the stored remote frame. If an 11-bit Identifier (standard frame) is used (Xtd = '0'), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a remote frame with an 11-bit Identifier is received, ID[17:0] will be set to '0.'

The data length code (DLC[3:0]) may be given by the application. When the message handler stores a remote frame in the message object, it will store the received data length code. The data bytes of the message object will remain unchanged.

If the RxIE bit is set, the IntPnd bit will be set when a received remote frame is accepted and stored in the message object.

24.10.4.7.5 Configuration of a FIFO Buffer

With the exception of the EoB bit, the configuration of receive objects belonging to a FIFO buffer is the same as the configuration of a single receive object.

To concatenate multiple message objects to a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest number will be the first message object of the FIFO buffer. The EoB bit of all message objects of a FIFO buffer except the last one have to be programmed to zero. The EoB bits of the last message object of a FIFO Buffer is set to one, configuring it as the end of the block.

24.10.4.8 Message Handling

When initialization is finished, the DCAN module synchronizes itself to the traffic on the CAN bus. It does acceptance filtering on received messages and stores those frames that are accepted into the designated message objects. The application has to update the data of the messages to be transmitted and to enable and request their transmission. The transmission is requested automatically when a matching remote frame is received.

The application may read messages which are received and accepted. Messages that are not read before the next messages is accepted for the same message object will be overwritten.

Messages may be read interrupt-driven or after polling of NewDat.

24.10.4.8.1 Message Handler Overview

The message handler state machine controls the data transfer between the Rx/Tx shift register of the CAN core and the message RAM. It performs the following tasks:

- Data transfer from message RAM to CAN core (messages to be transmitted)
- Data transfer from CAN core to the message RAM (received messages)
- Data transfer from CAN core to the acceptance filtering unit
- Scanning of message RAM for a matching message object (acceptance filtering)
- Scanning the same message object after being changed by IF1/IF2 registers when priority is the same

Copyright © 2015–2017, Texas Instruments Incorporated

or higher as the message the object found by last scanning

- Handling of TxRqst flags
- Handling of interrupt flags

The message handler registers contains status flags of all message objects grouped into the following topics:

- Transmission Request Flags
- New Data Flags
- Interrupt Pending Flags
- Message Valid Registers

Instead of collecting above listed status information of each message object via IFx registers separately, these message handler registers provides a fast and easy way to get an overview, for example, about all pending transmission requests.

All message handler registers are read-only.

24.10.4.8.2 Receive/Transmit Priority

The receive/transmit priority for the message objects is attached to the message number, not to the CAN identifier. Message object 1 has the highest priority, while the last implemented message object has the lowest priority. If more than one transmission request is pending, they are serviced due to the priority of the corresponding message object so messages with the highest priority, for example, can be placed in the message objects with the lowest numbers.

The acceptance filtering for received data frames or remote frames is also done in ascending order of message objects, so a frame that has been accepted by a message object cannot be accepted by another message object with a higher message number. The last message object may be configured to accept any data frame or remote frame that was not accepted by any other message object, for nodes that need to log the complete message traffic on the CAN bus.

24.10.4.8.3 Transmission of Messages in Event Driven CAN Communication

If the shift register of the CAN core is ready for loading and if there is no data transfer between the IFx registers and message RAM, the MSGVAL bits in the Message Valid register (DCAN_MSGVAL12 to DCAN_MSGVAL78) and the TXRQST bits in the transmission request register (DCAN_TXRQ12 to DCAN_TXRQ78) are evaluated. The valid message object with the highest priority pending transmission request is loaded into the shift register by the message handler and the transmission is started. The message object's NewDat bit is reset.

After a successful transmission and if no new data was written to the message object (NewDat = '0') since the start of the transmission, the TxRqst bit will be reset. If TxIE is set, IntPnd will be set after a successful transmission. If the DCAN has lost the arbitration or if an error occurred during the transmission, the message will be retransmitted as soon as the CAN bus is free again. If meanwhile the transmission of a message with higher priority has been requested, the messages will be transmitted in the order of their priority.

If automatic retransmission mode is disabled by setting the DCAN_CTL[5] DAR bit, the behavior of bits TXRQST and NEWDAT in the DCAN_IF1CMD/DCAN_IF2CMD register of the interface register set is as follows:

- When a transmission starts, the TxRqst bit of the respective interface register set is reset, while bit NewDat remains set.
- When the transmission has been successfully completed, the NewDat bit is reset.

When a transmission failed (lost arbitration or error), bit NewDat remains set. To restart the transmission, the application has to set TxRqst again.

Received remote frames do not require a receive object. They will automatically trigger the transmission of a data frame, if in the matching transmit object the RmtEn bit is set.

Copyright © 2015–2017, Texas Instruments Incorporated

24.10.4.8.4 Updating a Transmit Object

The software may update the data bytes of a transmit object any time via the IF1/IF2 interface registers, neither MSGVAL, nor TXRQST have to be reset before the update.

Even if only a part of the data bytes are to be updated, all four bytes in the corresponding IF1/IF2 Data A register (DCAN_IF1DATA/DCAN_IF2DATA) or IF1/IF2 Data B register (DCAN_IF1DATB/DCAN_IF2DATB) have to be valid before the content of that register is transferred to the message object. Either the software has to write all four bytes into the IF1/IF2 data register or the message object is transferred to the IF1/IF2 data register before the software writes the new data bytes.

When only the data bytes are updated, first 0x87 can be written to bits [23:16] of the IF1/IF2 Command register (DCAN_IF1CMD/DCAN_IF2CMD) and then the number of the message object is written to bits [7:0] MESSAGE_NUMBER of the command register, concurrently updating the data bytes and setting TXRQST with NEWDAT.

To prevent the reset of TxRqst at the end of a transmission that may already be in progress while the data is updated, NewDat has to be set together with TxRqst in event driven CAN communication. For details, see Section 24.10.4.8.3, *Transmission of Messages in Event Driven CAN Communication*.

When NewDat is set together with TxRqst, NewDat will be reset as soon as the new transmission has started.

24.10.4.8.5 Changing a Transmit Object

If the number of implemented message objects is not sufficient to be used as permanent message objects only, the transmit objects may be managed dynamically. The software can write the whole message (arbitration, control, and data) into the interface register. The bits [23:16] of the command register (DCAN_IF1CMD/DCAN_IF2CMD) can be set to 0xB7 for the transfer of the whole message object content into the message object. Neither Dir, nor TxRqst have to be reset before this operation.

If a previously requested transmission of this message object is not completed but already in progress, it will be continued; however, it will not be repeated if it is disturbed.

To only update the data bytes of a message to be transmitted, bits [23:16] of the command register (DCAN_IF1CMD/ DCAN_IF2CMD) should be set to 0x87.

NOTE: After the update of the transmit object, the interface register set will contain a copy of the actual contents of the object, including the part that had not been updated.

24.10.4.8.6 Acceptance Filtering of Received Messages

When the arbitration and control bits (Identifier + IDE + RTR + DLC) of an incoming message are completely shifted into the shift register of the CAN core, the message handler starts the scan of the message RAM for a matching valid message object:

- The acceptance filtering unit is loaded with the arbitration bits from the CAN core shift register.
- Then the arbitration and mask bits (including MsgVal, UMask, NewDat, and EoB) of message object 1 are loaded into the acceptance filtering unit and are compared with the arbitration bits from the shift register. This is repeated for all following message objects until a matching message object is found, or until the end of the message RAM is reached.
- If a match occurs, the scanning is stopped and the message handler proceeds depending on the type of the frame (data frame or remote frame) received.

24.10.4.8.7 Reception of Data Frames

The message handler stores the message from the CAN core shift register into the respective message object in the message RAM. Not only the data bytes, but all arbitration bits and the data length code are stored into the corresponding message object. This ensures that the data bytes stay associated to the identifier even if arbitration mask registers are used.

Copyright © 2015–2017, Texas Instruments Incorporated

The NewDat bit is set to indicate that new data (not yet seen by the software) has been received. The software should reset the NewDat bit when it reads the message object. If at the time of the reception the NewDat bit was already set, MsgLst is set to indicate that the previous data (supposedly not seen by the software) is lost. If the RxIE bit is set, the IntPnd bit is set, causing the DCAN_INT to point to this message object.

The TxRqst bit of this message object is reset to prevent the transmission of a remote frame, while the requested data frame has just been received.

24.10.4.8.8 Reception of Remote Frames

When a remote frame is received, three different configurations of the matching message object have to be considered:

- Dir = '1' (direction = transmit), RmtEn = '1', UMask = '1' or '0'

  The TxRqst bit of this message object is set at the reception of a matching remote frame. The rest of the message object remains unchanged.
- Dir = '1' (direction = transmit), RmtEn = '0', UMask = '0'

  The remote frame is ignored, this message object remains unchanged.
- Dir = '1' (direction = transmit), RmtEn = '0', UMask = '1'

  The remote frame is treated similar to a received data frame. At the reception of a matching Remote Frame, the TxRqst bit of this message object is reset. The arbitration and control bits (Identifier + IDE + RTR + DLC) from the shift register are stored in the message object in the message RAM and the NewDat bit of this message object is set. The data bytes of the message object remain unchanged.

24.10.4.8.9 Reading Received Messages

The software may read a received message any time via the IFx interface register. The data consistency is guaranteed by the message handler state machine. Typically the software will write first 0x7F to bits [23:16] and then the number of the message object to bits [7:0] MESSAGE_NUMBER of the command register (DCAN_IF1CMD/ DCAN_IF2CMD). That combination will transfer the entire received message from the message RAM into the interface register set. Additionally, the bits NewDat and IntPnd are cleared in the message RAM (not in the interface register set). The values of these bits in the message control register (DCAN_IF1MCTL/DCAN_IF2MCTL/DCAN_IF3MCTL) always reflect the status before resetting the bits. If the message object uses masks for acceptance filtering, the arbitration bits show which of the different matching messages has been received.

The actual value of NewDat shows whether a new message has been received since last time when this message object was read. The actual value of MsgLst shows whether more than one message has been received since the last time when this message object was read. MsgLst will not be automatically reset.

24.10.4.8.10 Requesting New Data for a Receive Object

By means of a remote frame, the software may request another CAN node to provide new data for a receive object. Setting the TxRqst bit of a receive object will cause the transmission of a remote frame with the identifier of the receive object. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the TxRqst bit is automatically reset. Setting the TxRqst bit without changing the contents of a message object requires the value 0x84 in bits [23:16] of the command register (DCAN_IF1CMD/ DCAN_IF2CMD).

24.10.4.8.11 Storing Received Messages in FIFO Buffers

Several message objects may be grouped to form one or more FIFO buffers. Each FIFO buffer configured to store received messages with a particular (group of) identifier(s). arbitration and mask registers of the FIFO buffer's message objects are identical. The end of buffer (EoB) bits of all but the last of the FIFO buffer's message objects are '0'; in the last one the EoB bit is '1.'

Copyright © 2015–2017, Texas Instruments Incorporated

Received messages with identifiers matching to a FIFO buffer are stored into a message object of this FIFO buffer, starting with the message object with the lowest message number. When a message is stored into a message object of a FIFO buffer, the NewDat bit of this message object is set. By setting NewDat while EoB is '0', the message object is locked for further write accesses by the message handler until the software has cleared the NewDat bit.

Messages are stored into a FIFO buffer until the last message object of this FIFO buffer is reached. If none of the preceding message objects is released by writing NewDat to '0,' all further messages for this FIFO buffer will be written into the last message object of the FIFO buffer (EoB = '1') and therefore overwrite previous messages in this message object.

24.10.4.8.12 Reading From a FIFO Buffer

Several messages may be accumulated in a set of message objects which are concatenated to form a FIFO buffer before the application program is required (in order to avoid the loss of data) to empty the buffer.

A FIFO buffer of length N will store N–1, plus the last received message since last time it was cleared.

A FIFO buffer is cleared by reading and resetting the NewDat bits of all its message objects, starting at the FIFO Object with the lowest message number. This should be done in a subroutine following the example shown in Figure 24-174.

NOTE: All message objects of a FIFO buffer needs to be read and cleared before the next batch of messages can be stored. Otherwise, true FIFO functionality can not be guaranteed, since the message objects of a partly read buffer will be re-filled according to the normal (descending) priority.

Reading from a FIFO buffer message object and resetting its NewDat bit is handled the same way as reading from a single message object.

24.10.4.9 CAN Bit Timing

The DCAN supports bit rates between < 1 kBit/s and 1000 kBit/s.

Copyright © 2015–2017, Texas Instruments Incorporated

Each member of the CAN network has its own clock generator, typically derived from a crystal oscillator. The bit timing parameters can be configured individually for each CAN node, creating a common bit rate even though the CAN nodes' oscillator periods (f_{osc}) may be different.

The frequencies of these oscillators are not absolutely stable. Small variations are caused by changes in temperature or voltage and by deteriorating components. As long as the variations remain inside a specific oscillator tolerance range (df), the CAN nodes are able to compensate for the different bit rates by resynchronizing to the bit stream.

In many cases, the CAN bit synchronization will amend a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive.

The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

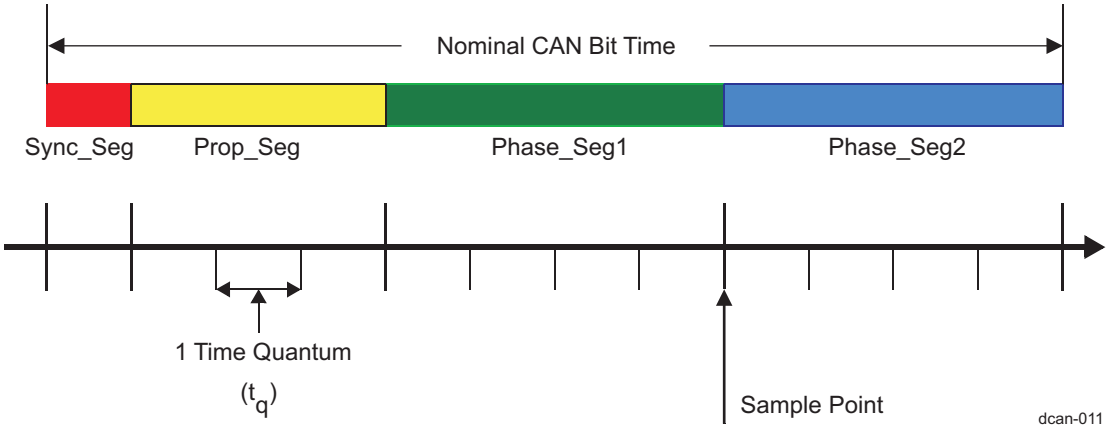
Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly.

24.10.4.9.1 Bit Time and Bit Rate

According to the CAN specification, the bit time is divided into four segments (see Figure 24-175):

- Synchronization segment (Sync_Seg)
- Propagation time segment (Prop_Seg)
- Phase buffer segment 1 (Phase_Seg1)
- Phase buffer segment 2 (Phase_Seg2)

Figure 24-175. Bit Timing



Each segment consists of a specific number of time quanta. The length of one time quantum (t_q), which is the basic time unit of the bit time, is given by the FCLK and the baud rate prescalers (BRPE and BRP). With these two baud rate prescalers combined, divider values from 1 to 1024 can be programmed:

t_q = Baud Rate Prescaler / FCLK

Apart from the fixed length of the synchronization segment, these numbers are programmable. Table 24-1112 describes the minimum programmable ranges required by the CAN protocol.

A given bit rate may be met by different bit time configurations.

Table 24-1112. Parameters of the CAN Bit Time

Parameter	Range	Remark
Sync_Seg	1 t_q (fixed)	Synchronization of bus input to FCLK
Prop_Seg	[1 … 8] t_q	Compensates for the physical delay times
Phase_Seg1	[1 … 8] t_q	May be lengthened temporarily by synchronization

Copyright © 2015–2017, Texas Instruments Incorporated

Table 24-1112. Parameters of the CAN Bit Time (continued)

Parameter	Range	Remark
Phase_Seg2	[1 … 8] t_q	May be shortened temporarily by synchronization
Synchronization Jump Width (SJW)	[1 … 4] t_q	May not be longer than either Phase Buffer Segment

NOTE: For proper functionality of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

24.10.4.9.1.1 Synchronization Segment

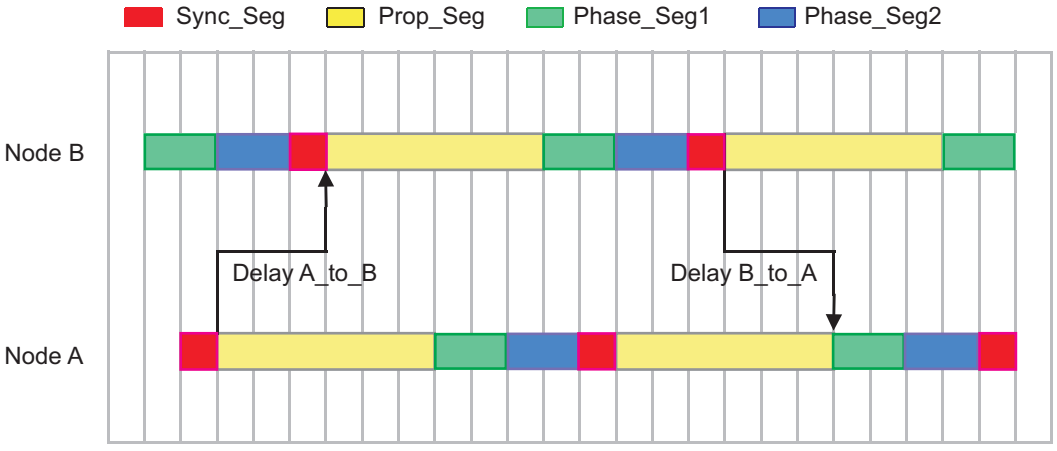
The synchronization segment (Sync_Seg) is the part of the bit time where edges of the CAN bus level are expected to occur. If an edge occurs outside of Sync_Seg, its distance to the Sync_Seg is called the phase error of this edge.

24.10.4.9.1.2 Propagation Time Segment

This part of the bit time is used to compensate physical delay times within the CAN network. These delay times consist of the signal propagation time on the bus and the internal delay time of the CAN nodes.

Any CAN node synchronized to the bit stream on the CAN bus can be out of phase with the transmitter of the bit stream, caused by the signal propagation time between the two nodes. The CAN protocol's nondestructive bitwise arbitration and the dominant acknowledge bit provided by receivers of CAN messages require that a CAN node transmitting a bit stream must also be able to receive dominant bits transmitted by other CAN nodes that are synchronized to that bit stream. The example in Figure 24-176 shows the phase shift and propagation times between two CAN nodes.

Figure 24-176. The Propagation Time Segment



Delay A_to_B ≥ node output delay(A) + bus line delay(AÆB) + node input delay(B)

Prop_Seg ≥ Delay A_to_B + Delay B_to_A

Prop_Seg ≥ 2 × [max(node output delay + bus line delay + node input delay)]

dcan-012

In this example, both nodes A and B are transmitters performing an arbitration for the CAN bus. The node A has sent its start of frame bit less than one bit time earlier than node B, therefore node B has synchronized itself to the received edge from recessive to dominant. Since node B has received this edge delay(A_to_B) after it has been transmitted, node B's bit timing segments are shifted with regard to node A. Node B sends an identifier with higher priority and so it will win the arbitration at a specific identifier bit when it transmits a dominant bit while node A transmits a recessive bit. The dominant bit transmitted by node B will arrive at node A after the delay (B_to_A).

Copyright © 2015–2017, Texas Instruments Incorporated

Due to oscillator tolerances, the actual position of node A's sample point can be anywhere inside the nominal range of node A's Phase Buffer Segments, so the bit transmitted by node B must arrive at node A before the start of Phase_Seg1. This condition defines the length of Prop_Seg.

If the edge from recessive to dominant transmitted by node B would arrive at node A after the start of Phase_Seg1, it could happen that node A samples a recessive bit instead of a dominant bit, resulting in a bit error and the destruction of the current frame by an error flag.

This error only occurs when two nodes arbitrate for the CAN bus which have oscillators of opposite ends of the tolerance range and are separated by a long bus line; this is an example of a minor error in the bit timing configuration (Prop_Seg too short) that causes sporadic bus errors.

Some CAN implementations provide an optional 3-Sample Mode. The DCAN does not. In this mode, the CAN bus input signal passes a digital low-pass filter, using three samples and a majority logic to determine the valid bit value. This results in an additional input delay of 1 t_q, requiring a longer Prop_Seg.

24.10.4.9.1.3 Phase Buffer Segments and Synchronization

The phase buffer segments (Phase_Seg1 and Phase_Seg2) and the synchronization jump width (SJW) are used to compensate for the oscillator tolerance.

The phase buffer segments surround the sample point and may be lengthened or shortened by synchronization.

The synchronization jump width (SJW) defines how far the resynchronizing mechanism may move the sample point inside the limits defined by the phase buffer segments to compensate for edge phase errors.

Synchronizations occur on edges from recessive to dominant. Their purpose is to control the distance between edges and sample points.

Edges are detected by sampling the actual bus level in each time quantum and comparing it with the bus level at the previous sample point. A synchronization may be done only if a recessive bit was sampled at the previous sample point and if the actual time quantum's bus level is dominant.

An edge is synchronous if it occurs inside of Sync_Seg; otherwise, its distance to the Sync_Seg is the edge phase error, measured in time quanta. If the edge occurs before Sync_Seg, the phase error is negative, else it is positive.

Two types of synchronization exist: hard synchronization and resynchronizing. A hard synchronization is done once at the start of a frame; inside a frame, only resynchronization is possible.

- Hard Synchronization

  After a hard synchronization, the bit time is restarted with the end of Sync_Seg, regardless of the edge phase error. Thus hard synchronization forces the edge which has caused the hard synchronization, to lie within the synchronization segment of the restarted bit time.

- Bit Resynchronizations

  Resynchronization leads to a shortening or lengthening of the Bit time such that the position of the sample point is shifted with regard to the edge.

  When the phase error of the edge which causes resynchronization is positive, Phase_Seg1 is lengthened. If the magnitude of the phase error is less than SJW, Phase_Seg1 is lengthened by the magnitude of the phase error, else it is lengthened by SJW.

  When the phase error of the edge which causes Resynchronization is negative, Phase_Seg2 is shortened. If the magnitude of the phase error is less than SJW, Phase_Seg2 is shortened by the magnitude of the phase error, else it is shortened by SJW.

If the magnitude of the phase error of the edge is less than or equal to the programmed value of SJW, the results of hard synchronization and resynchronization are the same. If the magnitude of the phase error is larger than SJW, the resynchronization cannot compensate the phase error completely, and an error of (phase error - SJW) remains.

Only one synchronization may be done between two sample points. The synchronizations maintain a minimum distance between edges and sample points, giving the bus level time to stabilize and filtering out spikes that are shorter than (Prop_Seg + Phase_Seg1).

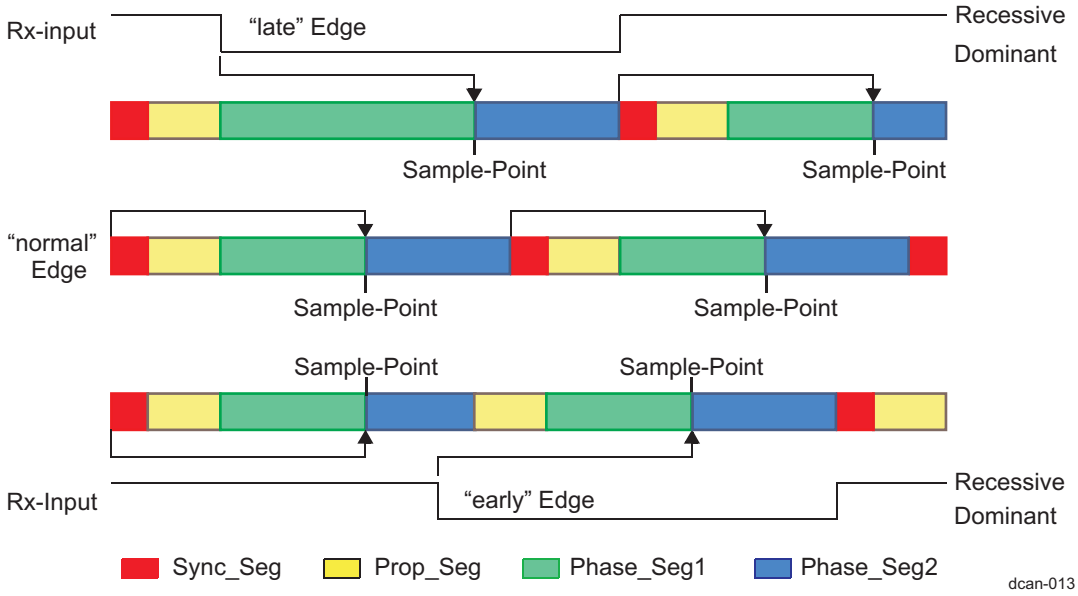
Copyright © 2015–2017, Texas Instruments Incorporated

Apart from noise spikes, most synchronizations are caused by arbitration. All nodes synchronize “hard” on the edge transmitted by the “leading” transceiver that started transmitting first, but due to propagation delay times, they cannot become ideally synchronized. The leading transmitter does not necessarily win the arbitration; therefore, the receivers have to synchronize themselves to different transmitters that subsequently take the lead and that are differently synchronized to the previously leading transmitter. The same happens at the acknowledge field, where the transmitter and some of the receivers will have to synchronize to that receiver that takes the lead in the transmission of the dominant acknowledge bit.

Synchronizations after the end of the arbitration will be caused by oscillator tolerance, when the differences in the oscillator’s clock periods of transmitter and receivers sum up during the time between synchronizations (at most ten bits). These summarized differences may not be longer than the SJW, limiting the oscillator’s tolerance range.

Figure 24-177 shows how the phase buffer segments are used to compensate for phase errors. There are three drawings of each two consecutive bit timings. The upper drawing shows the synchronization on a “late” edge, the lower drawing shows the synchronization on an “early” edge, and the middle drawing is the reference without synchronization.

Figure 24-177. Synchronization on Late and Early Edges



In the first example, an edge from recessive to dominant occurs at the end of Prop_Seg. The edge is "late" since it occurs after the Sync_Seg. Reacting to the late edge, Phase_Seg1 is lengthened so that the distance from the edge to the sample point is the same as it would have been from the Sync_Seg to the sample point if no edge had occurred. The phase error of this late edge is less than SJW, so it is fully compensated and the edge from dominant to recessive at the end of the bit, which is one nominal bit time long, occurs in the Sync_Seg.

In the second example, an edge from recessive to dominant occurs during Phase_Seg2. The edge is "early" since it occurs before a Sync_Seg. Reacting to the early edge, Phase_Seg2 is shortened and Sync_Seg is omitted, so that the distance from the edge to the sample point is the same as it would have been from a Sync_Seg to the sample point if no edge had occurred. As in the previous example, the magnitude of this early edge’s phase error is less than SJW, so it is fully compensated.

The phase buffer segments are lengthened or shortened temporarily only; at the next bit time, the segments return to their nominal programmed values.

In these examples, the bit timing is seen from the point of view of the CAN implementation’s state machine, where the bit time starts and ends at the sample points. The state machine omits Sync_Seg when synchronizing on an early edge because it cannot subsequently redefine that time quantum of Phase_Seg2 where the edge occurs to be the Sync_Seg.

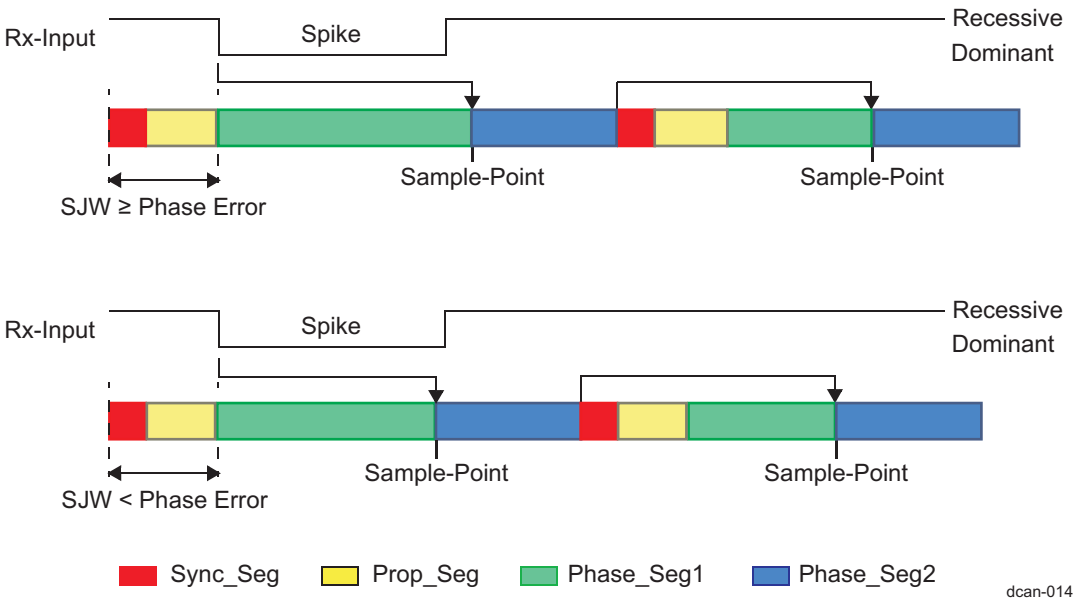
Figure 24-178 shows how short dominant noise spikes are filtered by synchronizations. In both examples, the spike starts at the end of Prop_Seg and has the length of (Prop_Seg + Phase_Seg1).

Copyright © 2015–2017, Texas Instruments Incorporated

In the first example, the synchronization jump width is greater than or equal to the phase error of the spike's edge from recessive to dominant. Therefore the sample point is shifted after the end of the spike; a recessive bus level is sampled.

In the second example, SJW is shorter than the phase error, so the sample point cannot be shifted far enough; the dominant spike is sampled as actual bus level.

Figure 24-178. Filtering of Short Dominant Spikes



24.10.4.9.1.4 Oscillator Tolerance Range

With the introduction of CAN protocol version 1.2, the option to synchronize on edges from dominant to recessive became obsolete. Only edges from recessive to dominant are considered for synchronization. The protocol update to version 2.0 (A and B) had no influence on the oscillator tolerance.

The tolerance range df for an oscillator's frequency f_{osc} around the nominal frequency f_{nom} with:

$$(1 - df) \bullet f_{nom} \le f_{osc} \le (1 + df) \bullet f_{nom}$$

dcan-e015

depends on the proportions of Phase_Seg1, Phase_Seg2, SJW, and the bit time. The maximum tolerance df is the defined by two conditions (both shall be met):

$$\text{I:} \quad df \le \frac{\min(TSeg1, TSeg2)}{2x\left(13x\left(bit_time - TSeg2\right)\right)}$$

$$\text{II:} \quad df \le \frac{SJW}{20xbit_time}$$

dcan-e016

It has to be considered that SJW may not be larger than the smaller of the phase buffer segments and that the propagation time segment limits that part of the bit time that may be used for the phase buffer segments.

The combination Prop_Seg = 1 and Phase_Seg1 = Phase_Seg2 = SJW = 4 allows the largest possible oscillator tolerance of 1.58%. This combination with a propagation time segment of only 10% of the bit time is not suitable for short bit times; it can be used for bit rates of up to 125 kBit/s (bit time = 8 µs) with a bus length of 40 m.

24.10.4.9.2 DCAN Bit Timing Registers

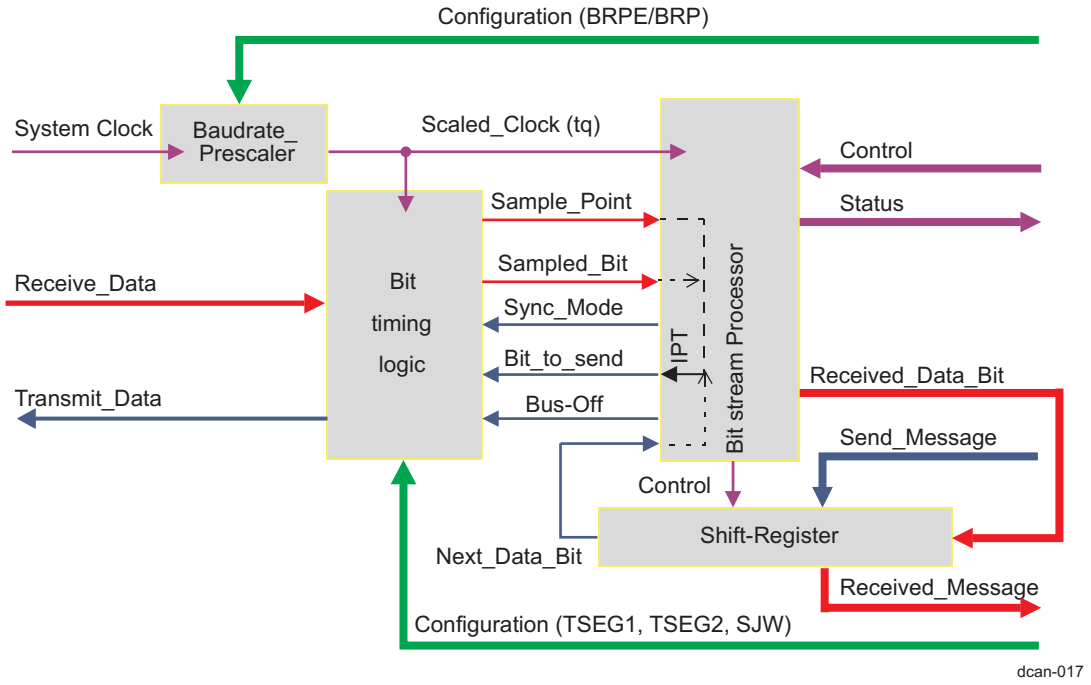
In the DCAN, the bit timing configuration is programmed in DCAN_BTR[14:0], additionally a baud rate prescaler extension of four bits (DCAN_BTR[19:16] BRPE) is provided.

Copyright © 2015–2017, Texas Instruments Incorporated

- The sum of Prop_Seg and Phase_Seg1 is set in [11:8] TSEG1
- Phase_Seg2 in [14:12] TSEG2
- SynchronizationJumpWidth in [7:6] SJW
- and baud rate prescaler [5:0] BRP (plus [19:16] BRPE)

Figure 24-179 shows the CAN protocol controller.

Figure 24-179. Structure of the CAN Core's CAN Protocol Controller



In DCAN_BTR register, the components TSEG1, TSEG2, SJW and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1…n], values in the range of [0…n–1] are programmed. That way, e.g., SJW (functional range of [1…4]) is represented by only two bits.

Therefore, the length of the bit time is (programmed values) [TSEG1 + TSEG2 + 3] t_q or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] t_q.

The data in the bit timing register (DCAN_BTR) is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by BRPE/BRP) defines the length of the time quantum (the basic time unit of the bit time); the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the sample point, and occasional synchronizations are controlled by the bit timing state machine, which is evaluated once each time quantum. The rest of the CAN protocol controller, the bit stream processor (BSP) state machine, is evaluated once each bit time, at the sample point.

The shift register serializes the messages to be sent and parallelizes received messages. Its loading and shifting is controlled by the BSP. The BSP translates messages into frames and vice versa. It generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. It is evaluated at the sample point and processes the sampled bus input bit. The time after the sample point that is needed to calculate the next bit to be sent (e.g., data bit, CRC bit, stuff bit, error flag, or idle) is called the information processing time (IPT), which is 0 tq for the DCAN.

Generally, the IPT is CAN controller-specific, but may not be longer than 2 tq. The IPC length is the lower limit of the programmed length of Phase_Seg2. In case of a synchronization, Phase_Seg2 may be shortened to a value less than IPT, which does not affect bus timing.

24.10.4.9.2.1 Calculation of the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting bit time (1 / Bit rate) must be an integer multiple of the CAN clock period.

The bit time may consist of 8 to 25 time quanta. The length of the time quantum t_q is defined by the baud rate prescaler with t_q = (Baud Rate Prescaler) / FCLK. Several combinations may lead to the desired bit time, allowing iterations of the following steps.

First part of the bit time to be defined is the Prop_Seg. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandible CAN bus systems. The resulting time for Prop_Seg is converted into time quanta (rounded up to the nearest integer multiple of t_q).

The Sync_Seg is 1 t_q long (fixed), leaving (bit time – Prop_Seg – 1) t_q for the two Phase Buffer Segments. If the number of remaining t_q is even, the Phase Buffer Segments have the same length, Phase_Seg2 = Phase_Seg1, else Phase_Seg2 = Phase_Seg1 + 1.

The minimum nominal length of Phase_Seg2 has to be regarded as well. Phase_Seg2 may not be shorter than any CAN controller's Information Processing Time in the network, which is device dependent and can be in the range of [0…2] t_q.

The length of the synchronization jump width is set to its maximum value, which is the minimum of four (4) and Phase_Seg1.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formulas given in Table 24-1113.

If more than one configurations are possible to reach a certain Bit rate, it is recommended to choose the configuration which allows the highest oscillator tolerance range.

CAN nodes with different clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol compliant configuration of the CAN bit timing.

The resulting configuration is written into the bit timing register (DCAN_BTR):

[14:12] TSEG2 = Phase_Seg2 - 1

[11:8] TSEG1 = Phase_Seg1+ Prop_Seg - 1

[7:6] SJW = SynchronizationJumpWidth - 1

[5:0] BRP = Prescaler - 1

24.10.4.9.2.2 Example for Bit Timing Calculation

In this example, the frequency of FCLK is 20 MHz, BRP is 2, the bit rate is 500 KBit/s.

Table 24-1113. Example For Bit Timing

Parameter	Formula	Value	t_q
bit time (500 KBit/s)	1/bit rate, consists of $t_{Sync\text{-}Seg} + t_{TSeg1} + t_{TSeg2}$	2000 ns	20
delay of bus driver		280 ns	-
delay of receiver circuit		29 ns	-
delay of bus line (16 m)	16 × 5.5 ns/m	88 ns	-
t_q	BRP/FCLK	100 ns	1
t_{Sync_Seg}	1 × t_q (fixed)	100 ns	1
t_{Prop_Seg}	INT (2×delays + 1) = 8 × t_q	800 ns	8
t_{Seg1}	$t_{Prop_Seg} + t_{Phase_Seg1}$	1400 ns	14

Copyright © 2015–2017, Texas Instruments Incorporated

Table 24-1113. Example For Bit Timing (continued)

Parameter	Formula	Value	t_q
t_{Seg2}	bit time - ($_{Sync_Seg}$ + t_{Seg1})	500 ns	5
t_{SJWmax}	MIN (4 × t_q, t_{Phase_Seg1})	400 ns	4

In this example, the bit timing register DCAN_BTR is programmed to:

- BRP = 2 - 1 = 1
- BRPE = 0
- TSEG1 = 14 - 1 = 13 (0xC)
- TSEG2 = 5 - 1 = 4
- SJW = 4 - 1 = 3

24.10.4.10 Message Interface Register Sets

The interface register sets control the software read and write accesses to the message RAM. There are two interface registers sets for read/write access, IF1 and IF2 and one interface register set for read access only, IF3.

Due to the structure of the message RAM, it is not possible to change single bits or bytes of a message object. Instead, always a complete message object in the message RAM is accessed. Therefore the data transfer from the IF1/IF2 registers to the message RAM requires the message handler to perform a read-modify-write cycle: First those parts of the message object that are not to be changed are read from the message RAM into the interface register set, and after the update the whole content of the interface register set is written into the message object.

After the partial write of a message object, those parts of the interface register set that are not selected in DCAN_IF1CMD/DCAN_IF2CMD, will be set to the actual contents of the selected message object.

After the partial read of a message object, those parts of the interface register set that are not selected in DCAN_IF1CMD/DCAN_IF2CMD, will be left unchanged.

By buffering the data to be transferred, the interface register sets avoid conflicts between concurrent software accesses to the message RAM and CAN message reception and transmission. A complete message object (see Section 24.10.4.11.1, *Structure of Message Objects*) or parts of the message object may be transferred between the message RAM and the IF1/IF2 register set (see Section 24.10.5, *DCAN Register Manual*) in one single transfer. This transfer, performed in parallel on all selected parts of the message object, guarantees the data consistency of the CAN message.

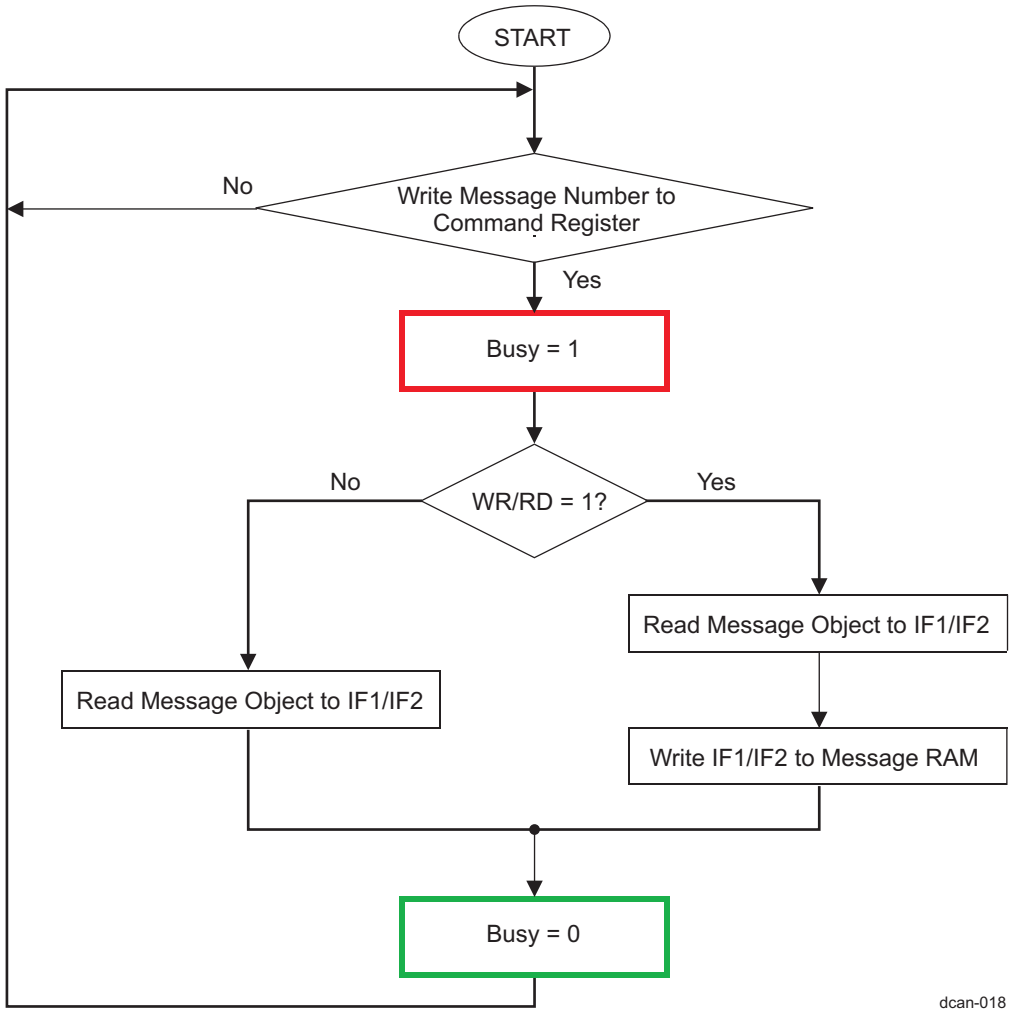
24.10.4.10.1 Message Interface Register Sets 1 and 2

The IF1 and IF2 register sets control the data transfer to and from the message object. DCAN_IF1CMD/DCAN_IF2CMD address the desired message object in the message RAM and specifies whether a complete message object or only parts should be transferred. The data transfer is initiated by writing the message number to the bits [7:0] MESSAGE_NUMBER.

When the software initiates a data transfer between the IF1/IF2 registers and message RAM, the message handler sets the [15] BUSY bit in respective DCAN_IF1CMD/DCAN_IF2CMD to 1. After the transfer has completed, the BUSY bit is set back to 0 (see Figure 24-180).

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 24-180. Data Transfer Between IF1/IF2 Registers and Message RAM



24.10.4.10.2 IF3 Register Set

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from message RAM by software. The intention of this feature of IF3 is to provide an interface for the DMA to read packets efficiently. The automatic update functionality can be programmed for each message object (DCAN_IF3UPD12 to DCAN_IF3UPD78).

All valid message objects in message RAM which are configured for automatic update, will be checked for active NewDat flags. If such a message object is found, it will be transferred to the IF3 register (if no previous DMA transfers are ongoing), controlled by IF3 Observation register (DCAN_IF3OBS). If more than one NewDat flag is active, the message object with the lowest number has the highest priority for automatic IF3 update.

The NewDat bit in the message object will be reset by a transfer to IF3.

If DCAN internal IF3 update is complete, a DMA request is generated. The DMA request stays active until first read access to one of the IF3 registers. The DMA functionality has to be enabled by setting bit DCAN_CTL[20] DE3 = 1.

NOTE: The IF3 register set cannot be used for transferring data into message objects.

Copyright © 2015–2017, Texas Instruments Incorporated

24.10.4.11 Message RAM

The DCAN message RAM contains message objects and parity bits for the message objects. There are up to 64 message objects in the message RAM.

During normal operation, accesses to the message RAM are performed via the interface register sets, and the software cannot directly access the message RAM.

The interface register sets IF1 and IF2 provide indirect read/write access from the software to the message RAM. The IF1 and IF2 register sets can buffer control and user data to be transferred to and from the message objects.

The third interface register set IF3 can be configured to automatically receive control and user data from the message RAM when a message object has been updated after reception of a CAN message. The software does not need to initiate the transfer from message RAM to IF3 register set.

The message handler avoids potential conflicts between concurrent accesses to message RAM and CAN frame reception/transmission.

There are two modes where the message RAM can be directly accessed by the software:

- Debug/Suspend mode (see Section 24.10.4.11.3, *Message RAM Representation in Debug/Suspend Mode*)
- RAM Direct Access (RDA) mode (see Section 24.10.4.11.4, *Message RAM Representation in Direct Access Mode*)

CAUTION

Writes to the DCAN RAM must not be done while it is in low-power mode. If such writes occur, the behavior is undefined and RAM content is corrupted. It has to be ensured in software that the low-power mode is removed from the DCAN RAM before writing to it.

24.10.4.11.1 Structure of Message Objects

Table 24-1114 shows the structure of a message object.

The highlighted fields are those parts of the message object which are represented in dedicated registers. For example, the transmit request flags of all message objects are represented in centralized transmit request registers.

Table 24-1114. Structure of a Message Object

UMask	Msk[28:0]	MXtd	MDir	EoB	unused	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
MsgVal	ID[28:0]	Xtd	Dir	DLC[3:0]	Data 0	Data 1	Data 2	Data 3	Data 4	Data 5	Data 6	Data 7

Table 24-1115. Message Object Field Descriptions

Field Name	Value	Description
MsgVal		Message valid
	0	The message object is ignored by the message handler.
	1	The message object is to be used by the message handler.
		Note: This bit may be kept at level '1' even when the identifier bits ID[28:0], the control bits Xtd, Dir, or the data length code are changed. It should be reset if the Messages Object is no longer required. The software must reset the MsgVal bit of all unused Messages Objects during the initialization before it resets the INIT bit in the DCAN_CTL register.

Copyright © 2015–2017, Texas Instruments Incorporated

Table 24-1115. Message Object Field Descriptions (continued)

Field Name	Value	Description
UMask		Use acceptance mask
	0	Mask bits (Msk[28:0], MXtd and MDir) are ignored and not used for acceptance filtering.
	1	Mask bits are used for acceptance filtering.
		Note: If the UMask bit is set to one, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to one.
ID[28:0]		Message identifier
	ID[28:0]	29-bit ("extended") identifier bits
	ID[28:18]	11-bit ("standard") identifier bits
Msk[28:0]		Identifier mask
	0	The corresponding bit in the message identifier is not used for acceptance filtering (don't care).
	1	The corresponding bit in the message identifier is used for acceptance filtering.
Xtd		Mask extended identifier
	0	The extended identifier bit (IDE) has no effect on the acceptance filtering.
	1	The extended identifier bit (IDE) is used for acceptance filtering.
		Note: When 11-bit ("standard") Identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered.
Dir		Message direction
	0	Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, the message is stored in this message object.
	1	Direction = transmit: On TxRqst, a data frame is transmitted. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = one).
MDir		Mask message direction
	0	The message direction bit (Dir) has no effect on the acceptance filtering.
	1	The message direction bit (Dir) is used for acceptance filtering.
EOB		End of block
	0	The message object is part of a FIFO Buffer block and is not the last message object of this FIFO Buffer block.
	1	The message object is a single message object or the last message object in a FIFO Buffer Block.
		Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one.
NewDat		New data
	0	No new data has been written into the data bytes of this message object by the message handler since the last time when this flag was cleared by the software.
	1	The message handler or the software has written new data into the data bytes of this message object.
MsgLst		Message lost (only valid for message objects with direction = receive)
	0	No message was lost since the last time when this bit was reset by the software.
	1	The message handler stored a new message into this message object when NewDat was still set, so the previous message has been overwritten.
RxIE		Receive interrupt enable
	0	IntPnd will not be triggered after the successful reception of a frame.
	1	IntPnd will be triggered after the successful reception of a frame.
TxIE		Transmit interrupt enable
	0	IntPnd will not be triggered after the successful transmission of a frame.
	1	IntPnd will be triggered after the successful transmission of a frame.
IntPnd		Interrupt pending
	0	This message object is not the source of an interrupt.
	1	This message object is the source of an interrupt. The interrupt Identifier in the interrupt register (DCAN_INT) will point to this message object if there is no other interrupt source with higher priority.

Copyright © 2015–2017, Texas Instruments Incorporated

Table 24-1115. Message Object Field Descriptions (continued)

Field Name	Value	Description
RmtEn		Remote enable
	0	At the reception of a remote frame, TxRqst is not changed.
	1	At the reception of a remote frame, TxRqst is set.
TxRqst		Transmit request
	0	This message object is not waiting for a transmission.
	1	The transmission of this message object is requested and is not yet done.
DLC[3:0]		Data length code
	0 - 8	Data frame has 0 - 8 data bytes.
	9 - 15	Data frame has 8 data bytes.
		Note: The data length code of a message object must be defined to the same value as in the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.
Data 0		1st data byte of a CAN data frame
Data 1		2nd data byte of a CAN data frame
Data 2		3rd data byte of a CAN data frame
Data 3		4th data byte of a CAN data frame
Data 4		5th data byte of a CAN data frame
Data 5		6th data byte of a CAN data frame
Data 6		7th data byte of a CAN data frame
Data 7		8th data byte of a CAN data frame
		Note: Byte Data 0 is the first data byte shifted into the shift register of the CAN core during a reception, byte Data 7 is the last. When the message handler stores a data frame, it will write all the eight data bytes into a message object. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by undefined values.

24.10.4.11.2 Addressing Message Objects in RAM

The starting location of a particular message object in RAM is:
Message RAM base address + (message object number) × 0x20

That is, message object 1 starts at offset 0x0020; message object 2 starts at offset 0x0040, etc.

NOTE: Because 0 is not a valid message object number, at offset 0x0000 is not located message object 0, but the last implemented: 64.

The base address for DCAN1 RAM is 0x4AE3 D000 and DCAN2 RAM is 0x4848 1000.

Message object number 1 has the highest priority.

Table 24-1116. Message RAM Addressing in Debug/Suspend and RDA Modes

Message Object Number	Offset	Word Number	Debug/Suspend Mode, see Section 24.10.4.11.3	RDA Mode, see Section 24.10.4.11.4
64 (last implemented)	0x0000	1	Parity	Data Bytes 4-7
	0x0004	2	MXtd,MDir,Mask	Data Bytes 0-3
	0x0008	3	Xtd,Dir,ID	ID[27:0],DLC

	0x07F4	6	Data Bytes 7-4	-

24.10.4.11.3 Message RAM Representation in Debug/Suspend Mode

In debug/suspend mode, the message RAM will be memory mapped. This allows the external debug unit to access the message RAM.

NOTE: During debug/suspend mode, the message RAM cannot be accessed via the IFx register sets.

24.10.4.11.4 Message RAM Representation in Direct Access Mode

When the DCAN_TEST[9] RDA bit is set while the DCAN module is in test mode (DCAN_CTL[7] TEST = 1), the software has direct access to the message RAM. Due to the 32-bit bus structure, the RAM is split into word lines to support this feature. The software has access to one word line at a time only.

In RAM direct access mode, the RAM is represented by a continuous memory space within the address frame of the DCAN module, starting at the message RAM base address.

Note: During direct access mode, the message RAM cannot be accessed via the IFx register sets.

Any read or write to the RAM addresses for RAM Direct Access during normal operation mode (TEST bit or RDA bit not set) will be ignored.

24.10.4.12 CAN Operation

After device reset, the DCAN_CTL[0] INIT is set and all CAN protocol functions are disabled. The CAN module must be initialized before operating it. Figure 24-181 illustrates the basic initialization flow for the CAN module.

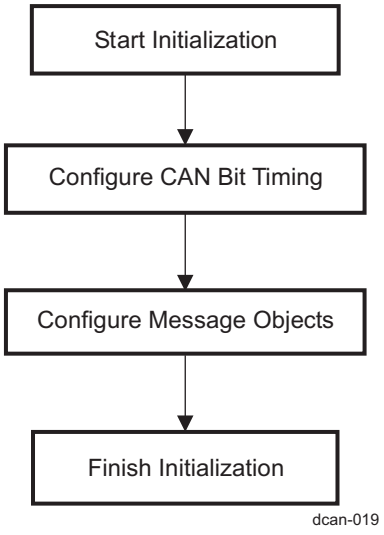
24.10.4.12.1 CAN Module Initialization

A general CAN module initialization would mean the following two critical steps:

- Configuration of the CAN bit timing
- Configuration of message objects

To initialize the CAN controller, the software has to set up the CAN bit timing and those message objects that have to be used for CAN communication. Message objects that are not needed, can be deactivated.

Figure 24-181. CAN Module General Initialization Flow



Copyright © 2015–2017, Texas Instruments Incorporated

24.10.4.12.1.1 Configuration of CAN Bit Timing

The CAN module must be in initialization mode to configure the CAN bit timing.

For CAN bit timing software configuration flow, see Figure 24-182, *CAN Bit-Timing Configuration*.

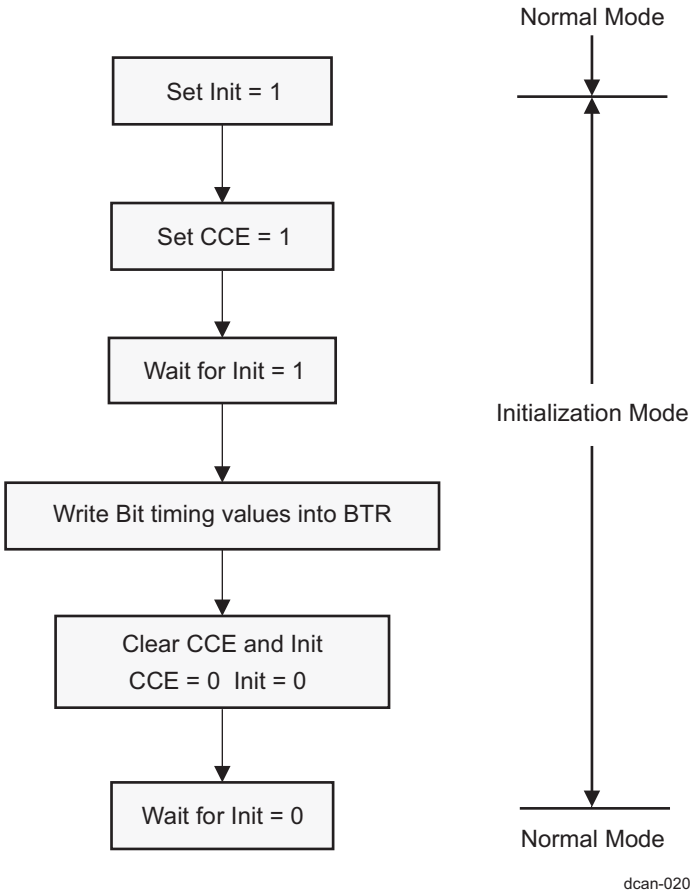
Step 1: Enter *initialization mode* (DCAN_CTL[0] INIT = 1).

While the INIT bit is set, the message transfer from and to the CAN bus is stopped, and the status of the CAN_TX output is recessive (high).

The CAN error counters are not updated. Setting the INIT bit does not change any other configuration register.

Also, note that the CAN module is in initialization mode on device reset and during Bus-Off.

Figure 24-182. CAN Bit-Timing Configuration



Step 2: Set the Configure Change Enable bit (DCAN_CTL[6] CCE = 1).

The access to the Bit Timing register (DCAN_BTR) for the configuration of the bit timing is enabled when both INIT = 1 and CCE = 1.

Step 3: Wait for the INIT bit to get set (=1). This would make sure that the module has entered Initialization mode.

Step 4: Write the bit timing values into DCAN_BTR. See Section 24.10.4.9.2, *DCAN Bit Timing Registers* for the values calculation for a given bit timing.

Step 5: Clear the CCE and INIT bits (=0).

Step 6: Wait for the INIT bit to clear (=0). This would ensure that the module has come out of Initialization mode.

Copyright © 2015–2017, Texas Instruments Incorporated

Following these steps, the module comes to operation by synchronizing itself to the CAN bus, provided the DCAN_BTR is configured as per the CAN bus baud rate, although the message objects have to be configured before carrying out any communication.

NOTE: The module will not come out of the Initialization mode if any incorrect DCAN_BTR values are written in step 4.

NOTE: The required message objects should be configured as transmit or receive objects before the start of data transfer as explained in Section 24.10.4.12.1, *CAN Module Initialization*.

24.10.4.12.1.2 Configuration of Message Objects

The message objects can be configured only through the interface registers; the software does not have direct access to the message object (message RAM) . Familiarize yourself with the interface register set (IFx) usage (see Section 24.10.4.10, *Message Interface Register Sets*) and the message object structure (see Section 24.10.4.11, *Message RAM*) before configuring the message objects.

For more information regarding the procedure to configure the message objects, see Section 24.10.4.7, *Configuration of Message Objects Description*. All the message objects should be configured to particular identifiers or set to not valid before the message transfer is started. It is possible to change the configuration of message objects during normal operation (that is between data transfers).

NOTE: The message objects initialization is independent of the bit-timing configuration.

24.10.4.12.1.3 DCAN RAM Hardware Initialization

The memory hardware initialization for the DCAN module is enabled in the device control module. Setting RAMINIT_START to 1, causes RAM initialization with zeros and sets parity bits accordingly. Software must wait for the RAMINIT_DONE bit to be set to ensure successful RAM initialization.

For more details on CTRL_CORE_CONTROL_IO_2 register, see Section 18.5, *Control Module Register Manual*.

24.10.4.12.2 CAN Message Transfer (Normal Operation)

Once the DCAN is initialized and DCAN_CTL[0] INIT bit is reset (=0), the CAN core synchronizes itself to the CAN bus and is ready for message transfer as per the configured message objects.

The software may enable the interrupt lines (DCAN_CTL[1] IE0 and [17] IE1 = 1) at the same time when it clears [0] INIT and [6] CCE = 0. The status interrupts [3] EIE and [2] SIE may be enabled (=1) simultaneously.

The CAN communication can be carried out in any of the following two modes: interrupt and polling.

The DCAN_INT register points to those message objects with IntPnd = 1. It is updated even if the interrupt lines to the host processor are disabled (DCAN_CTL[1] IE0 and [17] IE1 = 0).

The software may poll all MessageObject's NewDat and TxRqst bits in parallel from the DCAN_NWDAT_X and the DCAN_TXRQ_X registers respectively. Polling can be made easier if all transmit objects are grouped at the low numbers and all receive objects are grouped at the high numbers.

Received messages are stored into their appropriate message objects if they pass acceptance filtering.

The whole message (including all arbitration bits, DLC and up to eight data bytes) is stored into the message object. As a consequence (e.g., when the identifier mask is used), the arbitration bits which are masked to "don't care" may change in the message object when a received message is stored.

The software may read or write each message at any time via the interface registers, as the message handler guarantees data consistency in case of concurrent accesses.

Copyright © 2015–2017, Texas Instruments Incorporated

If a permanent message object (arbitration and control bits set up during configuration and leaving unchanged for multiple CAN transfers) exists for the message, it is possible to only update the data bytes.

If several transmit messages should be assigned to one message object, the whole message object has to be configured before the transmission of this message is requested.

The transmission of multiple message objects may be requested at the same time. They are subsequently transmitted, according to their internal priority.

Messages may be updated or set to not valid at any time, even if a requested transmission is still pending. However, the data bytes will be discarded if a message is updated before a pending transmission has started.

Depending on the configuration of the message object, a transmission may be automatically requested by the reception of a remote frame with a matching identifier.

24.10.4.12.2.1 Automatic Retransmission

According to the CAN Specification (ISO11898), the DCAN provides a mechanism to automatically retransmit frames which have lost arbitration or have been disturbed by errors during transmission. The frame transmission service will not be confirmed to the user before the transmission is successfully completed.

By default, this automatic retransmission is enabled. It can be disabled by setting bit disable automatic retransmission (DCAN_CTL[5] DAR = 1). Further details to this mode are provided in Section 24.10.4.8.3, *Transmission of Messages in Event Driven CAN Communication*.

24.10.4.12.2.2 Auto-Bus-On

By default, after the DCAN has entered Bus-Off state, the software can start a Bus-Off-Recovery sequence by resetting the DCAN_CTL[0] INIT bit to 0. If this is not done, the module will stay in Bus-Off state.

The DCAN provides an automatic Auto-Bus-On feature which is enabled by bit DCAN_CTL[9] ABO. If set, the DCAN will automatically start the Bus-Off-Recovery sequence. The sequence can be delayed by a user-defined number of interface clock cycles which can be defined in the Auto-Bus-On Time register (DCAN_ABOTR).

NOTE: If the DCAN goes to Bus-Off state due to a massive occurrence of CAN bus errors, it stops all bus activities and automatically sets the INIT bit. Once the INIT bit has been reset by the software or due to the Auto-Bus-On feature, the device will wait for 129 occurrences of bus Idle (equal to 129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus-Off recovery sequence, the error counters will be reset.

24.10.4.12.3 Test Modes

The DCAN module provides several test modes which are mainly intended for production tests or self test.

For all test modes, the DCAN_CTL[7] TEST bit needs to be set to 1. This enables write access to the test register (DCAN_TEST).

NOTE: It must be ensured by software that all message transfers are completed before entering test mode.

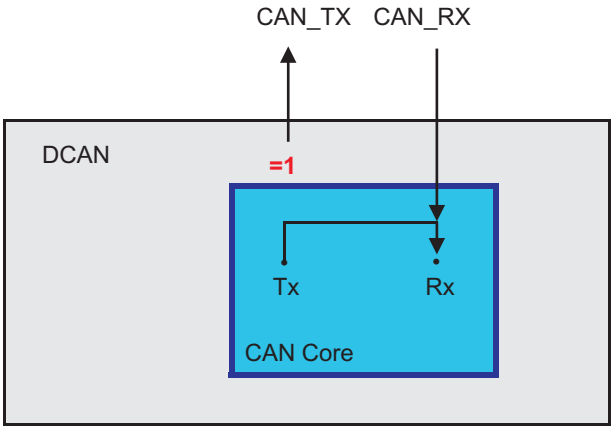
24.10.4.12.3.1 Silent Mode

The silent mode may be used to analyze the traffic on the CAN bus without affecting it by sending dominant bits (e.g., acknowledge bit, overload flag, active error flag). The DCAN is still able to receive valid data frames and valid remote frames, but it will not send any dominant bits. However, these are internally routed to the CAN core.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 24-183 shows the connection of signals CAN_TX and CAN_RX to the CAN core in silent mode. Silent mode can be activated by setting the DCAN_TEST[3] SILENT bit to 1. In ISO 11898-1, the silent mode is called the bus monitoring mode.

Figure 24-183. CAN Core in Silent Mode



24.10.4.12.3.2 Loopback Mode

The loopback mode is mainly intended for hardware self-test functions. In this mode, the CAN core uses internal feedback from Tx output to Rx input. Transmitted messages are treated as received messages, and can be stored into message objects if they pass acceptance filtering. The actual value of the CAN_RX input pin is disregarded by the CAN core. Transmitted messages can still be monitored at the CAN_TX pin.

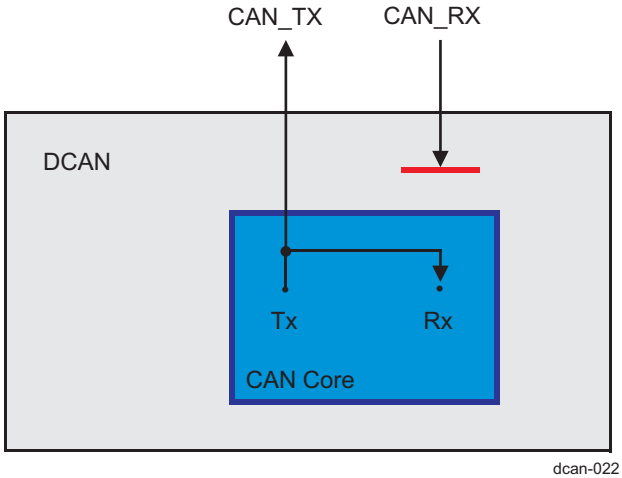
In order to be independent from external stimulation, the CAN core ignores acknowledge sampled in the acknowledge slot of a data/remote frame.

Figure 24-184 shows the connection of signals CAN_TX and CAN_RX to the CAN core in loopback mode.

Loopback mode can be activated by setting bit DCAN_TEST[4] LBACK to 1.

NOTE: In loopback mode, the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN core are disregarded. For including these into the testing, see Section 24.10.4.12.3.3, *External Loopback Mode*.

Figure 24-184. CAN Core in Loopback Mode



Copyright © 2015–2017, Texas Instruments Incorporated

24.10.4.12.3.3 External Loopback Mode

The external loopback mode is similar to the loopback mode; however, it includes the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN core. When external loopback mode is selected, the input of the CAN core is connected to the input buffer of the Tx pin.

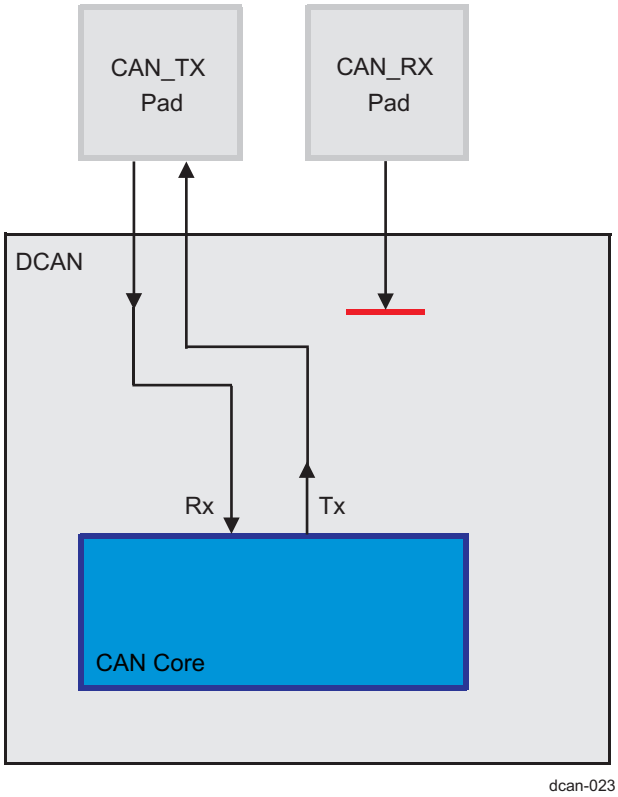
With this configuration, the Tx pin IO circuit can be tested.

External loopback mode can be activated by setting bit DCAN_TEST[8] EXL to 1.

Figure 24-185 shows the connection of signals CAN_TX and CAN_RX to the CAN core in external loopback mode.

NOTE: When loopback mode is active (LBACK bit set), the EXL bit will be ignored.

Figure 24-185. CAN Core in External Loopback Mode



24.10.4.12.3.4 Loopback Mode Combined With Silent Mode

It is also possible to combine loopback mode and silent mode by setting bits DCAN_TEST[4] LBACK and [3] SILENT at the same time. This mode can be used for a "Hot Selftest", that is, the DCAN hardware can be tested without affecting the CAN network. In this mode, the CAN_RX pin is disconnected from the CAN core and no dominant bits will be sent on the CAN_TX pin.

Figure 24-186 shows the connection of the signals CAN_TX and CAN_RX to the CAN core in case of the combination of loopback mode with silent mode.

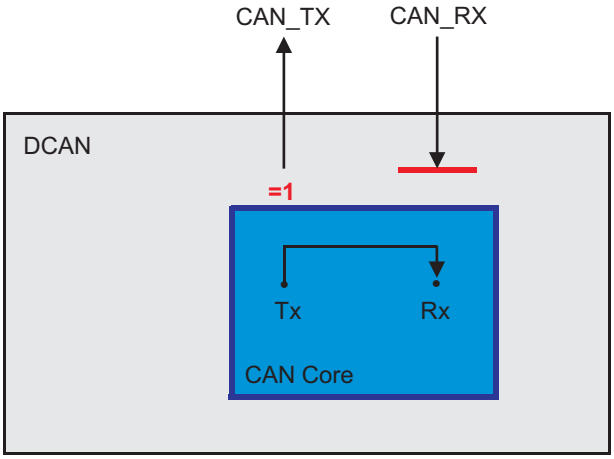
Figure 24-186. CAN Core in Loop Back Combined With Silent Mode



24.10.4.12.3.5 Software Control of CAN_TX Pin

Four output functions are available for the CAN transmit pin CAN_TX. In addition to its default function (serial data output), the CAN_TX pin can drive constant dominant or recessive values, or it can drive the CAN sample point signal to monitor the CAN core's bit timing.

Combined with the readable value of the CAN_RX pin, this function can be used to check the physical layer of the CAN bus.

The output mode of pin CAN_TX is selected by programming the DCAN_TEST[6:5] TX:

- 0x0: Normal operation, CAN_TX is controlled by the DCAN core
- 0x1: Sample point can be monitored at CAN_TX pin
- 0x2: CAN_TX pin drives a dominant value
- 0x3: CAN_TX pin drives a recessive value.

NOTE: The software control for the CAN_TX pin interferes with CAN protocol functions. For CAN message transfer or any of the test modes (loopback mode, external loopback mode or silent mode), the CAN_TX pin should operate in its default functionality.

24.10.4.13 GPIO Support

The CAN_RX and CAN_TX pins of the DCAN module can be used as general purpose IO pins, if CAN functionality is not needed. This function is controlled by the CAN TX IO control register (DCAN_TIOC) and the CAN RX IO control register (DCAN_RIOC).

24.10.5.1 DCAN Instance Summary

Table 24-1119. DCAN Instance Summary

Module Name	Base Address	Size
DCAN1	0x4AE3 C000	8 KiB
DCAN2	0x4848 0000	8 KiB

24.10.5.2 DCAN Registers

NOTE: After device reset, the registers of the DCAN hold the values shown in the register descriptions.

Additionally, the Bus-Off state is reset and the CAN_TX pin is set to recessive (HIGH). The INIT bit in the DCAN_CTL is set to enable the software initialization. The DCAN will not influence the CAN bus until the software resets INIT to 0.

Table 24-1121. DCAN_CTL

Address Offset	0x0000 0000		
Physical Address	0x4AE3 C000 0x4848 0000	**Instance**	DCAN1 DCAN2
Description	DCAN control register **NOTE**: The Bus-Off recovery sequence (refer to CAN specification) cannot be shortened by setting or resetting INIT bit. If the module goes Bus-Off, it will automatically set the INIT bit and stop all bus activities. When the INIT bit is cleared by the application again, the module will then wait for 129 occurrences of Bus Idle (129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the bus-off recovery sequence, the error counters will be reset. After the INIT bit is reset, each time when a sequence of 11 recessive bits is monitored, a Bit0 error code is written to DCAN_ES, enabling the software to check whether the CAN bus is stuck at dominant or continuously disturbed, and to monitor the proceeding of the bus-off recovery sequence.		
Type	RW

Bits	Field Name	Description	Type	Reset
31:26	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x00
25	WUBA	Automatic wake up on bus activity when in local power-down mode. Note: The CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power down and automatic wake-up mode, will be lost. 0: No detection of a dominant CAN bus level while in local power-down mode. 1: Detection of a dominant CAN bus level while in local power-down mode is enabled. On occurrence of a dominant CAN bus level, the wake up sequence is started (Additional information can be found in *Local Power-Down Mode*).	RW	0
24	PDR	Request for local low power-down mode 0: No application request for local low power-down mode. If the application has cleared this bit while DCAN in local power-down mode, also the INIT bit has to be cleared. 1: Local power-down mode has been requested by application. The DCAN will acknowledge the local power-down mode by setting bit PDA in the DCAN_ES register. The local clocks will be turned off by DCAN internal logic (Additional information can be found in *Local Power-Down Mode*).	RW	0
23:21	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x0
20	DE3	Enable DMA request line for IF3. Note: A pending DMA request for IF3 remains active until first access to one of the IF3 registers. 0: Disabled 1: Enabled	RW	0
19	DE2	Enable DMA request line for IF2. Note: A pending DMA request for IF2 remains active until first access to one of the IF2 registers. 0: Disabled 1: Enabled	RW	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
18	DE1	Enable DMA request line for IF1. Note: A pending DMA request for IF1 remains active until first access to one of the IF1 registers. 0: Disabled 1: Enabled	RW	0
17	IE1	Interrupt line 1 enable 0: Disabled - Module interrupt INT1 is always low. 1: Enabled - interrupts will assert line INT1 to one; line remains active until pending interrupts are processed.	RW	0
16	INITDBG	Internal init state while debug access 0: Not in debug mode, or debug mode requested but not entered. 1: Debug mode requested and internally entered; the DCAN is ready for debug accesses.	RW	0
15	SWR	Software reset enable. Note: To execute software reset, the following procedure is necessary: 1. Set INIT bit to shut down CAN communication. 2. Set SWR (this) bit additionally to INIT bit. 0: Normal Operation 1: Module is forced to reset state. This bit will automatically get cleared after execution of software reset after one OCP clock cycle.	RW	0
14	RESERVED	This bit is always read as 0. Writes have no effect.	R	0
13:10	PMD	Parityon/off 0x5: function disabled Others: function enabled	RW	0x5
9	ABO	Auto-Bus-On enable 0: The Auto-Bus-On feature is disabled 1: The Auto-Bus-On feature is enabled	RW	0
8	IDS	Interruption debug support enable 0: When Debug/Suspend mode is requested, DCAN will wait for a started transmission or reception to be completed before entering Debug/Suspend mode 1: When Debug/Suspend mode is requested, DCAN will interrupt any transmission or reception, and enter Debug/Suspend mode immediately.	RW	0
7	TEST	Test mode enable 0: Normal Operation 1: Test Mode	RW	0
6	CCE	Configuration change enable 0: The software has no write access to the configuration registers. 1: The software has write access to the configuration registers (when INIT bit is set).	RW	0
5	DAR	Disable automatic retransmission 0: Automatic retransmission of not successful messages enabled. 1: Automatic retransmission disabled.	RW	0
4	RESERVED	This bit is always read as 0. Writes have no effect.	R	0
3	EIE	Error interrupt enable 0: Disabled - PER, BOFF and EWARN bits can not generate an interrupt. 1: Enabled - PER, BOFF and EWARN bits can generate an interrupt at INT0 line and affect the interrupt register.	RW	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
2	SIE	Status change interrupt enable 0: Disabled - WAKEUPPND, RXOK, TXOK and LEC bits can not generate an interrupt. 1: Enabled - WAKEUPPND, RXOK, TXOK and LEC can generate an interrupt at INT0 line and affect the interrupt register.	RW	0
1	IE0	Interrupt line 0 enable 0: Disabled - Module interrupt INT0 is always low. 1: Enabled - interrupts will assert line INT0 to one; line remains active until pending interrupts are processed.	RW	0
0	INIT	Initialization 0: Normal operation 1: Initialization mode is entered	RW	1

Table 24-1123. DCAN_ES

Address Offset	0x0000 0004		
Physical Address	0x4AE3 C004 0x4848 0004	**Instance**	DCAN1 DCAN2
Description	Error and Status Register Interrupts are generated by bits PER, BOFF and EWARN (if EIE bit in DCAN_CTL is 1) and by bits WAKEUPPND, RXOK, TXOK, and LEC (if SIE bit in DCAN_CTL is 1). A change of bit EPASS will not generate an interrupt. Reading the DCAN_ES clears the WAKEUPPND, PER, RXOK and TXOK bits and set the LEC to value '7.' Additionally, the status interrupt value (0x8000) in the DCAN_INT will be replaced by the next lower priority interrupt value. For debug support, the auto clear functionality of DCAN_ES (clear of status flags by read) is disabled when in debug/suspend mode.

Bits	Field Name	Description	Type	Reset
31:11	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x00 0000
10	PDA	Local power-down mode acknowledge 0: DCAN is not in local power-down mode. 1: Application request for setting DCAN to local power-down mode was successful. DCAN is in local power-down mode.	R	0
9	WAKEUPPND	Wake up pending. This bit can be used by the software to identify the DCAN as the source to wake up the system. This bit will be reset if DCAN_ES is read. 0: No Wake Up is requested by DCAN. 1: DCAN has initiated a wake up of the system due to dominant CAN bus while module power down.	R	0
8	PER	Parity error detected. This bit will be reset if DCAN_ES register is read. Read 0: No parity error has been detected since last read access. Read 1: The parity check mechanism has detected a parity error in the Message RAM. Write 0: No effect Write 1: End of interrupt (EOI) for parity error on DCAN_PARITY interrupt line	RW	0
7	BOFF	Bus-Off state 0: The CAN module is not bus-off state. 1: The CAN module is in bus-off state.	R	0
6	EWARN	Warning state 0: Both error counters are below the error warning limit of 96. 1: At least one of the error counters has reached the error warning limit of 96.	R	0
5	EPASS	Error passive state 0: On CAN Bus error, the DCAN could send active error frames. 1: The CAN core is in the error passive state as defined in the CAN Specification.	R	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
4	RXOK	Received a message successfully. This bit will be reset if DCAN_ES register is read. 0: No message has been successfully received since the last time when this bit was read by the software. This bit is never reset by DCAN internal events. 1: A message has been successfully received since the last time when this bit was reset by a read access of the software (independent of the result of acceptance filtering).	R	0
3	TXOK	Transmitted a message successfully. This bit will be reset if DCAN_ES register is read. 0: No message has been successfully transmitted since the last time when this bit was read by the software. This bit is never reset by DCAN internal events. 1: A message has been successfully transmitted (error free and acknowledged by at least one other node) since the last time when this bit was reset by a read access of the software.	R	0
2:0	LEC	Last error code. The LEC field indicates the type of the last error on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. 0x0: No error 0x1: Stuff error: More than five equal bits in a row have been detected in a part of a received message where this is not allowed. 0x2: Form error: A fixed format part of a received frame has the wrong format. 0x3: Ack error: The message this CAN core transmitted was not acknowledged by another node. 0x4: Bit1 error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant. 0x5: Bit0 error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (logical value '0'), but the monitored bus level was recessive. During Bus-Off recovery, this status is set each time a sequence of 11 recessive bits has been monitored. This enables the software to monitor the proceeding of the Bus-Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 0x6: CRC error: In a received message, the CRC check sum was incorrect. (CRC received for an incoming message does not match the calculated CRC for the received data). 0x7: No CAN bus event was detected since the last time the software read DCAN_ES. Any read access to DCAN_ES re-initializes the LEC to value '7.'	R	0x7

Table 24-1133. DCAN_PERR

Address Offset	0x0000 001C		
Physical Address	0x4AE3 C01C 0x4848 001C	**Instance**	DCAN1 DCAN2
Description	Parity Error Code Register If a parity error is detected, the PER flag will be set in the DCAN_ES. This bit is not reset by the parity check mechanism; it must be reset by reading DCAN_ES. In addition to the PER flag, the parity error code register will indicate the memory area where the parity error has been detected (message number and word number). If more than one word with a parity error was detected, the highest word number with a parity error will be displayed. After a parity error has been detected, the register will hold the last error code until power is removed.

Address Offset	0x0000 00E4		
Physical Address	0x4AE3 C0E4 0x4848 00E4	**Instance**	DCAN1 DCAN2
Description	Interrupt Multiplexer Register The IntMux flag determine for each message object, which of the two interrupt lines (INT0 or INT1) will be asserted when the IntPnd of this message object is set. Both interrupt lines can be globally enabled or disabled by setting or clearing IE0 and IE1 bits in CAN control register. The IntPnd bit of a specific message object can be set or reset by the software via the IF1/IF2 interface register sets, or by message handler after reception or successful transmission of a frame. This will also affect the INT0ID resp INT1ID flags in the DCAN_INT register.

Table 24-1187. DCAN_IF1CMD

Address Offset	0x0000 0100		
Physical Address	0x4AE3 C100 0x4848 0100	**Instance**	DCAN1 DCAN2
Description	IF1 Command Register The IF1 Command Register (DCAN_IF1CMD) configure and initiate the transfer between the IF1 register set and the message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the software writes the message number to bits [7:0] MESSAGE_NUMBER. With this write operation, the BUSY bit is automatically set to 1 to indicate that a transfer is in progress. After 4 to 14 OCP clock cycles, the transfer between the interface register and the message RAM will be completed and the BUSY bit is cleared. The maximum number of cycles is needed when the message transfer concurs with a CAN message transmission, acceptance filtering, or message storage. If the software writes to both DCAN_IF1CMD/DCAN_IF2CMD consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed. While BUSY bit is one, IF1/IF2 register sets are write protected. For debug support, the auto clear functionality of the IF1/IF2 command registers (clear of DMAACTIVE flag by r/w) is disabled during Debug/Suspend mode. If an invalid Message Number is written to bits [7:0] MESSAGE_NUMBER, the message handler may access an implemented (valid) message object instead.

Address Offset	0x0000 0108		
Physical Address	0x4AE3 C108 0x4848 0108	**Instance**	DCAN1 DCAN2
Description	IF1 arbitration register The Arbitration bits ID[28:0], XTD, and DIR are used to define the identifier and type of outgoing messages and (together with the mask bits MSK[28:0], MXTD, and MDIR) for acceptance filtering of incoming messages. A received message is stored into the valid message object with matching identifier and Direction = receive (data frame) or Direction = transmit (remote frame). Extended frames can be stored only in message objects with XTD = 1, standard frames in message objects with XTD = 0. If a received message (data frame or remote frame) matches more than one valid message objects, it is stored into the one with the lowest message number. The bits of the IF1/IF2 arbitration registers mirror the arbitration bits of a message object. The function of the relevant message objects bits is described in Section 24.10.4.11.1 *Structure of Message Objects* While BUSY bit of DCAN_IF1CMD/DCAN_IF2CMD register is one, IF1/IF2 register set is write protected.

Table 24-1201. DCAN_IF2MSK

Address Offset	0x0000 0124		
Physical Address	0x4AE3 C124 0x4848 0124	**Instance**	DCAN1 DCAN2
Description	IF2 Mask Register The bits of the IF1/IF2 mask registers mirror the mask bits of a message object. The function of the relevant message objects bits is described in Section 24.10.4.11.1 *Structure of Message Objects*. While BUSY bit of DCAN_IF1CMD/DCAN_IF2CMD register is one, IF1/IF2 register set is write protected.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MXTD	MDIR	RESERVED	MSK																												

Bits	Field Name	Description	Type	Reset
31	MXTD	Mask Extended Identifier 0: The extended identifier bit (IDE) has no effect on the acceptance filtering. 1: The extended identifier bit (IDE) is used for acceptance filtering. When 11-bit (“standard”) identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered.	RW	1
30	MDIR	Mask Message Direction 0: The message direction bit (Dir) has no effect on the acceptance filtering. 1: The message direction bit (Dir) is used for acceptance filtering.	RW	1
29	RESERVED	This bit is always read as 1. Writes have no effect.	R	1
28:0	MSK	Identifier Mask 0: The corresponding bit in the identifier of the message object is not used for acceptance filtering (don't care). 1: The corresponding bit in the identifier of the message object is used for acceptance filtering.	RW	0x1FFF FFFF

Table 24-1203. DCAN_IF2ARB

Address Offset	0x0000 0128		
Physical Address	0x4AE3 C128 0x4848 0128	**Instance**	DCAN1 DCAN2
Description	IF2 arbitration register The Arbitration bits ID[28:0], XTD, and DIR are used to define the identifier and type of outgoing messages and (together with the mask bits MSK[28:0], MXTD, and MDIR) for acceptance filtering of incoming messages. A received message is stored into the valid message object with matching identifier and Direction = receive (data frame) or Direction = transmit (remote frame). Extended frames can be stored only in message objects with Xtd = 1, standard frames in message objects with Xtd = 0. If a received message (data frame or remote frame) matches more than one valid message objects, it is stored into the one with the lowest message number. The bits of the IF1/IF2 arbitration registers mirror the arbitration bits of a message object. The function of the relevant message objects bits is described in Section 24.10.4.11.1 *Structure of Message Objects* While BUSY bit of DCAN_IF1CMD/DCAN_IF2CMD register is one, IF1/IF2 register set is write protected.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSGVAL	XTD	DIR	ID																												

Bits	Field Name	Description	Type	Reset
31	MSGVAL	Message valid 0: The message object is ignored by the message handler. 1: The message object is to be used by the message handler. The software should reset the MsgVal bit of all unused Messages Objects during the initialization before it resets bit INIT in the DCAN_CTL. This bit must also be reset if the messages object is no longer required.	RW	0
30	XTD	Extended identifier 0: The 11-bit (“standard”) Identifier is used for this message object. 1: The 29-bit (“extended”) Identifier is used for this message object.	RW	0
29	DIR	Message direction 0: Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, this message is stored in this message object. 1: Direction = transmit: On TxRqst, the respective message object is transmitted as a data frame. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = 1).	RW	0
28:0	ID	Message identifier ID[28:0]: 29-bit identifier (extended frame) ID[28:18]: 11-bit identifier (standard frame)	RW	0x000 0000

Table 24-1205. DCAN_IF2MCTL

Address Offset	0x0000 012C		
Physical Address	0x4AE3 C12C 0x4848 012C	**Instance**	DCAN1 DCAN2
Description	IF2 Message Control Register The bits of the IF1/IF2 message control registers mirror the message control bits of a message object. The function of the relevant message objects bits is described in Section 24.10.4.11.1 *Structure of Message Objects* While BUSY bit of DCAN_IF1CMD/DCAN_IF2CMD register is one, IF1/IF2 register set is write protected.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																NEWDAT	MSGLST	INTPND	UMASK	TXIE	RXIE	RMTEN	TXRQST	EOB	RESERVED			DLC			

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x0000
15	NEWDAT	New data 0: No new data has been written into the data portion of this message object by the message handler since the last time when this flag was cleared by the software. 1: The message handler or the software has written new data into the data portion of this message object.	RW	0
14	MSGLST	Message lost (only valid for message objects with direction = receive) 0: No message lost since the last time when this bit was reset by the software. 1: The message handler stored a new message into this object when NewDat was still set, so the previous message has been overwritten.	RW	0
13	INTPND	Interrupt pending 0: This message object is not the source of an interrupt. 1: This message object is the source of an interrupt. The Interrupt Identifier in DCAN_INT will point to this message object if there is no other interrupt source with higher priority.	RW	0
12	UMASK	Use acceptance mask 0: Mask ignored 1: Use mask (Msk[28:0], MXtd, and MDir) for acceptance filtering If the UMask bit is set to one, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to one.	RW	0
11	TXIE	Transmit interrupt enable 0: IntPnd will not be triggered after the successful transmission of a frame. 1: IntPnd will be triggered after the successful transmission of a frame.	RW	0
10	RXIE	Receive interrupt enable 0: IntPnd will not be triggered after the successful reception of a frame. 1: IntPnd will be triggered after the successful reception of a frame.	RW	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
9	RMTEN	Remote enable 0: At the reception of a remote frame, TxRqst is not changed. 1: At the reception of a remote frame, TxRqst is set.	RW	0
8	TXRQST	Transmit request 0: This message object is not waiting for a transmission. 1: The transmission of this message object is requested and is not yet done.	RW	0
7	EOB	End of Block 0: The message object is part of a FIFO Buffer block and is not the last message object of the FIFO Buffer block. 1: The message object is a single message object or the last message object in a FIFO Buffer Block. Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one.	RW	0
6:4	RESERVED	These bits are always read as 0. Writes have no effect.	R	0x0
3:0	DLC	Data length code 0-8: Data frame has 0-8 data bytes. 9-15 Data frame has 8 data bytes. Note: The data length code of a message object must be defined the same as in all the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.	RW	0x0

Table 24-1211. DCAN_IF3OBS

Address Offset	0x0000 0140		
Physical Address	0x4AE3 C140 0x4848 0140	**Instance**	DCAN1 DCAN2
Description	IF3 Observation Register The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from message RAM by software (Additional information can be found in Section 24.10.4.11.1 *Structure of Message Objects*). The observation flags (Bits [4:0]) are used to determine, which data sections of the IF3 interface register set have to be read in order to complete a DMA read cycle. After all marked data sections are read, the DCAN is enabled to update the IF3 interface register set with new data. Any access order of single bytes or half-words is supported. When using byte or half-word accesses, a data section is marked as completed, if all bytes are read. NOTE: If IF3 Update Enable is used and no Observation flag is set, the corresponding message objects will be copied to IF3 without activating the DMA request line and without waiting for DMA read accesses. A write access to this register aborts a pending DMA cycle by resetting the DMA line and enables updating of IF3 interface register set with new data. To avoid data inconsistency, the DMA controller should be disabled before reconfiguring IF3 observation register. The status of the current read-cycle can be observed via status flags (Bits [12:8]).

24.11 Gigabit Ethernet Switch (GMAC_SW)

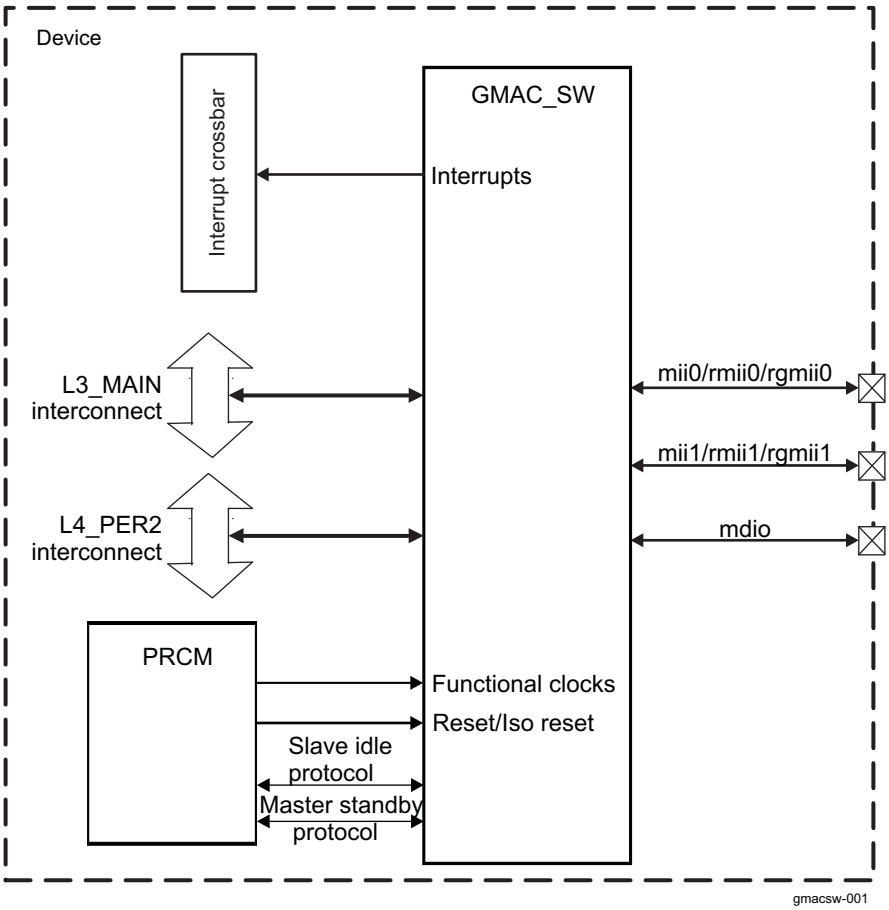
This chapter describes the three-port gigabit switch ethernet subsystem in the device.

24.11.1 GMAC_SW Overview

The three-port gigabit ethernet switch subsystem (GMAC_SW) provides ethernet packet communication and can be configured as an ethernet switch. It provides the gigabit media independent interface (G/MII) in MII mode, reduced gigabit media independent interface (RGMII), reduced media independent interface (RMII), and the management data input output (MDIO) for physical layer device (PHY) management.

Figure 24-187 shows the GMAC_SW subsystem overview.

Figure 24-187. GMAC_SW Overview



24.11.1.1 Features

The GMAC_SW subsystem provides the following features:

- Two Ethernet ports (port 1 and port 2) with selectable RGMII, RMII, and G/MII (in MII mode only) interfaces plus internal Communications Port Programming Interface (CPPI 3.1) on port 0
- Synchronous 10/100/1000 Mbit operation
- Wire rate switching (802.1d)
- Non-blocking switch fabric
- Flexible logical FIFO-based packet buffer structure
- Four priority level Quality Of Service (QOS) support (802.1p)
- CPPI 3.1 compliant DMA controllers
- Support for Audio/Video Bridging (P802.1Qav/D6.0)

Copyright © 2015–2017, Texas Instruments Incorporated

- Support for IEEE 1588 Clock Synchronization (2008 Annex D and Annex F)
  - Timing FIFO and time stamping logic embedded in the subsystem
- Device Level Ring (DLR) Support
- Energy Efficient Ethernet (EEE) support (802.3az)
- Flow Control Support (802.3x)
- Address Lookup Engine (ALE)
  - 1024 total address entries plus VLANs
  - Wire rate lookup
  - Host controlled time-based aging
  - Multiple spanning tree support (spanning tree per VLAN)
  - L2 address lock and L2 filtering support
  - MAC authentication (802.1x)
  - Receive-based or destination-based multicast and broadcast rate limits
  - MAC address blocking
  - Source port locking
  - OUI (Vendor ID) host accept/deny feature
  - Remapping of priority level of VLAN or ports
- VLAN support
  - 802.1Q compliant
    - Auto add port VLAN for untagged frames on ingress
    - Auto VLAN removal on egress and auto pad to minimum frame size
- Ethernet Statistics:
  - EtherStats and 802.3Stats Remote network Monitoring (RMON) statistics gathering (shared)
  - Programmable statistics interrupt mask when a statistic is above one half its 32-bit value
- Flow Control Support (802.3x)
- Digital loopback and FIFO loopback modes supported
- Maximum frame size 2016 bytes (2020 with VLAN)
- 8k (2048 × 32) internal CPPI buffer descriptor memory
- Management Data Input/Output (MDIO) module for PHY Management
- Programmable interrupt control with selected interrupt pacing
- Emulation support
- Programmable Transmit Inter Packet Gap (IPG)
- Reset isolation (switch function remains active even in case of all device resets except for POR pin reset and ICEPICK cold reset)
- Full duplex mode supported in 10/100/1000 Mbps. Half-duplex mode supported only in 10/100 Mbps.
- IEEE 802.3 gigabit Ethernet conformant

NOTE: G/MII interface is functional in MII mode only.

Terminology:

AVB— Audio Video Bridging

AVBTP— Audio Video Bridging Trasport Protocol

BMCA— Best Master Clock Algorithm

CFI— Canonical Format Indicator

CPPI— Communications Port Programming Interface

DLR— Device Level Ring

DSCP— Differentiated Services Code Point

EEE— Energy Efficient Ethernet

EMAC— Ethernet Media Access Control

EOP— End of Packet

EOQ— End of Queue

IPG— Inter-Packet Gap

LPI— Low Power Indicator

MDIO— Management Data Input/Output

MOF— Middle of Frame

PTP— Precision Time Protocol

RMON— Remote Monitoring

RTCP— RTP Control Protocol

RTP— Real-time Transport Protocol

SCR— Switched Central Resource

SRP— Stream Reservation Protocol

TOS— Type of Service

VLAN— Virtual Local Area Network

24.11.2 GMAC_SW Environment

24.11.2.1 G/MII Interface

G/MII Interface can operate only in MII Mode.

- In MII Mode (100/10 Mbps): GMAC_SW operates in full-duplex and half-duplex.

The pin connections of the G/MII Interface is shown in Figure 24-188. The detailed description of the signals are listed in the following tables.

Figure 24-188. MII Interface Typical Application

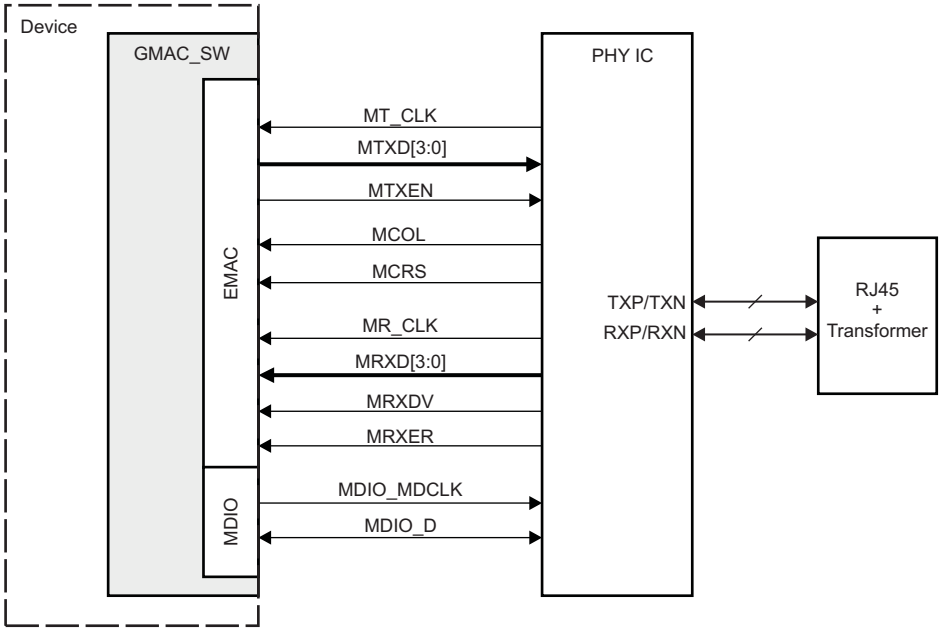

Table 24-1235. MII I/O Description

Signal	Device Pin(s)	I/O[1]	Description
MT_CLK	mii0_txclk mii1_txclk	I	The transmit clock is a continuous clock that provides the timing reference for transmit operations. The MTXD and MTXEN signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
MTXD[3:0]	mii0_txd[3:0] mii1_txd[3:0]	O	The transmit data pins are a collection of 4 data signals MTXD[3:0] comprising 4 bits of data. MTXD0 is the least-significant bit (LSB). The signals are synchronized by MT_CLK and valid only when MTXEN is asserted.
MTXEN	mii0_txen mii1_txen	O	The transmit enable signal indicates that the MTXD pins are generating 4bit data for use by the PHY. It is driven synchronously by MT_CLK.
MTXER	mii0_txer mii1_txer	O	Transmit data error. Used only for EEE to request PHY for low power transition.
MCOL	mii0_col mii1_col	I	In half-duplex operation, the MCOL pin is asserted by the PHY when it detects a collision on the network. It remains asserted while the collision condition persists. This signal is not necessarily synchronous to MT_CLK nor MR_CLK. In full-duplex operation, the MCOL pin is used for hardware transmit flow control. Asserting the MCOL pin will stop packet transmissions; packets in the process of being transmitted when MCOL is asserted will complete transmission. The MCOL pin should be held low if hardware transmit flow control is not used.

(1) I = Input; O = Output

Copyright © 2015–2017, Texas Instruments Incorporated

Table 24-1235. MII I/O Description (continued)

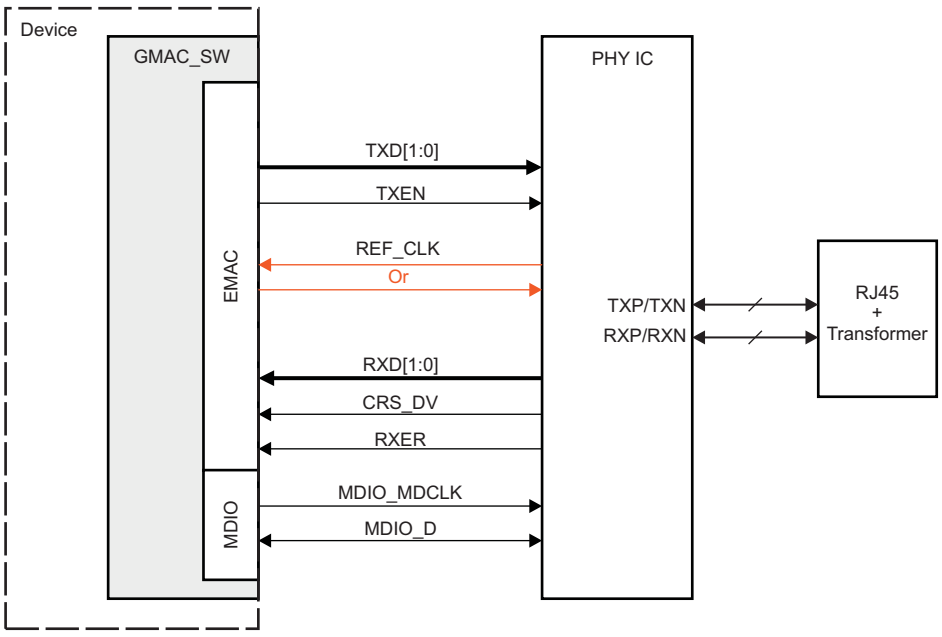
Signal	Device Pin(s)	I/O[1]	Description
MCRS	mii0_crs mii1_crs	I	In half-duplex operation, the MCRS pin is asserted by the PHY when the network is not idle in either transmit or receive. The pin is de-asserted when both transmit and receive are idle. This signal is not necessarily synchronous to MT_CLK nor MR_CLK. In full-duplex operation, the MCRS pin should be held low.
MR_CLK	mii0_rxclk mii1_rxclk	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The MRXD, MRXDV, and MRXER signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
MRXD	mii0_rxd[0:3] mii1_rxd[0:3]	I	The receive data pins are a collection of 4 data signals comprising 4 bits of data. MRXD0 is the least-significant bit (LSB).The signals are synchronized by MR_CLK and valid only when MRXDV is asserted.
MRXDV	mii0_rxdv mii1_rxdv	I	The receive data valid signal indicates that the MRXD pins are generating nibble data for use by the GMAC_SW. It is driven synchronously to MR_CLK.
MRXER	mii0_rxer mii1_rxer	I	Receive Data Error input
MDIO_MDCLK	mdio_mclk	O	Management data clock. The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO_D pin.
MDIO_D	mdio_d	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

24.11.2.2 RMII Interface

Figure 24-189 shows a device with integrated GMAC_SW and MDIO interfaced via a RMII connection in a typical system. The individual CPSW and MDIO signals for the RMII interface are summarized in Table 24-1236.

For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

Figure 24-189. RMII Interface Typical Application



Copyright © 2015–2017, Texas Instruments Incorporated

Table 24-1236. RMII I/O Description

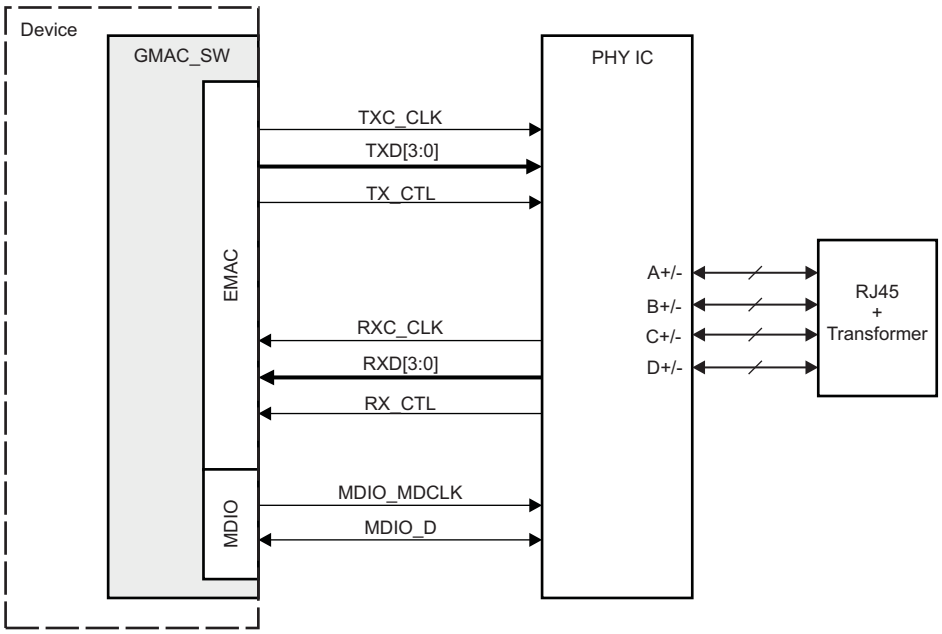
Signal	Device Pin(s)	I/O[1]	Description
TXD[1:0]	rmii0_txd[1:0] rmii1_txd[1:0]	O	Transmit data . The transmit data pins are a collection of 2 bits of data. TXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when TXEN is asserted.
TXEN	rmii0_txen rmii1_txen	O	Transmit enable. The transmit enable signal indicates that the RMII_TXD pins are generating data for use by the PHY. RMII_TXEN is synchronous to RMII_MHZ_50_CLK
RMII0_MHZ_50_CLK	RMII_MHZ_50_CLK	I/O	RMII reference clock.
RMII1_MHZ_50_CLK			The reference clock is used to synchronize all RMII signals. RMII_MHZ_50_CLK must be continuous and fixed at 50 MHz.
RXD[1:0]	rmii0_rxd[1:0] rmii1_rxd[1:0]	I	Receive data. The receive data pins are a collection of 2 bits of data. RXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when CRS_DV is asserted and RXER is de-asserted.
CRS_DV	rmii0_crs rmii1_crs	I	Carrier sense/receive data valid. Multiplexed signal between carrier sense and receive data valid.
RXER	rmii0_rxer rmii1_rxer	I	Receive error. The receive error signal is asserted to indicate that an error was detected in the received frame.
MDIO_MDCLK	mdio_mclk	O	Management data clock (MDIO_MCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO_D pin.
MDIO_D	mdio_d	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

(1) I = Input; O = Output

24.11.2.3 RGMII Interface

Figure 24-190 shows a device with integrated CPSW and MDIO interfaced via a RGMII connection in a typical system. The individual CPSW and MDIO signals for the RGMII interface are summarized in Table 24-1237.

Figure 24-190. RGMII Interface Typical Application



Copyright © 2015–2017, Texas Instruments Incorporated

Table 24-1237. RGMII I/O Description

Signal	Device Pin(s)	I/O[1]	Description
TXD[3:0]	rgmii0_txd[3:0] rgmii1_txd[3:0]	O	The transmit data pins are a collection of 4 bits of data. TXD0 is the least-significant bit (LSB). The signals are valid only when TX_CTL is asserted.
TX_CTL	rgmii0_rxctl rgmii1_rxctl	O	Transmit Control/enable. The transmit enable signal indicates that the TXD pins are generating data for use by the PHY.
TXC_CLK	rgmii0_txc rgmii1_txc	O	The transmit reference clock. The clock is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, and 125 MHz at 1000 Mbps of operation.
RXD[3:0]	rgmii0_rxd[3:0] rgmii1_rxd[3:0]	I	The receive data pins are a collection of 4 bits of data. RXD0 is the least-significant bit (LSB). The signals are valid only when RX_CTL is asserted
RX_CTL	rgmii0_rxctl rgmii1_rxctl	I	The receive data valid/control signal indicates that the RXD pins are nibble data for use by the GMAC_SW.
RXC_CLK	rgmii0_rxc rgmii1_rxc	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation, 25 MHz at 100 Mbps operation, 125 MHz at 1000 Mbps of operation.
MDIO_MDCLK	mdio_mclk	O	Management data clock (MDIO_MCLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin.
MDIO_D	mdio_d	I/O	MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

(1) I = Input; O = Output

NOTE: The path from a module pin to device pad(s) is defined at the device I/O logic level. The control module registers assign the specific function to the device pads. For more information on control module settings, see Section 18.4.6.1.1, *Pad Configuration Registers* in *Chapter 18, Control Module*.

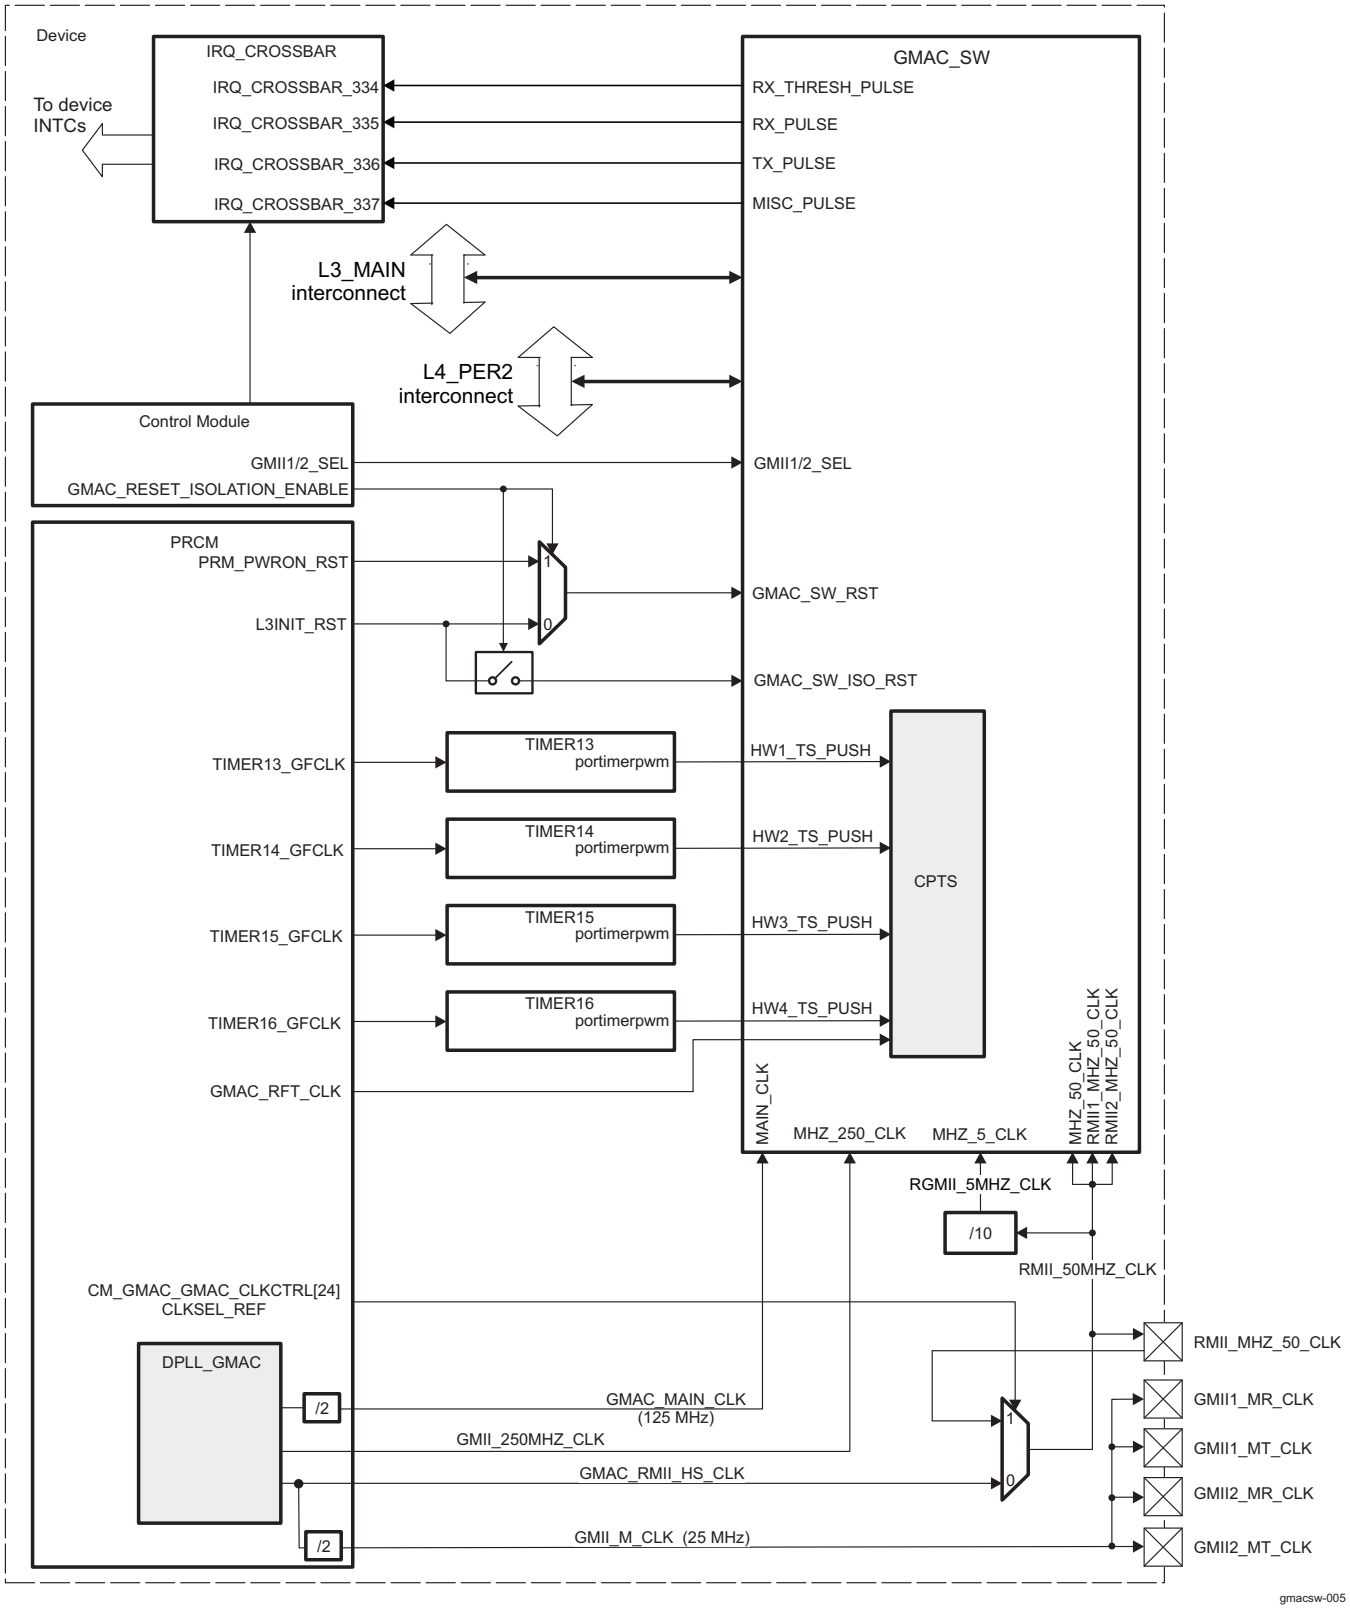
24.11.3 GMAC_SW Integration

Figure 24-191 shows the integration of the GMAC_SW module in the device.

Figure 24-191. GMAC_SW Integration



Copyright © 2015–2017, Texas Instruments Incorporated

NOTE: The device provides the option to receive or output the RMII reference clock (RMII_50MHZ_CLK) from/to external pin as shown in Figure 24-191. See the RMII_CLK_SETTING register bit in the Section 18.5*Control Module Register Manual*, and CLKSEL_REF in Section 3.11*, PRCM Register Manual* to configure the clocking option of RMII.

See Chapter 3, *PRCM* for details about power, clock and reset options for GMAC_SW.

Table 24-1238 through Table 24-1240 summarize the integration of the GMAC_SW module in the device.

Table 24-1240. GMAC_SW Hardware Requests (continued)

RX_PULSE	IRQ_CROSSBAR_335	-	Receive packet completion interrupt
TX_PULSE	IRQ_CROSSBAR_336	-	Transmit packet completion interrupt
MISC_PULSE	IRQ_CROSSBAR_337	-	Miscellaneous interrupt (SPF2_PEND, SPF1_PEND, EVNT_PEND,STAT_PEND, HOST_PEND, MDIO_LINKINT, MDIO_USERINT)

NOTE: GMAC_SW has no default IRQ mappings through the IRQ_CROSSBAR. For GMAC_SW, the IRQ_CROSSBAR module must be configured prior to unmask interrupts in the interrupt controller(s).
For more information about the IRQ_CROSSBAR module, see Section 18.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 18, *Control Module*.
For more information about the device interrupt controllers, see Chapter 17, *Interrupt Controllers*.

NOTE: For the description of the interrupt source, see Section 24.11.4.5, *Interrupt Functionality*.

24.11.4 GMAC_SW Functional Description

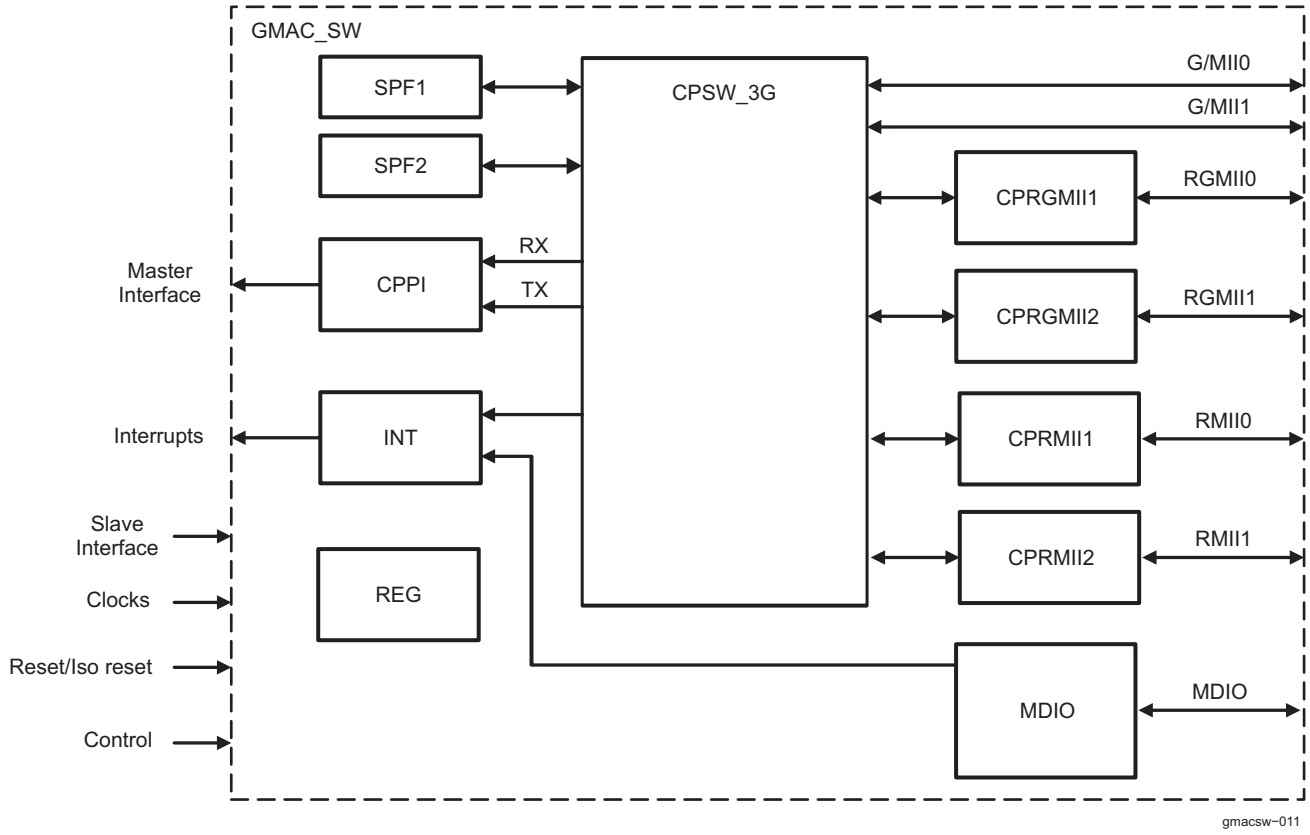
The 3-port switch (GMAC_SW) Ethernet subsystem modules are compliant to the IEEE Std 802.3 Specification.GMAC_SW is shown in Figure 24-192.

24.11.4.1 Functional Block Diagram

The GMAC_SW subsystem consists of:

- CPSW_3G which contains two G/MII interfaces
- Two RGMII interface modules
- Two RMII interface modules
- One MDIO interface module
- One Interrupt Controller module
- One CPPI interface
- Local CPPI memory of size 8 KiB
- Two Static Packet Filters

Figure 24-192. GMAC_SW Top Level Block Diagram



24.11.4.2 GMAC_SW Ports

Ethernet Subsystem has three Ports. Port 0 is the Host port (internal to the Subsystem). Ports 1 and 2 are the external ports connected to G/MII, RGMII, or RMII interfaces as per the interface selected.

Naming conventions followed in this chapter:

- Port0 is referred to the Host Port
- Port1 is referred to the interfaces GMII0/RGMII0/RMII0
- Port2 is referred to the interfaces GMII1/RGMII1/RMII1

Copyright © 2015–2017, Texas Instruments Incorporated

24.11.4.2.1 Interface Mode Selection

The 3-port switch (GMAC_SW) Ethernet Subsystem has two 10/100/1000 Ethernet ports with selectable MII, RMII, and RGMII interfaces.

The interface mode is selected by configuring the MII mode selection register bitfields (GMII1_SEL and GMII2_SEL) in the control module. See Section 18.5, *Control Module Register Manual* for details.

See device data manual for configuring the pin mux mode as per the interface selected.

24.11.4.3 Clocking

24.11.4.3.1 Subsystem Clocking

GMAC_SW clocking summary is shown in Section 24.11.3, *GMAC_SW Integration*.

24.11.4.3.2 Interface Clocking

Data is transmitted and received with respect to the reference clocks of the interface pins.

24.11.4.3.2.1 G/MII Interface Clocking

GMII1_MR_CLK, GMII1_MT_CLK, GMII2_MR_CLK, GMII2_MT_CLK frequencies are fixed by the 802.3 specification.

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps

24.11.4.3.2.2 RGMII Interface Clocking

RGMII_RXC, RGMII_TXC frequencies are:

- 2.5 MHz at 10 Mbps
- 25 MHz at 100 Mbps
- 125 MHz at 1000 Mbps

24.11.4.3.2.3 RMII Interface Clocking

RMII interface clock RMII_50MHZ_CLK frequency is:

- 50 MHz at 10 Mbps
- 50 MHz at 100 Mbps

See the RMII_CLK_SETTING bit in the device Control Module and CLKSEL_REF in PRCM to configure the clocking option of RMII (external pin or PRCM).

24.11.4.3.2.4 MDIO Clocking

The MDIO clock is based on a divide-down of the interface (MAIN_CLK) clock, running at 125 MHz.The application software or driver must control the divide-down value.

See the MDIO_CONTROL register for configuring the Clock Divider (CLKDIV) value.

24.11.4.4 Software IDLE

The submodule software idle register bits enable CPSW_3G operation to be completely or partially suspended by software control. There are three CPSW_3G submodules that contain software idle register bits (CPGMAC_SL1, CPGMAC_SL2, and CPDMA). Each of the three submodules may be individually commanded to enter the idle state. The idle state is entered at packet boundaries, and no further packet operations will occur on an idled submodule until the idle command is removed. The CPSW_3G module

Copyright © 2015–2017, Texas Instruments Incorporated

enters the idle state when all three submodules are commanded to enter and have entered the idle state. Idle status is determined by reading or polling the three submodule idle bits. The CPSW_3G is in the idle state when all three submodules are in the idle state. The CPSW_SOFT_IDLE[0] SOFT_IDLE bit may be set if desired after the submodules are in the idle state. The CPSW SOFT_IDLE bit causes packets to not be transferred from one FIFO to another FIFO internal to the switch.

24.11.4.5 Interrupt Functionality

GMAC_SW Ethernet Subsystem has four Interrupt outputs:

- RX_PULSE - Receive Interrupt
- TX_PULSE - Transmit Interrupt
- RX_THRESH_PULSE - Receive Threshold Interrupt
- MISC_PULSE - Miscellaneous Interrupt.

24.11.4.5.1 Receive Packet Completion Pulse Interrupt (RX_PULSE)

The RX_PULSE interrupt is a pulse interrupt selected from the GMAC_SW RX_PEND[7:0] interrupts. The receive DMA controller has eight channels with each channel having a corresponding (RX_PEND[7:0]).

The following steps will enable the receive packet completion interrupt:

1. Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the CPDMA_RX_INTMASK_SET register.
2. The receive completion interrupt(s) to be routed to RX_PULSE is selected by setting one or more bits in the receive interrupt enable register (WR_C0_RX_EN) . The masked interrupt status can be read in the address location of RX_STAT bit in the WR_C0_RX_STAT register.

When the GMAC_SW completes a packet reception, the subsystem issues an interrupt to the host processor by writing the packet's last buffer descriptor address to the appropriate channel queue's receive completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the software processes one or more packets from the buffer chain and then acknowledges one or more interrupt(s) by writing the address of the last buffer descriptor processed to the queue's associated receive completion pointer (RX *n*_CP) in the receive DMA state RAM.

Upon reception of an interrupt, software should perform the following:

1. Read the WR_C0_RX_STAT[7:0] RX_STAT bit address location to determine which channel(s) caused the interrupt.
2. Process received packets for the interrupting channel(s).
3. Write the GMAC_SW completion pointer(s) (RX *n*_CP). The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the subsystem (address of last buffer descriptor used by the subsystem). If the two values are not equal (which means that the GMAC_SW has received more packets than the software has processed), the receive packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the system has received), the pending interrupt is de-asserted. The value that the GMAC_SW is expecting is found by reading the receive channel *n* completion pointer register (RX *n*_CP).
4. Write the value 1h to the CPDMA_EOI_VECTOR register.

To disable the interrupt:

1. The eight channel interrupts may be individually disabled by writing to 1 the appropriate bit in the CPDMA_RX_INTMASK_CLEAR register.
2. The receive completion pulse interrupt could be disabled by clearing to 0 all the bits in the WR_C0_RX_EN register.

The software could still poll for the CPDMA_RX_INTSTAT_RAW and CPDMA_RX_INTSTAT_MASKED registers if the corresponding interrupts are enabled.

Copyright © 2015–2017, Texas Instruments Incorporated

24.11.4.5.2 Transmit Packet Completion Pulse Interrupt (TX_PULSE)

The TX_PULSE interrupt is a pulse interrupt selected from the GMAC_SW TX_PEND[7:0] interrupts. The transmit DMA controller has eight channels with each channel having a corresponding (TX_PEND[7:0]).

To enable the transmit packet completion interrupt:

1. Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the CPDMA_TX_INTMASK_SET register.
2. The transmit completion interrupt(s) to be routed to TX_PULSE is selected by setting one or more bits in the transmit interrupt enable register WR_C0_TX_EN .The masked interrupt status can be read in the address location of TX_STAT bit in the WR_C0_TX_STAT register.

When the GMAC_SW completes the transmission of a packet, the GMAC_SW subsystem issues an interrupt to the host processor by writing the packet's last buffer descriptor address to the appropriate channel queue's transmit completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon reception of an interrupt, software should perform the following:

1. Read the TX_STAT bit address location to determine which channel(s) caused the interrupt
2. Process received packets for the interrupting channel(s).
3. Write the GMAC_SW completion pointer(s) (TX *n*_CP). The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the GMAC_SW (address of last buffer descriptor used by the GMAC_SW). If the two values are not equal (which means that the GMAC_SW has transmitted more packets than the software has processed), the transmit packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the subsystem has transferred), the pending interrupt is cleared. The value that the GMAC_SW is expecting is found by reading the transmit channel *n*completion pointer register (TX *n*_CP).
4. Write the 2h to the CPDMA_EOI_VECTOR register.

To disable the interrupt:

1. The eight channel interrupts may be individually disabled by writing to 1 the appropriate bit in the CPDMA_TX_INTMASK_CLEAR register.
2. The receive completion pulse interrupt could be disabled by clearing to 0 all the bits in the WR_C0_TX_EN register.

The software could still poll for the CPDMA_TX_INTSTAT_RAW and CPDMA_TX_INTSTAT_MASKED registers, if the corresponding interrupts are enabled.

24.11.4.5.3 Receive Threshold Pulse Interrupt (RX_THRESH_PULSE)

The RX_THRESH_PULSE interrupt is an immediate (non-paced) pulse interrupt selected from the CPSW_3G RX_THRESH_PEND[7:0] interrupts. The receive DMA controller has eight channels with each channel having a corresponding threshold pulse interrupt (RX_THRESH_PEND[7:0]).

To enable the receive threshold pulse Interrupt:

1. Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the CPDMA_RX_INTMASK_SET register.
2. The receive threshold interrupt(s) to be routed to RX_THRESH_PULSE is selected by setting one or more bits in the receive threshold interrupt enable register WR_C0_RX_THRESH_EN. The masked interrupt status can be read in the address location of RX_THRESH_STAT bit in the WR_C0_RX_THRESH_STAT register.

The RX_THRESH_PULSE is asserted when enabled when the channel's associated free buffer count RX *n*_FREEBUFFER is less than or equal to the corresponding RX *n*_PENDTHRESH register.

Upon reception of an interrupt, software should perform the following:

1. Read the RX_THRESH_STAT bit address location to determine which channel(s) caused the interrupt.
2. Process the received packets in order to add more buffers to any channel that is below the threshold value.

Copyright © 2015–2017, Texas Instruments Incorporated

3. Write the CPSW_3G completion pointer(s).
4. Write the value 0h to the CPDMA_EOI_VECTOR register.

The threshold pulse interrupt is an immediate interrupt intended to indicate that software should immediately process packets to preclude an overrun condition from occurring for the particular channels.

To disable the interrupt:

1. The eight channel receive threshold interrupts may be individually disabled by writing to 1 the appropriate bit in the CPDMA_RX_INTMASK_CLEAR register.
2. The receive threshold pulse interrupt could be disabled by clearing to 0 the corresponding bits in the WR_C0_RX_THRESH_EN register.

The software could still poll for the CPDMA_RX_INTSTAT_RAW and CPDMA_RX_INTSTAT_MASKED registers, if the corresponding interrupts are enabled.

24.11.4.5.4 Miscellaneous Pulse Interrupt (MISC_PULSE)

The MISC_PULSE interrupt is an immediate pulse interrupt selected from the miscellaneous interrupts (SPF2_PEND, SPF1_PEND, EVNT_PEND,STAT_PEND, HOST_PEND, MDIO_LINKINT, MDIO_USERINT).

The miscellaneous interrupt(s) is selected by setting one or more bits in the miscellaneous interrupt enable register (WR_C0_MISC_EN).

Upon reception of an interrupt, software should perform the following:

- Read the MISC_STAT bit address location to determine the source of the interrupt.
- Process the interrupt.
- Write the value 3h to the CPDMA_EOI_VECTOR register.

NOTE: The WR_C0_MISC_STAT register's MDIO_LINKINT and MDIO_USERINT bitfields represent the Port0/Phy0 status. MDIO_LINKINT[1] and MDIO_USERINT[1] are not provided in WR_C0_MISC_STAT register. As such, MDIO Link and User interrupts can only be generated for Port0. For Port1, software must poll the status, visible in the MDIO_LINKINTMASKED or MDIO_USERINTMASKED registers.

24.11.4.5.4.1 EVNT_PEND(CPTS_PEND) Interrupt

See Section 24.11.4.10, *Common Platform Time Sync (CPTS)* for more details on this interrupt.

24.11.4.5.4.2 Statistics Interrupt

The statistics level interrupt (STAT_PEND) will be asserted, if enabled when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is cleared by writing to decrement all statistics values greater than 8000 0000h (such that their new values are less than 8000 0000h). The raw and masked statistics interrupt status may be read by reading the CPDMA_TX_INTSTAT_RAW and CPDMA_TX_INTSTAT_MASKED registers, respectively.

The Statistics interrupt is enabled by setting to 1 the STAT_INT_MASK bit in the CPDMA_DMA_INTMASK_SET register

24.11.4.5.4.3 Host Error interrupt

The host error interrupt (HOST_PEND) will be asserted, if enabled when a host error is detected during transmit or receive CPDMA transactions. The host error interrupt is intended for software debug, and is cleared by a warm reset or a system reset. The raw and masked host interrupt status can be read by reading the CPDMA_DMA_INTSTAT_RAW and CPDMA_DMA_INTSTAT_MASKED registers, respectively.

The transmit host error conditions are:

- SOP error

Copyright © 2015–2017, Texas Instruments Incorporated

- OWNERSHIP bit not set in SOP buffer
- next buffer descriptor pointer without EOP cleared to 0
- buffer pointer cleared to 0
- buffer length cleared to 0
- packet length error

The receive host error conditions are:

- OWNERSHIP bit not set in input buffer
- Zero buffer pointer
- Zero buffer Length on non-SOP descriptor
- SOP buffer length not greater than offset

The HOST_PEND is enabled by setting to 1 the HOST_ERR_INTMASK in the CPDMA_DMA_INTMASK_SET register. The host error interrupt is disabled by setting to 1 the appropriate bit in the CPDMA_DMA_INTMASK_CLEAR register.

24.11.4.5.4.4 MDIO Interrupts

MDIO_LINKINT is set if there is a change in the link state of the PHY corresponding to the address in the PHYADR_MON field of the MDIO_USERPHYSEL*n* register and the corresponding LINKINT_ENABLE bit is set. The MDIO_LINKINT event is also captured in the MDIO_LINKINTMASKED register. When the GO bit in the MDIO_USERACCESS*n* register transitions from 1 to 0, indicating the completion of a user access, and the corresponding USERINTMASKSET bit in the MDIO_USERINTMASKSET register is set, the MDIO_USERINT signal is asserted. The MDIO_USERINT event is also captured in the MDIO_USERINTMASKED register.

24.11.4.5.5 Interrupt Pacing

RX_PULSE and TX_PULSE interrupts can be paced. The RX_THRESH_PULSE and MISC_PULSE interrupts are not paced. The Interrupt pacing feature limits the number of interrupts that occur during a given period of time. For heavily loaded systems in which interrupts can occur at a very high rate (for example, 148,800 packets per second for Ethernet), the performance benefit is significant due to minimizing the overhead associated with servicing each interrupt. Interrupt pacing increases the processor cache hit ratio by minimizing the number of times that large interrupt service routines are moved to and from the processor instruction cache.

Each RX_PULSE and TX_PULSE interrupt contains an interrupt pacing sub-block (six total). Each sub-block is disabled by default allowing the selected interrupt inputs to pass through unaffected. The interrupt pacing module counts the number of interrupts that occur over a 1 ms interval of time. At the end of each 1 ms interval, the current number of interrupts is compared with a target number of interrupts (specified by the associated maximum number of interrupts register). Based on the results of the comparison, the length of time during which interrupts are blocked is dynamically adjusted. The 1 ms interval is derived from a 4 µs pulse that is created from a prescale counter whose value is set in the INT_PRESCALE field in the WR_INT_CONTROL register. The INT_PRESCALE value should be written with the number of ICLK periods in 4 µs. The pacing timer determines the interval during which interrupts are blocked and decrements every 4 µs. It is reloaded each time a zero count is reached. The value loaded into the pacing timer is calculated by hardware every 1 ms according to the following algorithm:

```
if (intr_count > 2*intr_max)
    pace_timer = 255;
  else if (intr_count > 1.5*intr_max)
    pace_timer = last_pace_timer*2 + 1;
  else if (intr_count > 1.0*intr_max)
    pace_timer = last_pace_timer + 1;
  else if (intr_count > 0.5*intr_max)
    pace_timer = last_pace_timer - 1;
  else if (intr_count != 0)
    pace_timer = last_pace_timer/2;
else
pace_timer = 0;
```

Copyright © 2015–2017, Texas Instruments Incorporated

If the rate of interrupt inputs is much less than the target interrupt rate specified in the associated maximum interrupts register, then the interrupt is not blocked. If the interrupt rate is greater than the target rate, the interrupt will be "paced" at the rate specified in the interrupt maximum register. The WR_C0_RX_IMAX/WR_C0_TX_IMAX register should be written with a value between 2 and 63 inclusive, indicating the target number of interrupts per millisecond.

24.11.4.6 Reset Isolation

Reset isolation for the GMAC_SW allows the switch function to remain active in during all device resets except for POR pin reset and ICEPICK COLD reset. Packet traffic to/from the GMAC_SW host will be flushed/dropped, but the ethernet switch will remain operational for all traffic between external devices on the switch even though the device is undergoing a device reset. Pin mux configuration for ethernet related I/O and reference clocks needed by the GMAC_SW to be active is controlled by a protected control module bit.

24.11.4.6.1 Reset Isolation Functional Description

The device has two modes of operation concerning the reset of the GMAC_SW Ethernet switch. The mode is controlled by the GMAC_RESET_ISOLATION_ENABLE bit in the Control Module. This bit defaults to 0. Any modification of this bit first requires writing an unlock pattern to lock register in device control module. After modification, the bit should again be locked by writing appropriate value to the lock register. Writes to the GMAC_RESET_ISOLATION_ENABLE bit and to the lock register must all be supervisor mode writes.

GMAC_RESET_ISOLATION_ENABLE = 0 (disabled)

1. This is the default state of the bit after control module reset.
2. Upon any device level resets, the entire GMAC_SW, DPLL_GMAC, L3/L4 interconnect, control module (including all pin mux control and the GMAC_RESET_ISOLATION_ENABLE bit itself) are immediately reset.

GMAC_RESET_ISOLATION_ENABLE = 1 (enabled)

1. This mode is selected when the GMAC_RESET_ISOLATION_ENABLE bit is set to 1 by software.
2. Upon any device reset source other than porz pin or ICEPICK cold (that is, this includes software global cold, any watchdog reset, warm resetn pin, ICEPICK warm, software global warm or security violation), the following is true:
   (a) The CPSW_3GSS_R is put into "isolate" mode and non-switch related portions of the subsystem are reset.
   (b) The 50 MHz and 125 MHz reference clocks to the GMAC_SW Ethernet Subsystem remain active throughout the entire reset condition.
   (c) The control for pin multiplexing for all of the signals maintain their current configuration throughout the entire reset condition.
   (d) The reset-isolated logic inside GMAC_SW Ethernet Subsystem maintains the switch functionality
3. Upon any cold reset sources, the entire GMAC_SW Ethernet Subsystem, DPLL_GMAC, control module (including all pin mux control and the GMAC_RESET_ISOLATION_ENABLE bit itself) are reset.

For more details on the register configuration, see the Control Module CTRL_CORE_CONTROL_IO_2 register in Section 18.5*, Control Module Register Manual*.

24.11.4.7 Software Reset

The CPSW_3G software reset register (CPSW_SOFT_RESET), CPSW_3GSS software reset register (WR_SOFT_RESET) and the three submodule software reset registers enable the CPSW_3GSS to be reset by software.

There are three CPSW_3G submodules that contain software reset registers (CPGMAC_SL1, CPGMAC_SL2 (SL_SOFT_RESET), and CPDMA (CPDMA_SOFT_RESET)). Each of the three submodules may be individually commanded to be reset by software.

Copyright © 2015–2017, Texas Instruments Incorporated

For the CPDMA, the reset state is entered at packet boundaries, at which time the CPDMA reset occurs. The CPGMAC_SL soft reset is immediate. Submodule reset status is determined by reading or polling the submodule reset bit. If the submodule reset bit is read as a one, then the reset process has not yet completed. The submodule soft reset process could take up to 2ms each. The reset has completed if the submodule reset bit is read as a zero.

After all three submodules (in any order) have been reset and a read of each submodule reset bit indicates that the reset process is complete, the CPSW_3G software reset register bit may be written to complete the CPSW_3G module software reset operation. The CPSW_3G software reset bit controls the reset of the FIFO's, the statistics submodule, and the address lookup engine (ALE). The CPSW_3G software reset is immediate and will be indicated by reading a zero from the soft reset bit.

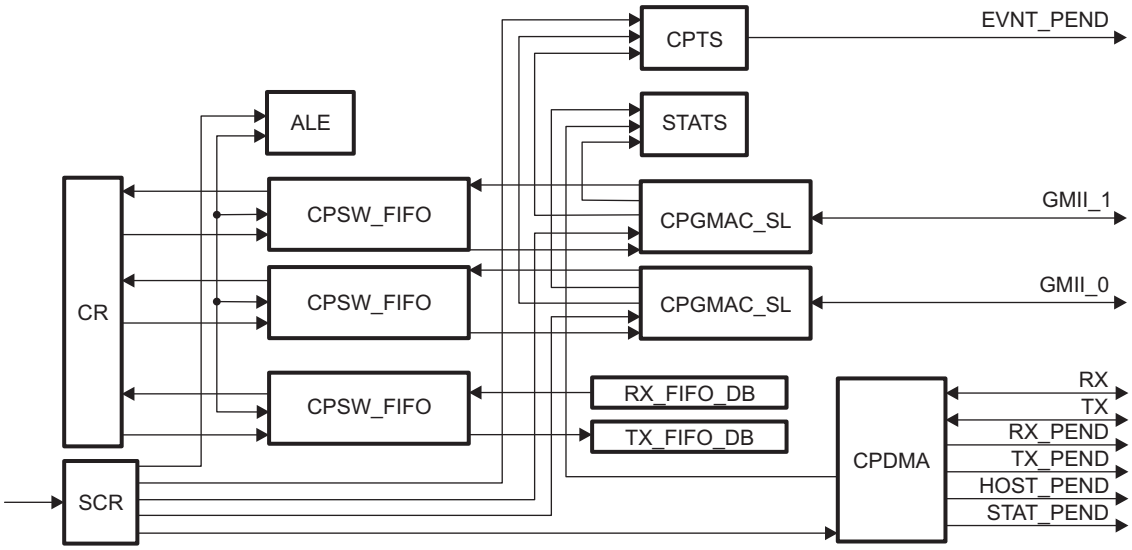
The CPSW_3GSS software reset bit controls the reset of the INT, REGS, and CPPI. The CPSW_3GSS software reset is immediate and will be indicated by reading a zero from the soft reset bit.

24.11.4.8 CPSW_3G

The CPSW_3G G/MII interfaces are compliant to the IEEE Std 802.3 Specification.

The CPSW_3G contains two CPGMAC_SL interfaces (ports 1 and 2), one CPPI interface Host Port (port 0), Common Platform Time Sync (CPTS), ALE Engine and CPDMA. A top-level block diagram of the CPSW_3G is shown in Figure 24-193.

Figure 24-193. CPSW_3G Block Diagram



24.11.4.8.1 CPDMA RX and TX Interfaces

The CPDMA submodule is a CPPI compliant packet DMA transfer controller. The CPPI interface is port 0.

24.11.4.8.1.1 Functional Operation

After reset, initialization, and configuration the host may initiate transmit operations. Transmit operations are initiated by host writes to the appropriate transmit channel head descriptor pointer contained in the STATERAM block. The transmit DMA controller then fetches the first packet in the packet chain from memory in accordance with CPPI protocol. The DMA controller writes the packet into the external transmit FIFO in 64-byte bursts (maximum).

Receive operations are initiated by host writes to the appropriate receive channel head descriptor pointer after host initialization and configuration. The receive DMA controller writes the receive packet data to external memory in accordance with CPPI protocol. For a detailed description of buffer descriptors, see Section 24.11.4.11, *CPPI Buffer Descriptors*.

Copyright © 2015–2017, Texas Instruments Incorporated

24.11.4.8.1.2 Receive DMA Interface

The receive DMA is an eight channel CPPI compliant interface. Each channel has a single queue for frame reception.

24.11.4.8.1.2.1 Receive DMA Host Configuration

To configure the RX DMA for operation the software must perform the following:

1. Initialize the receive addresses.
2. Initialize the RX_HDP registers to 0.
3. Enable the desired receive interrupts in the CPDMA_RX_INTMASK_SET register.
4. Write the CPDMA_RX_BUFFER_OFFSET register value.
5. Setup the receive channel(s) buffer descriptors in host memory as required by CPPI
6. Enable the RX DMA controller by setting the RX_EN bit in the CPDMA_RX_CONTROL register.

24.11.4.8.1.2.2 Receive Channel Teardown

The host commands a receive channel teardown by writing the channel number to the CPDMA_RX_TEARDOWN register. When a teardown command is issued to an enabled receive channel the following will occur:

- Any current frame in reception will complete normally.
- The teardown_complete bit will be set in the next buffer descriptor in the chain (if there is one).
- The channel head descriptor pointer will be cleared to 0.
- A receive interrupt for the channel will be issued to the host.
- The software should acknowledge a teardown interrupt with a FFFF FFFCh Acknowledge value.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by a set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a FFFF FFFCh acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be FFFF FFFCh if the interrupt was due to a teardown command.

24.11.4.8.1.3 Transmit DMA Interface

The tranmsit DMA is an eight channel CPPI compliant interface. Priority between the eight queues may be either fixed or round robin as selected by the TX_PTYPE bit in the CPDMA_DMACONTROL register. If the priority type is fixed, then channel 7 has the highest priority and channel 0 has the lowest priority. Round robin priority proceeds from channel 0 to channel 7.

24.11.4.8.1.3.1 Transmit DMA Host Configuration

To configure the TX DMA for operation the software must do the following:

1. Initialize the TX_HDP registers to 0.
2. Enable the desired transmit interrupts in the CPDMA_TX_INTMASK_SET register.
3. Setup the transmit channel(s) buffer descriptors in host memory as defined in CPPI.
4. Configure and enable the transmit operation as desired in the CPDMA_TX_CONTROL register.
5. Write the appropriate TX_HDP registers with the appropriate values to start transmit operations.

24.11.4.8.1.3.2 Transmit Channel Teardown

The host commands a transmit channel teardown by writing the channel number to the CPDMA_TX_TEARDOWN register. When a teardown command is issued to an enabled transmit channel the following will occur:

- Any frame currently in transmission will complete normally

Copyright © 2015–2017, Texas Instruments Incorporated

- The teardown complete bit will be set in the next sop buffer descriptor (if there is one).
- The channel head descriptor pointer will be cleared to 0.
- An interrupt will be issued to inform the host of the channel teardown.
- The software should acknowledge a teardown interrupt with a FFFF FFFCh acknowledge value

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a FFFF FFFCh acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be FFFF FFFCh if the interrupt was due to a teardown command.

24.11.4.8.1.4 Transmit Rate Limiting

Transmit operations can be configured to rate limit the transmit data for each transmit priority. Rate limiting is enabled for a channel when the TX_RLIM bit associated with that channel is set in the CPDMA_DMACONTROL register. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then TX_RLIM should be set to 11000000b with the MSB corresponding to channel 7. When any channels are configured to be rate-limiting, the priority type must be fixed for transmit. Round-robin priority type is not allowed when rate-limiting. Each of the eight transmit priorities has an associated register to control the rate at which the priority is allowed to send data (TX_PRI(0..7)_RATE) when the channel is rate-limiting. Each priority has a send count (PRI(0..7)_SEND_CNT) and an idle count (PRI(0..7)_IDLE_CNT). The transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second that each priority is allowed to send is controlled by the equation:

Priority Transfer rate in Mbit/s = ((PRI_IDLE_CNT/(PRI_IDLE_CNT + PRI_SEND_CNT)) × frequency × 32

Where *frequency* is the CPDMA interface clock (MAIN_CLK) frequency.

24.11.4.8.1.5 Command IDLE

The CMD_IDLE bit in the CPDMA_DMACONTROL register allows CPDMA operation to be suspended. When the idle state is commanded, the CPDMA will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the tx cell FIFO will be transmitted. For receive, frames that are detected by the CPDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Commanded idle is similar in operation to emulation control and clock stop.

24.11.4.8.2 Address Lookup Engine (ALE)

The address lookup engine (ALE) processes all received packets to determine which port(s) if any that the packet should the forwarded to. The ALE uses the incoming packet received port number, destination address, source address, length/type, and VLAN information to determine how the packet should be forwarded. The ALE outputs the port mask to the switch fabric that indicates the port(s) the packet should be forwarded to. The ALE is enabled when the ENABLE_ALE bit in the ALE_CONTROL register is set. All packets are dropped when the ENABLE_ALE bit is cleared to 0.

In normal operation, the CPGMAC_SL modules are configured to issue an abort, instead of an end of packet, at the end of a packet that contains an error (runt, frag, oversize, jabber, crc, alignment, code etc.) or at the end of a mac control packet. However, when the SL_MACCONTROL configuration bit(s) RX_CEF_EN, RX_CSF_EN, or RX_CMF_EN are set, error frames, short frames or mac control frames have a normal end of packet instead of an abort at the end of the packet. When the ALE receives a packet that contains errors (due to a set header error bit), or a mac control frame and does not receive an abort, the packet will be forwarded only to the host port (port 0). No ALE learning occurs on packets with errors or mac control frames. Learning is based on source address and lookup is based on destination address.

Copyright © 2015–2017, Texas Instruments Incorporated

The ALE may be configured to operate in bypass mode by setting the ALE_BYPASS bit in the ALE_CONTROL register. When in bypass mode, all CPGMAC_SL received packets are forwarded only to the host port (port 0). Packets from the two ports can be on separate RX DMA channels by configuring the P0_CPDMA_RX_CH_MAP register. In bypass mode, the ALE processes host port transmit packets the same as in normal mode. In general, packets would be directed by the host in bypass mode.

The ALE may be configured to operate in OUI deny mode by setting the ENABLE_OUI_DENY bit in the ALE_CONTROL register. When in OUI deny mode, a packet with a non-matching OUI source address will be dropped unless the destination address matches a multicast table entry with the super bit set. Broadcast packets will be dropped unless the broadcast address is entered into the table with the super bit set. Unicast packets will be dropped unless the unicast address is in the table with block and secure both set (supervisory unicast packet).

Multicast supervisory packets are designated by the super bit in the table entry. Unicast supervisory packets are indicated when block and secure are both set. Supervisory packets are not dropped due to rate limiting, OUI, or VLAN processing.

24.11.4.8.2.1 Address Table Entry

The ALE table contains 1024 entries. Each table entry represents a free entry, an address, a VLAN, an address/VLAN pair, or an OUI address. Software should ensure that there are not double address entries in the table. The double entry used would be indeterminate. Reserved table bits must be written with zeroes.

Source Address learning occurs for packets with a unicast, multicast or broadcast destination address and a unicast or multicast (including broadcast) source address. Multicast source addresses have the group bit (bit 40) cleared before ALE processing begins, changing the multicast source address to a unicast source address. A multicast address of all ones is the broadcast address which may be added to the table. A learned unicast source address is added to the table with the following control bits:

Table 24-1241. Learned Address Control Bits

Bit(s)	Value
unicast_type	11
Block	0
Secure	0

If a received packet has a source address that is equal to the destination address then the following occurs:

- The address is learned if the address is not found in the table.
- The address is updated if the address is found.
- The packet is dropped.

Table Entry Type

00 - Free Entry

01 - Address Entry : unicast or multicast determined by destination **address bit 40.**

10 - VLAN entry

11 - VLAN Address Entry : unicast or multicast determined by **address bit 40.**

Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

Port Mask(2:0) (PORT_MASK)

This 3-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Multicast Forward State (MCAST_FWD_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT_MASK has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

24.11.4.8.2.1.3 VLAN/Multicast Address Table Entry

Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

Port Mask(2:0) (PORT_MASK)

Copyright © 2015–2017, Texas Instruments Incorporated

This 3-bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Multicast Forward State (MCAST_FWD_STATE)

Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit PORT_MASk has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 - Forwarding

01 - Blocking/Forwarding/Learning

10 - Forwarding/Learning

11 - Forwarding

The forward state test returns a true value if both the RX and TX ports are in the required state.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

24.11.4.8.2.1.4 Unicast Address Table Entry

Table 24-1245. Unicast Address Table Entry Bit Values

71:68	67:66	65	64	63:62	61:60	59:48	47:0
Reseved	PORT_NUMBER	BLOCK	SECURE	UNICAST_TYPE (00) or (X1)	ENTRY_TYPE(01)	Reserved	UNICAST_ADDRESS

Port Number (PORT_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).

Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure

must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

Copyright © 2015–2017, Texas Instruments Incorporated

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry port_number.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source

address and do not update the address (block must be zero)

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (UNICAST_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

24.11.4.8.2.1.5 OUI Unicast Address Table Entry

Table 24-1246. OUI Unicast Address Table Entry Bit Values

71:64	63:62	61:60	59:48	47:24	23:0
Reserved	UNICAST_TYPE(10)	ENTRY_TYPE(01)	Reserved	UNICAST_OUI	Reserved

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (UNICAST_OUI)

For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup.

24.11.4.8.2.1.6 VLAN/Unicast Address Table Entry

Table 24-1247. Unicast Address Table Entry Bit Values

Port Number (PORT_NUMBER)

This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).]

Block (BLOCK)

The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 - Address is not blocked.

1 - Drop a packet with a matching source or destination address (secure must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry PORT_NUMBER.

0 - Received port number is a don't care.

1 - Drop the packet if the received port is not the secure port for the source

address and do not update the address (block must be zero)

Unicast Type (UNICAST_TYPE)

This field indicates the type of unicast address the table entry contains.

00 - Unicast address that is not ageable.

01 - Ageable unicast address that has not been touched.

10 - OUI address - lower 24-bits are don't cares (not ageable).

11 - Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Packet Address (UNICAST_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

24.11.4.8.2.1.7 VLAN Table Entry

Table 24-1248. VLAN Table Entry

Copyright © 2015–2017, Texas Instruments Incorporated

Table Entry Type (ENTRY_TYPE)

10: VLAN entry

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Force Untagged Packet Egress (FORCE_UNTAGGED_EGRESS)

This field causes the packet VLAN tag to be removed on egress (except on port 0).

Registered Multicast Flood Mask (REG_MCAST_FLOOD_MASK)

Mask [port 2-1-0] used for multicast when the multicast address is found.

Unregistered Multicast Flood Mask (UNREG_MCAST_FLOOD_MASK)

Mask [port 2-1-0] used for multicast when the multicast address is not found.

VLAN Member List (VLAN_MEMBER_LIST)

This 3-bit field indicates which port(s) are members of the associated VLAN.

24.11.4.8.2.2 Packet Forwarding Processes

There are four processes that an incoming received packet may go through to determine packet forwarding. The processes are Ingress Filtering, VLAN_Aware Lookup, VLAN_Unaware Lookup, and Egress.

Packet processing begins in the Ingress Filtering process. Each port has an associated packet forwarding state that can be one of four values (Disabled, Blocked, Learning, or Forwarding). The default state for all ports is Disabled. The host sets the packet forwarding state for each port.

In the packet ingress process (receive packet process), there is a forward state test for unicast destination addresses and a forward state test for multicast addresses. The multicast forward state test indicates the port states required for the receiving port in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state for the packet to be forwarded for transmission. The mcast_fwd_state indicates the required port state for the receiving port as indicated in the preceding table. The unicast forward state test indicates the port state required for the receiving port in order to forward the unicast packet. The transmit port must be in the Forwarding state in order to forward the packet. The block and secure bits determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state. The transmit port must be in the Forwarding state regardless. The forward state test used in the ingress process is determined by the destination address packet type (multicast/unicast).

In general, packets received with errors are dropped by the address lookup engine without learning, updating, or touching the address. The error condition and the abort are indicated by the CPGMAC_SL to the ALE. Packets with errors may be passed to the host (not aborted) by a CPGMAC_SL port, if the port has the RX_CMF_EN, RX_CEF_EN, or RX_CSF_EN bit(s) set. Error packets that are passed to the host by the CPGMAC_SL are considered to be bypass packets by the ALE and are sent only to the host. Error packets do not learn, update, or touch addresses regardless of whether they are aborted or sent to the host. Packets with errors received by the host are forwarded as normal.

The following control bits are in the SL_MACCONTROL register:

- [22] RX_CEF_EN - enables frames that are fragments, long, jabber, CRC, code, and alignment errors to be forwarded
- [23] RX_CSF_EN - enables short frames to be forwarded
- [24] RX_CMF_EN - enables MAC control frames to be forwarded.

24.11.4.8.2.3 Learning Process

The learning process is applied to each receive packet that is not aborted. The learning process is a concurrent process with the packet forwarding process.

Copyright © 2015–2017, Texas Instruments Incorporated

24.11.4.8.2.4 VLAN Aware Mode

The CPSW_3G is in VLAN aware mode when the VLAN_AWARE bit is set in the CPSW_CONTROL register. In VLAN aware mode, ports 0 receive packets (out of the CPSW_3G) may or may not be VLAN encapsulated depending on the RX_VLAN_ENCAP bit in the CPSW_CONTROL register. Port 0 receive packet data is never modified. VLAN is not removed regardless of the force untagged egress bit for Port 0. VLAN encapsulated receive packets have a 32-bit VLAN header encapsulation word added to the packet data. VLAN encapsulated packets are specified by a set rx_vlan_encap bit in the packet buffer descriptor.

Port 0 transmit packets are never VLAN encapsulated (encapsulation is not allowed).

In VLAN aware mode, transmitted packet data is changed depending on the packet type (pkt_type), packet priority (pkt_pri), and VLAN information.

24.11.4.8.2.5 VLAN Unaware Mode

The CPSW_3G is in VLAN unaware mode when the VLAN_AWARE bit is cleared to 0 in the CPSW_CONTROL register. Port 0 receive packets (out of the CPSW_3G) may or may not be VLAN encapsulated depending on the RX_VLAN_ENCAP bit in the CPSW_CONTROL register. Port 0 transmit packets are never VLAN encapsulated.

24.11.4.8.3 Packet Priority Handling

Packets are received on three ports, two are CPGMAC_SL Ethernet ports and the third port is the CPPI host port. Received packets have a received packet priority (0 to 7, with 7 being the highest priority).

The received packet priority is the port priority for untagged packets, and the actual packet priority for priority tagged and VLAN tagged packets. The received packet priority is mapped through the receive ports associated packet priority to header packet priority mapping register to obtain the header packet priority (the CPDMA RX and TX nomenclature is reversed from the CPGMAC_SL nomenclature).

The header packet priority is mapped through the header priority to switch priority mapping register to obtain the hardware switch priority (0 to 3, with 3 being the highest priority). The header packet priority is then used as the actual transmit packet priority if the VLAN information is to be sent on egress.

24.11.4.8.4 FIFO Memory Control

Each of the three CPSW_3G ports has an identical associated FIFO. Each FIFO contains a single logical receive queue and four logical transmit queues (priority 0 through 3). Each FIFO memory contains 20,480 bytes (20k) total organized as 2560 by 64-bit words contained in a single memory instance. The FIFO memory is used for the associated port transmit and receive queues. The TX_MAX_BLKS field in the FIFOs associated Px_MAX_BLKS register determines the maximum number of 1k FIFO memory blocks to be allocated to the four logical transmit queues (transmit total). The RX_MAX_BLKS field in the FIFO's associated Px_MAX_BLKS register determines the maximum number of 1k memory blocks to be allocated to the logical receive queue. The TX_MAX_BLKS value plus the RX_MAX_BLKS value must sum to 20 (the total number of blocks in the FIFO). If the sum were less than 20, then some memory blocks would be unused. The default is 17 (decimal) transmit blocks and three receive blocks. The FIFOs follow the naming convention of the Ethernet ports. Host Port is Port0 and External Ports are Port1 and Port2.

24.11.4.8.5 FIFO Transmit Queue Control

There are four transmit queues in each transmit FIFO. Software has some flexibility in determining how packets are loaded into the queues and on how packet priorities are selected for transmission (how packets are removed and transmitted from queues). All ports on the switch have identical FIFO's. For the purposes of the below the transmit FIFO is switch egress even though the port 0 transmit FIFO is connected to the CPDMA receive (also switch egress). The CPDMA nomenclature is reversed from the CPGMAC_SL nomenclature due to legacy reasons.

Copyright © 2015–2017, Texas Instruments Incorporated

24.11.4.8.5.1 Normal Priority Mode

When operating in normal mode, lower priority frames are dropped before higher priority frames. The intention is to give preference to higher priority frames. Priority 3 is the highest priority and is allowed to fill the FIFO. Priority 2 will drop packets if the packet is going to take space in the last 2k available. Priority 1 will drop packets if the packet is going to take space in the last 4k available. Priority 0 will drop packets if the packet is going to take space in the last 6k available. If fewer than 4 priorities are to be implemented then the priorities should be mapped such that the highest priorities are used. For example, if two priorities are going to be used then all packets should be mapped to priorities 3 and 2 and priorities 1 and 0 should be unused. Priority escalation may be used in normal priority mode if desired. Normal priority mode is configured as described below:

- Select normal priority mode by setting TX_IN_SEL = 00 for all ports (default value in P0/1/2_TX_IN_CTL)
- Configure priority mapping to use only the highest priorities if less than 4 priorities are used. Refer to Section 24.11.4.8.3, *Packet Priority Handling*.

24.11.4.8.5.2 Dual MAC Mode

When operating in dual MAC mode the intention is to transfer packets between ports 0 and 1 and ports 0 and 2, but not between ports 1 and 2. Each CPGMAC_SL appears as a single MAC with no bridging between MAC's. Each CPGMAC_SL has at least one unique (not the same) mac address.

Dual MAC mode is configured as described below:

- Set the ALE_VLAN_AWARE bit in the ALE_CONTROL register. This bit configures the ALE to process in VLAN aware mode. The CPSW_3G VLAN aware bit (VLAN_AWARE in CPSW_CONTROL) determines how packets VLAN's are processed on CPGMAC_SL egress and does not affect how the ALE processes packets or the packet destination. The CPSW_3G VLAN aware bit may be set or not as required (must be set, if VLAN's are to exit the switch).
- Configure the Port 1 to Port 0 VLAN
  - Add a VLAN Table Entry with ports 0 and 1 as members (clear the flood masks).
  - Add a VLAN/Unicast Address Table Entry with the Port1/0 VLAN and a port number of 0. Packets received on port 1 with this unicast address will be sent only to port 0 (egress). If multiple mac addresses are desired for this port then multiple entries of this type may be configured.
- Configure the Port 2 to Port 0 VLAN
  - Add a VLAN Table Entry with ports 0 and 2 as members (clear the flood masks).
  - Add a VLAN/Unicast Address Table Entry with the Port2/0 VLAN and a port number of 0. Packets received on port 2 with this unicast address will be sent only to port 0 (egress). If multiple mac addresses are desired for this port then multiple entries of this type may be configured.
- Packets from the host (port 0) to ports 1 and 2 should be directed. If directed packets are not desired then VLAN with addresses can be added for both destination ports.
- Select the dual mac mode on the port 0 FIFO by setting TX_IN_SEL = 01 in P0_TX_IN_CTL. The intention of this mode is to allow packets from both ethernet ports to be written into the FIFO without one port starving the other port.
- The priority levels may be configured such that packets received on port 1 egress on one CPDMA RX channel while packets received on port 2 egress on a different CPDMA RX channel.

24.11.4.8.5.3 Rate Limit Mode

Rate-limit mode is intended to allow some CPDMA transmit (switch ingress) channels and some CPGMAC_SL FIFO priorities (switch egress) to be rate-limited. Non rate-limited traffic (bulk traffic) is allowed on non rate-limited channels and FIFO priorities. The bulk traffic does not impact the rate-limited traffic. Rate-limited traffic must be configured to be sent to rate-limited queues (via packet priority handling). The allocated rates for rate-limited traffic must not be oversubscribed. For example, if port 1 is sending 15% rate limited traffic to port 2 priority 3, and port 0 is also sending 10% rate-limited traffic to

Copyright © 2015–2017, Texas Instruments Incorporated

port 2 priority 3, then the port 2 priority 3 egress rate must be configured to be 25% plus a percent or two for margin. The switch must be configured to allow some percentage of non rate-limited traffic. Non rate-limited traffic must be configured to be sent to non rate-limited queues. No packets from the host should be dropped, but non rate-limited traffic received on an ethernet port can be dropped. Rate-limited mode is configured as shown below:

1. Set TX_IN_SEL = 10 in P1/2_TX_IN_CTL to enable ports 1 and 2 transmit FIFO inputs to be configured for rate-limiting queues. Enabling a queue to be rate-limiting with this field affects only the packet being loaded into the FIFO, it does not configure the transmit for queue shaping.
2. Configure the number of rate-limited queues for port 1 and 2 transmit FIFO's by setting the TX_RATE_EN field in P1/2_TX_IN_CTL. Rate limited queues must be the highest number. For example, if there are two rate limited queues then 1100 would be written to this field for priorities 3 and 2. This field enables the FIFO to allow rate-limited traffic into rate-limited queues while discriminating against non rate-limited queues.
3. Set P1_PRIN_SHAPE_EN and P2_PRIN_SHAPE_EN in the CPSW_PTYPE register. These bits determine which queues actually shape the output data stream. In general, the same priorities that are set in TX_RATE_EN are set in these bits as well, but the FIFO input and output enable bits are separate to allow rate-limiting from the host to non shaped channels if desired. When queue shaping is not enabled for a queue then packets are selected for egress based on priority. When queue shaping is enabled then packets are selected for egress based on queue percentages. If shaping is required on a single queue then it must be priority 3 (priorities 2, 1 and 0 are strict priority). If shaping is required on two queues then it must be on priorities 2 and 3 (priorities 1 and 0 are strict priority). If shaping is required on three queues then it must be priorities 3, 2, and 1 (priority 0 would then get the leftovers). Priority shaping follows the requirements in the IEEE P802.1Qav/D6.0 specification. Priority shaping is not compatible with priority escalation (escalation must be disabled).
4. P0_TX_IN_CTL[17:16] TX_IN_SEL should be set to 00, so Port 0 egress (CPDMA RX) is not rate-limited.
5. The CPDMA is configured for rate-limited transmit (switch ingress) channels by setting the highest bits of the TX_RLIM field in the CPDMA_DMACONTROL register. If there are two rate-limited channels, then TX_RLIM = 11000000 (the rate limited channels must be the highest priorities). Also, the TX_PTYPE bit in the CPDMA_DMACONTROL register must be set (fixed priority mode). Rate-limited channels must go to rate-limited FIFO queues, and the FIFO queue rate must not be oversubscribed.

24.11.4.8.6 Audio Video Bridging

Audio Video Bridging is an ongoing project of IEEE 802.1 concerned with enabling low-latency streaming of time-sensitive audiovisual data over networks. Devices are designated as talkers (transmitters), bridges, or listeners (receivers). It is suggested that the maximum latency could be 2 ms over 7 hops for Class A devices and 20 ms over 7 hops for Class B devices. A hop is essentially a single local area network stage in the journey of a packet. Every time a bridge is encountered between one network section and another a hop is involved. One of the performance goals is that AVB streams will not use more than 75 percent of a link's bandwidth, leaving the remaining capacity for non-AVB streams.

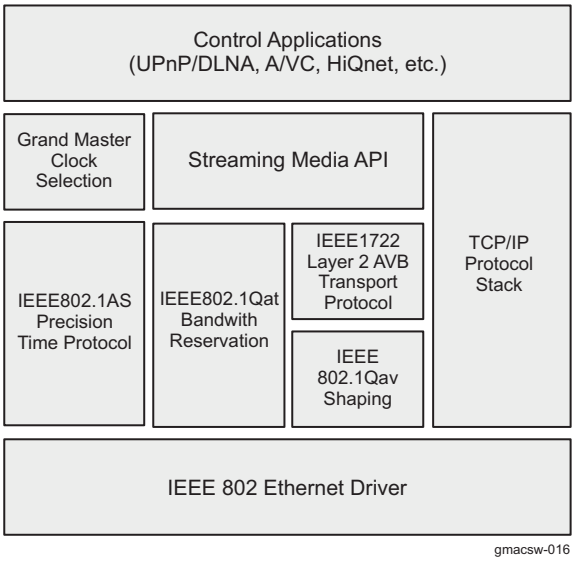
The goal of developing AVB is simply--extend Ethernet's data-networking capabilities to the realm of reliable real-time audio/video networking.

An "Audio Video Bridging" network is one that implements a set of protocols being developed by the IEEE 802.1 Audio/Video Bridging Task Group. There are four primary differences between the proposed Audio Video Bridging architecture and existing 802 architectures (from now on the term "AVB" will be used instead of "Audio Video Bridging"):

1. Precise synchronization - IEEE 802.1AS: "*Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks.* "a.k.a Precision Time Protocol (PTP).
2. Traffic shaping for media streams - IEEE 802.1Qav: "*Virtual Bridged Local Area Networks:* Forwarding and Queuing for Time-Sensitive Streams."
3. Admission controls - IEEE 802.1Qat: "*Virtual Bridged Local Area Networks - Amendment 9:* Stream Reservation Protocol (SRP)."
4. Identification of non-participating devices - IEEE 802.1BA: "Audio/Video Bridging (AVB) Systems"

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 24-194. The Network Static with AVB



The following sections describe the media transport protocols that work within the AVB framework.

24.11.4.8.6.1 IEEE 802.1AS: Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks (Precision Time Protocol (PTP))

The protocol defined by 802.1AS automatically selects a device to be the master clock, and then distributes this clock throughout the bridged LAN / IP subnet to all other network devices using link-specific transmit/receive time-stamping. However, we only use a two-step solution only on transmit. That is, we do not modify a packet with the timestamp on the way out. The timestamp packet is sent out and then a separate message with the timestamp is sent by the host afterward. Receive can be one or two step.

NOTE: The 802.1AS-distributed clock is not used as a media clock. Rather, the shared 802.1AS clock reference is used to regenerate the media clock at the listener/renderer. Such a reference removes the need to force the latency of the network to be constant, or compute long running averages in order to estimate the actual media rate of the transmitter in the presence of substantial network jitter. IEEE 802.1AS is based on the ratified IEEE 1588 standard.

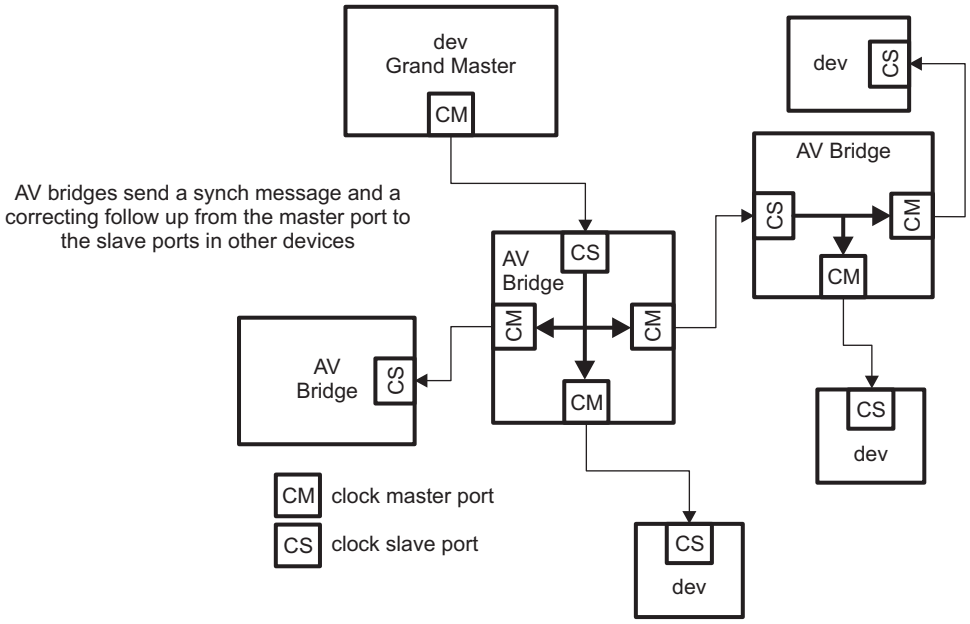
Based on IEEE 1588:2002,Â PTP devices exchange standard Ethernet messages that synchronize network nodes to a common time reference by defining clock master selection and negotiation algorithms, link delay measurement and compensation, and clock rate matching and adjustment mechanisms.

Designed as a simplified profile of IEEE 1588, a primary difference between 1588 and IEEE 802.1AS is that PTP is a layer 2--in other words, a non-IP routable protocol. Like IEEE 1588, PTP defines an automatic method for negotiating the network clock master, the Best Master Clock Algorithm (BMCA). PTP nodes can be assigned one of eight priority levels, presumably based on clock quality. BMCA defines the underlying negotiation and signaling mechanism whose purpose is to identify the AVB LAN Grandmaster. Once a Grandmaster has been selected, synchronization automatically begins.

Copyright © 2015–2017, Texas Instruments Incorporated

At the core of 802.1AS synchronization is time-stamping. In short, during PTP message ingress/egress from the 802.1AS-capable MAC, the PTP Ether type triggers the sampling of the value of a local real-time counter (RTC). Slave nodes compare the value of their RTC against the PTP Grandmaster and, by use of link delay measurement and compensation techniques, match their RTC value to the time of the AVB LAN PTP domain. After network time throughout the AVB LAN has converged, periodic SYNC and FOLLOW_UP messages provide the information that enables the PTP rate matching adjustment algorithms. The result is all PTP nodes are then synchronized to the same "Wall Clock" time. PTP assures 1-µs accuracy over seven network hops.

Figure 24-195. AVB Network & PTP Clock Entities



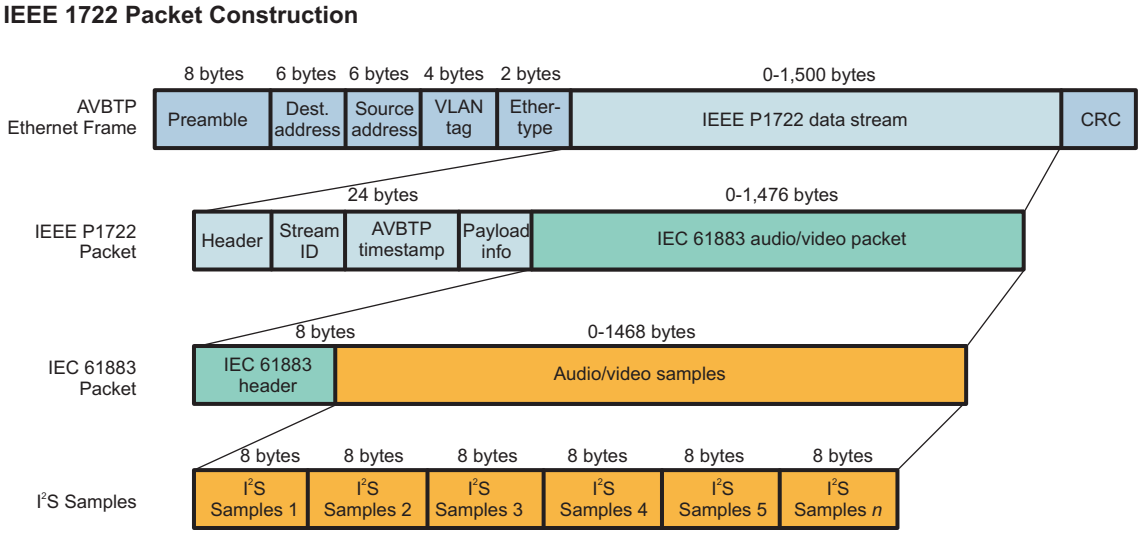
The media transport protocols that work within the AVB framework are:

24.11.4.8.6.1.1 IEEE 1722: "Layer 2 Transport Protocol for Time-Sensitive Streams"

AVBTP or 1722 sits above the IEEE 802.1 AVB plumbing and below the application layer. It acts as the conduit between an Ethernet MAC and a streaming application. AVBTP abstracts the underlying network transmission channel to enable the virtual connection of distributed audio and video CODECs over reliable Ethernet networks. A complete AVBTP Ethernet packet is shown in Figure 24-196 and illustrates how IEC 61883-6 AM824 uncompressed audio samples are encapsulated in an Ethernet frame.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 24-196. IEEE 1722 Packets



1722 or AVBTP Presentation Time and Synchronization:

Synchronization in an AVB network starts with the Precision Time Protocol but ends with synchronized media clocks. PTP is responsible for synchronizing all nodes in an AVB network to identical wall clock time; not for synchronizing media clocks. In other words, PTP does not actually transport synchronized media clocks but instead provides a low-level building block crucial for managing a distributed media synchronization system.

A crucial benefit of this approach is coexistence of multiple, independent media clock domains on an AVB network. Unrelated audio and video streams can simultaneously exist in the same LAN.

AVBTP assumes that AVB node media clocks are clocked by free-running oscillators. It is also assumed that the node's internal concept of wall clock time has been synchronized to the PTP Grandmaster. AVBTP media clock sources embed "AVBTP Presentation Timestamps" in AVBTP streaming packets. Figure 24-197 illustrates the relationship between PTP network time and AVBTP Presentation Timestamps.

24.11.4.8.6.1.2 IEEE 1733: Extends RTCP for RTP Streaming over AVB-supported Networks

This standard specifies the protocol, data encapsulations, connection management and presentation time procedures used to ensure interoperability between audio and video based end stations that use standard networking services provided by all IEEE 802 networks meeting QoS requirements for time-sensitive applications by leveraging the Real-time Transport Protocol (RTP) family of protocols and IEEE 802.1 Audio/Video Bridging (AVB) protocols.

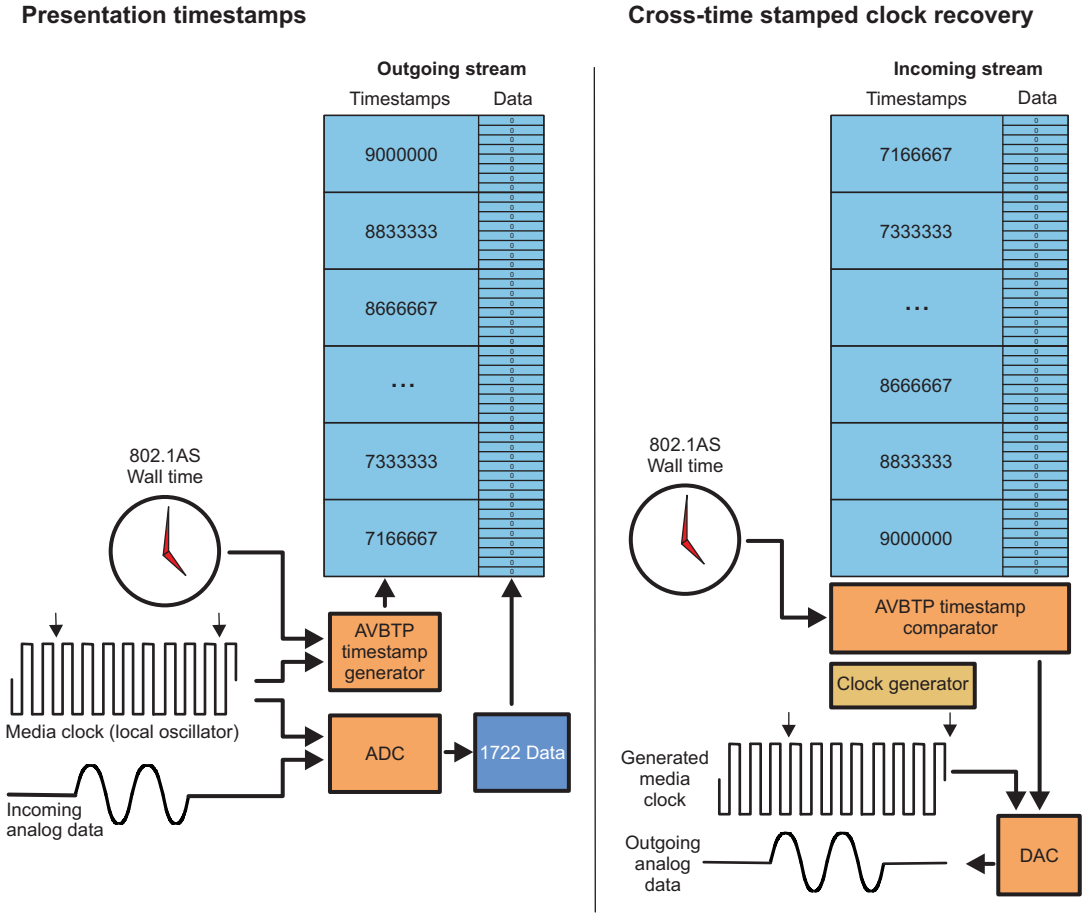
Figure 24-197. Cross Time Stamping and Presentation Timestamps



24.11.4.8.6.2 IEEE 802.1Qav: "Virtual Bridged Local Area Networks: Forwarding and Queuing for Time-Sensitive Streams"

This standard allows bridges to provide guarantees for time-sensitive (that is, bounded latency and delivery variation), loss-sensitive real-time audio video (AV) data transmission (AV traffic). It specifies per priority ingress metering, priority regeneration, and timing-aware queue draining algorithms. This standard uses the timing derived from IEEE 802.1AS. Virtual Local Area Network (VLAN) tag encoded priority values are allocated, in aggregate, to segregate frames among controlled and non-controlled queues, allowing simultaneous support of both AV traffic and other bridged traffic over and between wired and wireless Local Area Networks (LANs).

Such a guarantee in bandwidth is provided by two functional entities:

- A registration protocol, which registers the service and its maximum network utilization with a device or switch (IEEE 802.1Qat: "Virtual Bridged Local Area Networks - Amendment 9: Stream Reservation Protocol (SRP)")
- A hardware bandwidth management service.
  - Receive policing and
  - Transmit rate control.

End Station Behavior

In order for an end station to successfully participate in the transmission and reception of time-sensitive streams, it is necessary for their behavior to be compatible with the operation of the forwarding and queuing mechanisms employed in bridges.

Copyright © 2015–2017, Texas Instruments Incorporated

The requirements for end stations that participate as "talkers" i.e., sources of time-sensitive streams are different from the requirements that apply to "listeners", the destination station(s) for the streams.

Talker Behavior

In order for Talker-originated data streams to make use of the credit-based shaper behavior in Bridges, it is a requirement for a Talker to use the priorities that the Bridges in the network recognize as being associated with SR classes exclusively for transmitting stream data.

It is also necessary for the Talker and the Bridges in the path to the Listener(s), to have a common view of the bandwidth required in order to transmit the Talker's streams, and for that bandwidth to be reserved along the path to the Listener(s). This latter requirement can be met by means of stream reservation mechanisms, such as defined in SRP, or by other management means.

End stations that are Talkers shall exhibit transmission behavior for frames that are part of "time-sensitive streams" that is consistent with the operation of the credit-based shaper algorithm, both in terms of the way they transmit frames that are part of an individual data stream, and in terms of the way they transmit stream data frames from a Port.

In effect, the queuing model for a Talker Port (and a Listener port), and for given priorities, can be considered to look like Figure 24-198.

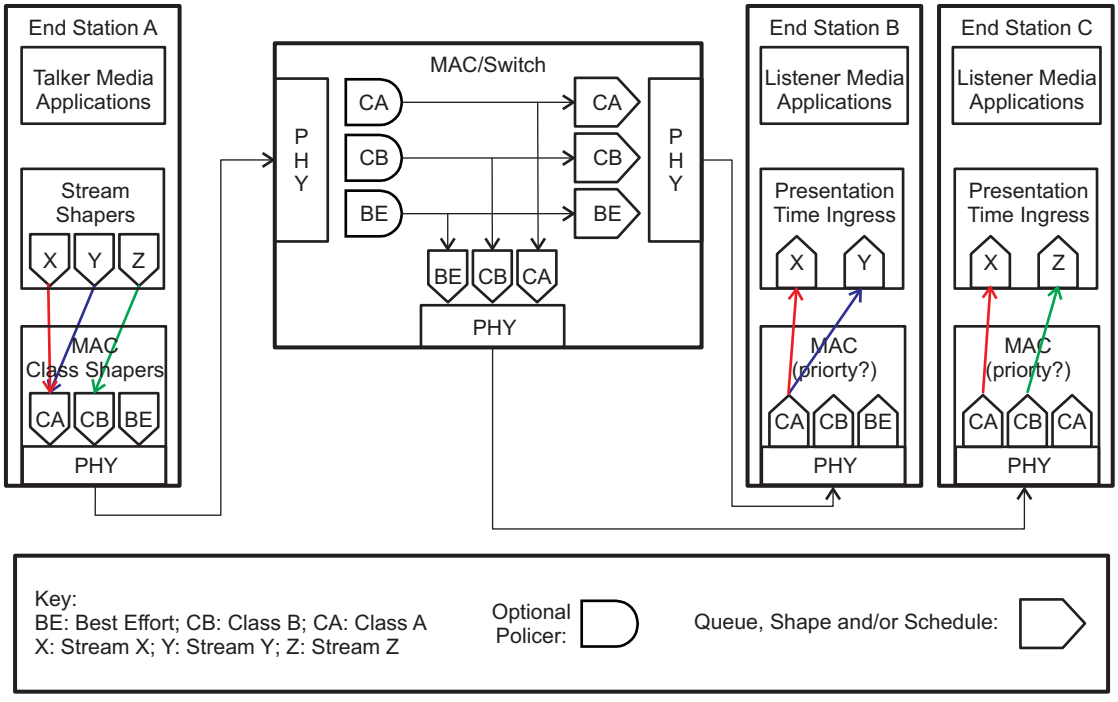
Listener Behavior

The primary requirement for a listener station is that it is capable of buffering the amount of data that could be transmitted for a stream during a time period equivalent to the accumulated maximum jitter that could be experienced by stream data frames in transmission between Talker and Listener.

From the point of view of the specification of the forwarding and queuing requirements for time-sensitive streams, it is assumed that the listener will assess the buffering required for a stream as part of the stream bandwidth reservation mechanisms employed by the implementation.

The credit-based shaper's operation details are beyond the scope of this document.

Figure 24-198. AV Stream Queuing/Policing



24.11.4.8.6.2.1 Configuring the Device for 802.1Qav Operation:

There is no dedicated register-set to be configured for the time-sensitive stream handling. The list of functional features of CPSW_3G that will have to be configured are:

0	3	0
0	1	0

- ALE Configuration:
  - ALE in VLAN-ware mode, Non-ALE in bypass mode.

Table 24-1251. Example of Rate-limit Configurations

Register	Value	Description
CPSW_PTYPE	0x0006 0000	For Port1 -- 2 highest priority channels.
P1_TX_IN_CTL[23:20] TX_RATE_EN	0b1100	2 highest priority channels are rate limited
P1_TX_IN_CTL[17:16] TX_IN_SEL	0b10	Rate limit mode
P1_SEND_PERCENT	0x14 3E00	20% PRI7, 62% PRI5
CPDMA_DMACONTROL	0xC001	Chan7, Chan6 are Rate Limited. Round-robin selection of DMA channel.
CPDMA_TX_PRI7_RATE	0x1 0013	200 Mbps
CPDMA_TX_PRI6_RATE	0x1 0005	~600 Mbps

24.11.4.8.7 Ethernet MAC Sliver (CPGMAC_SL)

The CPGMAC_SL peripheral shall be compliant to the IEEE Std 802.3 Specification. Half-duplex mode is supported in 10/100 Mbps mode, but not in 1000 Mbps (gigabit) mode.

Features:

- Synchronous 10/100/1000 Mbit operation
- G/MII Interface
- Hardware Error handling including CRC
- Full-Duplex Gigabit operation (half-duplex gigabit is not supported)
- EtherStats and 802.3Stats RMON statistics gathering support for external statistics collection module
- Transmit CRC generation selectable on a per channel basis
- Emulation Support
- VLAN Aware Mode Support
- Hardware flow control

Copyright © 2015–2017, Texas Instruments Incorporated

- Programmable Inter Packet Gap (IPG).

24.11.4.8.7.1 G/MII Media Independent Interface

The following sections cover operation of the Media Independent Interface in 10/100/1000 Mbps modes. An IEEE 802.3 compliant Ethernet MAC controls the interface.

24.11.4.8.7.1.1 Data Reception

24.11.4.8.7.1.1.1 Receive Control

Data received from the PHY is interpreted and output. Interpretation involves detection and removal of the preamble and start of frame delimiter, extraction of the address and frame length, data handling, error checking and reporting, cyclic redundancy checking (CRC), and statistics control signal generation.

24.11.4.8.7.1.1.2 Receive Inter-Frame Interval

The 802.3 required inter-packet gap (IPG) is 24 GMII clocks (96 bit times) for 10/100 Mbit modes, and 12 GMII clocks (96 bit times) for 1000 Mbit mode. However, the MAC can tolerate a reduced IPG (2 GMII clocks in 10/100 mode and 5 GMII clocks in 1000 mode) with a correct preamble and start frame delimiter.

This interval between frames must comprise (in the following order):

- An Inter-Packet Gap (IPG).
- A seven octet preamble (all octets 0x55).
- A one octet start frame delimiter (0x5D).

24.11.4.8.7.1.2 Data Transmission

The Gigabit Ethernet Mac Sliver (GMII) passes data to the PHY when enabled. Data is synchronized to the transmit clock rate. The smallest frame that can be sent is two bytes of data with four bytes of CRC (6 byte frame).

24.11.4.8.7.1.2.1 Transmit Control

A jam sequence is output if a collision is detected on a transmit packet. If the collision was late (after the first 64 bytes have been transmitted) the collision is ignored. If the collision is not late, the controller will back off before retrying the frame transmission. When operating in full duplex mode the carrier sense (CRS) and collision sensing modes are disabled.

24.11.4.8.7.1.2.2 CRC Insertion

The MAC generates and appends a 32-bit Ethernet CRC onto the transmitted data, if the transmit packet header PASS_CRC bit is 0. For the CPMAC_SL generated CRC case, a CRC at the end of the input packet data is not allowed.

If the header word PASS_CRC bit is set, then the last four bytes of the TX data are transmitted as the frame CRC. The four CRC data bytes should be the last four bytes of the frame and should be included in the packet byte count value. The MAC performs no error checking on the outgoing CRC when the PASS_CRC bit is set.

24.11.4.8.7.1.2.3 MTXER

The MTXER signal is only used for EEE. If an underflow condition occurs on a transmitted frame, the frame CRC will be inverted to indicate the error to the network. Underflow is a hardware error.

Copyright © 2015–2017, Texas Instruments Incorporated

24.11.4.8.7.1.2.4 Adaptive Performance Optimization (APO)

The Ethernet MAC port incorporates Adaptive Performance Optimization (APO) logic that may be enabled by setting the TX_PACE bit in the SL_MACCONTROL register. Transmission pacing to enhance performance is enabled when set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions) thereby increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision or excessive collision) the pacing counter is decremented by one, down to zero.

With pacing enabled, a new frame is permitted to immediately (after one IPG) attempt transmission only if the pacing counter is zero. If the pacing counter is non zero, the frame is delayed by the pacing delay, a delay of approximately four inter-packet gap delays. APO only affects the IPG preceding the first attempt at transmitting a frame. It does not affect the back-off algorithm for re-transmitted frames.

24.11.4.8.7.1.2.5 Inter-Packet-Gap Enforcement

The measurement reference for the IPG of 96 bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision, and MCRS is de-asserted within approximately 48 bit times of MTXEN being de-asserted, then 96 bit times is measured from MTXEN. If the frame suffered a collision, or if MCRS is not de-asserted until more than approximately 48 bit times after MTXEN is de-asserted, then 96 bit times (approximately, but not less) is measured from MCRS.

The transmit IPG can be shortened by eight bit times when enabled and triggered. The TX_SHORT_GAP_EN bit in the SL_MACCONTROL register enables the TX_SHORT_GAP input to determine whether the transmit IPG is shorted by eight bit times.

24.11.4.8.7.1.2.6 Back Off

The Gigabit Ethernet Mac Sliver (GMII) implements the 802.3 binary exponential back-off algorithm.

24.11.4.8.7.1.2.7 Programmable Transmit Inter-Packet Gap

The transmit inter-packet gap (IPG) is programmable through the SL_TX_GAP register. The default value is decimal 12. The transmit IPG may be increased to the maximum value of 1FFh. Increasing the IPG is not compatible with transmit pacing. The short gap feature will override the increased gap value, so the short gap feature may not be compatible with an increased IPG.

24.11.4.8.7.1.2.8 Speed, Duplex and Pause Frame Support Negotiation

The CPMAC_SL can operate in half duplex or full duplex in 10/100 Mbit modes, and can operate in full duplex only in 1000 Mbit mode. Pause frame support is included in 10/100/1000 Mbit modes as configured by the host.

24.11.4.8.7.2 RMII Interface

The CPRMII peripheral is compliant to the RMII specification document.

24.11.4.8.7.2.1 Features

- Source Synchronous 10/100 Mbit operation
- Full and Half Duplex support

24.11.4.8.7.2.2 RMII Receive (RX)

The CPRMII receive (RX) interface converts the input data from the external RMII PHY (or switch) into the required MII (CPGMAC) signals. The carrier sense and collision signals are determined from the RMII input data stream and transmit inputs as defined in the RMII specification.

Copyright © 2015–2017, Texas Instruments Incorporated

An asserted RMRXER on any di-bit in the received packet will cause an MRXER assertion to the CPGMAC during the packet. In 10Mbps mode, the error is not required to be duplicated on 10 successive clocks. Any di-bit which has an asserted RMII_RXER during any of the 10 replications of the data will cause the error to be propagated.

Any received packet that ends with an improper nibble boundary aligned RMCRSDV toggle will issue an MRXER during the packet to the CPGMAC. Also, a change in speed or duplex mode during packet operations will cause packet corruption.

The CPRMII can accept receive packets with shortened preambles, but 0x55 followed by a 0x5D is the shortest preamble that will be recognized (1 preamble byte with the start of frame byte). At least one byte of preamble with the start of frame indicator is required to begin a packet. An asserted RMCRSDV without at least a single correct preamble byte followed by the start of frame indicator will be ignored.

24.11.4.8.7.2.3 RMII Transmit (TX)

The CPRMII transmit (TX) interface converts the GMAC_SW MII input data into the RMII transmit format. The data is then output to the external RMII PHY.

The GMAC_SW does not source the transmit error (MII TXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be de-asserted at all times and is not an input into the CPRMII module. Zeroes are output on RMTXD[1:0] for each clock that RMTXEN is de-asserted.

24.11.4.8.7.3 RGMII Interface

The CPRGMII peripheral is compliant to the RGMII specification document.

24.11.4.8.7.3.1 RGMII Features

- Supports 1000/100/10 Mbps speed
- In SR1.0, Internal TXC delay on transmit is always enabled. SR1.0 information is valid only for the AM571x family of devices.
- In SR2.0, Internal TXC delay on transmit can be enabled or disabled using bits [26] RGMII2_ID_MODE_N and [25] RGMII1_ID_MODE_N of the CTRL_CORE_SMA_SW_1 register.
- MII mode is not supported

24.11.4.8.7.3.2 RGMII Receive (RX)

The CPRGMII receive (RX) interface converts the source synchronous DDR input data from the external RGMII PHY into the required G/MII (CPGMAC) signals.

24.11.4.8.7.3.3 In-Band Mode of Operation

The CPRGMII is operating in the in-band mode of operation when the EXT_EN bit of the SL_MACCONTROL register is set to 1. The link status, duplexity, and speed are determined from the RGMII input data stream RXD[3:0] when RX_CTL is deasserted, as defined in the RGMII specification. The PHY might need to be configured beforehand to output in-band data. The in-band data is indicated as shown in Table 24-1252.

Table 24-1252. In-Band Data

RXD3	RXD[2:1]		RXD0
Duplex status:	Link Speed:	RXC_CLK Speed:	Link Status:
0: half-duplex	00: 10-Mbps mode	2.5 MHz	0: Link is down
1: full-duplex	01: 100-Mbps mode	25 MHz	1: Link is up
	10: 1000-Mbps mode	125 MHz	
	11: reserved	reserved	

Copyright © 2015–2017, Texas Instruments Incorporated

24.11.4.8.7.3.4 Forced Mode of Operation

The CPRGMII is operating in the forced mode of operation when the EXT_EN bit of the SL_MACCONTROL register is set to 0. In the forced mode of operation, the in-band data is ignored if present. The link status is forced high, and the duplexity and speed are determined from the SL_MACCONTROL[0] FULLDUPLEX and [7] GIG bits. If GIG = 1, then operation is gigabit mode. If the GIG is 0, the operation is 100 Mbps mode.

24.11.4.8.7.3.5 RGMII Transmit (TX)

The CPRGMII transmit (TX) interface converts the CPGMAC G/MII input data into the DDR RGMII format. The DDR data is then output to the external PHY.

The CPGMAC does not source the transmit error (TXERR) signal. Any transmit frame from the CPGMAC with an error (underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be de-asserted at all times and is not an input into the CPRGMII module.

The TXD[7:0] data bus uses only the lower nibble. The CPRGMII will output the lower nibble twice in 10/100 mode to avoid unnecessary signal switching.

Packets will be precluded from transmission through the CPRGMII module for 4096 transmit clocks after the rising edge of RGMII_LINK. Packet transmission will begin on the first TX_CTL rising edge after the 4096 transmit clock count has expired.

24.11.4.8.7.4 Frame Classification

Received frames are proper (good) frames if they are between 64 and RX_MAXLEN in length (inclusive) and contain no errors (code/align/CRC).

Received frames are long frames if their frame count exceeds the value in the SL_RX_MAXLEN register. The SL_RX_MAXLEN register reset (default) value is 1518 (decimal). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames if their frame count is less than 64 bytes. Short frames that contain no errors are undersized frames. Short frames with CRC, code, or alignment errors are fragment frames.

A received long packet will always contain RX_MAXLEN number of bytes transferred to memory (if RX_CEF_EN = 1). An example with RX_MAXLEN = 1518 is:

- If the frame length is 1518, then the packet is not a long packet and there will be 1518 bytes transferred to memory.
- If the frame length is 1519, there will be 1518 bytes transferred to memory. The last three bytes will be the first three CRC bytes.
- If the frame length is 1520, there will be 1518 bytes transferred to memory. The last two bytes will be the first two CRC bytes.
- If the frame length is 1521, there will be 1518 bytes transferred to memory. The last byte will be the first CRC byte.

If the frame length is 1522, there will be 1518 bytes transferred to memory. The last byte will be the last data byte.

24.11.4.8.8 Embedded Memories

Table 24-1253. Embedded Memories

Memory Type Description	Number of Instances	
Single-port 2560 × 64 RAM	3	(Packet FIFO's)
Single-port 64-word × 1152-bit RAM	1	(ALE)
Single-port 2048-word × 32-bit RAM	1	(CPPI)

Copyright © 2015–2017, Texas Instruments Incorporated

24.11.4.8.9 Flow Control

There are two types of switch flow control: CPPI port flow control and Ethernet port flow control. The CPPI and Ethernet port naming conventions for data flow into and out of the switch are reversed. For the CPPI port (port 0), transmit operations move packets from external memory into the switch and then out to either or both Ethernet transmit ports (ports 1 and 2). CPPI receive operations move packets that were received on either or both Ethernet receive ports to external memory.

24.11.4.8.9.1 CPPI Port Flow Control

The CPPI port has flow control available for transmit (switch ingress). CPPI receive operations (switch egress) do not require flow control. CPPI Transmit flow control is initiated when enabled and triggered. CPPI transmit flow control is enabled by setting the P0_FLOW_EN bit in the CPSW_FLOW_CONTROL register. CPPI transmit flow control is enabled by default on reset because host packets should not be dropped in any mode of operation.

24.11.4.8.9.2 Ethernet Port Flow Control

The Ethernet ports have flow control available for transmit and receive. Transmit flow control stops the Ethernet port from transmitting packets to the wire (switch egress) in response to a received pause frame. Transmit flow control does not depend on FIFO usage.

The ethernet ports have flow control available for receive operations (packet ingress). Ethernet port receive flow control is initiated when enabled and triggered. Packets received on an ethernet port can be sent to the other ethernet port or the CPPI port (or both). Each destination port can trigger the receive ethernet port flow control. An ethernet destination port triggers another ethernet receive flow control when the destination port is full.

When a packet is received on an ethernet port interface with enabled flow control the below occurs:

- The packet will be sent to all ports that currently have room to take the entire packet.
- The packet will be retried until successful to all ports that indicate they don't have room for the packet.

The flow control trigger to the CPGMAC_SL will be asserted until the packet has been sent, and there is room in the logical receive FIFO for packet runout from another flow control trigger (RX_PKT_CNT = 0). Ethernet port receive flow control is disabled by default on reset. Ethernet port receive flow control requires that the RX_FLOW_EN bit in the associated CPGMAC_SL be set to 1. When receive flow control is enabled on a port, the port's associated FIFO block allocation must be adjusted. The port RX allocation must increase from the default three blocks to accommodate the flow control runout. A corresponding decrease in the TX block allocation is required. If a sending port ignores a pause frame then packets may overrun on receive (and be dropped) but will not be dropped on transmit. If flow control is disabled for G/MII ports, then any packets that are dropped are dropped on transmit and not on receive.

24.11.4.8.9.2.1 Receive Flow Control

When enabled and triggered, receive flow control is initiated to limit the CPGMAC_SL from further frame reception. Half-duplex mode receive flow control is collision based while full duplex mode issues 802.3X pause frames. In either case, receive flow control prevents frame reception by issuing the flow control appropriate for the current mode of operation. Receive flow control is enabled by the RX_FLOW_EN bit in the SL_MACCONTROL register. Receive flow control is triggered (when enabled) when the RX_FLOW_TRIGGER input is asserted. The CPGMAC_SL is configured for collision or IEEE 802.3X flow control via the FULLDUPLEX bit in the SL_MACCONTROL register.

Copyright © 2015–2017, Texas Instruments Incorporated

24.11.4.8.9.2.1.1 Collision Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the port is operating in half-duplex mode (FULLDUPLEX is cleared in SL_MACCONTROL). When receive flow control is enabled and triggered, the port will generate collisions for received frames. The jam sequence transmitted will be the twelve byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3 (hex). The jam sequence will begin no later than approximately as the source address starts to be received. Note that these forced collisions will not be limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm. Receive flow control does not depend on the value of the incoming frame destination address. A collision will be generated for any incoming packet, regardless of the destination address.

24.11.4.8.9.2.1.2 IEEE 802.3X Based Receive Flow Control

IEEE 802.3x based receive flow control provides a means of preventing frame reception when the port is operating in full-duplex mode (FULLDUPLEX is set in SL_MACCONTROL). When receive flow control is enabled and triggered, the port will transmit a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The CPGMAC_SL will transmit a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle, or following the completion of the frame currently being transmitted). The pause frame will contain the maximum possible value for the pause time (FFFFh). The MAC will count the receive pause frame time (decrements FF00h down to 0) and retransmit an outgoing pause frame if the count reaches zero. When the flow control request is removed, the MAC will transmit a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval will be received normally (provided the RX FIFO is not full).

Pause frames will be transmitted if enabled and triggered regardless of whether or not the port is observing the pause time period from an incoming pause frame.

The CPGMAC_SL will transmit pause frames as:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01.
- The 48-bit source address - from SL_SA[47:0] input.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause time value FF.FF. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request will have a pause time value of 00.00.
- Zero padding to 64-byte data length (The CPGMAC_SL will transmit only 64 byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

If RX_FLOW_EN is cleared to 0 while the pause time is nonzero, then the pause time will be cleared to 0 and a zero count pause frame will be sent.

24.11.4.8.9.2.2 Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the CPGMAC_SL from transmitting any further frames. Incoming pause frames are only acted upon when the FULLDUPLEX and TX_FLOW_EN bits in the SL_MACCONTROL register are set. Pause frames are not acted upon in half-duplex mode. Pause frame action will be taken if enabled, but normally the frame will be filtered and not transferred to memory. MAC control frames will be transferred to memory if the RX_CMF_EN (copy MAC frames) bit in the SL_MACCONTROL register is set. The TX_FLOW_EN and FULLDUPLEX bits effect whether or not MAC control frames are acted upon, but they have no effect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC Control Frames with an opcode field = 0001h. Incoming pause frames will only be acted upon by the port if:

Copyright © 2015–2017, Texas Instruments Incorporated

- TX_FLOW_EN is set in SL_MACCONTROL register, and
- the frame's length is 64 to SL_RX_MAXLEN bytes inclusive, and
- the frame contains no CRC error or align/code errors.

The pause time value from valid frames will be extracted from the two bytes following the opcode. The pause time will be loaded into the port's transmit pause timer and the transmit pause time period will begin.

If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- if the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer will immediately expire, or
- if the new pause time value is zero then the transmit pause timer will immediately expire, else
- the port transmit pause timer will immediately be set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame will be discarded).

If TX_FLOW_EN in SL_MACCONTROL register is cleared, then the pause-timer will immediately expire.

The port will not start the transmission of a new data frame any sooner than 512-bit times after a pause frame with a non-zero pause time has finished being received (MRXDV going inactive). No transmission will begin until the pause timer has expired (the port may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received will be completed and unaffected.

Incoming pause frames consist of the below:

- A 48-bit destination address equal to:
  - The reserved multicast destination address 01.80.C2.00.00.01
  - , or the CPGMAC_SL SL_SA [47:0] input.
- The 48-bit source address of the transmitting device.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause_time. A pause-quantum is 512 bit-times.
- Padding to 64-byte data length.
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 bytes. The standard allows pause frames longer than 64 bytes to be discarded or interpreted as valid pause frames. The CPGMAC_SL will recognize any pause frame between 64 bytes and RX_MAXLEN bytes in length.

24.11.4.8.10 Short Gap

The port 1 (and port 2) transmit inter-packet gap (IPG) may be shortened by eight bit times when enabled and triggered. The TX_SHORT_GAP_EN bit in the SL_MACCONTROL register enables the gap to be shortened when triggered. The condition is triggered when the port 1 (port 2) transmit FIFO has a user defined number of FIFO blocks used. The port 1 transmit FIFO blocks used determines if the port 1 gap is shortened, and the port 2 transmit FIFO blocks used determines if the port 2 gap is shortened. The CPSW_GAP_THRESH register value determines the port 1 short gap threshold, and the CPSW_GAP_THRESH register value determines the port 2 short gap threshold.

24.11.4.8.11 Switch Latency

The CPSW_3G is a store and forward switch. The switch latency is defined as the amount of time between the end of packet reception of the received packet to the start of the output packet transmit.

Copyright © 2015–2017, Texas Instruments Incorporated

Table 24-1254. Switch Latency

Mode	Latency
Gig (1000)	880 ns
100	1.3 µs
10	6.5 µs

24.11.4.8.12 Emulation Control

The emulation control input (EMUSUSP) and submodule emulation control registers allow CPSW_3G operation to be completely or partially suspended. There are three CPSW_3G submodules that contain emulation control registers (CPGMAC_SL1, CPGMAC_SL2, and CPDMA). The submodule emulation control registers must be accessed to facilitate CPSW_3G emulation control. The CPSW_3G module enters the emulation suspend state if all three submodules are configured for emulation suspend and the emulation suspend input is asserted. A partial emulation suspend state is entered if one or two submodules is configured for emulation suspend and the emulation suspend input is asserted. Emulation suspend occurs at packet boundaries. The emulation control feature is implemented for compatibility with other peripherals.

CPGMAC_SL Emulation Control

The emulation control input (TBEMUSUP) and register bits (SOFT and FREE bits in the SL_EMCONTROL register) allow CPGMAC_SL operation to be suspended. When the emulation suspend state is entered, the CPGMAC_SL will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For receive, frames that are detected by the CPGMAC_SL after the suspend state is entered are ignored. Emulation control is implemented for compatibility with other peripherals.

CPDMA Emulation Control

The emulation control input (TBEMUSUP) and register bits (SOFT and FREE bits in the CPDMA_EMCONTROL register) allow CPDMA operation to be suspended. When the emulation suspend state is entered, the CPDMA will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the tx cell FIFO will be transmitted. For receive, frames that are detected by the CPDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Emulation control is implemented for compatibility with other peripherals

Table 24-1255 shows the operations of the emulation control input and register bits.

Table 24-1255. Emulation Control Input

EMUSUSP	SOFT	FREE	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend
1	X	1	Normal Operation

24.11.4.8.13 FIFO Loopback

FIFO loopback mode is entered when the FIFO_LOOPBACK bit in the CPSW_CONTROL register is set. FIFO loopback mode causes packets received on a port to be turned around and transmitted back on the same port. Port 0 receive is fixed on channel 0 in FIFO loopback mode. The RXSOFOVERRUN statistic is incremented for each packet sent in FIFO loopback mode. Packets sent in with errors are returned with errors (they are not dropped). FIFO loopback is intended as a simple mechanism for test purposes. FIFO loopback should be performed in fullduplex mode only.

Copyright © 2015–2017, Texas Instruments Incorporated

24.11.4.8.14 Device Level Ring (DLR) Support

Device Level Ring (DLR) support is enabled by setting the DLR_EN bit in the CPSW_CONTROL register. When enabled, incoming received DLR packets are detected and sent to queue 3 (highest priority) of the egress port(s). If the host port is the egress port for a DLR packet then the packet is sent on the CPDMA Rx channel selected by the P0_DLR_CPDMA_CH field in the P0_CONTROL register. The supervisor node MAC address feature is supported with the dlr_unicast bit in the unicast address table entry. When set, the dlr_unicast bit causes a packet with the matching destination address to be flooded to the vlan_member_list minus the receive port and minus the host port (the port_number field in the unicast address table entry is a don't care). Matching dlr_unicast packets are flooded regardless of whether the packet is a DLR packet or not. The EN_P0_UNI_FLOOD bit in the ALE_CONTROL register has no effect on DLR unicast packets. Packets are determined to be DLR packets as shown below:

1. DLR is enabled (DLR_EN is set in the CPSW_CONTROL).
2. One of the sequences below are true.
   (a) The first packet ltype matches CPSW_VLAN_LTYPE[15:0] VLAN_LTYPE1 and Px_CONTROL[20] Px_VLAN_LTYPE1_EN is set and the second packet ltype matches CPSW_DLR_LTYPE[15:0] DLR_LTYPE.
   (b) The first packet ltype matches CPSW_VLAN_LTYPE[31:16] VLAN_LTYPE2 and Px_CONTROL[21] Px_VLAN_LTYPE2_EN is set and the second packet ltype matches CPSW_DLR_LTYPE[15:0] DLR_LTYPE.
   (c) The first packet ltype matches CPSW_VLAN_LTYPE[15:0] VLAN_LTYPE1 and Px_CONTROL[20] Px_VLAN_LTYPE1_EN is set and the second packet ltype matches CPSW_VLAN_LTYPE[31:16] VLAN_LTYPE2 and Px_CONTROL[21] Px_VLAN_LTYPE2_EN is set and the third packet ltype matches CPSW_DLR_LTYPE[15:0] DLR_LTYPE.

24.11.4.8.15 Energy Efficient Ethernet Support (802.3az)

NOTE: CM_GMAC_CLKSTCTRL[1:0]CLKTRCTRL bit field must not be programmed for SW_SLEEP or HW_AUTO.

Energy Efficient Ethernet (EEE) allows the PRCM to turn off the module clock during inactive periods as determined by network and host traffic. The module can then be awakened by host queued transmit packet(s) or by a port's external Ethernet PHY. EEE operations are configured as shown below:

1. The 10-bit EEE clock pre-scale value is written to the CPSW_EEE_PRESCALE register. The pre-scaler is used to clock all EEE-related counters
2. The port Idle to LPI count values (Px_IDLE2LPI) are written with the desired values
3. The port LPI to Wake count values (Px_LPI2WAKE) are written with the desired values
4. The EEE_EN bit is set in the switch CPSW_CONTROL register
5. Set the WR_CONTROL[8] SS_EEE_EN bit to enable energy efficient operations at subsystem level.

EEE operation can begin after configuration. The host allows (through PRCM) the CPSW_3G to enter a low power state by asserting the CLKSTOP_REQ signal. There are no requirements on host queues or traffic in order for the host to assert or de-assert CLKSTOP_REQ to the CPSW_3G.

Each ethernet port has a transmit and a receive LPI (low power indicate) state. The receive LPI state is entered when the port's corresponding PHY indicates the LPI state via the CPSW_3G GMII interface. The PHY indicates LPI by asserting MRXER with a MRXD[7:0] value of 0x01 while MRXDV is deasserted (inter-packet gap). The Ethernet transmit port indicates LPI after the Px_IDLE2LPI value has been counted (the transmit port has gone idle for the configured amount of time). If another packet is received for transmit during the count then the count is restarted. When the transmit port has been idle for the Idle to LPI time, the transmit port enters the LPI state and indicates LPI to the associated PHY. The LPI is indicated to the external PHY by an asserted MTXER with a MTXD[7:0] while MTXEN is deasserted (inter-packet gap). The CPDMA LPI state includes transmit and receive. The CPDMA LPI state is entered when the CPDMA transmit and receive have both been idle for the Idle to LPI time (P0_IDLE2LPI). The Idle to LPI time value for all ports must be large relative to the switch latency to ensure that the count is not able to complete between successive packets.

Copyright © 2015–2017, Texas Instruments Incorporated

NOTE: The procedure above is described for the GMII interfaces at the CPSW_3G boundary. External PHY signaling has the following conditions:

- GMII interface is used only in MII mode. Therefore, only MRXD[3:0] and MTXD[3:0] are pinned out
- RGMII is a DDR interface. TXEN and TXER are the sampled values of TX_CTL at the rising and the falling TXC_CLK edges, respectively. RXDV and RXER are the sampled values of RX_CTL at the rising and the falling RXC_CLK edges, respectively
- In RMII mode, EEE is not supported.

When all transmit and receive ports are in the LPI state (CPSW LPI state), the CLKSTOP_ACK signal is asserted, and the PRCM is allowed to stop the module clock. When CLKSTOP_ACK is asserted, the clock may be turned on and off as desired by the host. The host is allowed to restart the clock, perform slave read/write operations to the CPSW_3G memory address space, and then turn off the clock again while CLKSTOP_ACK is asserted.

The software can remove and disable from re-entering the CPSW LPI state by restarting the module clock and then de-asserting CLKSTOP_REQ. The host may queue transmit packets at any time including without regard to the CPSW_3G LPI state (the clock must be restarted in order to write the CPSW_3G slave address space as described above). Host writes to transmit head descriptor pointers will cause the CLKSTOP_WAKEUP signal to be asserted if the CPSW_3G is in the low power state (if CLKSTOP_ACK is asserted).

The external Ethernet PHY's can also wakeup the PRCM by removing the Ethernet receive LPI indication. If the module is in the CPSW Idle state with CLKSTOP_ACK asserted and the receive LPI indication is removed, the CLKSTOP_WAKEUP signal will be asynchronously asserted. On wakeup, the PRCM restarts the clock and de-assert the CLKSTOP_REQ signal. The CLKSTOP_WAKEUP signal will be synchronously deasserted with CLKSTOP_ACK. Upon the deassertion of CLKSTOP_REQ, the Ethernet ports will count the Px_LPI2WAKE time for each port at which time the port is available for transmit. Upon the de-assertion of CLKSTOP_REQ, the CPDMA transmit will count the P0_LPI2WAKE count at which time the CPDMA will begin to send any packets that the host has queued (switch ingress). The wait time on CPDMA transmit is included to preclude the host from filling up the Ethernet port transmit FIFO's while the Ethernet ports are in the LPI to wake time. There is no LPI to wake time on CPDMA receive (switch egress).

24.11.4.8.16 CPSW_3G Network Statistics

The CPSW_3G has a set of statistics that record events associated with frame traffic on selected switch ports. The statistics values are cleared to zero 38 clocks after the rising edge of GMAC_RST. When one or more port enable (Pn_STAT_EN) bits in the CPSW_STAT_PORT_EN register are set, all statistics registers are write to decrement. The value written will be subtracted from the register value with the result being stored in the register. If a value greater than the statistics value is written, then zero will be written to the register (writing 0xFFFF FFFF clears a statistics location). When all port enable bits are cleared to zero, all statistics registers are read/write (normal write direct, so writing 0x0000 0000 clears a statistics location). All write accesses must be 32-bit accesses. In the below statistics descriptions, "the port" refers to any enabled port (with a corresponding set Pn_STAT_EN bit).

The statistics interrupt (STAT_PEND) will be issued if enabled when any statistics value is greater than or equal to 0x8000 0000. The statistics interrupt is removed by writing to decrement any statistics value greater than 0x8000 0000. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from 0xFFFF FFFF to 0x0000 0000.

See Section 24.11.6.5, *STATS Registers* for description of every network statistic.

Table 24-1256 and Table 24-1257 summarize network statistics.

Table 24-1256. Rx Statistics Summary

Rx Statistic	Frame /Oct	Rx/Rx +Tx	Frame Type					Frame Size (bytes)								Event				
			MAC control		Data[1]															
			Pause frame	Non-pause [3]	Multi cast	Broad cast	Uni cast	<64	64	65-127	128-255	256-511	512-1023	1024-rx_maxlen	>rx_maxlen	Flow Coll.[2]	CRC Error	Align/ Code	Overrun	Addr. Disc.
Good Rx Frames	F	R	(y|[4]	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-[5]	n	n	-	n
Broadcast Rx Frames	F	R	(%|[6]	%|	n	y)	n	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	n
Multicast Rx Frames	F	R	(%|	%|	y)	n	n	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	n
Pause Rx Frames	F	R	y	n	n	n	n	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	-
Rx CRC Errors	F	R	(y|	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-	y	n	-	n
Rx Align/Code Errors	F	R	(y|	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-	-	y	-	n
Oversized Rx Frames	F	R	(y|	y|	y|	y|	y)	n	n	n	n	n	n	n	y	-	n	n	-	n
Rx Jabbers	F	R	(y|	y|	y|	y|	y)	n	n	n	n	n	n	n	y	-	(y|	y)	-	n
Undersized Rx Frames	F	R	n	n	(y|	y|	y)	y	n	n	n	n	n	n	n	-	n	n	-	n
Rx Fragments	F	R	n	n	(y|	y|	y)	y^[7]	n	n	n	n	n	n	n	-	(y|	y)	-	-
Rx Overruns[8]	F	R	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y|	y)	-	-	-	y	n
64octet Frames	F	R+T[9]	(y|	y|	y|	y|	y)	n	y	n	n	n	n	n	n	-	-	-	-	n
65-127octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	y	n	n	n	n	n	-	-	-	-	n
128-255octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	y	n	n	n	n	-	-	-	-	n
256-511octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	n	y	n	n	n	-	-	-	-	n
512-1023octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	n	n	y	n	n	-	-	-	-	n
1024-UPoctet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	n	n	n	n	y	n	-	-	-	-	n
Rx Octets	O	R	(y|	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	n
Net Octets	O	R+T	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y|	y|	y)	-	-	-	-

(1) The multicast, broadcast and unicast columns in the table refer to non-MAC Control/non-pause frames (i.e. data frames).

(2) Flow coll. are half-duplex collisions forced by the MAC to achieve flow-control. A collision will be forced during the first 8 bytes so should not show in frame fragments. Some of the '-'s in this column might in reality be 'n's.

(3) The non-pause column refers to all MAC control frames (for example, frames with length/type=88.08) with opcodes other than 0x0001. The pauseframe column refers to MAC frames with the opcode=0x0001.

(4) "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.

(5) "-" indicates conditions which are ignored in the formations of the statistic.

(6) "%" If either a MAC control frame or pause frame has a multicast or broadcast destination address then the appropriate statistics will be updated.

(7) "y^" Frame fragments are not counted if less than 8 bytes.

(8) The rx_overruns stat is for RX_MOF_OVERRUNS and RX_SOF_OVERRUNS added together.

(9) Statistics marked "R+T" are formed by summing the Rx and Tx statistics, each of which is formed independently.

Multiple Collision Tx Frames	F	T	n	(y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	n	y	n	n	n	-	-	-
Excessive Collisions	F	T	n	(y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	n	n	y	n	n	-	-	-
Late Collisions	F	T	n	(y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	-	-	-	-	-	y	-	-	-	-
Deferred Tx Frames	F	T	n	(y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	n	n	n	n	n	-	y	n
Carrier Sense Errors	F	T	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	-	-	-	-	y	-	-	-
64octet Frames	F	R+T[8]	(y|	y|	y|	y|	y)	y	n	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-
65-127octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	y	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-
128-255octet Frames	F	R+T	(y|	y|	y|	y|	y)	n	n	y	n	n	n	n	-	-	-	-	n	n	n	-	-	-

(1) When the transmit Tx FIFO is drained due to the MAC being disabled or link being lost, then the frames being purged will not appear in the Tx statistics.

(2) Pause (MAC) frames are issued in the MAC as perfect (no CRC error) 64 byte frames in full duplex only, so they cannot collide.

(3) The flow collision type is for half-duplex collisions forced by the MAC to achieve flow control. Some of the '-'s in this column might in reality be 'n's. To prevent double-counting, Net Octets are unaffected by the jam sequence – the 'received' bytes, however, are counted. (See Table 24-1256.)

(4) "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning "OR" is indicated. Parentheses are significant.

(5) "-" indicates conditions which are ignored in the formations of the statistic.

(6) "%" If a CPU sourced MAC control frame has a multicast or broadcast destination address then the appropriate statistics will be updated.

(7) "+" indicates collisions which are "summed" (i.e. every collision is counted in the Collisions statistic). Jam sequences used for halfduplex flow control are also counted.

(8) Statistics marked "R+T" are formed by summing the Rx and Tx statistics, each of which is formed independently.

24.11.4.9 Static Packet Filter (SPF)

24.11.4.9.1 SPF Overview

The Static Packet Filter (SPF) provides protection against some of the most common forms of Denial of Service (DoS) attacks that exploit the Layer 3 and Layer 4 functions of the network stack running on a system. The DoS attacks that are mitigated by the SPF module are:

- ARP Flood
- Fraggle
- Illegal Fragment Offset
- Illegal TCP Options
- Jolt2
- Jolt
- Land
- Micro Fragment
- Null Scan
- Ping Flood
- Short ICMP Packet
- Smurf
- SSPing
- SYN Fragment
- TCP SYN Flood
- Xmas Scan

24.11.4.9.2 SPF Functional Description

24.11.4.9.2.1 SPF Block Diagram

Figure 24-199 shows the block diagram of the Static Packet Filter module. There are three main components of the static packet filter – packet header extractor to decode packet formats, rule engine to check for malformed protocol header fields and a host interface to provide control and configuration access to a host processor and to keep a log of filtered packets in system memory.

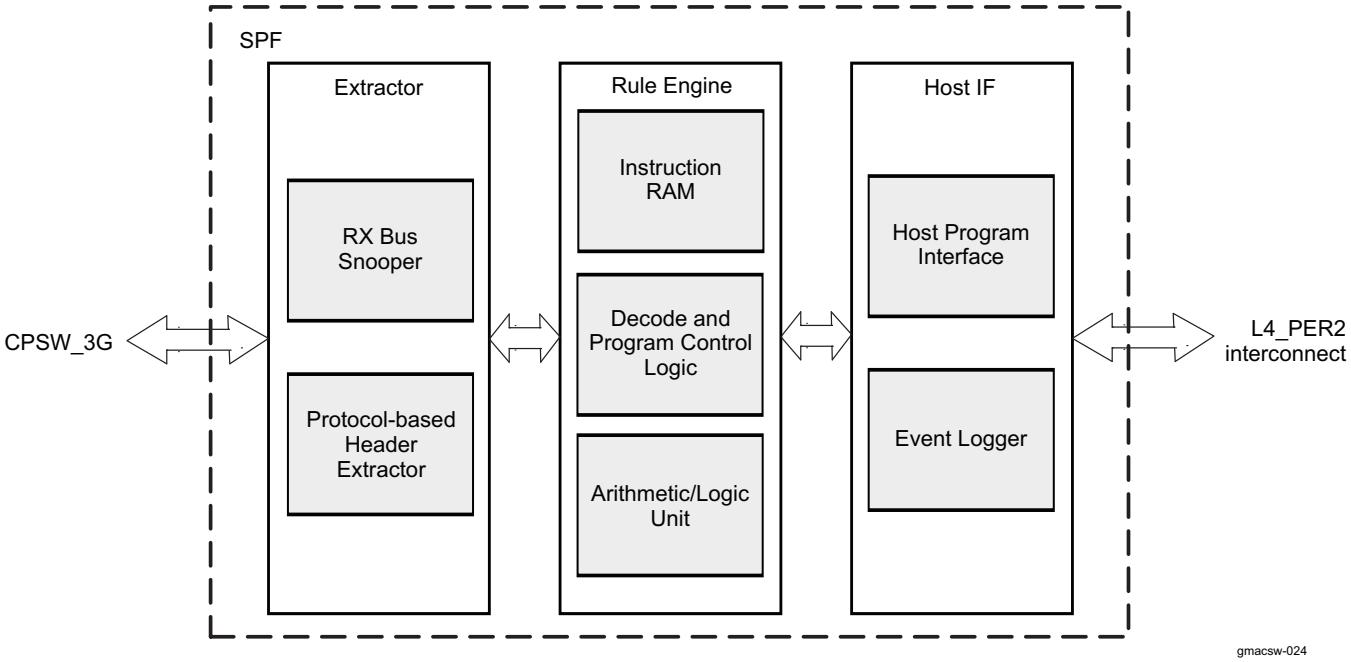
Figure 24-199. SPF Block Diagram



The packet parser interfaces to the three-port Ethernet switch (CPSW_3G). The CPSW_3G signals are snooped for receive traffic and the packet contents are provided to the packet header extractor. The parser can decode various network packet formats and determine the location of the header corresponding to each of the specified protocols and store the values in internal registers. The packet parser can decode VLAN, PPPoE, IP, TCP, UDP and ICMP frame formats and determine the location of each protocol header in a frame. The location of each of these headers is used by the rule engine for performing checks against preprogrammed conditions.

The rule engine monitors information in the header fields and upon detection of an abnormal combination of values in these packet header fields, issues an instruction to drop the packet to the external RFIFO interface. The rule engine can also monitor the receive rate of a particular class of packets and can limit the number of packets that actually pass through the system. The operation of rule engine is programmable and that gives flexibility to perform a range of different checks on the contents of packet to determine whether or not it should be accepted.

The event logger captures the activity in the packet filter. In addition, based upon the settings programmed by the host software, the event logger writes detailed information about any frames that have been dropped thus far. This information is written to a part of the system memory as configured by the host software.

24.11.4.9.2.2 Interrupts

The Static Packet Filter has one interrupt that is used to inform the host about excessive number of logged packet drops. The addresses of the instructions (or drop codes) in the instruction memory that cause packet to be dropped are associated with a threshold. When the threshold is met, the packet drop is logged. Each time a packet drop is logged, it is counted. When the number of logged records reaches the value specified by the SPF_INTCNT register, the host is interrupted. The threshold settings can be controlled by host software to limit the frequency of interrupts. Writing a zero to SPF_INTCNT disables the interrupt in this scenario. Whenever interrupt is enabled and is triggered, it can be cleared by writing one to either Raw register or Masked register.

Interrupts are controlled by the following registers:

1. Raw register SPF_INT_RAW: Holds the Raw state of interrupt, that is, without mask. The hardware interrupt is latched in this register and is only cleared when a one is written to either Raw register or Masked register. Writing a zero has no effect on this register.

Copyright © 2015–2017, Texas Instruments Incorporated

2. Masked register SPF_INT_MASKED: This is the actual interrupt given to the system. It is the result of bitwise AND operation of Raw and Mask registers. Once the interrupt is sensed by the system, this register should be cleared by writing one to this register or to Raw register during ISR execution. Writing zero has no effect on this register
3. Mask set register SPF_MASK_SET: Writing one to this register enables the interrupt. By default, the interrupt is disabled and needs to be enabled by writing a one to this register. Writing a zero has no effect on this register. Writing to this register also set clear register.
4. Mask clear register SPF_MASK_CLR: Writing one to this register disables interrupt. Writing a zero has no effect on this register.

24.11.4.9.2.3 Protocol Header Extractor

The extractor module has a protocol aware state machine. It decodes the header field in the current protocol header to determine the encapsulating protocol type and extracts various parameters used for software logging. The extractor module also provides the offset to octets in the packet, where Layer 3 and Layer 4 protocol headers start, to the rule engine. These protocol headers correspond to the location of IP and TCP/UDP/ICMP headers from the beginning of the packet.

Ethernet packets with VLAN, PPPoE, IP, IP Options, and ICMP/TCP/UDP protocol are supported by the extractor. When unknown protocols are detected, the extractor skips any additional packet processing. Some examples of how packet parsing is done by the Extractor are given below.

- Ethernet – VLAN - PPPoE – IP – IP Options –TCP/UDP/ICMP – Payload
- Ethernet – VLAN – PPPoE – IP – IP options – Unknown – Payload
- Ethernet – VLAN – PPPoE – IP – TCP/UDP/ICMP – Payload
- Ethernet – VLAN – PPPoE – IP – Unknown – Payload
- Ethernet – VLAN – PPPoE – Fragmented IP – Unknown – Payload
- Ethernet – VLAN – IP – IP Options –TCP/UDP/ICMP – Payload
- Ethernet – VLAN – IP – IP options – Unknown – Payload
- Ethernet – VLAN – IP – TCP/UDP/ICMP – Payload
- Ethernet – VLAN – IP – Unknown – Payload
- Ethernet – VLAN – Fragmented IP – Unknown – Payload
- Ethernet – IP – IP Options –TCP/UDP/ICMP – Payload
- Ethernet – IP – IP options – Unknown – Payload
- Ethernet – IP – TCP/UDP/ICMP – Payload
- Ethernet – IP – Unknown – Payload
- Ethernet – Fragmented IP – Unknown – Payload
- Ethernet – Unknown

The flow of Extractor state machine flow is as follows.

1. Wait for start of packet and proceed to step 2 if start of packet detected.
2. Read Ethernet header Length/Type field (at offset 13). Go to step 3 if next header is VLAN, to step 4 if it is PPP header, to step 5 if it is IP header and to step 8 otherwise.
3. Allow VLAN header to pass and read the Length/Type field. Go to step 4 if next header is PPP, to step 5 if it is IP header and to step 8 otherwise.
4. Read the protocol type in PPP header. Go to step 5 if protocol is IP and to step 8 for unknown protocol
5. Extract source IP address and destination IP address from the IP header. Determine if the packet has IP options or if the packet is fragmented. Go to step 6 if the packet has IP options and to step 8 if the packet is fragmented. If there are no options and the next protocol header is TCP/UDP, go to step 7. Otherwise, skip processing and go to step 8 because the packet has unrecognized protocol header
6. Skip IP options and determines the next protocol header. Go to step 7 if next header is TCP/UDP/ICMP. In case the packet contains an IP fragment or if the protocol in the next header is unknown, skip processing and go to step 8.

Copyright © 2015–2017, Texas Instruments Incorporated

7. The packet has TCP/UDP/ICMP header. Extract TCP/UDP source and destination port numbers for logging or ICMP type and code fields and go to step 8.
8. Wait for end of frame and go to step 1 at end of frame.

In case the packet is aborted (indicated by address 0x10 on VBUSP with request and write ready asserted), the extractor state machine flushes its current state, goes back to the idle state and waits for next packet.

The Extractor provides information to rule engine about location of Layer 3 and Layer 4 protocols. When this information is provided to rule engine, the Base Register 1 and Base register 2 are loaded with Layer 3 start offset and Layer 4 start offset respectively. Until the extractor completes decoding of these protocol headers and sends the offset values to rule engine, the rule engine does not execute any instruction that operates on fields in these protocol headers.

Extractor module extracts IP protocol, Source IP address, Destination IP address, TCP/UDP source port, TCP/UDP destination port and ICMP type/code from incoming packet and provides this information to the Host logger module for software reporting. In case IP header or TCP/UDP header does not contain the extractable fields then the corresponding field is logged as zero.

In case packet has unknown Layer 4 protocol or IP packet is fragmented such that the packet does not contain TCP/UDP/ICMP header then TCP/UDP source/destination ports or ICMP type/code fields are logged as zeros.

24.11.4.9.2.4 Programmable Rule Engine

The rule engine is a micro-coded machine that is programmed by the host software. The rule engine is programmed to evaluate various expressions involving the header fields of different protocols that the incoming packet belongs to. These expressions are coded into the instructions that are stored in an internal RAM and are used to check whether a packet is mal-formed or is potentially a DoS attack packet. The rule engine executes the instructions for each incoming packet and makes a decision about accepting or rejecting the packet.

Since each packet can have multiple distinct protocol headers, the location of the headers can be different from packet to packet. The rule engine gets information about the location of the protocol headers from the packet header extractor. The packet header extractor can decode several different protocol types. The octet number at which a particular protocol header is stored is loaded into SPF Base Registers. An application may require SPF to filter packets based on protocols that are not decoded by the extractor. In such cases, SPF allows bypassing the header extractor and then the rule engine can be programmed to analyze packets and figure out the location of each header.

The Rule Engine instructions are programmed before the SPF module is enabled. The instructions cannot be overwritten while the rule engine is processing packets. To modify the contents of code RAM during operation, SPF must be disabled temporarily and then new instructions can be loaded.

Once SPF is enabled, the rule engine starts to fetch instructions one at a time. For each instruction, the operands are obtained from either the packet octets that are being received, from internal registers or from the immediate values inside the instruction itself. If the octet that is needed for execution has not yet been received, then the execution stalls until the required octet is received. In case the operand specified in the instruction refers to a packet octet that has already gone by and is not available in the packet buffer, then the execution stalls until the end of packet. An instruction is executed only when all the required operands are available. Based on the instruction execution results, the packet may immediately be dropped or the results of the evaluated expressions may be stored for future use. In addition, the current instruction can also cause the rule engine to skip a specified number of instructions (immediately following the current instruction) and resume from another location in the instruction RAM.

The rule engine operates on multiple operands and performs multiple tasks in each clock cycle. In each cycle, it can perform one arithmetic and/or logical operation on two pairs of operands. The operands are masked with a 32-bit mask that is generated from the information provided in the instruction. The mask allows for operations that involve variable sized operands. Each operation generates a 32-bit number and a flag bit. The 32-bit number is typically either the sum or the output of bit-wise logical operation. The flag is a single bit result of a comparison operation. The result of each operation can be saved in the internal registers if a specified condition is satisfied. Similarly, depending on the result of the operation, the rule

Copyright © 2015–2017, Texas Instruments Incorporated

engine can jump to another location in the instruction memory. The program can instruct the rule engine to either perform two save operations, two conditional jumps or one jump and one save. The conditions must be mutually exclusive to prevent unspecified operation. In addition to providing an alternate path for execution, the instruction can cause the rule engine to accept or reject the current packet and exit from the program until the next packet is received.

When the execution of an instruction does not result in a decision to accept or reject the packet, the rule engine progresses to the next instruction. Instructions are executed until a final decision is made. If a packet is aborted in the middle at the network interface, the rule engine aborts execution and clears all base registers, program counter, octet counter and packet buffer. It is then ready to process next packet.

From a hardware perspective, the rule engine contains a buffer to store packet octets, several internal registers for temporary storage, instruction decoding logic and control circuitry. A description of each of the hardware resources in the rule engine follows.

24.11.4.9.2.4.1 Internal Registers

Several different types of registers are provided in the rule engine. The description of each of theese is provided below.

- Base Registers (B0-B4): There are four hardware base registers (B1-B4) that store the location of various protocol headers. The B0 register is not a hardware register and it always means a reference to the first octet in a packet. Each base register is eight bits wide and is used to reference octets in a packet. The base registers can point to any octet in the packet upto 255 octets. These registers are readable and writable by the rule engine. In addition, base registers B1 and B2 are loaded with data provided by the extractor when the rule engine is not running in extractor bypass mode (SPF_CONTROL[2] SPF_EXT_BYPASS). The rule engine can write to base registers irrespective of whether extractor bypass is enabled. When an operand needs to use contents of B1-B4 registers, the instruction only executes if the specified base register was loaded at least once after the beginning of current packet. If the specified base register was not loaded during the current packet, then the operand referenced by this base register cannot be extracted from the packet and will cause the rule engine to stall.
- Constant Registers (C0-C7): The rule engine can refer to any of eight 32-bit constant values. These are programmed by the host (SPF_CONSTj, j = 0 to 7) and the rule engine only has read access to these registers. Each of these registers can be changed at any time by the host software. However, changing the value of these registers is not recommended as unpredictable behavior may occur if contents are changed while the rule engine is executing instructions that use the C0-C7 values.
- General Purpose 32-bit registers (R0-R7): There are eight 32-bit registers that can be read/written by the rule engine. These are general purpose registers and can be used as temporary storage. In addition, when the rule engine is required to provide logging information, R4-R7 are used to store information that will be written to memory.
- Rate limit registers (L0-L3): Four 8-bit rate limit registers are used by rule engine to count specific types of packets that are to be rate limited. These registers are counters that are loaded with programmed threshold values (SPF_RATELIMi, i = 0 to 3) at the end of time interval determined by the clock pre-scaler (SPF_PRESCALE)
- General Purpose 1-bit registers (T0-T3): Four 1-bit registers are provided to store comparison results by the rule engine. These registers can be used to store 1-bit output from ALUs. In addition, the logical OR and logical AND of the flags can also be stored in T0-T3 registers. The 32-bit ALU results may also be stored in T0-T3 registers but only the LSB will be stored.

The rule engine instructions refer to these internal registers during execution. More details about instruction encoding are in subsequent sections.

24.11.4.9.2.4.2 Packet Buffer

When the rule engine is processing a packet, it stored a snapshot of latest 32 octets in an internal buffer. This buffer allows evaluation of expressions on packet octets even after the packet octets have gone by on the external receive VBUSP network interface.

Copyright © 2015–2017, Texas Instruments Incorporated

At the start of packet, the first eight octets received are loaded into the first eight locations of the packet buffer. When the next eight octets arrive, these are loaded into the first eight locations and the existing octets are moved to the following eight locations. This process is continued until the packet buffer is full. When packet buffer is full and additional octets arrive, the oldest eight octets are shifted out and are no longer available to the rule engine. Thus, the packet buffer provides a snapshot of most recent octets received.

When the rule engine encounters instructions that reference packet octets which have not yet been received then the rule engine stalls until the required octets are available. Similarly, instructions which require octets that have already been shifted out of the packet buffer will cause rule engine to stall. And since these octets will never be available, the rule engine will not execute any further instructions for the current packet. It will return to the first instruction when the packet ends.

Figure 24-200. Packet Octets as Stored in the Packet Buffer

RFIFO VBUSP	63:56	55:48	47:40	39:32	31:24	23:16	15:8	7:0

	32	31	30	29	28	27	26	25
	24	23	22	21	20	19	18	17

gmacsw-025

The contents of a packet, when used as one or more operands in an instruction, are always fetched from the packet buffer. The Base registers (B0-B4) in conjunction with an offset and bits are used to specify which octets are to be used as operands.

24.11.4.9.2.5 Intrusion Event Logger

The activity of the static packet filter is logged by the intrusion event logger. Based on the configuration, the event logger writes specific fields of the incoming packet that violate a particular rule to the system memory for software diagnostics.

The logging module allows controlling the frequency at which events are logged to the memory. A set of nine counters are provided and, of these, eight can be mapped to any address of the rule engine's instruction RAM using map registers. This mapping logically associates the log information with the instruction that caused the packet to be dropped. The 9th counter is not associated with any particular instruction and it can be used to count the packets that were dropped at instructions not mapped to any of the other eight counters.

Copyright © 2015–2017, Texas Instruments Incorporated

For each of the nine counters, there is a register to store the minimum number of attacks that must be detected before any information is logged to memory. Only when this threshold is met and logging is enabled, the host interface module writes log data in system memory. The memory area used to log is specified by the host in the SPF_LOG_BEGIN address and SPF_LOG_END address registers.

The event logger continues to write data to memory until it runs out of space and the log overwrite is disabled. With each update of the log, the SPF_LOG_HWPTR is updated. This information can be used by the host to determine how much data has been logged. The software in turn keeps the SPF_LOG_SWPTR updated to inform the SPF about the next address from where information will be read by the host software. It is required that software program correct value of SPF_LOG_END address to enable hardware to determine roll-over location. The SPF considers all space before the SPF_LOG_SWPTR as available for logging. In case SPF_CONTROL[9] SPF_LOGOW_EN control bit is set, SPF ignores SPF_LOG_SWPTR and logs data irrespective of software read log status. Note that the memory space allocated for logging is a multiple of four 32-bit words and end address SPF_LOG_END should be loaded with byte address of the next byte following the last log entry. For example if 16 bytes space is allocated for SPF logging from address 0x1400_0000, then SPF_LOG_BEGIN should be 0x1400_0000 and SPF_LOG_END should be 0x1400_0010.

The host software must set SPF_CONTROL[8] SPF_LOG_EN bit to activate logging. The setting of SPF_LOG_EN bit has no effect on the threshold based counters and they are always active. In addition to the log counters, SPF has one master drop count register (SPF_DROPCNT) which tracks the total number of packets dropped thus far. This counter does not roll over and must be cleared for re-run by the host processor once it reaches the maximum value.

The format in which packet information is written in the memory by the event logger is shown in Table 24-1258 and Table 24-1259.

Table 24-1258. Format for TCP/UDP Packets

Drop Code	-	-	Protocol
Source IP Address			
Destination IP Address			
Source TCP/UDP Port		Destination TCP/UDP Port	

Table 24-1259. Format for ICMP Packets

Drop Code	-	-	Protocol
Source IP Address			
Destination IP Address			
Type	Code	Checksum	

Each entry logged to memory has a drop code associated with it. The drop code is the address in instruction memory that actually triggered the drop. Up to eight drop codes can be monitored in this manner. In addition to drop code, the protocol, IP addresses and source/destination ports associated with the dropped packet are recorded.

Log data can be supplied by either Extractor module or by Rule engine. The SPF_CONTROL[3] SPF_RULE_LOG bit must be set to use log data from Rule Engine and cleared to use data supplied by the Extractor.

When logging is done through the Rule Engine, contents of internal registers R4-R7 are written to memory. The format of packet information stored can be programmed in the rule engine except for the drop code field which is static and cannot be changed. The format in which rule engine information is written in the memory by the event logger is shown in Table 24-1260.

Table 24-1260. Rule Engine Format

Drop Code	Register 4[23:0]
Register 5[31:0]	
Register 6[31:0]	

Copyright © 2015–2017, Texas Instruments Incorporated

Table 24-1260. Rule Engine Format (continued)

Register 7[31:0]

The rule engine programming must ensure that these registers contain all required information that is to be recorded before the packet drop instruction is executed. As soon as the drop instruction is executed, the logging module starts to send data from the registers R4, R5, R6 and R7 to the system memory and is not possible to modify the contents of these registers.

24.11.4.9.2.6 Rate Limiter

The static packet filter provides a way to limit the rate of specific types of incoming packets. The SPF module provides four rate limit registers (L0-L3) that are used in conjunction with a clock prescaler (SPF_PRESCALE) and rule engine instructions. The clock prescaler is a clock divider and every count down to zero and the subsequent roll-over indicates end of a time interval. At every such event, each of the four rate limit registers is loaded with a preset value (SPF_RATELIMi, i= 0 to 3) that is programmable by the host processor. When packets are received, the rule engine can identify packets of particular types and execute a limit operation. The limit operation specifies a condition (described in Table 24-1278) and a limit register. If the condition evaluates to true, the packet is dropped if the rate limit register is zero. If it is non-zero, then the rate limit register is decremented by one.

Thus, by using the prescaler and the limit registers, it is possible to control the rate of specific type of packets. By controlling the value of prescale counter (common to all rate limit registers) and the rate limit thresholds, the granularity of the rate can be modified. A lower value of prescale counter will cause frequent reloads of the rate limit registers and will allow rate control over small time intervals. Keeping the prescale counter at extremely small values may cause the rate limiter to be ineffective because the limit registers will be reloaded too frequently to count down to zero. Conversely, a higher value of prescale counter will cause less frequent reloads of the rate limit registers and the rate control will be over longer time intervals. The reload value of each 8-bit rate limit register and the prescale register are programmed by the host processor before SPF is enabled. A reload value of 0xFF can be used to disable any of the rate limiters at run-time without changing the firmware. Both the prescale and limit registers can be modified during run-time.

24.11.4.9.2.7 Rule Engine Instruction Set Architecture

24.11.4.9.2.7.1 Instruction Format

The design supports 64 deep instruction memory. Each of the instructions is 78 bit wide and is stored in a RAM internal to the SPF module. Each instruction can have up to four operands, two arithmetic/logical operations and two conditional jump/save actions based on the outcome of the operations.

The operand field is 52 bits wide and it can have up to four operands. The arithmetic and logical operation codes are four bits each. The operation codes are nine bits each.

Table 24-1261. Instruction Format

Bits	Field Name	Description
77:26	OPERAND	Up to four operands are specified in this field. The source of the operands can be the packet that is being received at the network interface, one of the internal register values or an 8/16/32 bit operand specified within the instruction.
25:22	FUNCTION0	This field specifies a single or dual operand Arithmetic/Logic Function. This function is applied to one or both of first two operands specified in the instruction.
21:18	FUNCTION1	This field also specifies a single or dual operand Arithmetic/Logic Function. This function is applied to one or both of the third and fourth operands specified in the instruction.

Copyright © 2015–2017, Texas Instruments Incorporated

Table 24-1261. Instruction Format (continued)

Bits	Field Name	Description
17:9	OPERATION0	A Save/Jump/Limit/Nop operation is specified in this function. Save operation code includes the source and destination information. The save source is the output of functions and the destination is one of the internal registers where data should be saved. Jump operation code has information about a condition and a destination. The jump occurs when the condition, which is based on the result of function0 and function1, is true. The Jump destination controls the flow of instruction execution. Jump to location 1 results in the packet being dropped. Rule engine goes back to initial instruction and waits for next packet. The event logger writes information to memory. Jump to location zero results in the packet being accepted. The rule engine goes back to initial instruction and waits for next packet. Limit operation code has information about a condition and a rate limit register. The Limit operation either causes the packet to be dropped or results in the specified rate limit register to be decremented by one.
8:0	OPERATION1	This field specifies a second save/jump operation. The format for this field is same as for Operation0.

24.11.4.9.2.7.2 Operand Field

The operand field specifies up to four operands. Each operand is obtained from the incoming packet data, from an internal register or as an immediate value specified in the instruction itself. In addition, there is a bit mask associated with each operand. The mask values are encoded in the instruction itself and the mask for each operand is applied before it is used by the Arithmetic and Logic Unit.

The operands are input to the two 32-bit Arithmetic and Logic units. For all calculations, a mask is used with each operand. The mask is a 32-bit number that is generated from a 5-bit code provided in the instruction or from an immediate value in the instruction. The 5-bit mask code specifies how many bits (from the LSB side) will be input to the ALU. An immediate mask must be used when the mask is not a continuous sequence of 1's. Whenever an immediate mask value is specified, the mask value specified by the 'Bits' fields is ignored.

Each operand is at least 13-bits long and the encoding for each operand types is shown in Table 24-1262 to Table 24-1269.

Table 24-1262. Packet Data Operand

Description	This type of operand is derived from the packet itself. The encoding specifies a number of bits (up to 32) to be extracted from a location in the packet indicated by the selected base register and offset. The format of 13-bit operand code is shown below. Internally, a 32-bit number is obtained from the packet. Then, a mask is created from the bits[4:0] field and bitwise ANDed with the 32- bits extracted from the packet.

12	11	10	9	8	7	6	5	4	3	2	1	0
Base[2:0]			Offset[4:0]					Bits[4:0]				

Bits	Field Name	Description
12:10	Base[2:0]	The Base field selects one of the Base registers B0, B1, B2, B3 or B4. The operand comprises of (Bits+1) bits extracted from the packet. The offset from where the operand octets are extracted is determined by the sum of the value of specified base register (Base 0 to Base 4) and the specified offset. Base 0 is start of packet.
9:5	Offset[4:0]	The value of the selected base register plus the specified offset is the octet location in the packet from where the specified number of bits will be picked.
4:0	Bits[4:0]	The number of bits to be used as operand is specified by Bits+1. When Bits[4:0] is zero, only one bit is used as operand. When Bits[4:0] is 31, then 32 bits are used as operand.

Copyright © 2015–2017, Texas Instruments Incorporated

Table 24-1263. Constant Operand

Description	One of the eight constants programmed by the host software can be used as operand. The bits field specifies the mask to be applied to the selected 32-bit constant.

12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	0	0	C[2:0]			Bits[4:0]				

Bits	Field Name	Description
7:5	C[2:0]	This field selects one of the constants (C0-C7).
4:0	Bits[4:0]	The number of bits to be used as operand is specified by Bits+1. When Bits[4:0] is zero, the least significant bit is used as operand. When Bits[4:0] is 2, then two LSBs are used as operand and so on.

Table 24-1264. 32-bit Register Operand

Description	One of eight 32-bit registers is used as operand and bits[4:0] field specifies the bitmask to be applied to that register.

12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	0	1	R[2:0]			Bits[4:0]				

Bits	Field Name	Description
7:5	R[2:0]	This field selects one of the 32-bits registers (R0-R7).
4:0	Bits[4:0]	The number of bits to be used as operand is specified by Bits+1. When Bits[4:0] is zero, the least significant bit is used as operand. When Bits[4:0] is 2, then two LSBs are used as operand and so on.

Table 24-1265. 1-bit Register Operand

Description	One of the four 1-bit registers is used as operand.

12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	0	0	T[1:0]		0	0	0	0	0

Bits	Field Name	Description
6:5	T[1:0]	This field selects one of the four 1-bits registers (T0-T3).

Table 24-1266. Base Register Operand

Description	One of the base registers is used. The 2-bit codes are 00, 01, 10 and 11 for B1 to B4 respectively.

12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	1	1	B[1:0]		0	0	Bits[2:0]		

Bits	Field Name	Description
6:5	B[1:0]	This field selects one of the four base registers (B1-B4). Note that B0 is a virtual register which is always zero and specifies the start of packet.
2:0	Bits[2:0]	The number of bits to be used as operand is specified by Bits+1. When Bits[4:0] is zero, the least significant bit is used as operand. When Bits[4:0] is 2, then two LSBs are used as operand and so on.

Copyright © 2015–2017, Texas Instruments Incorporated

Table 24-1267. End of Packet Operand

Description	The End-of-Packet (EOP) operand can be used to detect the end of current packet. Use of this operand will stall the CPU until the end of packet is reached. The end of packet operand will always be equal to one when the CPU detects end of packet. It will be zero until packet data is being received and will also stall the CPU. The recommended use of this operand is in the last instruction where a check may be made for size of current packet. Note that this operand only tracks the end of a complete successfully received packet by the RFIFO. The EOP operand does not detect abort of a packet.

12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	0	0	1	0	Bits[4:0]				

Bits	Field Name	Description
4:0	Bits[4:0]	The number of bits specifies the mask. However, these bits are inconsequential for EOP operand. Irrespective of the mask specified by bits[4:0], the EOP operand is always equal to 0x1 in the execution cycle of the instruction it is used.

Table 24-1268. Octet Count Operand

Description	The Octet count operand is used to determine the number of bytes that have been received by rule engine.

12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	0	0	1	1	1	Bits[4:0]				

Bits	Field Name	Description
4:0	Bits[4:0]	The number of bits specifies the mask that is applied to octet counter value. The recommend value for this field is 0x1F.

Table 24-1269. Immediate Data Operands

Description	The immediate data operands can be bigger than 13 bits as shown in the codes below. Each of such operands is directly sent to the ALU without applying any addition bit mask. The immediate data operands can be 8, 16 or 32 bits wide.

12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	0	Data[7:0]							

20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	Data[15:0]															

36	35	34	33	32	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	Data[31:0]																															

Table 24-1270. Immediate Operand Masks

Description	The operand fields can also be used to specify bit masks. These are used when only specific bits from an operand are to be extracted. There is provision for 8-bit and 16-bit masks that can be encoded into an instruction's operand field.

12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	0	0	Mask[7:0]							

20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	0	1	Mask[15:0]															

Copyright © 2015–2017, Texas Instruments Incorporated

When the operand field is all-ones it does not specify any operand and is considered zero.

The tables below list the combinations in which operands may be programmed in an instruction. In this list, Pkt/Reg operand is an operand consisting of octets from the packet or the contents of one of the internal registers; mask specifies the value that is used as a mask instead of the mask generated from the Bits field in the instruction; immediate operand (immediate[7:0], immediate[15:0] and immediate[31:0]) is an 8/16/32 bit number that is used as an operand. The format of Pkt/Reg operand is as shown previously. The decoding of operands for each ALU is dependent upon the type of operation specified in the ALU and the format of the operand field. When there are four operands in the operand field, the first and second operands are used in ALU0 and the rest by ALU1. When ALU0 needs only one operand, then the remaining operands are fed to ALU1. The order of decoding operands is designed to first provide operands to ALU0 from the more significant side of operand field and then to ALU1. If the number of operands specified in instruction does not match with the number of operands required by the ALUs, unspecified behavior can occur. For an instruction to execute, both ALUs must have valid data. If any of the ALUs uses a packet data operand which is not yet available then the rule engine stalls until data is available. During the stall phase, the instruction is decoded every cycle and all required operands must be available simultaneously for the instruction to be executed In addition, if an instruction refers to packet octets that are no longer available, the rule engine stalls until the end of packet.

Pkt/Reg Operand[12:0]	1101 Mask[15:0] 01 Immediate[15:0]		
Pkt / Reg / Imm[7:0] Operand[12:0]	11110 Immediate[31:0] 11		
11110 Immediate[31:0] 11			Pkt / Reg / Imm[7:0] Operand[12:0]

Table 24-1274. Operand Field With One Operand

Pkt / Reg / Imm[7:0] Operand[12:0]	Reserved	Reserved	Reserved
Pkt/Reg Operand[12:0]	11000 Mask[7:0]	Reserved	Reserved
Pkt/Reg Operand[12:0]	11001 Mask[15:0] 11111		Reserved
11101 Immediate[15:0] 11111		Reserved	Reserved
11110 Immediate[31:0] 11			Reserved

The formats in which operands are specified in the operand field have certain restrictions:

- a mask cannot follow an immediate value
- a mask cannot follow a previous mask
- a reserved field should have all following fields reserved as well
- the first field cannot be a mask

24.11.4.9.2.7.3 Arithmetic/Logical Function Field

There can be two codes for arithmetic and logical functions in each instruction. Each of the operations can involve one or two operands.

The location of each function field in an instruction is listed in Table 24-1275.

Table 24-1275. Arithmetic/Logical Instruction Field

	Bits	Description
	23:20	Single or Dual operand Arithmetic/Logic Function (function 0)
	19:16	Single or Dual operand Arithmetic/Logic Function (function 1)

The bit codes for each arithmetic/logic function that can be performed on the operands of an instruction are listed in Table 24-1276.

Table 24-1276. Arithmetic/Logical Operation Codes

Code	Description	Operands Required	32-bit result	1-bit flag result
0x0	Less Than	2	0	Set if true
0x1	Less Than Equal To	2	0	Set if true
0x2	Greater Than	2	0	Set if true
0x3	Greater Than Equal To	2	0	Set if true
0x4	Equal to Zero	1	0	Set if true
0x5	Not Equal to Zero	1	0	Set if true
0x6	Equal to One	1	0	Set if true
0x7	Not Equal to One	1	0	Set if true
0x8	Equal	2	0	Set if true
0x9	Not Equal	2	0	Set if true
0xA	Add	2	Sum	Set if overflow
0xB	Subtract	2	Difference	Set if output is negative
0xC	Bitwise AND	2	Bitwise AND	0
0xD	Bitwise OR	2	Bitwise OR	0
0xE	Result is same as Operand	1	Same as operand	0
0xF	No Function (NOF)	0	0	0

The ALU0 and ALU1 are assigned function0 and function1 respectively. In case only one function is to be performed in an instruction, function0 field should be used to do that. An instruction with no function for ALU0 and a valid function for ALU1 will result in unspecified behavior.

The output of each function is in the form of a 32-bit number and a single bit value. The single bit value is either the carry bit from an add/subtract operation or the Boolean result from a comparison function. The single bit output from each function is referred as the flag0 or flag1 result. The 32-bit number is the outcome of arithmetic or a bitwise logical operation and it is referred to as the word0 or word1 result.

24.11.4.9.2.7.4 Operation Field

The operation field specifies a limit, save or a jump operation. All of these operations involve two arguments that are specified within the instruction.

In case of limit operation, one of the arguments is a condition and the other argument is a limit register. In case of save operation, one of the arguments is source data and the other argument is a destination where the data will be saved. In jump operation, the first argument is a condition that must be true for the jump to occur and the second argument is a destination to which the program control will be moved to. The destination argument in a jump operation also specifies specific destinations that lead to the current packet being immediately rejected or accepted.

The location of operation field in an instruction is shown in Table 24-1277.

Copyright © 2015–2017, Texas Instruments Incorporated

Table 24-1277. Operation Fields

Bits	Description
17:9	Limit/Save/Jump Operation (operation 0) For limit operation, [17:16] is the operation field, [15:13] is the condition field and [12:9] is a limit register. For save operation, [17:16] is the operation field, [15:13] is the source field, and [12:9] is the destination field. For jump operation, [17:16] is the operation field, [15:13] is the condition field, and [12:9] is the destination field
8:0	Limit/Save/Jump Operation (operation 1) For limit operation, [8:7] is the operation field, [6:4] is the condition field and [3:0] is a limit register. For save operation, [8:7] is the operation field, [6:4] is the source field, and [3:0] is the destination field. For jump operation, [8:7] is the operation field, [6:4] is the condition field, and [3:0] is the destination field.

Table 24-1278. Limit Operation

Description	In a limit operation, the condition argument specifies a condition that must be true for the specified limit register to be decremented if non-zero or the packet to be dropped if the limit register is zero.

8	7	6	5	4	3	2	1	0
0	0	Condition Code			Limit Register			

Bits	Field Name	Description
6:4	Condition Code	It is a 3-bit code that specifies the condition that must be true for the operation to be executed. 0x0: Single bit flag (flag0 from function 0) 0x1: Single bit flag (flag1 from function 1) 0x2: Logical OR of flags (flag0 | flag1) 0x3: Logical NOR of flags (!(flag0 | flag1)) 0x4: Logical AND of flags (flag0 & flag1) 0x5: Logical NAND of flags (!(flag0 & flag1)) 0x6: XOR of flags (flag0 ^ flag1) 0x7: Unconditional Decrement/Limit
3:0	Limit Register	It is a 4-bit code that specifies the limit register that is to be decremented or checked for zero value. 0x0: Rate limit register L0 0x1: Rate limit register L1 0x2: Rate limit register L2 0x3: Rate limit register L3 0x4-0xF: Reserved

Table 24-1279. Save Operation

Description	The arguments for a save operation include a code for source data and a code for the destination. The source is either a single bit data or a 32-bit word. The single bit data is either a flag from the functions or a logical OR/AND of the flags. The 32-bit word is the result of the ALU arithmetic/logical functions.

8	7	6	5	4	3	2	1	0
0	1	Source Data Code			Destination Register Code			

Bits	Field Name	Description
6:4	Source Data Code	It is a 3-bit code that specifies the source data which is to be save in another register 0x0: Single bit flag (flag0 from function 0) 0x1: Single bit flag (flag1 from function 1) 0x2: Logical OR of flags (flag0 | flag1) 0x3: Logical AND of flags (flag0 & flag1) 0x4: Output of function (word0) 0x5: Output of function (word1) 0x6-0x7: Reserved
3:0	Destination Register Code	It is a 4-bit code that specified the register in which source data is to be stored 0x0-0x3: Single Bit register (T0-T3) 0x4-0x7: Base Register (B1-B3) 0x8-0xF: 32-bit Register (R0-R7)

Copyright © 2015–2017, Texas Instruments Incorporated

For some instructions, the rule engine extracts the operand from the current packet. To determine the packet bits to be used as operands, it refers to one or more base registers. Whenever an instruction causes a change in value of any of the base registers, it cause the rule engine to wait for one clock cycle before executing the next instruction. The rule engine is a pipelined processor and change in the value of a base register causes the prefetched operand values to become stale and these need to be fetched again. The clock cycle inserted allows rule-engine to fetch the data again before the instruction using this data is executed. Only the instructions that use packet data will be delayed by a clock cycle if the previous instruction caused a change in the base register that is referenced in the current instruction.

Table 24-1280. Jump Operation

Description	For jump operation, one of the operands is a condition that must evaluate to true for the jump operation to occur. The other operand is the destination to which the program counter will move to if the jump operation is executed. The condition in a jump operation is either one of the flags from the output of the arithmetic/logic unit or a logical AND/OR of the flags.

8	7	6	5	4	3	2	1	0
1	0	Condition Code			Destination Code			

Bits	Field Name	Description
6:4	Condition Code	Condition Code 0x0: Single bit flag (flag0 from function 0) 0x1: Single bit flag (flag1 from function 1) 0x2: Logical OR of flags (flag0 | flag1) 0x3: Logical NOR of flags (!(flag0 | flag1)) 0x4: Logical AND of flags (flag0 & flag1) 0x5: Logical NAND of flags (!(flag0 & flag1)) 0x6: XOR of flags (flag0 ^ flag1) 0x7: Unconditional Jump
3:0	Destination Code	Destination Code 0x0: Accept packet, return to instruction zero and wait for the next packet. 0x1: Reject packet and return to instruction zero. 0x2-0xF: Go to instruction at offset +2 ...+15

The jump operation results in a change of program execution flow. The jump destination determines the next instruction that will be executed by the rule engine. The destination is only specified as a positive offset to the current value of the program counter. The program counter can result in the rule engine skipping a given number of instructions instead of executing the next instruction. In addition, the destination field can instruct the rule engine to immediately reject or accept the current packet without any further checks. The rule engine then goes back to the first instruction and waits for a new packet to arrive before it executes any further instructions.

The rule engine is a pipelined processor. When it executes a jump operation, there is a delay of one clock cycle before the next instruction is executed.

The operations specified in the two operation fields are independent of each other. However, it is possible that conflicting operations are specified in the operation fields of an instruction. When conflicting operations are specified and conditions of both operations evaluate to true; then the execution flow is determined as described below:

1. If one of the ALUs has a limit/jump operation that will cause the packet to be dropped, then the packet will be dropped irrespective of what the other ALU indicates.
2. If case 1 above is false and one of the ALUs has a jump operation that will cause the packet to be accepted, then the packet will be accepted and the rule engine will return to idle state.
3. If case 1 and 2 above are false and one of the ALUs has a jump to offset with the respective condition true, the jump will be executed. If there is conflicting jump to offset information in the two ALUs, ALU0 is given priority.

Copyright © 2015–2017, Texas Instruments Incorporated

Table 24-1281. No Operation

Description	If there is no Save, Jump or Limit operation specified in the operation field, it is interpreted as a no operation. There is no change in execution flow, no change in any register values or rate limit registers when a no operation is encountered.

8	7	6	5	4	3	2	1	0
1	1	Reserved			Reserved			

It is expected that the rule engine will be programmed such that a decision to accept or discard the current packet is made before all instructions have executed. If the rule engine reaches the last instruction and it does not result in a decision to accept/reject the packet, then the execution flow does not stop and all instructions from the first instruction are executed again until the end of packet is reached.

24.11.4.9.3 Programming Guide

24.11.4.9.3.1 Initialization Routine

The packet filter must be initialized in order for it to operate as specified. A typical order in which the module can be initialized is shown below:

1. Initialize the firmware by programming the internal memory and verify it (SPF_INSTR_W2, SPF_INSTR_W1, SPF_INSTR_W0, SPF_INSTR_CTL)
2. Allocate memory for logs written by SPF and initialized the log space parameters (SPF_LOG_BEGIN, SPF_LOG_END, SPF_SW_PTR)
3. Program the log map registers to associate drop codes with the log thresholds. (SPF_LOG_MAP0, SPF_LOG_MAP1)
4. Program log thresholds (SPF_LOG_THRESHk, where k = 0 to 8)
5. Program constant registers if required by the firmware (SPF_CONSTj, where j = 0 to 7)
6. Program clock prescale counters and rate limit registers if required by the firmware (SPF_PRESCALE, SPF_RATELIMi , where i = 0 to 3)
7. Program the interrupt frequency control register and interrupt mask register to setup interrupts (SPF_INTCNT, SPF_MASK_SET)
8. Program the control registers to enable SPF filter and logger (SPF_CONTROL).

24.11.4.9.3.2 Interrupt Service Routine

The interrupt service routine in SPF should be designed to process the data logs generated by SPF. It should trigger a higher layer application software that can analyze the data logs and determine if any remedial measures are required based on the information in the logs. At the minimum, the interrupt service routine must reprogram the software pointer for the logging machine to be able to continue logging.

The typical tasks performed following an interrupt are listed in the pseudo code below.

```
SPF_ISR {
read log hardware pointer
read log software pointer
determine how many log entries are to be read
read each log entry starting with the software pointer
update software pointer to reflect the next unread entry
clear interrupt
}
```

24.11.4.9.3.3 Rule Engine Example Program

Here is an example of how the rule engine can be programmed to detect packets that resemble Denial of Service traffic. The pseudo code is shown below.

```
IDLE:
jump to ICMP if start_of_packet
```

Copyright © 2015–2017, Texas Instruments Incorporated

```
ICMP:
if (protocol==ICMP)
limit_ICMP
if (fragmented packet)
drop and jump to IDLE
accept and jump to IDLE
else
jump to IP
IP:
if (source_ip==dest_ip)
drop and jump to IDLE
if (fragmented and (fragment_offset+ip_size)>2^16)
drop and jump to IDLE
accept the packet and jump to IDLE
```

24.11.4.10 Common Platform Time Sync (CPTS)

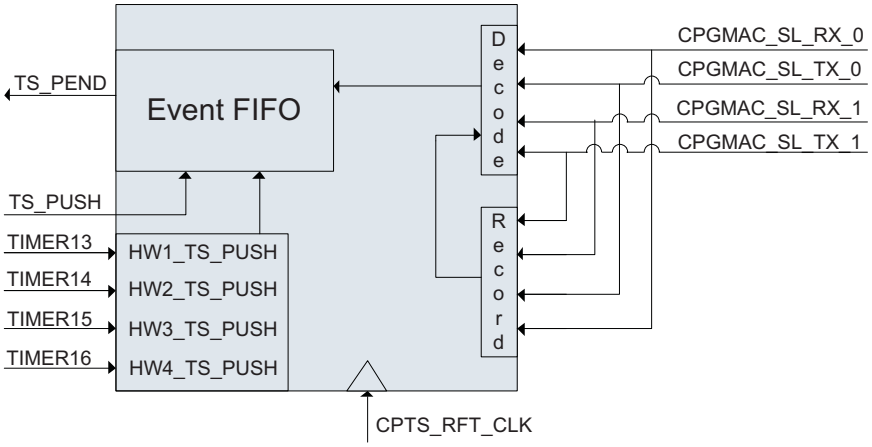
The Common Platform Time Sync (CPTS) module is used to facilitate host control of time sync operations. It enables compliance with the IEEE 1588-2008 standard for a precision clock synchronization protocol.

24.11.4.10.1 CPTS Architecture

Figure 24-201 shows the architecture of the CPTS module inside the GMAC_SW Ethernet Subsystem. Time stamp values for every packet transmitted or received on either port of the GMAC_SW are recorded. At the same time, each packet is decoded to determine if it is a valid time sync event. If so, an event is loaded into the Event FIFO for processing containing the recorded time stamp value when the packet was transmitted or received.

In addition, both hardware (HWx_TS_PUSH) and software (TS_PUSH) can be used to read the current time stamp value though the Event FIFO

Figure 24-201. CPTS Block Diagram



The reference clock used for the time stamp (CPTS_RFT_CLK) can be derived from several sources. See Chapter 3, *PRCM* for more details.

24.11.4.10.2 CPTS Initialization

The CPTS module should be configured as:

1. Reset the CPTS module.
2. Clear the CPTS_EN bit in the CPTS_CONTROL register.
3. Write the CLKSEL_RFT value in the CM_GMAC_GMAC_CLKCTRL register in the PRCM with the desired reference clock selection.
4. Set the CPTS_EN bit in the CPTS_CONTROL register.

Copyright © 2015–2017, Texas Instruments Incorporated

5. If using interrupts and not polling, enable the interrupt by setting the TS_PEND_EN bit in the CPTS_INT_ENABLE register.

24.11.4.10.3 Time Stamp Value

The time stamp value is a 32-bit value that increments on each CPTS_RFT_CLK rising edge when CPTS_EN is set to 1. When CPTS_EN is cleared to 0, the time stamp value is reset to 0.

If more than 32-bits of time stamp are required by the application, the host software must maintain the necessary number of upper bits. The upper time stamp value should be incremented by the host when the rollover event is detected.

For test purposes, the time stamp can be written via the time stamp load function (CPTS_TS_LOAD_VAL and CPTS_TS_LOAD_EN registers).

24.11.4.10.4 Event FIFO

All time sync events are push onto the Event FIFO. There are 16 locations in the event FIFO with no overrun indication supported. Software must service the event FIFO in a timely manner to prevent FIFO overrun.

24.11.4.10.5 Time Sync Events

Time Sync events are 64-bit values that are pushed onto the event FIFO and read in two 32-bit reads. Two 32-bit registers, CPTS_EVENT_HIGH and CPTS_EVENT_LOW hold the data of a time sync event. There are five types of sync events:

- Time stamp push event
- Time stamp counter rollover event
- Time stamp counter half-rollover event
- Ethernet receive event
- Ethernet transmit event

24.11.4.10.5.1 Time Stamp Push Event

Software can obtain the current time stamp value (at the time of the write) by initiating a time stamp push event. The push event is initiated by setting the TS_PUSH bit of the CPTS_TS_PUSH register. The time stamp value is returned in the event, along with a time stamp push event code. Software should not push a second time stamp event on to the FIFO until the first time stamp value has been read from the event FIFO.

24.11.4.10.5.2 Time Stamp Counter Rollover Event

The CPTS module contains a 32-bit time stamp value. The counter upper bits are maintained by host software. The rollover event indicates to software that the time stamp counter has rolled over from FFFF FFFFh to 0000 0000h, and the software maintained upper count value should be incremented.

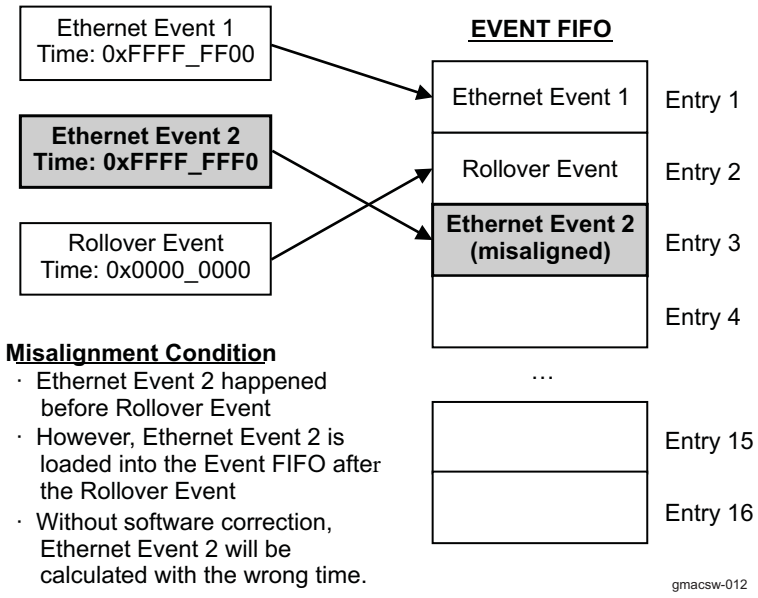
24.11.4.10.5.3 Time Stamp Counter Half-rollover Event

The CPTS includes a time stamp counter half-rollover event. The half-rollover event indicates to software that the time stamp value has incremented from 7FFF FFFFh to 8000 0000h. The half-rollover event is included to enable software to correct a misaligned event condition. The half-rollover event is included to enable software to determine the correct time for each event that contains a valid time stamp value, such as an Ethernet event. If an Ethernet event occurs around a counter rollover (full rollover), the rollover event could possibly be loaded into the event FIFO before the Ethernet event, even though the Ethernet event time was actually taken before the rollover. Figure 24-202 shows a misalignment condition.

Copyright © 2015–2017, Texas Instruments Incorporated

Host software must detect and correct for misaligned event conditions. For every event after a rollover and before a half-rollover, software must examine the time stamp most significant bit. If bit 31 of the time stamp value is low (0000 0000h through 7FFF FFFFh), then the event time stamp was taken after the rollover and no correction is required. If the value is high (8000 0000h through FFFF FFFFh), the time stamp value was taken before the rollover and a misalignment is detected. The misaligned case indicates to software that it must subtract one from the upper count value stored in software to calculate the correct time for the misaligned event. The misaligned event occurs only on the rollover boundary and not on the half-rollover boundary. Software only needs to check for misalignment from a rollover event to a half-rollover event.

Figure 24-202. Event FIFO Misalignment Condition

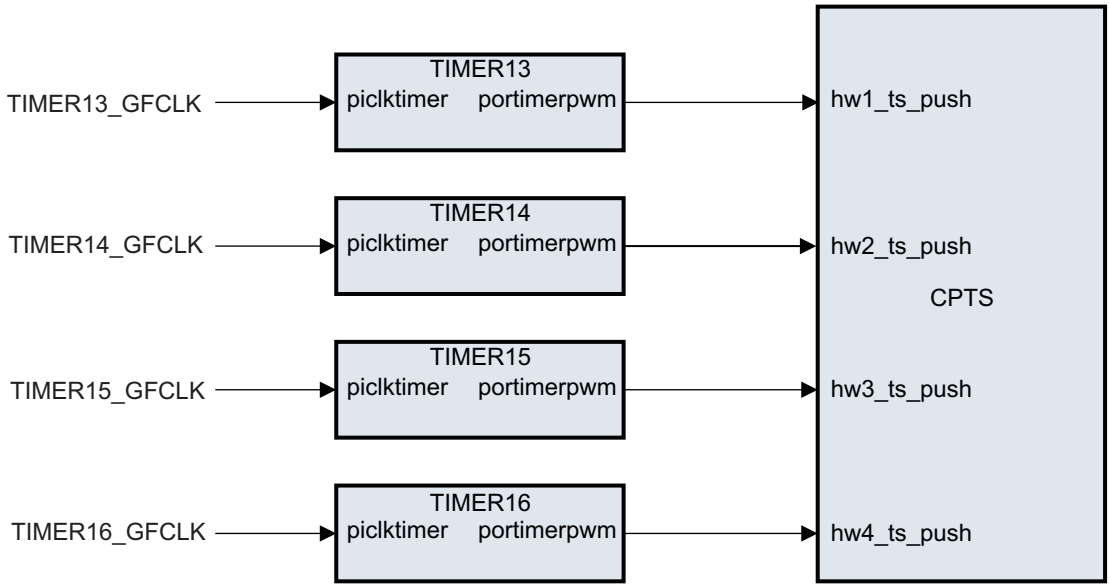


24.11.4.10.5.4 Hardware Time Stamp Push Event

There are four hardware time stamp inputs (HW1/4_TS_PUSH) that can cause hardware time stamp push events to be loaded into the Event FIFO. Each hardware time stamp input is internally connected to the PORTIMERPWM output of each timer as shown in Figure 24-203.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 24-203. HW1/4_TSP_PUSH Connection



The event is loaded into the event FIFO on the rising edge of the timer, and the PORT_NUMBER field in the CPTS_EVENT_HIGH register indicates the hardware time stamp input that caused the event.

Each hardware time stamp input must be asserted for at least 10 periods of the selected RCLK clock. Each input can be enabled or disabled by setting the respective bits in the CPTS_CONTROL register.

Hardware time stamps are intended to be an extremely low frequency signals, such that the event FIFO does not overrun. Software must keep up with the event FIFO and ensure that there is no overrun, or events will be lost.

24.11.4.10.5.5 Ethernet Port Events

Packets transmitted or received on each Ethernet port can generate Ethernet Transmit Events or Ethernet Receive Events, respectively. The CPTS hardware will decode each packet to determine if it is a valid CPTS time sync event.

According to the IEEE 802.3 Ethernet standard, each Ethernet frame contains a 2-octet EtherType field to indicate which protocol is encapsulated in the PayLoad field, as shown in Figure 24-204. For standard time sync packets, this will contain the EtherType for the Precision Time Protocol (IEEE 1588), which is defined as 0x88F7. The CPTS hardware will compare this field to the TS_LTYPE1 field or the TS_LTYPE2 field (depending on which enable bit was set) in the CPSW_TS_LTYPE register, which should also be programmed to 88F7h.

When a virtual LAN is used, an additional 4-octet 802.1Q tag is inserted in the Ethernet frame before the EtherType field, as shown in Figure 24-204. To indicate to the CPTS hardware that a virtual LAN is in use, the Pn_TS_VLAN_LTYPE1_EN (or Pn_TS_VLAN_LTYPE2_EN) enable bit must be set in the Pn_CONTROL register. The EtherType for the 802.1Q tag is defined as 0x8100, and the CPTS hardware will compare this value to the VLAN_LTYPE1 (or VLAN_LTYPE2 depending on which enable bit was set) field in the CPSW_VLAN_LTYPE register, which should also be programmed to 0x8100.

When two stacked VLANs are used, two additional 4-octet 801.Q tags are inserted in the Ethernet frame before the EtherType field, as shown in Figure 24-204. In this case, both VLAN_LTYPE1 and VLAN_LTYPE2 must be enabled. The outer tag must match the value of the VLAN_LTYPE1 field, and the inner tag must match the value of the VLAN_LTYPE2 field.

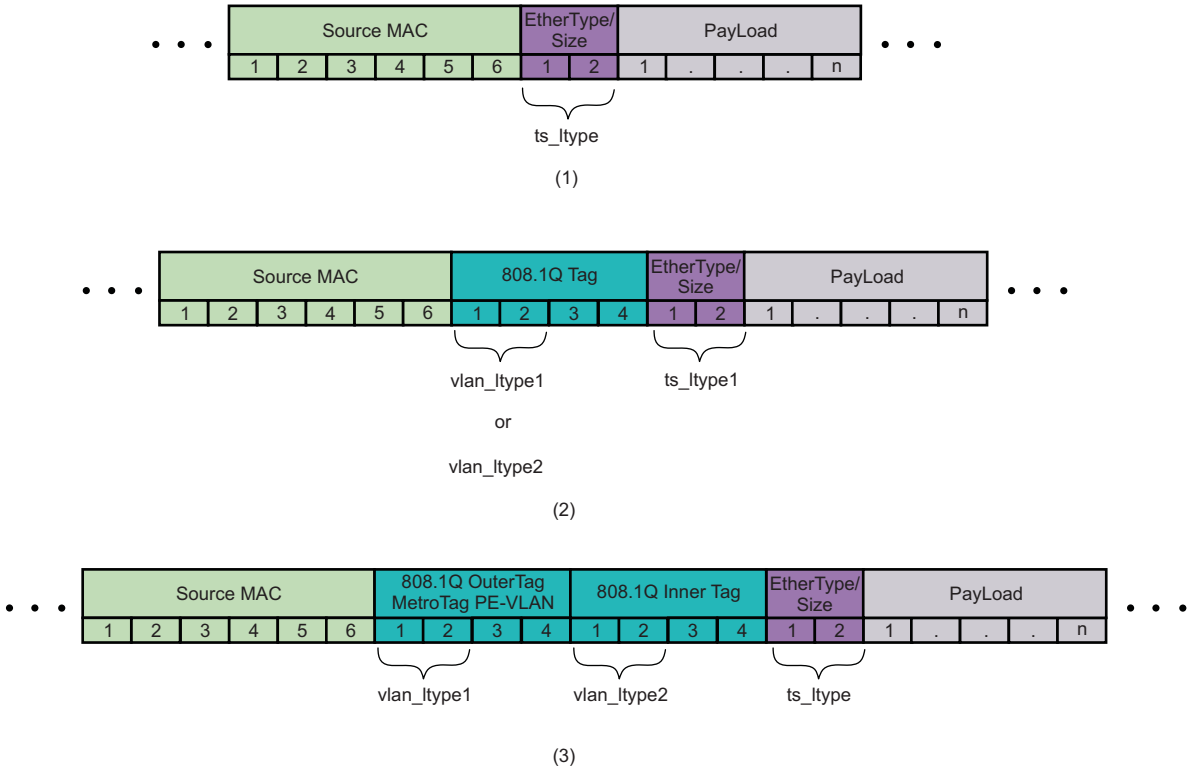
Figure 24-204. Partial Ethernet-II Frames Showing Register Mapping of EtherTypes for a Simple Frame (1), a Single 1Q Tag Added (2), and Two 1Q Tags Added (3)



To enable transmit/receive event packets on a given Ethernet port, perform the following steps, where n is the port number:

1. Set the [1] Pn_TS_TX_EN or the [0] Pn_TS_RX_EN bit in the Pn_CONTROL register to enable transmit/receive event packets
2. Configure the register fields as follows:
   (a) Set the Pn_CONTROL[2] Pn_TS_LTYPE1_EN or [3] Pn_TS_LTYPE2_EN bit to 1
   (b) Set the CPSW_TS_LTYPE[15:0] TS_LTYPE1 or [31:16] TS_LTYPE2 (depending on which enable bit was set in 2(a)) field to 88F7h, which corresponds to the Precision Time Protocol (IEEE 1588) EtherType.
   (c) Set the Pn_TS_SEQ_MTYPE[21:16] Pn_TS_SEQ_ID_OFFSET field to 1Eh, which is the sequence ID offset in the common message header given in the IEEE 1588 specification.
3. To enable support for VLAN tagging (IEEE 802.1Q):
   (a) Set the [20] Pn_TS_VLAN_LTYPE1_EN or [21] Pn_TS_VLAN_LTYPE2_EN bit in the Pn_CONTROL register.
   (b) Set the CPSW_VLAN_LTYPE[15:0] VLAN_LTYPE1 or [31:16] VLAN_LTYPE2 field (matching what was used in step 3a) to 8100h, which corresponds to the VLAN-tagged frame (IEEE 802.1Q) EtherType.
4. To enable support for up to two stacked VLANs (IEEE 802.1ad):
   (a) Set the Pn_TS_VLAN_LTYPE1_EN and Pn_TS_VLAN_LTYPE2_EN bits in the Pn_CONTROL register.
   (b) Set the VLAN_LTYPE1 field in the CPSW_VLAN_LTYPE register to match the EtherType of the outer tag.
   (c) Set the VLAN_LTYPE2 field in the CPSW_VLAN_LTYPE register to 8100h, which corresponds to the VLAN-tagged frame (IEEE 802.1Q) EtherType of the inner tag.
5. Set the Pn_TS_SEQ_MTYPE[15:0] Pn_TS_MSG_TYPE_EN field to choose which types of time stamp messages will push events onto the Event FIFO. Table 9-20 lists the message types defined in the

Copyright © 2015–2017, Texas Instruments Incorporated

IEEE 1588-2008 specification. Table 24-1282 lists the message types defined in the IEEE 1588-2008 specification.

Table 24-1282. Values of Message Type Field

Message Type	Value (hex)
Sync	0
Delay_Req	1
Pdelay_Req	2
Pdelay_Resp	3
Reserved	4-7
Follow_Up	8
Delay_Resp	9
Pdelay_Resp_Follow_Up	A
Announce	B
Signaling	C
Management	D
Reserved	E-F

Once a transmitted or received packet is determined to be a valid time sync packet, the Ethernet Transmit Event or Ethernet Receive Event is loaded onto the Event FIFO. The CPTS_EVENT_HIGH register contains the Message Type and Sequence ID values from the original time sync packet. The CPTS_EVENT_LOW register contains the time stamp value when the packet arrived at the corresponding port.

24.11.4.10.6 CPTS Interrupt Handling

When an event is push onto the Event FIFO, an interrupt can be generated to indicate to software that a time sync event occurred. The following steps should be taken to process time sync events using interrupts:

1. Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the CPTS_INT_ENABLE register.
2. Upon interrupt, read the CPTS_EVENT_LOW and CPTS_EVENT_HIGH registers values.
3. Set the EVENT_POP field (bit 0) of the CPTS_EVENT_POP register to pop the previously read value off of the event FIFO.
4. Process the interrupt as required by the application software.

Software has the option of processing more than a single event from the event FIFO in the interrupt service routine in the following way:

1. Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the CPTS_INT_ENABLE register.
2. Upon interrupt, read the CPTS_EVENT_LOW and CPTS_EVENT_HIGH registers values.
3. Set the EVENT_POP bit of the CPTS_EVENT_POP register to pop the previously read value off of the event FIFO.
4. Wait for an amount of time greater than four CPTS_RFT_CLK periods plus four MAIN_CLK periods.
5. Read the TS_PEND_RAW bit in the CPTS_INTSTAT_RAW register to determine if another valid event is in the event FIFO. If it is asserted, go to step 2; otherwise, go to step 6.
6. Process the interrupt(s) as required by the application software.

Software also has the option of disabling the interrupt and polling the TS_PEND_RAW bit of the CPTS_INTSTAT_RAW register to determine if a valid event is on the event FIFO.

24.11.4.11 CPPI Buffer Descriptors

The buffer descriptor is a central part of the GMAC_SW Ethernet Subsystem and is how the application software describes Ethernet packets to be sent and empty buffers to be filled with incoming packet data.

Copyright © 2015–2017, Texas Instruments Incorporated

Host Software sends and receives network frames via the CPPI compliant host interface. The host interface includes module registers and host memory data structures. The host memory data structures are buffer descriptors and data buffers. Buffer descriptors are data structures that contain information about a single data buffer. Buffer descriptors may be linked together to describe frames or queues of frames for transmission of data and free buffer queues available for received data.

NOTE: The 8K bytes of Ethernet Subsystem CPPI RAM begin at address 0x4848 6000 and end at 0x4848 7FFF from the GMAC_SW perspective. The buffer descriptors programmed to access the CPPI RAM memory should use this address range.

24.11.4.11.1 TX Buffer Descriptors

A TX buffer descriptor (Table 24-1283) is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

Table 24-1283. TX Buffer Descriptor Format

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

24.11.4.11.1.1 CPPI TX Data Word 0

Next Descriptor Pointer

The next descriptor pointer points to the 32-bit word aligned memory address of the next buffer descriptor in the transmit queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is zero, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC. The value of pNext should never be altered once the descriptor is in an active transmit queue, unless its current value is NULL. If the pNext pointer is initially NULL, and more packets need to be queued for transmit, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the transmitter will halt on the transmit channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC

24.11.4.11.1.2 CPPI TX Data Word 1

Buffer Pointer

Copyright © 2015–2017, Texas Instruments Incorporated

The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the buffer_pointer. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

24.11.4.11.1.3 CPPI TX Data Word 2

Buffer Offset

Indicates how many unused bytes are at the start of the buffer. A value of 0000h indicates that no unused bytes are at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 000Fh (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The host sets the Buffer_Offset value (which may be zero to the buffer length minus 1). Valid only on SOP.

Buffer Length

Indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host sets the Buffer_Length. The Buffer_Length must be greater than zero.

24.11.4.11.1.4 CPPI TX Data Word 3

Packet Length

Specifies the number of bytes in the entire packet. Offset bytes are not included. The sum of the Buffer_Length fields should equal the Packet_Length. Valid only on SOP. The packet length must be greater than zero. The packet data will be truncated to the packet length if the packet length is shorter than the sum of the packet buffer descriptor buffer lengths. A host error occurs if the packet length is greater than the sum of the packet buffer descriptor buffer lengths.

Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise,,the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

0 - Not start of packet buffer.

1 - Start of packet buffer.

End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

0 - Not end of packet buffer.

1 - End of packet buffer.

Ownership (OWNER) Flag

When set this flag indicates that all the descriptors for the given packet (from SOP to EOP) are currently owned by the EMAC. This flag is set by the software application on the SOP packet descriptor before adding the descriptor to the transmit descriptor queue. For a single fragment packet, the SOP, EOP, and OWNER flags are all set. The OWNER flag is cleared by the EMAC once it is finished with all the descriptors for the given packet. Note that this flag is valid on SOP descriptors only.

0 - The packet is owned by the host

1 - The packet is owned by the port

End of Queue (EOQ) Flag

Copyright © 2015–2017, Texas Instruments Incorporated

When set, this flag indicates that the descriptor in question was the last descriptor in the transmit queue for a given transmit channel, and that the transmitter has halted. This flag is initially cleared by the software application prior to adding the descriptor to the transmit queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet (the EOP flag is set), and there are no more descriptors in the transmit list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC transmitter for the corresponding channel has halted. This is useful when the application appends additional packet descriptors to a transmit queue list that is already owned by the EMAC. Note that this flag is valid on EOP descriptors only.

0 - The TX queue has more packets to transfer.

1 - The Descriptor buffer is the last buffer in the last packet in the queue.

Teardown Complete (TDOWNCMPLT) Flag

This flag is used when a transmit queue is being torn down, or aborted, instead of allowing it to be transmitted. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the SOP descriptor of each packet as it is aborted from transmission. Note that this flag is valid on SOP descriptors only. Also note that only the first packet in an unsent list has the TDOWNCMPLT flag set. Subsequent descriptors are not processed by the EMAC.

0 - The port has not completed the teardown process.

1 - The port has completed the commanded teardown process.

Pass CRC (PASSCRC) Flag

This flag is set by the software application in the SOP packet descriptor before it adds the descriptor to the transmit queue. Setting this bit indicates to the EMAC that the 4 byte Ethernet CRC is already present in the packet data, and that the EMAC should not generate its own version of the CRC. When the CRC flag is cleared, the EMAC generates and appends the 4-byte CRC. The buffer length and packet length fields do not include the CRC bytes. When the CRC flag is set, the 4-byte CRC is supplied by the software application and is already appended to the end of the packet data. The buffer length and packet length fields include the CRC bytes, as they are part of the valid packet data. Note that this flag is valid on SOP descriptors only.

0 - The CRC is not included with the packet data and packet length.

1 - The CRC is included with the packet data and packet length.

TO_PORT

Port number to send the directed packet to. This field is set by the host. This field is valid on SOP. Directed packets go to the directed port, but an ALE lookup is performed to determine untagged egress in VLAN_AWARE mode.

1 - Send the packet to port 1 if TO_PORT_EN is asserted.

2 - Send the packet to port 2 if TO_PORT_EN is asserted.

TO_PORT_ENABLE

Indicates when set that the packet is a directed packet to be sent to the TO_PORT field port number. This field is set by the host. The packet is sent to one port only (index not mask). This bit is valid on SOP.

0 - not a directed packet

1 - directed packet

24.11.4.11.2 RX Buffer Descriptors

A RX buffer descriptor (Table 24-1284) is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

24.11.4.11.2.1 CPPI RX Data Word 0

Next Descriptor Pointer

The 32-bit word aligned memory address of the next buffer descriptor in the RX queue. This is the mechanism used to reference the next buffer descriptor from the current buffer descriptor. If the value of this pointer is zero then the current buffer is the last buffer in the queue. The host sets the Next_Descriptor_Pointer.

24.11.4.11.2.2 CPPI RX Data Word 1

Buffer Pointer

The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the Buffer_Pointer.

24.11.4.11.2.3 CPPI RX Data Word 2

Buffer Offset

Indicates how many unused bytes are at the start of the buffer. A value of 0000h indicates that there are no unused bytes at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 000Fh (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The port writes the Buffer_Offset with the value from the CPDMA_RX_BUFFER_OFFSET register value. The host initializes the Buffer_Offset to zero for free buffers. The Buffer_Length must be greater than the CPDMARX_BUFFER_OFFSET register value. The buffer offset is valid only on SOP.

Buffer Length

Indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host initializes the Buffer_Length, but the port may overwrite the host initiated value with the actual buffer length value on SOP and/or EOP buffer descriptors. SOP buffer length values will be overwritten if the packet size is less than the size of the buffer or if the offset is nonzero. EOP buffer length values will be overwritten if the entire buffer is not filled up with data. The Buffer_Length must be greater than zero.

24.11.4.11.2.4 CPPI RX Data Word 3

Packet Length

Copyright © 2015–2017, Texas Instruments Incorporated

Specifies the number of bytes in the entire packet. Offset bytes are not included. The sum of the Buffer_Length fields should equal the Packet_Length. Valid only on SOP.

Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on SOP descriptors.

End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on EOP descriptors.

Ownership (OWNER) Flag

When set, this flag indicates that the descriptor is currently owned by the EMAC. This flag is set by the software application before adding the descriptor to the receive descriptor queue. This flag is cleared by the EMAC once it is finished with a given set of descriptors, associated with a received packet. The flag is updated by the EMAC on SOP descriptor only. So when the application identifies that the OWNER flag is cleared on an SOP descriptor, it may assume that all descriptors up to and including the first with the EOP flag set have been released by the EMAC. (Note that in the case of single buffer packets, the same descriptor will have both the SOP and EOP flags set.)

End of Queue (EOQ) Flag

When set, this flag indicates that the descriptor in question was the last descriptor in the receive queue for a given receive channel, and that the corresponding receiver channel has halted. This flag is initially cleared by the software application prior to adding the descriptor to the receive queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet received (also sets the EOP flag), and there are no more descriptors in the receive list (next descriptor pointer is NULL).The software application can use this bit to detect when the EMAC receiver for the corresponding channel has halted. This is useful when the application appends additional free buffer descriptors to an active receive queue. Note that this flag is valid on EOP descriptors only.

Teardown Complete (TDOWNCMPLT) Flag

This flag is used when a receive queue is being torn down, or aborted, instead of being filled with received data. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the descriptor of the first free buffer when the tear down occurs. No additional queue processing is performed.

Pass CRC (PASSCRC) Flag

This flag is set by the EMAC in the SOP buffer descriptor if the received packet includes the 4-byte CRC. This flag should be cleared by the software application before submitting the descriptor to the receive queue.

Long (Jabber) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is a jabber frame and was not discarded because the RX_CEF_EN bit was set in the SL_MACCONTROL register. Jabber frames are frames that exceed the RXMAXLEN in length, and have CRC, code, or alignment errors.

Short (Fragment) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is only a packet fragment and was not discarded because the RX_CSF_EN bit was set in the SL_MACCONTROL register.

Control Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an EMAC control frame and was not discarded because the RX_CMF_EN bit was set in the SL_MACCONTROL register.

Overrun Flag

Copyright © 2015–2017, Texas Instruments Incorporated

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet was aborted due to a receive overrun.

Packet Error (PKT_ERR) Flag

Packet Contained Error on Ingress:

00 - no error

01 - CRC error on ingress

10 - Code error on ingress

11 - Align error on ingress

VLAN Encapsulated Packet (RX_VLAN_ENCAP)

Indicates when set that the packet data contains a 32-bit VLAN header word that is included in the packet byte count. This field is set by the port to be the value of the CPSW_CONTROL register RX_VLAN_ENCAP bit.

FROM_PORT

Indicates the port number that the packet was received on (ingress to the switch).

24.11.4.12 MDIO

The MII Management interface module implements the 802.3 serial management interface to interrogate and control two Ethernet PHYs simultaneously using a shared two-wire bus. Two user access registers (MDIO_USERACCESS0/MDIO_USERACCESS1) control and monitor up to two PHYs simultaneously.

24.11.4.12.1 MDIO Frame Formats

Table 24-1285 shows the read format and Table 24-1286 shows the write format of the 32-bit MII Management interface frames.

Table 24-1285. MDIO Read Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	Register Address	Turnaround	Data
FFFF FFFFh	01	10	AAAAA	RRRRR	Z0	DDDD.DDDD.DDDD.DDDD

Table 24-1286. MDIO Write Frame Format

Pre-amble	Start Delimiter	Operation Code	PHY Address	Register Address	Turnaround	Data
FFFF FFFFh	01	01	AAAAA	RRRRR	10	DDDD.DDDD.DDDD.DDDD

The default or idle state of the two wire serial interface is a logic one. All tri-state drivers should be disabled and the PHY's pull-up resistor will pull the MDIO line to a logic 1. Prior to initiating any other transaction, the station management entity shall send a preamble sequence of 32 contiguous logic 1 bits on the MDIO line with 32 corresponding cycles on MDCLK to provide the PHY with a pattern that it can use to establish synchronization. A PHY shall observe a sequence of 32 contiguous logic one bits on MDIO with 32 corresponding MDCLK cycles before it responds to any other transaction.

Preamble

The start of a frame is indicated by a preamble, which consists of a sequence of 32 contiguous bits all of which are a 1. This sequence provides the PHY a pattern to use to establish synchronization.

Start Delimiter

The preamble is followed by the start delimiter which is indicated by a 01 pattern. The pattern assures transitions from the default logic 1 state to logic 0, and back to logic 1.

Copyright © 2015–2017, Texas Instruments Incorporated

Operation Code

The operation code for a read is 10, while the operation code for a write is a 01.

PHY Address

The PHY address is 5 bits allowing 32 unique values. The first bit transmitted is the MSB of the PHY address.

Register Address

The Register address is 5 bits allowing 32 registers to be addressed within each PHY. Refer to the 10/100 PHY address map for addresses of individual registers.

Turnaround

An idle bit time during which no device actively drives the MDIO signal shall be inserted between the register address field and the data field of a read frame in order to avoid contention. During a read frame, the PHY shall drive a zero bit onto MDIO for the first bit time following the idle bit and preceding the Data field. During a write frame, this field shall consist of a one bit followed by a zero bit.

Data

The Data field is 16 bits. The first bit transmitted and received is the MSB of the data word.

24.11.4.12.2 MDIO Functional Description

The MII Management I/F will remain idle until enabled by setting the ENABLE bit in the MDIO_CONTROL register. The MII Management I/F will then continuously poll the link status from within the Generic Status Register of all possible 32 PHY addresses in turn recording the results in the MDIO_LINK register. The LINKSEL bit in the MDIO_USERPHYSEL0/1 register determines the status input that is used. A change in the link status of the two PHYs being monitored will set the appropriate bit in the MDIO_LINKINTRAW register and the MDIO_LINKINTMASKED register, if enabled by the LINKINT_ENABLE bit in the MDIO_USERPHYSEL0/1 register.

The MDIO_ALIVE register is updated by the MII Management I/F module if the PHY acknowledged the read of the generic status register. In addition, any PHY register read transactions initiated by the host also cause the MDIO_ALIVE register to be updated.

At any time, the host can define a transaction for the MII Management interface module to undertake using the DATA, PHYADR, REGADR, and WRITE fields in a MDIO_USERACCESS0/1 register. When the host sets the GO bit in this register, the MII Management interface module will begin the transaction without any further intervention from the host. Upon completion, the MII Management interface will clear the GO bit and set the USERINTRAW bit in the MDIO_USERINTRAW register corresponding to the MDIO_USERACCESS0/1 register being used. The corresponding bit in the MDIO_USERINTMASKED register may also be set depending on the mask setting in the MDIO_USERINTMASKSET and MDIO_USERINTMASKCLR registers. A round-robin arbitration scheme is used to schedule transactions that may be queued by the host in different MDIO_USERACCESS0/1 registers. The host should check the status of the GO bit in the MDIO_USERACCESS0/1 register before initiating a new transaction to ensure that the previous transaction has completed. The host can use the ACK bit in the MDIO_USERACCESS0/1 register to determine the status of a read transaction.

It is necessary for software to use the MII Management interface module to setup the auto-negotiation parameters of each PHY attached to a MAC port, retrieve the negotiation results, and setup the SL_MACCONTROL register in the corresponding MAC.

24.11.5 GMAC_SW Programming Guide

24.11.5.1 Transmit Operation

After reset, the host must write zeroes to all TX DMA State head descriptor pointers. The TX port may then be enabled. To initiate packet transmission the host constructs transmit queues in memory (one or more packets for transmission) and then writes the appropriate TX DMA state head descriptor pointers. For each buffer added to a transmit queue, the host must initialize the TX buffer descriptor values as follows:

Copyright © 2015–2017, Texas Instruments Incorporated

1. Write the Next Descriptor Pointer with the 32-bit aligned address of the next descriptor in the queue (zero if last descriptor)
2. Write the Buffer Pointer with the byte aligned address of the buffer data
3. Write the Buffer Length with the number of bytes in the buffer
4. Write the Buffer Offset with the number of bytes in the offset to the data (nonzero with SOP only)
5. Set the SOP, EOP, and Ownership bits as appropriate
6. Clear the End Of Queue bit

The port begins TX packet transmission on a given channel when the host writes the channel's TX queue head descriptor pointer with the address of the first buffer descriptor in the queue (nonzero value). Each channel may have one or more queues, so each channel may have one or more head descriptor pointers. The first buffer descriptor for each TX packet must have the Start of Packet (SOP) bit and the Ownership bit set to one by the host. The last buffer descriptor for each TX packet must have the End of Packet (EOP) bit set to one by the host. The port will transmit packets until all queued packets have been transmitted and the queue(s) are empty. When each packet transmission is complete, the port will clear the Ownership bit in the packet's SOP buffer descriptor and issue an interrupt to the host by writing the packet's last buffer descriptor address to the queue's TX DMA State Completion Pointer. The interrupt is generated by the write, regardless of the value written. When the last packet in a queue has been transmitted, the port sets the End Of Queue bit in the EOP buffer descriptor, clears the Ownership bit in the SOP Descriptor, zeroes the appropriate DMA state head descriptor pointer, and then issues a TX interrupt to the host by writing to the queue's associated TX completion pointer (address of the last buffer descriptor processed by the port). The port issues a maskable level interrupt (which may then be routed through external interrupt control logic to the host).

On interrupt from the port, the host processes the buffer queue, detecting transmitted packets by the status of the Ownership bit in the SOP buffer descriptor. If the Ownership bit is cleared to zero, then the packet has been transmitted and the host may reclaim the buffers associated with the packet. The host continues queue processing until the end of the queue or until a SOP buffer descriptor is read that contains a set Ownership bit indicating that the packet transmission is not complete. The host determines that all packets in the queue have been transmitted when the last packet in the queue has a cleared Ownership bit in the SOP buffer descriptor, the End of Queue bit is set in the last packet EOP buffer descriptor, and the Next Descriptor Pointer of the last packet EOP buffer descriptor is zero. The host acknowledges an interrupt by writing the address of the last buffer descriptor to the queue's associated TX Completion Pointer in the TX DMA State. If the host written buffer address value is different from the buffer address written by the port, then the level interrupt remains asserted. If the host written buffer address value is equal to the port written value, then the level interrupt is de-asserted. The port write to the completion pointer actually stores the value in the state register (RAM). The host written value is actually not written to the register location. The host written value is compared to the register contents (which was written by the port) and if the two values are equal, the interrupt is removed, otherwise the interrupt remains asserted. The host may process multiple packets previous to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

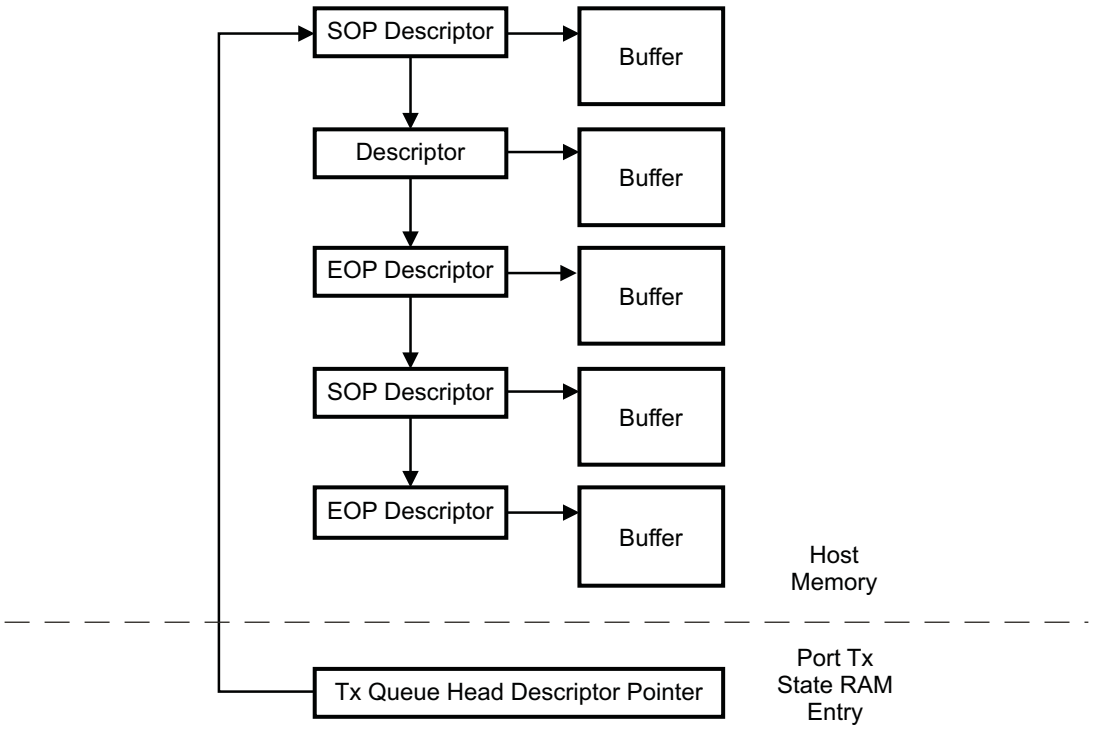
A mis-queued packet condition may occur when the host adds a packet to a queue for transmission as the port finishes transmitting the previous last packet in the queue. The mis-queued packet is detected by the host when queue processing detects a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and a nonzero Next Descriptor Pointer in the EOP buffer descriptor. A mis-queued packet means that the port read the last EOP buffer descriptor before the host added the new last packet to the queue, so the port determined queue empty just before the last packet was added. The host corrects the mis-queued packet condition by initiating a new packet transfer for the mis-queued packet by writing the mis-queued packet's SOP buffer descriptor address to the appropriate DMA State TX Queue head Descriptor Pointer.

The host may add packets to the tail end of an active TX queue at any time by writing the Next Descriptor Pointer to the current last descriptor in the queue. If a TX queue is empty (inactive), the host may initiate packet transmission at any time by writing the appropriate TX DMA State head descriptor pointer. The host software should always check for and reinitiate transmission for mis-queued packets during queue processing on interrupt from the port. In order to preclude software underrun, the host should avoid adding buffers to an active queue for any TX packet that is not complete and ready for transmission.

Copyright © 2015–2017, Texas Instruments Incorporated

The port determines that a packet is the last packet in the queue by detecting the End of Packet bit set with a zero Next Descriptor Pointer in the packet buffer descriptor. If the End of Packet bit is set and the Next Descriptor Pointer is nonzero, then the queue still contains one or more packets to be transmitted. If the EOP bit is set with a zero Next Descriptor Pointer, then the port will set the EOQ bit in the packet's EOP buffer descriptor and then zero the appropriate head descriptor pointer previous to interrupting the port (by writing the completion pointer) when the packet transmission is complete.

Figure 24-205. TX Queue Head Descriptor



24.11.5.2 Receive Operation

After reset, the host must write zeroes to all RX DMA State head descriptor pointers. The RX port may then be enabled. To initiate packet reception, the host constructs receive queues in memory and then writes the appropriate RX DMA state head descriptor pointer. For each RX buffer descriptor added to the queue, the host must initialize the RX buffer descriptor values as follows:

1. Write the Next Descriptor Pointer with the 32-bit aligned address of the next descriptor in the queue (zero if last descriptor)
2. Write the Buffer Pointer with the byte aligned address of the buffer data
3. Clear the Offset field
4. Write the Buffer Length with the number of bytes in the buffer
5. Clear the SOP, EOP, and EOQ bits
6. Set the Ownership bit

The host enables packet reception on a given channel by writing the address of the first buffer descriptor in the queue (nonzero value) to the channel's head descriptor pointer in the channel's RX DMA state. When packet reception begins on a given channel, the port fills each RX buffer with data in order starting with the first buffer and proceeding through the RX queue. If the Buffer Offset in the RX DMA State is nonzero, then the port will begin writing data after the offset number of bytes in the SOP buffer. The port performs the following operations at the end of each packet reception:

1. Overwrite the buffer length in the packet's EOP buffer descriptor with the number of bytes actually received in the packet's last buffer. The host initialized value is the buffer size. The overwritten value

Copyright © 2015–2017, Texas Instruments Incorporated

will be less than or equal to the host initialized value.

2. Set the EOP bit in the packet's EOP buffer descriptor.
3. Set the EOQ bit in the packet's EOP buffer descriptor if the current packet is the last packet in the queue.
4. Overwrite the packet's SOP buffer descriptor Buffer Offset with the RX DMA state value (the host initialized the buffer descriptor Buffer Offset value to zero). All non SOP buffer descriptors must have a zero Buffer Offset initialized by the host.
5. Overwrite the packet's SOP buffer descriptor buffer length with the number of valid data bytes in the buffer. If the buffer is filled up, the buffer length will be the buffer size minus buffer offset.
6. Set the SOP bit in the packet's SOP buffer descriptor.
7. Write the SOP buffer descriptor Packet Length field.
8. Clear the Ownership bit in the packet's SOP buffer descriptor.
9. Issue an RX host interrupt by writing the address of the packet's last buffer descriptor to the queue's RX DMA State Completion Pointer. The interrupt is generated by the write to the RX DMA State Completion Pointer address location, regardless of the value written.

On interrupt the host processes the RX buffer queue detecting received packets by the status of the Ownership bit in each packet's SOP buffer descriptor. If the Ownership bit is cleared then the packet has been completely received and is available to be processed by the host. The host may continue RX queue processing until the end of the queue or until a buffer descriptor is read that contains a set Ownership bit indicating that the next packet's reception is not complete. The host determines that the RX queue is empty when the last packet in the queue has a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and the Next Descriptor Pointer in the EOP buffer descriptor is zero.

A mis-queued buffer may occur when the host adds buffers to a queue as the port finishes the reception of the previous last packet in the queue. The mis-queued buffer is detected by the host when queue processing detects a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and a nonzero Next Descriptor Pointer in the EOP buffer descriptor. A mis-queued buffer means that the port read the last EOP buffer descriptor before the host added buffer descriptor(s) to the queue, so the port determined queue empty just before the host added more buffer descriptor(s). In the transmit case, the packet transmission is delayed by the time required for the host to determine the condition and reinitiate the transaction, but the packet is not actually lost. In the receive case, receive overrun condition may occur in the mis-queued buffer case. If a new packet reception is begun during the time that the port has determined the end of queue condition, then the received packet will overrun (start of packet overrun). If the mis-queued buffer occurs during the middle of a packet reception then middle of packet overrun may occur. If the mis-queued buffer occurs after the last packet has completed, and is corrected before the next packet reception begins, then overrun will not occur. The host acts on the mis-queued buffer condition by writing the added buffer descriptor address to the appropriate RX DMA State Head Descriptor Pointer.

24.11.5.3 MDIO Software Interface

24.11.5.3.1 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO Control register (MDIO_CONTROL).
2. Enable the MDIO module by setting the ENABLE bit in MDIO_CONTROL.
3. The MDIO PHY alive status register (MDIO_ALIVE) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (MDIO_LINK) can determine whether this PHY already has a link.
4. Setup the appropriate PHY addresses in the MDIO user PHY select register (MDIO_USERPHYSEL0/1), and set the LINKINTENB bit to enable a link change event interrupt if desirable.
5. If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (MDIO_USERINTMASKSET) to use the MDIO user access register (MDIO_USERACCESS0/1). Since only one PHY is used in this device, the application software can use one MDIO_USERACCESS0/1 to trigger a completion interrupt; the other MDIO_USERACCESS0/1 is not setup.

24.11.5.3.2 Writing Data To a PHY Register

The MDIO module includes a user access register (MDIO_USERACCESS0/1) to directly access a specified PHY device.To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (MDIO_USERACCESS0/1) is cleared.
2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in MDIO_USERACCESS0/1 corresponding to the PHY and PHY register you want to write.

Copyright © 2015–2017, Texas Instruments Incorporated

3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in MDIO_USERACCESS0/1 for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (MDIO_USERINTRAW) corresponding to MDIO_USERACCESS0/1 used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (MDIO_USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (MDIO_USERINTMASKED) and an interrupt is triggered on the host processor.

24.11.5.3.3 Reading Data From a PHY Register

The MDIO module includes a user access register (MDIO_USERACCESS0/1) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (MDIO_USERACCESS*n*) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in MDIO_USERACCESS0/1 corresponding to the PHY and PHY register you want to read.
3. The read data value is available in the DATA bits in MDIO_USERACCESS0/1 after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in MDIO_USERACCESS0/1. After the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (MDIO_USERINTRAW) corresponding to MDIO_USERACCESS0/1 used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (MDIO_USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (MDIO_USERINTMASKED) and an interrupt is triggered on the host processor.

24.11.5.4 Initialization and Configuration of CPSW

To configure the GMAC_SW Ethernet Subsystem for operation, the host must perform the following:

1. Select the Interface (G/MII, RGMII, RMII) Mode
2. Configure pads (PIN muxing), as per the interface selected.
3. Enable the GMAC_SW Ethernet Subsystem Clocks
4. Configure the PRCM registers CM_GMAC_CLKSTCTRL and CM_GMAC_GMAC_CLKCTRL to enable power and clocks to GMAC_SW Ethernet Subsystem.
5. Apply Soft Reset to GMAC_SW Subsystem, CPSW_3G, CPGMAC_SL1/2, and CPDMA
6. Initialize the HDPs (Header Description Pointer) and CPs (Completion Pointer) to NULL
7. Configure the Interrupts
8. Configure the CPSW_CONTROL register
9. Configure the CPSW_STAT_PORT_EN register
10. Configure the ALE
11. Configure the MDIO
12. Configure the CPDMA receive DMA controller
13. Configure the CPDMA transmit DMA controller
14. Configure the CPPI TX and RX Descriptors
15. Configure CPGMAC_SL1 and CPGMAC_SL2, as per the desired mode of operations.
16. Start up RX and TX DMA (Write to HDP of RX and TX)
17. Wait for the completion of Transfer (HDP cleared to 0)

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		R	0x0
8:4	P1_TX_MAX_BLKS	Transmit FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical transmit priority queues. 0x11 is the recommended value of P1_TX_MAX_BLKS unless the port is in fullduplex flow control mode. In flow control mode, the P1_RX_MAX_BLKS will need to increase in order to accept the required run out in fullduplex mode. This value will need to decrease by the amount of increase in P1_RX_MAX_BLKS. 0xE is the minimum value for P1_TX_MAX_BLKS.	RW	0x11
3:0	P1_RX_MAX_BLKS	Receive FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical receive queue. This value must be greater than or equal to 0x3. It should be increased In fullduplex flow control mode to 0x5 or 0x6 depending on the required runout space. The P1_TX_MAX_BLKS value must be decreased by the amount of increase in P1_RX_MAX_BLKS. 0x6 is the maximum value for P1_RX_MAX_BLKS.	RW	0x3

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		RW	0x0
8:4	P2_TX_MAX_BLKS	Transmit FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical transmit priority queues. 0x11 is the recommended value of P2_TX_MAX_BLKS unless the port is in fullduplex flow control mode. In flow control mode, the P2_RX_MAX_BLKS will need to increase in order to accept the required run out in fullduplex mode. This value will need to decrease by the amount of increase in P2_RX_MAX_BLKS. 0xE is the minimum value P2_TX_MAX_BLKS.	RW	0x11
3:0	P2_RX_MAX_BLKS	Receive FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical receive queue. This value must be greater than or equal to 0x3. It should be increased In fullduplex flow control mode to 0x5 or 0x6 depending on the required runout space. The P2_TX_MAX_BLKS value must be decreased by the amount of increase in P2_RX_MAX_BLKS. 0x3 is the minimum value P2_RX_MAX_BLKS and 0x6 is the maximum value.	RW	0x3

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								P2_LPI2WAKE																							

Bits	Field Name	Description	Type	Reset
31:20	RESERVED		R	0x0
19:0	P2_LPI2WAKE	Port 2 EEE LPI to wake counter load value – When the port is in the transmit LPI state and the CLKSTOP_REQ signal is deasserted, this value is loaded into the port 2 LPI to wake counter. Transmit packet operations may begin (resume) when the LPI to wake count decrements to zero (on the pre-scale count). This is the time that the CPDMA transmit must wait before transmit (switch ingress) packet operations begin (resume after wakeup).	RW	0x0

RESERVED																															SOFT_RESET

Bits	Field Name	Description	Type	Reset
31:1	RESERVED		R	0x0
0	SOFT_RESET	Software reset - Writing a one to this bit causes the CPDMA logic to be reset. Software reset occurs when the RX and TX DMA Controllers are in an idle state to avoid locking up the VBUSP bus. After writing a one to this bit, it may be polled to determine if the reset has occurred. If a one is read, the reset has not yet occurred. If a zero is read then reset has occurred.	RW	0x0

RESERVED																TX_RLIM								RESERVED			RX_CEF	CMD_IDLE	RX_OFFLEN_BLOCK	RX_OWNERSHIP	TX_PTYPE

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:8	TX_RLIM	Transmit Rate Limit Channel Bus 00000000 - no rate-limited channels 10000000 - channel 7 is rate-limited 11000000 - channels 7 downto 6 are rate-limited 11100000 - channels 7 downto 5 are rate-limited 11110000 - channels 7 downto 4 are rate-limited 11111000 - channels 7 downto 3 are rate-limited 11111100 - channels 7 downto 2 are rate-limited 11111110 - channels 7 downto 1 are rate-limited 11111111 - channels 7 downto 0 are rate-limited all others invalid - this bus must be set MSB towards LSB. TX_PTYPE must be set if any TX_RLIM bit is set for fixed priority.	RW	0x0
7:5	RESERVED		R	0x0
4	RX_CEF	RX Copy Error Frames Enable - Enables DMA overrun frames to be transferred to memory (up to the point of overrun). The overrun error bit will be set in the frame EOP buffer descriptor. Overrun frame data will be filtered when RX_CEF is not set. Frames coming from the receive FIFO with other error bits set are not effected by this bit. 0 - Frames containing overrun errors are filtered. 1 - Frames containing overrun errors are transferred to memory.	RW	0x0
3	CMD_IDLE	Command Idle 0 - Idle not commanded 1 - Idle Commanded (read IDLE in CPDMA_DMASTATUS)	RW	0x0
2	RX_OFFLEN_BLOCK	Receive Offset/Length word write block. 0 - Do not block the DMA writes to the receive buffer descriptor offset/buffer length word. The offset/buffer length word is written as specified in CPPI 3.0. 1 - Block all CPDMA DMA controller writes to the receive buffer descriptor offset/buffer length words during CPPI packet processing. when this bit is set, the CPDMA will never write the third word to any receive buffer descriptor.	RW	0x0
1	RX_OWNERSHIP	Receive Ownership Write Bit Value. 0 - The CPDMA writes the receive ownership bit to zero at the end of packet processing as specified in CPPI 3.0. 1 - The CPDMA writes the receive ownership bit to one at the end of packet processing. Users who do not use the ownership mechanism can use this mode to preclude the necessity of software having to set this bit each time the buffer descriptor is used.	RW	0x0
0	TX_PTYPE	Transmit Queue Priority Type 0 - The queue uses a round robin scheme to select the next channel for transmission. 1 - The queue uses a fixed (channel 7 highest priority) priority scheme to select the next channel for transmission	RW	0x0

RESERVED																RX_BUFFER_OFFSET															

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:0	RX_BUFFER_OFFSET	Receive Buffer Offset Value - The RX_BUFFER_OFFSET will be written by the port into each frame SOP buffer descriptor buffer_offset field. The frame data will begin after the rx_buffer_offset value of bytes. A value of 0x0000 indicates that there are no unused bytes at the beginning of the data and that valid data begins on the first byte of the buffer. A value of 0x000F (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. This value is used for all channels.	RW	0x0

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x0
15:0	RX_FREEBUFFER	Rx Free Buffer Count - This field contains the count of free buffers available. The CPDMA_RX0_PENDTHRESH[7:0] RX_PENDTHRESH value is compared with this field to determine if the receive threshold pending interrupt should be asseted (if enabled). This is a write to increment field. This field rolls over to zero on overflow. If receive threshold pending interrupts are used, the host must initialize this field to the number of available buffers (one register per channel). The port decrements (by the number of buffers in the received frame) the associated channel register for each received frame. This is a write to increment field. The host must write this field with the number of buffers that have been freed due to host processing.	W	0x0

24.11.6.5.2 STATS Register Description

Table 24-1534. GOOD_RX_FRAMES

Address Offset	0x0000 0000		
Physical Address	0x4848 4900	**Instance**	STATS
Description	The total number of good frames received on the port. A good frame is defined to be: - Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode - Had a length of 64 to SL_RX_MAXLEN[13:0] RX_MAXLEN bytes inclusive - Had no CRC error, alignment error or code error. See the RX_ALIGN_CODE_ERRORS and RX_CRC_ERRORS statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

Table 24-1540. PAUSE_RX_FRAMES

Address Offset	0x0000 000C		
Physical Address	0x4848 490C	**Instance**	STATS
Description	The total number of IEEE 802.3X pause frames received by the port (whether acted upon or not). Such a frame: - Contained any unicast, broadcast, or multicast address - Contained the length/type field value 88.08 (hex) and the opcode 0x0001 - Was of length 64 to SL_RX_MAXLEN[13:0] RX_MAXLEN bytes inclusive - Had no CRC error, alignment error or code error - Pause-frames had been enabled on the port (SL_MACCONTROL[4] TX_FLOW_EN = 1). The port could have been in either half or full-duplex mode. See the RX_ALIGN_CODE_ERRORS and RX_CRC_ERRORS statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

Table 24-1544. RX_ALIGN_CODE_ERRORS

Address Offset	0x0000 0014		
Physical Address	0x4848 4914	**Instance**	STATS
Description	The total number of frames received on the port that experienced an alignment error or code error. Such a frame: - Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode - Was of length 64 to SL_RX_MAXLEN[13:0] RX_MAXLEN bytes inclusive - Had either an alignment error or a code error Overruns have no effect upon this statistic. An alignment error is defined to be: - A frame containing an odd number of nibbles - Failing the Frame Check Sequence test if the final nibble is ignored A code error is defined to be a frame which has been discarded because the port's MRXER pin driven with a one for at least one bit-time's duration at any point during the frame's reception. Note: RFC 1757 etherStatsCRCAlignErrors Ref. 1.5 can be calculated by summing RX_ALIGN_CODE_ERRORS and RX_CRC_ERRORS.

Table 24-1562. PAUSE_TX_FRAMES

Address Offset	0x0000 0040		
Physical Address	0x4848 4940	**Instance**	STATS
Description	This statistic indicates the number of IEEE 802.3X pause frames transmitted by the port. Pause frames cannot underrun or contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect upon the statistic. Pause frames sent by software will not be included in this count. Since pause frames are only transmitted in full duplex carrier loss and collisions have no effect upon this statistic. Transmitted pause frames are always 64 byte multicast frames so will appear in the MULTICAST_TX_FRAMES and RX_TX_64_OCTET_FRAMES statistics.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

- STATS Register Summary: [0]

Table 24-1566. COLLISIONS

Address Offset	0x0000 0048		
Physical Address	0x4848 4948	**Instance**	STATS
Description	This statistic records the total number of times that the port experienced a collision. Collisions occur under two circumstances. 1. When a transmit data or MAC control frame: - Was destined for any unicast, broadcast or multicast address - Was any size - Had no carrier loss and no underrun - Experienced a collision. A jam sequence is sent for every non-late collision, so this statistic will increment on each occasion if a frame experiences multiple collisions (and increments on late collisions) CRC errors have no effect upon this statistic. 2. When the port is in half-duplex mode, flow control is active, and a frame reception begins.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

- STATS Register Summary: [0]

Table 24-1574. LATE_COLLISIONS

Address Offset	0x0000 0058		
Physical Address	0x4848 4958	**Instance**	STATS
Description	The total number of frames on the port for which transmission was abandoned because they experienced a late collision. Such a frame: - Was any data or MAC control frame destined for any unicast, broadcast or multicast address - Was any size - Experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions which had previously required the transmission to be re-attempted. The Late Collisions statistic dominates over the single, multiple and excessive Collisions statistics - if a late collision occurs the frame will not be counted in any of these other three statistics. CRC errors have no effect upon this statistic.

Table 24-1578. CARRIER_SENSE_ERRORS

Address Offset	0x0000 0060		
Physical Address	0x4848 4960	**Instance**	STATS
Description	The total number of frames received on the port that had a CPDMA middle of frame (MOF) overrun. MOF overrun frame is defined to be: - Was any data or MAC control frame destined for any unicast, broadcast or multicast address - Was any size - The carrier sense condition was lost or never asserted when transmitting the frame (the frame is not retransmitted). This is a transmit only statistic. Carrier Sense is a don't care for received frames. Transmit frames with carrier sense errors are sent until completion and are not aborted. CRC errors have no effect upon this statistic.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 24-1594. NET_OCTETS

Address Offset	0x0000 0080		
Physical Address	0x4848 4980	**Instance**	STATS
Description	The total number of bytes of frame data received and transmitted on the port. Each frame counted: - was any data or MAC control frame destined for any unicast, broadcast or multicast address (address match does not matter) - Any length (including less than 64 bytes and greater than SL_RX_MAXLEN[13:0] RX_MAXLEN bytes) Also counted in this statistic is: - Every byte transmitted before a carrier- loss was experienced - Every byte transmitted before each collision was experienced, (i.e. multiple retries are counted each time) - Every byte received if the port is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence was not counted to prevent double-counting) Error conditions such as alignment errors, CRC errors, code errors, overruns and underruns do not affect the recording of bytes by this statistic. The objective of this statistic is to give a reasonable indication of ethernet utilization		
Type	RW

TX_HDP																															

Bits	Field Name	Description	Type	Reset
31:0	TX_HDP	TX Channel (0..7) DMA Head Descriptor Pointer - Writing a TX DMA Buffer Descriptor address to a head pointer location initiates TX DMA operations in the queue for the selected channel. Writing to these locations when they are non-zero is an error (except at reset). Host software must initialize these locations to zero on reset.	RW	0x0

Bits	Field Name	Description	Type	Reset
31:0	RX_CP	Rx Completion Pointer Register - This register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The port uses the value written to determine if the interrupt should be deasserted. Note: The value read is the completion pointer (interrupt acknowledge) value that was written by the CPDMA DMA controller (port). The value written to this register by the host is compared with the value that the port wrote to determine if the interrupt should remain asserted. The value written is not actually stored in the location. The interrupt is deasserted if the two values are equal.	RW	0x0

RESERVED																															TS_PUSH

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
31:1	RESERVED		R	0x0
0	TS_PUSH	Time stamp event push - When a logic high is written to this bit a time stamp event is pushed onto the event FIFO. The time stamp value is the time of the write of this register, not the time of the event read. The time stamp value can then be read on interrupt via the event registers. Software should not push a second time stamp event onto the event FIFO until the first time stamp value has been read from the event FIFO (there should be only one time stamp event in the event FIFO at any given time). This bit is write only and always reads zero.	W	0x0

Bits	Field Name	Description	Type	Reset
31	ENABLE_ALE	Enable ALE - 0 - Drop all packets 1 - Enable ALE packet processing	RW	0x0
30	CLEAR_TABLE	Clear ALE address table - Setting this bit causes the ALE hardware to write all table bit values to zero. Software must perform a clear table operation as part of the ALE setup/configuration process. Setting this bit causes all ALE accesses to be held up for 64 clocks while the clear is performed. Access to all ALE registers will be blocked (wait states) until the 64 clocks have completed. This bit cannot be read as one because the read is blocked until the clear table is completed at which time this bit is cleared to zero.	RW	0x0
29	AGE_OUT_NOW	Age Out Address Table Now - Setting this bit causes the ALE hardware to remove (free up) any ageable table entry that does not have a set touch bit. This bit is cleared when the age out process has completed. This bit may be read. The age out process takes 4096 clocks best case (no ale packet processing during ageout) and 66550 clocks absolute worst case.	RW	0x0
28:9	RESERVED		R	0x0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
8	EN_P0_UNI_FLOOD	Enable Port 0 (Host Port) unicast flood 0 - do not flood unknown unicast packets to host port (p0) 1 - flood unknown unicast packets to host port (p0)	RW	0x0
7	LEARN_NO_VID	Learn No VID - 0 - VID is learned with the source address 1 - VID is not learned with the source address (source address is not tied to VID).	RW	0x0
6	EN_VID0_MODE	Enable VLAN ID = 0 Mode 0 - Process the packet with VID = PORT_VLAN[11:0]. 1 - Process the packet with VID = 0.	RW	0x0
5	ENABLE_OUI_DENY	Enable OUI Deny Mode - When set this bit indicates that a packet with a non OUI table entry matching source address will be dropped to the host unless the destination address matches a multicast table entry with the super bit set.	RW	0x0
4	BYPASS	ALE Bypass - When set, all packets received on ports 0 and 1 are sent to the host (only to the host).	RW	0x0
3	RATE_LIMIT_TX	Rate Limit Transmit mode - 0 - Broadcast and multicast rate limit counters are received port based 1 - Broadcast and multicast rate limit counters are transmit port based.	RW	0x0
2	VLAN_AWARE	ALE VLAN Aware - Determines what is done if VLAN not found. 0 - Flood if VLAN not found 1 - Drop packet if VLAN not found	RW	0x0
1	ENABLE_AUTH_MODE	Enable MAC Authorization Mode - Mac authorization mode requires that all table entries be made by the host software. There are no learned address in authorization mode and the packet will be dropped if the source address is not found (and the destination address is not a multicast address with the super table entry bit set). 0 - The ALE is not in MAC authorization mode 1 - The ALE is in MAC authorization mode	RW	0x0
0	ENABLE_RATE_LIMIT	Enable Broadcast and Multicast Rate Limit 0 - Broadcast/Multicast rates not limited 1 - Broadcast/Multicast packet reception limited to the port control register rate limit fields.	RW	0x0

Table 24-1699. ALE_TBLCTL

Address Offset	0x0000 0020		
Physical Address	0x4848 4D20	**Instance**	ALE
Description	Address lookup engine table control		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WRITE_RDZ	RESERVED																							ENTRY_POINTER							

Bits	Field Name	Description	Type	Reset
31	WRITE_RDZ	Write Bit - This bit is always read as zero. Writing a 1 to this bit causes the three table word register values to be written to the entry_pointer location in the address table. Writing a 0 to this bit causes the three table word register values to be loaded from the entry_pointer location in the address table so that they may be subsequently read. A read of any ALE address location will be stalled until the read or write has completed.	RW	0x0
30:10	RESERVED		R	0x0
9:0	ENTRY_POINTER	Table Entry Pointer - The entry_pointer contains the table entry value that will be read/written with accesses to the table word registers.	RW	0x0

Description	CPGMAC_SL MAC control register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								RX_CMF_EN	RX_CSF_EN	RX_CEF_EN	TX_SHORT_GAP_LIM_EN	RESERVED		EXT_EN	GIG_FORCE	IFCTL_B	IFCTL_A	RESERVED			CMD_IDLE	TX_SHORT_GAP_EN	RESERVED	GIG	TX_PACE	GMII_EN	TX_FLOW_EN	RX_FLOW_EN	MTEST	LOOPBACK	FULLDUPLEX

Bits	Field Name	Description	Type	Reset
31:25	RESERVED		R	0x0
24	RX_CMF_EN	RX Copy MAC Control Frames Enable - Enables MAC control frames to be transferred to memory. MAC control frames are normally acted upon (if enabled), but not copied to memory. MAC control frames that are pause frames will be acted upon if enabled in the SL_MACCONTROL register, regardless of the value of RX_CMF_EN. Frames transferred to memory due to RX_CMF_EN will have the control bit set in their EOP buffer descriptor. 0 - MAC control frames are filtered (but acted upon if enabled). 1 - MAC control frames are transferred to memory.	RW	0x0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
23	RX_CSF_EN	RX Copy Short Frames Enable - Enables frames or fragments shorter than 64 bytes to be copied to memory. Frames transferred to memory due to RX_CSF_EN will have the fragment or undersized bit set in their receive footer. Fragments are short frames that contain CRC/align/code errors and undersized are short frames without errors. 0 - Short frames are filtered 1 - Short frames are transferred to memory.	RW	0x0
22	RX_CEF_EN	RX Copy Error Frames Enable - Enables frames containing errors to be transferred to memory. The appropriate error bit will be set in the frame receive footer. Frames containing errors will be filtered when RX_CEF _EN is not set. 0 - Frames containing errors are filtered. 1 - Frames containing errors are transferred to memory.	RW	0x0
21	TX_SHORT_GAP_LIM_EN	Transmit Short Gap Limit Enable When set this bit limits the number of short gap packets transmitted to 100ppm. Each time a short gap packet is sent, a counter is loaded with 10,000 and decremented on each wireside clock. Another short gap packet will not be sent out until the counter decrements to zero. This mode is included to preclude the host from filling up the FIFO and sending every packet out with short gap which would violate the maximum number of packets per second allowed.	RW	0x0
20:19	RESERVED		R	0x0
18	EXT_EN	Control Enable - Enables the fullduplex and gigabit mode to be selected from the FULLDUPLEX_IN and GIG_IN input signals and not from the FULLDUPLEX and GIG bits in this register. The FULLDUPLEX_MODE bit reflects the actual fullduplex mode selected 0 - Use this setting for RMII/GMII mode . 1 - Use this setting for RGMII mode	RW	0x0
17	GIG_FORCE	Gigabit Mode Force - This bit is used to force the CPGMAC_SL into gigabit mode if the input GMII_MTCLK has been stopped by the PHY.	RW	0x0
16	IFCTL_B	Interface Control B (NOT FUNCTIONAL) 0 - 10Mbps operation 1 - 100Mbps operation	RW	0x0
15	IFCTL_A	Interface Control A 0 - 10Mbps operation 1 - 100Mbps operation	RW	0x0
14:12	RESERVED		R	0x0
11	CMD_IDLE	Command Idle 0 - Idle not commanded 1 - Idle Commanded (read IDLE in SL_MACSTATUS)	RW	0x0
10	TX_SHORT_GAP_EN	Transmit Short Gap Enable 0 - Transmit with a short IPG is disabled 1 - Transmit with a short IPG (when TX_SHORT_GAP input is asserted) is enabled.	RW	0x0
9:8	RESERVED		R	0x0
7	GIG	Gigabit Mode - 0 - 10/100 mode 1 - Gigabit mode (full duplex only) The GIG_OUT output is the value of this bit.	RW	0x0
6	TX_PACE	Transmit Pacing Enable 0 - Transmit Pacing Disabled 1 - Transmit Pacing Enabled	RW	0x0
5	GMII_EN	GMII Enable - 0 - GMII RX and TX held in reset. 1 - GMII RX and TX released from reset.	RW	0x0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
4	TX_FLOW_EN	Transmit Flow Control Enable - Determines if incoming pause frames are acted upon in full-duplex mode. Incoming pause frames are not acted upon in half-duplex mode regardless of this bit setting. The RX_MBP_Enable bits determine whether or not received pause frames are transferred to memory. 0 - Transmit Flow Control Disabled. Full-duplex mode - Incoming pause frames are not acted upon. 1 - Transmit Flow Control Enabled . Full-duplex mode - Incoming pause frames are acted upon.	RW	0x0
3	RX_FLOW_EN	Receive Flow Control Enable - 0 - Receive Flow Control Disabled Half-duplex mode - No flow control generated collisions are sent. Full-duplex mode - No outgoing pause frames are sent. 1 - Receive Flow Control Enabled Half-duplex mode - Collisions are initiated when receive flow control is triggered. Full-duplex mode - Outgoing pause frames are sent when receive flow control is triggered.	RW	0x0
2	MTEST	Manufacturing Test mode - This bit must be set to allow writes to the SL_BOFFTEST and SL_RX_PAUSE/SL_TX_PAUSE registers.	RW	0x0
1	LOOPBACK	Loop Back Mode - Loopback mode forces internal fullduplex mode regardless of whether the FULLDUPLEX bit is set or not. The LOOPBACK bit should be changed only when GMII_EN is deasserted. 0 - Not looped back 1 - Loop Back Mode enabled	RW	0x0
0	FULLDUPLEX	Full Duplex mode - Gigabit mode forces fullduplex mode regardless of whether the FULLDUPLEX bit is set or not. The FULLDUPLEX_OUT output is the value of this register bit 0 - half duplex mode 1 - full duplex mode	RW	0x0

Address Offset	0x0000 0014		
Physical Address	0x4848 4D94 0x4848 4DD4	**Instance**	SL1 SL2
Description	CPGMAC_SL backoff test register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								PACEVAL								RNDNUM								COLL_COUNT							
RESERVED								TX_BACKOFF																							

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
31	RESERVED		R	0x0
30:26	PACEVAL	Pacing Register Current Value. A non-zero value in this field indicates that transmit pacing is active. A transmit frame collision or deferral causes PACEVAL to loaded with decimal 31, good frame transmissions (with no collisions or deferrals) cause PACEVAL to be decremented down to zero. When PACEVAL is nonzero, the transmitter delays 4 IPGs between new frame transmissions after each successfully transmitted frame that had no deferrals or collisions. Transmit pacing helps reduce 'capture' effects improving overall network bandwidth.	RW	0x0
25:16	RNDNUM	Backoff Random Number Generator - This field allows the Backoff Random Number Generator to be read (or written in test mode only). This field can be written only when mtest has previously been set. Reading this field returns the generator's current value. The value is reset to zero and begins counting on the clock after the deassertion of reset.	RW	0x0
15:12	COLL_COUNT	Collision Count - The number of collisions the current frame has experienced.	R	0x0
11:10	RESERVED		R	0x0
9:0	TX_BACKOFF	Backoff Count - This field allows the current value of the backoff counter to be observed for test purposes. This field is loaded automatically according to the backoff algorithm, and is decremented by one for each slot time after the collision.	R	0x0

ALIVE																															

Bits	Field Name	Description	Type	Reset
31:0	ALIVE	MDIO alive. Each of the 32 bits of this register is set if the most recent access to the PHY with address corresponding to the register bit number was acknowledged by the PHY, the bit is reset if the PHY fails to acknowledge the access. Both the user and polling accesses to a PHY will cause the corresponding alive bit to be updated. The alive bits are only meant to be used to give an indication of the presence or not of a PHY with the corresponding address. Writing a 1 to any bit will clear it, writing a 0 has no effect.	RW	0x0

LINK																															

Bits	Field Name	Description	Type	Reset
31:0	LINK	MDIO link state. This register is updated after a read of the Generic Status Register of a PHY. The bit is set if the PHY with the corresponding address has link and the PHY acknowledges the read transaction. The bit is reset if the PHY indicates it does not have link or fails to acknowledge the read transaction. Writes to the register have no effect. In addition, the status of the two PHYs specified in the MDIO_USERPHYSEL registers can be determined using the MLINK input pins (NOT PINNED OUT). This is determined by the LINKSEL bit in the MDIO_USERPHYSEL register.	R	0x0

Description	MDIO User Command Complete Interrupt		
Type	RW		

Bits	Field Name	Description	Type	Reset
31:2	RESERVED		R	0x0
1:0	USERINTMASKED	Masked value of MDIO user command complete interrupt for the MDIO_USERACCESS1 and MDIO_USERACCESS0 register, respectively. When asserted 1, a bit indicates that the previously scheduled PHY read or write command using that particular MDIO_USERACCESS register has completed and the corresponding USERINTMASKSET bit is set to 1. Writing a 1 will clear the interrupt and writing 0 has no effect. If the INTTESTENB bit in the MDIO_CONTROL register is set, the host may set the USERINTMASKED bits to a 1. This mode may be used for test purposes.	RW	0x0

Gigabit Ethernet Switch (GMAC_SW)

- SPF Register Summary: [0]

Table 24-1809. SPF_CONTROL

Address Offset	0x0000 0008		
Physical Address	0x4848 5C08 0x4848 5E08	**Instance**	SPF1 SPF2
Description	SPF control register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																						SPF_LOGOW_EN	SPF_LOG_EN	RESERVED				SPF_RULE_LOG	SPF_EXT_BYPASS	SPF_DROP	SPF_ENABLE

Bits	Field Name	Description	Type	Reset
31:10	RESERVED		R	0x0
9	SPF_LOGOW_EN	SPF Log Overwrite Enable. Setting this bit will cause SPF to overwrite previously logged data whether or not software has updated the software_working_pointer. Overwriting only occurs if there is new data but no space to write it in the space indicated by log_start_address and log_end_address.	RW	0x0
8	SPF_LOG_EN	SPF Log Enable. Setting this bit will allow SPF to log information about dropped packets to memory.	RW	0x0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
7:4	RESERVED		R	0x0
3	SPF_RULE_LOG	SPF Rule Engine Log Enable. Setting this bit will allow SPF to log data from rule engine. The default is log data from extractor.	RW	0x0
2	SPF_EXT_BYPASS	SPF Extractor Bypass Enable. The extractor will not provide any offset information to rule engine if this bit is set. The rule engine must load each of the base registers it intends to use to determine if the packet should be discarded.	RW	0x0
1	SPF_DROP	SPF Drop Enable. This bit must be set to activate packet drops.	RW	0x0
0	SPF_ENABLE	SPF Enable. This bit must be set to enable any operation in SPF. The SPF instruction memory can only be accessed by host processor when the spf_enable is deasserted. Once spf_enable is set, writing a zero to this bit will only take effect when spf_busy signal is low. This ensures that spf stops only on packet boundaries.	RW	0x0

25.1 eMMC/SD/SDIO Overview

The eMMC/SD/SDIO host controller provides an interface between a local host (LH) such as a microprocessor unit (MPU) or digital signal processor (DSP) and either eMMC, SD® memory cards, or SDIO cards and handles eMMC/SD/SDIO transactions with minimal LH intervention.

Optionally, the controller is connected to the L3_MAIN interconnect to have a direct access to system memory. It also supports two direct memory access (DMA) slave channels or a DMA master access (in this case, slave DMA channels are deactivated) depending on its integration.

The eMMC/SD/SDIO host controller deals with eMMC/SD/SDIO protocol at transmission level, data packing, adding cyclic redundancy checks (CRCs), start/end bit, and checking for syntactical correctness.

The application interface can send every eMMC/SD/SDIO command and poll for the status of the adapter or wait for an interrupt request, which is sent back in case of exceptions or to warn of end of operation.

The application interface can read card responses or flag registers. It can also mask individual interrupt sources. All these operations can be performed by reading and writing control registers. The eMMC/SD/SDIO host controller also supports two DMA channels.

There are four eMMC/SD/SDIO host controllers inside the device. Figure 25-1 gives an overview of the eMMC/SD/SDIOi (i = 1 to 4) controllers.

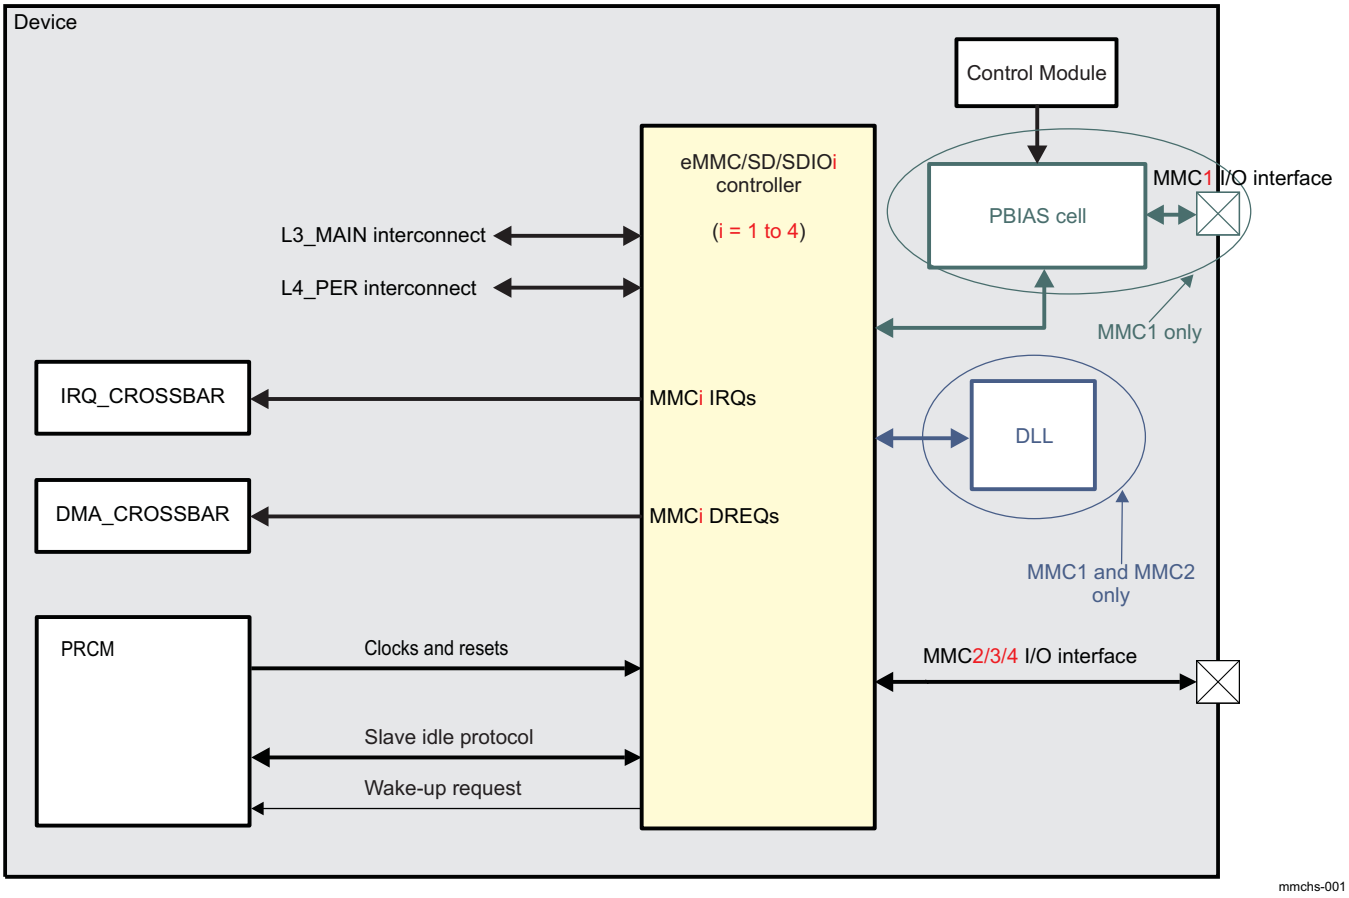
Each controller has the following data width:

- eMMC/SD/SDIO1 - 4-bit wide data bus
- eMMC/SD/SDIO2 - 8-bit wide data bus
- eMMC/SD/SDIO3 - 8-bit wide data bus
- eMMC/SD/SDIO4 - 4-bit wide data bus

The eMMC/SD/SDIOi controller is also referred to as MMCi.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 25-1. eMMC/SD/SDIOi Overview (i = 1 to 4)



25.1.1 eMMC/SD/SDIO Features

This section describes the features supplied by the eMMC/SD/SDIO controllers.

Compliance with standards:

- Full compliance with MMC/eMMC command/response sets as defined in the JC64 MMC/eMMC standard specification, v4.5.
- Full compliance with SD command/response sets as defined in the SD Physical Layer specification v3.01
- Full compliance with SDIO command/response sets and interrupt/read-wait suspend-resume operations as defined in the SD part E1 specification v3.00
- Full compliance with SD Host Controller Standard Specification sets as defined in the SD card specification Part A2 v3.00

Main features of the eMMC/SD/SDIO host controllers:

- Flexible architecture allowing support for new command structure
- 32-bit wide access bus to maximize bus throughput
- Designed for low power
- Programmable clock generation
- Dedicated DLL to support SDR104 mode (MMC1 only)
- Dedicated DLL to support HS200 mode (MMC2 only)
- Card insertion/removal detection and write protect detection
- L4 slave interface supports:

Copyright © 2015–2017, Texas Instruments Incorporated

  - 32-bit data bus width
  - 8/16/32 bit access supported
  - 9-bit address bus width
  - Streaming burst supported only with burst length up to 7
  - WNP supported
- L3 initiator interface Supports:
  - 32-bit data bus width
  - 8/16/32 bit access supported
  - 32-bit address bus width
  - Burst supported
- Built-in 1024-byte buffer for read or write
- Two DMA channels, one interrupt line
- Support JC 64 v4.4.1 boot mode operations
- Support SDA 3.00 Part A2 programming model
- Support SDA 3.00 Part A2 DMA feature (ADMA2)
- Supported data transfer rates:
  - MMCi supports the following SD v3.0 data transfer rates:
    - DS mode (3.3V IOs): up to 12 MBps (24 MHz clock)
    - HS mode (3.3V IOs): up to 24 MBps (48 MHz clock)
    - SDR12 (1.8V IOs): up to 12 MBps (24 MHz clock)
    - SDR25 (1.8V IOs): up to 24 MBps (48 MHz clock)
    - SDR50 (1.8V IOs): up to 48 MBps (96 MHz clock) - MMC1 and MMC3 only
    - DDR50 (1.8V IOs): up to 48 MBps (48 MHz clock) - MMC1 only
    - SDR104 (1.8V IOs) cards can be supported up to 192 MHz clock (96 MBps max) - MMC1 only
  - MMCi supports the Default SD mode 1-bit data transfer up to 24Mbps (3MBps)
  - Only MMC2 supports also the following JC64 v4.5 data transfer rates:
    - Up to 192 MBps in eMMC mode, 8-bit SDR mode (192 MHz clock frequency)
    - Up to 96 MBps in eMMC mode, 8-bit DDR mode (48 MHz clock frequency)
- All eMMC/SD/SDIO controllers are connected to 1,8V/3.3V compatible I/Os to support 1,8V/3.3V signaling

NOTE: eMMC functionality is supported fully by MMC2 only. The other MMC modules are capable of eMMC functionality, but are not timing-optimized for eMMC. For more information about timing limitations, see the data manual of the device.

The differences between the eMMC/SD/SDIO host controllers and a standard SD host controller defined by the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v3.00 are:

- The clock divider in the eMMC/SD/SDIO host controller supports a wider range of frequency than specified in the *SD Memory Card Specifications*, v3.0. The eMMC/SD/SDIO host controller supports odd and even clock ratio.
- The eMMC/SD/SDIO host controller supports configurable busy time-out.
- ADMA2 64-bit mode is not supported.
- There is no external LED control.

NOTE: Only even ratios are supported in DDR mode.

Table 25-1 lists the features supported in the 4.5 standard.

Copyright © 2015–2017, Texas Instruments Incorporated

Table 25-1. Standard 4.5 Supported Features

Feature	Support	Limitation	Comment
Bus width	1-bit mode		x 1, 4, 8 bits
	4-bit mode		
	8-bit mode		
Support density	No hardware limitation for density support	Limitation can come from file system (32 GiB).	
Simple boot (CMD, alternate boot)	Yes		Device ROM code supports the following boot modes: 1. Alternate Boot 2. Raw (UDA) Boot 3. File System For more information about boot modes, see Section 33.3.7, *Memory Booting*. in Chapter 33, *Initialization.*
Sleep mode	Yes		
Reliable write	Yes		
Secure write protection	Yes		
Hardware reset	No		Use the reset command if hardware reset is needed.
Secure memory block (RPMB)	Yes		
Partition feature	Yes		
Secure erase	Yes		
DDR interface (bandwidth)	Up to 96 MBps in DDR mode – 8-bit		
High-priority interrupt (read while write)	Yes		
Background operation	Yes		
Enhanced reliable write	Yes		
HS200 mode	Yes		

Table 25-2 shows the supported by each MMCi host controller transfer rates and functionalities (SD, eMMC and SDIO).

Table 25-2. MMCi Supported Transfer Rates and Functionalities

	SD[1]	eMMC	SDIO
MMC1	Yes (Up to SDR104 mode)	Yes (Up to High Speed DDR mode; timings optimized for SD)	Yes (timings optimized for SD)
MMC2	Yes (Up to SDR25 mode; timings optimized for eMMC)	Yes (Up to HS200 mode)	Yes (timings optimized for eMMC)
MMC3	Yes (Up to SDR50 mode)	Yes (Up to High Speed SDR mode; timings optimized for SD/SDIO)	Yes (Up to SDR50 mode)
MMC4	Yes (Up to SDR25 mode)	Yes (Up to High Speed SDR mode; timings optimized for SD/SDIO)	Yes (Up to SDR25 mode)

(1) 3.3V IO required for initial SD Card communication.

Copyright © 2015–2017, Texas Instruments Incorporated

25.2 eMMC/SD/SDIO Environment

One eMMC/SD/SDIO host controller can support one eMMC memory card, one SD memory card, or one SDIO card.

Other combinations (for example, two SD cards, one eMMC, and one SD card) are not supported through a single controller. The following is supported:

- The MMC1 instance supports 1- and 4-bit data transfers. (mainly used for connection with SD cards)
- The MMC2 instance supports 1-, 4-, and 8-bit data transfers. (mainly used for connection with eMMC cards)
- The MMC3 instance supports 1-, 4-, and 8-bit data transfers. (mainly used for connection with SDIO cards)
- The MMC4 instance supports 1- and 4-bit data transfers. (mainly used for connection with SDIO cards)

25.2.1 eMMC/SD/SDIO Functional Modes

25.2.1.1 eMMC/SD/SDIO Connected to an eMMC, SD, or SDIO Card

Figure 25-2 shows the eMMC/SD/SDIOi host controller (where i = 1 to 4) connected to an eMMC, SD, or SDIO card and its related external connections.

Figure 25-2. eMMC/SD/SDIOi Controller Connected to an eMMC, SD, or SDIO Card (where i = 1 to 4)

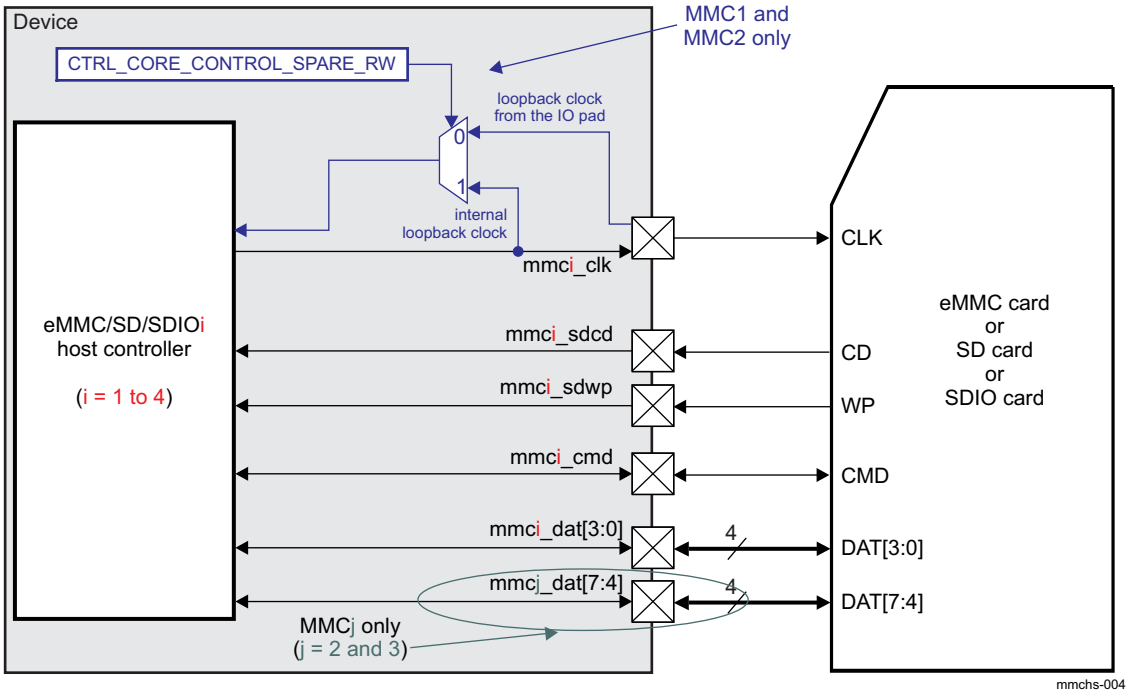


Table 25-3 describes the eMMC/SD/SDIOi host controller I/O's (where i = 1 to 4).

Copyright © 2015–2017, Texas Instruments Incorporated

Table 25-3. Description of eMMC/SD/SDIOi host controller I/O's (where i = 1 to 4)

Instance	Signal name	I/O[1]	Description	Reset Value[2]
MMC1	mmc1_clk	I/O	External clock for eMMC/SD/SDIO card	0
	mmc1_cmd	I/O	Command line	Hi-Z[3]
	mmc1_dat[3:0]	I/O	Data signals	Hi-Z[3]
	mmc1_sdcd	I	Card insertion/removal detection signal	Hi-Z
	mmc1_sdwp	I	Write protect detection signal	Hi-Z
MMC2	mmc2_clk	I/O	External clock for eMMC/SD/SDIO card	0
	mmc2_cmd	I/O	Command line	Hi-Z[3]
	mmc2_dat[7:0]	I/O	Data signals	Hi-Z[3]
	mmc2_cd	I	Card insertion/removal detection signal	Hi-Z
	mmc2_wp	I	Write protect detection signal	Hi-Z
MMC3	mmc3_clk	I/O	External clock for eMMC/SD/SDIO card	0
	mmc3_cmd	I/O	Command line	Hi-Z[3]
	mmc3_dat[7:0]	I/O	Data signals	Hi-Z[3]
	mmc3_cd	I	Card insertion/removal detection signal	Hi-Z
	mmc3_wp	I	Write protect detection signal	Hi-Z
MMC4	mmc4_clk	I/O	External clock for eMMC/SD/SDIO card	0
	mmc4_cmd	I/O	Command line	Hi-Z[3]
	mmc4_dat[3:0]	I/O	Data signals	Hi-Z[3]
	mmc4_cd	I	Card insertion/removal detection signal	Hi-Z
	mmc4_wp	I	Write protect detection signal	Hi-Z

(1) I = Input; O = Output; I/O = Bidirectional
(2) Hi-Z = High Impedance
(3) Initialized as input upon reset

NOTE: For mmc2_clk, mmc3_clk and mmc4_clk signals to work properly, the INPUTENABLE bit of the appropriate CTRL_CORE_PAD_x registers must be set to 0x1 by software. This is because the eMMC/SD/SDIO controller uses the input from the pad as loopback clock, which the controller can use for read capture depending on the mode it is in.

NOTE: On SR2.0 devices the internal PU/PD resistors on pads mmc2_dat[7:0] can be permanently disabled. For more information, see Section 18.4.6.1.1.1, *Permanent PU/PD disabling (SR 2.0 only)* in Chapter 18, *Control Module*.

25.2.2 Protocol and Data Format

The bus protocol between the eMMC/SD/SDIOi host controller and the card is message-based. Each message is represented by one of the following parts:

- Command: A command starts an operation. The command is transferred serially from the eMMC/SD/SDIO host controller to the card on the CMD line.
- Response: A response is an answer to a command. The response is sent from the card to the

Copyright © 2015–2017, Texas Instruments Incorporated

eMMC/SD/SDIO host controller. It is transferred serially on the CMD line.

- Data: Data are transferred from the eMMC/SD/SDIO host controller to the card or from a card to the eMMC/SD/SDIO host controller using the data lines.
- Busy: The DAT[0] signal is maintained low by the card as far as it is programming the data received.
- CRC status: The CRC result is sent by the card through the DAT[0] line when executing a write transfer. In the case of transmission error, occurring on any of the active data lines, the card sends a negative CRC status on DAT[0]. In the case of successful transmission, over all active data lines, the card sends a positive CRC status on DAT[0] and starts the data programming procedure.

25.2.2.1 Protocol

There are two types of data transfer:

- Sequential operation
- Block-oriented operation

There are specific commands for each type of operation (sequential or block-oriented).

For information about commands and programming sequences supported by the MMC, SD, and SDIO cards, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification (Part E1)*.

Figure 25-3 and Figure 25-4 show how sequential operations are defined. Sequential operation is only for 1-bit transfer and initiates a continuous data stream. The transfer terminates when a stop command follows on the mmci_cmd line.

NOTE: Stream commands are supported only by MMC cards.

Figure 25-3. Sequential Read Operation (MMC Cards Only)

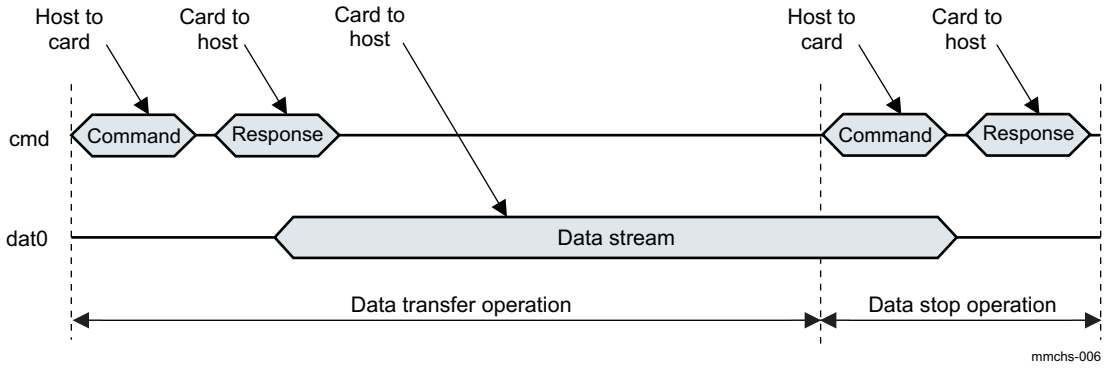

Figure 25-4. Sequential Write Operation (MMC Cards Only)

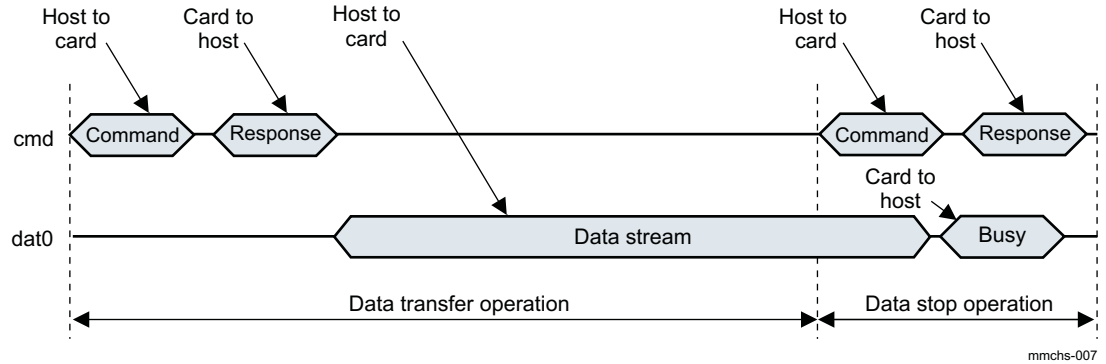

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 25-5 and Figure 25-6 show how multiple block-oriented operations are defined. A multiple block-oriented operation sends a data block plus CRC bits. The transfer terminates when a stop command follows on the mmci_cmd line. These operations are available for all kinds of cards.

Figure 25-5. Multiple Block Read Operation

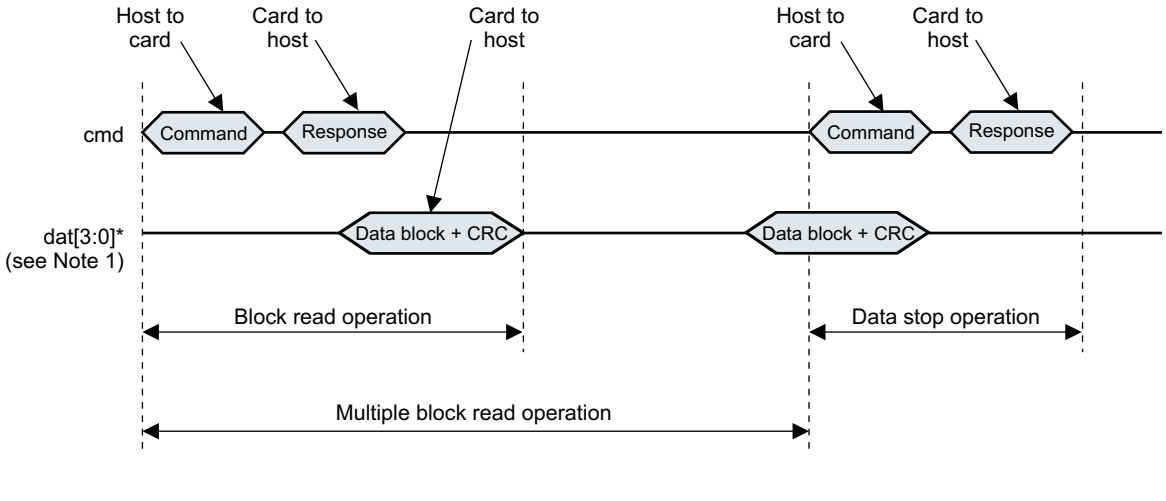

Figure 25-6. Multiple Block Write Operation With Card Busy Signal

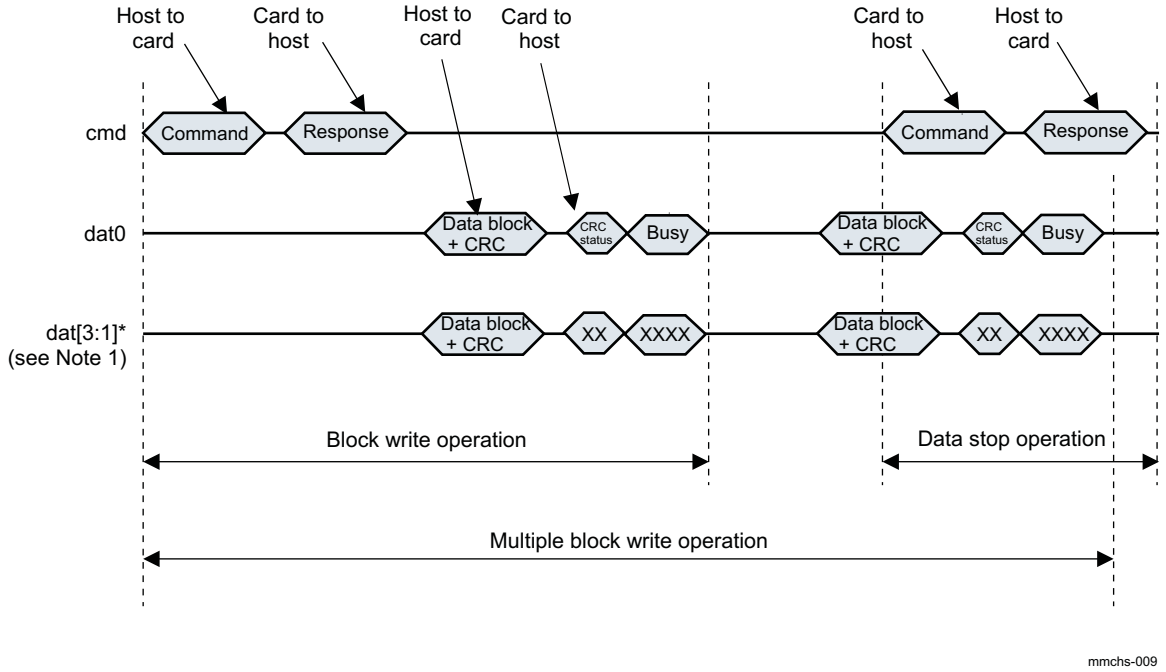


NOTE:

- The card busy signal is not always generated by the card; refer to Figure 25-5 and Figure 25-6, that show a particular case.
- Software must perform a software reset (set the MMCi.MMCHS_SYSCTL[26] SRD bit to 0x1) after a data time-out to ensure that CLK is stopped.
- For multiblock transfer, and especially for MMC cards, a transfer can be aborted without using a stop command. If a CMD23 is used before data transfer to define the number of blocks that will be transferred, then the transfer stops automatically after the last block (if the MMC card supports this feature).

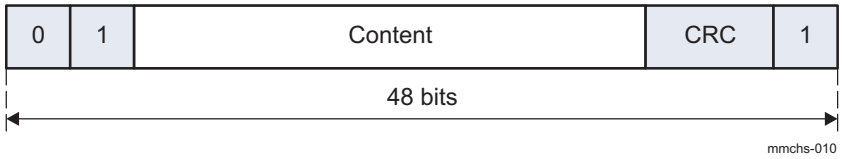
Copyright © 2015–2017, Texas Instruments Incorporated

25.2.2.2 Data Format

Coding Scheme for Command Token

Command tokens always start with 0 and end with 1. The second bit is a transmitter bit: 1 for a host command. The content is the command index (coded by 6 bits) and an argument (for example, an address), coded by 32 bits. The content is protected by 7-bit CRC checksum (see Figure 25-7).

Figure 25-7. Command Token Format



Coding Scheme for Response Token

Response tokens always start with 0 and end with 1. The second bit is a transmitter bit: 0 for a card response. The content is different for each type of response (R1, R2, R3, R4, and R5, R6, R7 [for SD]) and the content is protected by 7-bit CRC checksum (see Figure 25-8 and Figure 25-9). Depending on the type of commands sent to the card, the MMCHS_CMD register must be configured differently to avoid false CRC or index errors to be flagged on command response (see Table 25-4). For more information about response types, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification*.

Figure 25-8. Response Token Format (R1, R3, R4, R5, R6, R7)

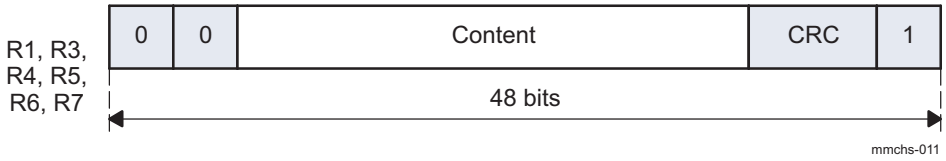


Figure 25-9. Response Token Format (R2)

25.3 eMMC/SD/SDIO Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 25-13 shows the integration of the MMC1 and MMC2 controllers which are connected to both L3_MAIN and L4_PER1 interconnects and are able to act as master or slave. In master mode the L3_MAIN interconnect is used. In slave mode the L4_PER1 interconnect is used.

Figure 25-14 shows the integration of the MMC3 and MMC4 controllers which are connected to the L4_PER1 interconnect and act as a slave only.

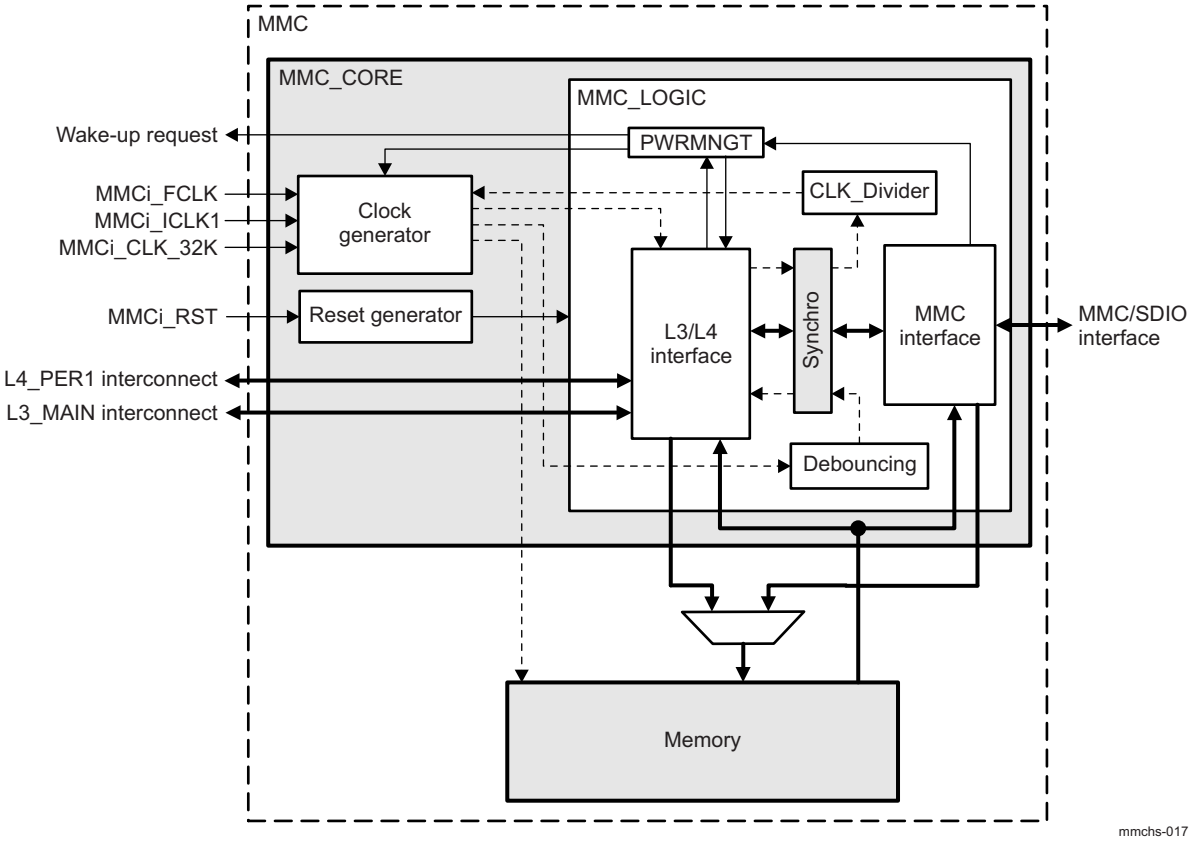
25.4 eMMC/SD/SDIO Functional Description

25.4.1 Block Diagram

Figure 25-15 is a block diagram of the eMMC/SD/SDIOi host controller.

Figure 25-15. eMMC/SD/SDIO Diagram



25.4.2 Resets

25.4.2.1 Hardware Reset

The module is reinitialized by the hardware (see Table 25-6 for more information about reset signals).

The MMCi.MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by software to check whether the module is ready to use after a hardware reset.

NOTE: The functional clock (MMCi_FCLK) and interface clock (MMCi_ICLK) must be provided to the module to allow the RESETDONE status bit to be set.

The debounce clock (MMCi_32K) must be active to reset the module correctly.

This hardware reset signal has a global reset action on the module. All configuration registers and all state-machines are reset in all clock domains.

25.4.2.2 Software Reset

The module is reinitialized by software through the MMCi.MMCHS_SYSCONFIG[1] SOFTRESET bit. This bit has the same effect on the module logic as the hardware signal (MMCi_RST), with the following exceptions:

- Debounce logic

Copyright © 2015–2017, Texas Instruments Incorporated

- MMCi.MMCHS_PSTATE, MMCi.MMCHS_CAPA, and MMCi.MMCHS_CUR_CAPA registers (see the corresponding register description)

The SOFTRESET bit is active high. The bit is automatically reinitialized to 0 by hardware. The MMCi.MMCHS_SYSCTL[24] SRA bit has the same action on the design as the SOFTRESET bit.

The MMCi.MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by software to check whether the module is ready to use after a software reset.

Moreover, two partial software reset bits are provided:

- MMCi.MMCHS_SYSCTL[26] SRD
- MMCi.MMCHS_SYSCTL[25] SRC

These 2 reset bits are useful to reinitialize data or command processes, respectively, in case of line conflict. When these bits are set to 1, a reset process is automatically released when the reset completes:

- The MMCi.MMCHS_SYSCTL[26] SRD bit resets all finite state-machines (FSMs) and status management that handle data transfers on the interface and functional sides.
- The MMCi.MMCHS_SYSCTL[25] SRC bit resets all FSMs and status management that handle command transfers on the interface and functional sides.

25.4.3 Power Management

The eMMC/SD/SDIO host controller can enter into different modes and save power:

- Normal mode
- Idle mode

The two modes are mutually exclusive (the module can be in normal mode or in idle mode). The eMMC/SD/SDIO host controller is compliant with the handshake protocol of the power, reset, and clock management (PRCM) module.

Normal Mode

The autogating of interface and functional clocks occurs when the following conditions are met:

- The MMCi.MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1.
- There is no transaction on the MMC interface.

The autogating of interface and functional clocks stops when the following conditions are met:

- A register access occurs through the L4 interconnect.
- A wake-up event occurs (card insertion, card removal, an interrupt from a SDIO card).
- A transaction on the MMC/SD/SDIO interface starts.

When a card removal event is detected the eMMC/SD/SDIO host controller automatically clears MMCHS_HCTL[8] SDBP and MMCHS_SYSCTL[2] CEN bits. Then it enters into low power state with auto gated interface clock even if MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 0. The functional clock is internally switched off and only interconnect read and write accesses are allowed.

Idle Mode

The MMCi_ICLK and MMCi_FCLK clocks provided to the eMMC/SD/SDIO host controller are switched off upon a PRCM module request. They are switched back upon module request.

The eMMC/SD/SDIO host controller complies with the handshaking protocol of the PRCM module:

- IDLE request from the system power manager
- Idle acknowledgment from the eMMC/SD/SDIO host controller
- Wake-up request from the eMMC/SD/SDIO host controller

The idle acknowledgment varies according to the MMCi.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field:

- 0x0: Force-idle mode. The eMMC/SD/SDIO host controller acknowledges the system power manager request unconditionally.
- 0x1: No-idle mode. The eMMC/SD/SDIO host controller ignores the system power manager request and behaves normally as if the request was not asserted.

Copyright © 2015–2017, Texas Instruments Incorporated

- 0x2: Smart-idle mode. The eMMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state.
- 0x3: Smart-idle wake-up-capable mode. The eMMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state. However, the module may generate wake-up events when it is in IDLE state (related to IRQ or DMA requests)

During the smart-idle mode period, the eMMC/SD/SDIO host controller acknowledges that the MMCi_ICLK and MMCi_FCLK clocks may be switched off, regardless of the value set in the MMCi.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY bit field.

The debounce clock is used to debounce the signals related to the card insertion and the card removal that are also sources of wake-up in idle mode. The debounce clock must never be switched off by the system power manager in order to detect card removal in functional mode, and detect wake-up in idle mode.

Transition From Normal Mode to Smart-Idle Mode

Smart-idle mode is enabled when the MMCi.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x2 or 0x3.

The eMMC/SD/SDIOi host controller goes into idle mode when the PRCM issues an IDLE request, according to its internal activity.

The eMMC/SD/SDIO host controller acknowledges the IDLE request from the PRCM after ensuring the following:

- The current multi- or single-block transfer is complete.
- Any interrupt or DMA request is asserted.
- There is no card interrupt on the DATA[1] signal.

As long as the eMMC/SD/SDIOi controller does not acknowledge the IDLE request, if an event occurs, the eMMC/SD/SDIOi host controller can still generate an interrupt or a DMA request. In this case, the module ignores the IDLE request from the PRCM module.

As soon as the eMMC/SD/SDIOi controller acknowledges the IDLE request from the PRCM module:

- If smart-idle mode: The module does not assert any new interrupt or DMA request.
- If smart-idle wake-up-capable mode: The module may generate wake-up events related to an interrupt or DMA request.

Wake-Up Event in Smart-Idle Mode

The wake-up feature is enabled when both the MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit and one of the three bits MMCi.MMCHS_HCTL[26] REM, MMCi.MMCHS_HCTL[25] INS, MMCi.MMCHS_HCTL[24] IWE are set to 0x1.

The corresponding interrupt status enable bits must also be set before going in idle mode. Setting one of the following bits:

- MMCi.MMCHS_IE[8] CIRQ_ENABLE
- MMCi.MMCHS_IE[7] CREM_ENABLE
- MMCi.MMCHS_IE[6] CINS_ENABLE

to 0x1 enables the wakeup event detection. The source of wakeup can be identified after idle mode exiting by reading one of the corresponding MMCHS_STAT bits.

The wakeup is generated only in smart-idle mode, when the module is in idle mode.

Table 25-8 lists the supported cases in smart-idle mode.

Copyright © 2015–2017, Texas Instruments Incorporated

Table 25-8. Smart-Idle Mode and Wake-Up Capabilities

Mode	MMCi_ICLK Clock	MMCi_FCLK Clock	Wake-Up Event
Card interrupt	May be switched off(1)	May be switched off(1)	The module sends an asynchronous wake-up request when a card interrupt on the DATA[1] signal is detected.
Card insertion	May be switched off(1)	May be switched off(1)	The module sends an asynchronous wake-up request when card insertion is detected.
Card removal	May be switched off(1)	May be switched off(1)	The module sends an asynchronous wake-up request when card removal is detected.

(1) The eMMC/SD/SDIOi host controller assumes that both clocks may be switched off, regardless of the value set in the MMCi.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY bit field.

Transition From Smart-Idle Mode to Normal Mode

The eMMC/SD/SDIO host controller detects the end of the idle period when the PRCM module deasserts the IDLE request.

For the wake-up event, there is a corresponding interrupt status in the MMCi.MMCHS_STAT register. The eMMC/SD/SDIOi host controller operates the conversion between the wake-up and interrupt (or DMA request) upon exit from smart-idle mode, if the associated enable bit is set in the MMCi.MMCHS_ISE register.

Interrupts and wake-up events have independent enable and disable controls, accessible through the MMCi.MMCHS_HCTL and MMCi.MMCHS_ISE registers. The overall consistency must be ensured by software.

One of the bits MMCHS_STAT[8] CIRQ, MMCHS_STAT[7] CREM, MMCHS_STAT[6] CINS in the interrupt status register is updated with the event that caused the wake-up when one of the bits MMCHS_IE[8] CIRQ_ENABLE, MMCHS_IE[7] CREM_ENABLE, MMCHS_IE[6] CINS_ENABLE is enabled.

Then, the wake-up event at the origin of the transition from smart-idle mode to normal mode is converted into its corresponding interrupt or DMA request. (The MMCi.MMCHS_STAT register is updated and the status of the interrupt signal changes.)

When the IDLE request from the PRCM module is deasserted, the module switches back to normal mode. The module is fully operational.

Force-Idle Mode

Force-idle mode is enabled when the MMCi.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0.

Force-idle mode is an idle mode in which the eMMC/SD/SDIOi host controller responds unconditionally to the IDLE request from the PRCM module. Moreover, in this mode, the eMMC/SD/SDIOi host controller unconditionally deasserts interrupts and DMA request lines if they are asserted.

The transition from normal mode to force-idle mode does not affect the bits of the MMCi.MMCHS_STAT register.

In force-idle mode, the interrupt and DMA request lines are deasserted. MMCi_ICLK and MMCi_FCLK can be switched off.

CAUTION

In force-idle mode, an IDLE request from the PRCM module during a command or a data transfer can lead to an unexpected and unpredictable result. When the module is idle, any access to the module generates an error as long as the MMCi_ICLK clock is alive.

Copyright © 2015–2017, Texas Instruments Incorporated

The module exits force-idle mode when the PRCM module deasserts the IDLE request. Then the module switches back to normal mode. The module is fully operational. Interrupt and DMA request lines are optionally asserted one clock cycle later.

Standby Mode

The eMMC/SD/SDIO host controller also provides standby information to the system power manager if the generic parameter MMCHS_HL_HWINFO[0] MADMA_EN is set to 1.

The eMMC/SD/SDIO host controller complies with the handshaking protocol of the PRCM module:

- Standby request from the eMMC/SD/SDIO host controller
- Wait acknowledgement from the PRCM module

The standby request varies according to the MMCi.MMCHS_SYSCONFIG[13:12] STANDBYMODE bit field:

- 0x0: Force-standby. The eMMC/SD/SDIO host controller sends the standby request to the system power manager unconditionally.
- 0x1: No-standby. The eMMC/SD/SDIO host controller does not generate any standby request to the system power manager and behaves normally
- 0x2: Smart-standby. The eMMC/SD/SDIO host controller sends the standby request to the system power manager according to the master L3 interface state.

Power Pad Control

The eMMC/SD/SDIO host controller has the ability to reduce the pad power leakage when no transfer is sent through the pad. According to the MMCHS_CON[15] PADEN there are two different pad power management modes: automatic and manual.

If MMCHS_CON[15] PADEN is set to 1, pads CLK, CMD, DAT[0] and DATA[i] (where i = 2 through 7) are always powerd on.

If MMCHS_CON[15] PADEN is set to 0, the power for pads CLK, CMD, DAT[0] and DATA[i] (where i = 2 through 7) is "ON" only when there is a transfer on going. This is automatically managed by an internal state machine of the eMMC/SD/SDIO host controller.

The DATA[1] pad active state is controlled through MMCHS_CON[11] CTPL in order to detect SDIO asynchronous interrupt when there is no transaction.

The delay between pad power "ON" and the command transmission is controlled through the MMCHS_PWCNT register which act as a programmable counter. It is also used to delay the pad power "OFF" after the end of transmission. By default this counter is reset which means that no additional delay is added. But there is approximately 6-7 clock cycles margin between pad power "ON" and real start of the command due to an internal state machine of the eMMC/SD/SDIO host controller.

NOTE: The MMCHS_PWCNT register is considered as static. No dynamic configuration during the transfer is supported. This results in an unpredictable behavior.

Local Power Management

Table 25-9 describes the power-management features available for the eMMC/SD/SDIOi modules.

NOTE: For information about source clock gating and a description of the sleep/wake-up transitions, see Section 3.6, *Clock Management Functional Description*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 25-9. Local Power-Management Features

Feature	Registers	Description
Clock auto gating	MMCHS_SYSCONFIG[0] AUTOIDLE	This bit allows a local power optimization inside the module by gating the MMCi_ICLK clock upon the interface activity, or gating the MMCi_FCLK clock upon the internal activity.

Copyright © 2015–2017, Texas Instruments Incorporated

Table 25-9. Local Power-Management Features (continued)

Feature	Registers	Description
Slave-idle modes	MMCHS_SYSCONFIG[3:4] SIDLEMODE	Force-idle, No-idle, Smart-idle and Smart-idle wake-up-capable modes are available.
Clock activity	MMCHS_SYSCONFIG[8:9] CLOCKACTIVITY	For configuration details, see Table 25-10.
Master standby modes	MMCHS_SYSCONFIG[12:13] STANDBYMODE	Force-standby, No-standby and Smart-standby modes are available.
Global wake-up enable	MMCHS_SYSCONFIG[2] ENAWAKEUP	This bit enables the wake-up feature at the module level.
Wake-up sources enable	MMCHS_HCTL register	This register holds one active-high enable bit per event source that is able to generate a wake-up signal.

Table 25-10. Clock Activity Settings

CLOCKACTIVITY Values	Clock State When Module is in IDLE State		Features Available When Module is in IDLE State	Wake-Up Events
	MMCi_ICLK	MMCi_ FCLK		
00	OFF	OFF	None	Card interrupt, Card insertion, Card removal
10	OFF	ON	None	
01	ON	OFF	None	
11	ON	ON	All	

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the CLOCKACTIVITY and MMCi clock PRCM control bits. For a description of the Clock activity feature, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

25.4.4 Interrupt Requests

Several internal module events can generate an interrupt. Each interrupt has a status bit, an interrupt enable bit, and a signal status enable:

- The status of each type of interrupt is automatically updated in the MMCi.MMCHS_STAT register; it indicates which service is required.
- The interrupt status enable bits of the MMCi.MMCHS_IE register enable or disable the automatic update of the MMCi.MMCHS_STAT register on an event-by-event basis.
- The interrupt signal enable bits of the MMCi.MMCHS_ISE register enable or disable the transmission of an interrupt request on the interrupt line MMCi_IRQ on an event-by-event basis.

If an interrupt status is disabled in the MMCi.MMCHS_IE register, then the corresponding interrupt request is not transmitted, and the value of the corresponding interrupt signal enable in the MMCi.MMCHS_ISE register is ignored.

When an interrupt event occurs, the corresponding status bit is automatically set to 0x1 (the eMMC/SD/SDIOi host controller updates the status bit) in the MMCi.MMCHS_STAT register. If a mask is later applied on the interrupt in the MMCi.MMCHS_ISE register, the interrupt request is deactivated.

When the interrupt source has not been serviced, if the interrupt status is cleared in the MMCi.MMCHS_STAT register and the corresponding mask is removed from the MMCi.MMCHS_ISE register, the interrupt status is not asserted again in the MMCi.MMCHS_STAT register and the eMMC/SD/SDIOi host controller does not transmit an interrupt request.

Copyright © 2015–2017, Texas Instruments Incorporated

NOTE: If the buffer write ready (BWR) interrupt or the buffer read ready (BRR) only interrupt are not serviced and are cleared in the MMCi.MMCHS_STAT register, and the corresponding mask is removed, then the eMMC/SD/SDIOi host controller waits for the service of the interrupt without updating the status MMCi.MMCHS_STAT register or transmitting an interrupt request.

Table 25-11 lists the event flags, and their mask, that can cause module interrupts.

Table 25-11. Events

Event Flag	Event Mask	Map to	Description
MMCHS_STAT[29] BADA	MMCHS_IE[29] BADA_ENABLE	MMCi_IRQ	Bad access to data space. This bit is set automatically to indicate a bad access to buffer when not allowed: This bit is set during a read access to the data register (MMCHS_DATA) while buffer reads are not allowed (MMCHS_PSTATE[11] BRE = 0). This bit is set during a write access to the data register (MMCHS_DATA) while buffer writes are not allowed (MMCHS_PSTATE[10] BWE = 0).
MMCHS_STAT[28] CERR	MMCHS_IE[28] CERR_ENABLE	MMCi_IRQ	Card error. This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5, or R5b. Only bits referenced as type E (error) in the status field in the response can set a card status error. An error bit in the response is flagged only if the corresponding bit in the card status response error MMCHS_CSRE is set. There is no card error detection for the auto CMD12 command.
MMCHS_STAT[26] TE	MMCHS_IE[26] TE_ENABLE	MMCi_IRQ	Tuning Error. This bit is set when an unrecoverable error is detected in a tuning circuit except during tuning procedure. The Tuning Error is with higher priority than the other error interrupts generated during data transfer.
MMCHS_STAT[25] ADMAE	MMCHS_IE[25] ADMAE_ENABLE	MMCi_IRQ	ADMA error. This bit is set when the host controller detects errors during an ADMA-based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA error status register. In addition, the host controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state.
MMCHS_STAT[24] ACE	MMCHS_IE[24] ACE_ENABLE	MMCi_IRQ	Auto CMD12 error and Auto CMD23 error. This bit is set automatically when one of the bits MMCHS_AC12[4:0] changes from 0 to 1.
MMCHS_STAT[22] DEB	MMCHS_IE[22] DEB_ENABLE	MMCi_IRQ	Data end bit error. This bit is set automatically when detecting a 0 at the end bit position of read data on the DAT line or at the end position of the CRC status in write mode.
MMCHS_STAT[21] DCRC	MMCHS_IE[21] DCRC_ENABLE	MMCi_IRQ	Data CRC error. This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status difference of a position 010 token during a block write command.
MMCHS_STAT[20] DTO	MMCHS_IE[20] DTO_ENABLE	MMCi_IRQ	Data time-out error. This bit is set automatically according to the following conditions: • Busy time-out for R1b, R5b response type • Busy time-out after write CRC status • Write CRC status time-out • Read data time-out

Copyright © 2015–2017, Texas Instruments Incorporated

Table 25-11. Events (continued)

Event Flag	Event Mask	Map to	Description
MMCHS_STAT[19] CIE	MMCHS_IE[19] CIE_ENABLE	MMCi_IRQ	Command index error. This bit is set automatically when the response index differs from the corresponding command index previously emitted. The check is enabled through the MMCHS_CMD[20] CICE bit.
MMCHS_STAT[18] CEB	MMCHS_IE[18] CEB_ENABLE	MMCi_IRQ	Command end bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response.
MMCHS_STAT[17] CCRC	MMCHS_IE[17] CCRC_ENABLE	MMCi_IRQ	Command CRC error. This bit is set automatically when a CRC7 error occurs in the command response. CRC check is enabled through the MMCHS_CMD[19] CCCE bit.
MMCHS_STAT[16] CTO	MMCHS_IE[16] CTO_ENABLE	MMCi_IRQ	Command time-out error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within five clock cycles, the time-out is still detected at 64 clock cycles.
MMCHS_STAT[15] ERRI	MMCHS_IE[15] ERRI_ENABLE	MMCi_IRQ	Error interrupt. If any of the bits in the error interrupt status register (MMCHS_STAT[31:16]) are set, this bit is set to 1.
MMCHS_STAT[10] BSR	MMCHS_IE[10] BSR_ENABLE	MMCi_IRQ	Boot status received interrupt. This bit is set automatically when the MMCHS_CON[18] BOOT_CF0 bit is set to 0x1 or 0x2 and a boot status is received on the dat0 line. This interrupt is useful only for the MMC card.
MMCHS_STAT[8] CIRQ	MMCHS_IE[8] CIRQ_ENABLE	MMCi_IRQ	Card interrupt. This bit is used only for SD, SDIO, and CE-ATA cards. In 1-bit mode, the interrupt source is asynchronous (can be a source of asynchronous wakeup). In 4-bit mode, the interrupt source is sampled during the interrupt cycle. In CE-ATA mode, the interrupt source is detected when the card drives the CMD line to 0 during one cycle after data transmission end.
MMCHS_STAT[7] CREM	MMCHS_IE[7] CREM_ENABLE	MMCi_IRQ	Card removal. This bit is set automatically when MMCHS_PSTATE[16] CINS changes from 1 to 0.
MMCHS_STAT[6] CINS	MMCHS_IE[6] CINS_ENABLE	MMCi_IRQ	Card insertion. This bit is set automatically when MMCHS_PSTATE[16] CINS changes from 0 to 1.
MMCHS_STAT[5] BRR	MMCHS_IE[5] BRR_ENABLE	MMCi_IRQ	Buffer read ready. This bit is set automatically during a read operation to the card (see class 2 block-oriented read commands) when one block specified by the MMCHS_BLK[10:0] BLEN bit field is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the LH must empty the buffer by reading it.
MMCHS_STAT[4] BWR	MMCHS_IE[4] BWR_ENABLE	MMCi_IRQ	Buffer write ready. This bit is set automatically during a write operation to the card (see class 4 block-oriented write command) when the host can write a complete block as specified by the MMCHS_BLK[10:0] BLEN bit field. It indicates that the memory card has emptied one block from the buffer and that the LH can write one block of data into the buffer.
MMCHS_STAT[3] DMA	MMCHS_IE[3] DMA_ENABLE	MMCi_IRQ	DMA interrupt. This status is set when an interrupt is required in the ADMA instruction and after the data transfer completes.

Table 25-11. Events (continued)

Event Flag	Event Mask	Map to	Description
MMCHS_STAT[2] BGE	MMCHS_IE[2] BGE_ENABLE	MMCi_IRQ	Block gap event. When a stop at the block gap is requested (MMCHS_HCTL[16] SBGR), this bit is automatically set when transaction is stopped at the block gap during a read or write operation.
MMCHS_STAT[1] TC	MMCHS_IE[1] TC_ENABLE	MMCi_IRQ	Transfer completed. This bit is always set when a read/write transfer is complete or between two blocks when the transfer is stopped because of a stop at block gap request (MMCHS_HCTL[16] SBGR). • In read mode: This bit is automatically set when a read transfer completes (MMCHS_PSTATE[9] RTA). • In write mode: This bit is automatically set when the DAT line use completes (MMCHS_PSTATE[2] DLA).
MMCHS_STAT[0] CC	MMCHS_IE[0] CC_ENABLE	MMCi_IRQ	Command complete. This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCHS_PSTATE[0] CMDI). If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command time-out error (MMCHS_STAT[16] CTO) has higher priority than command complete (MMCHS_STAT[0] CC). If a response is expected but none is received, then a command time-out error is detected and signaled, instead of the command complete interrupt.

NOTE: To send an interrupt request to the MMCi_IRQ line, the mask/unmask bit must be set in the MMCi.MMCHS_IE and MMCi.MMCHS_ISE registers.

The eMMC/SD/SDIOi host controller supports interrupt-driven operation and polling.

25.4.4.1 Interrupt-Driven Operation

An interrupt-enable bit must be set in the MMCi.MMCHS_IE register to enable the module internal source of interrupt.

When an interrupt event occurs, the single interrupt line is asserted and the LH must:

1. Read the MMCi.MMCHS_STAT register to identify which event occurred.
2. Write 1 into the corresponding bit of the MMCi.MMCHS_STAT register to clear the interrupt status and release the interrupt line (if a read is done after this write, this returns 0).

NOTE: In the MMCi.MMCHS_STAT register, the card interrupt (CIRQ) and error interrupt (ERRI) bits cannot be cleared.

The MMCi.MMCHS_STAT[8] CIRQ status bit must be masked by disabling the MMCi.MMCHS_IE[8] CIRQ_ENABLE bit (set to 0x0), and then the interrupt routine must clear the SDIO interrupt source in the SDIO card common control register (CCCR).

The MMCi.MMCHS_STAT[15] ERRI bit is automatically cleared when all status bits in the MMCi.MMCHS_STATregister (bits 31 through 16) are cleared.

25.4.4.2 Polling

When the interrupt capability of an event is disabled in the MMCi.MMCHS_ISE register, the interrupt line is not asserted:

Copyright © 2015–2017, Texas Instruments Incorporated

- Software can poll the status bit in the MMCi.MMCHS_STAT register to detect when the corresponding event occurs.
- Writing 1 into the corresponding bit of the MMCi.MMCHS_STAT register clears the interrupt status and does not affect the interrupt line state.

NOTE: See the previous note concerning clearing of the CIRQ and ERRI bits.

25.4.4.3 Asynchronous Interrupt

Asynchronous interrupt is defined in *SDIO Card Specification version 3.00, part E*. This interrupt is effective in 4-bit mode and is generated without SD clock. Asynchronous interrupt period is defined in the synchronous interrupt period after the last data block and until a next command is received.

Asynchronous interrupt period in a multiple block write operation.

If MMCHS_CAPA[29] AIS is set to 0, writing to MMCHS_AC12[30] AI_ENABLE is ignored. This bit is set to 0. A synchronous interrupt period starts two clocks after the last data block. If MMCHS_AC12[30] AI_ENABLE is set to 1, the asynchronous interrupt period starts four clocks after the start of the synchronous interrupt period. Four clocks after the start bit of the next command, the asynchronous interrupt period ends and goes back to the synchronous interrupt period.

25.4.5 DMA Modes

Two DMA management modes can be used to load data from memory to the internal buffer of the controller (or vice versa). These modes are exclusive and depend on the module integration.

- DMA master mode:

  DMA master mode is selected by setting the MMCHS_CON[20] DMA_MNS bit to 1. In this case, the controller has direct access to data using a specific algorithm called ADMA2 (prevents the system from being interrupted). Data are exchanged using the L3_MAIN master interface, which supports burst accesses to maximize throughput.

  NOTE: This mode is supported only by modules connected to the L3_MAIN interconnect. For more information and/or to check the value of the MMCHS_HL_HWINFO[0] MADMA_EN bit, see Section 25.1, *eMMC/SD/SDIO Overview*.

  This mode is available for modules MMC1 and MMC2.

- DMA slave mode:

  DMA slave mode is selected by setting the MMCHS_CON[20] DMA_MNS bit to 0. In this case, the controller is slave on the DMA transaction managed by two separated requests (MMCi_DMA_TX and MMCi_DMA_RX).

  NOTE: This mode is the only mode supported by modules that are not connected to the L3_MAIN interconnect (regardless of the value of the MMCHS_CON[20] DMA_MNS bit). For more information and/or to check the value of the MMCHS_HL_HWINFO[0] MADMA_EN bit, see Section 25.1, *eMMC/SD/SDIO Overview*.

  This mode is available for all MMC modules.

25.4.5.1 Master DMA Operations

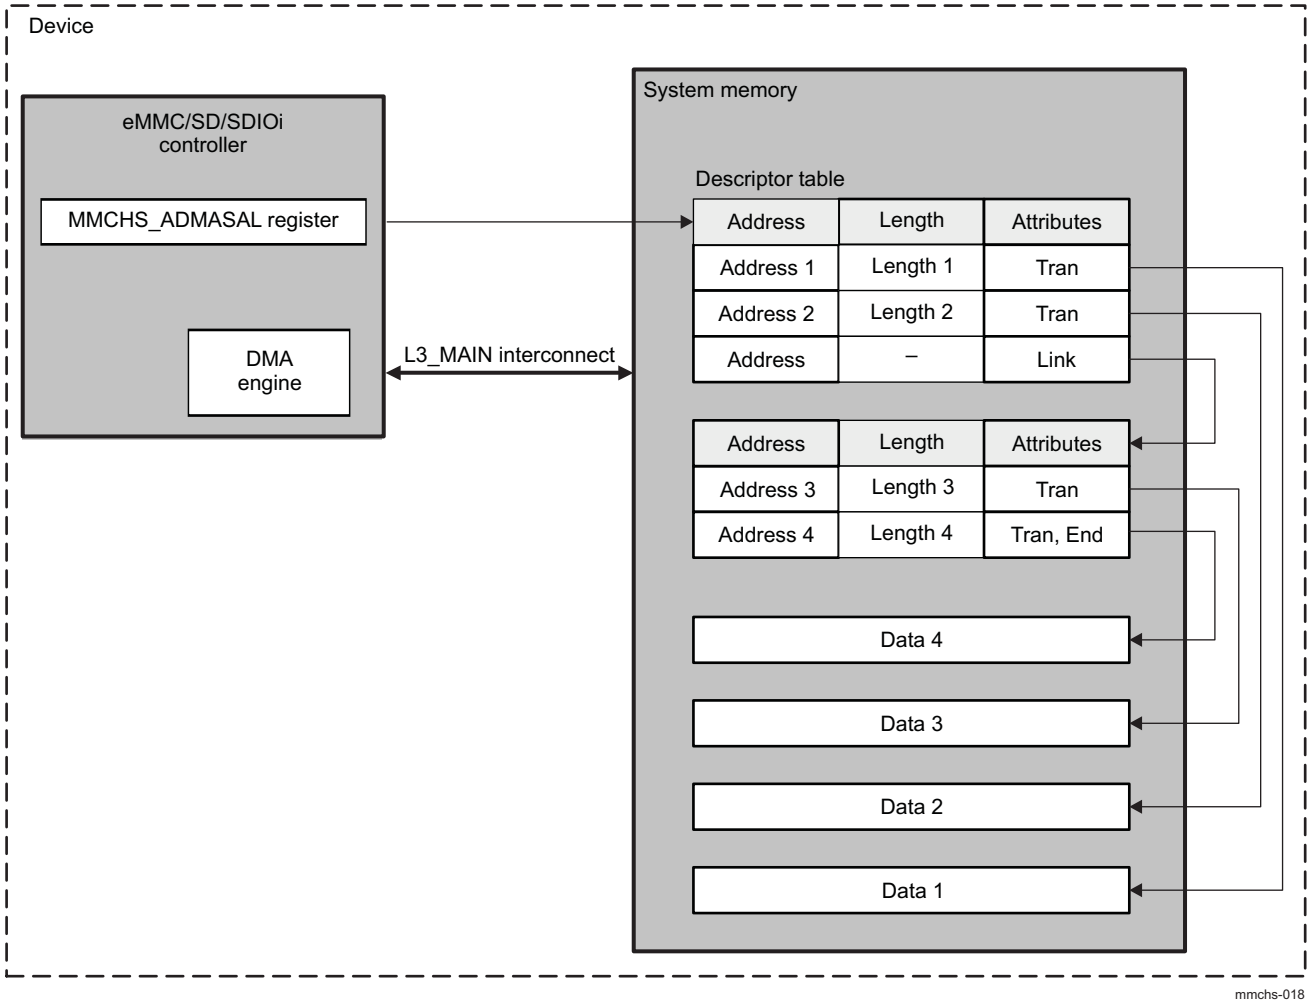
The eMMC/SD/SDIOi host controller has direct access to the internal data. This feature is called advanced DMA (ADMA). It follows a specific algorithm (ADMA2) defined by an instruction in memory that starts at an address previously loaded in the MMCHS_ADMASAL register before any data command issued to the MMC card. Only 32-bit address spacing is supported by the controller for data storage.

Copyright © 2015–2017, Texas Instruments Incorporated

NOTE: This mode is supported only by modules connected to the L3_MAIN interconnect. For more information and/or to check the value of the MMCHS_HL_HWINFO[0] MADMA_EN bit, see Section 25.1, *eMMC/SD/SDIO Overview*.

These instructions must be loaded by software in a 32-bit-addressed descriptor table in system memory, as shown in Figure 25-16. In this case the MMCHS_ADMASAL register is used as the program address pointer

Figure 25-16. ADMA Block Diagram Overview



25.4.5.1.1 Descriptor Table Description

Each descriptor line contains an address, a length, and attributes fields. The attributes define which operation will be processed. Every descriptor line is a 64-bit-wide register that is fetched in the controller using the L3_MAIN master interface, and requires two 32-bit accesses to memory.

Table 25-12 shows the structure of a descriptor line.

Table 25-12. Descriptor Line Overview

Address Field		Length		Reserved		Attributes					
63	32	31	16	15	6	5	4	3	2	1	0
32-bit address		16-bit length		0x0		Act2	Act1	0	Int	Ent	Valid

Copyright © 2015–2017, Texas Instruments Incorporated

The attribute of the descriptor line is divided into two parts:

- Attributes[5:4]: The action to be processed by the ADMA engine
- Attributes[3:0]: Additional parameters characterizing the behavior of the ADMA engine

Table 25-13 describes the available actions of a descriptor line.

Table 25-13. Available Actions of a Descriptor Line

Act2	Act1	Symbol	Comment	Operation
0	0	Nop	No operation	Do not execute the current line and go to the next line.
0	1	Rsv	Reserved	Reserved action. Behaves the same as the Nop command.
1	0	Tran	Transfer data	Transfer data of one descriptor line.
1	1	Link	Link descriptor	Link to another descriptor.

Table 25-14 describes the additional parameters of a descriptor line.

Table 25-14. Additional Parameters of a Descriptor Line

Bit	Description
Valid	Valid = 1 indicates that this descriptor line is effective. If Valid = 0, an ADMA error interrupt is generated and the ADMA is stopped. This prevents runaways.
End	End = 1 indicates the end of a descriptor. The transfer-complete interrupt is generated when the operation of the descriptor line is complete.
Int	Int = 1 generates a DMA interrupt when the operation of the descriptor line is complete.

25.4.5.1.2 Requirements for Descriptors

The following sections discuss restrictions and tips on how to correctly configure the descriptors to be used by the ADMA engine.

25.4.5.1.2.1 Data Length

There are three requirements to program descriptors:

- The minimum unit of address is 4 bytes.
- The maximum data length of each descriptor line is less than 64 KiB.
- Total length = $Length_1$ + $Length_2$+ $Length_3$ + ... + $Length_n$ must be a multiple of the block size.

If the total length of a descriptor is not a multiple of the block size, data transfer with the ADMA engine may not have been terminated. In this case, the controller returns a data time-out event and the transfer is aborted.

The block count register (the MMCHS_BLK[31:16] NBLK bit field) is defined as 16 bits and limits data transfers to a maximum of 65,535 blocks. If the ADMA data transfer size is less than or equal to the 65,535-block transfer, the block count register can be used. In this case, the total length of the descriptor table must be equivalent to "block size" by "block count." If the ADMA data transfer is greater than 65,535 blocks, the block count register must be disabled by setting the block count enable bit (MMCHS_CMD[1] BCE) to 0. In this case, the length of the data transfer is not designated by the block count but by the descriptor table.

NOTE: The timing for detecting the last block on the SD bus may differ, which affects control of the read transfer active (MMCHS_PSTATE[9] RTA), write transfer active (MMCHS_PSTATE[8] WTA), and DAT line active (MMCHS_PSTATE[2] DLA) bits. In case of a read operation, more blocks than required may be read from the card. The host driver must ignore an out-of-range error if the read operation is for the last block of the memory area.

Copyright © 2015–2017, Texas Instruments Incorporated

25.4.5.1.2.2 Supported Features

The ADMA engine does not support the suspend/resume function. However, the stop and continue functions are available.

When the stop-at-block-gap request (the MMCHS_HCTL[16] SBGR bit) is set during the ADMA operation, the block gap event interrupt is generated when the ADMA is stopped at block gap (the MMCHS_STAT[2] BGE bit). The host controller must stop the ADMA read operation by using read wait or by stopping the SD clock. While stopping ADMA, SD commands cannot be issued.

25.4.5.1.2.3 Error Generation

When an error occurs during an ADMA transfer, the ADMA operation is stopped and the ADMA error interrupt is generated. The ADMA error state field (the MMCHS_ADMAES[1:0] AES bit field) holds the state of the ADMA when it is stopped. Software can identify the erroneous descriptor line by using the following method:

- If the ADMA stopped at ST_FDS state, the ADMA system address register (MMCHS_ADMASAL) points to the erroneous descriptor line.
- If the ADMA stopped at ST_TFR or ST_STOP state, the ADMA system address register points to the descriptor line following the erroneous one.

25.4.5.1.3 Advanced DMA Description

The ADMA is a DMA controller embedded in each eMMC controller. It can be seen as a small sequencer that fetches a descriptor line and executes the corresponding action. The base address of the descriptor table is stored in the MMCHS_ADMASAL register.

NOTE: Software must write the base address of the descriptor table in the MMCHS_ADMASAL register before the first use of the ADMA engine.

The ADMA program is executed according to descriptor attributes (see Section 25.4.5.1.1, *Descriptor Table Description*) and an FSM, as shown in Figure 25-17.

Figure 25-17. ADMA Finite State-Machine

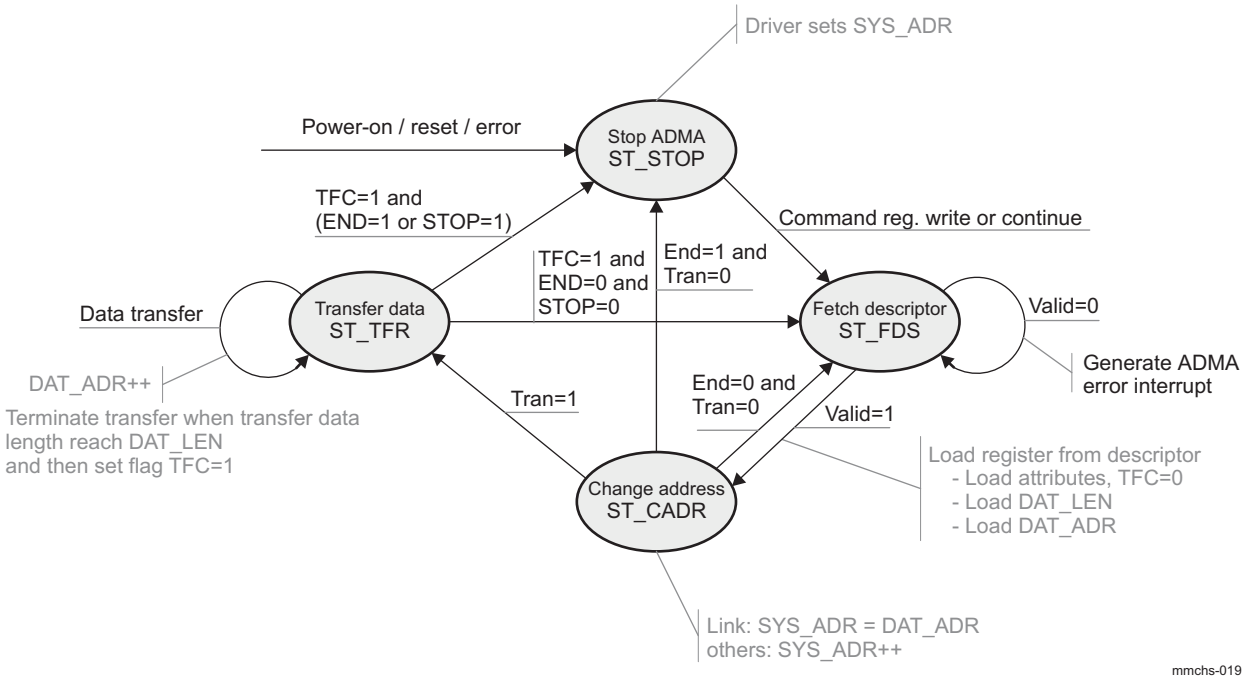


Table 25-15 describes each state of the ADMA FSM.

Copyright © 2015–2017, Texas Instruments Incorporated

Table 25-15. ADMA2 States Description

State Name	Operation
ST_FDS (fetch descriptor)	ADMA2 fetches a descriptor line and sets parameters in internal registers. It then goes to ST_CADR state.
ST_CADR (change address)	Link operation loads another descriptor address to the ADMA system address register (MMCHS_ADMASAL). In other operations, the ADMA system address register is incremented to point to the next descriptor line. If End = 0, go to ST_FDS state. **NOTE**: ADMA2 does not stop at this state if some errors occur.
ST_TFR (transfer data)	Data transfer of one descriptor line is executed between system memory and the SD card: • If data transfer continues (End = 0), go to ST_FDS state. • If data transfer completes, go to ST_STOP state.
ST_STOP (stop DMA)	ADMA2 stays in this state in the following cases: • After power-on reset (POR) or software reset • All descriptor data transfers are complete. If a new ADMA operation is stated by writing the command register, go to ST_FDS state.

Table 25-16 gives the description of each symbol used in the ADMA FSM (see Figure 25-17).

Table 25-16. ADMA FSM Symbol Definition

Symbol	Definition
SYS_ADR	ADMA system address register
SYS_ADR++	Point to next descriptor line
DAT_ADR	Data address register (internal)
DAT_LEN	Data length register (internal)
TFC	Transfer complete flag (internal)
STOP	Stop-at-block-gap request

25.4.5.2 Slave DMA Operations

The eMMC/SD/SDIOi host controller can be interfaced with a DMA controller. At the system level, the advantage is to discharge the LH of the data transfers. The module does not support wide DMA access (more than 1024 bytes) for SD cards, as specified in the *SD Card Specification* and *SD Host Controller Standard Specification*.

NOTE: This mode is implied by modules that are not connected to the L3_MAIN interconnect (regardless of the value of the MMCHS_CON[20] DMA_MNS bit). For more information and/or to check the value of the MMCHS_HL_HWINFO[0] MADMA_EN bit, see Section 25.4.5.1, *Master DMA Operations*.

The DMA request is issued if the following conditions are met:

- The MMCi.MMCHS_CMD[0] DE bit is set to 1 to trigger the initial DMA request (the write must be done when running the data transfer command).
- A command was emitted on the CMD line.
- There is enough space in the buffer of the eMMC/SD/SDIOi host controller to write an entire block (BLEN writes).

25.4.5.2.1 DMA Receive Mode

In a DMA block read operation (single or multiple), the request signal MMCi_DMA_RX is asserted to its active level when a complete block is written in the buffer. The block size transfer is specified in the MMCi.MMCHS_BLK[10:0] BLEN bit field.

MMCi_DMA_RX is deasserted to its inactive level when the a certain device DMA module reads one word from the buffer.

Copyright © 2015–2017, Texas Instruments Incorporated

Only one request is sent per block; the DMA controller can make a 1-shot read access or several DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to the BLEN bit field block size.

New DMA requests are internally masked if the DMA has not read exactly BLEN bytes and a new complete block is not ready. Because DMA accesses are 32-bit accesses, the number of DMA reads is Integer(BLEN / 4) + 1.

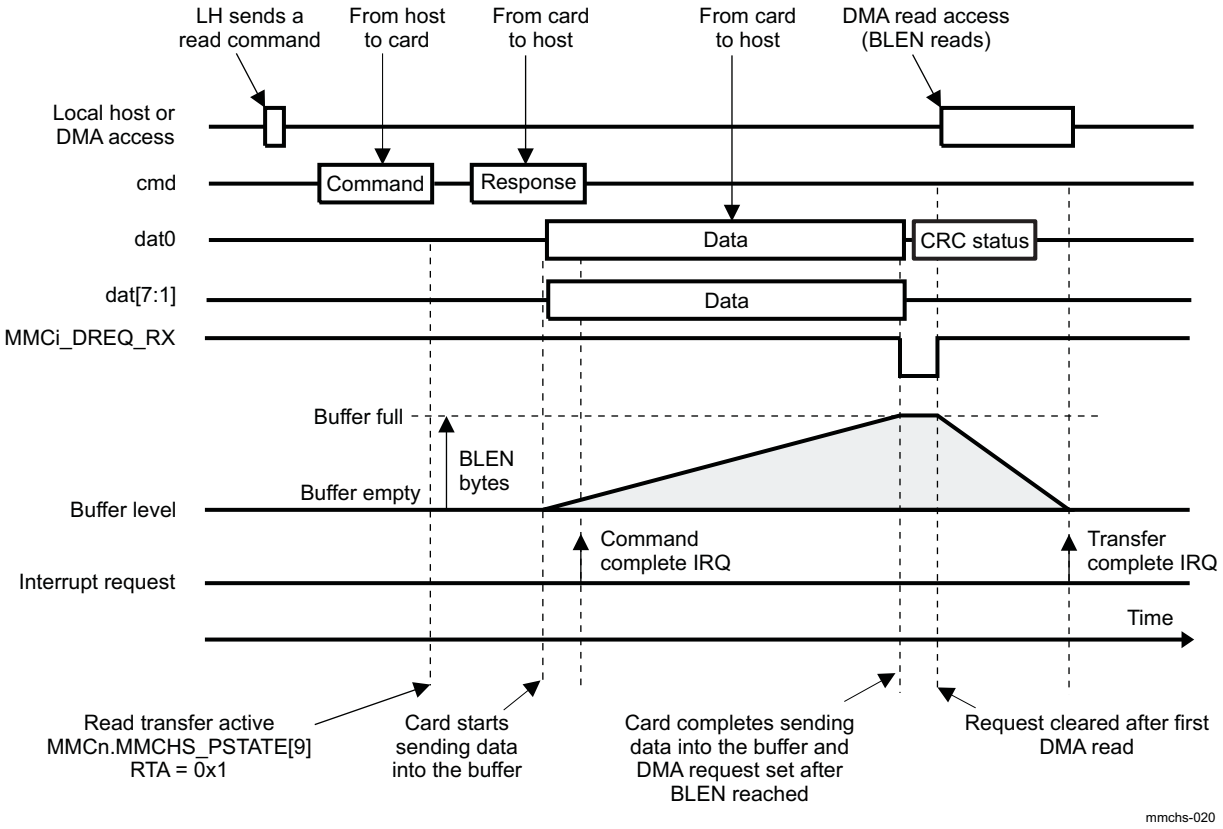
The receive buffer never overflows. In multiple block transfers for block sizes larger than 512 bytes, when the buffer becomes full, the mmci_clk clock signal (provided to the card) is momentarily stopped until a certain device DMA or the MPU performs a read access, which reads a complete block in the buffer.

To summarize:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 25-18 shows DMA receive mode.

Figure 25-18. DMA Receive Mode



25.4.5.2.2 DMA Transmit Mode

In a DMA block write operation (single or multiple), the request signal MMCi_DMA_TX is asserted to its active level when a complete block is to be written to the buffer. The block size transfer is specified in the MMCi.MMCHS_BLK[10:0] BLEN bit field.

MMCi_DMA_TX is deasserted to its inactive level when a certain device DMA writes one word to the buffer.

Only one request is sent per block; the DMA controller can make a 1-shot write access or multiple write DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to the BLEN bit field block size.

Copyright © 2015–2017, Texas Instruments Incorporated

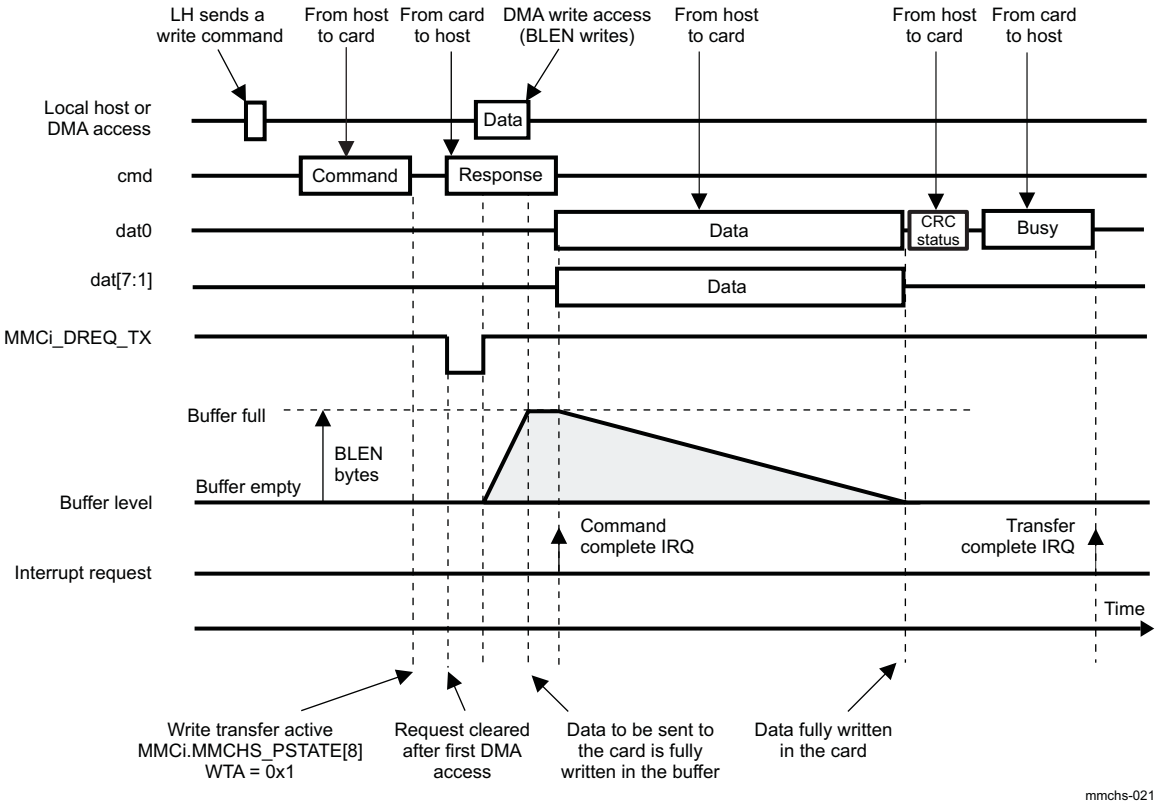
New DMA requests are internally masked if the DMA has not written exactly BLEN bytes (because DMA accesses are 32-bit accesses, the number of DMA reads is Integer(BLEN / 4) + 1) and if there is not enough memory space to write a complete block in the buffer.

To summarize:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 25-19 shows DMA transmit mode.

Figure 25-19. DMA Transmit Mode



25.4.6 Mode Selection

The eMMC/SD/SDIO host controller can be used in two modes: MMC and SD/SDIO. It has been designed to be the most transparent with the type of card.

The type of the card connected is differentiated by the software initialization procedure. Software identifies the type of card connected during software initialization. For each card type, there are corresponding commands. Some commands are not supported by all cards. For more information, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification, Part E1*.

The purpose of the module is to transfer commands and data to whatever card is connected, respecting the protocol of the connected card.

Writes and reads to the card must respect the appropriate protocol of that card.

25.4.7 Buffer Management

25.4.7.1 Data Buffer

The eMMC/SD/SDIOi host controller uses a data buffer. This buffer transfers data from one data bus (interconnect) to another data bus (SD/SDIO or MMC card bus) and vice versa.

Copyright © 2015–2017, Texas Instruments Incorporated

The buffer is the heart of the interface and ensures the transfer between the two interfaces (interconnect and the card).

To enhance performance, the data buffer is completed by a prefetch register and a post-write buffer that are not accessible by the host controller.

The read access time of the prefetch register is faster than that of the data buffer. The prefetch register allows data to be read from the data buffer at an increased speed by preloading data into the prefetch register.

The entry point of the prefetch buffer and the post-write buffer is the 32-bit MMCi.MMCHS_DATA register. A write access to the MMCi.MMCHS_DATA register followed by a read access from the MMCi.MMCHS_DATA register corresponds to a write access to the post-write buffer followed by a read access to the prefetch buffer. As a consequence, it is normal that the data of the write access to the MMCi.MMCHS_DATA register and the data of the read access to the MMCi.MMCHS_DATA register are different.

The number of 32-bit accesses to the MMCi.MMCHS_DATA register that are needed to read (or write) a data block with a size of the MMCi.MMCHS_BLK[11:0] BLEN bit field is equal to the rounded up result of BLEN divided by 4.

The maximum block size supported by the host controller is hard-coded in the MMCi.MMCHS_CAPA[17:16] MBL bit field and cannot be changed.

A read access to the MMCi.MMCHS_DATA register is allowed only when the buffer read-enable status is set to 1 (the MMCi.MMCHS_PSTATE[11] BRE bit); otherwise, a bad access (the MMCi.MMCHS_STAT[29] BADA bit) is signaled.

A write access to the MMCi.MMCHS_DATA register is allowed only when the buffer write-enable status is set to 1 (the MMCi.MMCHS_PSTATE[10] BWE bit); otherwise, a bad access (the MMCi.MMCHS_STAT[29] BADA bit) is signaled and the data are not written.

The data buffer has two modes of operation to store and read of the first and second portions of the data buffer:

- When the size of the data block to transfer is less than or equal to MEM_SIZE/2 (in double-buffering), two data transfers can occur at the same time from one data bus to the other data bus, and vice versa. The eMMC/SD/SDIOi host controller uses the two portions of the data buffer in a ping-pong manner so that storing and reading the first and second portions of the data buffer are automatically interchanged from time to time. In this way, data can be read from one portion (for instance, through a DMA read access on the interconnect bus) while data (for instance, from the card) are being stored into the other portion, and vice versa. When BLEN is less than or equal to 0x200 (that is, less than or equal to 512 bytes), each of the two portions of the buffer that can be used have a size of BLEN (that is, 32 bits × BLEN divided by 4). No more than this total size of 2 × 32 bits × BLEN divided by 4 can be used.

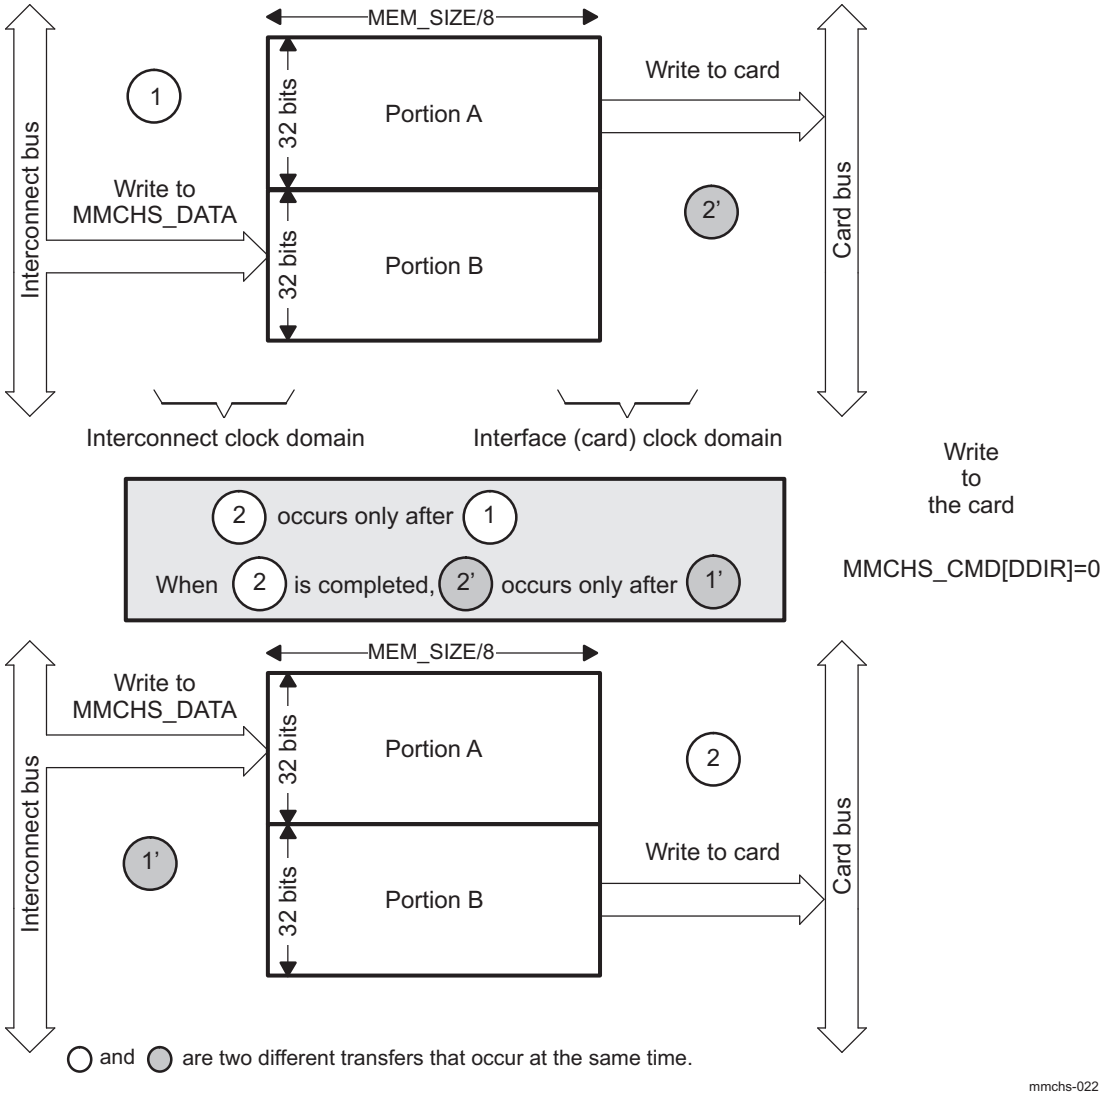
CAUTION

The MMCi.MMCHS_CMD[4] DDIR bit must be configured before a transfer to indicate the direction of the transfer.

Figure 25-20 and Figure 25-21 show the buffer management for a write and a read, respectively.

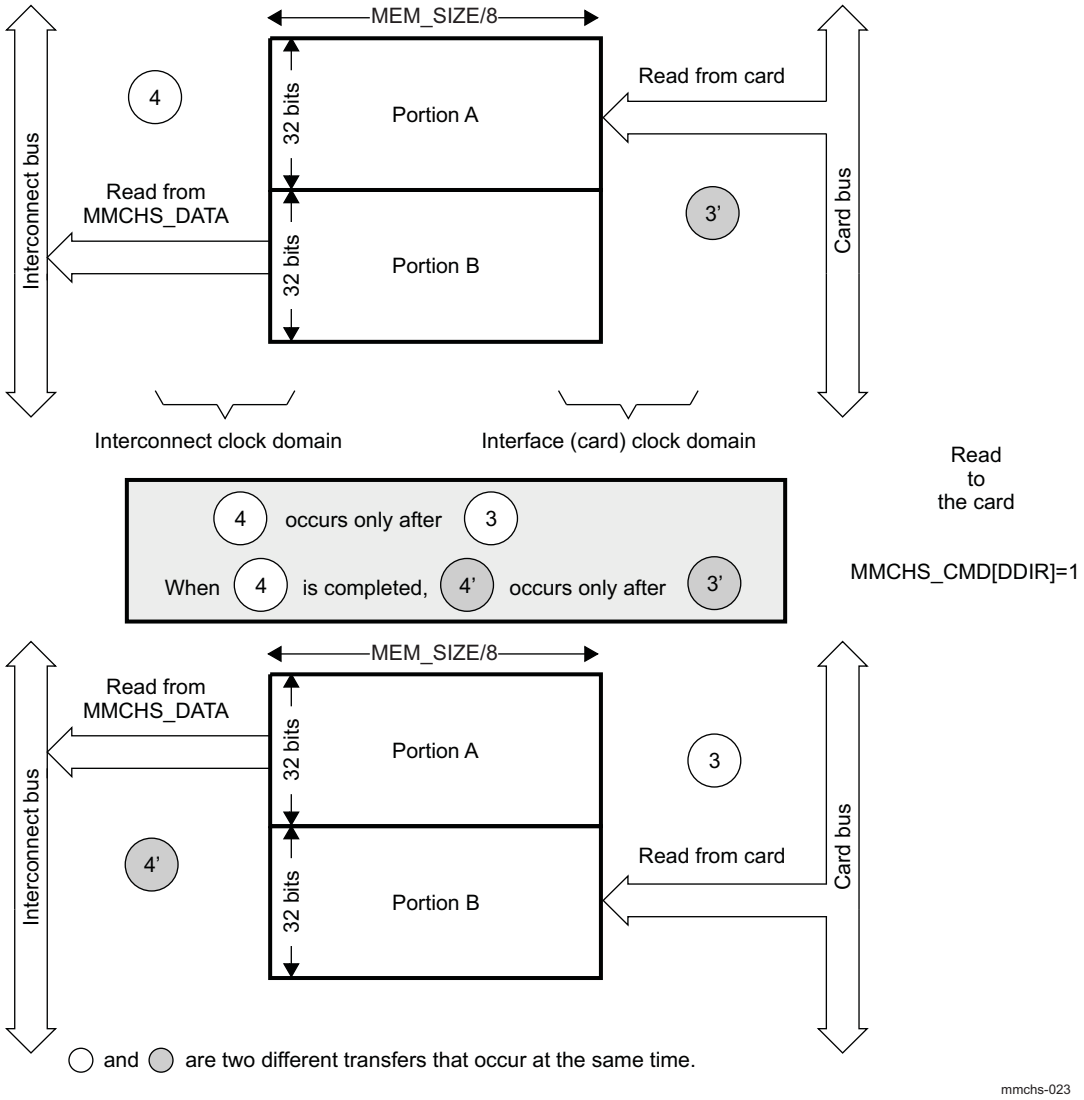
Copyright © 2015–2017, Texas Instruments Incorporated

Figure 25-20. Buffer Management for a Write



Copyright © 2015–2017, Texas Instruments Incorporated

Figure 25-21. Buffer Management for a Read



- When the size of the data block to transfer is larger than MEM_SIZE / 2, only one data transfer at a time can occur from one data bus to the other data bus. The eMMC/SD/SDIOi host controller uses the entire data buffer as a single portion.

  In this mode, a bad access (the MMCi.MMCHS_STAT[29] BADA bit) is signaled when two data transfers occur at the same time from one data bus to the other data bus, and vice versa.

25.4.7.1.1 Memory Size, Block Length, and Buffer-Management Relationship

The maximum block length and buffer management that can be targeted by the system depend on the memory depth setting (see Table 25-17).

NOTE: Double-buffering is always the buffer management for large memory depth.

Table 25-17. Memory Size, BLEN, and Buffer Relationship

Memory Size (MMCHS_HL_HWINFO[5:2] MEM_SIZE in bytes)	512	1024
Maximum block length supported	512	1024

Copyright © 2015–2017, Texas Instruments Incorporated

Table 25-17. Memory Size, BLEN, and Buffer Relationship (continued)

Memory Size (MMCHS_HL_HWINFO[5:2] MEM_SIZE in bytes)	512	1024
Double-buffering for maximum block length	N/A	BLEN <= 512
Single-buffering for block length	BLEN <= 512	512 < BLEN <= 1024

NOTE: For single-buffering management, throughput on the MMC bus interface deteriorates in multiblock transfers, because the controller must wait for the filling or emptying of the buffer between each block transfer on the MMC bus. The clock is maintained on write MMC transfers (the MMCHS_CMD[4] DDIR bit is 0) and halted on read MMC transfers (the MMCHS_CMD[4] DDIR bit is 1).

25.4.7.1.2 Data Buffer Status

The data buffer status is defined in the following interrupt status register and status register:

- Interrupt status registers:
  - MMCi.MMCHS_STAT[29] BADA: Bad access to data space
  - MMCi.MMCHS_STAT[5] BRR: Buffer read ready
  - MMCi.MMCHS_STAT[4] BWR: Buffer write ready
- Status registers:
  - MMCi.MMCHS_PSTATE[11] BRE: Buffer read enable
  - MMCi.MMCHS_PSTATE[10] BWE: Buffer write enable

25.4.8 Transfer Process

The process of a transfer depends on the type of command. It can be with or without a response, and with or without data.

25.4.8.1 Different Types of Commands

Different types of commands are specific to the MMC, SD, and SDIO cards. For more information, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, *SDIO Card Specification, Part E1*; or *the SD Card Specification, Part A2, SD Host Controller Standard Specification*.

25.4.8.2 Different Types of Responses

Different types of responses are specific to the eMMC, SD, and SDIO cards. For more information, see the *Multimedia Card System Specification*; *SD Memory Card Specifications*; *SDIO Card Specification, Part E1*, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification*.

Table 25-18 describes how the eMMC, SD, and SDIO responses are stored in the MMCHS_RSPxx registers.

Table 25-18. MMC, SD, SDIO Responses in the MMCHS_RSPxx Registers

Type of Response	Response Field	Response Register
R1, R1b (normal response), R3, R4, R5, R5b, R6, R7	RESP[39:8](1)	MMCHS_RSP10[31:0]
R1b (Auto CMD12 response), R1(Auto CMD23 response)	RESP[39:8](1)	MMCHS_RSP76[31:0]
R2	RESP[127:0](1)	MMCHS_RSP76[31:0] MMCHS_RSP54[31:0] MMCHS_RSP32[31:0] MMCHS_RSP10[31:0]

(1) RESP refers to the command response format described in the specifications mentioned.

Copyright © 2015–2017, Texas Instruments Incorporated

When the host controller modifies part of the MMCHS_RSPxx registers, it preserves the unmodified bits.

The host controller stores the Auto CMD12 response in the MMCHS_RSP76[31:0] register because the host controller may execute multiple block data transfers on the DATA line concurrently with a command. This allows the host controller to avoid overwriting the response of Auto CMD12 with the command response stored in the MMCHS_RSP10 register, and vice versa.

While executing Auto CMD23 the response of CMD23 is saved in the MMCHS_RSP76[31:0] register and the response of multiple-block read and write command is saved in the MMCHS_RSP10 register. The response error of CMD23 is indicated in the MMCHS_AC12 register, bits [7:0].

25.4.9 Transfer or Command Status and Errors Reporting

Flags in the eMMC/SD/SDIOi host controller show the status of communication with the card:

- A time-out (of a command, data, or response)
- A CRC error

Error conditions generate interrupts. For more information, see Table 25-19 and the register description.

Table 25-19. CC and TC Values Upon Error Detected

Error Hold in MMCi.MMCHS_STAT		CC	TC	Comments
29	BADA			No dependency with CC or TC BADA is related to the MMCHS_DATA register accesses. Its assertion does not depend on the ongoing transfer.
28	CERR	1		CC is set upon CERR.
22	DEB		1	TC is set upon DEB.
21	DCRC		1	TC is set upon DCRC.
20	DTO			DTO and TC are mutually exclusive. DCRC and DEB cannot occur with DTO.
19	CIE	1		CC is set upon CIE.
18	CEB	1		CC is set upon CEB.
17	CCRC	1		CC can be set upon CCRC. See CTO comment.
16	CTO			CTO and CC are mutually exclusive. CIE, CEB, and CERR cannot occur with CTO. CTO can occur at the same time as CCRC: It indicates a command abort due to contention on the CMD line. In this case no CC appears.

A MMCHS_STAT[20] DTO event can be asserted in the following conditions:

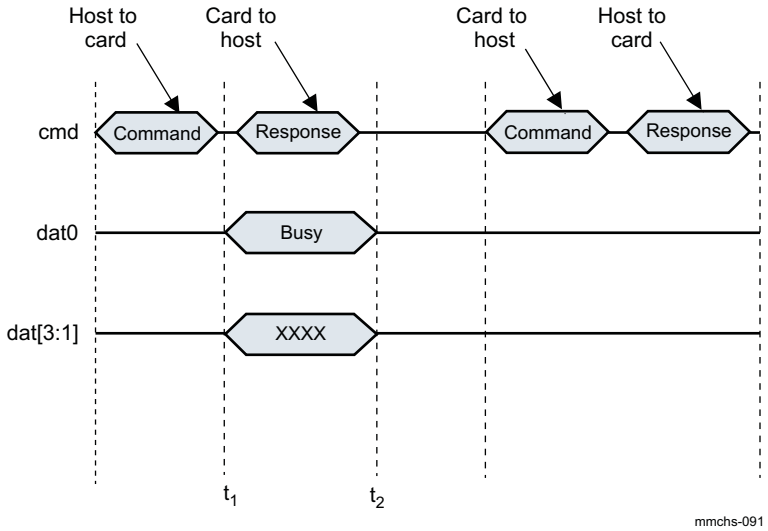
- Busy time-out for R1b, R5b response type
- Busy time-out after write CRC status
- Write CRC status time-out
- Read data time-out
- Boot acknowledge time-out

Copyright © 2015–2017, Texas Instruments Incorporated

25.4.9.1 Busy Time-Out for R1b, R5b Response Type

Figure 25-22 shows the DTO event condition asserted when there is a busy time-out for Rb1, R5b response.

Figure 25-22. Busy Time-Out for R1b, R5b Response Type



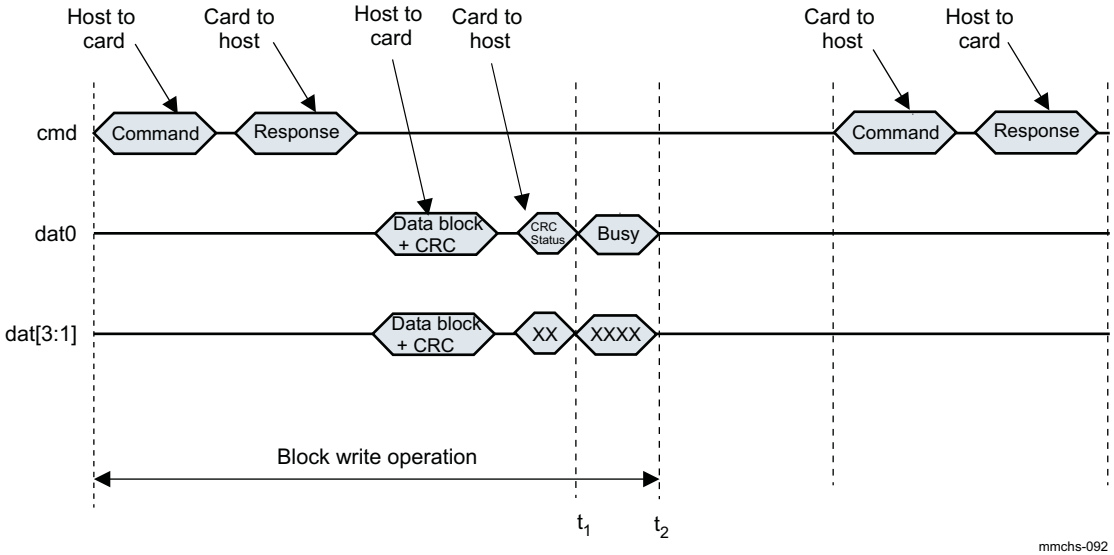
t_1 – Data time-out counter is loaded and starts after R1b, R5b response type.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

25.4.9.2 Busy Time-Out After Write CRC Status

Figure 25-23 shows the DTO event condition asserted when there is a busy time-out after write CRC status.

Figure 25-23. Busy Time-Out After Write CRC Status



t_1 – Data time-out counter is loaded and starts after CRC status.

t_2 – Data time-out counter stops and if it is 0, the MMCHS_STAT[20] DTO bit is generated.

25.4.9.3 Write CRC Status Time-Out

25.4.10 Auto Command 12 Timings

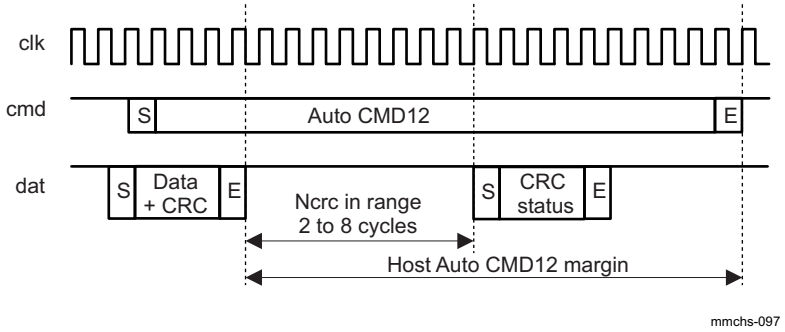
With the UHS definition of SD cards with higher frequency for MMC clock up to 208, the SD standard imposes a specific timing for the arrival of the auto command 12 (Auto CMD12) end bit.

25.4.10.1 Auto CMD12 Timings During Write Transfer

A margin named Ncrc in the range of two to eight cycles has been defined for SDR50 and SDR104 card components for write data transfers, because the Auto CMD12 end bit must arrive after the CRC status end bit.

Figure 25-28 shows the Auto CMD12 timings during write transfer.

Figure 25-28. Auto CMD12 Timings During Write Transfer



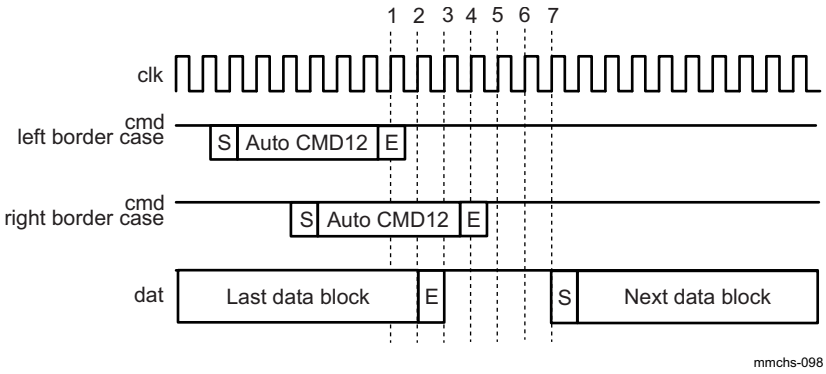
The host controller has a margin of 18 clock cycles to enure that the Auto CMD12 end bit arrives after the CRC status. This margin does not depend on the MMC/SD bus configuration, DDR, or standard transfer, 1-, 4-, or 8-bit bus width.

25.4.10.2 Auto CMD12 Timings During Read Transfer

With UHS cards, the gap timing between two successive cards is extended from two cycles to four cycles. It provides more flexibility for the host Auto CMD12 arrival to receive the last complete and reliable block. The MMCHS controller follows only the left border case defined by the SD UHS specification.

Figure 25-29 shows Auto CMD12 timings during read transfer.

Figure 25-29. Auto CMD12 Timings During Read Transfer



The Auto CMD12 arrival sent by the host controller is not sensitive to the MMC/SD bus configuration, whether it is a DDR or standard transfer and whether it is a 1-, 4-, or 8-bit bus width transfer.

25.4.11 Transfer Stop

Whenever a transfer is initiated, the transmission can be stopped before it finishes. Several cases are possible, depending on the transfer type:

- Multiple-block-oriented transfers (transfer length is known)

Copyright © 2015–2017, Texas Instruments Incorporated

- Continuous stream transfers (transfer has an infinite length)

NOTE: Because the eMMC/SD/SDIOi controller manages transfers based on a block granularity, the buffer accepts a block only if there is enough space to store it completely. Consequently, if a block is pending in the buffer, no command is sent to the card because the card clock will be shut off by the controller.

The eMMC/SD/SDIOi controller includes three features that make a transfer stop more convenient and easier to manage:

- Auto CMD12/Auto CMD23 (for eMMC and SD only):

  Auto CMD12/Auto CMD23 feature is enabled by setting the MMCi.MMCHS_CMD[3:2] ACEN bit field to 0x1 or to 0x2 respectively (this setting is relevant for an MMC/SD transfer with a known number of blocks to transfer). When the Auto CMD12/Auto CMD23 feature is enabled, the eMMC/SD/SDIOi controller automatically issues a CMD12/CMD23 command when the expected number of blocks is exchanged.
- Stop at block gap:

  This feature is enabled by setting the MMCi.MMCHS_HCTL[16] SBGR bit to 0x1. When enabled, this capability holds the transfer on until the end of a block boundary. If a stop transmission is needed, software can use this pause to send a CMD12 to the card.
- ADMA mode:

  For ADMA-capable modules (MMC1 and MMC2) (for more information, see Section 25.4.5, *DMA Modes*), the last instruction can stop the transfer (the END bit is enabled in the descriptor line).

NOTE: For eMMC and SD cards, the stop-at-block-gap feature is not supported in read mode.

For SDIO cards, this setting can be supported in read mode if the card has read-wait capability.

NOTE: In SDR104 mode Auto CMD23 is used to stop multiple block read/write operation instead of Auto CMD12. In the other bus speed modes, if the card supports CMD23, Auto CMD23 is used instead of Auto CMD12.

Table 25-20 shows the common way to stop a transfer, indicating the command to send and the features to enable.

Table 25-20. eMMC/SD/SDIOi Controller Transfer Stop Command Summary

		Write Transfer		Read Transfer	
		SD/MMC	SDIO	SD/MMC	SDIO
Single block		Transfer ends automatically. Wait TC.	Transfer ends automatically. Wait TC.	Transfer ends automatically. Wait TC.	Transfer ends automatically. Wait TC.
Multiblocks (finite or infinite)	Before the programmed block boundary	Send CMD12/CMD23. Wait TC.	Send CMD52. Wait TC.	Send CMD12/CMD23. Wait TC.	Send CMD52. Wait TC.
	Stop at the end of the transfer (finite transfer only)	Auto CMD12/Auto CMD23 active. Transfer ends automatically. Wait TC.	Set MMCi.MMCHS_HCTL[16] SBGR bit to 0x1. Send CMD52. Wait TC.	Auto CMD12/Auto CMD23 active. Transfer ends automatically. Wait TC.	**If READ_WAIT supported** Stop at block gap. Wait TC.
					If READ_WAIT not supported Send CMD52. Wait TC.

Copyright © 2015–2017, Texas Instruments Incorporated

NOTE: The eMMC/SD/SDIOi controller sends the stop command to the card on a block boundary, regardless of when the command was written to the controller registers.

25.4.12 Output Signals Generation

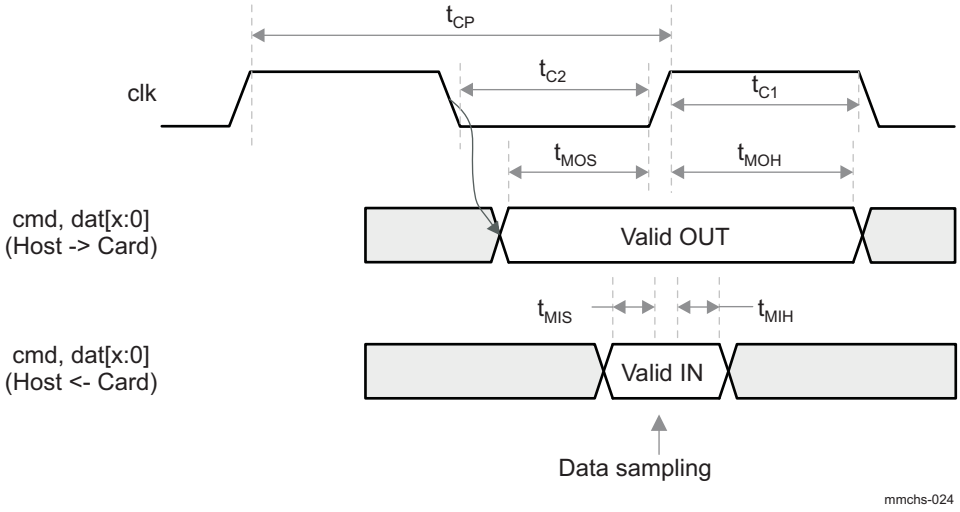
The eMMC/SD/SDIO output signals can be driven on the falling edge or rising edge, depending on the MMCHS_HCTL[2] HSPE bit.

25.4.12.1 Generation on Falling Edge of MMC Clock

The controller defaults to this mode to maximize hold timings. In this case, the MMCHS_HCTL[2] HSPE bit is set to 0.

Figure 25-30 shows the output signals of the module when generating from the falling edge of the MMC clock.

Figure 25-30. Output Driven on Falling Edge



25.4.12.2 Generation on Rising Edge of MMC Clock

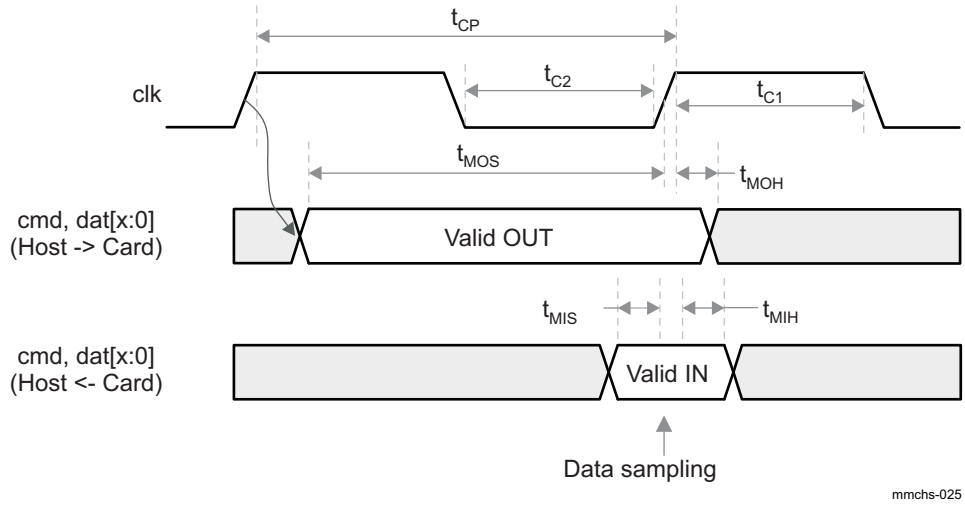
This mode is intended to increase setup timings. This feature is activated by setting the MMCHS_HCTL[2] HSPE bit to 1.

NOTE: Do not use this feature in DDR mode (when the MMCHS_CON[19] DDR bit is set to 1).

Figure 25-31 shows the output signals of the module when generating from the rising edge of the MMC clock.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 25-31. Output Driven on Rising Edge



25.4.13 Sampling Clock Tuning

In UHS-I mode the SD bus operates in high clock frequency mode and the data window from the card on CMD and DAT lines get smaller. The position of the data window varies depending on the card and the host system. To adjust the sampling clock when SDR104/HS200 operation mode is used the eMMC/SD/SDIOi host controller supports a tuning circuit. This tuning circuit is a dedicated DLL which delays the clock signal used for data sampling. The DLL is not part of the eMMC/SD/SDIOi host controller. It is instantiated at top level between the IOs and the host controller. There are two DLLs. One for MMC1 when SDR104 mode is used and one for MMC2 when HS200 mode is used.

In the default, lower frequency operation, a fixed sampling clock is used to receive signals on CMD and DAT lines. Before using the SDR104/HS200 or SDR50 (if MMCHS_CAPA2[13] TSDR50 = 0x1) modes software must execute the tuning procedure at the initialization sequence regardless of MMCHS_CAPA2[15:14] RTM value.

The software starts the tuning sequence by setting MMCHS_DLL[20] SWT to 1. Then it issues CMD19 for a SD card or CMD21 for an eMMC device repeatedly while cycling through 32 DLL ratios and recording pass/fail results for each. Thereafter the MMCHS_AC12[23] SCLK_SEL bit is checked and if it is set to 0 this indicates that the tuning procedure has failed. When MMCHS_AC12[23] SCLK_SEL is set to 1, this indicates that the tuning procedure has completed successfully. For more information about the DLL tuning procedure, see Section 25.5.1.2.4, *SDR104/HS200 DLL Tuning Procedure*.

NOTE: The eMMC/SD/SDIO controller supports a Conflict Error (CFT Error) on the CMD line. This error detection logic must be disabled for SDR104/HS200 mode by setting the MMCHS_DLL[20] SWT bit to 0x1 during the DLL tuning procedure. This value (0x1) must be kept while SDR104/HS200 mode is used.

The eMMC/SD/SDIO controller generates a CFT error when it detects that the value sent on the CMD line is not the same as the value returned, indicating an external source is overriding the value.

25.4.14 Card Boot Mode Management

Boot operation mode lets the eMMC/SD/SDIOi host controller read boot data from the connected slave (MMC device) by keeping the CMD line low after power on (or sending CMD0 with a specific argument) before issuing CMD1. The data can be read from the boot area or user area, depending on the register setting.

Copyright © 2015–2017, Texas Instruments Incorporated

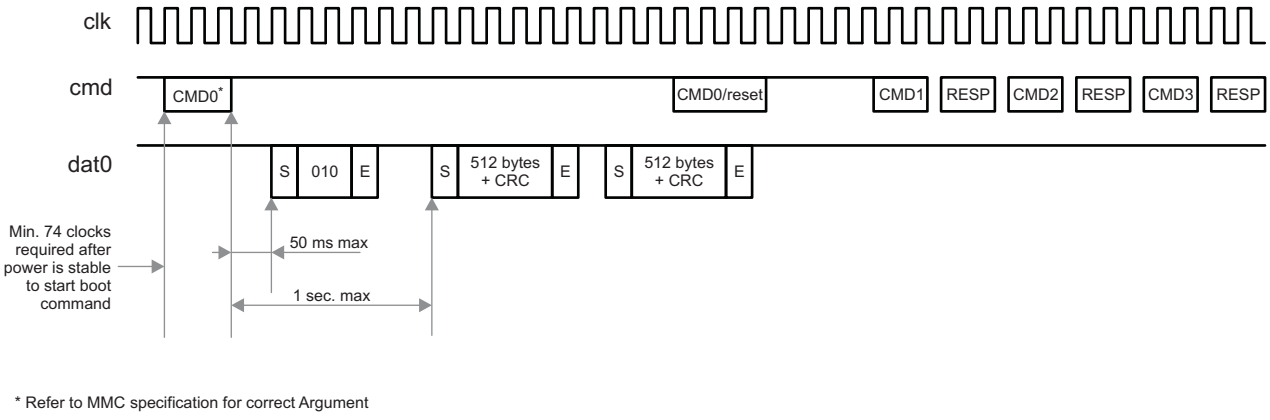
Power-on boot defines a way for the boot code to be accessed by the eMMC/SD/SDIOi host controller without an upper-level software driver, thus speeding the time it takes for a controller to access the boot code.

The two possible ways to issue a boot command (issuing a CMD0 or driving the CMD line to 0 during the whole boot phase) are described in the following sections.

25.4.14.1 Boot Mode Using CMD0

Figure 25-32 shows the timing diagram of a boot sequence using CMD0.

Figure 25-32. Boot Mode Using the CMD0 Timing Diagram



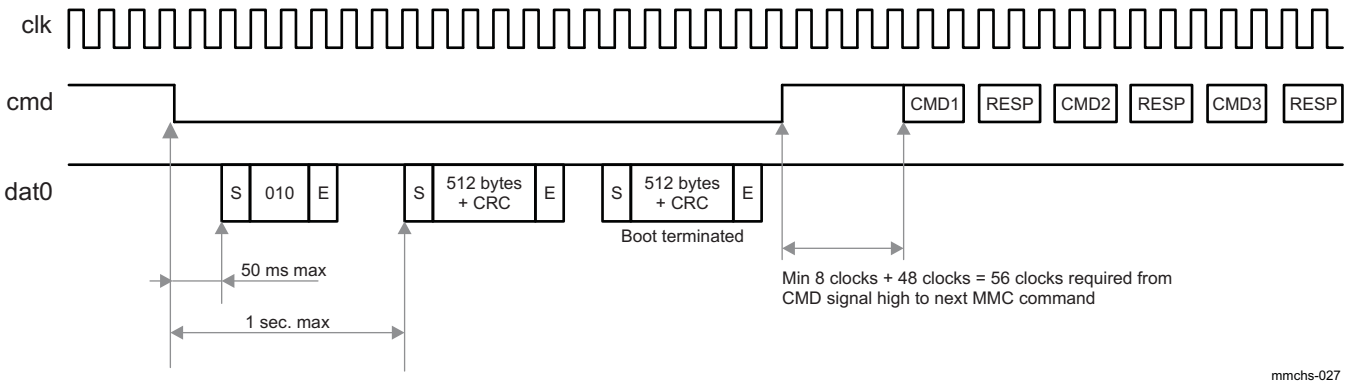
NOTE: Refer to MMC specification for correct Argument.

For more information about how to configure the eMMC/SD/SDIO host controller, see Section 25.5.1.2.3.1, *Boot Using the CMD0*.

25.4.14.2 Boot Mode With CMD Line Tied to 0

Figure 25-33 shows the timing diagram of a boot sequence with CMD line tied to 0.

Figure 25-33. Boot Mode With CMD Line Tied to 0 Timing Diagram



For more information about how to configure the eMMC/SD/SDIO host controller, see Section 25.5.1.2.3.2, *Boot With CMD Line Tied to 0*.

Copyright © 2015–2017, Texas Instruments Incorporated

25.4.15 MMC CE-ATA Command Completion Disable Management

The eMMC/SD/SDIOi host controller supports CE-ATA features, in particular the detection of the command completion token. When a command that requires a CCS (the MMCHS_CON[12] CEATA bit is set to 1 and the MMCHS_CMD[3:2] ACEN bit field is set to 0x1) is launched, the host system is no longer allowed to emit a new command in parallel to the data transfer unless it is a command completion disable token.

The settings to emit a command completion disable token are:

- Set the MMCHS_CON[12] CEATA bit to 1.
- Set the MMCHS_CON[2] HR bit to 1.
- Clear the MMCHS_ARG register.
- Write into the MMCHS_CMD register with the value 0x00000000.

When a command completion disable token was emitted (that is, the MMCHS_STAT[0] CC bit is received), the host system is again allowed to emit another type of command (for example, a CMD12 to abort transfer).

A critical case can be encountered when CCSD is emitted during the last data block transfer, and the sequence on the command line is sent close to the CCS token sent by the card.

Three possible cases are:

- CCS is received immediately before CCSD is emitted:

  An interrupt CIRQ is generated when CCS is detected, CCSD is transmitted to the card, and then an interrupt CC is generated when CCSD ends. In this case, the card considers the CCSD sequence.
- CCS is not generated or is generated during the CCSD transfer:

  The CCS bit cannot be detected (conflict is not possible because they drive the same level on the command line, and no CIRQ interrupt is generated; a CC interrupt is generated when CCSD ends).
- CCS is generated without CCSD token required:

  Only the interrupt CIRQ is generated when CCS is detected.

25.4.16 Test Registers

Test registers are available to comply with the *SD Host Controller Specification*. This feature is useful to generate interrupts manually for driver debugging.

The force event register (MMCHS_FE) is used to control the error status and error interrupt status for Auto CMD12 and Auto CMD23.

The system test register (MMCHS_SYSTEST) is used to control the signals that connect to I/O pins when the module is configured in the system test mode (the MMCHS_CON[4] MODE bit = 1) for boundary connectivity verification.

The MMCHS_HCTL[7] CDSS and MMCHS_HCTL[6] CDTL bits enable manual control of MMCHS_PSTATE[16] CINS and interrupt generating indicated in MMCHS_STAT[7] CREM and MMCHS_STAT[6] CINS.

25.4.17 eMMC/SD/SDIO Hardware Status Features

Table 25-21 describes the eMMC/SD/SDIO hardware status features.

Table 25-21. eMMC/SD/SDIO Hardware Status Features

Feature	Type	Register/Bit Field	Description
Interrupt flags		See Section 25.4.4, *Interrupt Requests.*	
CMD line signal level	Status	MMCHS_PSTATE[24] CLEV	Indicates the level of the command line
DAT lines signal level	Status	MMCHS_PSTATE[23:20] DLEV	Indicates the level of the data lines
Write protect switch pin level	Status	MMCHS_PSTATE[19] WP	Indicates whether the SD card is write protected or not.

Copyright © 2015–2017, Texas Instruments Incorporated

Table 25-21. eMMC/SD/SDIO Hardware Status Features (continued)

Feature	Type	Register/Bit Field	Description
Card detect pin level	Status	MMCHS_PSTATE[18] CDPL	Indicates the level of the mmci_sdcd signal/pad
Card State Stable	Status	MMCHS_PSTATE[17] CSS	Used for testing. Indicates mmci_sdcd stable state
Card inserted	Status	MMCHS_PSTATE[16] CINS	Indicates whether the SD card is inserted
Buffer read enable	Status	MMCHS_PSTATE[11] BRE	Readable data exists in the buffer.
Buffer write enable	Status	MMCHS_PSTATE[10] BWE	Indicates whether there is enough space in the buffer to write BLEN bytes of data
Read transfer active	Status	MMCHS_PSTATE[9] RTA	Used to detect completion of a read transfer.
Write transfer active	Status	MMCHS_PSTATE[8] WTA	Indicates a write transfer active
Re - Tuning Request	Status	MMCHS_PSTATE[3] RTR	Indicates whether the sampling clock needs re - tuning or not.
Data line active	Status	MMCHS_PSTATE[2] DLA	Indicates whether the data lines are active
Command Inhibit (DAT lines)	Status	MMCHS_PSTATE[1] DATI	Indicates whether issuing of command using data lines is allowed
Command inhibit (CMD line)	Status	MMCHS_PSTATE[0] CMDI	Indicates whether issuing of command using command line is allowed

Table 25-22 describes the eMMC/SD/SDIO preset value features.

Table 25-22. eMMC/SD/SDIO Preset Value Registers

Feature	Type	Register	Description
Preset value register	Status	MMCHS_PVINITSD	Preset Values for Initialization and Default Speed modes
Preset value register	Status	MMCHS_PVHSSDR12	Preset Values for High Speed and SDR12 speed modes
Preset value register	Status	MMCHS_PVSDR25SDR50	Preset Values for SDR25 and SDR50 speed modes
Preset value register	Status	MMCHS_PVSDR104DDR50	Preset Values for SDR104 and DDR50 speed modes

25.5 eMMC/SD/SDIO Programming Guide

25.5.1 Low-Level Programming Models

25.5.1.1 Global Initialization

25.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the module must be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the eMMC/SD/SDIO modules. For more information, see Section 25.3, *eMMC/SD/SDIO Integration*, and Section 25.2, *eMMC/SD/SDIO Environment*.Table 25-23 shows the global initialization of surrounding modules.

Table 25-23. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. See Chapter 3, *Power, Reset, and Clock Management*.
Control module	Module-specific pad muxing and configuration must be set in the control module. See Chapter 18, *Control Module* .
DMA_CROSSBAR	DMA_CROSSBAR configuration must be done to allow module DREQs to be mapped to certain device DMA line. For more information see Section 18.4.6.5, *DMA_CROSSBAR Module Functional Description*, in Chapter 18, *Control Module*.
Device DMAs	Device DMAs configuration must be done to enable the module DMA channel requests.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 18.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 18, *Control Module*
Device INTCs	Device INTCs must be configured to enable the interrupt request generation. For more information see Chapter 17 *Interrupt Controllers*

25.5.1.1.2 eMMC/SD/SDIO Host Controller Initialization Flow

Table 25-24 shows the general boot process.

Table 25-24. eMMC/SD/SDIO Controller Meta Initialization Steps

Step	Access Type	Register/Bit Field/Programming Model	Value
Initialize clocks.		See Section 25.5.1.1.2.1, *Enable Interface and Functional Clock for MMC Controller.*	
Software reset of the controller.		See Section 25.5.1.1.2.2, *MMCHS Soft Reset Flow*.	
Set module hardware capabilities.		See Section 25.5.1.1.2.3,*Set MMCHS Default Capabilities*.	
Set module idle and wake-up modes.		See Section 25.5.1.1.2.4, *Wake-Up Configuration*.	

25.5.1.1.2.1 Enable Interface and Functional Clock for MMC Controller

Before any MMCHS register access, the MMCHS interface clock and functional clock in the PRCM module registers must be enabled. See Section 3.6.4.1.4, *Clock Domain Module Attributes*, in Chapter 3, *Power, Reset, and Clock Management*.

25.5.1.1.2.2 MMCHS Soft Reset Flow

Figure 25-34 shows the soft reset process of the MMCHS controller.

25.5.1.2 Operational Modes Configuration

25.5.1.2.1 Basic Operations for eMMC/SD/SDIO Host Controller

The eMMC/SD/SDIO host controller performs data transfers: data to card (referred to as write transfers) and data from card (referred to as read transfers).

The host controller requires transfers to run on a block-by-block basis rather than on a DMA burst size basis. A single DMA request (or block request interrupt) is signaled for each block. Pipelining is supported as long as the block size is less than one half of the memory buffer size.

25.5.1.2.1.1 Card Detection, Identification, and Selection

Figure 25-36 and Figure 25-37 show the card detection, identification and selection process.

25.5.1.2.2 Bus Voltage Selection

The eMMC/SD/SDIO1 controller can operate with two types of card voltages: 1.8 V and 3.3 V. For this reason, dual voltage pads are implemented on this interface. For technological concerns, those pads must have an internal bias voltage reference to operate. The PBIAS module supplies this bias voltage, depending on the settings of the CTRL_CORE_CONTROL_PBIAS register.

For more information about the PBIAS cell, see Section 18.4.6.3, *PBIAS Cell And MMC1 I/O Cells Control Registers*, in Chapter 18, *Control Module*.

Figure 25-48 shows how to configure the MMC1 controller to fit with power switching sequence.

Figure 25-48. eMMC/SD/SDIO Power Switching Procedure

Subprocess Name	Cross-Reference
Send a READ_DAT_UNTIL_STOP command (CMD11).	See Section 25.5.1.2.1.7.1, *Command Transfer Flow*.

25.5.1.2.3 Boot Mode Configuration

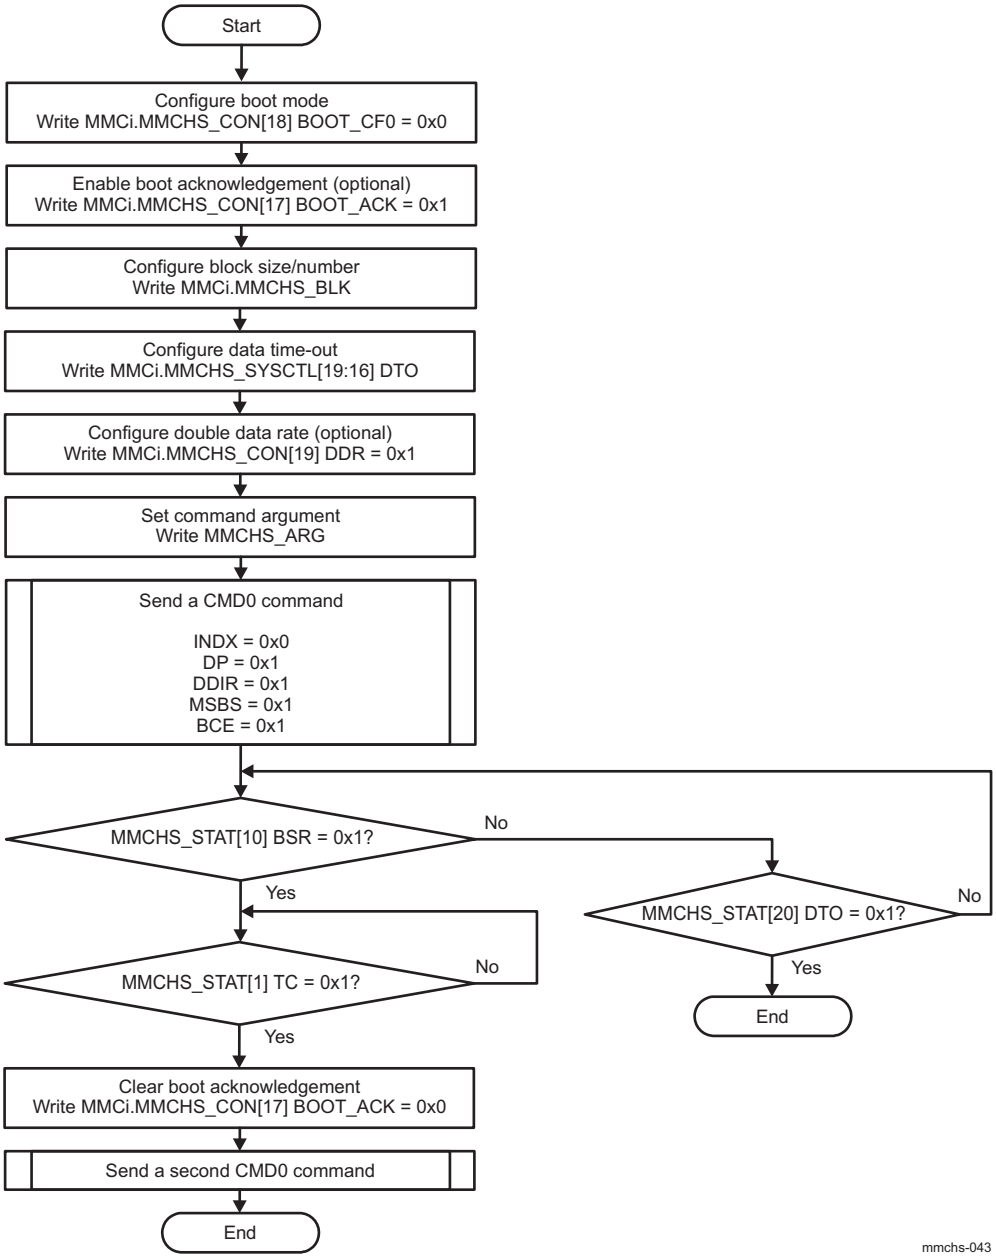
The following sections describe the two possible ways to issue a boot command: issue a CMD0 or drive the CMD line to 0 during the whole boot phase.

25.5.1.2.3.1 Boot Using CMD0

Figure 25-49 shows the necessary steps to configure the controller boot mode using CMD0.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 25-49. eMMC/SD/SDIO Controller Boot Using CMD0



To abort a boot sequence, the system must issue a CMD0 with the MMCHS_CMD[23:22] CMD_TYPE bit field set to 0x3 (the MMCHS_CON[17] BOOT_ACK bit previously cleared to 0x0) during the transfer to abort the transfer and enable the card to exit from boot state.

Table 25-53. Register Call Summary for Main Sequence – Boot Using CMD0

Register Name	Register Name	Register Name

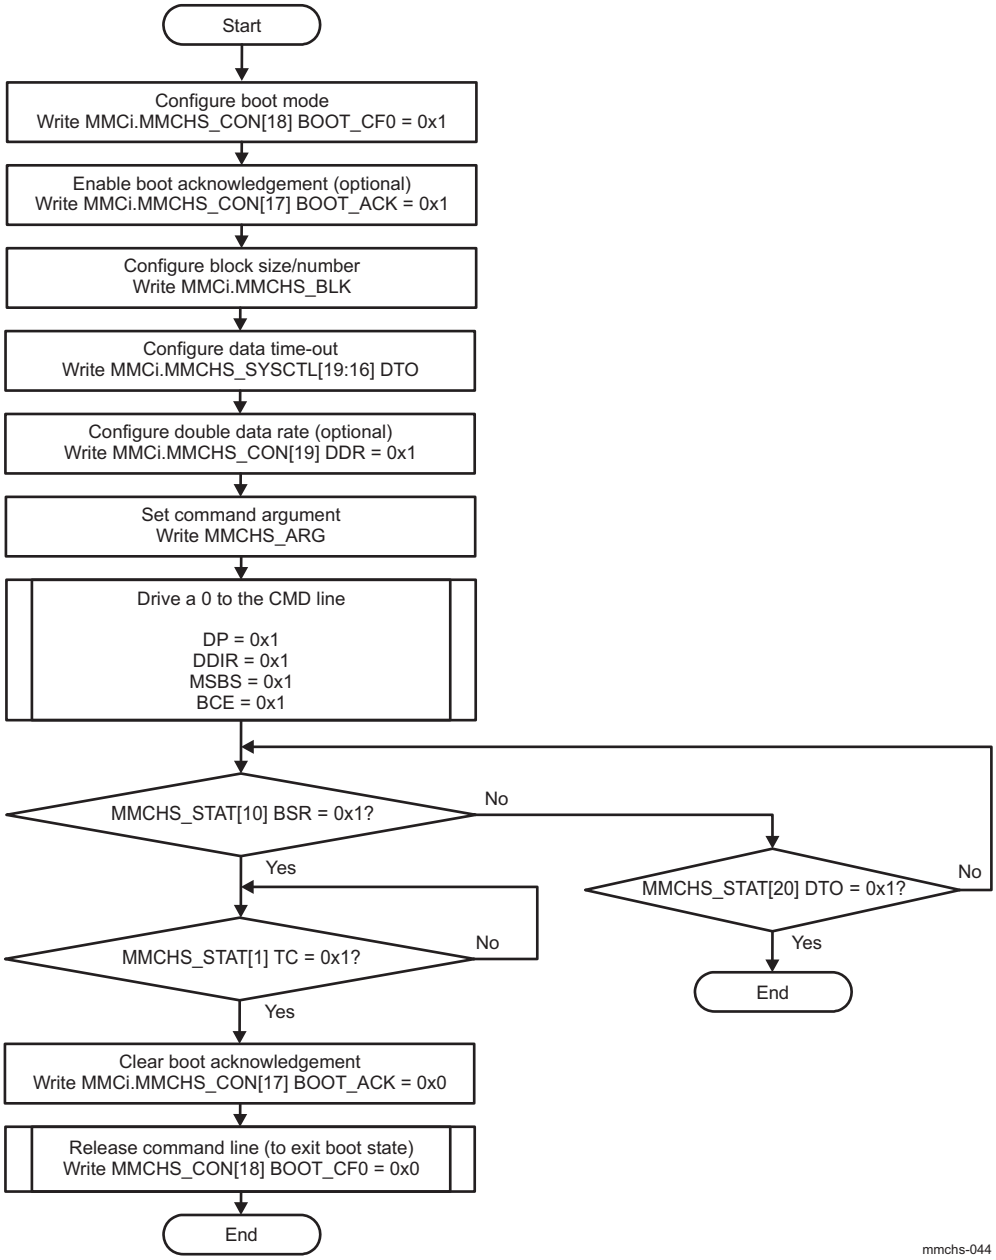
Table 25-54. Subprocess Call Summary for Main Sequence – Boot Using CMD0

Subprocess Name	Cross-Reference
Send a CMD0 command.	See Section 25.5.1.2.1.7.1, *Command Transfer Flow*.

25.5.1.2.3.2 Boot With CMD Line Tied to 0

Figure 25-50 shows the necessary steps to configure the controller in this mode; the driver must follow this sequence.

Figure 25-50. eMMC/SD/SDIO Controller Boot With CMD Line Tied to 0



To abort the boot sequence, the system must clear the MMCHS_CON[18] BOOT_CF0 bit to 0x0 during the transfer to abort the transfer and enable the card to exit from boot state.

Send a CMD0 command.	See Section 25.5.1.2.1.7.1, *Command Transfer Flow*.

25.5.1.2.4 SDR104/HS200 DLL Tuning Procedure

Figure 25-51 shows the DLL tuning procedure when SDR104 and HS200 modes are used.

NOTE: The BRR interrupt has to be enabled during tuning for functionality to succeed. The other error flags in MMCHS_IE can also be enabled for debug purposes. The MMCHS_SYSCTL[25] SRC bit can be set for command related interrupts, but caution has to be taken such that the MMCHS_SYSCTL[26] SRD bit is not set even when DAT related errors occurred, until after tuning completion.

Table 25-66. MMCHS_SYSCONFIG

Address Offset	0x0000 0110		
Physical Address	0x4809 C110 0x480B 4110 0x480A D110 0x480D 1110	**Instance**	MMC1 MMC2 MMC3 MMC4
Description	System Configuration Register This register allows controlling various parameters of the Interconnect interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																		STANDBYMODE		RESERVED		CLOCKACTIVITY		RESERVED			SIDLEMODE		ENAWAKEUP	SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:14	RESERVED		R	0x0 0000
13:12	STANDBYMODE	Master interface power Management, standby/wait control. The bit field is only useful when generic parameter MMCHS_HL_HWINFO[0] MADMA_EN (Master ADMA enable) is set as active, otherwise it is a read only register read a '0'. 0x0: Force-standby. Mstandby is forced unconditionnaly. 0x1: No-standby. Mstandby is never asserted. 0x2: Smart-standby mode: local initiator standby status depends on local conditions, i.e. the module's functional requirement from the initiator.IP module shall not generate (initiator-related) wakeup events.	RW	0x2
11:10	RESERVED		R	0x0
9:8	CLOCKACTIVITY	Clocks activity during wake up mode period. Bit8: Interface clock Bit9: Functional clock 0x0: Interface and Functional clock may be switched off. 0x1: Interface clock is maintained. Functional clock may be switched-off. 0x3: Interface and Functional clocks are maintained. 0x2: Functional clock is maintained. Interface clock may be switched-off.	RW	0x0
7:5	RESERVED	This bit is initialized to zero, and writes to it are ignored. Reads return 0.	R	0x0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
4:3	SIDLEMODE	Power management 0x0: If an IDLE request is detected, the MMCHS acknowledges it unconditionally and goes in Inactive mode. Interrupt and DMA requests are unconditionally de-asserted. 0x1: If an IDLE request is detected, the request is ignored and the module keeps on behaving normally. 0x3: Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's IDLE requests, depending on the IP module's internal requirements.IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state.Mode is only relevant if the appropriate IP module "swakeup" output(s) is (are) implemented. 0x2: Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's IDLE requests, depending on the IP module's internal requirements.IP module shall not generate (IRQ- or DMA-request-related) wakeup events.	RW	0x2
2	ENAWAKEUP	Wakeup feature control 0x0: Wakeup capability is disabled 0x1: Wakeup capability is enabled	RW	1
1	SOFTRESET	Software reset. The bit is automatically reset by the hardware. During reset, it always returns 0. Write 0x0: No effect. Write 0x1: Trigger a module reset. Read 0x1: The module is reset. Read 0x0: Normal mode	RW	0
0	AUTOIDLE	Internal Clock gating strategy 0x0: Clocks are free-running 0x1: Automatic clock gating strategy is applied, based on the Interconnect and MMC interface activity	RW	1

Table 25-70. MMCHS_CSRE

Address Offset	0x0000 0124		
Physical Address	0x4809 C124 0x480B 4124 0x480A D124 0x480D 1124	**Instance**	MMC1 MMC2 MMC3 MMC4
Description	Card Status Response Error This register enables the host controller to detect card status errors of response type R1, R1b for all cards and of R5, R5b and R6 response for cards types SD or SDIO. When a bit MMCHS_CSRE[i] is set to 1, if the corresponding bit at the same position in the response MMCHS_RSP0[i] is set to 1, the host controller indicates a card error (MMCHS_STAT[CERR]) interrupt status to avoid the host driver reading the response register (MMCHS_RSP0). Note: No automatic card error detection for autoCMD12 is implemented; the host system has to check autoCMD12 response register (MMCHS_RESP76) for possible card errors.

Address Offset	0x0000 0128		
Physical Address	0x4809 C128 0x480B 4128 0x480A D128 0x480D 1128	**Instance**	MMC1 MMC2 MMC3 MMC4
Description	System Test Register This register is used to control the signals that connect to I/O pins when the module is configured in system test (SYSTEST) mode for boundary connectivity verification. Note: In SYSTEST mode, a write into MMCHS_CMD register will not start a transfer. The buffer behaves as a stack accessible only by the local host (push and pop operations). In this mode, the Transfer Block Size (MMCHS_BLK[BLEN]) and the Blocks count for current transfer (MMCHS_BLK[NBLK]) are needed to generate a Buffer write ready interrupt (MMCHS_STAT[BWR]) or a Buffer read ready interrupt (MMCHS_STAT[BRR]) and DMA requests if enabled.

Bits	Field Name	Description	Type	Reset
31:17	RESERVED		R	0x0000
16	OBI	Out-Of-Band Interrupt (OBI) data value Read 0x1: The Out-of-Band Interrupt pin is driven high. Read 0x0: The Out-of-Band Interrupt pin is driven low.	R	0
15	SDCD	Card detect input signal (mmci_sdcd) data value Read 0x1: The card detect pin is driven high. Read 0x0: The card detect pin is driven low.	R	0
14	SDWP	Write protect input signal (mmci_sdwp) data value Read 0x1: The write protect pin mmci_sdwp is driven high. Read 0x0: The write protect pin mmci_sdwp is driven low.	R	0
13	WAKD	Wake request output signal data value Write 0x0: The pin SWAKEUP is driven low. Write 0x1: The pin SWAKEUP is driven high. Read 0x1: No action. Returns 1. Read 0x0: No action. Returns 0.	RW	0
12	SSB	Set status bit This bit must be cleared prior attempting to clear a status bit of the interrupt status register (MMCHS_STAT). Write 0x0: Clear this SSB bitfield. Writing 0 does not clear already set status bits; Write 0x1: Force to 1 all status bits of the interrupt status register (MMCHS_STAT) only if the corresponding bitfield in the Interrupt signal enable register (MMCHS_ISE) is set. Read 0x1: No action. Returns 1. Read 0x0: No action. Returns 0.	RW	0
11	D7D	DAT7 input/output signal data value Write 0x0: If SYSTEST[DDIR] = 0 (output mode direction), the DAT7 line is driven low. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Write 0x1: If SYSTEST[DDIR] = 0 (output mode direction), the DAT7 line is driven high. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Read 0x1: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT7 line (high) If SYSTEST[DDIR] = 0 (output mode direction), returns 1 Read 0x0: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT7 line (low). If SYSTEST[DDIR] = 0 (output mode direction), returns 0	RW	0
10	D6D	DAT6 input/output signal data value Write 0x0: If SYSTEST[DDIR] = 0 (output mode direction), the DAT6 line is driven low. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Write 0x1: If SYSTEST[DDIR] = 0 (output mode direction), the DAT6 line is driven high. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Read 0x1: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT6 line (high) If SYSTEST[DDIR] = 0 (output mode direction), returns 1 Read 0x0: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT6 line (low). If SYSTEST[DDIR] = 0 (output mode direction), returns 0	RW	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
9	D5D	DAT5 input/output signal data value Write 0x0: If SYSTEST[DDIR] = 0 (output mode direction), the DAT5 line is driven low. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Write 0x1: If SYSTEST[DDIR] = 0 (output mode direction), the DAT5 line is driven high. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Read 0x1: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT5 line (high) If SYSTEST[DDIR] = 0 (output mode direction), returns 1 Read 0x0: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT5 line (low). If SYSTEST[DDIR] = 0 (output mode direction), returns 0	RW	0
8	D4D	DAT4 input/output signal data value Write 0x0: If SYSTEST[DDIR] = 0 (output mode direction), the DAT4 line is driven low. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Write 0x1: If SYSTEST[DDIR] = 0 (output mode direction), the DAT4 line is driven high. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Read 0x1: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT4 line (high) If SYSTEST[DDIR] = 0 (output mode direction), returns 1 Read 0x0: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT4 line (low). If SYSTEST[DDIR] = 0 (output mode direction), returns 0	RW	0
7	D3D	DAT3 input/output signal data value Write 0x0: If SYSTEST[DDIR] = 0 (output mode direction), the DAT3 line is driven low. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Write 0x1: If SYSTEST[DDIR] = 0 (output mode direction), the DAT3 line is driven high. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Read 0x1: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT3 line (high) If SYSTEST[DDIR] = 0 (output mode direction), returns 1 Read 0x0: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT3 line (low). If SYSTEST[DDIR] = 0 (output mode direction), returns 0	RW	0
6	D2D	DAT2 input/output signal data value Write 0x0: If SYSTEST[DDIR] = 0 (output mode direction), the DAT2 line is driven low. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Write 0x1: If SYSTEST[DDIR] = 0 (output mode direction), the DAT2 line is driven high. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Read 0x1: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT2 line (high) If SYSTEST[DDIR] = 0 (output mode direction), returns 1 Read 0x0: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT2 line (low). If SYSTEST[DDIR] = 0 (output mode direction), returns 0	RW	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
5	D1D	DAT1 input/output signal data value Write 0x0: If SYSTEST[DDIR] = 0 (output mode direction), the DAT1 line is driven low. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Write 0x1: If SYSTEST[DDIR] = 0 (output mode direction), the DAT1 line is driven high. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Read 0x1: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT1 line (high) If SYSTEST[DDIR] = 0 (output mode direction), returns 1 Read 0x0: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT1 line (low). If SYSTEST[DDIR] = 0 (output mode direction), returns 0	RW	0
4	D0D	DAT0 input/output signal data value Write 0x0: If SYSTEST[DDIR] = 0 (output mode direction), the DAT0 line is driven low. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Write 0x1: If SYSTEST[DDIR] = 0 (output mode direction), the DAT0 line is driven high. If SYSTEST[DDIR] = 1 (input mode direction), no effect. Read 0x1: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT0 line (high) If SYSTEST[DDIR] = 0 (output mode direction), returns 1 Read 0x0: If SYSTEST[DDIR] = 1 (input mode direction), returns the value on the DAT0 line (low). If SYSTEST[DDIR] = 0 (output mode direction), returns 0	RW	0
3	DDIR	Control of the DAT[7:0] pins direction. Write 0x0: The DAT lines are outputs (host to card) Write 0x1: The DAT lines are inputs (card to host) Read 0x1: No action. Returns 1. Read 0x0: No action. Returns 0.	RW	0
2	CDAT	CMD input/output signal data value Write 0x0: If SYSTEST[CDIR] = 0 (output mode direction), the CMD line is driven low. If SYSTEST[CDIR] = 1 (input mode direction), no effect. Write 0x1: If SYSTEST[CDIR] = 0 (output mode direction), the CMD line is driven high. If SYSTEST[CDIR] = 1 (input mode direction), no effect. Read 0x1: If SYSTEST[CDIR] = 1 (input mode direction), returns the value on the CMD line (high) If SYSTEST[CDIR] = 0 (output mode direction), returns 1 Read 0x0: If SYSTEST[CDIR] = 1 (input mode direction), returns the value on the CMD line (low). If SYSTEST[CDIR] = 0 (output mode direction), returns 0	RW	0
1	CDIR	Control of the CMD pin direction. Write 0x0: The CMD line is an output (host to card) Write 0x1: The CMD line is an input (card to host) Read 0x1: No action. Returns 1. Read 0x0: No action. Returns 0.	RW	0
0	MCKD	MMC clock output signal data value Write 0x0: The output clock is driven low. Write 0x1: The output clock is driven high. Read 0x1: No action. Returns 1. Read 0x0: No action. Returns 0.	RW	0

Table 25-74. MMCHS_CON

Address Offset	0x0000 012C		
Physical Address	0x4809 C12C 0x480B 412C 0x480A D12C 0x480D 112C	**Instance**	MMC1 MMC2 MMC3 MMC4
Description	Configuration Register This register is used: - to select the functional mode or the SYSTEST mode for any card. - to send an initialization sequence to any card. - to enable the detection on DAT[1] of a card interrupt for SDIO cards only. and also to configure : - specific data and command transfers for MMC cards only. - the parameters related to the card detect and write protect input signals.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED										SDMA_LNE	DMA_MNS	DDR	BOOT_CF0	BOOT_ACK	CLKEXTFREE	PADEN	OBIE	OBIP	CEATA	CTPL	DVAL		WPP	CDP	MIT	DW8	MODE	STR	HR	INIT	OD

Bits	Field Name	Description	Type	Reset
31:22	RESERVED		R	0x000
21	SDMA_LNE	Slave DMA Level/Edge Request: The waveform of the DMA request can be configured either edge sensitive with early de-assertion on first access to MMCHS_DATA register or late de-assertion, request remains active until last allowed data written into MMCHS_DATA. 0x0: Slave DMA edge sensitive, Early DMA de-assertion 0x1: Slave DMA level sensitive, Late DMA de-assertion	RW	0
20	DMA_MNS	DMA Master or Slave selection: When this bit is set and the controller is configured to use the DMA, Interconnect master interface is used to get datas from system using ADMA2 procedure (direct access to the memory).This option is only available if generic parameter MADMA_EN is asserted to '1'. 0x0: The controller is slave on data transfers with system. 0x1: The controller is master on data exchange with system, controller must be configured as using DMA.	RW	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
19	DDR	Dual Data Rate mode: When this register is set, the controller uses both clock edge to emit or receive data. Odd bytes are transmitted on falling edges and even bytes are transmitted on rise edges. It only applies on Data bytes and CRC, Start, end bits and CRC status are kept full cycle. This bit field is only meaningful and active for even clock divider ratio of MMCHS_SYSCTL[CLKD], it is insensitive to MMCHS_HCTL[HSPE] setting. 0x0: Standard mode : data are transmitted on a single edge depending on MMCHS_HCTRL[HSPE]. 0x1: Data Bytes and CRC are transmitted on both edge.	RW	0
18	BOOT_CF0	Boot status supported: This register is set when the CMD line need to be forced to '0' for a boot sequence. CMD line is driven to '0' after writing in MMCHS_CMD. The line is released when this bit field is de-asserted and abort data transfer in case of a pending transaction. Write 0x0: CMD line is released when it was previously forced to '0' by a boot sequence. Write 0x1: CMD line forced to '0' is enabled and will be active after writing into MMCHS_CMD Read 0x1: CMD line forced to '0' is enabled Read 0x0: CMD line not forced	RW	0
17	BOOT_ACK	Boot acknowledge received: When this bit is set the controller should receive a boot status on DAT0 line after next command issued. If no status is received a data timeout will be generated. 0x0: No acknowledge to be received 0x1: A boot status will be received on DAT0 line after issuing a command.	RW	0
16	CLKEXTFREE	External clock free running: This register is used to maintain card clock out of transfer transaction to enable slave module for example to generate a synchronous interrupt on DAT[1]. The Clock will be maintain only if MMCHS_SYSCTL[CEN] is set. 0x0: External card clock is cut off outside active transaction period. 0x1: External card clock is maintain even out of active transaction period only if MMCHS_SYSCTL[CEN] is set.	RW	0
15	PADEN	Control Power for MMC Lines: This register is only useful when MMC PADs contain power saving mechanism to minimize its leakage power. It works as a GPIO that directly control the ACTIVE pin of PADs. Excepted for DAT[1], the signal is also combine outside the module with the dedicated power control MMCHS_CON[CTPL] bit. 0x0: ADPIDLE module pin is not forced, it is automatically generated by the MMC fsms. 0x1: ADPIDLE module pin is forced to active state.	RW	0
14	OBIE	Out-of-Band Interrupt Enable MMC cards only: This bit enables the detection of Out-of-Band Interrupt on MMCOBI input pin. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration. 0x0: Out-of-Band interrupt detection disabled 0x1: Out-of-Band interrupt detection enabled	RW	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
13	OBIP	Out-of-Band Interrupt Polarity MMC cards only: This bit selects the active level of the out-of-band interrupt coming from MMC cards. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration. 0x0: Active high level 0x1: Active low level	RW	0
12	CEATA	CE-ATA control mode MMC cards compliant with CE-ATA:By default, this bit is set to 0. It is used to indicate that next commands are considered as specific CE-ATA commands that potentially use 'command completion' features. 0x0: Standard MMC/SD/SDIO mode. 0x1: CE-ATA mode next commands are considered as CE-ATA commands.	RW	0
11	CTPL	Control Power for DAT[1] line MMC and SD cards: By default, this bit is set to 0 and the host controller automatically disables all the input buffers outside of a transaction to minimize the leakage current. SDIO cards: When this bit is set to 1, the host controller automatically disables all the input buffers except the buffer of DAT[1] outside of a transaction in order to detect asynchronous card interrupt on DAT[1] line and minimize the leakage current of the buffers. 0x0: Disable all the input buffers outside of a transaction. 0x1: Disable all the input buffers except the buffer of DAT[1] outside of a transaction.	RW	0
10:9	DVAL	Debounce filter value All cards This register is used to define a debounce period to filter the card detect input signal (mmci_sdcd). The usage of the card detect input signal (mmci_sdcd) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: 33 us debounce period 0x1: 231 us debounce period 0x3: 8,4 ms debounce period 0x2: 1 ms debounce period	RW	0x3
8	WPP	Write protect polarity For SD and SDIO cards only This bit selects the active level of the write protect input signal (mmci_sdwp). The usage of the write protect input signal (mmci_sdwp) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: Active high level 0x1: Active low level	RW	0
7	CDP	Card detect polarity All cards This bit selects the active level of the card detect input signal (mmci_sdcd). The usage of the card detect input signal (mmci_sdcd) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: Active low level 0x1: Active high level	RW	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
6	MIT	MMC interrupt command Only for MMC cards. This bit must be set to 1, when the next write access to the command register (MMCHS_CMD) is for writing a MMC interrupt command (CMD40) requiring the command timeout detection to be disabled for the command response. 0x0: Command timeout enabled 0x1: Command timeout disabled	RW	0
5	DW8	8-bit mode MMC select For SD/SDIO cards, this bit must be set to 0. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliancy with MMC standard specification 4.x (see section 3.6). 0x0: 1-bit or 4-bit Data width (DAT[0] used, MMC, SD cards) 0x1: 8-bit Data width (DAT[7:0] used, MMC cards)	RW	0
4	MODE	Mode select All cards This bit select between Functional mode and SYSTEST mode. 0x0: Functional mode. Transfers to the MMC/SD/SDIO cards follow the card protocol. MMC clock is enabled. MMC/SD transfers are operated under the control of the CMD register. 0x1: SYSTEST mode The signal pins are configured as general-purpose input/output and the 1024-byte buffer is configured as a stack memory accessible only by the local host or system DMA. The pins retain their default type (input, output or in-out). SYSTEST mode is operated under the control of the SYSTEST register.	RW	0
3	STR	Stream command Only for MMC cards. This bit must be set to 1 only for the stream data transfers (read or write) of the adtc commands. Stream read is a class 1 command (CMD11: READ_DAT_UNTIL_STOP). Stream write is a class 3 command (CMD20: WRITE_DAT_UNTIL_STOP). 0x0: Block oriented data transfer 0x1: Stream oriented data transfer	RW	0
2	HR	Broadcast host response Only for MMC cards. This register is used to force the host to generate a 48-bit response for bc command type. It can be used to terminate the interrupt mode by generating a CMD40 response by the core (see section 4.3, "Interrupt Mode", in the MMC specification). In order to have the host response to be generated in open drain mode, the register MMCHS_CON[OD] must be set to 1. When MMCHS_CON[CEATA] is set to 1 and MMCHS_ARG set to 0x00000000 when writing 0x00000000 into MMCHS_CMD register, the host controller performs a 'command completion signal disable' token i.e. CMD line held to '0' during 47 cycles followed by a 1. 0x0: The host does not generate a 48-bit response instead of a command. 0x1: The host generates a 48-bit response instead of a command or a command completion signal disable token.	RW	0

Bits	Field Name	Description	Type	Reset
1	INIT	Send initialization stream All cards. When this bit is set to 1, and the card is idle, an initialization sequence is sent to the card. An initialization sequence consists of setting the CMD line to 1 during 80 clock cycles. The initialisation sequence is mandatory - but it is not required to do it through this bit - this bit makes it easier. Clock divider (MMCHS_SYSCTL[CLKD]) should be set to ensure that 80 clock periods are greater than 1ms. (see section 9.3, "Power-Up", in the MMC card specification, or section 6.4 in the SD card specification). Note: in this mode, there is no command sent to the card and no response is expected 0x0: The host does not send an initialization sequence. 0x1: The host sends an initialization sequence.	RW	0
0	OD	Card open drain mode. Only for MMC cards. This bit must be set to 1 for MMC card commands 1, 2, 3 and 40, and if the MMC card bus is operating in open-drain mode during the response phase to the command sent. Typically, during card identification mode when the card is either in idle, ready or ident state. It is also necessary to set this bit to 1, for a broadcast host response (see Broadcast host response register MMCHS_CON[HR]) 0x0: No Open Drain 0x1: Open Drain or Broadcast host response	RW	0

SDMA_ARG2																															

Bits	Field Name	Description	Type	Reset
31:0	SDMA_ARG2	SDMA System Address / Argument 2 This register contains the physical system memory address used for DMA transfers or the second argument for the Auto CMD23. (1) SDMA System Address This register contains the system memory address for a SDMA transfer. When the Host Controller stops a SDMA transfer, this register shall point to the system address of the next contiguous data position. It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value. The Host Driver shall initialize this register before starting a SDMA transaction. After SDMA has stopped, the next system address of the next contiguous data position can be read from this register. The SDMA transfer waits at the every boundary specified by the Host SDMA Buffer Boundary in the Block Size register. The Host Controller generates DMA Interrupt to request the Host Driver to update this register. The Host Driver sets the next system address of the next data position to this register. When the most upper byte of this register (003h) is written, the Host Controller restarts the SDMA transfer. When restarting SDMA by the Resume command or by setting Continue Request in the Block Gap Control register, the Host Controller shall start at the next contiguous address stored here in the SDMA System Address register. ADMA does not use this register. (2) Argument 2 This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23. If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without AMDA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case.	RW	0x0000 0000

Physical Address	0x4809 C204 0x480B 4204 0x480A D204 0x480D 1204	**Instance**	MMC1 MMC2 MMC3 MMC4
Description	Transfer Length Configuration Register MMCHS_BLK[BLEN] is the block size register. MMCHS_BLK[NBLK] is the block count register. This register shall be used for any card.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NBLK																RESERVED				BLEN											

Bits	Field Name	Description	Type	Reset
31:16	NBLK	Blocks count for current transfer This register is enabled when Block count Enable (MMCHS_CMD[BCE]) is set to 1 and is valid only for multiple block transfers. Setting the block count to 0 results no data blocks being transferred. Note: The host controller decrements the block count after each block transfer and stops when the count reaches zero. This register can be accessed only if no transaction is executing (i.e, after a transaction has stopped). Read operations during transfers may return an invalid value and write operation will be ignored. In suspend context, the number of blocks yet to be transferred can be determined by reading this register. When restoring transfer context prior to issuing a Resume command, The local host shall restore the previously saved block count. 0xFFFF: 65535 blocks 0x0: Stop count 0x1: 1 block 0x2: 2 blocks	RW	0x0000
15:12	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
		These bits shall be set to 00b for all other commands. 0x0: Others Commands 0x1: CMD52 for writing "Bus Suspend" in CCCR 0x3: Abort command CMD12, CMD52 for writing " I/O Abort" in CCCR 0x2: CMD52 for writing "Function Select" in CCCR		
21	DP	Data present select This register indicates that data is present and DAT line shall be used. It must be set to 0 in the following conditions: - command using only CMD line - command with no data transfer but using busy signal on DAT[0] - Resume command 0x0: Command with no data transfer 0x1: Command with data transfer	RW	0
20	CICE	Command Index check enable This bit must be set to 1 to enable index check on command response to compare the index field in the response against the index of the command. If the index is not the same in the response as in the command, it is reported as a command index error (MMCHS_STAT[CIE] set to1). **Note:** The register CICE cannot be configured for an Auto CMD12, then index check is automatically checked when this command is issued. 0x0: Index check disable 0x1: Index check enable	RW	0
19	CCCE	Command CRC check enable This bit must be set to 1 to enable CRC7 check on command response to protect the response against transmission errors on the bus. If an error is detected, it is reported as a command CRC error (MMCHS_STAT[CCRC] set to 1). **Note:** The register CCCE cannot be configured for an Auto CMD12, and then CRC check is automatically checked when this command is issued. 0x0: CRC7 check disable 0x1: CRC7 check enable	RW	0
18	RESERVED		R	0
17:16	RSP_TYPE	Response type This bits defines the response type of the command 0x0: No response 0x1: Response Length 136 bits 0x3: Response Length 48 bits with busy after response 0x2: Response Length 48 bits	RW	0x0
15:6	RESERVED		R	0x000
5	MSBS	Multi/Single block select This bit must be set to 1 for data transfer in case of multi block command. For any others command this bit shall be set to 0. 0x0: Single block. If this bit is 0, it is not necessary to set the register MMCHS_BLK[NBLK].	RW	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
		0x1: Multi block. When Block Count is disabled (MMCHS_CMD[BCE] is set to 0) in Multiple block transfers (MMCHS_CMD[MSBS] is set to 1), the module can perform infinite transfer.		
4	DDIR	Data transfer Direction Select This bit defines either data transfer will be a read or a write. 0x0: Data Write (host to card) 0x1: Data Read (card to host)	RW	0
3:2	ACEN	Auto CMD Enable - SD card only. This field determines use of auto command functions. There are two methods to stop Multiple-block read and write operation 1. Auto CMD12 Enable When this field is set to 01b, the Host Controller issues CMD12 automatically when last block transfer is completed. Auto CMD12 error is indicated to the Auto CMD Error Status register (MMCHS_AC12). The Host Driver shall not set this bit if the command does not require CMD12. In particular, secure commands defined in the Part 3 File Security specification do not require CMD12. 2. Auto CMD23 Enable When this bit field is set to 10b, the Host Controller issues a CMD23 automatically before issuing a command specified in the Command Register. The Host Controller Version 3.00 and later shall support this function. The following conditions are required to use the Auto CMD23. – Auto CMD23 Supported (Host Controller Version is 3.00 or later) – A memory card that supports CMD23 (SCR[33]=1) – If DMA is used, it shall be ADMA. –Only when CMD18 or CMD25 is issued (**Note:** the Host Controller does not check command index.) Auto CMD23 can be used with or without ADMA. By writing the Command register, the Host Controller issues a CMD23 first and then issues a command specified by the Command Index in Command register. If response errors of CMD23 are detected, the second command is not issued. A CMD23 error is indicated in the Auto CMD Error Status register (MMCHS_AC12). 32-bit block count value for CMD23 is set to SDMA System Address / Argument 2 register (MMCHS_SDMASA). 0x0: Auto Command Disabled 0x1: Auto CMD12 enable or CCS detection enabled. 0x3: Reserved 0x2: Auto CMD23 Enable	RW	0x0
1	BCE	Block Count Enable Multiple block transfers only.	RW	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
		This bit is used to enable the block count register (MMCHS_BLK[NBLK]). When Block Count is disabled (MMCHS_CMD[BCE] is set to 0) in Multiple block transfers (MMCHS_CMD[MSBS] is set to 1), the module can perform infinite transfer. 0x0: Block count disabled for infinite transfer. 0x1: Block count enabled for multiple block transfer with known number of blocks		
0	DE	DMA Enable This bit is used to enable DMA mode for host data access. 0x0: DMA mode disable 0x1: DMA mode enable	RW	0

Table 25-96. MMCHS_DATA

Address Offset	0x0000 0220		
Physical Address	0x4809 C220 0x480B 4220 0x480A D220 0x480D 1220	**Instance**	MMC1 MMC2 MMC3 MMC4
Description	Data Register This register is the 32-bit entry point of the buffer for read or write data transfers. The buffer size is 32bits x256(1024 bytes). Bytes within a word are stored and read in little endian format. This buffer can be used as two 512 byte buffers to transfer data efficiently without reducing the throughput. Sequential and contiguous access is necessary to increment the pointer correctly. Random or skipped access is not allowed. In little endian, if the local host accesses this register byte-wise or 16bit-wise, the least significant byte (bits [7:0]) must always be written/read first. The update of the buffer address is done on the most significant byte write for full 32-bit DATA register or on the most significant byte of the last word of block transfer. Example 1: Byte or 16-bit access Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1100 (2-bytes) OK Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=0100 (1-byte) OK Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1000 (1-byte) Bad

RESERVED							CLEV	DLEV				WP	CDPL	CSS	CINS	RESERVED				BRE	BWE	RTA	WTA	RESERVED				RTR	DLA	DATI	CMDI

Bits	Field Name	Description	Type	Reset
31:25	RESERVED		R	0x00
24	CLEV	CMD line signal level This status is used to check the CMD line level to recover from errors, and for debugging. The value of this register after reset depends on the CMD line level at that time. Read 0x1: The CMD line level is 1. Read 0x0: The CMD line level is 0.	R	-
23:20	DLEV	DAT[3:0] line signal level DAT[3] => bit 23 DAT[2] => bit 22 DAT[1] => bit 21 DAT[0] => bit 20 This status is used to check DAT line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DAT[0]. The value of these registers after reset depends on the DAT lines level at that time.	R	0x-
19	WP	Write protect switch pin level For SDIO cards only. This bit reflects the write protect input pin (mmci_sdwp) level. The value of this register after reset depends on the protect input pin (mmci_sdwp) level at that time. Read 0x1: If MMCHS_CON[WPP] is set to 0 (default), the card is not write protected, otherwise the card is protected. Read 0x0: If MMCHS_CON[WPP] is set to 0 (default), the card is write protected, otherwise the card is not protected.	R	-
18	CDPL	Card detect pin level This bit reflects the inverse value of the card detect input pin (mmci_sdcd), debouncing is not performed on this bit and bit is valid only when Card State Stable (MMCHS_PSTAE[CSS]) is set to 1. Use of this bit is limited to testing since it must be debounced y software. The value of this register after reset depends on the card detect input pin (mmci_sdcd) level at that time. Read 0x1: The value of the card detect input pin (mmci_sdcd) is 0 Read 0x0: The value of the card detect input pin (mmci_sdcd) is 1	R	-

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
17	CSS	Card State Stable This bit is used for testing. It is set to 1 only when Card Detect Pin Level is stable (MMCHS_PSTATE[CDPL]). Debouncing is performed on the card detect input pin (mmci_sdcd) to detect card stability. This bit is not affected by a software reset. Read 0x1: No card or card inserted Read 0x0: Reset or Debouncing	R	0
16	CINS	Card inserted This bit is the debounced value of the card detect input pin (mmci_sdcd). An inactive to active transition of the card detect input pin (mmci_sdcd) will generate a card insertion interrupt (MMCHS_STAT[CINS]). A active to inactive transition of the card detect input pin (mmci_sdcd) will generate a card removal interrupt (MMCHS_STAT[REM]). This bit is not affected by a software reset. Read 0x1: If MMCHS_CON[CDP] is set to 1, the card has been inserted from the card slot. If MMCHS_CON[CDP] is set to 0, no card is detected. The card may have been removed from the card slot. Read 0x0: If MMCHS_CON[CDP] is set to 1, no card is detected. The card may have been removed from the card slot. If MMCHS_CON[CDP] is set to 0, the card has been inserted.	R	0
15:12	RESERVED		R	0x0
11	BRE	Buffer read enable This bit is used for non-DMA read transfers. It indicates that a complete block specified by MMCHS_BLK[BLEN] has been written in the buffer and is ready to be read. It is set to 0 when the entire block is read from the buffer. It is set to 1 when a block data is ready in the buffer and generates the Buffer read ready status of interrupt (MMCHS_STAT[BRR]). Read 0x1: Read BLEN bytes enable. Readable data exists in the buffer. Read 0x0: Read BLEN bytes disable	R	0
10	BWE	Buffer Write enable This status is used for non-DMA write transfers. It indicates if space is available for write data. Read 0x1: There is enough space in the buffer to write BLEN bytes of data. Read 0x0: There is no room left in the buffer to write BLEN bytes of data.	R	0
9	RTA	Read transfer active This status is used for detecting completion of a read transfer. It is set to 1 after the end bit of read command or by activating a continue request (MMCHS_HCTL[CR]) following a stop at block gap request. This bit is set to 0 when all data have been read by the local host after last block or after a stop at block gap request. Read 0x1: read data transfer on going. Read 0x0: No valid data on the DAT lines.	R	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
8	WTA	Write transfer active This status indicates a write transfer active. It is set to 1 after the end bit of write command or by activating a continue request (MMCHS_HCTL[CR]) following a stop at block gap request. This bit is set to 0 when CRC status has been received after last block or after a stop at block gap request. Read 0x1: Write data transfer on going. Read 0x0: No valid data on the DAT lines.	R	0
7:4	RESERVED		R	0x0
3	RTR	Re-Tuning Request Host Controller may request Host Driver to execute re-tuning sequence by setting this bit when the data window is shifted by temperature drift and a tuned sampling point does not have a good margin to receive correct data. This bit is cleared when a command is issued with setting MMCHS_AC12[22] ET. This bit isn't set to 1 if MMCHS_AC12[23] SCLK_SEL is set to 0 (using fixed sampling clock). Refer to MMCHS_CAPA2[15:14] RTM for more detail. Read 0x1: Sampling clock needs re-tuning Read 0x0: Fixed or well tuned sampling clock	R	0
2	DLA	DAT line active This status bit indicates whether one of the DAT line is in use. In the case of read transactions (card to host): This bit is set to 1 after the end bit of read command or by activating continue request MMCHS_HCTL[CR]. This bit is set to 0 when the host controller received the end bit of the last data block or at the beginning of the read wait mode. In the case of write transactions (host to card): This bit is set to 1 after the end bit of write command or by activating continue request MMCHS_HCTL[CR]. This bit is set to 0 on the end of busy event for the last block; host controller must wait 8 clock cycles with line not busy to really consider not "busy state" or after the busy block as a result of a stop at gap request. Read 0x1: DAT Line active Read 0x0: DAT Line inactive	R	0
1	DATI	Command inhibit(DAT) This status bit is generated if either DAT line is active (MMCHS_PSTATE[DLA]) or Read transfer is active (MMCHS_PSTATE[RTA]) or when a command with busy is issued. This bit prevents the local host to issue a command. A change of this bit from 1 to 0 generates a transfer complete interrupt (MMCHS_STAT[TC]). Read 0x1: Issuing of command using DAT lines is not allowed Read 0x0: Issuing of command using the DAT lines is allowed	R	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
0	CMDI	Command inhibit(CMD) This status bit indicates that the CMD line is in use. This bit is set to 0 when the most significant byte is written into the command register. This bit is not set when Auto CMD12 is transmitted. This bit is set to 0 in either the following cases: - After the end bit of the command response, excepted if there is a command conflict error (MMCHS_STAT[CCRC] or MMCHS_STAT[CEB] set to 1) or a Auto CMD12 is not executed (MMCHS_AC12[ACNE]). - After the end bit of the command without response (MMCHS_CMD[RSP_TYPE] set to "00") In case of a command data error is detected (MMCHS_STAT[CTO] set to 1), this register is not automatically cleared. Read 0x1: Issuing of command using CMD line is not allowed Read 0x0: Issuing of command using CMD line is allowed	R	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
31:28	RESERVED		R	0x0
27	OBWE	Wakeup event enable for 'Out-of-Band' Interrupt. This bit enables wakeup events for 'Out-of-Band' assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[ENAWAKEUP]). The write to this register is ignored when MMCHS_CON[OBIE] is not set. 0x0: Disable wakeup on 'Out-of-Band' Interrupt 0x1: Enable wakeup on 'Out-of-Band' Interrupt	RW	0
26	REM	Wakeup event enable on SD card removal This bit enables wakeup events for card removal assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[ENAWAKEUP]). 0x0: Disable wakeup on card removal 0x1: Enable wakeup on card removal	RW	0
25	INS	Wakeup event enable on SD card insertion This bit enables wakeup events for card insertion assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[ENAWAKEUP]). 0x0: Disable wakeup on card insertion 0x1: Enable wakeup on card insertion	RW	0
24	IWE	Wakeup event enable on SD card interrupt This bit enables wakeup events for card interrupt assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[ENAWAKEUP]). 0x0: Disable wakeup on card interrupt 0x1: Enable wakeup on card interrupt	RW	0
23:20	RESERVED		R	0x0
19	IBG	Interrupt block at gap This bit is valid only in 4-bit mode of SDIO card to enable interrupt detection in the interrupt cycle at block gap for a multiple block transfer. For MMC cards and for SD card this bit should be set to 0. 0x0: Disable interrupt detection at the block gap in 4-bit mode 0x1: Enable interrupt detection at the block gap in 4-bit mode	RW	0
18	RWC	Read wait control The read wait function is optional only for SDIO cards. If the card supports read wait, this bit must be enabled, then requesting a stop at block gap (MMCHS_HCTL[SBGR]) generates a read wait period after the current end of block. Be careful, if read wait is not supported it may cause a conflict on DAT line. 0x0: Disable Read Wait Control. Suspend/Resume cannot be supported. 0x1: Enable Read Wait Control	RW	0
17	CR	Continue request This bit is used to restart a transaction that was stopped by requesting a stop at block gap (MMCHS_HCTL[SBGR]). Set this bit to 1 restarts the transfer. The bit is automatically set to 0 by the host controller when transfer has restarted i.e DAT line is active (MMCHS_PSTATE[DLA]) or transferring data (MMCHS_PSTATE[WTA]). The Stop at block gap request must be disabled (MMCHS_HCTL[SBGR]=0) before setting this bit. 0x0: No affect 0x1: transfer restart	RW	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
16	SBGR	Stop at block gap request This bit is used to stop executing a transaction at the next block gap. The transfer can restart with a continue request (MMCHS_HCTL[CR]) or during a suspend/resume sequence. In case of read transfer, the card must support read wait control. In case of write transfer, the host driver shall set this bit after all block data written. Until the transfer completion (MMCHS_STAT[TC] set to 1), the host driver shall leave this bit set to 1. If this bit is set, the local host shall not write to the data register (MMCHS_DATA). 0x0: Transfer mode 0x1: Stop at block gap	RW	0
15:12	RESERVED		R	0x0
11:9	SDVS	SD bus voltage select All cards. The host driver should set to these bits to select the voltage level for the card according to the voltage supported by the system (MMCHS_CAPA[VS18,VS30,VS33]) before starting a transfer. 0x6: 3.0V (Typical) 0x7: 3.3V (Typical) 0x5: 1.8V (Typical)	RW	0x0
8	SDBP	SD bus power Before setting this bit, the host driver shall select the SD bus voltage (MMCHS_HCTL[SDVS]). If the host controller detects the No card state, this bit is automatically set to 0. If the module is power off, a write in the command register (MMCHS_CMD) will not start the transfer. A write to this bit has no effect if the selected SD bus voltage MMCHS_HCTL[SDVS] is not supported according to capability register (MMCHS_CAPA[VS*]). 0x0: Power off 0x1: Power on	RW	0
7	CDSS	Card Detect Signal Selection This bit selects source for the card detection.When the source for the card detection is switched, the interrupt should be disabled during the switching period by clearing the Interrupt Status/Signal Enable register in order to mask unexpected interrupts caused by the glitch. The Interrupt Status/Signal Enable should be disabled during over the period of debouncing. 0x0: mmci_sdcd is selected (for normal use) 0x1: MMCHS_HCTL[6] CDTL is selected (for test purpose)	RW	0
6	CDTL	Card Detect Test Level: This bit is enabled while MMCHS_HCTL[7] CDSS is set to 1 and it indicates whether the card is inserted or not. 0x0: No Card 0x1: Card Inserted	RW	0
5	RESERVED		R	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
4:3	DMAS	DMA Select Mode: One of supported DMA modes can be selected. The host driver shall check support of DMA modes by referring the Capabilities register MMCHS_CAPA . Use of selected DMA is determined by DMA Enable of the Transfer Mode register. This register is only meaningful when MADMA_EN is set to 1. When MADMA_EN is set to 0 the bit field is read only and returned value is 0. 0x0: Reserved 0x1: Reserved 0x3: Reserved 0x2: 32-bit Address ADMA2 is selected	RW	0x0
2	HSPE	Before setting this bit, the Host Driver shall check the MMCHS_CAPA[21] HSS. This bit shall not be set when dual data rate mode is activated in MMCHS_CON[DDR]. 0x0: The Host Controller outputs CMD line and DAT lines at the falling edge of the SD Clock 0x1: The Host Controller outputs CMD line and DAT lines at the rising edge of the SD Clock **NOTE: Do not set this bit to 0x1 as timings cannot be met at high speeds. It is recommended to not modify it and keep its default value of 0x0.**	RW	0
1	DTW	Data transfer width For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliance with MMC standard specification 4.x (see section 3.6). This register has no effect when the MMC 8-bit mode is selected (register MMCHS_CON[DW8] set to1), For SD/SDIO cards, this bit must be set following a valid SET_BUS_WIDTH command (ACMD6) with the value written in bit 1 of the argument. Prior to this command, the SD card configuration register (SCR) must be verified for the supported bus width by the SD card. 0x0: 1-bit Data width (DAT[0] used) 0x1: 4-bit Data width (DAT[3:0] used)	RW	0
0	LED	Reserved bit. LED control feature is not supported This bit is initialized to zero, and writes to it are ignored.	R	0

23:20	RESERVED		R	0x0
19:16	DTO	Data timeout counter value and busy timeout. This value determines the interval by which DAT lines timeouts are detected. The host driver needs to set this bitfield based on - the maximum read access time (NAC) (Refer to the SD Specification Part1 Physical Layer), - the data read access time values (TAAC and NSAC) in the card specific data register (CSD) of the card, - the timeout clock base frequency (MMCHS_CAPA[TCF]). If the card does not respond within the specified number of cycles, a data timeout error occurs (MMCHS_STA[DTO]). The MMCHS_SYSCTL[DTO] register is also used to check busy duration, to generate busy timeout for commands with busy response or for busy programming during a write command. Timeout on CRC status is generated if no CRC token is present after a block write. 0xF: Reserved 0x0: TCF x 2^13 0x1: TCF x 2^14 0xE: TCF x 2^27	RW	0x0
15:6	CLKD	Clock frequency select These bits define the ratio between MMCi_FCLK and the output clock frequency on the CLK pin of either the memory card (MMC, SD or SDIO). 0x0: MMCi_FCLK bypass 0x1: MMCi_FCLK bypass 0x2: MMCi_FCLK / 2 0x3: MMCi_FCLK / 3 0x3FF: MMCi_FCLK / 1023	RW	0x000
5	CGS	Clock Generator Select - For SD cards Host Controller Version 3.00 supports this bit. This bit is used to select the clock generator mode in MMCHS_SYSCTL[15:6] CLKD. If the Programmable Clock Mode is supported (non-zero value is set to MMCHS_CAPA2[23:16] CM), this bit attribute is RW, and if not supported, this bit attribute is RO and zero is read. This bit depends on the setting of MMCHS_AC12[31] PV_ENABLE. If PV_ENABLE = 0, this bit is set by Host Driver. If PV_ENABLE = 1, this bit is automatically set to a value specified in one of Preset Value registers, see, Table 25-22.	R	0
4:3	RESERVED		R	0x0
2	CEN	Clock enable This bit controls if the clock is provided to the card or not. 0x0: The clock is not provided to the card . Clock frequency can be changed . 0x1: The clock is provided to the card and can be automatically gated when MMCHS_SYSCONFIG[AUTOIDLE] is set to 1 (default value) . The host driver shall wait to set this bit to 1 until the Internal clock is stable (MMCHS_SYSCTL[ICS]).	RW	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
1	ICS	Internal clock stable (status) This bit indicates either the internal clock is stable or not. Read 0x1: The internal clock is stable after enabling the clock (MMCHS_SYSCTL[ICE]) or after changing the clock ratio (MMCHS_SYSCTL[CLKD]). Read 0x0: The internal clock is not stable.	R	0
0	ICE	Internal clock enable This register controls the internal clock activity. In very low power state, the internal clock is stopped. Note: The activity of the debounce clock (used for wakeup events) and the interface clock (used for reads and writes to the module register map) are not affected by this register. 0x0: The internal clock is stopped (very low power state). 0x1: The internal clock oscillates and can be automatically gated when MMCHS_SYSCONFIG[AUTOIDLE] is set to 1 (default value) .	RW	0

Bits	Field Name	Description	Type	Reset
31:30	RESERVED		R	0x0
29	BADA	Bad access to data space This bit is set automatically to indicate a bad access to buffer when not allowed: -This bit is set during a read access to the data register (MMCHS_DATA) while buffer reads are not allowed (MMCHS_PSTATE[BRE] =0) -This bit is set during a write access to the data register (MMCHS_DATA) while buffer writes are not allowed (MMCHS_STATE[BWE] =0) Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Bad Access Read 0x0: No Interrupt.	RW	0
28	CERR	Card error This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5 or R5b. Only bits referenced as type E(error) in status field in the response can set a card status error. An error bit in the response is flagged only if corresponding bit in card status response error MMCHS_CSRE in set. There is no card error detection for autoCMD12 command. The host driver shall read MMCHS_RSP76 register to detect error bits in the command response. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Card error Read 0x0: No Error	RW	0
27	RESERVED		R	0
26	TE	Tuning Error This bit is set when an unrecoverable error is detected in a tuning circuit except during tuning procedure (Occurrence of an error during tuning procedure is indicated by Sampling Select). By detecting Tuning Error, Host Driver needs to abort a command executing and perform tuning. To reset tuning circuit, Sampling Clock shall be set to 0 before executing tuning procedure. The Tuning Error is higher priority than the other error interrupts generated during data transfer. By detecting Tuning Error, the Host Driver should discard data transferred by a current read/write command and retry data transfer after the Host Controller retrieved from tuning circuit error. The bit is set if the lock is lost (but not during the tuning process) or if the lock counter expires without the lock being asserted. If the latter happens, the SW can decide to ignore the interrupt and wait some more for the lock to be set. 0x0: No Error 0x1: Error	RW	0
25	ADMAE	ADMA Error: This bit is set when the Host Controller detects errors during ADMA based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA Error Status Register.In addition, the Host Controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. ADMA Error State in the ADMA Error Status indicates that an error occurs in ST_FDS state. The Host Driver may find that Valid bit is not set at the error descriptor. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: ADMA error Read 0x0: No Interrupt.	RW	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
24	ACE	Auto CMD error Auto CMD12 and Auto CMD23 use this error status. This bit is set when detecting that one of the bits D00-D04 in Auto CMD Error Status register (MMCHS_AC12) has changed from 0 to 1. In case of Auto CMD12, this bit is set to 1, not only when the errors in Auto CMD12 occur but also when Auto CMD12 is not executed due to the previous command error. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Auto CMD error Read 0x0: No Error.	RW	0
23	RESERVED		R	0
22	DEB	Data End Bit error This bit is set automatically when detecting a 0 at the end bit position of read data on DAT line or at the end position of the CRC status in write mode. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Data end bit error Read 0x0: No Error	RW	0
21	DCRC	Data CRC Error This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status different of a position "010" token during a block write command. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Data CRC error Read 0x0: No Error.	RW	0
20	DTO	Data timeout error This bit is set automatically according to the following conditions: - busy timeout for R1b, R5b response type - busy timeout after write CRC status - write CRC status timeout - read data timeout Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Time out Read 0x0: No error.	RW	0
19	CIE	Command index error This bit is set automatically when response index differs from corresponding command index previously emitted. It depends on the enable in MMCHS_CMD[CICE] register. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Command index error Read 0x0: No error.	RW	0
18	CEB	Command end bit error This bit is set automatically when detecting a 0 at the end bit position of a command response. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Command end bit error Read 0x0: No error.	RW	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
17	CCRC	Command CRC Error This bit is set automatically when there is a CRC7 error in the command response depending on the enable in MMCHS_CMD[CCCE] register. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Command CRC error Read 0x0: No Error.	RW	0
16	CTO	Command Timeout Error This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within 5 clock cycles - the timeout is still detected at 64 clock cycles. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Time Out Read 0x0: No error	RW	0
15	ERRI	Error Interrupt If any of the bits in the Error Interrupt Status register (MMCHS_STAT[31:16]) are set, then this bit is set to 1. Therefore the host driver can efficiently test for an error by checking this bit first. Writes to this bit are ignored. Read 0x1: Error interrupt event(s) occurred Read 0x0: No Interrupt.	R	0
14:11	RESERVED		R	0x0
10	BSR	Boot status received interrupt This bit is set automatically when MMCHS_CON[BOOT] is set 0x1 or 0x2 and a boot status is received on DAT[0] line. This interrupt is only useful for MMC card. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Boot status received interrupt. Read 0x0: No Interrupt.	RW	0
9	OBI	Out-Of-Band interrupt This bit is set automatically when MMCHS_CON[OBIE] is set and an Out-of-Band interrupt occurs on OBI pin. The interrupt detection depends on polarity controlled by MMCHS_CON[OBIP]. This interrupt is only useful for MMC card. The Out-of-Band interrupt signal is a system specific feature for future use, this signal is not required for existing specification implementation. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Interrupt Out-Of-Band occurs Read 0x0: No Out-Of-Band interrupt.	RW	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
8	CIRQ	Card interrupt This bit is only used for SD and SDIO and CE-ATA cards. In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wakeup). In 4-bit mode, interrupt source is sampled during the interrupt cycle. In CE-ATA mode, interrupt source is detected when the card drives CMD line to zero during one cycle after data transmission end.All modes above are fully exclusive. The controller interrupt must be clear by setting MMCHS_IE[CIRQ] to 0, then the host driver must start the interrupt service with card (clearing card interrupt status) to remove card interrupt source. Otherwise the Controller interrupt will be reasserted as soon as MMCHS_IE[CIRQ] is set to 1. Writes to this bit are ignored. Read 0x1: Generate card interrupt Read 0x0: No card interrupt	R	0
7	CREM	Card removal This bit is set automatically when MMCHS_PSTATE[CINS] changes from 1 to 0. A clear of this bit doesn't affect Card inserted present state (MMCHS_PSTATE[CINS]). Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Card removed Read 0x0: Card state stable or Debouncing	RW	0
6	CINS	Card insertion This bit is set automatically when MMCHS_PSTATE[CINS] changes from 0 to 1. A clear of this bit doesn't affect Card inserted present state (MMCHS_PSTATE[CINS]). Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Card inserted Read 0x0: Card state stable or debouncing	RW	0
5	BRR	Buffer read ready This bit is set automatically during a read operation to the card (see class 2 - block oriented read commands) when one block specified by MMCHS_BLK[BLEN] is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the local host needs to empty the buffer by reading it. Note: If the DMA receive-mode is enabled, this bit is never set; instead a DMA receive request to the main DMA controller of the system is generated. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Ready to read buffer Read 0x0: Not Ready to read buffer	RW	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
4	BWR	Buffer write ready This bit is set automatically during a write operation to the card (see class 4 - block oriented write command) when the host can write a complete block as specified by MMCHS_BLK[BLEN]. It indicates that the memory card has emptied one block from the buffer and that the local host is able to write one block of data into the buffer. Note: If the DMA transmit mode is enabled, this bit is never set; instead, a DMA transmit request to the main DMA controller of the system is generated. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Ready to write buffer Read 0x0: Not Ready to write buffer	RW	0
3	DMA	DMA interrupt : This status is set when an interrupt is required in the ADMA instruction and after the data transfer completion. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: No dma interrupt Read 0x0: Dma interrupt detected	RW	0
2	BGE	Block gap event When a stop at block gap is requested (MMCHS_HCTL[SBGR]), this bit is automatically set when transaction is stopped at the block gap during a read or write operation. This event does not occur when the stop at block gap is requested on the last block. In read mode, a 1-to-0 transition of the DAT Line active status (MMCHS_PSTATE[DLA]) between data blocks generates a Block gap event interrupt. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Transaction stopped at block gap Read 0x0: No block gap event	RW	0
1	TC	Transfer completed This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap request (MMCHS_HCTL[SBGR]). In Read mode: This bit is automatically set on completion of a read transfer (MMCHS_PSTATE[RTA]). In write mode: This bit is set automatically on completion of the DAT line use (MMCHS_PSTATE[DLA]). Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Data transfer complete Read 0x0: No transfer complete	RW	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
0	CC	Command complete This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCHS_PSTATE[CMDI]) If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command timeout error (MMCHS_STAT[CTO]) has higher priority than command complete (MMCHS_STAT[CC]). If a response is expected but none is received, then a command timeout error is detected and signaled instead of the command complete interrupt. Write 0x0: Status bit unchanged Write 0x1: Status is cleared Read 0x1: Command complete Read 0x0: No Command complete	RW	0

Description	Host Control 2 Register and Auto CMD Error Status Register This register is used to indicate CMD12 response error of Auto CMD12 and CMD23 response error of Auto CMD23. The Host driver can determine what kind of Auto CMD12 / CMD23 errors occur by this register. Auto CMD23 errors are indicated only in bits[4:1]. Bits[7:0] are valid only when the MMCHS_CMD[3:2] ACEN bitfield is configured to enable Auto CMD and the Auto CMD Error bit (MMCHS_STAT[24]ACE) is set.

Bits	Field Name	Description	Type	Reset
31	PV_ENABLE	Preset Value Enable Host Controller Version 3.00 supports this bit. As the operating SDCLK frequency and I/O driver strength depend on the Host System implementation, it is difficult to determine these parameters in the Standard Host Driver. When Preset Value Enable is set, automatic SDCLK frequency generation and driver strength selection is performed without considering system specific conditions. This bit enables the functions defined in the Preset Value registers, see, Table 25-22. If this bit is set to 0, MMCHS_SYSCTL[15:6] CLKD, MMCHS_SYSCTL[5] CGS and MMCHS_AC12[21:20] DS_SEL are set by Host Driver. If this bit is set to 1, MMCHS_SYSCTL[15:6] CLKD, MMCHS_SYSCTL[5] CGS and MMCHS_AC12[21:20] DS_SEL are set by Host Controller as specified in the Preset Value registers, see, Table 25-22. 0x0: SDCLK and Driver Strength (DS_SEL) are controlled by Host Driver. 0x1: Automatic Selection by Preset Value are Enabled.	RW	0
30	AI_ENABLE	Asynchronous Interrupt Enable This bit can be set to 1 if a card supports asynchronous interrupts and MMCHS_CAPA[29] AIS is set to 1. Asynchronous interrupt is effective when DAT[1] interrupt is used in 4-bit SD mode (and zero is set to Interrupt Pin Select in the Shared Bus Control register). If this bit is set to 1, the Host Driver can stop the SDCLK during asynchronous interrupt period to save power. During this period, the Host Controller continues to deliver the Card Interrupt to the host when it is asserted by the Card. 0x0: Disabled 0x1: Enabled	RW	0
29:24	RESERVED		R	0x00
23	SCLK_SEL	Sampling Clock Select Host Controller uses this bit to select sampling clock to receive CMD and DAT. This bit is set by tuning procedure and valid after the completion of tuning (when MMCHS_AC12[22] ET is cleared). Setting 1 means that tuning is completed successfully and setting 0 means that tuning is failed. Writing 1 to this bit is meaningless and ignored. A tuning circuit is reset by writing to 0. This bit can be cleared with setting MMCHS_AC12[22] ET. Once the tuning circuit is reset, it will take time to complete tuning sequence. Therefore, Host Driver should keep this bit to 1 to perform re-tuning sequence to compete re-tuning sequence in a short time. Change of this bit is not allowed while the Host Controller is receiving response or a read data block. 0x0: Fixed clock is used to sample data 0x1: Tuned clock is used to sample data	RW	0
22	ET	Execute Tuning This bit is set to 1 to start tuning procedure and automatically cleared when tuning procedure is completed. The result of tuning is indicated to MMCHS_AC12[23] SCLK_SEL. Tuning procedure is aborted by writing 0. This is Read-Write with automatic clear register 0x0: Not Tuned or Tuning Completed 0x1: Execute Tuning	RW	0

Bits	Field Name	Description	Type	Reset
21:20	DS_SEL	Driver Strength Select Host Controller output driver in 1.8V signaling is selected by this bit. In 3.3V signaling, this field is not effective. This field can be set depending on Driver Type A, C and D support bits (DTA, DTC and DTD respectively) in the MMCHS_CAPA2 register. This bit depends on setting of Preset Value Enable. If Preset Value Enable = 0, this field is set by Host Driver. If Preset Value Enable = 1, this field is automatically set by a value specified in the one of Preset Value registers, see, Table 25-22. 0x0: Driver Type B is selected (Default) 0x1: Driver Type A is selected 0x3: Driver Type D is selected 0x2: Driver Type C is selected	RW	0x0
19	V1V8_SIGEN	1.8V Signaling Enable This bit controls voltage regulator for I/O cell. 3.3V is supplied to the card regardless of signaling voltage. Setting this bit from 0 to 1 starts changing signal voltage from 3.3V to 1.8V. 1.8V regulator output shall be stable within 5ms. Host Controller clears this bit if switching to 1.8V signaling fails. Clearing this bit from 1 to 0 starts changing signal voltage from 1.8V to 3.3V. 3.3V regulator output shall be stable within 5ms. Host Driver can set this bit to 1 when Host Controller supports 1.8V signaling (One of support bits is set to 1: SDR50, SDR104 or DDR50 in MMCHS_CAPA2 register) and the card or device supports UHS-I (S18A=1. Refer to Bus Signal Voltage Switch Sequence in the Physical Layer Specification Version 3.0x). 0x0: 3.3V Signaling 0x1: 1.8V Signaling	RW	0
18:16	UHSMS	UHS Mode Select This field is used to select one of UHS-I modes or eMMC HS200 mode and is effective when 1.8V Signaling Enable is set to 1. If MMCHS_AC12[31] PV_ENABLE is set to 1, Host Controller sets MMCHS_SYSCTL[15:6] CLKD, MMCHS_SYSCTL[5] CGS and MMCHS_AC12[21:20] DS_SEL according to Preset Value registers, see, Table 25-22. In this case, one of preset value registers is selected by this field. Host Driver needs to reset MMCHS_SYSCTL[2] CEN before changing this field to avoid generating clock glitch. After setting this field, Host Driver sets MMCHS_SYSCTL[2] CEN again. When SDR50, SDR104 or DDR50 is selected for SDIO card, interrupt detection at the block gap shall not be used. Read Wait timing is changed for these modes. Refer to the SDIO Specification Version 3.00 for more detail. 0x0: SDR12 0x1: SDR25 0x2: SDR50 0x3: SDR104/HS200 0x4: DDR50 0x5: Reserved 0x6: Reserved 0x7: Reserved	RW	0x0
15:8	RESERVED		R	0x00

Bits	Field Name	Description	Type	Reset
7	CNI	Command Not Issued By Auto CMD12 Error Setting this bit to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 Error (D04-D01) in this register. This bit is set to 0 when Auto CMD Error is generated by Auto CMD23. Read 0x1: Command not issued Read 0x0: No error	R	0
6:5	RESERVED		R	0x0
4	ACIE	Auto CMD Index Error - For Auto CMD12 and Auto CMD23 This bit is set if the Command Index error occurs in response to a command. Read 0x1: Error Read 0x0: No error	R	0
3	ACEB	Auto CMD End Bit Error - For Auto CMD12 and Auto CMD23 This bit is set when detecting that the end bit of command response is 0. Read 0x1: End bit Error Generated Read 0x0: No error	R	0
2	ACCE	Auto CMD CRC Error - For Auto CMD12 and Auto CMD23 This bit is set when detecting a CRC error in the command response. Read 0x1: CRC Error Generated Read 0x0: No error	R	0
1	ACTO	Auto CMD Timeout Error - For Auto CMD12 and Auto CMD23 This bit is set if no response is returned within 64 SDCLK cycles from the end bit of command. If this bit is set to1, the other error status bits (D04-D02) are meaningless. Read 0x1: Auto CMD Time Out Read 0x0: No error	R	0
0	ACNE	Auto CMD12 Not Executed If memory multiple block data transfer is not started due to command error, this bit is not set because it is not necessary to issue Auto CMD12. Setting this bit to 1 means the Host Controller cannot issue Auto CMD12 to stop memory multiple block data transfer due to some error. If this bit is set to 1, other error status bits (D04-D01) are meaningless. This bit is set to 0 when Auto CMD Error is generated by Auto CMD23. Read 0x1: Auto CMD12 Not Executed Read 0x0: Auto CMD12 Executed	R	0

Bits	Field Name	Description	Type	Reset
15:8	BCF	Base Clock Frequency For SD Clock This value indicates the base (maximum) clock frequency for the SD Clock. 8-bit Base Clock Frequency This mode is supported by the Host Controller Version 3.00. Unit values are 1MHz. The supported clock range is 10MHz to 255MHz. FFh : 255MHz .... : ..... 02h : 2MHz 01h : 1MHz 00h : Get information via another method If the real frequency is 16.5MHz, the lager value shall be set 0001 0001b (17MHz) because the Host Driver use this value to calculate the clock divider value (Refer to MMCHS_SYSCTL[15:6] CLKD) and it shall not exceed upper limit of the SD Clock frequency. If these bits are all 0, the Host System has to get information via another method. Read 0x0: The value indicating the base (maximum) frequency for the output clock provided to the card is system dependent and is not available in this register. Get the information via another method.	R	0x00
7	TCU	Timeout clock unit This bit shows the unit of base clock frequency used to detect Data Timeout Error (MMCHS_STAT[DTO]). Read 0x1: MHz Read 0x0: KHz	R	1
6	RESERVED		R	0
5:0	TCF	Timeout clock frequency The timeout clock frequency is used to detect Data Timeout Error (MMCHS_STAT[DTO]). Read 0x0: The timeout clock frequency depends on the frequency of the clock provided to the card. The value of the timeout clock frequency is not available in this register.	R	0x00

Bits	Field Name	Description	Type	Reset
15:14	RTM	Re-Tuning Modes This field selects re-tuning method and limits the maximum data length. Bit47-46 Re-Tuning Mode Re-Tuning Method Data Length There are two re-tuning timings: Re-Tuning Request controlled by the Host Controller and expiration of a Re-Tuning Timer controlled by the Host Driver. By receiving either timing, the Host Driver executes the re-tuning procedure just before a next command issue. The maximum data length per read/write command is restricted so that re-tuning procedures can be inserted during data transfers. (1) Re-Tuning Mode 1 The host controller does not have any internal logic to detect when the re-tuning needs to be performed. In this case, the Host Driver should maintain all re-tuning timings by using a Re-Tuning Timer. To enable inserting the re-tuning procedure during data transfers, the data length per read/write command shall be limited up to 4 MiB. (2) Re-Tuning Mode 2 The host controller has the capability to indicate the re-tuning timing by Re-Tuning Request during data transfers. Then the data length per read/write command shall be limited up to 4 MiB. During non data transfer, re-tuning timing is determined by either Re-Tuning Request or Re-Tuning Timer. If Re-Tuning Request is used, Re-Tuning Timer should be disabled. (3) Re-Tuning Mode 3 The host controller has the capability to take care of the re-tuning during data transfer (Auto Re-Tuning). Re-Tuning Request shall not be generated during data transfers and there is no limitation to data length per read/write command. During non data transfer, re-tuning timing is determined by either Re-Tuning Request or Re-Tuning Timer. If Re-Tuning Request is used, Re-Tuning Timer should be disabled. Re-Tuning Timer Control Example for Re-Tuning Mode 1 The initial value of re-tuning timer is provided by Timer Count for Re-Tuning field in this register. The timer starts counting by loading the initial value. When the timer expires, the Host Driver marks an expiration flag. On receiving a command request, the Host driver checks the expiration flag. If the expiration flag is set, then the Host Driver should perform the re-tuning procedure before issuing a command. If the expiration flag is not set, then the Host Driver issues a command without performing the re-tuning procedure. Every time the re-tuning procedure is performed, the timer loads the new initial value and the expiration flag is cleared. Re-Tuning Timer Control Example for Re-Tuning Mode 2 and Mode 3 The timer control is almost the same as Re-Tuning Mode 1 except the timer loads the new initial value after data transfer (when receiving Transfer Complete). In case of Mode 3, Timer Count for Re-Tuning is set either smaller value: Tuning effective time after re-tuning procedure or after data transfer. If a Host System goes into power down mode, the Host Driver should stop the re-tuning timer and set the expiration flag to 1 when the Host System resumes from power down mode. Read 0x3: Reserved Read 0x2: Auto Re-Tuning (for transfer) - Timer and Re-Tuning Request Read 0x1: Timer and Re-Tuning Request - Max data length 4 MiB Read 0x0: Timer - Max data length 4 MiB	R	0x0

Description	ADMA Error Status Register When ADMA Error Interrupt is occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address Register holds the address around the error descriptor. For recovering the error, the Host Driver requires the ADMA state to identify the error descriptor address as follows: ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address ST_FDS: Current location set in the ADMA System Address register is the error descriptor address ST_CADR: This sate is never set because do not generate ADMA error in this state. ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address In case of write operation, the Host Driver should use ACMD22 to get the number of written block rather than using this information, since unwritten data may exist in the Host Controller. The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. In this case, ADMA Error State indicates that an error occurs at ST_FDS state. The Host Driver may find that the Valid bit is not set in the error descriptor.

ADMA_A32B																															

Bits	Field Name	Description	Type	Reset
31:0	ADMA_A32B	ADMA System address 32 bits.This register holds byte address of executing command of the Descriptor table. 32-bit Address Descriptor uses lower 32-bit of this register. At the start of ADMA, the Host Driver shall set start address of the Descriptor table. The ADMA increments this register address, which points to next line, when every fetching a Descriptor line. When the ADMA Error Interrupt is generated, this register shall hold valid Descriptor address depending on the ADMA state. The Host Driver shall program Descriptor Table on 32-bit boundary and set 32-bit boundary address to this register. ADMA2 ignores lower 2-bit of this register and assumes it to be 00b. Shared PHY Component Subsystem

This chapter describes the shared PHY component subsystems of the device.

Topic **Page**

26.1 SATA PHY Subsystem **6809**
26.2 USB3_PHY Subsystem **6828**
26.3 USB3 PHY and SATA PHY Register Manual **6848**
26.4 PCIe PHY Subsystem **6865**

Copyright © 2015–2017, Texas Instruments Incorporated

26.1 SATA PHY Subsystem

This chapter describes the features and functions of the serial advanced technology attachment (SATA) PHY subsystem of the device.

26.1.1 SATA PHY Subsystem Overview

NOTE: SATA is not supported on the AM570x family of devices.

The physical layer (PHY) is responsible for transmitting and receiving the parallel 8b/10b encoded information as a serial data stream on the wire.

The SATA host controller subsystem instantiates a single serializer (transmitter), SATA_PHY_TX, and a single deserializer (receiver), SATA_PHY_RX. Together the transmitter and receiver are also signified as SATA_PHY throughout this chapter. The role of the TX and RX components is to adapt SATA Link parallel 10-bit input/output (I/O) data stream for a serialized differential transmission and reception over SATA electrical interface, respectively.

The high speed transmission clock is generated by and integrated into the SATA host subsystem dpll (DPLL_SATA).

The DPLL_SATA is configured and controlled through a SATA dedicated PLL controller (DPLLCTRL_SATA) with associated registers, accessible over a L4_CFG interface adapter.

The components (SATA_PHY_RX, SATA_PHY_TX, DPLL_SATA, DPLLCTRL_SATA, and DPLLCTRL_SATA L4-interface adapter) build the SATA PHY subsystem. This subsystem is responsible for PHY components clock generation and physical layer transmission/reception within the device SATA subsystem.

Figure 26-1 gives an overview of the SATA PHY subsystem. As shown in Figure 26-1, at one side the SATA_PHY components directly interface the attached to host controller SATA mass storage device (over TXP/TXN transmission and RXP/RXN reception interface I/Os) and on the other side they interface the SATA controller, described in detail in Section 24.8, *SATA Controller*.

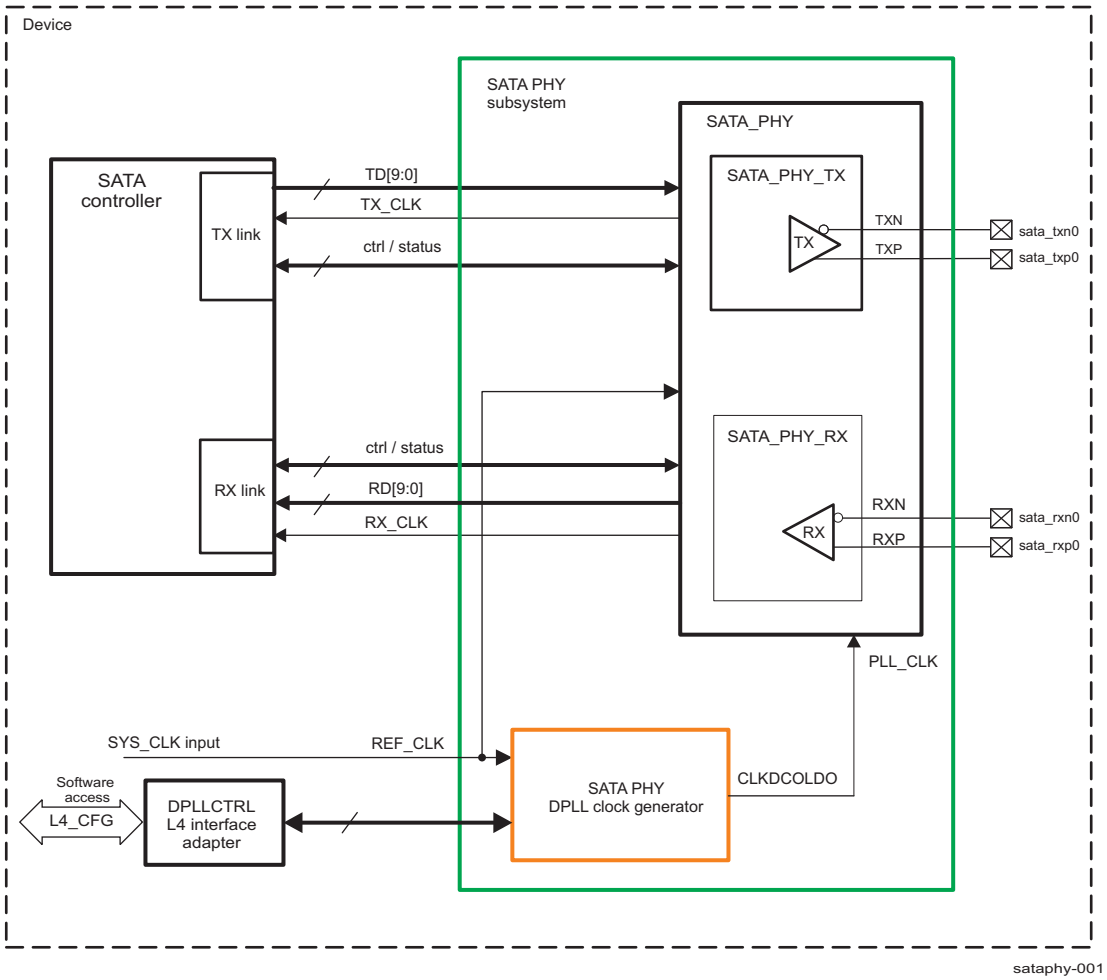
Figure 26-1. SATA PHY Subsystem Overview



Copyright © 2015–2017, Texas Instruments Incorporated

26.1.2 SATA PHY Subsystem Environment

NOTE: SATA is not supported on the AM570x family of devices.

26.1.2.1 SATA PHY I/O Signals

Table 26-1 lists the module pins and their corresponding signal names at the device level, and also specifies their links to functions.

Table 26-1. SATA PHY I/O Signals

Module Pin Name	Device Level Signal Name	I/O[1]	Description	Module Pin Reset Value
TXP[2]	sata_txp0	O	TXP output of the SATA PHY differential transmission line	0
TXN[2]	sata_txn0	O	TXN output of the SATA PHY differential transmission line	0
RXP[2]	sata_rxp0	I	RXP input of the SATA PHY differential reception line	HiZ
RXN[2]	sata_rxn0	I	RXN input of the SATA PHY differential reception line	HiZ

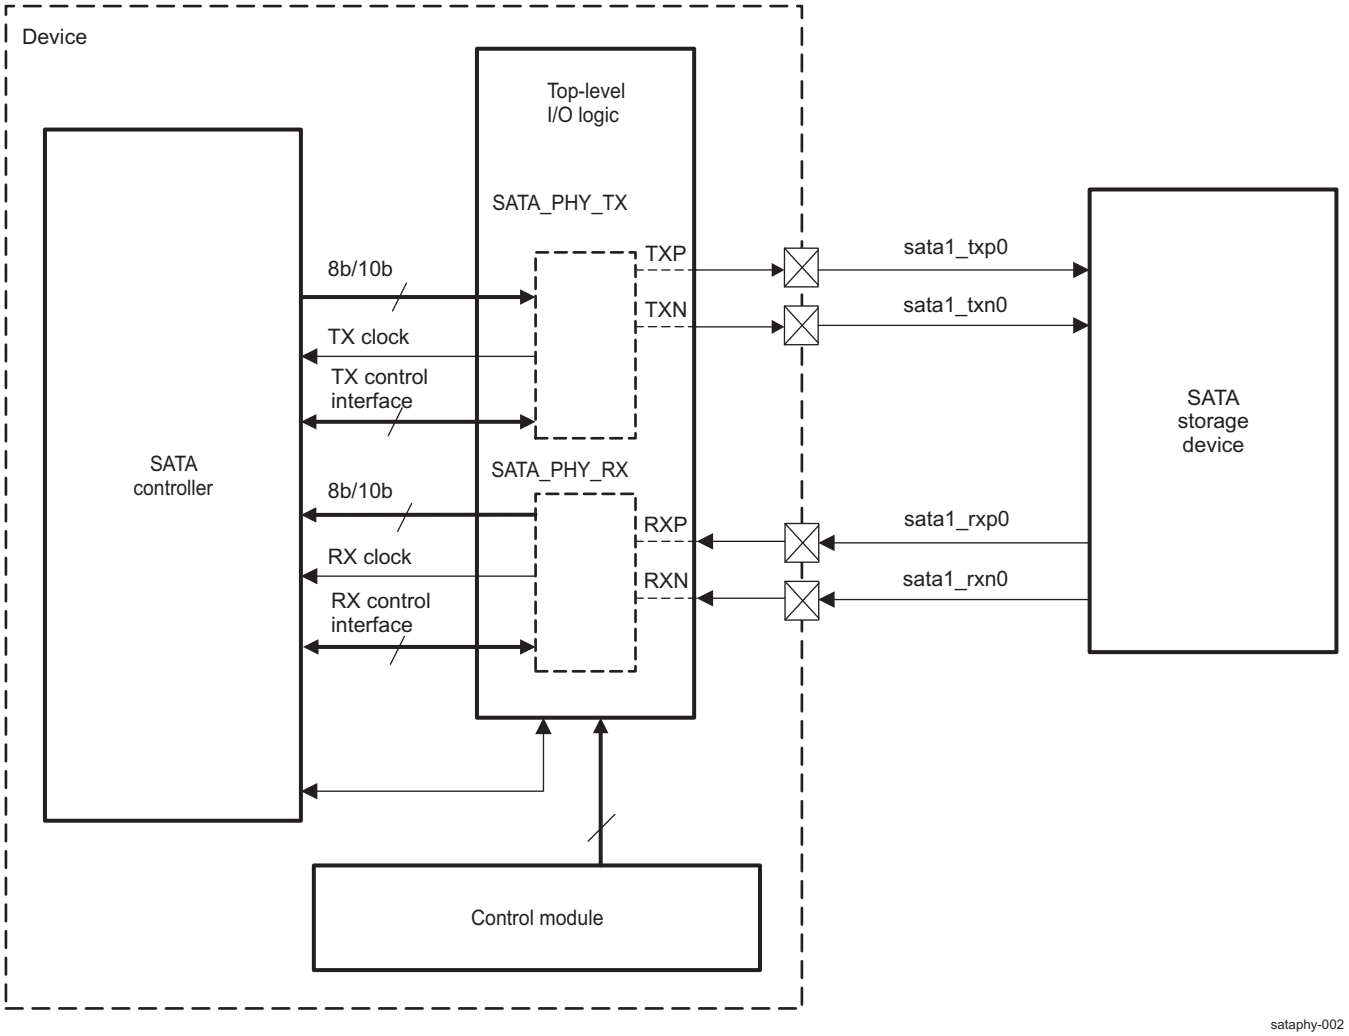
(1) I = Input; O = Output

(2) The SATA PHY subsystem signals that implement the physical interface with an external SATA storage device.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 26-2 shows module pin signals mapping to SATA PHY I/O signals visible at device pad level.

Figure 26-2. SATA PHY I/O Signals



NOTE: The path from module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the control module registers. See Chapter 18, *Control Module*, for more information.

Copyright © 2015–2017, Texas Instruments Incorporated

26.1.3 SATA PHY Subsystem Integration

NOTE: SATA is not supported on the AM570x family of devices.

This section describes the SATA PHY subsystem-related components (SATA_PHY, DPLL_SATA, DPLLCTRL_SATA, OCP2SPC3) integration in the device, including information about clocks, resets, and hardware requests.

Figure 26-3 shows the SATA_PHY integration.

The SATA_PHY module integration features are:

- A low-power nonretention reset, L3INIT_RST
- A DPLL reference input clock, PLL_CLK
- Parallel 10-bit TD[9:0] (SATA_PHY_TX) and 10-bit RD[9:0] (SATA_PHY_RX) data interfaces to SATA controller
- TX_CLK output clock for the parallel TX data interface between SATA_PHY.SATA_PHY_TX and SATA controller
- RX_CLK output clock for the parallel RX data interface between SATA_PHY.SATA_PHY_RX and SATA controller
- REF_CLK clock input (SATA_REF_GFCLK)
- A device core control module command port to the SATA_PHY integrated power sequencer

The DPLL_SATA integration features are:

- A low-power nonretention reset, L3INIT_RST
- A power, reset, and clock management (PRCM) gated version of SYS_CLK (SATA_REF_GFCLK) supplying the DPLL_SATA.CLKINP pin
- A single high-frequency clock output (DPLL_SATA.CLKDCOLDO to the SATA_PHY TX/RX components)
- No high-speed (HS) divider integration
- Idle signaling implementation
- LDO and DCO PWRDNZ monitoring signals
- A DPLL_LOCK locked status indication output to SATA_PHY and the SATA controller

The DPLLCTRL_SATA integration features are:

- A low-power nonretention reset, L3INIT_RST
- (OCP2SPC3) Interconnect adapter target interface
- Configuration/control programming interface to the DPLL_SATA
- No direct gate control for DPLL_SATA.CLKINP and CLKDCOLDO

26.1.4 SATA PHY Subsystem Functional Description

NOTE: SATA is not supported on the AM570x family of devices.

26.1.4.1 SATA PLL Controller L4 Interface Adapter Functional Description

The L4_CFG interconnect adapter (OCP2SCP3), allows user software to configure the DPLLCTRL_SATA registers over the L4_CFG port. Hence it is expected that this adapter is configured to operate before any programming of the DPLLCTRL_SATA.

Aa value of 0x6 or more should be written to the register bitfield OCP2SCP_TIMING[3:0] SYNC2.

L4_CFG interconnect adapter software reset is performed via writing OCP2SCP_SYSCONFIG[1] SOFTRESET to 0b1. The software reset completion is observed in bit OCP2SCP_SYSSTATUS[0] RESETDONE.

By default a smart-idle power mode is selected for OCP2SCP3. The smart-idle mode supported by OCP2SCP3 is not wake-up capable, which means software must explicitly take care to wake the OCP2SCP3 by setting the OCP2SCP_SYSCONFIG [4:3] IDLEMODE bit field to 0x1 (no idle), once it has previously gone to an idle mode.

By default OCP2SCP_SYSCONFIG[0] AUTOIDLE =0x1, which defines that the PLLCTRL L4 interface adapter automaticaly gates its L4 input clock based on L4_CFG interconnect activity. To enable a free-running clock, one should set bit AUTOIDLE to 0x0.

26.1.4.2 SATA PHY Serializer and Deserializer Functional Descriptions

26.1.4.2.1 SATA PHY Reset

No software reset is applicable to SATA_PHY. L3INIT reset assertion is automatically managed by hardware.

26.1.4.2.2 SATA_PHY Clocking

26.1.4.2.2.1 SATA_PHY Input Clocks

A standard high-speed 1.5 GHz input clock of SATA_PHY is provided by the DPLL_SATA.CLKDCOLDO output. PRCM. SATA_REF_GFCLK (derived from the SYS_CLK) should be enabled, to provide the necessary DPLL_SATA and SATA_PHY clocking within the SATA subsystem.

Depending on the SATA_REF_GFCLK (SYS_CLK derived) frequency, following settings should be made in the CTRL_MODULE_CORE.CONTROL_PHY_POWER_SATA[31:22] SATA_PWRCTL_CLK_FREQ bitfield for proper operation:

- 0x26: If SYSCLK = 38.4 MHz
- 0x1A: If SYSCLK = 26.0 MHz
- 0x13: If SYSCLK = 19.2 MHz
- 0x10: If SYSCLK = 16.8 MHz
- 0x0C: If SYSCLK = 12.0 MHz

26.1.4.2.2.2 SATA_PHY Output Clocks

The 10-bit data parallelly transmitted data between SATA_PHY_TX and SATA controller link logic is sampled with respect to the TX_CLK. Frequency of this clock is obtained as the SATA_PHY.PLL_CLK clock frequency:

- Divided by 10 if a 1.5-Gbps limit is negotiated by software setting DWC_ahsata.SATA_PxSCTL[7:4] SPD = 0x1
- Divided by 5 if a 3-Gbps limit is negotiated by software setting DWC_ahsata.SATA_PxSCTL[7:4] SPD = 0x0 or 0x2

Copyright © 2015–2017, Texas Instruments Incorporated

The actually negotiated between host and the attached SATA device speed is indicated in the read-only SATA controller.SATA_PxSSTS[7:4] SPD bit field. For more information, see Section 24.8.6, *SATA Controller Register Manual*, in Section 24.8, *SATA Controller*.

RX_CLK: The SATA_PHY_RX output RX_CLK is a clock that is recovered from the serial data received over the RXP/RXN lines serial data. The RX_CLK clock supplies the SATA controller link parallel 10-bit data reception logic.

26.1.4.2.3 SATA_PHY Power Management

The SATA_PHY power sequencer receives a power-up/power-down command input from the device general core control module. The power sequencer takes care to execute different stages of the SATA_PHY_TX and SATA_PHY_RX power-up/-down processes. Besides a power-up/-down functionality, the SATA PHY accepts power transition commands/states (Ready state, Partial or Slumber states) from the SATA controller link power management port .

26.1.4.2.3.1 SATA_PHY Power-Up/-Down Sequences

Powering up/down the SATA_PHY_TX and SATA_PHY_RX modules is triggered by software writing corresponding power-up/-down commands in the CTRL_MODULE_CORE. CONTROL_PHY_POWER_SATA register of the device core control module, as follows:

- CONTROL_PHY_POWER_SATA[21:14] SATA_PWRCTL_CLK_CMD = 0x0 (default value), commands both SATA_PHY_TX and SATA_PHY_RX to power-down (OFF) state.
- CONTROL_PHY_POWER_SATA[21:14] SATA_PWRCTL_CLK_CMD = 0x1, powers up the SATA_PHY_RX only.
- CONTROL_PHY_POWER_SATA[21:14] SATA_PWRCTL_CLK_CMD = 0x2, powers up the SATA_PHY_TX only.
- CONTROL_PHY_POWER_SATA[21:14] SATA_PWRCTL_CLK_CMD = 0x3, simultaneously powers up the SATA_PHY_RX and the SATA_PHY_TX.

For more information, see Chapter 18, *Control Module*.

26.1.4.2.3.2 SATA_PHY Low-Power Modes

Setting the DWC_ahsata.SATA_PxSCTL[3:0] DET bit field to 0x4 automatically puts the SATA_PHY_RX deserializer in offline mode. This software operation has no impact over the SATA_PHY_TX serializer.

NOTE: The SATA controller transition to partial or slumber mode has no impact over the SATA_PHY_RX deserializer.

NOTE: The SATA_PHY_TX.TX_CLK output clock is a free-running clock and cannot be gated, even when the transmitter is disabled by a SATA controller.

26.1.4.2.4 SATA_PHY Hardware Requests

No DMA, interrupt or wake-up requests are generated by the SATA_PHY to the surrounding SATA controller subsystem components.

26.1.4.3 SATA Clock Generator Subsystem Functional Description

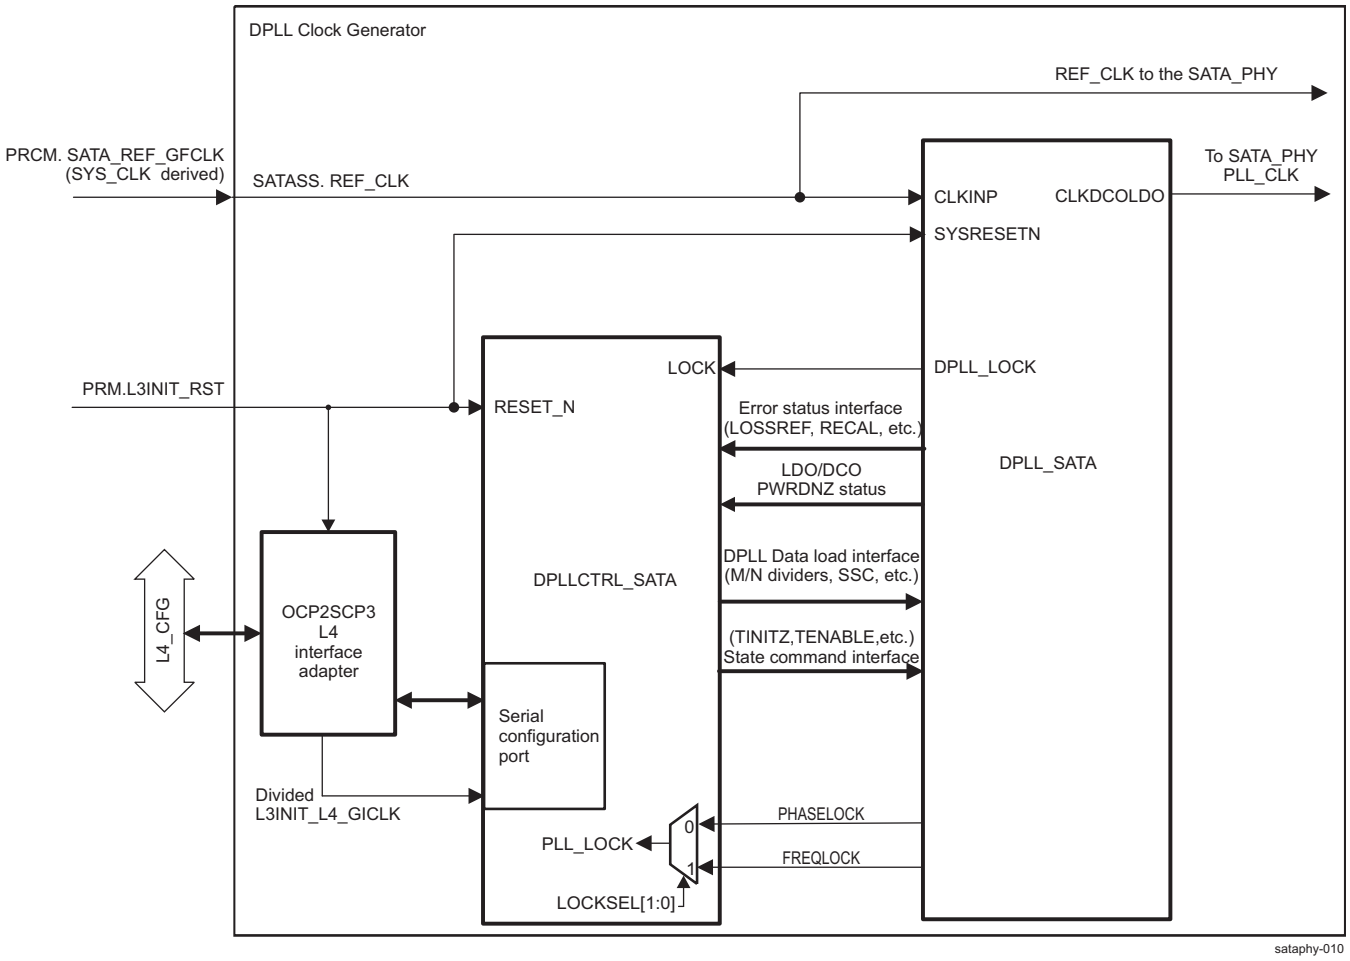
The DPLL_SATA, which is located outside the PRCM boundaries and is part of the SATA host controller subsystem, directly injects a high-speed clock into the SATA_PHY serializer/deserializer input, PLL_CLK. The DPLL generator is controlled through a programmable interface from a dedicated PLL controller, DPLLCTRL_SATA.

Copyright © 2015–2017, Texas Instruments Incorporated

26.1.4.3.1 SATA DPLL Clock Generator Overview

The SCP interface of the SATA PLL controller (the DPLLCTRL_SATA instance) is used to set the configuration of the digital phase-locked loop (DPLL) modules, primarily the various counter values. Figure 26-4 is an overview of the DPLL clock generator embedded into the SATA host controller subsystem.

Figure 26-4. SATA DPLL Clock Generator Overview



NOTE: The DPLLCTRL_SATA module is user accessible on the L4_CFG interconnect. However, to make access possible, the user must configure the OCP2SCP3 instance prior to accessing the DPLLCTRL_SATA registers.

The DPLL_SATA features are:

- A programmable 8-bit input divider: N
- A programmable 12-bit integer, 18-bit fractional loop multiplier: M
- Digital control and loop filter
- Internal oscillator output clock on internal LDO domain (CLKDCOLDO output)
- DPLL output clock spread spectrum clocking (SSC) support
- No retention capabilities
- No idle-bypass fast relock capabilities
- Idle-bypass low-power mode
- M/N bypass mode

Copyright © 2015–2017, Texas Instruments Incorporated

- Relock from standby

The DPLLCTRL_SATA components features are:

- DPLL error and status notification
- DPLL initialization and configuration
- DPLL lock criteria selectable between frequency and phase lock
- Idle command implementation
- No software reset implementation

26.1.4.3.2 SATA DPLL Clock Generator Reset

The SATA PLL controller and SATA DPLL clock generator share a common hardware nonretention reset (L3INIT_RST) which comes from the device power and reset manager. When the DPLL_SATA hardware reset completes, the DPLLCTRL_SATA.PLL_STATUS[0] PLLCTRL_RESET_DONE bit is automatically updated to 1. For more information on the hardware reset source, see Section 3.5.5, *Reset Domains*, in Chapter 3, *Power, Reset, and Clock Management*.

The DPLLCTRL_SATA itself has no software reset capabilities.

The DPLLCTRL_SATA performs a software reset sequence on the DPLL_SATA in hardware (through the TINITZ signal activation).

26.1.4.3.3 SATA DPLL Low-Power Modes

The power-management port (PMP) is not integrated for DPLLCTRL_SATA. The DPLL_SATA has no retention capabilities. This means the DPLL digital power supply remains switched on during all modes of operation.

The low-power (LP) modes supported by DPLL_SATA are idle-bypass low power and MN-bypass modes, which are both characterized by:

- Internal LDO switched off
- DCO oscillator switched off
- CLKDCOLDO output pulled low

For more details on the PLL settings and conditions necessary to enter idle-bypass and MN-bypass low-power modes, see Section 26.1.4.3.6.4, *SATA DPLL Idle-Bypass Low-Power Mode*, and Section 26.1.4.3.6.5, *SATA DPLL MN-Bypass Mode*.

DPLL_SATA is held in a similar low-power state (DCO and LDO switched off, with CLKDCOLDO = 0) after POR, before the first PLL_GO command has been software-triggered on the PLL controller. See Section 26.1.4.3.6.1, *SATA Clock Generator Power Up*.

26.1.4.3.4 SATA DPLL Clocks Configuration

26.1.4.3.4.1 SATA DPLL Input Clock Control

The DPLL_SATA accepts the functional clock (SATA_REF_GFCLK) on its CLKINP pin (REF_CLK input at SATA SS level) directly from the device PRCM, without involving any DPLLCTRL_SATA interactions. The SATA_REF_GFCLK is derived from SYS_CLK1, and can be optionally software-gated by setting the PRCM.CM_L3INIT_SATA_CLKCTRL[8] OPTFCLKEN_REF_CLK bit. The status of the SATA_REF_GFCLK clock can be monitored in the PRCM.CM_L3INIT_CLKSTCTRL[19] CLKACTIVITY_SATA_REF_GFCLK bit. See Section 3.6.4.1.4, *Clock Domain Module Attributes* in Chapter 3, *Power, Reset, and Clock Management*.

If CLKINP signal is lost for some time, the LOSSREF output signal, which serves as a feedback to DPLLCTRL_SATA, is asserted high. When CLKINP resumes, the LOSSREF signal goes low (LOSSREF inactive state). The LOSSREF status signal can be monitored by software in the DPLLCTRL_SATA.PLL_STATUS[3] PLL_LOSSREF bit.

Copyright © 2015–2017, Texas Instruments Incorporated

26.1.4.3.4.2 SATA DPLL Output Clock Configuration

Only the DPLL_SATA output, CLKDCOLDO, is used to provide the high-speed clock at the PLL_CLK pin of the SATA_PHY. Only the REGM, REGN, and SD divider values are used within the DPLL clock generator subsystem to adjust the CLKDCOLDO output clock frequency. This is done by programming the DPLLCTRL_SATA.PLL_CONFIGURATION1[20:9] PLL_REGM, DPLLCTRL_SATA.PLL_CONFIGURATION1[8:1] PLL_REGN, and DPLLCTRL_SATA.PLL_CONFIGURATION3[17:10] PLL_SD bit fields, respectively. The SATA DPLL CLKOUT and CLKOUTLDO outputs are not used, and internal REGM2 and REGM1 dividers are not software controllable.

NOTE: At the DPLL/PLLCTRL integration level, the PLL_REGM1[3:0] and PLL_REGM2[6:0] divider control signals are tied-off by hardware to 0x0 and 0x1, respectively.

For more details on output clock settings sequence, see Section 26.1.4.3.7.2, *SATA DPLL Clock Programming Sequence*.

26.1.4.3.4.2.1 SATA DPLL Output Clock Gating

There is no direct software gate control for the DPLL_SATA.CLKDCOLDO output.

The DPLL_SATA.CLKDCOLDO clock output is automatically gated (CLKDCOLDO pulled low) in the following scenarios:

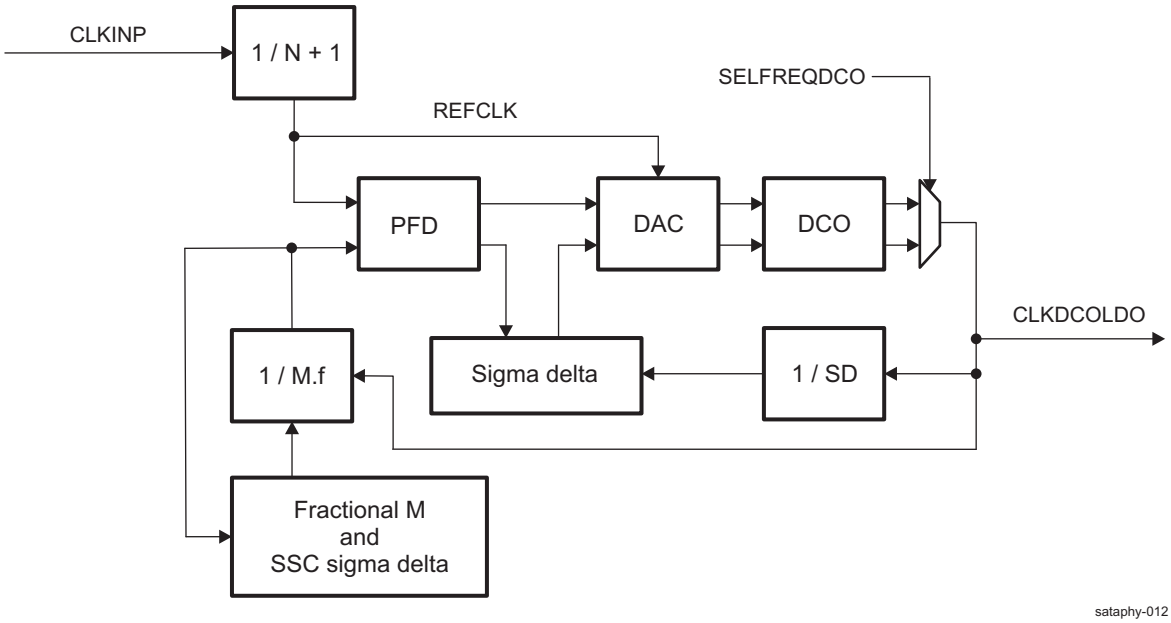
- DPLL power-up sequence. For more information on the power-up sequence, see Section 26.1.4.3.6.1, *SATA Clock Generator Power Up*.
- DPLL entering a relock sequence. For more information on the relocking sequence, see Section 26.1.4.3.6.2, *SATA DPLL Sequences*.
- DPLL entering idle-bypass low-power mode. For more information on idle-bypass mode, see Section 26.1.4.3.6.4, *SATA DPLL Idle-Bypass Mode*.
- DPLL entering MN-bypass mode. For more information on MN-bypass mode, see Section 26.1.4.3.6.5, *SATA DPLL MN Bypass Mode*.

26.1.4.3.5 SATA DPLL Subsystem Architecture

Figure 26-5 is a simplified block diagram of the DPLL_SATA instance integration in the SATA clock generator subsystem.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 26-5. DPLL_SATA Functional Block Diagram



The input clock CLKINP goes to a predivider N + 1. The entire loop runs on the REFCLK clock after this predivider. The value of N + 1 is controlled through the DPLLCTRL_SATA.PLL_CONFIGURATION1[8:1] PLL_REGN bit field.

The frequency ranges for the DPLL_SATA input clock (CLKINP) and the DPLL internal reference clock (REFCLK = CLKINP/N + 1) are:

- 0.62 to 60 MHz for CLKINP
- 0.62 to 2.5 MHz for the REFCLK

The output clock CLKDCOLDO is synthesized by digitally controlled oscillator (the DCO block), that automatically detects the frequency range. The CLKDCOLDO frequency can be given with CLKDCOLDO = CLKINP × M/(N + 1). For that purpose the feedback multiplier M must be configured through the DPLLCTRL_SATA.PLL_CONFIGURATION1[20:9] PLL_REGM bit field.

The DPLL_SATA module supports fractional synthesis (that is, the frequency multiplication factor M can be programmed as fractional). This is achieved by having a sigma delta feedback divider (M). A fractional value (Fractional M) of 18 bits is supported enabling control for a better accuracy. Programming the 18-bit Fractional M value is done by setting the DPLLCTRL_SATA.PLL_CONFIGURATION4[17:0] PLL_REGM_F bit field (similar to REGM). To enable integer only division Fractional M should be set to 000…0.

NOTE: Fractional synthesis is not supported for M > 4093.

26.1.4.3.6 SATA DPLL Clock Generator Modes and State Transitions

The DPLL_SATA can be set in different modes during operation. PLLCTRL triggers DPLL_SATA state transitions to different static modes by means of TINITZ and TENABLE hardware control signals.

Copyright © 2015–2017, Texas Instruments Incorporated

26.1.4.3.6.1 SATA Clock Generator Power Up

After power up, the DPLL_SATA.SYSRESETN input is automatically pulled low by PRM, together with DPLLCTRL_SATA.RESET_N input. Because PRM.L3INIT_RST is an asynchronous reset, the DPLL_SATA input clock (DPLL_SATA.CLKINP) is not demanded upon reset. The LOSSREF signal, which monitors the presence of CLKINP clock, remains 1 during SYSRESETN = 0 irrespective of presence/absence on the CLKINP clock. If CLKINP is present upon reset assertion, the LOSSREF signal is deasserted to 0, a certain time after the hardware reset completion. During DPLL power-up mode, CLKDCOLDO clock is maintained inactive (pulled low). After POR, the DPLL_LOCK (internal lock loop) signal is maintained deasserted, too.

26.1.4.3.6.2 SATA DPLL Sequences

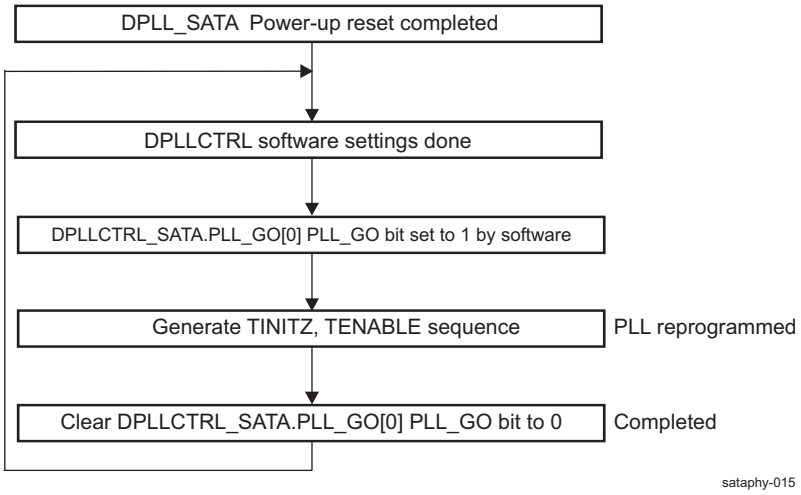
Once all the configuration values have been initially programmed into the DPLLCTRL_SATA registers (see Section 26.1.4.3.7.2, *SATA DPLL Clock Programming Sequence*), the DPLLCTRL_SATA.PLL_GO[0] PLL_GO bit should be set to update the configuration values and start the DPLL calibration and locking sequence.

After DPLLCTRL_SATA.PLL_GO[0] PLL_GO bit is set high in software, the DPLLCTRL_SATA state-machine takes the following action:

1. Sets TINITZ signal to 0. TINITZ acts as a soft reset to DPLL_SATA. This starts the DPLL initialization procedure. During initialization mode, the CLKDCOLDO, FREQLOCK, and PHASELOCK signals are kept at 0 and the BYPASSACK signal is kept at 1.
   VDDA power supply of DPLL should be active before DPLL_SATA initialization is performed, but it is not required to be switched on immediately after device power up.
2. The TENABLE signal is asserted high by the PLLCTRL hardware to load the user-programmed values of REGM, REGN, REGSD, and SELFREQDCO into DPLL registers.
3. After TENABLE is asserted, TINITZ is driven high (disabled) by the PLLCTRL to trigger a DPLL calibration and lock sequence after the loop control values are loaded. The module calibration-lock sequence will begin from the first CLKINP edge after TINITZ is disabled.

Figure 26-6 summarizes the software and hardware sequences flow of DPLL_SATA.

Figure 26-6. SATA PLL GO Sequence



NOTE: All thick-outlined blocks in Figure 26-6 show operations performed by software. Other blocks show operations performed by hardware.

DPLL_SATA Relock Sequence: When DPLL leaves a lost clock condition (LOSSREF = 1 → 0) or idle-bypass mode it enters relock sequence from the first CLKINP edge (after bypass mode leaving). Relock sequence is the same as calibration-lock sequence already described.

A DPLL relock sequence is also software triggered by setting DPLLCTRL_SATA.PLL_GO[0] PLL_GO bit to 0b1 for DPLL parameters update.

Copyright © 2015–2017, Texas Instruments Incorporated

When DPLL_SATA enters a relock sequence, CLKDCOLDO is pulled low. FREQLOCK and PHASELOCK status signals are also low. CLKDCOLDO output clock is activated after FREQLOCK or PHASELOCK signal goes high, depending on the selected locking criteria.

The DPLLCTRL_SATA.PLL_GO[0] PLL_GO bit can be used by software to monitor if PLLCTRL locking process is still pending (PLL_GO = 0b1).

26.1.4.3.6.3 SATA DPLL Locked Mode

When DPLL_SATA finishes calibration and lock sequences it enters the LOCKED state. During the LOCKED state, LOSSREF is deasserted, BYPASSACK is deasserted, and the FREQLOCK or PHASELOCK signals are asserted.

DPLL lock event criteria (FREQLOCK or PHASELOCK) is software selectable through the DPLLCTRL_SATA.PLL_CONFIGURATION2[10:9] PLL_LOCKSEL bit field.

The DPLL indicates it is in the LOCKED state to the DPLLCTRL_SATA, SATA controller core controller, and SATA_PHY through assertion of the DPLL_LOCK signal, which reflects the internal lock loop status. The user software can monitor the DPLL locked event in the DPLLCTRL_SATA.PLL_STATUS[1] PLL_LOCK bit, which is active high.

26.1.4.3.6.4 SATA DPLL Idle-Bypass Mode

Idle-bypass fast relock mode is not supported for DPLL_SATA.

DPLL_SATA supports idle-bypass low-power mode. A transition from a normal operation to idle-bypass mode is performed when software sets the DPLLCTRL_SATA.PLL_CONFIGURATION2[0] PLL_IDLE bit to 0x1. IDLE signal assertion triggers a power-down sequence on DPLL internal LDO analog blocks and DCO oscillator.

In idle-bypass low-power mode, the PHASELOCK and FREQLOCK output signals are asserted low and CLKDCOLDO goes low, respectively. Also, the internal reference clock REFCLK = CLKINP/N + 1 is gated inside the DPLL digital control logic to save power.

In the functional mode, DPLL_SATA.TICOPWDN output indicates to the PLL controller the status of the power-down signal (active high) of the internal DCO oscillator. The internal DCO oscillator is powered down in idle-bypass mode or during period from SYSRESETN 0 → 1 to module initialization. The DCO oscillator exits power down (TICOPWDN goes low) whenever the module internally tries to lock or relock after initialization or exiting idle-bypass mode.

In the functional mode, DPLL_SATA.LDOPWDN output indicates to the PLL controller the status of the power-down signal (active high) of the internal LDO. LDOPWDN goes high as soon as the internal LDO is powered down. LDOPWDN goes low after the LDO output voltage is stable. The internal LDO is powered down in period from SYSRESETN 0 → 1 to module initialization or when entering into idle-bypass mode. LDOPWDN is cleared whenever the module internally tries to lock or relock after initialization or exiting idle-bypass mode after the internal LDO output voltage has stabilized.

The DCO and LDO power ON/OFF states are reflected within the read-only DPLLCTRL_SATA.PLL_STATUS[16] PLL_TICOPWDN and DPLLCTRL_SATA.PLL_STATUS[15] LDOPWDN monitor bits.

To exit idle-bypass mode and restore clock generation, the user should set DPLLCTRL_SATA.PLL_CONFIGURATION2[0] PLL_IDLE to 0x0, which deasserts the IDLE signal and DPLL_SATA automatically enters a relock sequence. The CLKDCOLDO output clock is activated after the FREQLOCK or PHASELOCK signal goes high, depending on selected locking criteria.

26.1.4.3.6.5 SATA DPLL MN-Bypass Mode

The MN-Bypass mode will be activated if REGM = 0 or 1 is loaded into the module on the rising edge of TENABLE. TINITZ also should be pulsed to enter MN-Bypass mode. The module enters a low-power mode by gating all its internal clocks (REFCLK) and powering down the internal LDO (LDOPWDN = 1) and DCO (DCOPWDN = 1). CLKDCOLDO remains gated (low) during this mode.

Copyright © 2015–2017, Texas Instruments Incorporated

NOTE: When the DPLLCTRL_SATA.PLL_CONFIGURATION1[20:9] PLL_REGM bit field is updated to 0x0 or 0x1, the CLKDCOLDO output clock is gated.

26.1.4.3.6.6 SATA DPLL Error Conditions

The PLL lock and recalibration signals can be monitored to detect the loss of lock condition and the DPLL requirement to recalibrate (caused by a large temperature change since the last lock request):

- The DPLLCTRL_SATA.PLL_STATUS[2] PLL_RECAL bit informs whether the DPLL_SATA must be recalibrated.

The PLL reference clock (CLKINP) loss status and PLL-in-high-jitter condition can also be monitored:

- The DPLLCTRL_SATA.PLL_STATUS[1] PLL_LOCK bit gives the SATA PLL LOCKED state.
- The DPLLCTRL_SATA.PLL_STATUS[3] PLL_LOSSREF bit informs whether the DPLLCTRL_SATA has lost the reference clock.
- The DPLLCTRL_SATA.PLL_STATUS[5] PLL_HIGHJITTER bit informs whether the PLL has entered a high-jitter condition.

26.1.4.3.7 SATA PLL Controller Functions

26.1.4.3.7.1 SATA PLL Controller Register Access

The configuration registers are accessed through the OCP2SCP3 L4 adapter register space using the SCP interface of the DPLLCTRL_SATA. This includes all the configuration signals and returning status signals.

CAUTION

All writes must be 32-bit operations, because the SCP interface always transfers 32 bits; 16- or 8-bit operations may lead to unpredictable errors.

NOTE: Because the SATA_PHY directly provides parallel data interface clocks RX_CLK and TX_CLK to the SATA controller, the DPLLCTRL_SATA and DPLL_SATA must be configured before any data transfer between the SATA controller and an external SATA storage device.

26.1.4.3.7.2 SATA DPLL Clock Programming Sequence

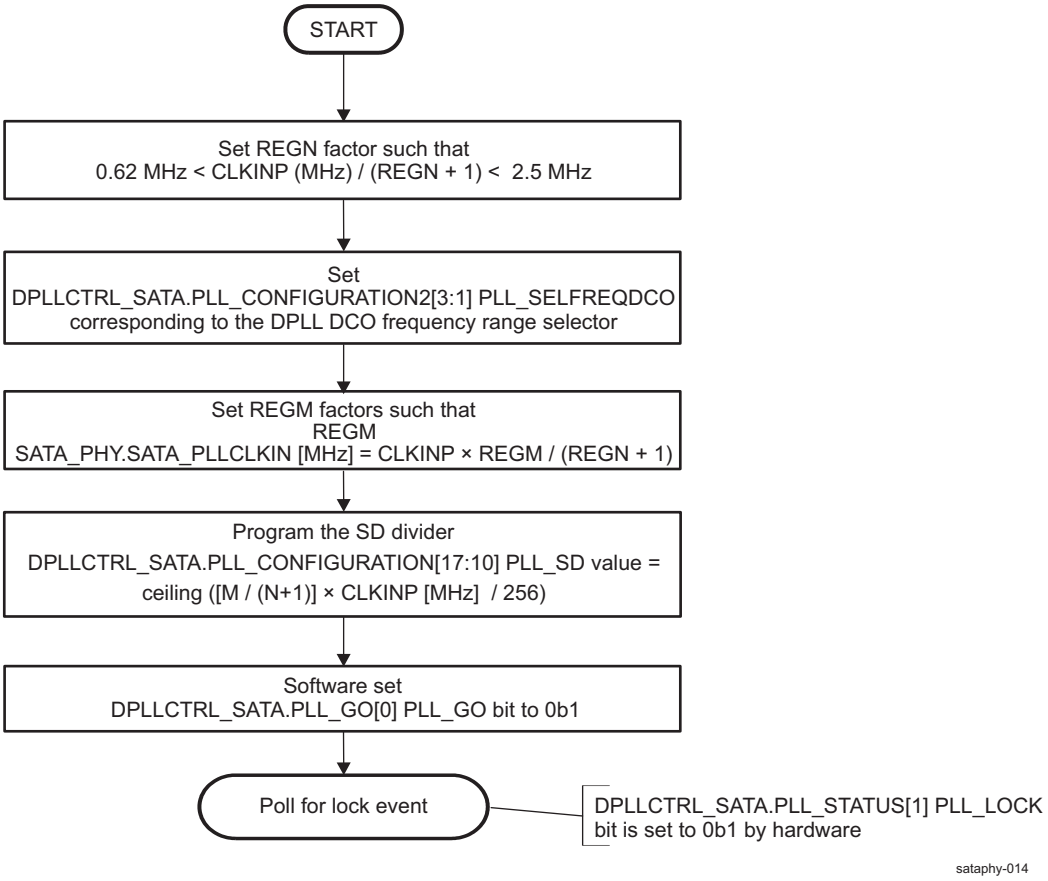
The DPLL_SATA factors must be calculated based on the required input and output frequencies, keeping the PLL internal reference frequency (REFCLK) in the appropriate range (0.62 to 2.5 MHz).

- The REGM factor is programmed in the DPLLCTRL_SATA.PLL_CONFIGURATION1[20:9] PLL_REGM bit field.
- The fractional part of REGM factor is programmed in the DPLLCTRL_SATA.PLL_CONFIGURATION4[17:0] PLL_REGM_F bit field.
- The REGN factor is programmed in the DPLLCTRL_SATA.PLL_CONFIGURATION1[8:1] PLL_REGN bit field.
- The DCO frequency range is set in the DPLLCTRL_SATA.PLL_CONFIGURATION2[3:1] PLL_SELFREQDCO bit field.
  - PLL_SELFREQDCO should be set to 0x2, if 500 MHz < CLKDCOLDO [MHz] < 1000 MHz
  - PLL_SELFREQDCO should be set to 0x4, if 1000 MHz < CLKDCOLDO [MHz] < 2000 MHz
- The SD divider is programmed in the DPLLCTRL_SATA.PLL_CONFIGURATION3[17:10] PLL_SD bit field. The DPLLCTRL_SATA.PLL_CONFIGURATION2[3:1] PLL_SELFREQDCO bit field should be programmed depending on the value of CLKDCOLDO = CLKINP × M/(N + 1). The formulas are shown in Figure 26-7.

Figure 26-7 shows the programming sequence.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 26-7. SATA PLL Programming Sequence



NOTE:

- The equation for SATA_PHY_TX/SATA_PHY_RX (MHz) applies to the CLKDCOLDO of the DPLL_SATA.
- For normal operation CLKDCOLDO output frequency of the DPLL_SATA should be either 750 MHz (SATA-1 mode) or 1500 MHz (SATA-2 mode).

Table 26-5 summarizes the registers for the DPLLCTRL_SATA programming sequence.

Table 26-5. Register Call Summary for SATA PLL Programming Sequence

Register Name	Register Name	Register Name	Register Name
DPLLCTRL_SATA.PLL_CONFIGURATION2	DPLLCTRL_SATA.PLL_GO	DPLLCTRL_SATA.PLL_STATUS	DPLLCTRL_SATA.PLL_CONFIGURATION3

26.1.4.3.7.3 SATA DPLL Recommended Values

Table 26-6 lists the DPLL_SATA recommended values.

Table 26-6. Recommended Programming Values

Field Name	Value	Description
DPLLCTRL_SATA.PLL_CONFIGURATION1[20:9] PLL_REGM	See (1).	Feedback clock divider

(1) The value of the bit field must be set according to the desired clock frequencies – 750 MHz for SATA-1 and 1.5 GHz for SATA-2 speeds.

Copyright © 2015–2017, Texas Instruments Incorporated

Table 26-6. Recommended Programming Values (continued)

Field Name	Value	Description
DPLLCTRL_SATA.PLL_CONFIGURATION1[8:1] PLL_REGN	See (1).	Reference clock divider
DPLLCTRL_SATA.PLL_CONFIGURATION2[10:9] PLL_LOCKSEL	0x-	Criteria to lock the PLL
DPLLCTRL_SATA.PLL_CONFIGURATION2[3:1] PLL_SELFREQDCO	See (1).	Program based on the PLL choice and lock frequency.
DPLLCTRL_SATA.PLL_CONFIGURATION2[0] PLL_IDLE	0	PLL active
DPLLCTRL_SATA.PLL_CONFIGURATION3[17:10] PLL_SD	See (1).	Ceiling { [PLL_REGM/(PLL_REGN + 1)] × CLKINP(MHz)/256 }
DPLLCTRL_SATA.PLL_GO[0] PLL_GO	0x1	Write 1 when PLL is to be (re)locked with new parameters. This bit is cleared by hardware when the PLL request completes.

26.1.5 SATA PHY Subsystem Low-Level Programming Model

NOTE: SATA is not supported on the AM570x family of devices.

Table 26-7 summarizes the low-level programming sequence to set up the SATA PHY subsystem for SATA I/O operations.

Table 26-7. SATA PHY Subsystem Low-Level Programming Sequence

Step	Description	Comment
1.	Set the startup low-performance OPP in the appropriate PRCM registers.	For more information regarding demanded OPP, see the device *Data Manual*.
2.	Enable the PRCM.SATA_REF_GFCLK.	See Section 3.6.4.1.4, *Clock Domain Module Attributes*, in Chapter 3, *Power, Reset, and Clock Management*.
3.	Enable the PRCM.L3INIT_L4_GICLK clock to enable the OCP2SCP3 interface adapter operation.	See Section 3.6.4.1.4, *Clock Domain Module Attributes*, in Chapter 3, *Power, Reset, and Clock Management*.
4.	Software reset the OCP2SCP3 and poll until soft reset completion is indicated in status.	See Section 26.1.4.1.
5.	Set up division ratio between the OCP clock (PRCM.L3INIT_L4_GICLK) and SCP clock to supply the serial configuration register domains of the DPLLCTRL_SATA.	See Section 26.1.4.1.
6.	Set up necessary SYNC1 and SYNC2 timings to ensure no blocking of transactions over the SCP bus.	. See Section 26.1.4.1.After this step user is ready to access DPLLCTRL_SATA.
7.	Configure DPLL_SATA to generate frequency (CLKDCOLDO) = 1.5 GHz.	See Section 26.1.4.3.7.2 and Table 26-8.
8.	Soft assert bit DPLLCTRL_SATA.PLL_GO[0] PLL_GO to 0x1.	Start the DPLL lock with desired parameters.
9.	Poll DPLLCTRL_SATA.PLL_STATUS[1] PLL_LOCK bit until it is seen 1.	DPLL locked event
10.	Perform a SATA_PHY tuning required for SATA i/f operation	Follow steps described in Table 26-9, *SATA PHY Tuning Table*.
11.	Software trigger the SATA_PHY_TX power-up sequence.	For more details, see Section 26.1.4.2.3.1, *SATA_PHY Power-Up/-Down Sequences*.
12.	Software trigger the SATA_PHY_RX power-up sequence.	For more details, see Section 26.1.4.2.3.1, *SATA_PHY Power-Up/-Down Sequences*.

Table 26-8. DPLL CLKDCOLDO Recommended Settings

Parameter	Setting				
F(CLKDCOLDO) MHz	1500				
SYS_CLK (MHz)	12	16.8	19.2	26	38.4
N	4	6	7	12	15
SELFREQDCO[2:0]	100	100	100	100	100
M	625	625	625	750	625
Frac	0	0	0	0	0
SD	6	7	6	6	6

Table 26-9. SATA PHY Tuning Table

Physical address[(1)] [bits to modify]	Preferred value setting[(2)]
0x4A09 600C [31:27]	0b01000 for SATA 1.5 Gbps mode 0b00100 for SATA 3 Gbps mode
0x4A09 600C [17:14]	0b1010 for SATA-Gen1x and SATA-Gen2x 0b0101 for SATA-Gen1m and SATA-Gen2m
0x4A09 6028 [23:19]	0b11100 if spread-spectrum is ON 0b00001 if spread-spectrum is OFF
0x4A09 6028 [18:11]	0b01100110(regardless of spread-spectrum being ON or OFF)
0x4A09 600C [6:5]	0b00
0x4A09 601C [31:30]	0b01
0x4A09 6038 [31:16]	0x0000
0x4A09 6038 [15:7]	0b111110000
0x4A09 6038 [2:1]	0b11
0x4A09 6044 [10:9]	0b00

(1) Accesses to these locations have to be done in 32-bits only. User must NOT modify SATA PHY bits different than those described in Table 26-9.

(2) These are the preferred settings of SATA_PHY, in case that SATA PHY PLL_CLK=1.5 GHz.

26.2 USB3_PHY Subsystem

This chapter describes the features and functions of the USB3_PHY subsystem of the device.

26.2.1 USB3_PHY Subsystem Overview

The USB3.0 physical layer (PHY) is responsible for transmitting the USB1 controller media access layer (MAC) 32-bit parallel data output as a serial data stream over a differential pair (TXP/TXN) and converting the differentially received serial data (RXP/RXN) to 32-bit parallel input data demanded by the MAC receiver logic.

The USB3_PHY component operates with a 2.5 GHz-source clock, to achieve the USB 3.0 super-speed throughput of 5 Gbps. The USB3_PHY serializer/deserializer source clock is generated by a DPLL clock generator (DPLL_USB_OTG_SS) which isintegrated into the USB1 host subsystem.

The DPLL_USB_OTG_SS is configured and controlled through the USB3_PHY dedicated PLL controller (DPLLCTRL_USB_OTG_SS) with associated serial configuration port (SCP) accessible registers.

A common interconnect adapter component, OCP2SCP1, lets the user program the USB3_PHY serializer/deserializer and DPLLCTRL_USB_OTG_SS through the L4_CFG interconnect.

Figure 26-8 gives an overview of the USB3_PHY subsystem. Figure 26-8 shows that the USB3_PHY serializer and deserializer directly interract with the attached to USB OTG SS controller USB3.0 compatible device (over TXP/TXN transmission and RXP/RXN reception interface I/Os). The PIPE port interracts with the USB1 MAC port, described in details in Section 24.7, *SuperSpeed USB DRD*.

26.2.2 USB3_PHY Subsystem Environment

26.2.2.1 USB3_PHY I/O Signals

Table 26-10 represents module pins and their corresponding signal names at the device level, and also specifies their links to functions.

Table 26-10. USB3_PHY I/O Signals

Module Pin Name	Device-Level Signal Name	I/O[1]	Description	Module Pin Reset Value[2]
TXP	usb_txp0	O	TX output of the USB3_PHY differential transmission line	0
TXN	usb_txn0	O	TY output of the USB3_PHY differential transmission line	0
RXP	usb_rxp0	I	RX input of the USB3_PHY differential reception line	HiZ
RXN	usb_rxn0	I	RY input of the USB3_PHY differential reception line	HiZ

(1) I = Input; O = Output
(2) HiZ = High impedance

Figure 26-9 shows module pin signals mapping to USB3_PHY signals visible at the device pad level.

Figure 26-9. USB3_PHY I/O Signals

26.2.3 USB3_PHY Subsystem Integration

This section describes the USB3_PHY subsystem-related components (USB3_PHY module, DPLL_USB_OTG_SS, DPLLCTRL_USB_OTG_SS, and OCP2SPC1) integration in the device, including information about clocks, resets, and hardware requests.

Figure 26-10 shows the USB3_PHY integration.

The USB3_PHY module integration features:

- A low-power nonretention reset, L3INIT_RST
- (OCP2SPC1) Interconnect adapter target interface
- A high-frequency input clock (PLL_CLK) tied to the DPLL_USB_OTG_SS.CLKDCOLDO output
- A local port connected to the USB1 MAC PIPE3 port
- A clock output (PIPE_PCLK) to the USB1 PIPE port
- A clock output (PIPE_MCLK) from the USB1 PIPE port
- A common clock from PRCM - REF_CLK, to supply DPLL and PHY RX/TX logic
- PRCM.CORE_USB_OTG_SS_LFPS_TX_CLK clock tied to the USB3_PHY_TX
- A device CORE CONTROL MODULE command port to the power sequencer

The DPLL_USB_OTG_SS integration features:

- A low-power nonretention reset, L3INIT_RST
- A PRCM gated version of the device SYS_CLK (USB_OTG_SS_REF_CLK) supplying DPLL_USB_OTG_SS.CLKINP pin
- A single high-frequency clock output, DPLL_USB_OTG_SS.CLKDCOLDO, to the PLL_CLK input of the USB3_PHY_TX/RX components.
- No HS divider integration
- IDLE signaling implementation
- LDO and DCO PWRDNZ monitoring signals
- A DPLL_LOCK LOCKED status indication

The DPLLCTRL_USB_OTG_SS integration features:

- A low-power nonretention reset, L3INIT_RST
- (OCP2SPC1) Interconnect adapter target interface also providing the input SCP clock to the DPLLCTRL_USB_OTG_SS
- Configuration/control programming interface to the DPLL_USB_OTG_SS
- No direct gate control for DPLL_USB_OTG_SS.CLKINP and CLKDCOLDO

26.2.4 USB3_PHY Subsystem Functional Description

26.2.4.1 Super-Speed USB PLL Controller L4 Interface Adapter Functional Description

The L4_CFG interconnect adapter (OCP2SCP1), allows user software to configure the DPLLCTRL_USB_OTG_SS registers over the L4_CFG port. Hence it is expected that this adapter is configured to operate before any programming of the DPLLCTRL_USB_OTG_SS.

Before initiating any software reset to this adapter, a value >= 0x6 should be written to the register bitfield OCP2SCP_TIMING[3:0] SYNC2.

L4_CFG interconnect adapter software reset is performed via writing OCP2SCP_SYSCONFIG[1] SOFTRESET to 0b1. The software reset completion is observed in bit OCP2SCP_SYSSTATUS[0] RESETDONE.

By default a smart-idle power mode is selected for OCP2SCP1. The smart-idle mode supported by OCP2SCP1 is not wake-up capable, which means software must explicitly take care to wake the OCP2SCP1 by setting the OCP2SCP_SYSCONFIG [4:3] IDLEMODE bit field to 0x1 (no idle), once it has previously gone to an idle mode.

By default OCP2SCP_SYSCONFIG[0] AUTOIDLE =0x1, which defines that the DPLLCTRL L4 interface adapter automaticaly gates its L4 input clock based on L4_CFG interconnect activity. To enable a free-running clock, one should set bit AUTOIDLE to 0x0.

26.2.4.2 USB3_PHY Serializer and Deserializer Functional Descriptions

26.2.4.2.1 USB3_PHY Module Resets

26.2.4.2.1.1 Hardware Reset

The USB3_PHY active low reset which is sourced from PRCM module. L3INIT_RST is hardware-asserted upon power up. For more information on the hardware reset source , see Section 3.5.5, *Reset Domains*, in Chapter 3, *Power, Reset, and Clock Management*.

26.2.4.2.1.2 Software Reset

The USB3_PHY PIPE i/f logic is software reset from USB1 over PIPE port by software assertion of the USBOTGSS_GUSB3PIPECTL[31] PHYSOFTRST bit to 0x1. The user must set USBOTGSS_GUSB3PIPECTL[31] PHYSOFTRST to 0x1 before triggering the serializer and deserializer power-up sequence in the CTRL_CORE_PHY_POWER_USB register. For more information on power-up sequence, see Section 26.2.4.2.3.1, *USB3_PHY Power-Up/Down Sequences*.

The user should deassert USBOTGSS_GUSB3PIPECTL[31] PHYSOFTRST to 0x0, after the serializer and deserializer power-up sequence completes. For more information, see Section 26.2.4.2.3.1, *USB3_PHY Power-Up/Down Sequences*.

26.2.4.2.2 USB3_PHY Subsystem Clocking

26.2.4.2.2.1 USB3_PHY Subsystem Input Clocks

The USB3_PHY component receives a feedback clock, PIPE_MCLK, which is the reflected version of the PIPE_PCLK (PIPE port synchronizing clock) generated by the USB3_PHY component. The clock is turned on/off according to the PIPE power-down port states. As PIPE port works in source-synchronous mode, all data movement from the MAC layer to the PIPE interface is synchronous to PIPE_PCLK.

The USB3_PHY.PLL_CLK high-speed transmission (2.5 GHz) clock input pin is connected to the DPLL_USB_OTG_SS clock output, CLKDCOLDO. For more information on the DPLL_USB_OTG_SS.CLKDCOLDO output clock settings, see Section 26.2.4.3.4.2, *USB3_PHY DPLL Output Clock Configuration*.

As shown in Figure 26-11, the same PRCM-sourced clock (USB_OTG_SS_REF_CLK), tied at the USB3_PHY subsystem REF_CLK input, supplies the USB3_PHY RX/TX components and the DPLL_USB_OTG_SS.CLKINP inputs.

Copyright © 2015–2017, Texas Instruments Incorporated

The PHY associated power sequencer receives PRCM.USB_OTG_SS_REF_CLK as a functional clock. Software must notify the PHY logic about which REF_CLK frequency is selected by writing the CTRL_CORE_PHY_POWER_USB[31:22] USB_PWRCTL_CLK_FREQ bit field, as follows:

- 0x26: If SYSCLK = 38.4 MHz
- 0x1A: If SYSCLK = 26.0 MHz
- 0x13: If SYSCLK = 19.2 MHz
- 0x10: If SYSCLK = 16.8 MHz
- 0x0C: If SYSCLK = 12.0 MHz

The USB3PHY_LFPS_CLK clock input is used to support different USB3_PHY functions, such as the low-frequency periodic signaling (LFPS) generator. This USB3_PHY_TX clock input is tied to the PRCM.CORE_USB_OTG_SS_LFPS_TX_CLK functional clock.

The USB3_PHY_RX deserializer I/O wake-up logic is supported by the PRCM.COREAON_32K_GFCLK clock, applied at the USB3PHY_WKUP_CLK input.

26.2.4.2.2.2 USB3_PHY Subsystem Output Clocks

- PIPE_PCLK: The PIPE interface is source-synchronous. A PIPE_PCLK clock is generated by the USB3_PHY component, used to synchronize USB1 PIPE port inputs, and reflected back as the PIPE_MCLK along with the PIPE outputs. The clock is turned on/off according to the power control port. All data movement from the PIPE interface to the USB1 MAC layer is synchronous to this clock.

The PIPE_PCLK clock which drives the PIPE3 logic is sourced by the on-chip USB3_PHY. The PIPE interface is source-synchronous (that is, the clock is received from the PHY), used to synchronize USB1 PIPE inputs, and reflected back along with the PIPE outputs as the PIPE_MCLK. The PIPE_PCLK clock is turned on/off according to the USB3_PHY power control port. For more details, see Section 26.2.4.2.3, *USB3_PHY Power Management*.

26.2.4.2.3 USB3_PHY Power Management

From one side the control over power up/down states of the USB3_PHY is provided through a power sequencer module tightly integrated with the the USB3_PHY physical layer TX/RX components.

26.2.4.2.3.1 USB3_PHY Power-Up/-Down Sequences

Powering-up/-down the USB3_PHY_TX and USB3_PHY_RX modules is triggered through software writing corresponding power-up/down commands in the CTRL_CORE_PHY_POWER_USB register of the device core control module, as follows:

- CONTROL_PHY_POWER_USB[21:14] USB_PWRCTL_CLK_CMD=0x0 (default value) commands both USB3_PHY_TX and USB3_PHY_RX to power-down (OFF) state.
- CONTROL_PHY_POWER_USB[21:14] USB_PWRCTL_CLK_CMD=0x1 powers up the USB3_PHY_RX only.
- CONTROL_PHY_POWER_USB[21:14] USB_PWRCTL_CLK_CMD=0x2 powers up the USB3_PHY_TX only.
- CONTROL_PHY_POWER_USB[21:14] USB_PWRCTL_CLK_CMD=0x3 simultaneously powers up the USB3_PHY_RX and the USB3_PHY_TX

For more information, see Chapter 18, *Control Module*.

26.2.4.2.3.2 USB3_PHY Low-Power Modes

An implemented powerdown control port allows USB3_PHY to support four low-power states:

- 0b00: P0, normal operation (used for all Polling, Configuration, Recovery, Loopback, and Hot_Reset states, and U0 state),
- 0b01: P1, low recovery time latency, power saving state (used for U1 state)
- 0b10: P2, longer recovery time latency, lower power state (used for U2, Rx.Detect and SS.Inactive states)

Copyright © 2015–2017, Texas Instruments Incorporated

- 0b11: P2, lowest power state (used for SS.disabled and U3)

The USB3_PHY transitions from P0-active mode to low-power P1, or either of the two P2 states, is synchronized with USB1 transitions from U0 active state to U1, U2, and U3 low-power states through the input PIPE_POWERDOWN[1:0]. The PIPE port low-power behavior is configured from various bit fields inside the USB1.USB_GUSB3PIPECTL register. For more information on PIPE port low-power (LP) configuration, see , *USB Register Description* in Section 24.7, *SuperSpeed USB DRD*.

26.2.4.2.3.3 Clock Gating

The USB3_PHY component high-speed clocks, PLL_CLK and PIPE_PCLK, are gated during the P1 low-power state.

26.2.4.2.4 USB3_PHY Hardware Requests

An asynchronous wake-up request is generated to the PRCM module by the USB3_PHY_RX I/Os (RXP, RXN). When the wake-up request is acknowledged, the DPLL_USB_OTG_SS and PIPE_PCLK are restarted.

Neither interrupt nor DMA requests are generated.

26.2.4.3 USB3_PHY Clock Generator Subsystem Functional Description

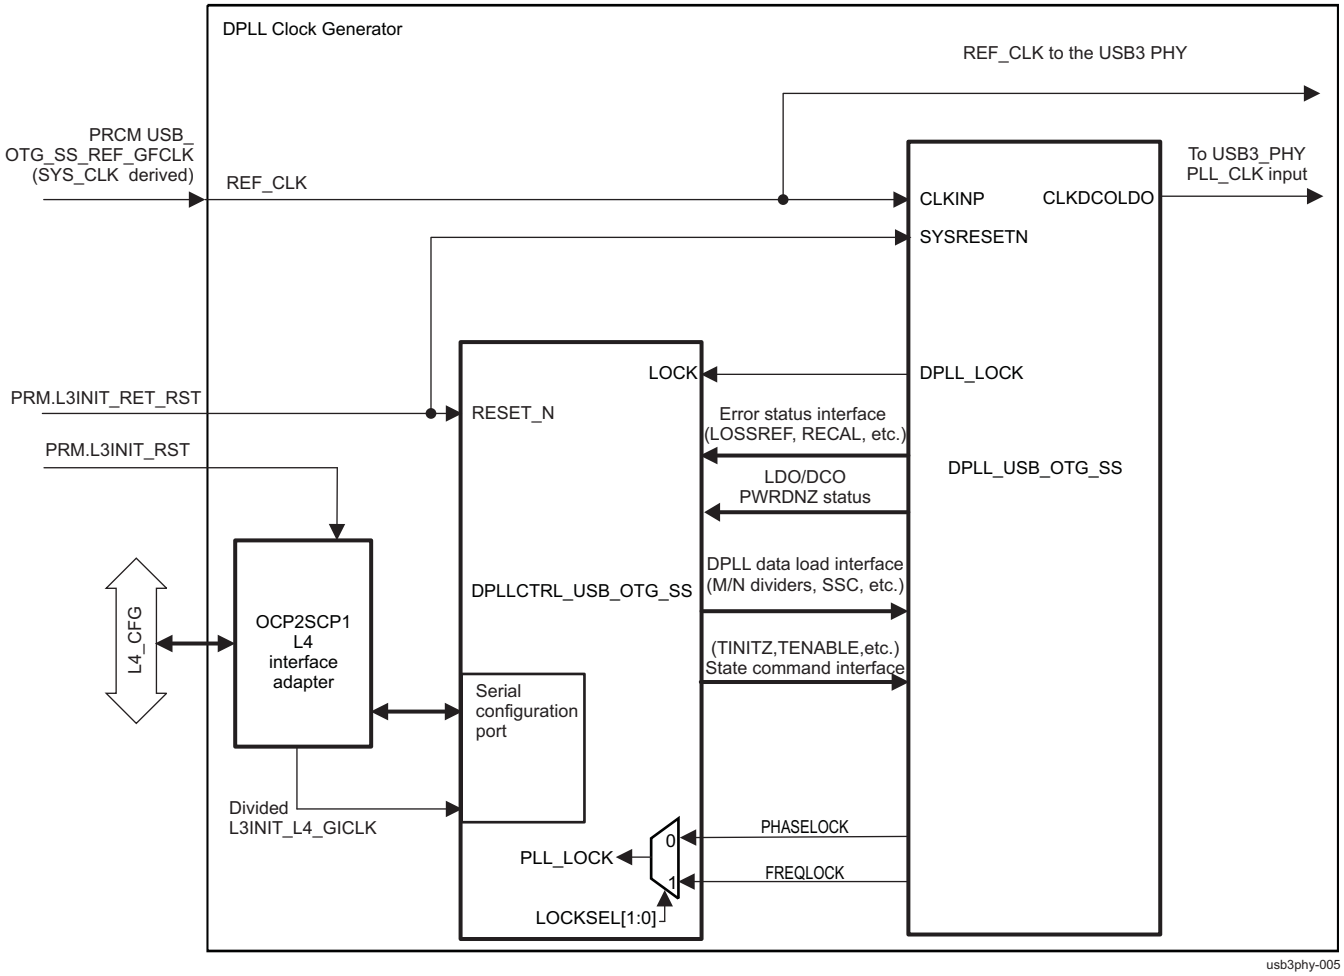
The DPLL_USB_OTG_SS, which is located outside the PRCM boundaries and is part of the USB1 controller subsystem, directly injects a high-speed clock into the USB3_PHY serializer/deserializer input, PLL_CLK. The DPLL generator is controlled through a programmable interface from a dedicated PLL controller, DPLLCTRL_USB_OTG_SS.

26.2.4.3.1 USB3_PHY DPLL Clock Generator Overview

The SCP interface of the USB3_PHY PLL controller (DPLLCTRL_USB_OTG_SS instance) is used to set the configuration of the DPLL modules, primarily the various counter values. Figure 26-11 is an overview of the DPLL clock generator embedded into the USB1 controller subsystem.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 26-11. USB3_PHY DPLL Clock Generator Overview



The DPLL_USB_OTG_SS features:

- A programmable 8-bit input divider: N
- A programmable 12-bit integer, 18-bit fractional loop multiplier: M
- Digital control and loop filter
- Internal oscillator output clock on internal LDO domain (CLKDCOLDO output)
- DPLL output clock SSC (spread spectrum clocking) support
- No retention capabilities
- No Idle-bypass fast relock capabilities
- Idle-bypass low-power mode
- M/N bypass mode
- Relock from standby

The DPLLCTRL_USB_OTG_SS components features:

- DPLL error and status notification
- DPLL initialization and configuration
- DPLL lock criteria selectable between frequency and phase lock
- Idle command implementation
- No software reset implementation
- Automatic enable/disable control, synchronized with USB1 controller PIPE port commands to set

Copyright © 2015–2017, Texas Instruments Incorporated

USB3_PHY to P1, P2, and P3 low-power states

26.2.4.3.2 USB3_PHY DPLL Clock Generator Reset

The USB3_PHY PLL controller and USB3_PHY DPLL clock generator share a common hardware nonretention reset, L3INIT_RST, which comes from the device power and reset manager. Upon DPLL_USB_OTG_SS hardware reset completion, the DPLLCTRL_USB_OTG_SS.PLL_STATUS[0] PLLCTRL_RESET_DONE bit is automatically updated to 1. For more information on the hardware reset source, see Section 3.5.5, *Reset Domains* in Chapter 3, *Power, Reset, and Clock Management*.

The DPLLCTRL_USB_OTG_SS itself has no software reset capabilities.

DPLLCTRL_USB_OTG_SS performs a software reset sequence on the DPLL_USB_OTG_SS in hardware (through the TINITZ signal activation).

26.2.4.3.3 USB3_PHY DPLL Low-Power Modes

The power-management port (PMP) is not integrated for DPLLCTRL_USB_OTG_SS. The DPLL_USB_OTG_SS has no retention capabilities. This means, the DPLL digital power supply remains switched on during all modes of operation.

The low-power modes supported by DPLL_USB_OTG_SS are Idle-bypass low-power and MN-bypass modes, which are both characterized by:

- Internal LDO switched off
- DCO oscillator switched off
- CLKDCOLDO output pulled low

For more details on the PLL settings and conditions necessary to enter Idle-bypass and MN-bypass low-power modes, see Section 26.2.4.3.6.4, *USB3_PHY DPLL Idle-bypass low-power Mode* , and Section 26.2.4.3.6.5, *USB3_PHY DPLL MN-Bypass Mode*.

DPLL_USB_OTG_SS is held in a similar low-power state (DCO and LDO switched off, with CLKDCOLDO = 0) after Power-up Reset, before first PLL_GO command has been software triggered on the PLL controller. See Section 26.2.4.3.6.1, *USB3_PHY Clock Generator Power Up*.

26.2.4.3.4 USB3_PHY DPLL Clocks Configuration

26.2.4.3.4.1 USB3_PHY DPLL Input Clock Control

The DPLL_USB_OTG_SS accepts the functional clock, USB_OTG_SS_REF_CLK, on its CLKINP pin (REF_CLK input at USB3_PHY subsystem level) directly from the device PRCM, without involving any DPLLCTRL_USB_OTG_SS interactions. The USB_OTG_SS_REF_CLK is derived from SYS_CLK1. See Section 3.6.4.1.4, *Clock Domain Module Attributes* in Chapter 3, *Power, Reset, and Clock Management*.

If the CLKINP signal is lost for some time, the LOSSREF output signal, which serves as a feedback to DPLLCTRL_USB_OTG_SS, is asserted high. When CLKINP resumes, LOSSREF goes low (LOSSREF inactive state). The LOSSREF status signal can be software-monitored in the DPLLCTRL_USB_OTG_SS.PLL_STATUS[3] PLL_LOSSREF bit.

NOTE: DPLLCTRL_USB_OTG_SS has no software or hardware mechanisms to control DPLL_USB_OTG_SS input clock (CLKINP).

Copyright © 2015–2017, Texas Instruments Incorporated

26.2.4.3.4.2 USB3_PHY DPLL Output Clock Configuration

Only the DPLL_USB_OTG_SS output, CLKDCOLDO, is used to provide the high-speed clock at the PLL_CLK pin of the USB3_PHY. Only the REGM, REGN, and SD divider values are used within the DPLL clock generator subsystem to adjust the CLKDCOLDO output clock frequency. This is done through programming the DPLLCTRL_USB_OTG_SS.DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[20:9], PLL_REGM, DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[8:1], PLL_REGN, and DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION3[17:10] PLL_SD bit fields, respectively. The USB3_PHY DPLL CLKOUT and CLKOUTLDO outputs are not used, and internal REGM2 and REGM1 dividers are not software controllable.

NOTE: At DPLL/DPLLCTRL integration level the PLL_REGM1[3:0] and PLL_REGM2[6:0] divider control signals are hardware tie-off to 0x0 and 0x1, respectively.

For more details on output clock settings sequence, see Section 26.2.4.3.7.2, *USB3_PHY DPLL Clock Programming Sequence*.

26.2.4.3.4.2.1 USB3_PHY DPLL Output Clock Gating

There is no direct software gate control for the DPLL_USB_OTG_SS.CLKDCOLDO output.

DPLL_USB_OTG_SS.CLKDCOLDO clock output is automatically gated (CLKDCOLDO pulled low) in the following scenarios:

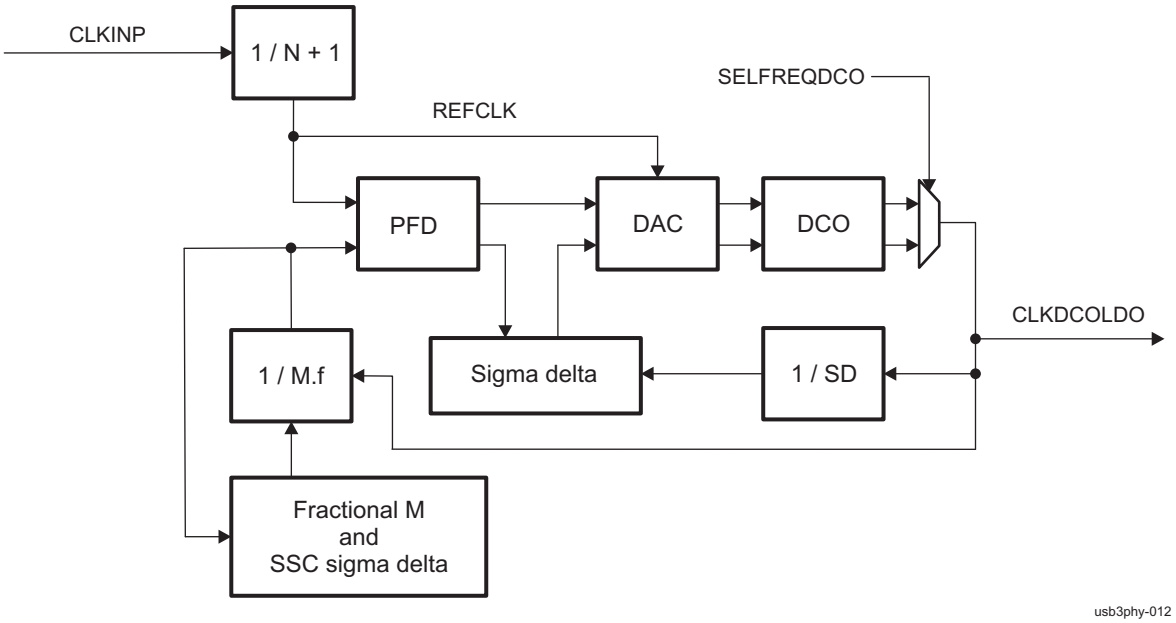
- DPLL power-up sequence. For more information on power-up sequence, see Section 26.2.4.3.6.1, *USB3_PHY Clock Generator Power Up*.
- DPLL entering a relock sequence. For more information on relocking sequence, see Section 26.2.4.3.6.2, *USB3_PHY DPLL Sequences*.
- DPLL entering Idle-bypass low-power mode. For more information on idle-bypass mode, see Section 26.2.4.3.6.4, *USB3_PHY DPLL Idle-Bypass Mode*.
- DPLL entering MN-bypass mode. For more information on MN-bypass mode, see Section 26.2.4.3.6.5, *USB3_PHY DPLL MN-Bypass Mode*.

26.2.4.3.5 USB3_PHY DPLL Subsystem Architecture

Figure 26-12 is a simplified block diagram of the DPLL_USB_OTG_SS instance integration in the USB3_PHY clock generator subsystem.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 26-12. DPLL_USB_OTG_SS Functional Block Diagram



The input clock CLKINP goes to a predivider N + 1. The entire loop runs on the REFCLK clock after this predivider. The value of N + 1 is controlled through the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[8:1] PLL_REGN bit field.

The frequency ranges for the DPLL_USB_OTG_SS input clock - CLKINP and the DPLL internal reference clock, REFCLK = CLKINP/N + 1 are:

- 0.62 to 60 MHz for CLKINP
- 0.62 to 2.5 MHz for the REFCLK

The output clock CLKDCOLDO is synthesized by digitally controlled oscillator (the DCO block), that automatically detects the frequency range. The CLKDCOLDO frequency can be given with CLKDCOLDO = CLKINP×M/(N + 1). For that purpose the feedback multiplier M must be configured through the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[20:9] PLL_REGM bit field.

The DPLL_USB_OTG_SS module supports fractional synthesis (that is, the frequency multiplication factor M can be programmed as fractional). This is achieved by having a sigma delta feedback divider (M). A fractional value (Fractional M) of 18 bits is supported, thus enabling control for a better accuracy. Programming the 18-bit Fractional M value is done by setting the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION4[17:0] PLL_REGM_F bit field (similar to REGM). To enable integer only division, Fractional M should be set to 000…0.

NOTE: Fractional synthesis is not supported for M > 4093.

The module also supports SSC on its output clocks. SSC is used to spread the spectral peaking of the clock to reduce any electromagnetic interference (EMI). When SSC is enabled, the clock spectrum is spread by the amount of frequency spread, and the attenuation is given by the ratio of the frequency spread (df) and the modulation frequency (fm); that is, {10×log10(df/fm)} dB.

The SSC is performed by changing the feedback divider (M) in a triangular pattern, which means the frequency of the output clock varies in a triangular pattern. The frequency of the triangular pattern is modulation frequency (fm). The peak (dM) or the amplitude of the triangular pattern as a percent of M is equal to the percent of the frequency spread (df); that is, $dM/M = df/F_{OUT}$.

Because this is in-band modulation for the DPLL_USB_OTG_SS, the modulation frequency must be within the loop bandwidth of the DPLL. A higher modulation frequency would result in less spreading in the output clock.

Copyright © 2015–2017, Texas Instruments Incorporated

The SSC can be enabled and disabled by asserting the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION1[0] EN_SSC bit. The acknowledge signal SSCACK, observed by the DPLLCTRL_USB_OTG_SS.PLL_STATUS[12] SSC_EN_ACK bit, notifies the exact start and end of SSC. When EN_SSC is deasserted, SSC is disabled only after completion of one full cycle of the triangular pattern given by the modulation frequency. This is done to maintain the average frequency.

The modulation frequency (fm) can be programmed as a ratio of REFCLK/4; that is, the value programmed in the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[29:20] MODFREQDIVIDER bit field must be = REFCLK/(4×fm).The ModFreqDivider is split into Mantissa and 2 $^{\text{Exponent}}$ (ModFreqDivider = ModFreqDividerMantissa × 2 $^{\text{ModFreqDividerExponent}}$).

- The Mantissa is controlled by bits [29:23] of the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[29:20] MODFREQDIVIDER bit field.
- The Exponent is controlled by bits [22:20] of the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[29:20] MODFREQDIVIDER bit field.

Although the same value of ModFreqDivider could be obtained by different combinations of Mantissa and Exponent values, it is preferred to get the target ModFreqDivider by programming maximum Mantissa and minimum Exponent values.

To define the frequency spread (df), dM must be controlled as previously explained. To define dM, the step size of M for each REFCLK during the triangular pattern must be programmed.This is defined as follows:

- dM =(2 $^{\text{ModFreqDividerExponent}}$) × ModFreqDividerMantissa × DeltaMStep, if ModFreqDividerExponent <= 3
- dM = 8 × ModFreqDividerMantissa × DeltaMStep, if ModFreqDividerExponent > 3

DeltaMStep value is split into integer part and fractional part, as follows:

- The MSB of 3-bit integer part, DeltaMStepInteger, is controlled by the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[30] DELTAM2 bit and the remaining LSBs by bits [19:18] of the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[19:0] DELTAM bit field.
- The 18-bit fractional part, DeltaMStepFraction, is controlled by bits [17:0] of the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION2[19:0] DELTAM bit field.

If the DPLLCTRL_USB_OTG_SS.PLL_SSC_CONFIGURATION1[2] DOWNSPREAD bit is set to 1, the frequency spread on the lower side is twice the programmed value. The frequency spread on the higher side is 0 (except for 20 percent overshot).

26.2.4.3.6 USB3_PHY DPLL Clock Generator Modes and State Transitions

The DPLL_USB_OTG_SS can be set in different modes during operation. DPLLCTRL triggers DPLL_USB_OTG_SS state transitions to different static modes by means of the TINITZ and TENABLE hardware control signals.

26.2.4.3.6.1 USB3_PHY Clock Generator Power Up

After power up, the DPLL_USB_OTG_SS.SYSRESETN input is automatically pulled low by the PRM, together with the DPLLCTRL_USB_OTG_SS.RESET_N input. Because PRM.L3INIT_RST is an asynchronous reset, the DPLL_USB_OTG_SS input clock (DPLL_USB_OTG_SS.CLKINP) is not demanded upon reset. The LOSSREF signal, which monitors the presence of CLKINP clock, remains 1 during SYSRESETN = 0 irrespective of presence/absence of the CLKINP clock. If CLKINP is present when reset is asserted, the LOSSREF signal is deasserted to 0, a certain time after the hardware reset completes. During DPLL power-up mode, CLKDCOLDO clock is maintained inactive (pulled low). After power-up reset, the DPLL_LOCK (internal lock loop) signal is maintained deasserted, too.

26.2.4.3.6.2 USB3_PHY DPLL Sequences

Once all the configuration values have been initially programmed into the DPLLCTRL_USB_OTG_SS registers (see Section 26.2.4.3.7.2) , the DPLLCTRL_USB_OTG_SS.PLL_GO[0] PLL_GO bit should be set to update the configuration values and start the DPLL calibration and locking sequence.

Copyright © 2015–2017, Texas Instruments Incorporated

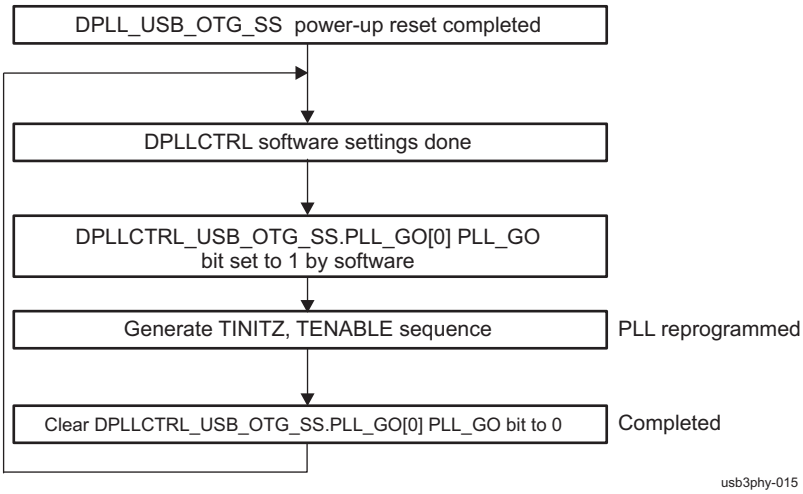
After the DPLLCTRL_USB_OTG_SS.PLL_GO[0] PLL_GO bit is set high in software, the DPLLCTRL_USB_OTG_SS state-machine takes the following action:

1. Sets the TINITZ signal to 0, which acts as a soft reset to DPLL_USB_OTG_SS. This starts the DPLL initialization procedure. During initialization mode, the CLKDCOLDO, FREQLOCK, and PHASELOCK signals are kept at 0 and the BYPASSACK signal is kept at 1.
   VDDA power supply of DPLL should be active before DPLL_USB_OTG_SS Initialization is performed, but it is not required to be switched on immediately after device power up.
2. The TENABLE signal is asserted high by DPLLCTRL hardware to load the user-programmed values of REGM, REGN, REGSD, and SELFREQDCO into DPLL registers.
3. After TENABLE is asserted, TINITZ is driven high (disabled) by the DPLLCTRL to trigger a DPLL calibration and lock sequence after the loop control values are loaded. The module calibration-lock sequence will begin from the first CLKINP edge after TINITZ is disabled.

Figure 26-13 summarizes the software and hardware sequences flow of DPLL_USB_OTG_SS.

NOTE: All thick-outlined blocks show operations performed by software. Other blocks show operations performed by hardware.

Figure 26-13. USB3_PHY PLL GO Sequence



DPLL_USB_OTG_SS relock sequence:

When the DPLL leaves a lost clock condition (LOSSREF = 1 → 0) or idle-bypass mode it enters relock sequence from the first CLKINP edge (after bypass mode leaving). Relock sequence is the same as calibration-lock sequence already described.

A DPLL relock sequence is also software triggered by setting the DPLLCTRL_USB_OTG_SS.PLL_GO[0] PLL_GO bit to 0b1 for DPLL parameters update.

When DPLL_USB_OTG_SS enters a relock sequence, CLKDCOLDO is pulled low. FREQLOCK and PHASELOCK status signals are also low. CLKDCOLDO output clock is activated after the FREQLOCK or PHASELOCK signal goes high, depending on the selected locking criteria.

The DPLLCTRL_USB_OTG_SS.PLL_GOUSB3PHY_PLL_GO[0] PLL_GO bit can be used by software to monitor if DPLLCTRL locking process is still pending (PLL_GO = 0b1).

26.2.4.3.6.3 USB3_PHY DPLL Locked Mode

When DPLL_USB_OTG_SS finishes calibration and lock sequences it enters a locked state. During the locked state, LOSSREF and BYPASSACK are deasserted, FREQLOCK or PHASELOCK is asserted.

DPLL lock event criteria (FREQLOCK or PHASELOCK) is software-selectable through the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[10:9] PLL_LOCKSEL bit field.

Copyright © 2015–2017, Texas Instruments Incorporated

The DPLL signalizes the locked state to DPLLCTRL_USB_OTG_SS, USB_OTG_SS core controller, and USB3_PHY through assertion of the DPLL_LOCK signal, which reflects the internal lock loop status. The user software can monitor the DPLL locked event in the DPLLCTRL_USB_OTG_SS.PLL_STATUS[1] PLL_LOCK bit, which is active high.

26.2.4.3.6.4 USB3_PHY DPLL Idle-Bypass Mode

Idle-bypass fast relock mode is not supported for DPLL_USB_OTG_SS.

DPLL_USB_OTG_SS supports idle-bypass low-power mode. A transition from a normal operation to idle-bypass mode is performed when software sets the DPLLCTRL_USB_OTG_SS.DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[0] PLL_IDLE bit to 0x1. IDLE signal assertion triggers a power-down sequence on DPLL internal LDO analog blocks and the DCO oscillator.

In idle-bypass low-power mode, the PHASELOCK and FREQLOCK output signals are asserted low and CLKDCOLDO goes low. Also, the internal reference clock REFCLK = CLKINP/N + 1 is gated inside the DPLL digital control logic to save power.

In the functional mode, the DPLL_USB_OTG_SS.TICOPWDN output indicates to the PLL controller the status of the power-down signal (active high) of the internal DCO oscillator. The internal DCO oscillator is powered down in idle-bypass mode or during period from SYSRESETN 0->1 to module initialization. The DCO oscillator exits power-down (TICOPWDN goes low) whenever the module internally tries to lock/relock after initialization or exiting idle-bypass mode.

In the functional mode, DPLL_USB_OTG_SS.LDOPWDN output indicates to the PLL controller the status of the power-down signal (active high) of the internal LDO. LDOPWDN goes high as soon as the internal LDO is powered down. LDOPWDN goes low after the LDO output voltage is stable. The internal LDO is powered down in the period from SYSRESETN 0 → 1 to module initialization or when entering into idle-bypass mode. LDOPWDN is cleared whenever the module internally tries to lock/relock after initialization or exiting idle-bypass mode after the internal LDO output voltage has stabilized.

The DCO and LDO power ON and OFF states are reflected within the read-only DPLLCTRL_USB_OTG_SS.PLL_STATUS[16] PLL_TICOPWDN and DPLLCTRL_USB_OTG_SS.PLL_STATUS[15] LDOPWDN monitor bits.

To exit idle-bypass mode and restore clock generation, the user should write DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[0] PLL_IDLE to 0x0, which deasserts the IDLE signal, and DPLL_USB_OTG_SS automatically enters a relock sequence. CLKDCOLDO output clock is activated after the FREQLOCK or the PHASELOCK signal goes high, depending on selected locking criteria.

26.2.4.3.6.5 USB3_PHY DPLL MN-Bypass Mode

The MN-bypass mode will be activated if REGM = 0 or 1 is loaded into the module on the rising edge of TENABLE. TINITZ also should be pulsed to enter MN-bypass mode. The module enters a low-power mode by gating all its internal clocks (REFCLK) and powering down internal LDO (LDOPWDN = 1) and DCO (DCOPWDN = 1). CLKDCOLDO remains gated (low) during this mode.

NOTE: When the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[20:9] PLL_REGM bit field is updated to 0x0 or 0x1, the CLKDCOLDO is gated.

26.2.4.3.6.6 USB3_PHY DPLL Error Conditions

The PLL lock and recalibration signals can be monitored to detect the loss-of-lock condition and the DPLL requirement to recalibrate (caused by a large temperature change since the last lock request):

- The DPLLCTRL_USB_OTG_SS.PLL_STATUS[2] PLL_RECAL bit informs whether the DPLL_USB_OTG_SS must be recalibrated.

The PLL reference clock (CLKINP) loss status and PLL-in-high-jitter condition can also be monitored:

- The DPLLCTRL_USB_OTG_SS.PLL_STATUS[1] PLL_LOCK bit gives the USB3_PHY PLL lock state.

Copyright © 2015–2017, Texas Instruments Incorporated

- The DPLLCTRL_USB_OTG_SS.PLL_STATUS[3] PLL_LOSSREF bit informs whether the DPLLCTRL_USB_OTG_SS has lost the reference clock.
- The DPLLCTRL_USB_OTG_SS.PLL_STATUS[5] PLL_HIGHJITTER bit informs whether the PLL has entered a high-jitter condition.

26.2.4.3.7 USB3_PHY PLL Controller Functions

26.2.4.3.7.1 USB3_PHY PLL Controller Register Access

The configuration registers are accessed through the OCP2SCP1 L4 adapter register space using the SCP interface of the DPLLCTRL_USB_OTG_SS. This includes all the configuration signals and returning status signals.

CAUTION

All writes must be 32-bit operations, because the SCP interface always transfers 32 bits; 16- or 8-bit operations may lead to unpredictable errors.

NOTE: Because the USB3_PHY directly provides parallel data interface clocks RX_CLK and TX_CLK to the USB1 MAC controller, the DPLLCTRL_USB_OTG_SS and DPLL_USB_OTG_SS must be configured before any data transfer between the USB1 controller MAC layer and an external USB3 device.

26.2.4.3.7.2 USB3_PHY DPLL Clock Programming Sequence

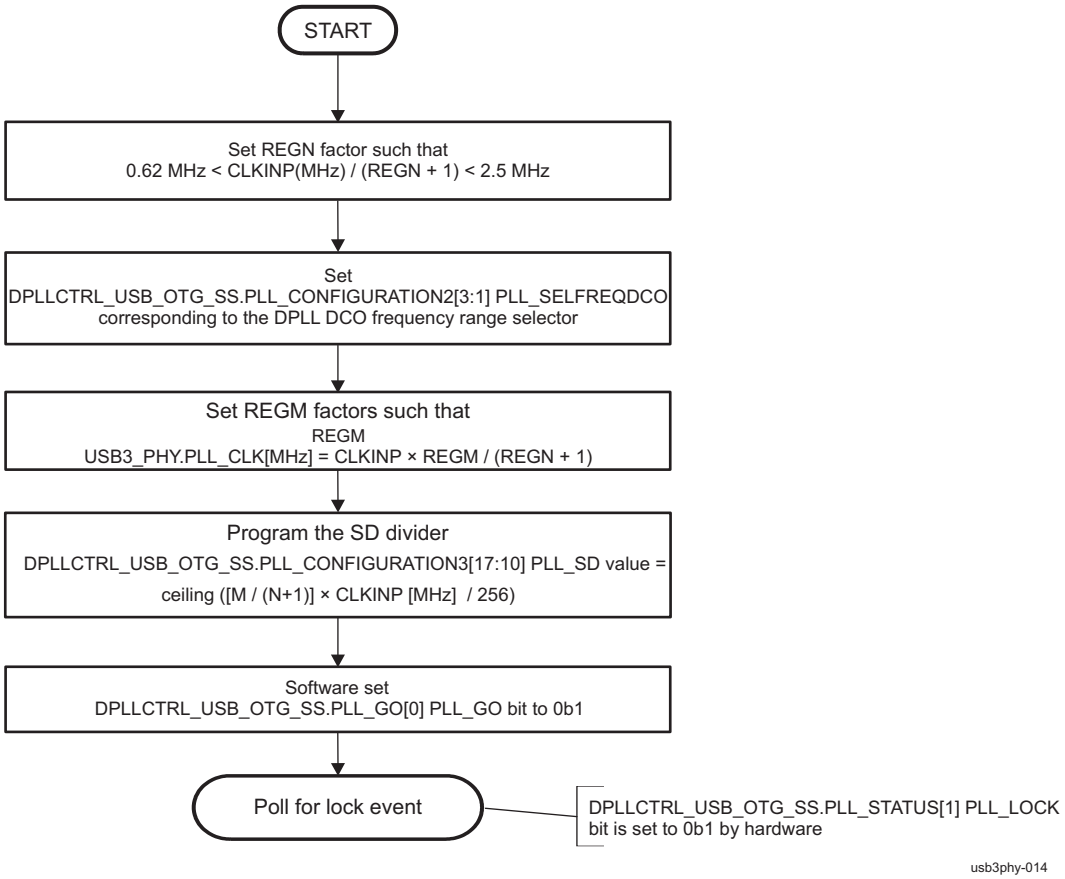
The DPLL_USB_OTG_SS factors must be calculated based on the required input and output frequencies, keeping the PLL internal reference frequency (REFCLK) in the appropriate range (0.62 to 2.5 MHz).

- REGM factor is programmed in the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[20:9] PLL_REGM bit field.
- Fractional part of REGM factor is programmed in the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION4[17:0] PLL_REGM_F bit field.
- REGN factor is programmed in the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[8:1] PLL_REGN bit field.
- DCO frequency range is set in the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[3:1] PLL_SELFREQDCO bit field.
  - PLL_SELFREQDCO should be set to 0x2 if 500 MHz < CLKDCOLDO [MHz] < 1000 MHz.
  - PLL_SELFREQDCO should be set to 0x4 if 1000 MHz < CLKDCOLDO [MHz] < 2000 MHz.
- SD divider is programmed in the DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION3[17:10] PLL_SD bit field. The DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[3:1] PLL_SELFREQDCO register bit field should be programmed depending on the value of CLKDCOLDO = CLKINP × M/(N + 1).

Figure 26-14 shows the formulae and programming sequence.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 26-14. USB3_PHY PLL Programming Sequence



NOTE:

- The equation for USB3_PHY_TX/USB3_PHY_RX (MHz) applies to the CLKDCOLDO of the DPLL_USB_OTG_SS.
- CLKDCOLDO output frequency of the DPLL_USB_OTG_SS should be programmed to 2.5 GHz, for the super-speed USB (5 Gbps) mode.

Table 26-14 summarizes the registers for the DPLLCTRL_USB_OTG_SS programming sequence.

Table 26-14. Register Call Summary for USB3_PHY PLL Programming Sequence

Register Name	Register Name	Register Name	Register Name
DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2	DPLLCTRL_USB_OTG_SS.PLL_GO	DPLLCTRL_USB_OTG_SS.PLL_STATUS	DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION3

26.2.4.3.7.3 USB3_PHY DPLL Recommended Values

Table 26-15 lists the DPLL_USB_OTG_SS recommended values.

Table 26-15. Recommended Programming Values

Field Name	Value	Description
DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[20:9] PLL_REGM	See (1).	Feedback clock divider
DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION1[8:1] PLL_REGN	See (1).	Reference clock divider

(1) The value of the bit field must be set according to the desired clock frequency.

Copyright © 2015–2017, Texas Instruments Incorporated

Table 26-15. Recommended Programming Values (continued)

Field Name	Value	Description
DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[10:9] PLL_LOCKSEL	0x-	Criteria to lock the PLL
DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[3:1] PLL_SELFREQDCO	See (1).	Program based on the PLL choice and lock frequency.
DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION2[0] PLL_IDLE	0	PLL active
DPLLCTRL_USB_OTG_SS.PLL_CONFIGURATION3[17:10] PLL_SD	See (1).	Ceiling { [PLL_REGM/(PLL_REGN+1)] × CLKINP(MHz)/256 }
DPLLCTRL_USB_OTG_SS.PLL_GO[0] PLL_GO	0x1	Write 1 when PLL is to be (re)locked with new parameters. This bit is cleared by hardware when the PLL request completes.

26.2.5 USB3_PHY Subsystem Low-Level Programming Model

The low-level programming sequence to set up the USB3_PHY subsystem for USB superspeed I/O operations is summarized in the Table 26-16

Table 26-16. USB3_PHY Subsystem Low-Level Programming Sequence

Step	Description	Comment
1.	Set the startup low performance OPP in the appropriate PRCM registers.	For more information regarding demanded OPP, see the device *Data Manual*.
2.	Enable the PRCM.USB_OTG_SS_REF_CLK.	See Section 3.6.4.1.4, *Clock Domain Module Attributes*, in Chapter 3, *Power, Reset, and Clock Management*.
3.	Enable the PRCM.L3INIT_L4_GICLK to enable the OCP2SCP1 interface adapter operation.	See Section 3.6.4.1.4, *Clock Domain Module Attributes*, in Chapter 3, *Power, Reset, and Clock Management*.
4.	Software reset the OCP2SCP1 and poll until soft reset completion is indicated in status.	See Section 26.2.4.1.
5.	Set up division ratio between the OCP clock (PRCM.L3INIT_L4_GICLK) and SCP clock to supply the serial configuration register domains of the DPLLCTRL_USB_OTG_SS .	See Section 26.2.4.1.
6.	Set up necessary SYNC1 and SYNC2 timings to ensure no blocking of transactions over the SCP bus.	See Section 26.2.4.1. After this step, the user is ready to access the DPLLCTRL_USB_OTG_SS registers.
7.	Configure DPLL_USB_OTG_SS to generate frequency (CLKDCOLDO) = 2.5 GHz.	See Section 26.2.4.3.7.2.
8.	Software-assert the DPLLCTRL_USB_OTG_SS.PLL_GO[0] PLL_GO bit to 0x1	Start the DPLL lock with desired parameters.
9.	Poll the DPLLCTRL_USB_OTG_SS.PLL_STATUS[1] PLL_LOCK bit until it reads 1.	DPLL locked event
10.	Perform a USB3_PHY tuning required for the Super-Speed OTG USB i/f operation	Follow steps described in Table 26-17, *USB3_PHY Tuning Table*.
11.	Set USBOTGSS_GUSB3PIPECTL[31] PHYSOFTRST to 0x1	Software reset the USB3_PHY over USB OTG SS controller PIPE port. Note that this reset does not impact settings made in step 10.
12.	Software-trigger the USB3_PHY_TX power-up sequence.	For more details, see Section 26.2.4.2.3.1.
13.	Software-trigger the USB3_PHY_RX power-up sequence.	For more details, see Section 26.2.4.2.3.1.
14.	Clear USBOTGSS_GUSB3PIPECTL[31] PHYSOFTRST to 0x0	Deassert the software reset bit after power-up sequence completion is indicated

Description	This register contains control bits which affect different circuits in digital section of the PHY.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MEM_INV_RXPN_PAIR	MEM_OVRD_INV_RXPN_PAIR	RESERVED	MEM_HS_RATE		MEM_OVRD_HS_RATE	RESERVED		MEM_CDR_FASTLOCK		MEM_CDR_LBW		MEM_CDR_STEPCNT		MEM_CDR_STL		MEM_CDR_THR			MEM_CDR_THR_MODE	MEM_CDR_2NDO_SDM_MODE	RESERVED										

Bits	Field Name	Description	Type	Reset
31	MEM_INV_RXPN_PAIR	If '1', interchanges RXP and RXN effectively by inverting the received data samples.	RW	0
30	MEM_OVRD_INV_RXPN_PAIR	Pin override control. See register bit MEM_INV_RXPN_PAIR.	RW	0

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
29	RESERVED		R	0
28:27	MEM_HS_RATE	Determines the ratio of PLL_CLK (after the bypassing by MEM_EN_PLLBYP and the division by MEM_PLLDIV) frequency and the output data rate. Full Rate means PLL_CLK (after the bypassing by MEM_EN_PLLBYP and the division by MEM_PLLDIV) frequency = Data Rate/2 00=Full Rate 01=Half Rate 10=Quarter Rate 11=RESERVED. This takes effect only if register bit MEM_OVRD_HS_RATE is '1', else the same is controlled by input pins hs_rate.	RW	0x0
26	MEM_OVRD_HS_RATE	Pin override control. See register bit MEM_HS_RATE.	RW	0
25:24	RESERVED		R	0x2
23	MEM_CDR_FASTLOCK	'1' to reduce lock time of CDR (clock-data-recovery circuit).	RW	1
22:21	MEM_CDR_LBW	CDR band-width control.	RW	0x3
20:19	MEM_CDR_STEPCNT	CDR 2nd order setting.	RW	0x0
18:16	MEM_CDR_STL	CDR settling time. Determines the number of vote clocks to blank ELV (Early-Late-Voter circuit) after update of phase.	RW	0x3
15:13	MEM_CDR_THR	CDR 1st order threshold. Determines how much early/late votes should differ by before a phase change in the receiver sampling clock is triggered.	RW	0x1
12	MEM_CDR_THR_MODE	CDR 1st order threshold.	RW	1
11	MEM_CDR_2NDO_SDM_MODE	If '1', the 2nd Order CDR block uses a 1st order Sigma Delta Modulator to accomplish frequency offset If '0', a simple rate transformer is used for the same purpose.	RW	0
10:0	RESERVED		R	0x000

Table 26-28. USB3PHYRX_EQUALIZER_REG1

Address Offset	0x0000 0038		
Physical Address	0x4A08 4438	**Instance**	USB3_PHY_RX
Description	The IP has an Equalizer (with analog and digital parts) which addresses Inter Symbol Interference (ISI). This register is for its controllability. The equalizer can be configured via the EQCTL bits which are part of the SCP register. The options are: No adaptive equalisation. The equalizer provides a flat response at the maximum gain. This setting may be appropriate if jitter at the receiver occurs predominantly as a result of crosstalk rather than frequency dependent loss. Fully adaptive equalisation. Both the low frequency gain and zero position of the equalizer are determined algorithmically by analysing the data patterns and transition positions in the received data. This setting should be used for most applications. Partially adaptive equalisation. The low frequency gain of the equalizer is determined algorithmically by analysing the data patterns and transition positions in the received data. The zero position is fixed in one of eight zero positions. When enabled, the receiver equalization logic analyzes data patterns and transition times to determine whether the low frequency gain of the equalizer should be increased or decreased. For the fully adaptive setting (EQCTL = 0001), if the low frequency gain reaches the minimum value, the zero frequency is then reduced. Likewise, if it reaches the maximum value, the zero frequency is then increased.

26.4 PCIe PHY Subsystem

This chapter describes the features and functions of the device Peripheral Component Interconnect Express (PCIe) physical layer (PHY) subsystem.

26.4.1 PCIe PHY Subsystem Overview

The device has two PCI Express physical ports - PCIe 0 and USB (shared). Each of the two device PCIe ports has an associated PMA (physical media attachment) component pair of a high-speed operating differential transmitter (serializer) and a differential receiver (de-serializer). While the device PCIe port 0 PHY is always mapped to device PCIe_SS1 controller, the device PCIe port 1 PHY can be software multiplexed to the PCIe_SS1 (dual-lane configuration) or to the PCIe_SS2 (single-lane configuration) or to USB3.0. In addition, the PCIe shared PHY subsystem encompasses a PCIe PCS (physical coding sublayer), a PCIe power management logic, APLL, a DPLL reference clock generator and an APLL low-jitter clock buffer.

- PCIe PCS (a physical coding sublayer component) converts an 8-bit portion of parallel data over a PCIe lane to a 10-bit parallel data to adapt the process of serialization and deserialization in the TX/RX PHYs to various requirements. At the same time it transforms the transmission rate to maintain the PCIe Gen2 bandwidth. A PCS component is hardware mapped to each of the PCIe_SS1 (16-bit) and PCIe_SS2 controller (32-bit) PIPE ports.
- A programmable multiplexing logic which maps either PCIe_SS1 or PCIe_SS2 PCS logic to USB3.0 PHY
- PHY serializer (TX) and deserializer (RX) components with associated power control logic, building the so called PMA (physical media attachment) part.
- DPLL_PCIe_REF is a DPLL clock source, controlled from the device PRCM, that provides (typically 20 MHz/100 MHz) clock to the PCIe PHY serializer/de-serializer components reference clock inputs.
- Contains an integrated APLL (APLLPCIe) which multiplies the DPLL_PCIe_REF clock to 2.5 GHz.
- The APLLPCIe low-jitter buffer and additional logic takes care to provide the PCIe APLL reference input clock.
- An L4_CFG interface adapter - OCP2SCP3 enables accessing the PCIe PHY serial configuration protocol compatible (SCP) registers via L4_CFG interconnect accesses.

Figure 26-15 shows an overview of the device PCIe subsystem with its integrated components.

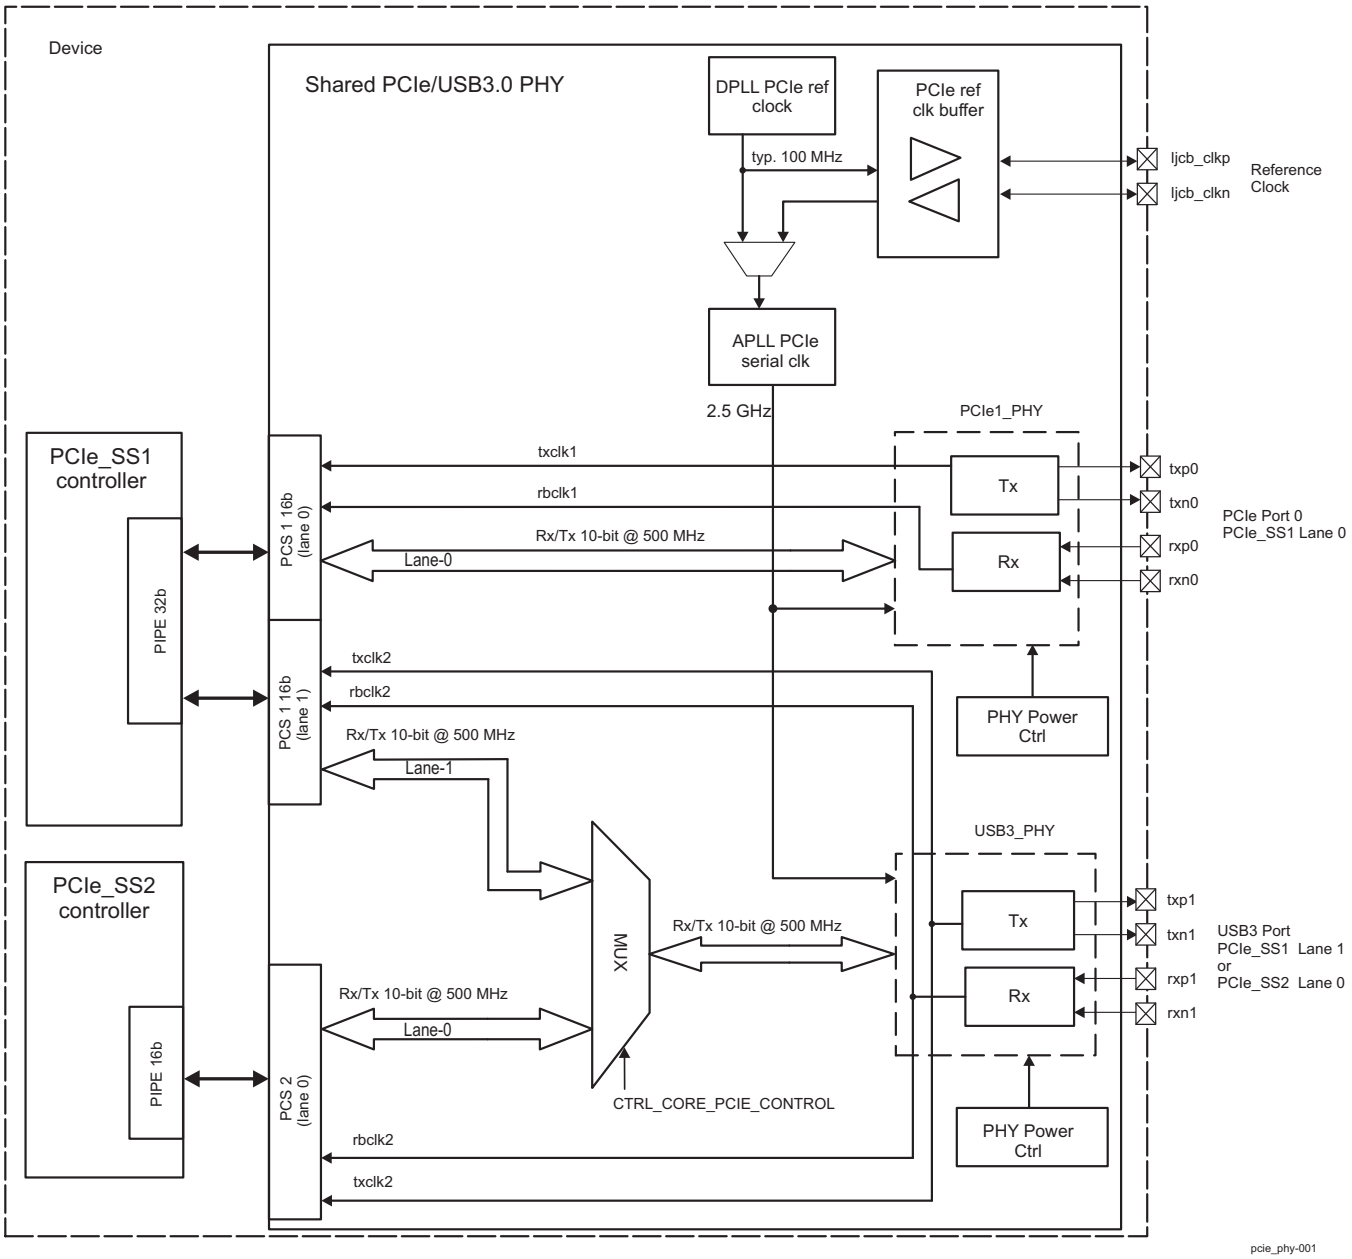
Figure 26-15. PCIe Controller Subsystem Overview



26.4.1.1 PCIe PHY Subsystem Key Features

This section describes the features supplied by the PCIe PHY subsystem. The device integrated PCIe PHY comply with the following standard:

- *PHY Interface for PCI Express Gen 2 and USB3.0 architectures (PIPE for USB3)*

The device supports PCI express interface in the following configurations:

- The PCIe PHYs can be mapped either as 2-lane to one controller (PCIe_SS1) or two separate lanes to two controllers (PCIe_SS1 and PCIe_SS2), as follows:
  - One 2x-lane functional (Gen2) PCIe port, built on the device two PCIe PHY ports (0 and 1), using the dual-lane PCIe_SS1 controller (the PCIe_SS1 controller)
  - Two 1x-lane (Gen2) PCIe ports - PCIe port 0 and USB, mapped to the PCIe_SS1 and PCIe_SS2 controllers, each configured to operate in a single-lane mode, respectively. In this case the two

Copyright © 2015–2017, Texas Instruments Incorporated

device PCIe PHY ports function independently from each other.

- A power control module for each PCIe port which:
  - ensures the Rx/Tx PHYs power-up sequence
  - ensures the Rx/Tx PHYs power-down sequence
- Embedded PCIe DPLL generator, software controlled in device PRCM
- A PLL reference clock - (typically 20MHz or 100MHz), which can be programmed to be:
  - an externally supplied differential clock
  - internally supplied by DPLL_PCIE_REF generated clock, controlled from device PRCM
  - output to external systems when supplied by the DPLL_PCIE_REF
- A bidirectional low-jitter asynchronous buffer which:
  - is used to supply an external reference clock to the PCIe APLL.
  - can output DPLL_PCIE_REF clock to external chips
  - can be bypassed, when DPLL clock is used but NOT output to external chips.
- Polarity inversion on receiver

26.4.2 PCIe PHY Subsystem Environment

26.4.2.1 PCIe PHY I/O Signals

Table 26-54 represents module pins and their corresponding signal names at the device level, and also specifies their links to functions.

Table 26-54. PCIe PHY I/O Signals

Module Pin Name	Device-Level Signal Name	I/O[1]	Description	Pin Reset Value[2]
TXP0	pcie_txp0	O	TXP output of the PCIe Port 0 PHY differential transmission line	0
TXN0	pcie_txn0	O	TXN output of the PCIe Port 0 PHY differential transmission line	0
RXP0	pcie_rxp0	I	RXP input of the PCIe Port 0 PHY differential reception line	HiZ
RXN0	pcie_rxn0	I	RXN input of the PCIe Port 0 PHY differential reception line	HiZ
TXP1	usb_txp0	O	TXP output of the USB3 PHY differential transmission line, used as TXP output of the PCIe Port 1	0
TXN1	usb_txn0	O	TXN output of the USB3 PHY differential transmission line, used as TXN output of the PCIe Port 1	0
RXP1	usb_rxp0	I	RXP input of the USB3 PHY differential reception line, used as RXP output of the PCIe Port 1	HiZ
RXN1	usb_rxn0	I	RXN input of the USB3 PHY differential reception line, used as RXN output of the PCIe Port 1	HiZ
LJCB_CLKP	ljcb_clkp	I/O	Differential input/output of reference clock buffer (positive)	HiZ
LJCB_CLKN	ljcb_clkn	I/O	Differential input/output of reference clock buffer (negative)	HiZ

(1) I = Input, O = Output
(2) HiZ = High-impedance

To swap polarity of the PHY_TX serializer outputs - TXP and TXN such that, TXP becomes the negative and TXN becomes the positive terminal, user software has to assert bit PCIEPHYTX_FUNC_CONFIG_REG[31] MEM_INVPAIR to 0b1.

To swap polarity of the PHY_RX de-serializer inputs - RXP and RXN, such that, RXP becomes the negative and RXN becomes the positive terminal, user software has to:

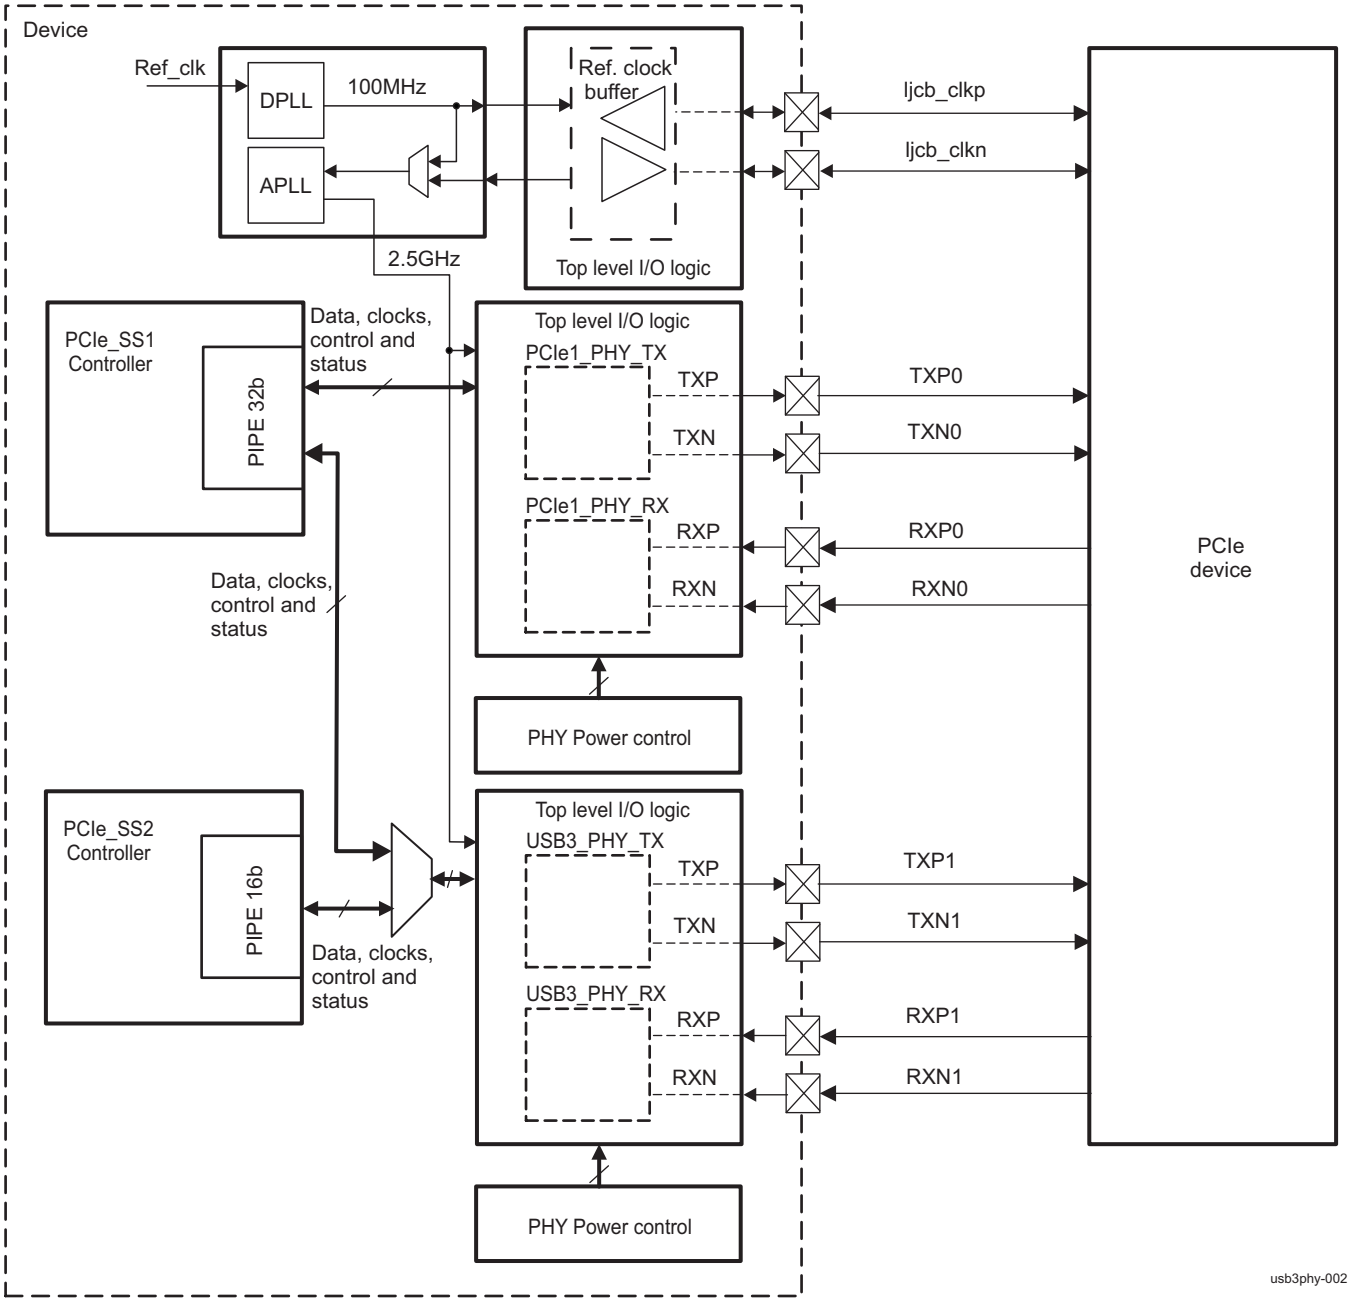
- First assert the bit PCIEPHYRX_DIGITAL_MODES_REG1[30] MEM_OVRD_INV_RXPN_PAIR to 0b1, in order to be able to override the internal HW polarity control of the de-serializer.
- Assert bit PCIEPHYRX_DIGITAL_MODES_REG1[31] MEM_INV_RXPN_PAIR to 0b1.

For more information on the necessary SCP register access configuration refer to Section 26.4.6, *PCIe PHY Subsystem Register Manual* and Section 26.4.5, *PCIePHY Subsystem Low-Level Programming Model*.

Figure 26-16 shows module pin signals mapping to PCIe PHY signals visible at the device pad level.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 26-16. PCIe PHY I/O Signals



NOTE: The path from module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and can be programmed in the control module registers. For more information, see Section 18.4.6.1.1, *Pad Configuration Rregisters*, and *Section 18.5, Control Module Register Manual*, in Chapter 18, *Control Module*.

Copyright © 2015–2017, Texas Instruments Incorporated

26.4.3 PCIe Shared PHY Subsystem Integration

This section describes the PCIe PHY subsystem-related components (PCIe_PHY, DPLL_PCIE_REF, APLL_PCIE, and OCP2SPC3) integration in the device, including information about clocks, resets, and hardware requests.

Figure 26-17 shows the PCIe PHY integration.

The PCIe PHY module integration features:

- A low-power non retention reset, L3INIT_RST
- A low power non retention Power-on Reset, L3INIT_PWRON_RST
- Interconnect adapter target interface (OCP2SCP3)
- A high-frequency input clock for RX module PCIE_PHY_GCLK, tied to the PCIE_APLL.CLKVCOLDO output
- A high frequency divided input clock for TX module PCIE_PHY_DIV_GCLK, tied to PCIE_APLL.CLKVCOLDO_DIV output
- A local PCIE PHY PIPE compatible port connected to the PCIe_SS1 controller PIPE port
- A clock output (PIPE_PCLK) to the PCIe_SS module PIPE port
- A clock input (PIPE_MCLK) from the PCIe_SS module PIPE port
- A power control logic integrated for PCIe PHY reciever/transmiter pair
- PRCM.PCIE_32K_GFCLK for debounce and wakeup logic inside the PCIe1_PHY_RX
- PRCM.PCIE_REF_GFCLK clock (based on PRCM.CORE_USB_OTG_SS_LFPS_TX_CLK clock) tied to the PCIe1_PHY_TX input
- PRCM.PCIE_SYS_GFCLK clock tied to power control module clock input
- A device CORE CONTROL MODULE command port to the power control module

The DPLL_PCIE_REF integration features:

- A low-power non retention reset, COREAON_PWRON_RST
- A gated version of the device SYS_CLK1 - PCIE_DPLL_CLK supplying DPLL_PCIE_REF.CLKINP pin.
- A single clock output, DPLL_PCIE_REF.CLKOUTLDO, to the APLL_PCIE input multiplexer
- No HS divider integration
- Direct PRCM register control

The APLL_PCIE integration features:

- A low-power non retention reset, COREAON_PWRON_RST
- Direct PRCM register control
- Selectable input clock from DPLL_PCIE_REF.CLKOUTLDO or external differential input clock conducted from device PCIe ljcb_clkp/n pads via the ACSPCIE buffer
- High frequency output clock on APLL_PCIE.CLKVCOLDO output tied to PCIE PHY RX modules
- High frequency divided output clock on APLL_PCIE.CLKVCOLDO_DIV output tied to PCIE PHY TX modules

The ACSPCIE integration features:

- A difirential clock input from the device pads or differential output to device pads supplied from DPLL_PCIE_REF.CLKOUTLDO.
- Single ended clock output to APLL_PCIE input multiplexer

The OCP2SCP3 (interconnect adapter) integration features:

- L4_CFG slave configuration interface
- One interface clock, L3INIT_L4_GICLK
- A nonretention reset, L3INIT_RST

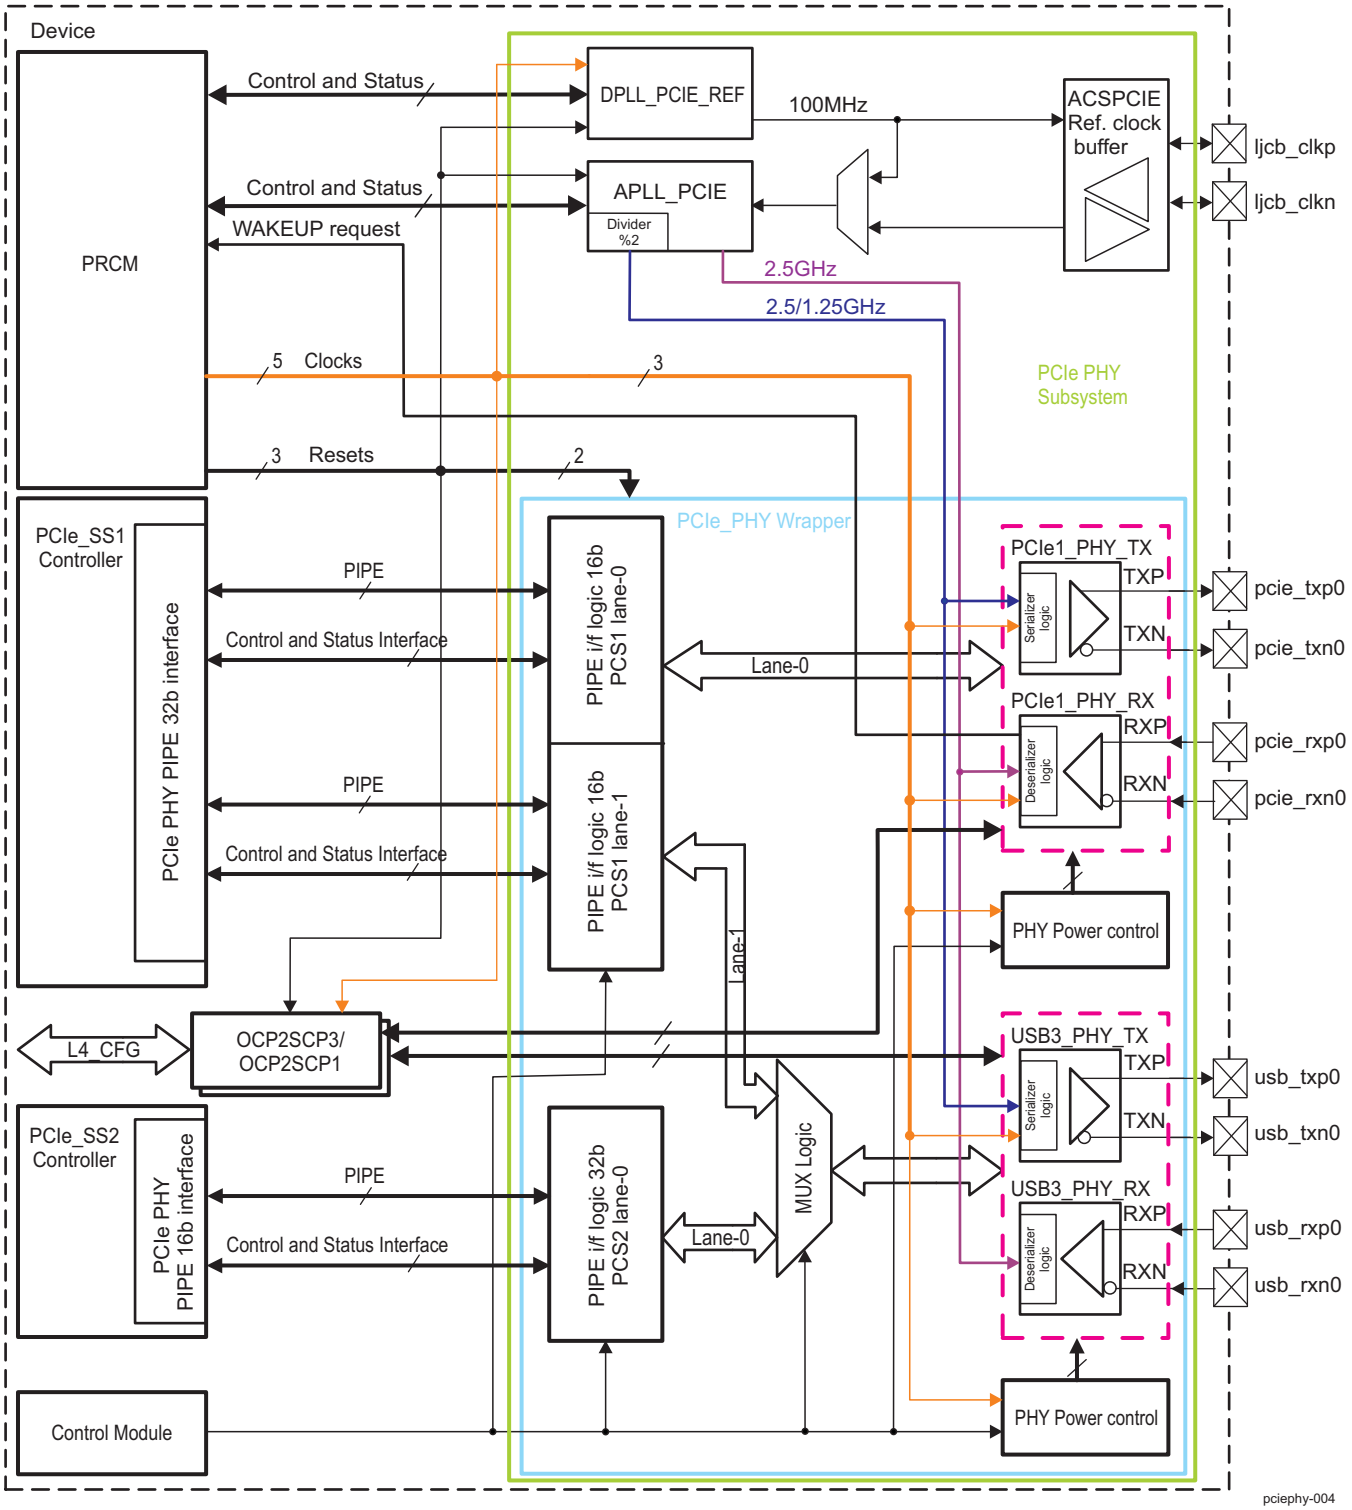
26.4.4 PCIe PHY Subsystem Functional Description

26.4.4.1 PCIe PHY Subsystem Block Diagram

Figure 26-18 shows a block diagram of the PCIe PHY subsystem.

Figure 26-18. PCIe PHY Subsystem Block Diagram



Copyright © 2015–2017, Texas Instruments Incorporated

26.4.4.2 OCP2SCP Functional Description

The OCP2SCP3 module (OCP2SCP instantiation 3), allows user software to configure the PCIe_PHY over the L4_CFG port. All PCIe_PHY_TX and PCIe_PHY_RX configuration registers are accessible through OCP2SCP3.

26.4.4.2.1 OCP2SCP Reset

26.4.4.2.1.1 Hardware Reset

The module receives an asynchronous hardware reset (L3INIT_RST) upon power-on reset (POR) at its active low PIRSTNA input. Table 26-57 lists the OCP2SCP3 system reset signal. For more information on the hardware reset source, see Section 3.5.5, *Reset Domains* in Chapter 3, *Power Reset and Clock Management*.

26.4.4.2.1.2 Software Reset

Setting the OCP2SCP_SYSCONFIG[1] SOFTRESET bit to 1 triggers a software reset on the OCP2SCP interconnect adapter. The OCP2SCP_SYSSTATUS[0] RESETDONE bit is used by software to monitor the status of reset completion. Hardware keeps this bit at 0 while the reset is being executed. A RESETDONE bit transition from 0 to 1 indicates OCP2SCP reset completion.

26.4.4.2.2 OCP2SCP Power Management

The OCP2SCP features idle acknowledgement protocol with the PRCM module.

26.4.4.2.2.1 Idle Mode

The smart-idle mode supported by OCP2SCP is not wake-up capable, which means software must explicitly take care to wake the OCP2SCP by setting the OCP2SCP_SYSCONFIG[4:3] IDLEMODE bit field to 0x1 (no idle), once it has previously gone to an idle mode.

For more information, see Section 3.1.1.1.2, *Module-Level Clock Management* in Chapter 3, *Power, Reset, and Clock Management*.

NOTE: Software must take the OCP2SCP module out of IDLE state by setting the OCP2SCP_SYSCONFIG[4:3] IDLEMODE bit field to 0x1, once smart-idle mode has been selected (OCP2SCP_SYSCONFIG[4:3] IDLEMODE = 0x2).

26.4.4.2.2.2 Clock Gating

The OCP2SCP module has local support for an automatic clock gating based on L4_CFG interconnect activity. This feature is enabled by setting the OCP2SCP_SYSCONFIG[0] AUTOIDLE bit to 0x1, otherwise the module interface clock is free running.

For more information, see Section 3.1.1.1.4, *Clock Domain-Level Clock Management* in Chapter 3, *Power, Reset, and Clock Management*.

26.4.4.2.3 OCP2SCP Timing Registers

The timing configuration register sets various parameters controlling the timing constraints of the OCP2SCP module.

The division ratio between the L4_CFG interconnect clock (L3INIT_L4_GICLK) and the serial configuration port output clock is set through the OCP2SCP_TIMING[9:7] DIVISIONRATIO bit field, with a valid range of 0x1 to 0x7.

The OCP2SCP_TIMING[6:4] SYNC1 timing information is programmable in the range 0 to 7 clock cycles, and shows the acceptable delay between the enable and command availability on SCP. The value of OCP2SCP_TIMING[3:0] SYNC2 is also programmable in the range of 1 to 15 clock cycles, measured from the moment the command is available on SCP until data is accessible.

Copyright © 2015–2017, Texas Instruments Incorporated

NOTE: When the value 000 is programmed for the SCP clock division ratio, and the transaction to be made is a valid transaction on the SCP interface, the value of the DIVISIONRATIO bit field is set internally to 0x7 (to avoid a block on the L4_CFG interconnect interface).

NOTE: When the value 0000 is programmed for the SYNC2 bit field, and the transaction to be made is a valid transaction on the SCP interface, the value of SYNC2 is set to the minimum allowed 0x0001 (to avoid a block on the L4_CFG interconnect interface).

CAUTION

To ensure correct operation, DIVISIONRATIO must not be modified and the value of SYNC2 must be set to 0x6 or more. See OCP2SCP_TIMING register for details.

26.4.4.3 PCIe PHY Serializer and Deserializer Functional Descriptions

26.4.4.3.1 PCIe PHY Module Resets

26.4.4.3.1.1 Hardware Reset

The PCIe PHY Serializer and Deserializer modules recives two active low non-retention resets from PRCM modules.

- The Power-on reset L3INIT_PWRON_RST
- The main reset L3INIT_RST

For more information on the hardware reset source, see Section 3.5.5, *Reset Domains*, in Chapter 3, *Power, Reset, and Clock Management*.

26.4.4.3.1.2 Software Reset

No software reset is available for PCIe PHY Serializer and Deserializer modules.

26.4.4.3.2 PCIe PHY Subsystem Clocking

There are two clock domains within the PCIe PHY:

- PCIe_PHY PIPE port clock domain (PIPE_PCLK and PIPE_MCLK), where 32/16 bit-data is transferred between PCIe_SS controller and PCIe_PHY
- txclk/rbclk functional clock domain in which PCIe PHY generates clock: txclk for 10-bit parallel data transmission, and recovers the rbclk from serially received data.

26.4.4.3.2.1 PCIe PHY Subsystem Input Clocks

The PCIe PHY component receives a feedback clock, PIPE_MCLK, which is the loopback version of the PIPE_PCLK (PIPE port synchronizing clock) generated by the PCIe PHY component. The clock is turned on/off according to the PIPE power-down port states. As PIPE port works in source-synchronous mode, all data movement from the MAC layer to the PIPE interface is synchronous to PIPE_PCLK.

The high speed transmission clock input of the PCIe_PHY serializer and deserializer are connected to APLL_PCIE output pins. The PHY_RX module input clock pin is tied to APLL_PCIE_REF.CLKVCOLDO (PCIE_PHY_GCLK) clock. The PHY_TX input clock pin is tied to divided APLL_PCIE_REF.CLKVCOLDO_DIV (PCIE_PHY_DIV_GCLK) output clock. For more information on the APLL_PCIE_REF.CLKVCOLDO and APLL_PCIE_REF.CLKVCOLDO_DIV output clocks settings, see Section 26.4.4.4.1.4.2, *PCIe PHY APLL Output Clock Configuration*.

Copyright © 2015–2017, Texas Instruments Incorporated

The high speed clock APLL_PCIE_REF.CLKVCOLDO_DIV (PCIE_PHY_DIV_GCLK) could be divided by 2 on two places, in the APLL_PCIE own by-2-divider or in the PHY_TX internal by-2-divider. These dividers support force-bypass mode where the divider is bypassed and no division is performed. The dividers of the APLL_PCIE and of the PHY_TX are cascaded: one divider should always be bypassed, and the other active. For one lane operation the APLL_PCIE divider could be force-baypassed and only internal PCIe_PHY divider to be active.

The APLL_PCIE by-2-divider bypass is controlled in PRCM register CM_CLKMODE_APLL_PCIE[8] CLKDIV_BYPASS bit.

The PCIe1_PHY_TX by-2-divider bypass mode is controled by PCIe1_PHY_TX.PCIEPHYTX_DRIVER_DATA_CONFIG1 register bits as follows:

- Bypassed not forced: FB=0 (default mode):
  PCIEPHYTX_DRIVER_DATA_CONFIG1[1] MEM_OVRD_HS_RATE_ANA_OVERRIDE = 0b0
- Bypassed forced: FB=1:
  PCIEPHYTX_DRIVER_DATA_CONFIG1[1] MEM_OVRD_HS_RATE_ANA_OVERRIDE = 0b1
  PCIEPHYTX_DRIVER_DATA_CONFIG1[3:2] MEM_HS_RATE_ANA_OVERRIDE = 0b00

The receivers PCIe1_PHY_RX allways supplied with non divided clock APLL_PCIE_REF.CLKVCOLDO (PCIE_PHY_GCLK) and the internal dividers always active and controlled by the PCIe controllers.

The APLL_PCIE input clock is MUX selectable between DPLL_PCIE_REF.CLKOUTLDO output and ACSPCIE output derived from device differential clock input pins.

The DPLL_PCIE_REF input clock pin CLKINP is tied to PRCM.PCIE_DPLL_CLK (SYS_CLK1 based) clock.

As shown in Table 26-56, the PCIe PHY Power control module clock input is supplied from SYS_CLK1 based clock PRCM.PCIE_SYS_GFCLK.

Software must notify the PHY logic about which clock frequency is selected by writing CTRL_CORE_PHY_POWER_PCIESS1[31:22] PCIESS1_PWRCTL_CLKFREQ bit field.

The REF_CLKIN clock input is used to support different PCIe_PHY functions. REF_CLKIN clock input is tied to the PRCM.PCIE_REF_GFCLK (CORE_USB_OTG_SS_LFPS_TX_CLK based) functional clock.

The PCIE1_PHY_RX deserializer I/O wake-up logic is supported by the PRCM.PCIE_32K_GFCLK clock, applied at the logic clock input.

The input clock for PCIe_PHY SCP port configuration interface is delivered from the OCP2SCP3 interface adaclockpter.

The SCP port clock input of PCIe_PHY is driven by the OCP2SCP3 gateable output . The ratio of the OCP2SCP3 gateable output clock to the OCP2SCP3 input clock (L3INIT_L4_GICLK) is controlled through the OCP2SCP_TIMING[9:7] DIVISIONRATIO bit field. For more information, see Section 26.4.4.2.3, *OCP2SCP3 Timing Registers*.

26.4.4.3.2.2 PCIe PHY Subsystem Output Clocks

- PIPE_PCLK: The PIPE interface is source-synchronous. A PIPE_PCLK clock is generated by the PCIe_PHY components, used to synchronize PCIe_SS PIPE port inputs, and reflected back as the PIPE_MCLK along with the PIPE outputs. The clock is turned on/off according to the power control port. All data movement from the PIPE interface to the PCIe_SS MAC layer is synchronous to this clock.
- txclk1: Some clock division is performed over the high frequency PCIE_PHY_DIV_GCLK signal before its derivative txclk1 clock is output from the PCIe1_PHY_TX.
- rbclk1: The PCIe1_PHY_RX output rbclk1 is the clock recovered by the PCIe1_PHY_RX on base of the serial data, received over the RXP0 and RXN0 lines from the attached to the PCIe PHY external device. The rbclk1 clock supplies the PCS1 link parallel 10-bit data reception logic.

Copyright © 2015–2017, Texas Instruments Incorporated

The PIPE_PCLK clock which drives the PIPE logic is sourced by the on-chip PCIe_PHY. The PIPE interface is source-synchronous (that is, the clock is received from the PHY), used to synchronize PCIe_SS1 and PSIe_SS2 PIPE inputs, and reflected back along with the PIPE outputs as the PIPE_MCLK. The PIPE_PCLK clock is turned on/off according to the PCIe_PHY power control port. For more details, see Section 26.4.4.3.3, *PCIe PHY Power Management*.

26.4.4.3.3 PCIe PHY Power Management

From one side the control over power up/down states of the USB3_PHY is provided through a Power control modules tightly integrated with the the PCIe1_PHY and PCIe2_PHY physical layer TX/RX components. On the other side, the PCIe_PHY PIPE i/f logic of the PCIe_PHY wrapper conveys power transition commands/states (L0–L3) from the PCIe_SS1 and PCIe_SS2 MAC PIPE power management-ports to the PCIe1_PHY and PCIe2_PHY components as their corresponding P0 (active) and P0s, P1, P2 (low-power) states.

26.4.4.3.3.1 PCIe PHY Power-Up/-Down Sequences

The PHY power control module receives a power-up/power-down command input from the device general core control module. The power control module takes care to execute different stages of the PHY_TX and PHY_RX power-up/-down processes and ensures that the necessary timing intervals are applied between these stages.

Powering-up/-down the PHY_TX and PHY_RX modules is triggered through software writing corresponding power-up/down commands in the CTRL_CORE_PHY_POWER_PCIESS1 register of the device core control module.

For more information, see Chapter 18, *Control Module*.

26.4.4.3.3.2 PCIe PHY Low-Power Modes

An implemented powerdown control port allows PCIe_PHY to support four low-power states:

- **P0 (pipe_powerdown = 0b00): active state**, for high-speed (HS) data transmission and reception. Used for L0 link state.
- **P0s (pipe_powerdown = 0b01):** active HS receiver, suspended transmitter. Used for L0s link state.
- **P1 (pipe_powerdown = 0b10):** Suspended HS receiver and transmitter, but PIPE clock still running.
- **P2 (pipe_powerdown = 0b11):** Suspended HS receiver and transmitter, PIPE clock stopped (i.e. asynchronous mode). Th to transmit and receive the "beacon".

The PCIe PHY power transitions are managed from connected PCIe_SS controller power management state machines according to desired Link and physical layer power states via signal PIPE_POWERDOWN[1:0]. For more information see Section 24.9.4.5 *PCIe Controller Power Management* in Section 24.9 *PCIe Controllers* chapter.

26.4.4.3.3.3 Clock Gating

The PCIe_PHY component high-speed clocks, PLL_CLK and PIPE_PCLK, are gated during the P2 low-power state.

26.4.4.3.4 PCIe PHY Hardware Requests

An asynchronous wake-up request is generated to the PRCM module by the PCIe1_PHY_RX I/Os (RXP0, RXN0).

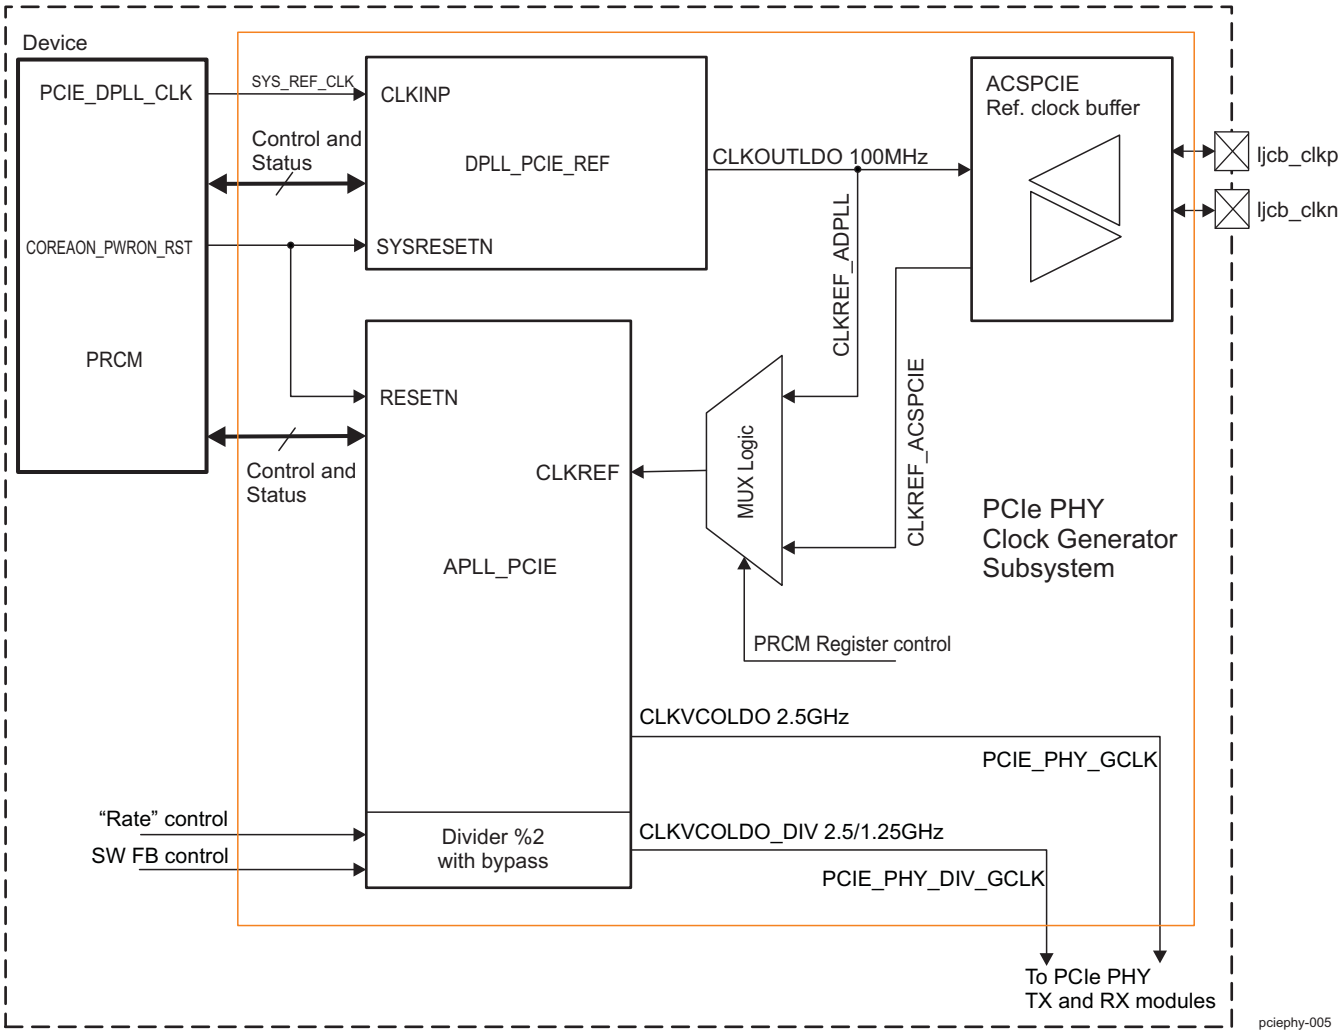
Neither interrupt nor DMA requests are generated.

26.4.4.4 PCIe PHY Clock Generator Subsystem Functional Description

The clock generator subsystem of PCIe PHY module consists of integrated DPLL generator DPLL_PCIE_REF, an APLL high frequency generator for PHY transmision clocks APLL_PCIE and ACSPCIE input/output reference low-jitter clock buffer for connecting with external PCIe device. Figure 26-19 shows the block diagram of Clock Generator Subsistem of PCIe PHY module.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 26-19. PCIe PHY Clock Generator Overview



The DPLL_PCIE_REF clock generator receives its input clock directly from PRCM as PCIE_DPLL_CLK (SYS_CLK1 based). The status and control registers for DPLL_PCIE_REF are located in the PRCM module and allow direct programming of the DPLL_PCIE_REF. The output clock of DPLL_PCIE_REF is on output pin CLKOUTLDO and is fed directly in the APLL_PCIE input clock multiplexer. In input mode, the reference low-jitter clock buffer ACSPCIE receives his clock from diferential input pins directly from outside device and after only buffering feeds this clock to the APLL_PCIE input clock multiplexer.

The APLL_PCIE input clock multiplexer chooses the input clock for APLL_PCIE according to register programming and feeds it to the input of APLL_PCIE. The selection of clock source is made by the register PRCM.CM_CLKMODE_APLL_PCIE[7] REFSEL bit as follows:

PRCM.CM_CLKMODE_APLL_PCIE[7] REFSEL = 0b0 - input clock CLKREF_ADPLL, APLL reference input clock is from DPLL_PCIE_REF

PRCM.CM_CLKMODE_APLL_PCIE[7] REFSEL = 0b1 - input clock CLKREF_ACSPCIE, APLL reference input clock is from ACSPCIE

The APLL_PCIE has two output high frequency transmission clocks. The main undivided clock PCIE_PHY_GCLK is delivered from output CLKVCOLDO and is fed directly to the PHY RX module. The second divided clock PCIE_PHY_DIV_GCLK is delivered after passing the main APLL output clock through a by-2-divider (with baypass capabilities) and is outputed on CLKVCOLDO_DIV output. This clock is fed to the PCIe PHY TX modules and delivers sinchronization of the TX modules in two lane mode.

26.4.4.4.1 PCIe PHY DPLL Clock Generator

This section describes the PCIe PHY DPLL reference clock generator DPLL_PCIE_REF.

26.4.4.4.1.1 PCIe PHY DPLL Clock Generator Overview

The DPLL module integrated in the PCIe PHY is a single instance high speed clock generator, used to deliver the reference clock to the main clock generator APLL_PCIE. The DPLL_PCIE_REF is directly controlled from the PRCM module and all the necessary control and status signals are exported by the subsystem.

The DPLL_PCIE_REF features:

- A programmable 8-bit input divider: N
- A programmable 12-bit integer multiplier: M
- A programmable 7-bit integer post divider M2
- Digital control and loop filter
- Internal oscillator divided output clock (CLKOUTLDO output)
- Idle-bypass low-power mode
- Low Power Stop mode

26.4.4.4.1.2 PCIe PHY DPLL Clock Generator Reset

The PCIe PHY DPLL clock generator receive hardware non-retention reset, COREAON_PWRON_RST, which comes from the device power and reset manager. For more information on the hardware reset source, see Section 3.5.5, *Reset Domains* in Chapter 3, *Power, Reset, and Clock Management*.

The DPLL_PCIE_REF itself has no software reset capabilities.

26.4.4.4.1.3 PCIe PHY DPLL Low-Power Modes

The DPLL_PCIE_REF module supports two types of low power mode controlled by the PRCM register PRCM.CM_CLKMODE_DPLL_PCIE_REF[2:0] DPLL_EN bits.

The low-power modes supported by DPLL_PCIE_REF are Idle-bypass low-power and Low Power Stop modes, which are both characterized by:

- Internal LDO switched off
- DCO oscillator switched off
- CLKOUTLDO output pulled low

For more details on the DPLL settings and conditions necessary to enter Idle-bypass and Low Power Stop modes, see Section 26.4.4.4.1.6.4, *PCIe PHY DPLL Idle-bypass low-power Mode*, and Section 26.4.4.4.1.6.5, *PCIe PHY DPLL Low Power Stop Mode*.

DPLL_PCIE_PHY is held in a similar low-power state (DCO and LDO switched off, with CLKOUTLDO = 0) after Power-up Reset.

26.4.4.4.1.4 PCIe PHY DPLL Clocks Configuration

26.4.4.4.1.4.1 PCIe PHY DPLL Input Clock Control

The DPLL_PCIE_REF accepts the functional clock, PCIE_DPLL_CLK, on its CLKINP pin directly from the device PRCM, without involving any control interactions. The PCIE_DPLL_CLK is derived from SYS_CLK1. See Section 3.6.4.1.4, *Clock Domain Module Attributes* in Chapter 3, *Power, Reset, and Clock Management*.

Copyright © 2015–2017, Texas Instruments Incorporated

26.4.4.4.1.4.2 PCIe PHY DPLL Output Clock Configuration

Only the DPLL_PCIE_REF output CLKOUTLDO is used to supply the reference clock to the APLL input multiplexer. To adjust the output clock frequency and jitter, the following values must be programmed, dividers SD, N and M2 and the multiplier M. The values for these parameters must be programmed in the corresponding registers in PRCM as follows:

PRCM.CM_CLKSEL_DPLL_PCIE_REF[31:24] DPLL_SD_DIV - Sigma-Delta divider SD, must be set by software to ensure optimum jitter performance.

PRCM.CM_CLKSEL_DPLL_PCIE_REF[19:8] DPLL_MULT - multiplier M, multiplier factor (2 to 4095).

PRCM.CM_CLKSEL_DPLL_PCIE_REF[7:0] DPLL_DIV - dvider N, input clock divider factor (0 to 255) (actual division factor is N+1).

PRCM.CM_DIV_M2_DPLL_PCIE_REF[6:0] DIVHS - divider M2, output clock post-divider factor (1 to 127).

The state of the output clock CLKOUTLDO is indicated by the PRCM.CM_DIV_M2_DPLL_PCIE_REF[10] CLKLDOST bit.

For more details on output clock settings sequence, see Section 26.4.4.4.1.6.6, *PCIe PHY DPLL Clock Programming Sequence*.

26.4.4.4.1.4.2.1 PCIe PHY DPLL Output Clock Gating

There is no direct software gate control for the DPLL_PCIE_REF.CLKOUTLDO output.

DPLL_PCIE_REF.CLKOUTLDO clock output is automatically gated (CLKOUTLDO pulled low) in the following scenarios:

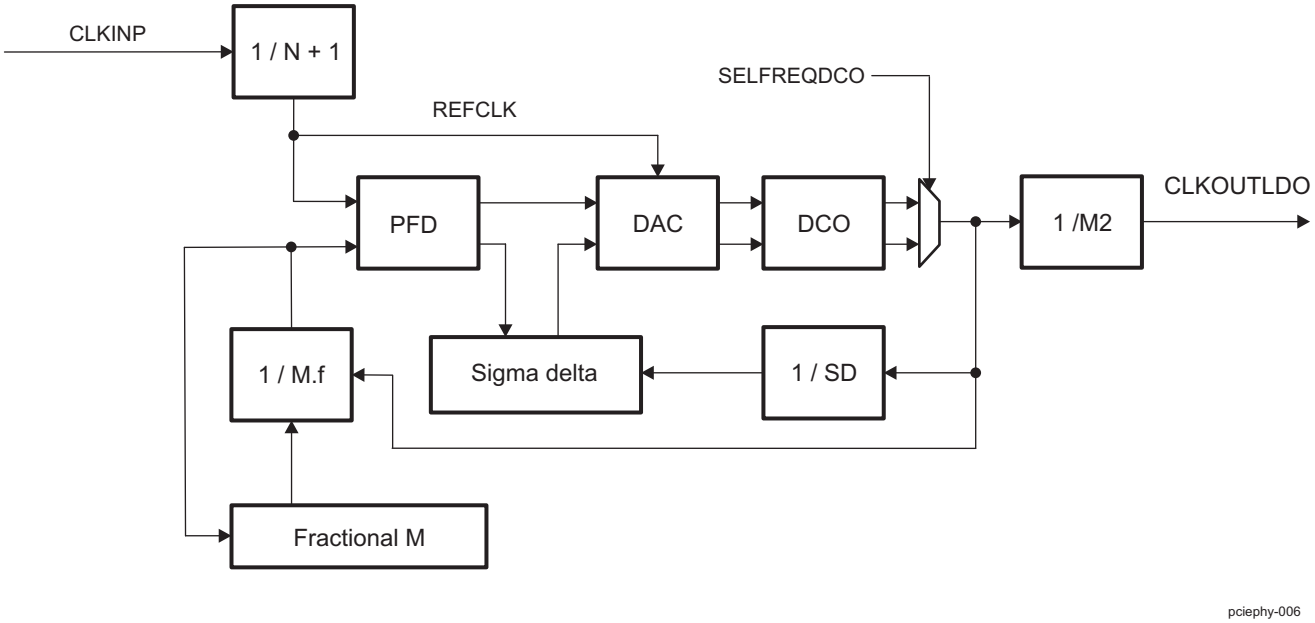
- DPLL power-up sequence. For more information on power-up sequence, see Section 26.4.4.4.1.6.1, *PCIe PHY Clock Generator Power Up*.
- DPLL entering a relock sequence. For more information on relocking sequence, see Section 26.4.4.4.1.6.2, *PCIe PHY DPLL Sequences*.
- DPLL entering Idle-bypass low-power mode. For more information on idle-bypass mode, see Section 26.4.4.4.1.6.4, *PCIe PHY DPLL Idle-Bypass Mode*.
- DPLL entering Low Power Stop mode. For more information on Low Power Stop mode, see Section 26.4.4.4.1.6.5, *PCIe PHY DPLL Low Power Stop Mode*.

26.4.4.4.1.5 PCIe PHY DPLL Subsystem Architecture

Figure 26-20 is a simplified block diagram of the DPLL_PCIE_REF instance integrated in the PCIe PHY clock generator subsystem.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 26-20. DPLL_PCIE_REF Functional Block Diagram



The input clock CLKINP goes to a predivider N + 1. The entire loop runs on the REFCLK clock after this predivider. The value of N + 1 is controlled through the PRCM.CM_CLKSEL_DPLL_PCIE_REF[7:0] DPLL_DIV bit field.

The frequency ranges for the DPLL_PCIE_REF input clock - CLKINP and the DPLL internal reference clock, REFCLK = CLKINP/N + 1 are:

- 0.62 to 60 MHz for CLKINP
- 0.62 to 2.5 MHz for the REFCLK

The output clock CLKOUTLDO is synthesized by digitally controlled oscillator (the DCO block), that automatically detects the frequency range divided by the M2 value. The CLKOUTLDO frequency can be given with CLKOUTLDO = [CLKINP×M/(N + 1)]/M2. For that purpose the feedback multiplier M must be configured through the PRCM.CM_CLKSEL_DPLL_PCIE_REF[19:8] DPLL_MULT bit field and the output clock divider M2 must be configured through the PRCM.CM_DIV_M2_DPLL_PCIE_REF[6:0] DIVHS bit field.

NOTE: Fractional synthesis is not supported for M.

26.4.4.4.1.6 PCIe PHY DPLL Clock Generator Modes and State Transitions

The DPLL_PCIE_REF can be set in different modes during operation. PRCM triggers DPLL_PCIE_REF state transitions to different static modes by setting the bit field of the PRCM.CM_CLKMODE_DPLL_PCIE_REF[2:0] DPLL_EN. Automatic state transitions could be enabled if corresponding bits in PRCM.CM_AUTOIDLE_DPLL_PCIE_REF register are set. The DPLL_PCIE_REF then can automaticly enter the low power condition as follows:

If PRCM.CM_AUTOIDLE_DPLL_PCIE_REF[2:0] AUTO_DPLL_MODE is set to 0x0 - automatic control is disabled.

If PRCM.CM_AUTOIDLE_DPLL_PCIE_REF[2:0] AUTO_DPLL_MODE is set to 0x1- The DPLL is automatically put in Low Power Stop mode when its DPLL generated clocks are not required anymore. It is also restarted automatically.

If PRCM.CM_AUTOIDLE_DPLL_PCIE_REF[2:0] AUTO_DPLL_MODE is set to 0x5 - The DPLL is automatically put in Idle Bypass Low Power mode when its DPLL generated clocks are not required anymore. It is also restarted automatically.

Copyright © 2015–2017, Texas Instruments Incorporated

For more information see Chapter 3, *Power, Reset, and Clock Management*.

26.4.4.4.1.6.1 PCIe PHY Clock Generator Power Up

After power up, the DPLL_PCIE_REF.SYSRESETN input is automatically pulled low by the PRM, together with the APLL_PCIE.RESETN input. Because PRM.COREAON_PWRON_RST is an asynchronous reset, the DPLL_PCIE_REF input clock (DPLL_PCIE_REF.CLKINP) is not demanded upon reset. During DPLL power-up mode, CLKOUTLDO clock is maintained inactive (pulled low). After power-up reset, the DPLL_LOCK (internal lock loop) signal is maintained deasserted, too. The default value of the mode select register bit field PRCM.CM_CLKMODE_DPLL_PCIE_REF[2:0] DPLL_EN puts the DPLL_PCIE_REF in Idle Bypass Low Power mode. It is software responability to change the state of the DPLL_PCIE_REF to desired mode after PRCM reset.

26.4.4.4.1.6.2 PCIe PHY DPLL Sequences

Once all the configuration values have been initially programmed into the PRCM registers controlling DPLL_PCIE_REF (see Section 26.4.4.4.1.4.2), the PRCM.CM_CLKMODE_DPLL_PCIE_REF[2:0] DPLL_EN bit should be set to 0x7 to start the DPLL calibration and locking sequence. After performing the locking sequence a lock status is indicated for DPLL_PCIE_REF by PRCM.CM_IDLEST_DPLL_PCIE_REF[0] ST_DPLL_CLK bit asserted to 0b1.

26.4.4.4.1.6.3 PCIe PHY DPLL Locked Mode

When DPLL_PCIE_REF finishes calibration and lock sequences it enters a locked state. DPLL_PCIE_REF locked state is indicated by PRCM.CM_IDLEST_DPLL_PCIE_REF[0] ST_DPLL_CLK bit asserted to 0b1. In locked mode all the parameters of DPLL_PCIE_REF are set and the loop is running. The output clock CLKOUTLDO is active.

26.4.4.4.1.6.4 PCIe PHY DPLL Idle-Bypass Mode

Idle-bypass fast relock mode is not supported for DPLL_PCIE_REF.

DPLL_PCIE_REF supports idle-bypass low-power mode. A transition from a normal operation to idle-bypass mode is performed when software sets the PRCM.CM_CLKMODE_DPLL_PCIE_REF[2:0] DPLL_EN bit field to 0x5. IDLE signal assertion triggers a power-down sequence on DPLL internal LDO analog blocks and the DCO oscillator. This mode is also the default state after PRCM reset for the DPLL_PCIE_REF.

In idle-bypass low-power mode, the CLKOUTLDO goes low. Also, the internal reference clock REFCLK = CLKINP/N + 1 is gated inside the DPLL digital control logic to save power, the internal LDO and the DCO are turned off.

To exit idle-bypass mode and restore clock generation, the user should write PRCM.CM_CLKMODE_DPLL_PCIE_REF[2:0] DPLL_EN bit field to 0x7, which deasserts the IDLE signal, and DPLL_PCIE_REF automatically enters a relock sequence. CLKOUTLDO output clock is activated after DPLL_PCIE_REF enters locked mode.

26.4.4.4.1.6.5 PCIe PHY DPLL Low Power Stop Mode

The Low Power Stop mode will be activated if software writes PRCM.CM_CLKMODE_DPLL_PCIE_REF[2:0] DPLL_EN bit field to 0x1. The module enters a low Power Stop mode by gating all its internal clocks (REFCLK) and powering down internal LDO and DCO. CLKOUTLDO remains gated (low) during this mode.

NOTE: When the DPLL_PCIE_REF is in Low Power Stop mode, the input clock on CLKINP pin is not needed.

26.4.4.4.1.6.6 PCIe PHY DPLL Clock Programming Sequence

The DPLL_PCIE_REF factors must be calculated based on the required input and output frequencies, keeping the PLL internal reference frequency (REFCLK) in the appropriate range (0.62 to 2.5 MHz).

Copyright © 2015–2017, Texas Instruments Incorporated

The values that must be considered during programming are:

- The internal reference frequence REFCLK. Must be kept in the range of 0.62 to 2.5 MHz. The value is calculated as REFCLK = CLKINP/(N+1).
- The Sigma-Delta divider to ensure optimum jitter performance. Must ensure that the sigma-delta operation frequency is as close as possible, but less than 250MHz for optimal performance. The value is calculated as SD = CEILING([(M)/(N+1)] × CLKINP/250) where CLKINP is the input clock of the DPLL in MHz.
- The output clock CLKOUTLDO frequency. This frequency must be programmed to 100 MHz fixed value for correct PCIe operation. The value is calculated as CLKOUTLDO = [CLKINP×M/(N + 1)]/M2
- The DCO frequency range must be set according to needed DCO output clock DCOCLK = CLKINP × [M/(N+1)]. The value of the SELFREQDCO[2:0] DPLL input selects the DCO internal oscilator ICO1 or ICO2 as follows:
  - If 750 < DCOCLK < 1500, SELFREQDCO[2:0] must be set to 0b010 (HS2 mode, ICO2 selected)
  - If 1250 < DCOCLK < 2500, SELFREQDCO[2:0] must be set to 0b100 (HS1 mode, ICO1 selected)
  - All other combinations of SELFREQDCO[2:0] are reserved

The following registers set the requred parameters values for the DPLL_PCIE_REF.

- PRCM.CM_CLKSEL_DPLL_PCIE_REF[7:0] DPLL_DIV - sets dvider N, input clock divider factor (0 to 255) (actual division factor is N+1)
- PRCM.CM_CLKSEL_DPLL_PCIE_REF[21] DPLL_SELFREQDCO bit sets DCO frequency range.
  - DPLL_SELFREQDCO should be set to 0b0 if 750 MHz < CLKDCOLDO [MHz] < 1500 MHz (SELFREQDCO[2:0] set to 0b010)
  - DPLL_SELFREQDCO should be set to 0b1 if 1250 MHz < CLKDCOLDO [MHz] < 2500 MHz (SELFREQDCO[2:0] set to 0b100).
- PRCM.CM_CLKSEL_DPLL_PCIE_REF[19:8] DPLL_MULT - sets multiplier M, multiplier factor (2 to 4095).
- PRCM.CM_DIV_M2_DPLL_PCIE_REF[6:0] DIVHS - sets divider M2, output clock post-divider factor (1 to 127).
- PRCM.CM_CLKSEL_DPLL_PCIE_REF[31:24] DPLL_SD_DIV - sets Sigma-Delta divider SD, must be set by software to ensure optimum jitter performance.

To maintain proper PCIe operation of the PCIe PHY submodule a set of parameters values are recomended. The DCO frequency of the PCIe reference DPLL is not used directly, so it can be changed to optimize jitter, power, or lock time. Only the divided-by-M2 CLKOUTLDO output clock is a required. The tables below give ratios that have been verified to meet PCIe jitter requirements. Other ratios combinations exist, to obtain a lower DCO frequency and lower power, but they should be checked against the PCIe standard.

Table 26-58. DPLL_PCIE_REF Recommended Configuration

CLKINP (MHz)	N	N+1	REFCLK (MHz)	M	DCOCLK (GHz)	DPLL_SELF REQDCO	M2	CLKOUTLDO (MHz)
20	9	10	2	750	1.5	0	15	100

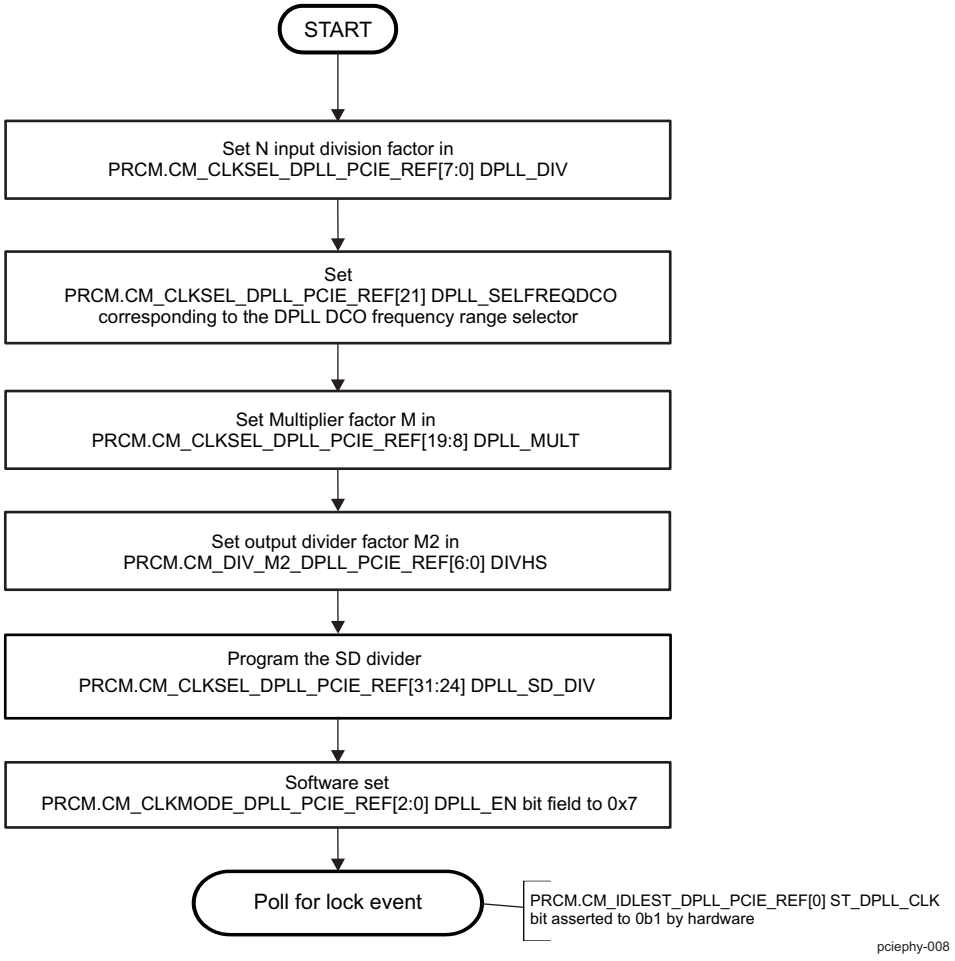
Figure 26-21 shows the programming sequence for DPLL_PCIE_REF.

Figure 26-21. DPLL_PCIE_REF Programming Sequence



NOTE:

- The sequence applies to the CLKOUTLDO output of the DPLL_PCIE_REF.
- CLKOUTLDO output frequency of the PLL_PCIE_REF should be programmed to 100 MHz, for the proper PCIe operation.

Table 26-59 summarizes the PRCM registers for the DPLL_PCIE_REF programming sequence.

Table 26-59. Register Call Summary for DPLL_PCIE_REF Programming Sequence

Register Name	Register Name	Register Name
CM_CLKSEL_DPLL_PCIE_REF	CM_DIV_M2_DPLL_PCIE_REF	CM_CLKMODE_DPLL_PCIE_REF

26.4.4.4.1.6.7 PCIe PHY DPLL Recommended Values

Table 26-60 lists the DPLL_PCIE_REF setup registers in PRCM recommended values.

Table 26-60. Recommended Programming Values

Field Name	Value	Description
CM_CLKSEL_DPLL_PCIE_REF[7:0] DPLL_DIV	See Table 26-58	Sets dvider N, input clock divider factor (0 to 255) (actual division factor is N+1)

Copyright © 2015–2017, Texas Instruments Incorporated

Table 26-60. Recommended Programming Values (continued)

Field Name	Value	Description
CM_CLKSEL_DPLL_PCIE_REF[21] DPLL_SELFREQDCO	See Table 26-58	Sets DCO frequency range
CM_CLKSEL_DPLL_PCIE_REF[19:8] DPLL_MULT	See Table 26-58	Sets multiplier M, multiplier factor (2 to 4095)
CM_DIV_M2_DPLL_PCIE_REF[6:0] DIVHS	See Table 26-58	Sets divider M2, output clock post-divider factor (1 to 127)
CM_CLKSEL_DPLL_PCIE_REF[31:24] DPLL_SD_DIV	See (1)	Sets Sigma-Delta divider SD, SD = CEILING([(M)/(N+1)] × CLKINP/250)
CM_CLKMODE_DPLL_PCIE_REF[2:0] DPLL_EN	0x7	Enables the DPLL in Lock mode
CM_IDLEST_DPLL_PCIE_REF[0] ST_DPLL_CLK	=1	Poll this bit for DPLL lock status. Set by hardware.

(1) The value of the bit field must be set according to the desired clock frequency and M, N and input frequency values.

26.4.4.4.2 PCIe PHY APLL Clock Generator

This section describes the PCIe PHY APLL high speed clock generator APLL_PCIE.

26.4.4.4.2.1 PCIe PHY APLL Clock Generator Overview

The APLL module integrated in the PCIe PHY is a single instance high speed clock generator, used to deliver the high speed clocks to the PCIe PHY RX and TX modules. The APLL_PCIE is directly controlled from the PRCM module and all the necessary control and status signals are exported by the subsystem.

The APLL_PCIEF features:

- Fixed multiplication ratio to generate 2.5 GHz output clock
- High frequency direct output CLKVCOLDO
- High frequency divided output CLKVCOLDO_DIV
- A bypass feature of by-2-divider of CLKVCOLDO_DIV
- Internal voltage controlled oscilator VCO
- Auto Idle mode

26.4.4.4.2.2 PCIe PHY APLL Clock Generator Reset

The PCIe PHY APLL_PCIE clock generator receive hardware non-retention reset, COREAON_PWRON_RST, which comes from the device power and reset manager. For more information on the hardware reset source, see Section 3.5.5, *Reset Domains* in Chapter 3, *Power, Reset, and Clock Management*.

The APLL_PCIE itself has no software reset capabilities.

26.4.4.4.2.3 PCIe PHY APLL Low-Power Mode

The APLL_PCIE module supports one type of low power mode controlled by the PRCM register PRCM.CM_CLKMODE_APLL_PCIE[1:0] MODE_SELECT bits.

The low-power mode supported by APLL_PCIE is Auto Idle mode.

26.4.4.4.2.4 PCIe PHY APLL Clocks Configuration

26.4.4.4.2.4.1 PCIe PHY APLL Input Clock Control

The APLL_PCIE accepts the functional clock from its input multiplexer, which selects between the DPLL_PCIE_REF output clock CLKREF_ADPLL and the clock from the reference clock buffer ACSPCIE output (delivered from outside the device) CLKREF_ACSPCIE. The selection is made by PRCM register PRCM.CM_CLKMODE_APLL_PCIE[7] REFSEL bit as folows:

Copyright © 2015–2017, Texas Instruments Incorporated

- PRCM.CM_CLKMODE_APLL_PCIE[7] REFSEL = 0b0 - input clock CLKREF_ADPLL, APLL reference input clock is from DPLL_PCIE_REF
- PRCM.CM_CLKMODE_APLL_PCIE[7] REFSEL = 0b1 - input clock CLKREF_ACSPCIE, APLL reference input clock is from ACSPCIE

The APLL module does not have software capabilitites for gating the input clock.

26.4.4.4.2.4.2 PCIe PHY APLL Output Clock Configuration

Two high frequency output clocks are available from APLL_PCIE. The direct output CLKVCOLDO supplies 2.5 GHz high speed transmision clock for the PCIe PHY RX module and the divided by 2 clock output CLKVCOLDO_DIV supplies high speed transmision clock (1.25 or 2.5 GHz) for the PCIe PHY TX module. The internal parameters of APLL (multipliers, dividers) are fixed and do not need programming to generate the output clocks. The output clock CLKVCOLDO_DIV is by default the divided by 2 version of the CLKVCOLDO. The divider is controled by the RATE signal from the PCIe_SS controller. The by-2-divider has a bypass feature to ignore the division control from PCIe_SS and to output a clock with same frequency like CLKVCOLDO. This bypass feature is controlled by PRCM.CM_CLKMODE_APLL_PCIE[8] CLKDIV_BYPASS bit as follows:

- PRCM.CM_CLKMODE_APLL_PCIE[8] CLKDIV_BYPASS = 0b0 - the division by 2 is controlled from Rate signal from PCIe_SS controller;
- PRCM.CM_CLKMODE_APLL_PCIE[8] CLKDIV_BYPASS = 0b1 - the CLKOUTLDO_DIV is not divided by 2 and has same frequency like CLKVCOLDO. Select this option for the current device.

The frequency of CLKVCOLDO_DIV can be changed on-the-fly, but glitches can occur on the clock. Best approach is to disable the CLKVCOLDO_DIV when changing the frequency. See Section 26.4.4.4.2.4.2.1 *PCIe PHY APLL Output Clock Gating* for CLKVCOLDO_DIV gating options.

The availability of the APLL_PCIE output clocks can be monitored in PRCM.CM_CLKVCOLDO_APLL_PCIE register as follows:

- PRCM.CM_CLKVCOLDO_APLL_PCIE[9] CLKST bit gives the status (gated or enabled) of CLKVCOLDO clock
- PRCM.CM_CLKVCOLDO_APLL_PCIE[10] CLK_DIVST bit gives the status (gated or enabled) of CLKVCOLDO_DIV clock.

26.4.4.4.2.4.2.1 PCIe PHY APLL Output Clock Gating

Because the APLL_PCIE.CLKVCOLDO and APLL_PCIE.CLKVCOLDO_DIV are implemented as optional functional clocks the PRCM has software control on them. The two clocks can be controlled by PRCM registers corresponding to the implemented PCIe_SS controllers.

PRCM.CM_PCIE_PCIESS1_CLKCTRL[9] OPTFCLKEN_PCIEPHY_CLK bit controls the CLKVCOLDO clock for the PCIe PHY modules.

PRCM.CM_PCIE_PCIESS1_CLKCTRL[10] OPTFCLKEN_PCIEPHY_CLK_DIV bit controls the CLKVCOLDO_DIV clock for the PCIe PHY modules.

APLL_PCIE.CLKVCOLDO and APLL_PCIE.CLKVCOLDO_DIV clock outputs are automatically gated (pulled low) in the following scenarios:

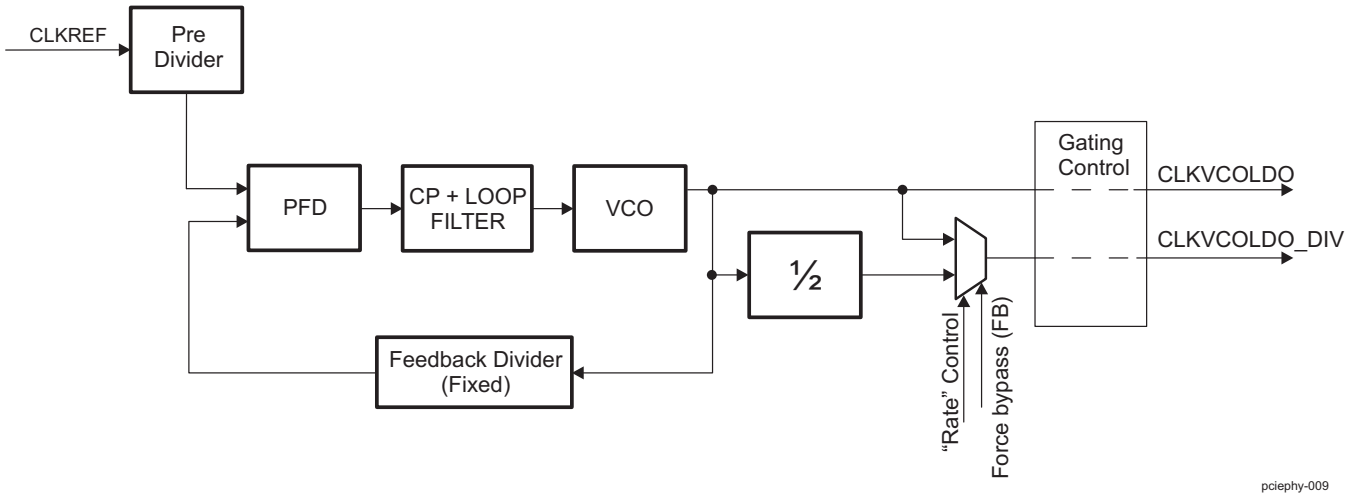
- APLL power-up sequence. For more information on power-up sequence, see Section 26.4.4.4.2.6.1, *PCIe PHY APLL Clock Generator Power Up* .
- APLL entering Auto Idle mode.

26.4.4.4.2.5 PCIe PHY APLL Subsystem Architecture

Figure 26-22 is a simplified block diagram of the APLL_PCIE instance integrated in the PCIe PHY clock generator subsystem.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 26-22. APLL_PCIE Functional Block Diagram



The input clock CLKINP goes to a predivider with fixed value. Then goes to the clock generation loop with fixed Feedback Divider. The output of the VCO is split in two. One path directly goes out on CLKVCOLDO output. The other path passes the internal divider by 2 and then goes to bypass multiplexor where is selected the output frequency of the CLKVCOLDO_DIV output. The selection is made either from "Rate" signal from PCIe_SS controller or with higher priority from Force bypass signal controlled from PRCM.CM_CLKMODE_APLL_PCIE[8] CLKDIV_BYPASS bit.

The frequency of the VCO output is fixed to 2.5 GHz and is not programmable in software. No changes could be made on the internal parameters of the APLL_PCIE. Output clocks are controllable through PRCM registers and can be gated by software. See Section 26.4.4.4.2.4.2.1 *PCIe PHY APLL Output Clock Gating* for more information.

26.4.4.4.2.6 PCIe PHY APLL Clock Generator Modes and State Transitions

NOTE: In order to disable the APLL_PCIE, the user needs to disable PCIe_SSx (where x = 1 or 2) using the CM_PCIE_PCIESSx_CLKCTRL[1:0] MODULEMODE registers. When PCIe_SS is disabled, the PRCM module automatically disables the APLL_PCIE. Please note that setting CM_CLKMODE_APLL_PCIE[1:0] MODE_SELECT bitfield to 0x0 does not disable the APLL_PCIE.

The APLL_PCIE can be set in different modes during operation. PRCM triggers APLL_PCIE state transitions to different static modes by setting the bit field of the PRCM.CM_CLKMODE_APLL_PCIE[1:0] MODE_SELECT. Only two static modes are available for APLL_PCIE:

- PRCM.CM_CLKMODE_APLL_PCIE[1:0] MODE_SELECT = 0x1 – APLL_FORCE_LOCK_MODE is set. This puts the APLL in Force Lock mode
- PRCM.CM_CLKMODE_APLL_PCIE[1:0] MODE_SELECT = 0x2 – APLL_FORCE_IDLE_MODE is set. This puts the APLL in Auto Idle mode

For more information see Chapter 3, *Power, Reset, and Clock Management*.

26.4.4.4.2.6.1 PCIe PHY APLL Clock Generator Power Up

After power up, the APLL_PCIE.RESETN input is automatically pulled low by the PRM, together with the DPLL_PCIE_REF.SYSRESETN input. Because PRM.COREAON_PWRON_RST is an asynchronous reset, the DPLL_PCIE_REF input clock (DPLL_PCIE_REF.CLKINP) is not demanded upon reset. During APLL power-up mode, CLKVCOLDO and CLKVCOLDO_DIV clocks are maintained inactive (pulled low). After power-up reset, the APLL_LOCK (internal lock loop) signal is maintained deasserted, too. The default value of the mode select register bit field PRCM.CM_CLKMODE_APLL_PCIE[1:0] MODE_SELECT = 0x0 puts the DPLL_PCIE_REF in unknown state. It is software responability to change the state of the APLL_PCIE to desired mode after PRCM reset.

Copyright © 2015–2017, Texas Instruments Incorporated

26.4.4.4.2.6.2 PCIe PHY APLL Sequences

After setting the APLL_PCIE in Force Lock mode, a inital lock sequence is started and the module enters working state. The output clocks CLKVCOLDO and CLKVCOLDO_DIV are gated until the lock sequence is finished and APLL_LOCK signal is aserted. After that all clocks are operational and their states depend on the software control.

26.4.4.4.2.6.3 PCIe PHY APLL Locked Mode

When APLL_PCIE finishes calibration and lock sequences it enters a locked state. APLL_PCIE locked state is indicated by PRCM.CM_IDLEST_APLL_PCIE[0] ST_APLL_CLK bit asserted to 0b1. In locked mode all the parameters of DPLL_PCIE_REF are set and the loop is running. The output clocks CLKVCOLDO and CLKVCOLDO_DIV are active under software control.

26.4.4.4.3 ACSPCIE reference clock buffer

The ACSPCIE module is a clock buffer circuit, which has both receive (RX) and transmission (TX) mode. This clock buffer is used to provide low jitter input clock to APLL. In receive mode it takes in an external differential clock and converts it to single-ended CMOS level clock signal. In transmission mode it takes in an internal single-ended clock and converts it to differential HCSL[1] level (in presence of external terminations). The I/O pins of ACSPCIE are *ljcb_clkp* and *ljcb_clkn* differential pair.

- Receive mode: RX is a clock slicer that receives HCSL or LVDS differential clock (typically from on-board Crystal Oscillator) between ljcb_clkp and ljcb_clkn and converts it to CMOS single-ended output CLKREF_ACSPCIE. This CMOS clock signal is the input clock for APLL.
- Transmission mode: TX is a current switching driver that receives CMOS single-ended clock CLKREF_ADPLL at it's input pin from DPLL_PCIE_REF and converts it to HCSL differential-ended output ljcb_clkp and ljcb_clkn. The termination for TX is on-board and 50 Ohms single-ended or 100 Ohms differential.

The ACSPCIE module has two modes of operation:

- Functional mode: The module is powered up automatically and acts as either an input or output buffer.
- Power-down mode: The module is powered down. RX output is held low and TX output is tri-stated/terminated.

26.4.5 PCIePHY Subsystem Low-Level Programming Model

The low-level programming sequence to set up the PCIe PHY subsystem is summarized in the Table 26-61

NOTE: Registers prefixed with CM_ are system Clock Manager registers and are described in Chapter 3, *Power, Reset, and Clock Management*.

Registers prefixed with CTRL_ are system Control Module registers and are described in Chapter 18, *Control Module*.

Table 26-61. PCIePHY Subsystem Low-Level Programming Sequence

Step	Register/Bit Field/Programming Model	Value
Start a software forced wake-up transition on the PCIE clock domain	CM_PCIE_CLKSTCTRL[1:0] CLKTRCTRL	0x2
Start a software forced wake-up transition on the L3INIT clock domain	CM_L3INIT_CLKSTCTRL[1:0] CLKTRCTRL	0x2
Configure the PCIESS1 module to be explicitly enabled	CM_PCIE_PCIESS1_CLKCTRL[1:0] MODULEMODE	0x2
Poll for PCIESS1 module fully functional?	CM_PCIE_PCIESS1_CLKCTRL[17:16] IDLEST	=0x0
Optional: Configure the PCIESS2 module to be explicitly enabled	CM_PCIE_PCIESS2_CLKCTRL[1:0] MODULEMODE	0x2
Optional: Poll for PCIESS2 module fully functional?	CM_PCIE_PCIESS2_CLKCTRL[17:16] IDLEST	=0x0

Step	Register/Bit Field/Programming Model	Value
Configure the OCP2SCP3 module to be managed automatically by hardware according to clock domain transition	CM_L3INIT_OCP2SCP3_CLKCTRL[1:0] MODULEMODE	0x1
Perform a software reset on OCP2SCP3	OCP2SCP_SYSCONFIG[1] SOFTRESET	1
Wait until reset is finished?	OCP2SCP_SYSSTATUS[0] RESETDONE	=1
Configure the OCP2SCP3 Division Ratio and SYNC values	OCP2SCP_TIMING	0x8F
IF: Either PCIESS1 Second Lane or PCIESS2 is required (both are available via USB3 PHY)	Software test condition	
Configure the OCP2SCP1 module to be managed automatically by hardware according to clock domain transition	CM_L3INIT_OCP2SCP1_CLKCTRL[1:0] MODULEMODE	0x1
Perform a software reset on OCP2SCP1	OCP2SCP_SYSCONFIG[1] SOFTRESET	1
Wait until reset is finished?	OCP2SCP_SYSSTATUS[0] RESETDONE	=1
Configure the OCP2SCP1 Division Ratio and SYNC values	OCP2SCP_TIMING	0x8F
ENDIF		
Configure DPLL_PCIE_REF registers to select CLKOUTLDO = 100 MHz. Lock the PLL.	See Section 26.4.4.4.1.6.7, *PCIe PHY DPLL Recommended Values*.	
Select the desired direction of the ACSPCIE buffer (connected to the ljcp_clkn/ljcp_clkp pins)	CTRL_CORE_SMA_SW_6[17:16] PCIE_TX_RX_CONTROL	0x1 (output) 0x2 (input)
Select the APLL_PCIE 100MHz reference clock source	CM_CLKMODE_APLL_PCIE[7] REFSEL	0 (DPLL_PCIE) 1 (ACSPCIE)
Configure APLL_PCIE registers to select CLKVCOLDO = 2.5 GHz and CLKVCOLDO_DIV = 2.5 GHz	See Section 26.4.4.4.2.4, *PCIe PHY APLL Clocks Configuration*.	
Request the APLL_PCIE Force Lock mode	CM_CLKMODE_APLL_PCIE[1:0] MODE_SELECT	0x1
Wait for APLL_PCIE Lock	CM_IDLEST_APLL_PCIE[0] ST_APLL_CLK	=1
Configure the PCIE PHYs to ×1 or ×2 mode	CTRL_CORE_PCIE_CONTROL[3:2] PCIE_B1C0_MODE_SEL	0x0 (×1 mode) 0x1 (×2 mode)
	CTRL_CORE_PCIE_CONTROL[0] PCIE_B0_B1_TSYNCEN	0 (×1 mode) 1 (×2 mode)
Enable the CLKVCOLDO clock for the PCIESS1 PHY	CM_PCIE_PCIESS1_CLKCTRL[9] OPTFCLKEN_PCIEPHY_CLK	1
Enable the CLKVCOLDO_DIV clock for the PCIESS1 PHY	CM_PCIE_PCIESS1_CLKCTRL[10] OPTFCLKEN_PCIEPHY_CLK_DIV	1
IF: PCIESS2 is enabled	Software test condition	
Enable the CLKVCOLDO clock for the PCIESS2 PHY	CM_PCIE_PCIESS2_CLKCTRL[9] OPTFCLKEN_PCIEPHY_CLK	1
Enable the CLKVCOLDO_DIV clock for the PCIESS2 PHY	CM_PCIE_PCIESS2_CLKCTRL[10] OPTFCLKEN_PCIEPHY_CLK_DIV	1
ENDIF		
IF: Either PCIESS1 Second Lane or PCIESS2 is required (both are available via USB3 PHY)	Software test condition	
Configure USB3PHYTX to select the CLK_SLICER clock	USB3PHYTX_TEST_CONFIG_REG[31] MEM_ENTESTCLK	1
Configure USB3PHYRX to select the PLLBYPCLK input clock	USB3PHYRX_ANA_PROGRAMMABILITY_REG1[7] MEM_EN_PLLBYP	1
ENDIF		
Configure the PCIESS1 Power Control clock frequency to match SYS_CLK1 in MHz	CTRL_CORE_PHY_POWER_PCIESS1[31:22] PCIESS1_PWRCTL_CLKFREQ	0x14 (20 MHz)
Power up PCIESS1_PHY_TX and PCIESS1_PHY_RX	CTRL_CORE_PHY_POWER_PCIESS1[21:14] PCIESS1_PWRCTL_CMD	0x3
IF: Either PCIESS1 Second Lane or PCIESS2 is required	Software test condition

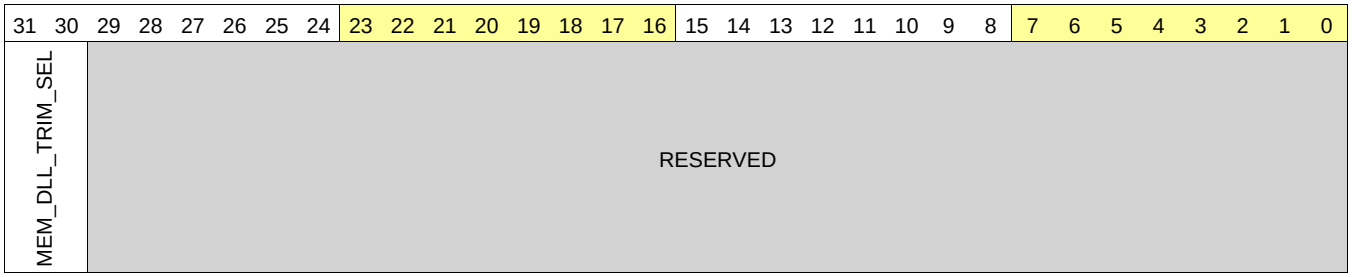
Table 26-68. PCIEPHYRX_TRIM_REG4

Address Offset	0x0000 001C		
Physical Address	0x4A09 401C	**Instance**	PCIe1_PHY_RX
Description	The IP requires some values to be remembered in EFUSE. This register provides an alternative to EFUSE.		
Type	RW		



Bits	Field Name	Description	Type	Reset
31:30	MEM_DLL_TRIM_SEL	Determines which of the 4 EFUSE registers EFUSE_dll_rateN_coarsetrim should be used as the trim code by the DLL. This feature is so that the user may find and store the trim codes corresponding to different (at most 4) DLL frequencies (pll_clk pll_clk (after the bypassing by MEM_en_pllbyp and the division by MEM_plldiv) frequencies) and at wake-up, instruct the IP to choose one of these available trim values depending on the Application's frequency requirement. 00 selects dll_rate0_coarsetrim 01 selects dll_rate1_coarsetrim 10 selects dll_rate2_coarsetrim 11 selects dll_rate3_coarsetrim.	RW	0x0
29:0	RESERVED		RW	0x0000 0000

Table 26-72. PCIEPHYRX_DIGITAL_MODES_REG1

Address Offset	0x0000 0028		
Physical Address	0x4A09 4028	**Instance**	PCIe1_PHY_RX
Description	This register contains control bits which affect different circuits in digital section		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MEM_INV_RXPN_PAIR	MEM_OVRD_INV_RXPN_PAIR	RESERVED	MEM_HS_RATE		MEM_OVRD_HS_RATE	RESERVED		MEM_CDR_FASTLOCK	MEM_CDR_LBW		MEM_CDR_STEPCNT		MEM_CDR_STL			MEM_CDR_THR			MEM_CDR_THR_MODE	MEM_CDR_2NDO_SDM_MODE	RESERVED									

Bits	Field Name	Description	Type	Reset
31	MEM_INV_RXPN_PAIR	If '1', interchanges RXP and RXN effectively by inverting the received data samples.	RW	0
30	MEM_OVRD_INV_RXPN_PAIR	Pin override control. See register bit MEM_inv_rxpn_pair.	RW	0
29	RESERVED		R	0
28:27	MEM_HS_RATE	Determines the ratio of pll_clk (after the bypassing by MEM_en_pllbyp and the division by MEM_plldiv) frequency and the output data rate. Full Rate means pll_clk (after the bypassing by MEM_en_pllbyp and the division by MEM_plldiv) frequency = Data Rate/2 00=Full Rate 01=Half Rate 10=Quarter Rate 11=RESERVED. This takes effect only if register bit MEM_ovrd_hs_rate is '1', else the same is controlled by input pins hs_rate.	RW	0x0
26	MEM_OVRD_HS_RATE	Pin override control. See register bit MEM_hs_rate.	RW	0
25:24	RESERVED		R	0x2
23	MEM_CDR_FASTLOCK	'1' to reduce lock time of CDR (clock-data-recovery circuit).	RW	1
22:21	MEM_CDR_LBW	CDR band-width control.	RW	0x3

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
20:19	MEM_CDR_STEPCNT	CDR 2nd order setting.	RW	0x0
18:16	MEM_CDR_STL	CDR settling time. Determines the number of vote clocks to blank ELV (Early-Late-Voter circuit) after update of phase.	RW	0x3
15:13	MEM_CDR_THR	CDR 1st order threshold. Determines how much early/late votes should differ by before a phase change in the receiver sampling clock is triggered.	RW	0x1
12	MEM_CDR_THR_MODE	CDR 1st order threshold.	RW	1
11	MEM_CDR_2NDO_SDM_MODE	If '1', the 2nd Order CDR block uses a 1st order Sigma Delta Modulator to accomplish frequency offset If '0', a simple rate transformer is used for the same purpose.	RW	0
10:0	RESERVED		R	0x000

Table 26-74. PCIEPHYRX_EQUALIZER_REG1

Address Offset	0x0000 0038		
Physical Address	0x4A09 4038	**Instance**	PCIe1_PHY_RX
Description	The module has an Equalizer (with analog and digital parts) which addresses Inter Symbol Interference (ISI). The equalizer can be configured via the EQCTL bits. The options are: No adaptive equalization. The equalizer provides a flat response at the maximum gain. This setting may be appropriate if jitter at the receiver occurs predominantly as a result of crosstalk rather than frequency dependent loss. Fully adaptive equalization. Both the low frequency gain and zero position of the equalizer are determined algorithmically by analysing the data patterns and transition positions in the received data. This setting should be used for most applications. Partially adaptive equalization. The low frequency gain of the equalizer is determined algorithmically by analysing the data patterns and transition positions in the received data. The zero position is fixed in one of eight zero positions. When enabled, the receiver equalization logic analyzes data patterns and transition times to determine whether the low frequency gain of the equalizer should be increased or decreased. For the fully adaptive setting (EQCTL = 0001), if the low frequency gain reaches the minimum value, the zero frequency is then reduced. Likewise, if it reaches the maximum value, the zero frequency is then increased.

27.1 General-Purpose Interface Overview

The general-purpose interface combines eight general-purpose input/output (GPIO) banks.

Each GPIO module provides 32 dedicated general-purpose pins with input and output capabilities; thus, the general-purpose interface supports up to 256 (8 × 32) pins. Some of the pins may be reserved in this Device. For more information of the supported number of GPIO pins, see the device Data Manual.

These pins can be configured for the following applications:

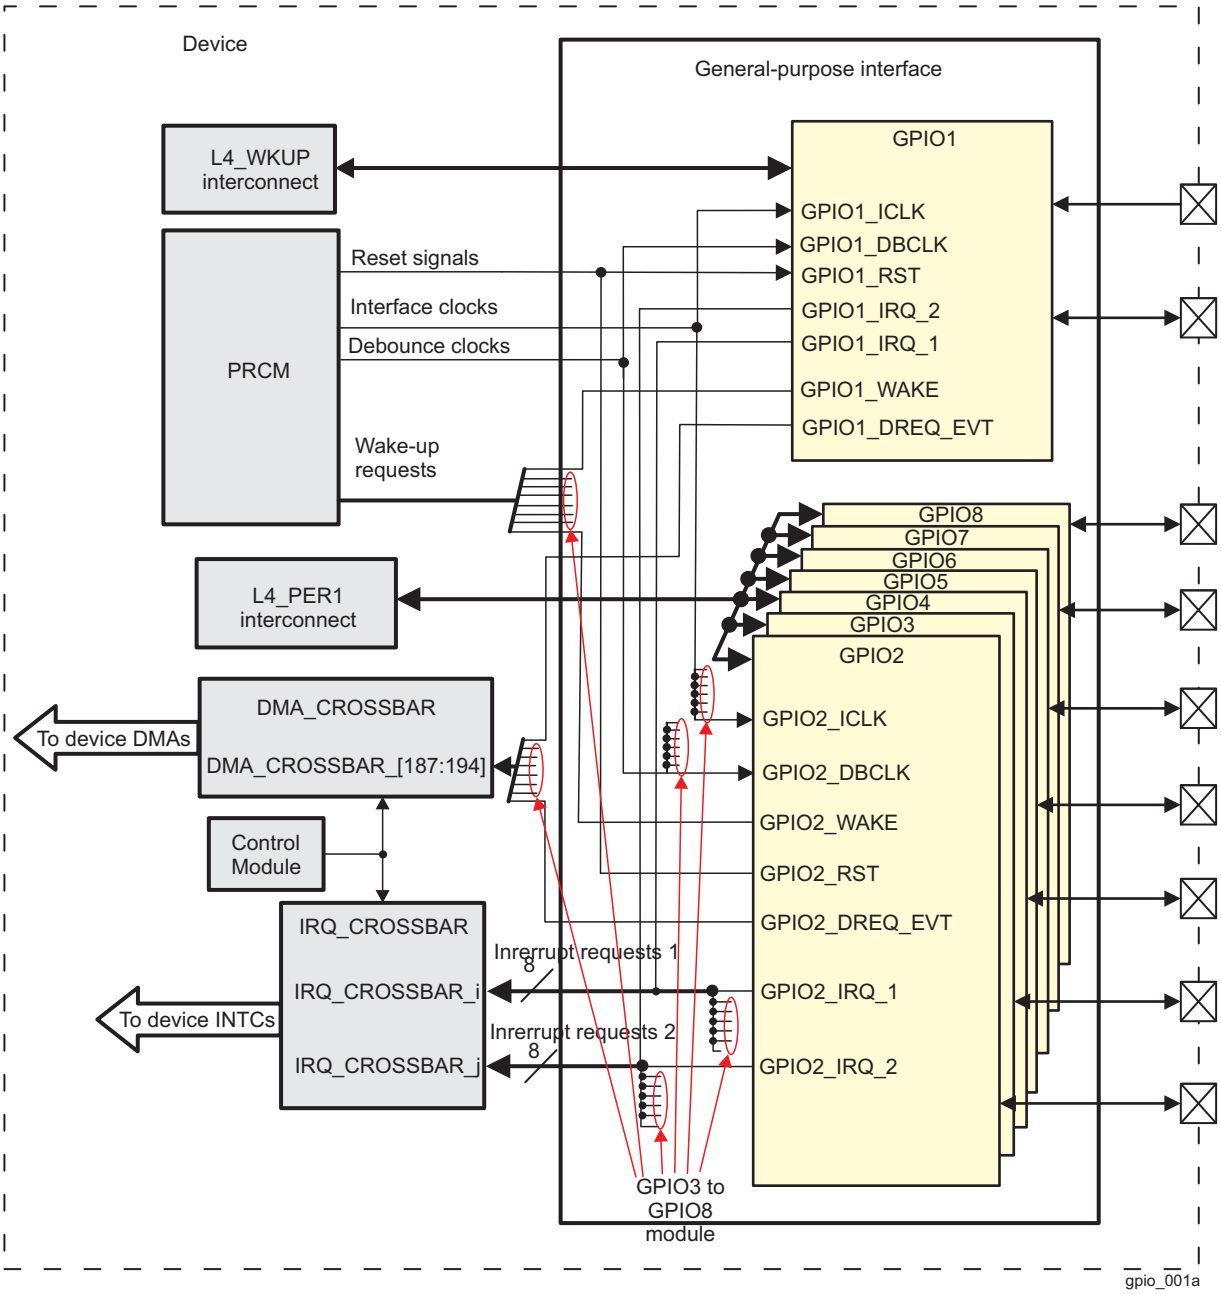
- Data input (capture)/output (drive)
- Keyboard interface with a debounce cell
- Interrupt generation in active mode upon the detection of external events. Detected events are processed by two parallel independent interrupt-generation submodules to support biprocessor operations.
- Wake-up request generation in idle mode upon the detection of external events

These modules do not include pad control (pullup/down control, open-drain feature). For more information, see Section 18.4.6.1.1, *Pad Configuration Registers,* in Chapter 18, *Control Module*.

Figure 27-1 is an overview of the general-purpose interface.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 27-1. General-Purpose Interface Overview



The GPIO modules include the following global features:

- Two identical submodules can process synchronous interrupt requests from each channel to be used independently in a biprocessor environment. Each submodule controls its own synchronous interrupt request line. Each submodule also has its own interrupt-enable and interrupt status registers. The interrupt-enable register (GPIO_IRQSTATUS_SET_x [where x = 0 or 1]) selects the channel considered for the interrupt request generation. The interrupt status register (GPIO_IRQSTATUS_RAW_x) determines which channel has activated the interrupt request. Event detection on GPIO channels is reflected into GPIO_IRQSTATUS_RAW independently from the content of the interrupt-enable registers.
- Wake-up requests in idle mode from input channels are merged together to issue one wake-up signal per GPIO module.
- Data input (capture)/output (drive)

Copyright © 2015–2017, Texas Instruments Incorporated

- Power-management support

The general-purpose interface has 16 interrupt lines (two interrupt lines on GPIO1 through GPIO8 modules).

Each GPIO module produces a wake-up request signal to the power, reset, and clock management (PRCM) module.

Each channel in the GPIO modules has the following features:

- The GPIOi.GPIO_OE register controls the output capability for each pin.
- The output line level reflects the value written in the GPIOi.GPIO_DATAOUT register through the level 4 (L4_WKUP and L4_PER1) interconnect.
- The input line can be fed to the GPIO module through an optional and configurable debounce cell. (Because the debouncing time value is global for all ports of one GPIO module, up to five different debouncing time values are possible.)
- The value of the input line is sampled into the GPIOi.GPIO_DATAIN register and can be read through the L4 (L4_WKUP and L4_PER1) interconnect.
- In active mode, the input line can be used through level and edge detectors to trigger synchronous interrupts. The edge (rising, falling, or both) or the level used (logical 0, logical 1, or both) can be configured.
- In idle mode, the input line can be used to activate the asynchronous wake-up request (on edge detection: rising edge, falling edge, or both).

The module provides an alternative to the atomic test and set operations for the data-output register (GPIO_DATAOUT). For this register, the module implements the set-and-clear protocol register update (see Section 27.4.9, *General-Purpose Interface Set-and-Clear Protocol*).

All module registers are 8-, 16-, or 32-bit accessible through the OCP-compatible interface (little-endian encoding)

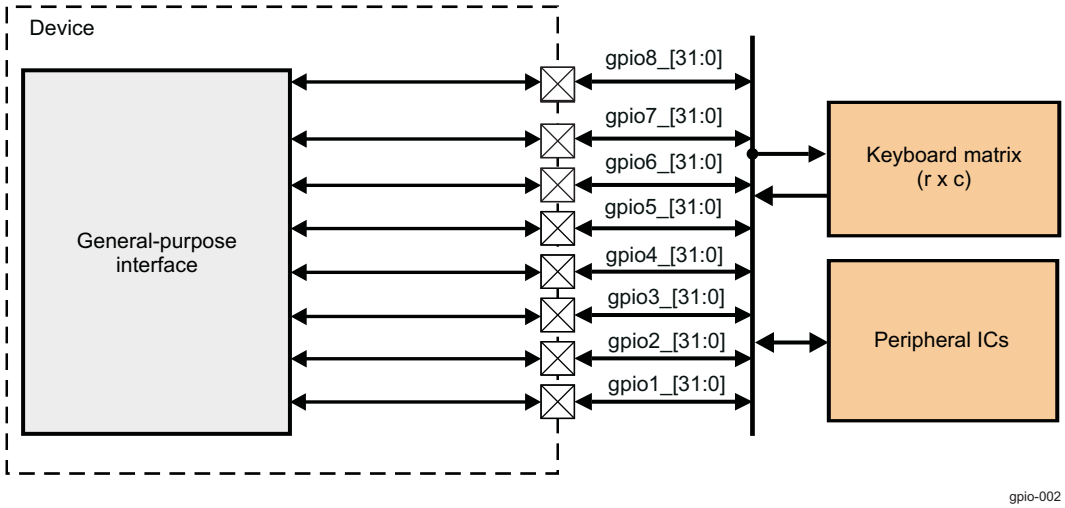
Copyright © 2015–2017, Texas Instruments Incorporated

27.2 General-Purpose Interface Environment

The general-purpose interface combines eight GPIO modules for a flexible, user-programmable, general-purpose input/output (I/O) controller. The general-purpose interface implements functions that are not implemented with the dedicated controllers in the device and require simple input and/or output software-controlled signals. The GPIO allows a variety of custom connections and expands the I/O capabilities of the system to the real world.

Figure 27-2 shows a typical application using the general-purpose interface.

Figure 27-2. General-Purpose Interface Typical Application



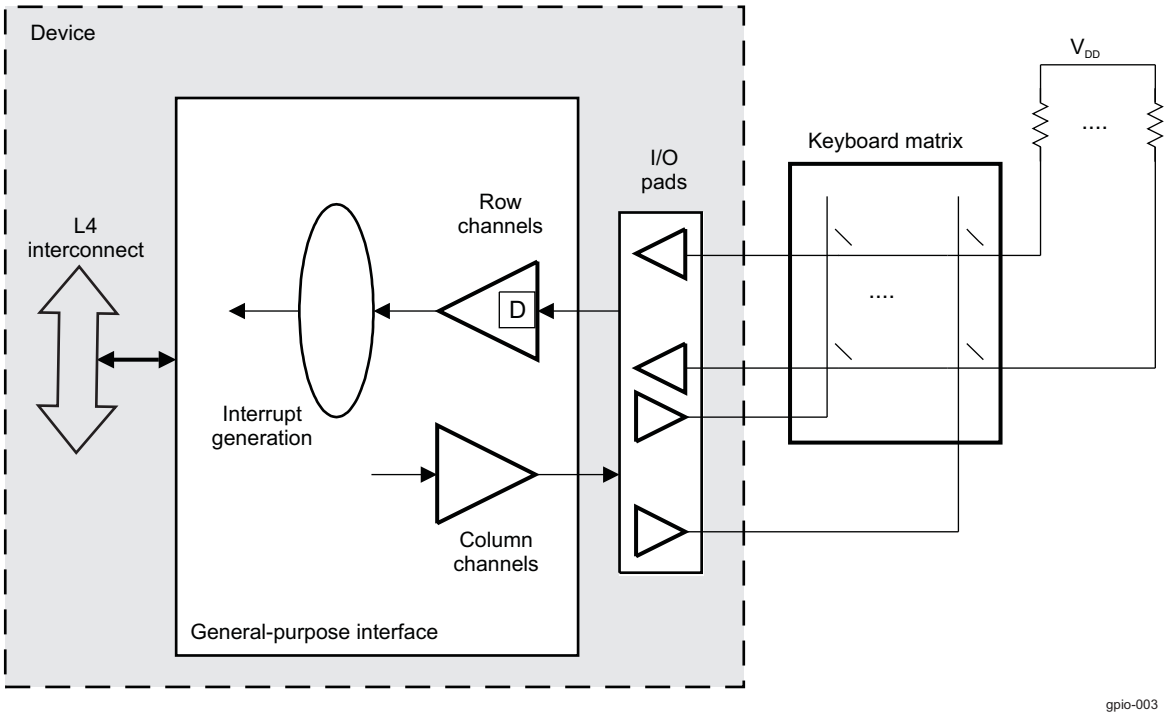
The general-purpose interface can physically connect the device to a keyboard matrix and peripheral integrated circuits (ICs).

27.2.1 General-Purpose Interface as a Keyboard Interface

The general-purpose interface can be used as a keyboard interface. Channels can be dedicated based on the keyboard matrix (r × c). Figure 27-3 shows row channels configured as inputs with the input debounce feature enabled. The row channels are driven high with an external pullup. Column channels are configured as outputs and drive a low level.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 27-3. General-Purpose Interface Used as a Keyboard Interface



When a keyboard matrix key is pressed, the corresponding row and column lines are shorted together and a low level is driven on the corresponding row channel. This generates an interrupt based on the proper configuration (see Section 27.4.6, *Interrupt and Wake-up Requests*).

When the keyboard interrupt is received, the processor (microprocessor unit [MPU] and/or digital signal processor [DSP] subsystem) can disable the keyboard interrupt and scan the column channels for the key coordinates.

- The scanning sequence has as many states as column channels: For each step in the sequence, the processor drives one column channel low and the others high.
- The processor reads the values of the row channels and thus detects which keys in the column are pressed.

At the end of the scanning sequence, the processor establishes which keys are pressed. The keyboard interface can then be reconfigured in the interrupt waiting state.

27.2.2 General-Purpose Interface Signals

Table 27-1 describes the module signals.

Table 27-1. I/O Description

Signal	I/O[1]	Description	Reset Value[2]
gpio1_0	I	GPIO (input only)	Hi-Z
gpio1_3	I	GPIO (input only)	Hi-Z
gpio1_[4:31]	I/O	GPIO	Hi-Z
gpio2_[0:29]	I/O	GPIO	Hi-Z
gpio3_[28:31]	I/O	GPIO	Hi-Z
gpio4_[0:31]	I/O	GPIO	Hi-Z
gpio5_[0:31]	I/O	GPIO	Hi-Z
gpio6_[4:31]	I/O	GPIO	Hi-Z

(1) I = Input; O = Output; I/O = Bidirectional
(2) Hi-Z = High Impedance

GPIO7	GPIO7_DREQ_EVT	DMA_CROSSBAR_193	N/A	GPIO7 module - event/interrupt1.This DREQ source signal is not mapped by default to any device DMA controller.
GPIO8	GPIO8_DREQ_EVT	DMA_CROSSBAR_194	N/A	GPIO8 module - event/interrupt1.This DREQ source signal is not mapped by default to any device DMA controller.

NOTE: The "**Default Mapping**" column in Table 27-4 *GPIO Hardware Requests* shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.
For more information about the IRQ_CROSSBAR module, see Section 18.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 18, *Control Module*.
For more information about the DMA_CROSSBAR module, see Section 18.4.6.5, *DMA_CROSSBAR Module Functional Description*, in Chapter 18, *Control Module*.
For more information about the device interrupt controllers, see Chapter 17, *Interrupt Controllers*.

NOTE: For the description of the interrupt source, see Section 27.4.6, *Interrupt and Wake-Up Requests.*

27.4 General-Purpose Interface Functional Description

27.4.1 General-Purpose Interface Block Diagram

Figure 27-7 shows the general-purpose interface block diagram.

Figure 27-7. General-Purpose Interface Block Diagram

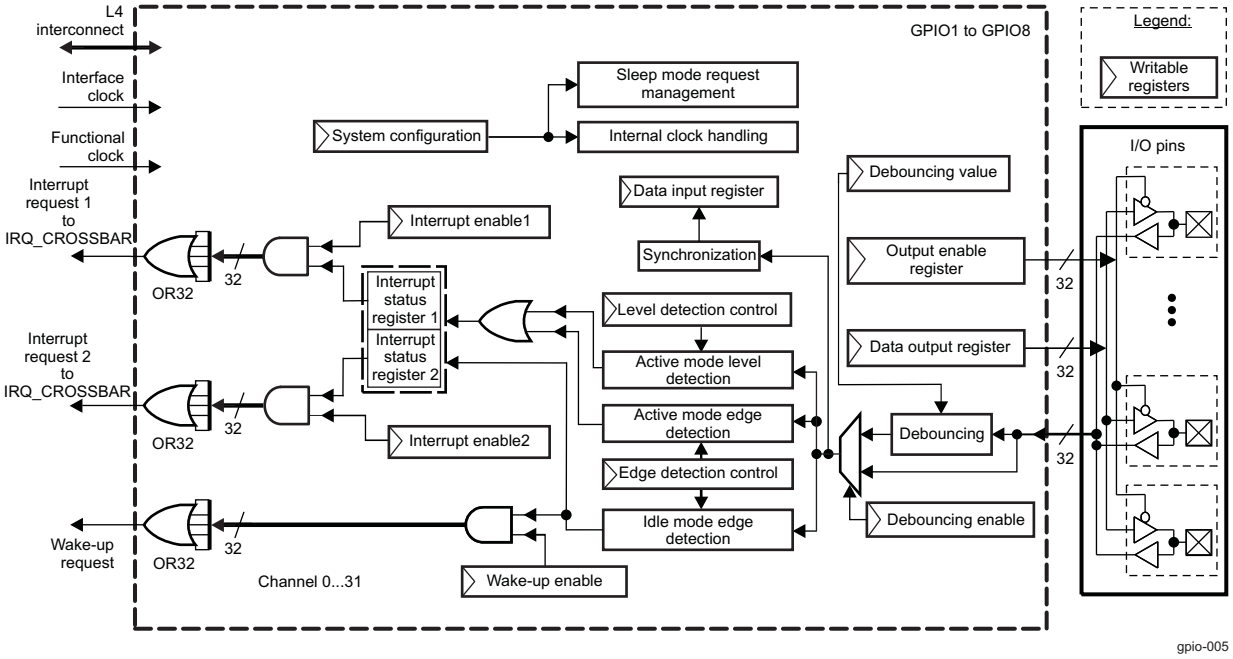

Figure 27-7 shows the details of the GPIO modules in the general-purpose interface block diagram, including their configuration registers and main functional paths:

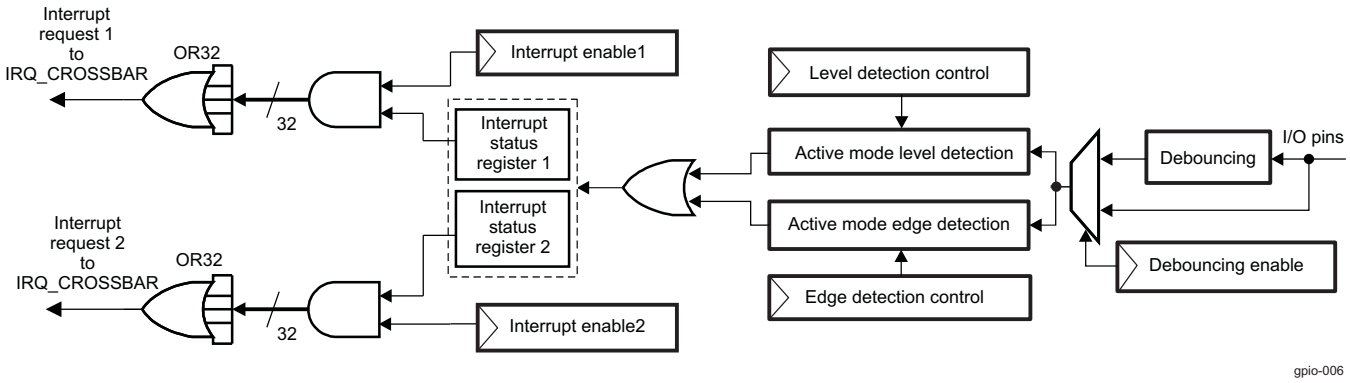
- The synchronous path (for active mode operation) used to generate a synchronous interrupt request on expected event detection on any input GPIO. Synchronous interrupt request lines 1 and 2 are active based on their respective interrupt-enable1 and 2 registers (GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_SET_1, GPIOi.GPIO_IRQSTATUS_CLR_0, and GPIOi.GPIO_IRQSTATUS_CLR_1). See Figure 27-8.

Figure 27-8. Synchronous Path



- The asynchronous path (for idle mode operation) used to generate an asynchronous wake-up request on the expected edge detection on any input GPIO. The asynchronous wake-up request line is active based on the wake-up-enable register. See Figure 27-9.

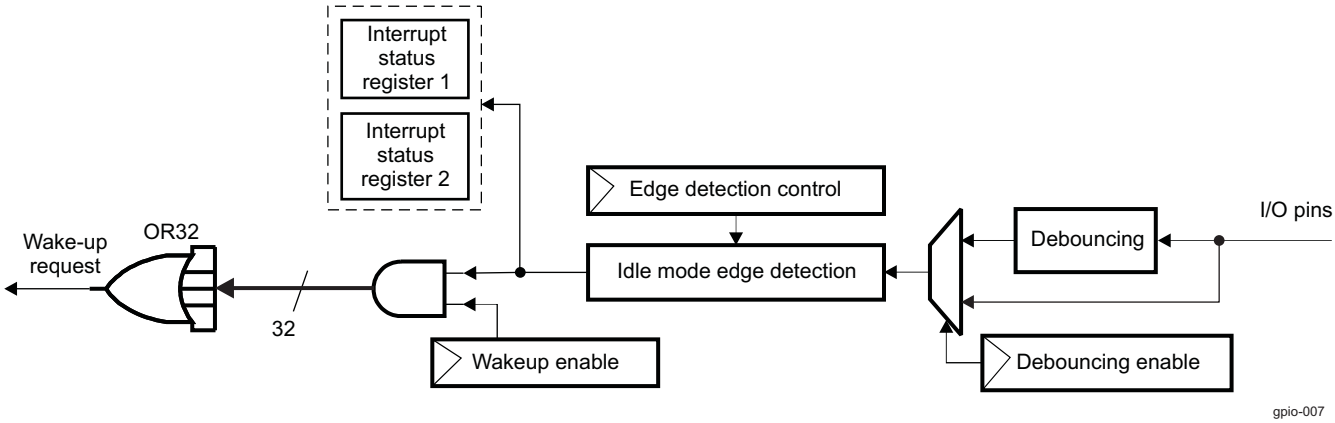
Figure 27-9. Asynchronous Path



- The blocks handling the internal clock (clock gating) and managing the sleep mode request/acknowledge protocol (enabling the synchronous path in active mode and the asynchronous path in idle mode)

27.4.2 General-Purpose Interface Interrupt and Wake-Up Features

27.4.2.1 Synchronous Path: Interrupt Request Generation

The general-purpose interface has 14 interrupt lines (two interrupt lines per GPIO module instance for biprocessor operation for GPIO1 through GPIO6 and one interrupt line for GPIO7 and GPIO8 module instance). The 16 interrupt signals are GPIOi_IRQ_1 (used by the MPU, DSP and IPU subsystems) and GPIOi_IRQ_2 (used by the CROSSBAR), where i = 1 to 8.

Synchronous interrupt requests from each channel are processed by two identical interrupt generation submodules used independently by the CROSSBAR subsystem on one side and by the MPU, IPU, and DSP subsystems on the other side. Each submodule controls its own synchronous interrupt request line and has its own interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_SET_1, GPIOi.GPIO_IRQSTATUS_CLR_0, and GPIOi.GPIO_IRQSTATUS_CLR_1) and interrupt status registers (GPIOi.GPIO_IRQSTATUS_RAW_0 and GPIOi.GPIO_IRQSTATUS_RAW_1). The interrupt-enable register selects the channel(s) considered for the interrupt request generation, and the interrupt status register determines which channel(s) activate the interrupt request. Event detection on GPIO channels is reflected in the interrupt status registers independent of the content of the interrupt-enable registers.

In active mode, when the GPIO configuration registers are set to enable the interrupt generation (see Section 27.4.6, *General-Purpose Interface Interrupt and Wake-Up Requests*), a synchronous path samples the transitions and levels on the input GPIO with the internally gated interface clock (see Section 27.4.5.2.4, *Module Power Saving*). When an event matches the programmed settings (see Section 27.4.6, *General-Purpose Interface Interrupt and Wake-Up Requests*), the corresponding bit in the interrupt status register (GPIO_IRQSTATUS_RAW_x [where x = 0 or 1]) is set to 1, and on the following interface clock cycle, interrupt lines 1 and/or 2 are activated (depending on the interrupt-enable registers GPIO_IRQSTATUS_SET_x [where x = 0 or 1]).

Because of the sampling operation, the minimum pulse width on the input GPIO to trigger a synchronous interrupt request is two times the internally gated interface clock period (that is, *N* times the interface clock period; see Section 27.4.5.2.4, *Module Power Saving*). This minimum pulse width must be met before and after any expected level transition detection. Level detection requires the selected level to be stable for at least two times the internally gated interface clock period to trigger a synchronous interrupt.

Because the module is synchronous, latency is minimal between the expected event occurrence and the activation of the interrupt line(s). This latency must not exceed three internally gated interface clock cycles plus two interface clock cycles when the debounce feature is not used.

Copyright © 2015–2017, Texas Instruments Incorporated

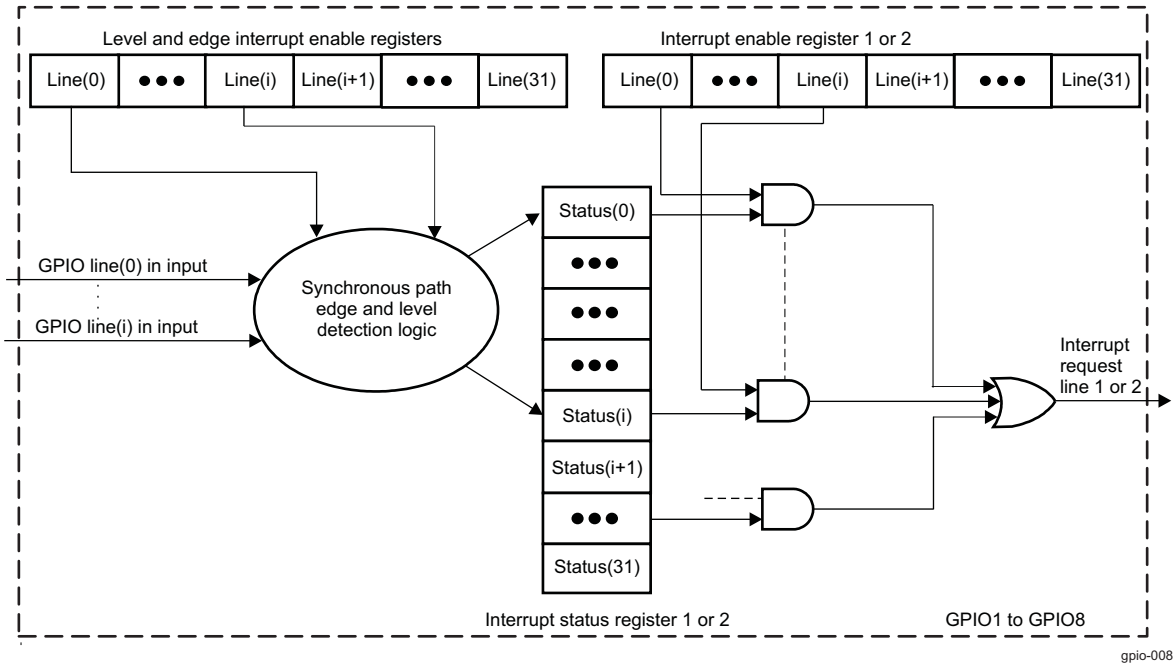
When the debounce feature is active, the latency depends on the value of the debouncing time register (GPIOi.GPIO_DEBOUNCINGTIME) (see Section 27.4.3, *General-Purpose Interface Clock Configuration*) and is less than three internally gated interface clock cycles plus two interface clock cycles plus GPIOi.GPIO_DEBOUNCINGTIME register value debounce clock cycles plus three debounce clock cycles.

Synchronous interrupt request line 1 is default mapped on the MPU, IPU, DSP subsystems.

Synchronous interrupt request line 2 is mapped on the CROSSBAR.

Figure 27-10 is an overview of the interrupt request generation.

Figure 27-10. Interrupt Request Generation



27.4.2.2 Asynchronous Path: Wake-Up Request Generation

The general-purpose interface has eight wake-up lines (one wake-up line per GPIO module instance) connected to the PRCM module.

Asynchronous wake-up requests from input channels are merged to issue one wake-up signal to the system per GPIO module. The wake-up-enable registers (GPIOi.GPIO_IRQWAKEN_0 and GPIOi.GPIO_IRQWAKEN_1) select the channel(s) considered for the wake-up request generation. The asynchronous wake-up request is reflected into the synchronous interrupt status registers (GPIOi.GPIO_IRQSTATUS_RAW_0 and GPIOi.GPIO_IRQSTATUS_RAW_1).

In idle mode (the interface clock is shut down and the GPIO configuration registers are programmed; see Section 27.4.6, *General-Purpose Interface Interrupt and Wake-Up Requests*), an asynchronous path detects the expected transition(s) on a GPIO input (based on register programming) and activates an asynchronous wake-up request by the sideband signal (GPIOi_SWAKEUP [where i = 1 to 8), if the wake-up-enable register is set.

When the system is awakened, the interface clock is restarted and synchronously set to 1 based on the input GPIO pin triggering the wake-up request and the corresponding bit in the interrupt status registers (GPIOi.GPIO_IRQSTATUS_RAW_0 and GPIOi.GPIO_IRQSTATUS_RAW). On the following internal clock cycle, interrupt lines 1 and/or 2 are active (active high) when the corresponding bits are set in the interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_CLR_0, and GPIOi.GPIO_IRQSTATUS_CLR_1).

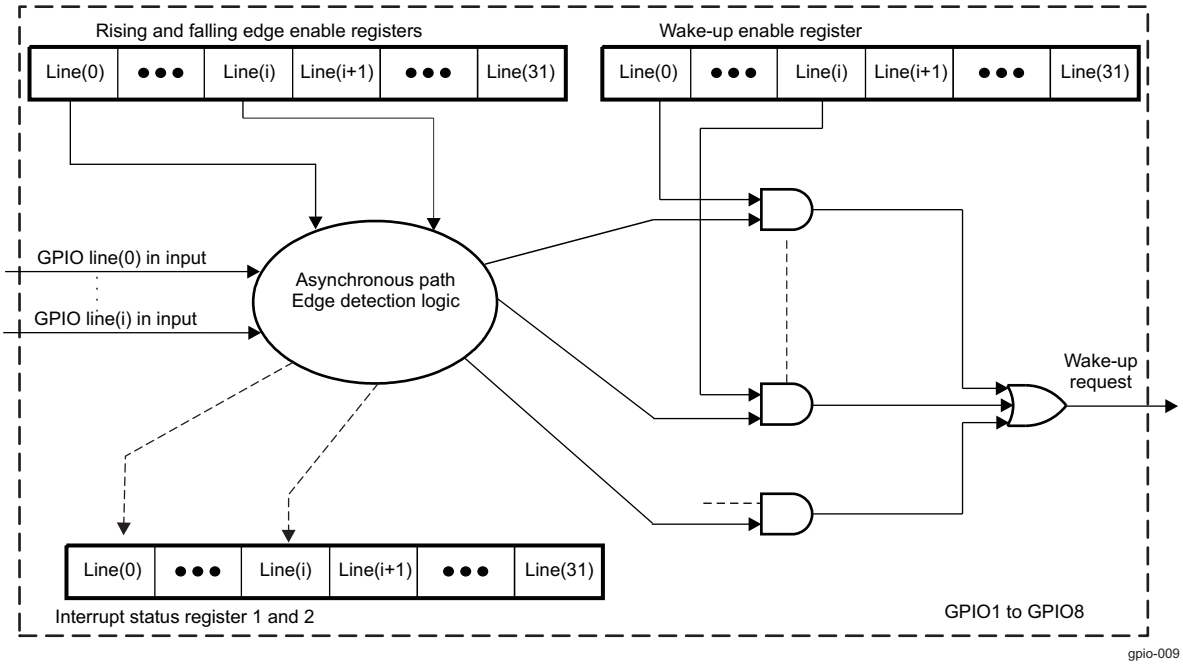
Copyright © 2015–2017, Texas Instruments Incorporated

NOTE:

- If the debouncing is not enabled, there is no minimum input pulse width to trigger the wake-up request, because there is no sampling operation.
- If the debouncing is used, the minimum pulse width is set by the debouncing specified time.
- The ENAWAKEUP bit of the GPIO_SYSCONFIG register allows the enabling or disabling of the GPIO wake-up feature globally: if this bit is set to 0, GPIO_IRQWAKEN_x has no effect

Figure 27-11 is an overview of the wake-up request generation.

Figure 27-11. Wake-Up Request Generation



27.4.2.3 Wake-Up Event Conditions During Transition To/From IDLE State

In phase A, only the synchronous path is enabled. A synchronous interrupt request (see Section 27.4.2.1, *Synchronous Path: Interrupt Request Generation*) activates the interrupt line(s) and prevents the GPIO from transitioning into IDLE state until the interrupt is cleared.

In phase B, the asynchronous path and synchronous path are enabled during the first five functional clock cycles of SLEEPTRANS state. During this period a synchronous interrupt request (see Section 27.4.2.1, *Synchronous Path: Interrupt Request Generation*) prevents the GPIO from transitioning into IDLE state. A shorter pulse puts the module into IDLE state but triggers a wakeup once in IDLE.

In phase C, only the asynchronous path is enabled. A wake-up request (see Section 27.4.2.2, *Asynchronous Path: Wake-Up Request Generation*) triggers a wake-up request from the GPIO and when the module is awakened an interrupt is generated. If debouncing is not enabled, there is no minimum input pulse width to trigger the wake-up request.

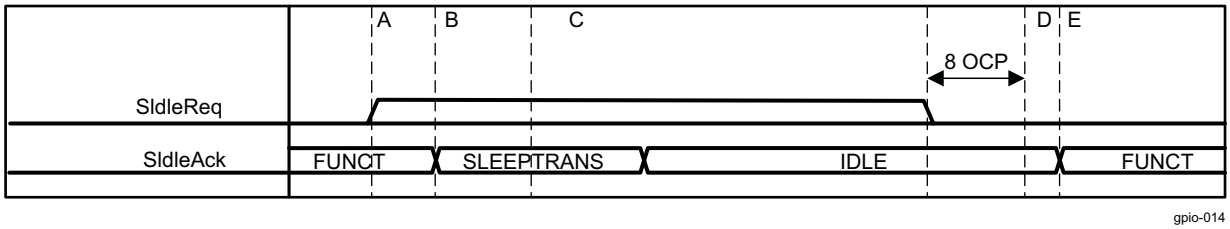
In phase D, eight open-core protocol (OCP) clock cycles occur until the module is in FUNCT state, the synchronous path is enabled, and an event that fulfills the pulse width requirements (see Section 27.4.2.1, *Synchronous Path: Interrupt Request Generation*) activates the interrupt line(s).

In phase E, only the synchronous path is enabled. A synchronous interrupt request (see Section 27.4.2.1, *Synchronous Path: Interrupt Request Generation*) activates the interrupt line(s).

Figure 27-12 shows the wake-up event conditions.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 27-12. Wake-Up Event Conditions



27.4.2.4 Interrupt (or Wake-Up) Line Release

When the host processor (the MPU and/or DSP subsystem in the device) receives an interrupt request issued by the GPIO module, it reads the corresponding interrupt status register (GPIOi.GPIO_IRQSTATUS_0 or GPIOi.GPIO_IRQSTATUS_1) to determine which GPIO input triggered the interrupt (or the wake-up request).

After servicing the interrupt (or acknowledging the wake-up request), the software resets the status bit and releases the interrupt line by setting the corresponding bit of the interrupt status register to 1. If there is still a pending interrupt request to serve (all bits in the interrupt status register that are not masked by the interrupt-enable register are not cleared), the interrupt line is reasserted.

NOTE: The status bit must be reset to re-enter idle mode.

Copyright © 2015–2017, Texas Instruments Incorporated

27.4.3 General-Purpose Interface Clock Configuration

27.4.3.1 Clocking

Each GPIO module uses two clocks:

- Debounce clock: The 32-kHz debounce clock, GPIOi_DBCLK (where i = 1 to 8 with one debounce clock per module), comes from the PRCM module and is used to debounce the submodule logic (without the corresponding configuration registers). This module can sample the input line and filter the input level using a programmed delay.

  The debouncing value register (GPIOi.GPIO_DEBOUNCINGTIME) is used to set the debouncing time for all input lines in the GPIO module. Because the value is global for all the ports of one GPIO module, up to eight different debouncing values are possible. The debounce cell runs with the debounce clock (32 kHz). This register represents the number of clock cycle(s) to be used.

  The following formula describes the required input stable time to be propagated to the debounced output:

  Required input line stable = (the value of the GPIOi.GPIO_DEBOUNCINGTIME[7:0] DEBOUNCETIME bit field + 1) × 31,

  where the value of the GPIOi.GPIO_DEBOUNCINGTIME[7:0] DEBOUNCETIME bit field is from 0 to 255.

  For more information, see Section 3.6.4.5, *CD_L4_PER1 Clock Domain*, and Section 3.6.4.1, *CD_WKUPAON Clock Domain*, in Chapter 3, *Power, Reset, and Clock Management*.
- Interface clock: The interface clock, GPIOi_ICLK (where i = 1 to 8), comes from the PRCM module and is used throughout the GPIO module (except within the debounce cell logic). GPIOi_ICLK clocks the data exchanges between the L4 interconnect and the internal logic. The clock-gating features allow module power consumption to be adapted to the activity.

  For more information, see Section 3.6.4.5, *CD_L4_PER1_Clock Domain*, and Section 3.6.4.1, *CD_WKUPAON Clock Domain*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 27-3 describes the clocks in the GPIO modules.

Table 27-5 summarizes the functional clock configuration.

Table 27-5. Functional Clock Configuration

Interface Clock	GPIO_CTRL[2:1]GATINGRATIO	Functional Clock
GPIOi_ICLK (where i = 1 to 8)	00	GPIOi_ICLK /1
GPIOi_ICLK (where i = 1 to 8)	01	GPIOi_ICLK /2
GPIOi_ICLK (where i = 1 to 8)	10	GPIOi_ICLK /4
GPIOi_ICLK (where i = 1 to 8)	11	GPIOi_ICLK /8

27.4.4 General-Purpose Interface Hardware and Software Reset

The GPIO can be reset by using the domain reset (hardware reset) or by setting a dedicated configuration bit (software reset) in each GPIO module.

- Hardware reset: The GPIO2 to GPIO8 modules are attached to the L4PER_RET_RST reset domain. GPIO1 is attached to the WKUPAON_RST reset domain.

  The hardware reset has a global reset action on the GPIO modules of the general-purpose interface. All configuration registers and internal logic are reset when it is active (low level). In each GPIO module, the GPIOi.GPIO_SYSSTATUS[0] RESETDONE bit monitors the internal reset status; it is set when the reset completes. For more information, see Section 3.5.5, *Reset Domains*, in Chapter 3, *Power, Reset, and Clock Management*.
- Software reset: Each GPIO module has its own software reset using the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit. The software reset has the same effect as the hardware reset signal, but this reset can be applied on one or more modules.

  Setting the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit to 1 resets the module. A bit value of 1 remains until the reset completes. When the software reset completes, the

Copyright © 2015–2017, Texas Instruments Incorporated

GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit is automatically reset to 0 and has the same effect as a hardware reset. The GPIOi.GPIO_SYSSTATUS[0] RESETDONE bit is cleared during a software reset. RESETDONE is set to 1 when the software reset completes.

27.4.5 General-Purpose Interface Power Management

27.4.5.1 Power Domain

GPIO1 is attached to the PD_WKUPAON power domain (see Section 3.1.1.2, *Power Management*, in Chapter 3, *Power, Reset, and Clock Management*). This domain is composed of the logic permanently supplied to manage domain power state transitions and detect wake-up events. The WKUPAON power domain is continuously active. The GPIO2 to GPIO8 modules are attached to the PD_L4PER power domain (see Section 3.1.1.2, *Power Management*, in Chapter 3, *Power, Reset, and Clock Management*). The PD_L4PER power domain is not active continuously.

27.4.5.2 Power Management

27.4.5.2.1 Idle Scheme

To reduce dynamic consumption, an efficient idle scheme is based on the following:

- Efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated and deactivated safely without requiring complex software management.

The idle mode request, idle acknowledge, and wake-up request (GPIOi_WAKEUP) are sideband signals between the PRCM module and the general-purpose interface (see Section 27.4.6.2, *Wake-Up Requests Generation*).

27.4.5.2.2 Operating Modes

Three operating modes are defined for the module:

- Active mode: The module runs synchronously on the interface clock; interrupts can be generated based on the configuration and external signals.
- Idle mode: Power-saving mode with the module in a waiting state. The interface clock can be stopped, an interrupt cannot be generated, and a wake-up signal can be generated based on the configuration and external signals.

  If the debounce clock provided by the PRCM module is active, the debounce cell can sample and filter the input to generate a wake-up event. If the debounce clock is inactive, the debounce cell gates all input signals and thus cannot be used.
- Disabled mode: The module is not used. The internal clock paths are gated, and an interrupt or wake-up request cannot be generated.

Idle mode is configured within the module and activated on request by the host processor through sideband signals (see Section 27.4.5.2.3, *System Power Management and Wakeup*).

The disabled mode is set by software through a dedicated configuration bit, GPIOi.GPIO_CTRL[0] DISABLEMODULE (0: The module is enabled and clocks are not gated; 1: The module is disabled and clocks are gated). It unconditionally gates the internal clock paths that are not used for the system interface. When setting the GPIO_CTRL[0] DISABLEMODULE bit (enabling or disabling the GPIO module), it is important to switch the debouncing clock on or off in the following order:

- The GPIO optional debouncing clock must be enabled before the GPIO module is set (GPIO_CTRL[0]DISABLEMODULE = 0x0).
- The GPIO optional debouncing clock must be disabled after the GPIO module is disabled (GPIO_CTRL[0]DISABLEMODULE = 0x1).

Copyright © 2015–2017, Texas Instruments Incorporated

27.4.5.2.3 System Power Management and Wakeup

The PRCM module can require the GPIO modules to be idled for power-saving purposes.

The general-purpose interface has eight identical idle mode request/acknowledge (handshake) mechanisms with the PRCM module (see Section 27.4.6.2, *Wake-Up Requests Generation*): one per GPIO module. The general-purpose interface allows the GPIO modules to enter idle mode based on the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field.

Idle acknowledge depends on the configuration and activity of each GPIO module:

- Smart-idle mode

  When the GPIO module is configured in smart-idle mode, it checks for more activity (capture of the input GPIO pins in the GPIOi.GPIO_DATAIN register is complete with no pending interrupt; all interrupt status bits are cleared), and there is no write access to the GPIO.GPIO_DEBOUNCINGTIME register, which is waiting to be synchronized.

  Idle acknowledge is then asserted and the module enters into idle mode. It waits for active system clock gating by the PRCM module (when all peripherals supplied by the same L4 interface clock domain are also ready for idle).

  In idle mode (that is, when the PRCM module gates the interface clock), no interrupt occurs.

- Smart-idle wake-up mode

  If the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field selects smart-idle or smart-idle wake-up mode, the GPIO module evaluates its internal capability to have the interface clock switched off. Once all internal activity ceases (the DATA INPUT REGISTER completed to capture the input GPIO pins, there is no pending interrupt, all interrupt status bits are cleared, and there is no write access to the GPIO_DEBOUNCINGTIME register pending to be synchronized), the idle acknowledge is asserted and the GPIO enters into Idle mode, ready to issue a wake-up request when the expected transition occurs on an enabled GPIO input pin. This wake-up request is effectively sent only if the GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP bit of the system configuration register enables the GPIO wake-up capability (see). When the system is awake, the IDLE request goes inactive, the idle acknowledge and wake-up request (if the GPIO triggered the wake-up in the system) signals are immediately deasserted, and the asynchronous wake-up request (if it exists) is reflected into the synchronous interrupt status registers.

- Force-idle mode

  When the GPIO module is configured in force-idle mode (the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field = 0x0) and receives an IDLE request from the PRCM module, the GPIO module waits unconditionally for active system clock gating by the PRCM module. (This occurs only when all peripherals supplied by the same L4 interface clock domain are also ready for idle.)

  When in idle mode (that is, when the PRCM module gates the interface clock), the module (in inactive mode) has no activity, the interface clock paths are gated, an interrupt cannot be generated, and the wake-up feature is totally inhibited.

- No-idle mode

  When the GPIO module is configured in no-idle mode (the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field = 0x1) and receives an IDLE request from the PRCM module, the GPIO module does not go into idle mode and the idle acknowledge is never sent.

NOTE: For more information about the idle modes, see Section 3.1.1.2, *Power Management*, in Chapter 3, *Power, Reset, and Clock Management*.

27.4.5.2.4 Module Power Saving

The GPIO module has local power management by internal clock-gating features:

- Internal interface clock gating: The clock for the system interface logic can be gated when the module is not accessed, if the GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit is set. Otherwise, this logic is free-running on the interface clock.
- Clock gating for the input data sample logic: Clock for the input data sample logic can be gated when the data in the GPIOi.GPIO_DATAIN register is not accessed.

Copyright © 2015–2017, Texas Instruments Incorporated

- Clock gating for the event detection logic: Each GPIO module implements four clock groups used for the logic in the synchronous event detection. Each group of eight input GPIO pins has a separate enable signal depending on the edge/level detection register setting (because the input is 32 bits, four groups of eight inputs are defined for each GPIO module). If a group requires no detection, the corresponding clock is gated off.

  All channels are also gated using a one-out-of-N scheme. N is the GPIOi.GPIO_CTRL[2:1] GATINGRATIO bit field and can take the values 1, 2, 4, and 8. The interface clock is enabled for this logic one cycle every N cycles. When N is 1, there is no gating and this logic is free-running on the interface clock. When N is 2, 4, or 8, this logic runs at the equivalent frequency of interface clock frequency divided by N.
- Inactive mode: In inactive mode, all internal clock paths are gated.
- Disabled mode: All internal clock paths not used for the L4 interconnect are gated. The GPIOi.GPIO_CTRL[0] DISABLEMODULE bit controls a clock-gating feature at the module level. Setting this bit to 1 forces clock gating for all internal clock paths. Module internal activity is suspended. The L4 interconnect is not affected by this bit.

The interface clock gating is controlled with the GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit, which is used to save power when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits.

Table 27-6 describes the power-management features available for the general-purpose interface module.

NOTE: For information about source clock gating and sleep/wake-up transitions, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

For descriptions of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 27-6. Local Power-Management Features

Feature	Register Bits/Bit Fields	Description
Clock autogating	GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE	It sets the clock-gating strategy for the OCP interface block.
Slave-idle modes	GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE	Force-idle, no-idle, and smart-idle wake-up-capable modes are available.
Clock activity	GPIOi.GPIO_CTRL[0] DISABLEMODULE	Enable and disable the module.
Debouncing enable	GPIOi.GPIO_DEBOUNCENABLE[31:0] DEBOUNCEENABLE	Debouncing mode is available.
Global wake-up enable	GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP	This bit enables the wake-up feature at the module level.
Wake-up sources enable	GPIOi.GPIO_IRQWAKEN_0[31:0] INTLINE GPIOi.GPIO_IRQWAKEN_1[31:0] INTLINE	This register enables or disables a specific IRQ request source to generate a wake-up signal.

Table 27-7 describes the clock activity settings.

Table 27-7. Clock Activity Settings

GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE	Selected Mode	Description	Wake-Up Events
00	Force-idle	The GPIO module goes into inactive mode independently of the internal module state, and the IDLE acknowledge is never sent.	No
01	No-idle	The GPIO module does not go into Idle mode and the IDLE acknowledge is never sent.	No

Copyright © 2015–2017, Texas Instruments Incorporated

Table 27-7. Clock Activity Settings (continued)

GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE	Selected Mode	Description	Wake-Up Events
10	Smart-idle	The GPIO module evaluates its internal capability to have the interface clock switched off. If there is no more internal activity, the IDLE acknowledge is asserted and the GPIO enters idle mode.	No
11	Smart-idle wake-up	The GPIO module evaluates its internal capability to have the interface clock switched off. If there is no more internal activity, the IDLE acknowledge is asserted and the GPIO enters idle mode.	Yes

27.4.6 General-Purpose Interface Interrupt and Wake-Up Requests

27.4.6.1 Interrupt Requests Generation

All interrupt sources (the 32 GPIO input channels) are merged to issue two synchronous interrupt requests in each GPIO module. Thus, the general-purpose interface has 16 interrupt lines (two interrupt lines per GPIO module instance).

- Synchronous interrupt request line 1 is default mapped on the MPU,DSP and IPU INTC subsystem.
- Synchronous interrupt request line 2 is mapped on the CROSSBAR.

Table 27-8 lists the event flags, and their mask, that can cause module interrupts.

Table 27-8. Events

Event Flag	Event Mask	Synchronous	Sensitivity	Description
GPIOi.GPIO_IRQSTATUS_0 [31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_SET_0[31:0] INTLINE	Yes	Edge/ level	Corresponding to the first line of interrupt
GPIOi.GPIO_IRQSTATUS_1 [31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_SET_1[31:0] INTLINE	Yes	Edge/ level	Corresponding to the second line of interrupt
GPIOi.GPIO_IRQSTATUS_0 [31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_SET_0[31:0] INTLINE	Yes	Edge/ level	Corresponding to the first line of interrupt
GPIOi.GPIO_IRQSTATUS_1 [31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_SET_1[31:0] INTLINE	Yes	Edge/ level	Corresponding to the second line of interrupt
GPIOi.GPIO_IRQSTATUS_0 [31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_CLR_0[31:0] INTLINE	Yes	Edge/ level	Corresponding to the first line of interrupt
GPIOi.GPIO_IRQSTATUS_1 [31:0] INTLINE	GPIOi.GPIO_IRQSTATUS_CLR_1[31:0] INTLINE	Yes	Edge/ level	Corresponding to the second line of interrupt
GPIOi.GPIO_IRQSTATUS_0 [31:0] INTLINE	GPIOi.GPIO_IRQWAKEN_0 [31:0] INTLINE	No	Edge/ level	Corresponding to the first line of interrupt
GPIOi.GPIO_IRQSTATUS_1 [31:0] INTLINE	GPIOi.GPIO_IRQWAKEN_1 [31:0] INTLINE	No	Edge/ level	Corresponding to the second line of interrupt

NOTE: For more information about interrupt mapping, see Table 27-4, *GPIO Hardware Request*.

Synchronous interrupt request line 1 and line 2 are active depending on their respective interrupt-enable1 and interrupt-enable 2 registers (GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_SET_1, GPIOi.GPIO_IRQSTATUS_CLR_0, and GPIOi.GPIO_IRQSTATUS_CLR_1).

- interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_1)

  The interrupt enable1 (or interrupt enable2) register allows masking of the expected transition on input GPIO to prevent the generation of an interrupt request on line 1 (or line 2). The interrupt-enable registers are programmed synchronously with the interface clock.

  These registers can be accessed with direct read/write operations or by using the alternate set-and-

Copyright © 2015–2017, Texas Instruments Incorporated

clear protocol feature for register update. This feature allows setting or clearing explicit bits of these registers with a single write access (see Section 27.4.9, *General-Purpose Interface Set-and-Clear Protocol*).

- Interrupt status registers (GPIOi.GPIO_IRQSTATUS_0 and GPIOi.GPIO_IRQSTATUS_1)

  The interrupt status 1 (or interrupt status 2) register determines which of the input GPIO pins triggered the interrupt line1 (or interrupt line 2) request (or the wake-up line).

  When a bit in this register is set to 1, it indicates that the corresponding GPIO pin is requesting the interrupt (or the wakeup). To reset a bit in this register, set the appropriate bit to 1. However, an interrupt cannot be generated by writing 1 to the interrupt status 1 (or interrupt status 2) register.

  If 0 is written to a bit in this register, the value in the corresponding bit in the interrupt status 1 and remains unchanged. The interrupt status 1 (or interrupt status 2) register is synchronous with the interface clock. In idle mode, the event is detected through an asynchronous path, and interrupt status 2 registers are set when the GPIO module is awaken.

CAUTION

After servicing the interrupt, the status bit in the interrupt status register (GPIOi.GPIO_IRQSTATUS_0 or GPIOi.GPIO_IRQSTATUS_1) must be reset and the interrupt line released (by setting the corresponding bit of the interrupt status register to 1).

Before enabling an interrupt for the GPIO channel in the interrupt-enable register (GPIOi.GPIO_IRQSTATUS_SET_0 or GPIOi.GPIO_IRQSTATUS_SET_1) the corresponding status bit in the interrupt status register (GPIOi.GPIO_IRQSTATUS_0 or GPIOi.GPIO_IRQSTATUS_1) must be reset to prevent the occurrence of unexpected interrupts when enabling an interrupt for the GPIO channel.

27.4.6.2 Wake-Up Requests Generation

The GPIO1 module of the general-purpose interface is attached to the WKUPAON power domain (see Section 3.1.1.2, *Power Management*, in Chapter 3, *Power, Reset, and Clock Management*, and can wake up the system.

NOTE: The GPIO2 to GPIO8 modules belong to the PD_L4PER power domain and thus their wake-up capabilities are operational only when the PD_L4PER power domain is active.

All wake-up sources (the 32 input GPIO channels) are merged together to issue a single asynchronous wake-up request in each GPIO module following the expected transition(s) (based on register programming). Each GPIO module generates a wake-up signal to the PRCM module.

NOTE: Only gpio1_[3:0] can be used to generate a direct wake-up event.

The asynchronous wake-up request line is active based on the GPIOi.GPIO_IRQWAKEN_0 and GPIO_IRQWAKEN_1 wake-up-enable registers (where i = 1 to 8).

The wake-up-enable register allows masking of the expected transition on input GPIO to prevent the generation of a wake-up request. The wake-up-enable register is programmed synchronously with the interface clock before any idle mode request coming from the host processor.

This register can be accessed with direct read/write operations.

Copyright © 2015–2017, Texas Instruments Incorporated

NOTE: There must be a correlation between the wake-up enable and interrupt-enable registers. If a GPIO pin has a wake-up configured on it, it must also have the corresponding interrupt enabled (on one of the two interrupt lines). Otherwise, it is possible to have a wake-up event, but after exiting the IDLE state, no interrupt is generated; thus, the corresponding bit from the interrupt status register is not cleared, and the module does not acknowledge a future IDLE request.

Table 27-9 lists the mapping of the wake-up signals.

Table 27-9. Wake-Up Signals

Name	Mapping	Comments
GPIOi_WAKE	GPIOi_SWAKEUP	Where i = 1 to 8. The destination is the PRCM module.

27.4.7 General-Purpose Interface Channels Description

Table 27-10 describes the GPIO channels.

Table 27-10. GPIO Channels Description

Channel Number	Type [1]	Mapping	Wake-Up Feature	Comments
GPIO1				
[0]	I/O	gpio1_0	Yes	GPIO. Wake-up path. Input only.
[2:1]	-	Reserved	Reserved	Not pinned-out
[3]	I/O	gpio1_3	Yes	GPIO. Wake-up path. Input only.
[31:4]	I/O	gpio1_[31:4]	Yes	GPIO. Wake-up path.
GPIO2				
[29:0]	I/O	gpio2_[29:0]	Yes	GPIO

Table 27-10. GPIO Channels Description (continued)

Channel Number	Type [1]	Mapping	Wake-Up Feature	Comments
[26]	—	Reserved	Reserved	Not pinned out.
[27]	I	gpio8_27	Yes	GPIO. Input only.
[31:28]	I/O	gpio8_in[31:28]	Yes	GPIO

NOTE: For more information about pin configuration, see Section 18.4.6.1.1, *Pad Configuration Registers*, in Chapter 18, *Control Module*.

27.4.8 General-Purpose Interface Data Input/Output Capabilities

The output-enable register (GPIOi.GPIO_OE) controls the I/O capability of each pin. At reset, all the GPIO-related pins are configured as inputs, and their output capabilities are disabled. This register is not used within the module. Its only function is to carry the pad configuration.

When configured as an output (the desired bit reset in the GPIOi.GPIO_OE register), the value of the corresponding bit in the GPIOi.GPIO_DATAOUT register is driven on the corresponding GPIO pin. Data is written to the data-output register synchronously with the interface clock. This register can be accessed with read/write operations or by using the alternate set-and-clear protocol register update feature. This feature gives the possibility to set or clear specific bits of this register with a single write access to the set output data register (GPIOi.GPIO_SETDATAOUT) or to the clear output data register (GPIOi.GPIO_CLEARDATAOUT) address (see Section 27.4.9, *General-Purpose Interface Set-and-Clear Protocol*). If the application uses a pin as an output and does not want interrupt/wake-up generation from this pin, the application must properly configure the wake-up enable (GPIOi.GPIO_ WAKEUPENABLE) and the interrupt-enable (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_1) registers.

When configured as an input (the desired bit is set to 1 in the GPIOi.GPIO_OE register), the state of the input can be read from the corresponding bit in the GPIOi.GPIO_DATAIN register. The input data is sampled synchronously with the interface clock and then captured in the data input register synchronously with the interface clock. When the GPIO pin levels change, they are captured into this register after two interface clock cycles (the required cycles to synchronize and write data). If the application uses a pin as an input, the application must properly configure the wake-up enable (GPIOi.GPIO_IRQWAKEN_0 and GPIOi.GPIO_IRQWAKEN_1) and the interrupt-enable (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_0) registers to the interrupt and wake-up feature as needed. For using the alternate set-and-clear protocol, see Section 27.4.9, *General-Purpose Interface Set-and-Clear Protocol.*

27.4.9 General-Purpose Interface Set-and-Clear Protocol

27.4.9.1 Description

The GPIO module implements the set-and-clear protocol register update for the following registers:

- GPIOi.GPIO_DATAOUT
- GPIOi.GPIO_IRQSTATUS_CLR_0
- GPIOi.GPIO_IRQSTATUS_CLR_1
- GPIOi.GPIO_IRQSTATUS_SET_0
- GPIOi.GPIO_IRQSTATUS_SET_1

This protocol is an alternative to the atomic test and set operations and consists of writing operations at dedicated addresses (one address for setting bit[s] and one address for clearing bit[s]). The data to write is 1 at bit position(s) to clear (or to set) and 0 at unaffected bit(s). Registers can be accessed in two ways:

- Standard: Full register read and write operations at the primary register address
- Set and clear: Separate addresses are provided to set (and clear) bits in registers. Writing 1 at these addresses sets (or clears) the corresponding bit into the equivalent register; writing 0 has no effect.

Copyright © 2015–2017, Texas Instruments Incorporated

Therefore, for these registers, three addresses are defined for one unique physical register. Reading these addresses has the same effect and returns the register value.

27.4.9.2 Clear Instruction

27.4.9.2.1 Clear Register Addresses

- Clear interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_CLR_0 and GPIOi.GPIO_IRQSTATUS_CLR_1).

  A write operation in the GPIO_IRQSTATUS_CLR_0 (or GPIO_IRQSTATUS_CLR_1) register clears the corresponding bit in the same register when the written bit is 1; a written bit at 0 has no effect.

  A read of the clear interrupt enable0 (or enable1) register returns the value of the GPIO_IRQSTATUS_CLR_0 (or GPIO_IRQSTATUS_CLR_1) register.
- Clear data-output register (GPIOi.GPIO_CLEARDATAOUT).

  A write operation in the clear data-output register clears the corresponding bit in the data-output register when the written bit is 1; a written bit at 0 has no effect.

  A read of the clear data-output register returns the value of the data-output register.

27.4.9.2.2 Clear Instruction Example

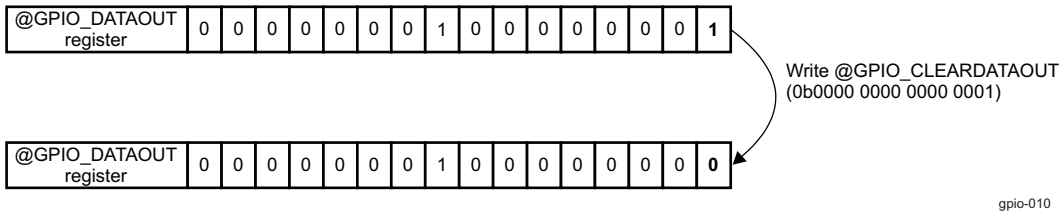
Assume the data-output register (or one of the interrupt or wake-up-enable registers) contains the binary value 0b0000 0001 0000 0001 and bit 0 is to be cleared.

With the clear instruction feature, write 0b0000 0000 0000 0001 at the address of the clear data-output register (or at the address of the clear interrupt or wake-up-enable register). After this write operation, a reading of the data-output register (or the interrupt or wake-up-enable register) returns 0b0000 0001 0000 0000; bit 0 is cleared.

NOTE: Although the general-purpose interface registers are 32 bits wide, only the 16 least-significant bits (LSBs) are represented in this example.

Figure 27-13 is an example of a clear instruction.

Figure 27-13. GPIO_CLEARDATAOUT Register Example



27.4.9.3 Set Instruction

27.4.9.3.1 Set Register Addresses

- Set interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_1).

  A write operation in the GPIOi.GPIO_IRQSTATUS_SET_0 (or GPIOi.GPIO_IRQSTATUS_SET_1) register sets the corresponding bit in the same register when the written bit is 1; a written bit at 0 has no effect.

  A read of the set interrupt-enable 0 (or enable1) register returns the value of the interrupt GPIOi.GPIO_IRQSTATUS_SET_0 (or GPIOi.GPIO_IRQSTATUS_SET_1) register.
- Set data-output register (GPIOi.GPIO_SETDATAOUT).

  A write operation in the set data-output register sets the corresponding bit in the data-output register when the written bit is 1; a written bit at 0 has no effect.

Copyright © 2015–2017, Texas Instruments Incorporated

A read of the set data-output register returns the value of the data-output register.

27.4.9.3.2 Set Instruction Example

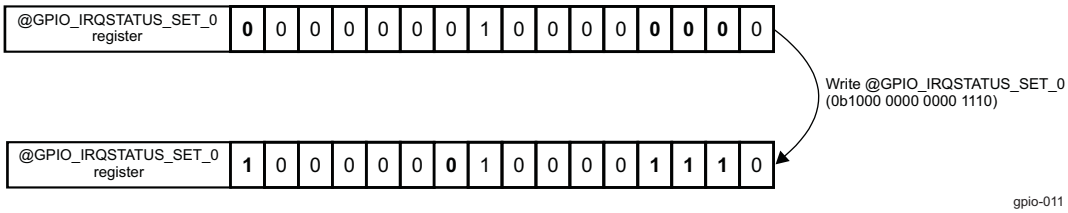
Assume the interrupt enable1 (or enable2) register (or the data-output register) contains the binary value 0b0000 0001 0000 0000 and bits 15, 3, 2, and 1 are to be set.

With the set instruction feature, the user has only to write 0b1000 0000 0000 1110 at the address of the GPIO_SETDATAOUT register. After this write operation, a reading of the GPIO_SETDATAOUT register returns 0b1000 0001 0000 1110: bits 15, 3, 2, and 1 have been set.

NOTE: Although the general-purpose interface registers are 32 bits wide, only the 16 LSBs are represented in this example.

Figure 27-14 is an example of a set instruction.

Figure 27-14. Write in GPIO_IRQSTATUS_SET_0 Register Example



The set wake-up-enable register offers the same feature with the wake-up-enable register.

27.5 General-Purpose Interface Programming Guide

27.5.1 General-Purpose Interface Low-Level Programming Models

27.5.1.1 Global Initialization

27.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the general-purpose interface module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the environment and integration of the general-purpose interface. For more information, see Section 27.2, *General-Purpose Interface Environment*, and Section 27.3, *General-Purpose Interface Integration*.

Table 27-11. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. For more information about the module configuration, see Section 3.1.1.1, *Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.
Control module	Module specific pad muxing must be set in the control module. For more information about the module configuration, see Section 18.4.6.1.1, *Pad Configuration Registers*, in Chapter 18, *Control Module*.
Device INTCs	Device INTCs must be configured to enable the interrupt request generation. For more information see Chapter 17, *Interrupt Controllers*.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow module IRQs to be mapped to certain device INTC line. For more information see Section 18.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 18, *Control Module*.

27.5.1.1.2 General-Purpose Interface Module Global Initialization

This procedure initializes the general-purpose Interface module after a power-on reset (POR) or software reset.

Table 27-12. General-Purpose Interface Global Initialization

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	GPIO_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset completed?	GPIO_SYSSTATUS[0] RESETDONE	= 0x1
Configure idle mode.	GPIO_SYSCONFIG[4:3] IDLEMODE	0x-
Configure interface clock gating.	GPIO_SYSCONFIG[0] AUTOIDLE	0x-
Set clock-gating ratio.	GPIO_CTRL [2:1] GATINGRATIO	0x-
Configure GPIO channels as input or output.	GPIO_OE[31:0] OUTPUTEN	0x-
Set debounce time value.	GPIO_DEBOUNCINGTIME[7:0] DEBOUNCINGTIME	0x-
Enable/disable debouncing for desired input line. (For example, when used with a push-button)	GPIO_DEBOUNCENABLE[31:0] DEBOUNCENABLE	0x-
Interrupt and wake-up requests configuration		
(Optional) Enable/disable wake-up for desired input lines.	GPIO_IRQWAKEN_0[31:0] INTLINE and/or GPIO_IRQWAKEN_1[31:0] INTLINE	0x-
(Optional) Enable wake-up generation.	GPIO_SYSCONFIG[2] ENAWAKEUP	0x1

Copyright © 2015–2017, Texas Instruments Incorporated

Table 27-12. General-Purpose Interface Global Initialization (continued)

Step	Register/Bit Field/Programming Model	Value
Configure detection events. NOTE: Simultaneous enabling of high-level and low-level detection for one given pin creates a constant-interrupt generator.	GPIO_LEVELDETECT0[31:0] LEVELDETECT0 and/or GPIO_LEVELDETECT1[31:0] LEVELDETECT1 and/or GPIO_RISINGDETECT[31:0] RISINGDETECT and/or GPIO_FALLINGDETECT[31:0] FALLINGDETECT	0x-
Clear interrupt status	GPIO_IRQSTATUS_0[31:0] INTLINE and/or GPIO_IRQSTATUS_1[31:0] INTLINE	0xFFFF FFFF
Enable interrupts for desired input lines. If wakeup is enabled, it is mandatory to enable the corresponding interrupt.	GPIO_IRQSTATUS_SET_0[31:0] INTLINE and/or GPIO_IRQSTATUS_SET_1[31:0] INTLINE	0x-

NOTE: Detection of events requires a functional clock running for every group of 8 bits. If detection of events is enabled only within one octet (for example, 0x0012 0000), power saving can be achieved. Else (for example, 0x0102 0000), using two octets requires one more clock to be run by the module.

27.5.1.2 General-Purpose Interface Operational Modes Configuration

27.5.1.2.1 General-Purpose Interface Read Input Register

Table 27-13. General-Purpose Interface Read Input Register

Step	Register/Bit Field/Programming Model	Value
Read interrupt status	GPIO_IRQSTATUS_0[31:0] INTLINE and/or GPIO_IRQSTATUS_1[31:0] INTLINE	0x-
Read input register value.	GPIO_DATAIN[31:0] DATAIN	0x-
Clear interrupt status	GPIO_IRQSTATUS_0[31:0] INTLINE and/or GPIO_IRQSTATUS_1[31:0] INTLINE	0xFFFF FFFF

27.5.1.2.2 General-Purpose Interface Set Bit Function

Table 27-14. General-Purpose Interface Set Bit Function

Step	Register/Bit Field/Programming Model	Value
Write 0x1 to set desired bit(s) in DATAOUT register.	GPIO_SETDATAOUT [31:0] INTLINE	0x-

27.5.1.2.3 General-Purpose Interface Clear Bit Function

Table 27-15. General-Purpose Interface Clear Bit Function

Step	Register/Bit Field/Programming Model	Value
Write 0x1 to clear desired bit(s) in DATAOUT register.	GPIO_CLEARDATAOUT [31:0] INTLINE	0x-

- General-Purpose Interface Register Summary: [0][2][3]

Table 27-22. GPIO_SYSCONFIG

Address Offset	0x0000 0010		
Physical Address	0x4805 1010	**Instance**	GPIO7
	0x4805 3010		GPIO8
	0x4805 5010		GPIO2
	0x4805 7010		GPIO3
	0x4805 9010		GPIO4
	0x4805 B010		GPIO5
	0x4805 D010		GPIO6
	0x4AE1 0010		GPIO1
Description	System configuration register		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																											IDLEMODE		ENAWAKEUP	SOFTRESET	AUTOIDLE

Copyright © 2015–2017, Texas Instruments Incorporated

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Reserved	R	0x0000000
4:3	IDLEMODE	0x0: Force-idle: An IDLE request is acknowledged unconditionally. 0x1: No-idle: An IDLE request is never acknowledged. 0x2: Smart-idle: The acknowledgment to an IDLE request is given based on the internal activity (see Section 27.4.5.2.3, *System Power Management and Wakeup*). 0x3: Smart-idle wakeup	RW	0x0
2	ENAWAKEUP	Wake-up control. 0x0: Wake-up generation is disabled. 0x1: Wake-up capability is enabled upon expected transition on input GPIO pin	RW	0
1	SOFTRESET	Software reset. Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset.	RW	0
0	AUTOIDLE	OCP clock gating control. 0x0: Internal interface OCP clock is free-running. 0x1: Automatic internal OCP clock gating, based on the OCP interface activity	RW	0

Keyboard Controller

This chapter describes the keyboard module (KBD) of the device.

Topic **Page**

28.1 Keyboard Controller Overview **6957**
28.2 Keyboard Controller Environment **6959**
28.3 Keyboard Controller Integration **6962**
28.4 Keyboard Controller Functional Description **6964**
28.5 Keyboard Controller Programming Guide **6973**
28.6 Keyboard Controller Register Manual **6977**

Copyright © 2015–2017, Texas Instruments Incorporated

28.1 Keyboard Controller Overview

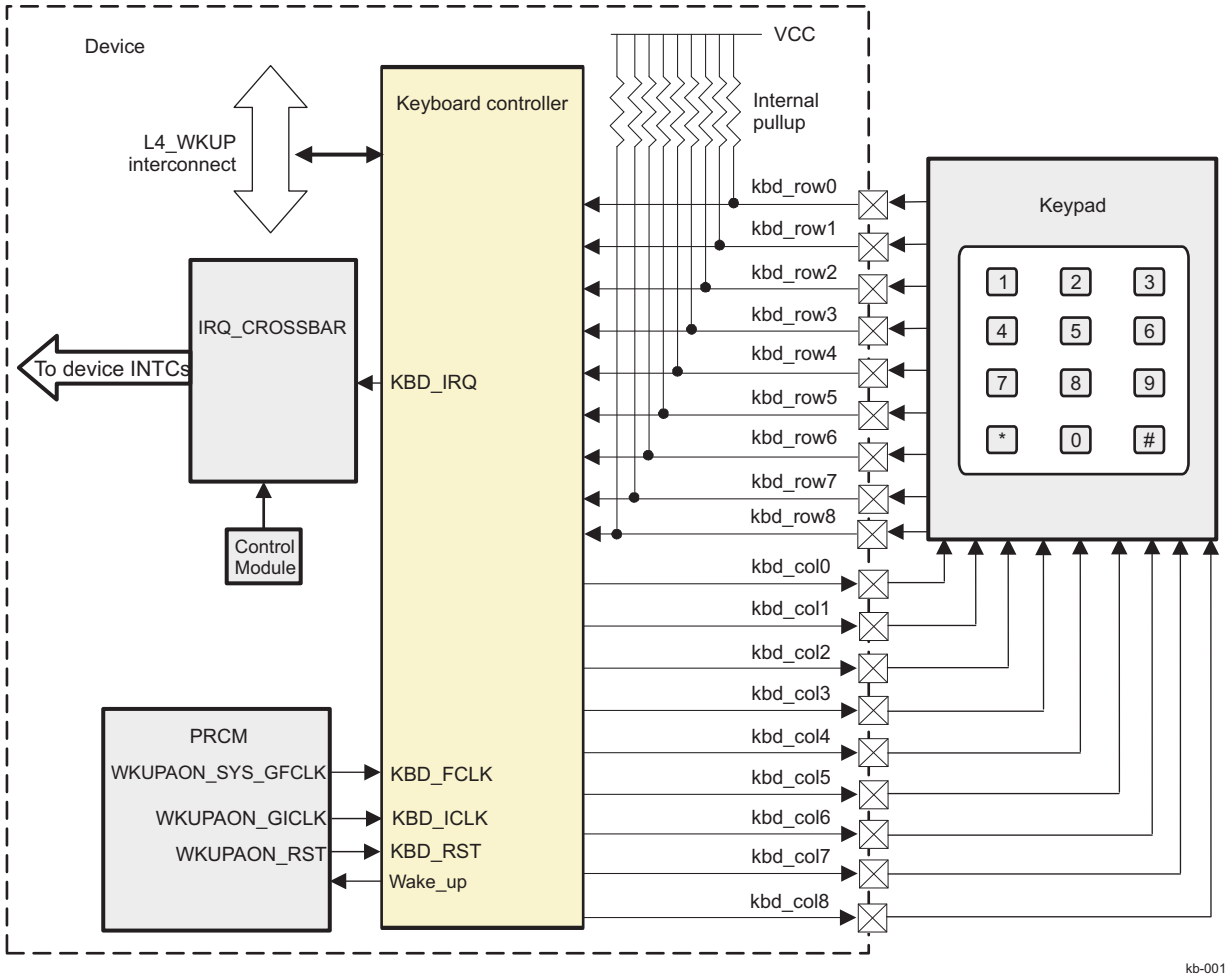
The keyboard controller implements a built-in scanning algorithm for hardware-based key-press decoding and reduces overhead in the microprocessor unit (MPU) software.

The keyboard controller includes a debouncing feature to ensure that only one key combination can be registered in the programmed time.

The keyboard controller can handle up to 9 × 9 keys, works on a 32-kHz clock, and can generate wake-up events when the chip is in sleep mode.

Figure 28-1 shows the keyboard controller.

Figure 28-1. Keyboard Controller Overview



The keyboard controller includes the following main features:

- Support of multiconfiguration keyboards up to 9 rows × 9 columns
- Each key coded on 1 bit in two 32-bit registers
- Long-key value or repeat timing reconfigurable on the fly
- Event detection on key press and key release
- Multikey-press detection and decoding
- Long-key detection on prolonged key press
- Integrated timer with four programmable comparison values
- Programmable time-out on permanent key press or after keyboard release
- Programmable interrupt generation on key events

Copyright © 2015–2017, Texas Instruments Incorporated

- Software reset capability
- Read/write-posted register access modes
- 8-/16-/32-bit access supported on the level 4 (L4) interface
- 32-bit data bus
- 7-bit address bus
- An over run generation if a master reads a register to late

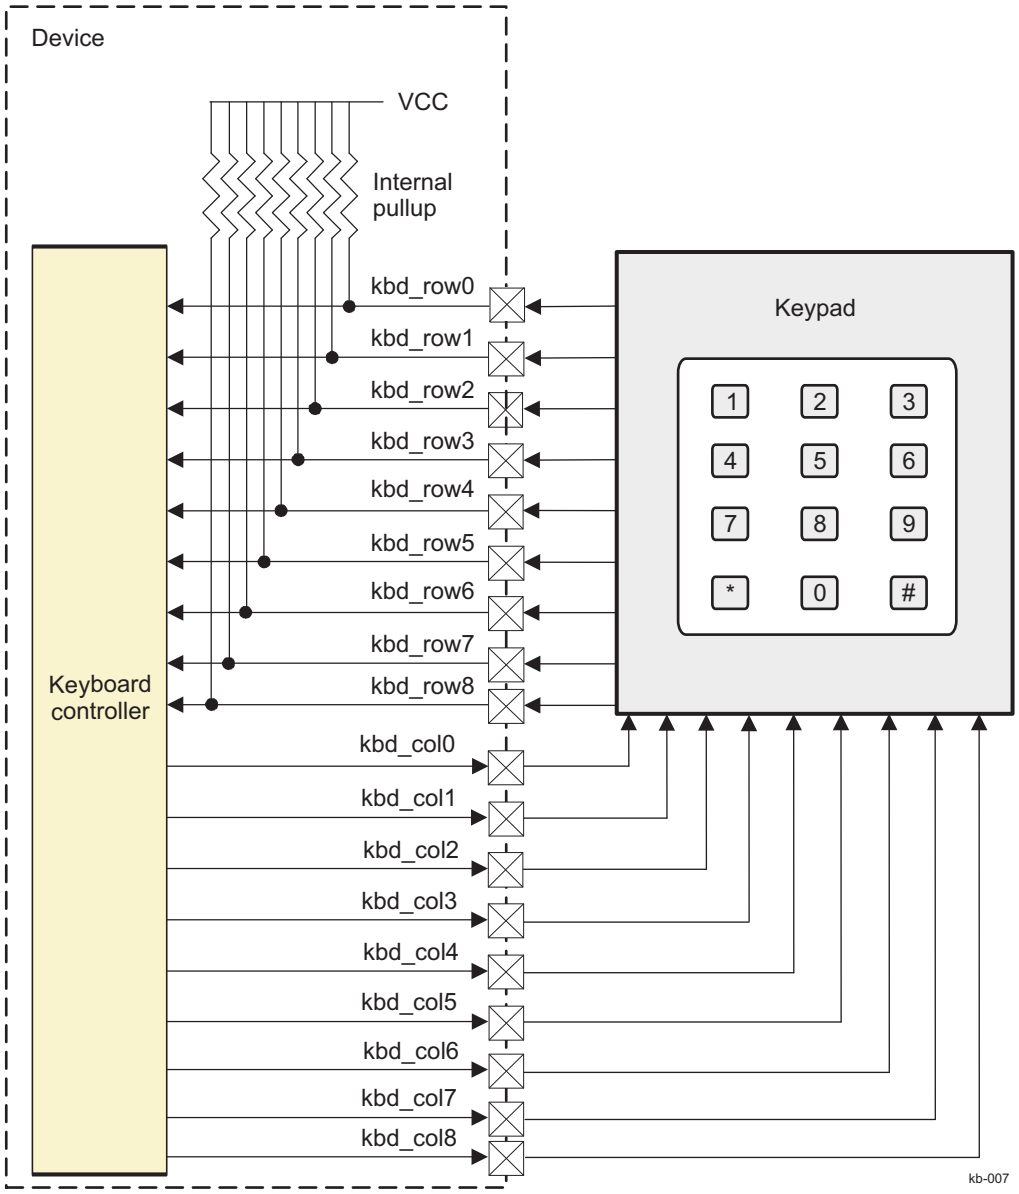
Copyright © 2015–2017, Texas Instruments Incorporated

28.2 Keyboard Controller Environment

The keyboard controller external interface pins map on the device pads when the device IO cells are configured and multiplexed for the keypad function by the control module. For more information, see Section 18.4.6.1.1, *Pad Configuration Registers*, and Section 27.2.1, *General-Purpose Interface as a Keyboard interface*.

The external keypad typically connects directly to the keyboard controller of the device (see Figure 28-2).

Figure 28-2. Typical Keyboard Environment



NOTE: To acheive the configuration shown in Figure 28-2 software needs to reconfigure the internal pulls on the kbd_* pads appropriately. The settings of those pads default to pull down resistors selected, software must reconfigure to pull ups on rows and to disable the pulls on columns.

28.2.1 Keyboard Controller Functions/Modes

The keyboard controller executes two functions:

Copyright © 2015–2017, Texas Instruments Incorporated

- Keypad scanning and decoding for input of the external key presses. For more information, see Section 28.4.5, *Keyboard Controller Software Mode*, and Section 28.4.6, *Keyboard Controller Hardware Decoding Modes*.
- Device wakeup by interrupt request to the processor when a key is pressed and the device is in idle or sleep mode. For more information, see Section 28.4.6.4, *Keyboard Controller Interrupt Generation*.

28.2.2 Keyboard Controller Signals

Table 28-1 describes the module signals and specifies their links to functions.

Table 28-1. I/O External Keyboard Signals

Signal	I/O[1]	Description	Reset Value	Function	Wake-Up Capability
kbd_row0	I	Keypad row 0 feed	HiZ (pulled up)	Key reading	Yes
kbd_row1	I	Keypad row 1 feed	HiZ (pulled up)	Key reading	Yes
kbd_row2	I	Keypad row 2 feed	HiZ (pulled up)	Key reading	Yes
kbd_row3	I	Keypad row 3 feed	HiZ (pulled up)	Key reading	Yes
kbd_row4	I	Keypad row 4 feed	HiZ (pulled up)	Key reading	Yes
kbd_row5	I	Keypad row 5 feed	HiZ (pulled up)	Key reading	Yes
kbd_row6	I	Keypad row 6 feed	HiZ (pulled up)	Key reading	Yes
kbd_row7	I	Keypad row 7 feed	HiZ (pulled up)	Key reading	Yes
kbd_row8	I	Keypad row 8 feed	HiZ (pulled up)	Key reading	Yes
kbd_col0	O	Keypad column 0 feed, active low	HiZ	Key reading	No
kbd_col1	O	Keypad column 1 feed, active low	HiZ	Key reading	No
kbd_col2	O	Keypad column 2 feed, active low	HiZ	Key reading	No
kbd_col3	O	Keypad column 3 feed, active low	HiZ	Key reading	No
kbd_col4	O	Keypad column 4 feed, active low	HiZ	Key reading	No
kbd_col5	O	Keypad column 5 feed, active low	HiZ	Key reading	No
kbd_col6	O	Keypad column 6 feed, active low	HiZ	Key reading	No
kbd_col7	O	Keypad column 7 feed, active low	HiZ	Key reading	No
kbd_col8	O	Keypad column 8 feed, active low	HiZ	Key reading	No

(1) I = Input; O = Output

28.2.3 Protocols and Data Formats

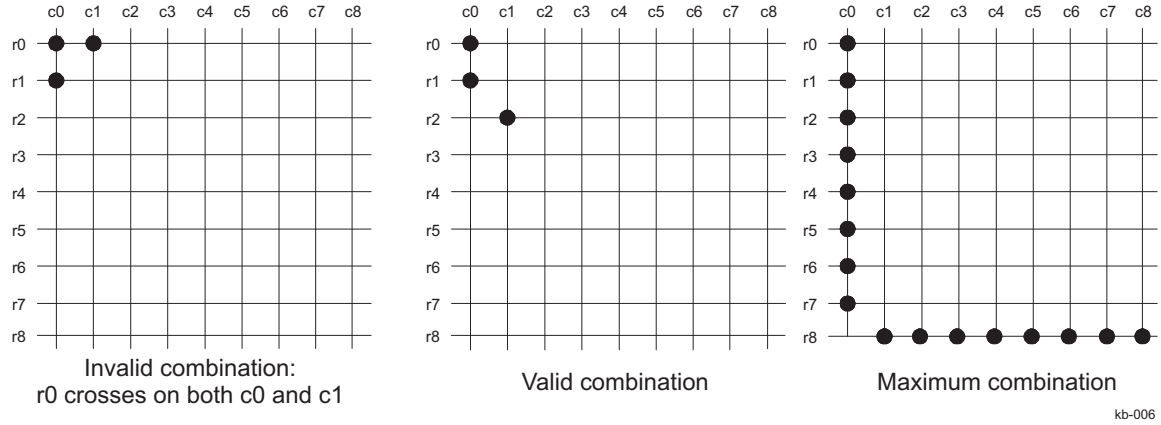
The keyboard controller detects and decodes multikey combinations using the following rules:

- Any 2-key combination is valid and can be decoded.
- Combinations using more than two keys are valid only if the rows and columns used do not cross over on another key to be detected. This is caused by equipotent propagation on a row/column (multikey limitations).

Figure 28-3 shows an example of multikey limitation.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 28-3. Multikey Limitation Example



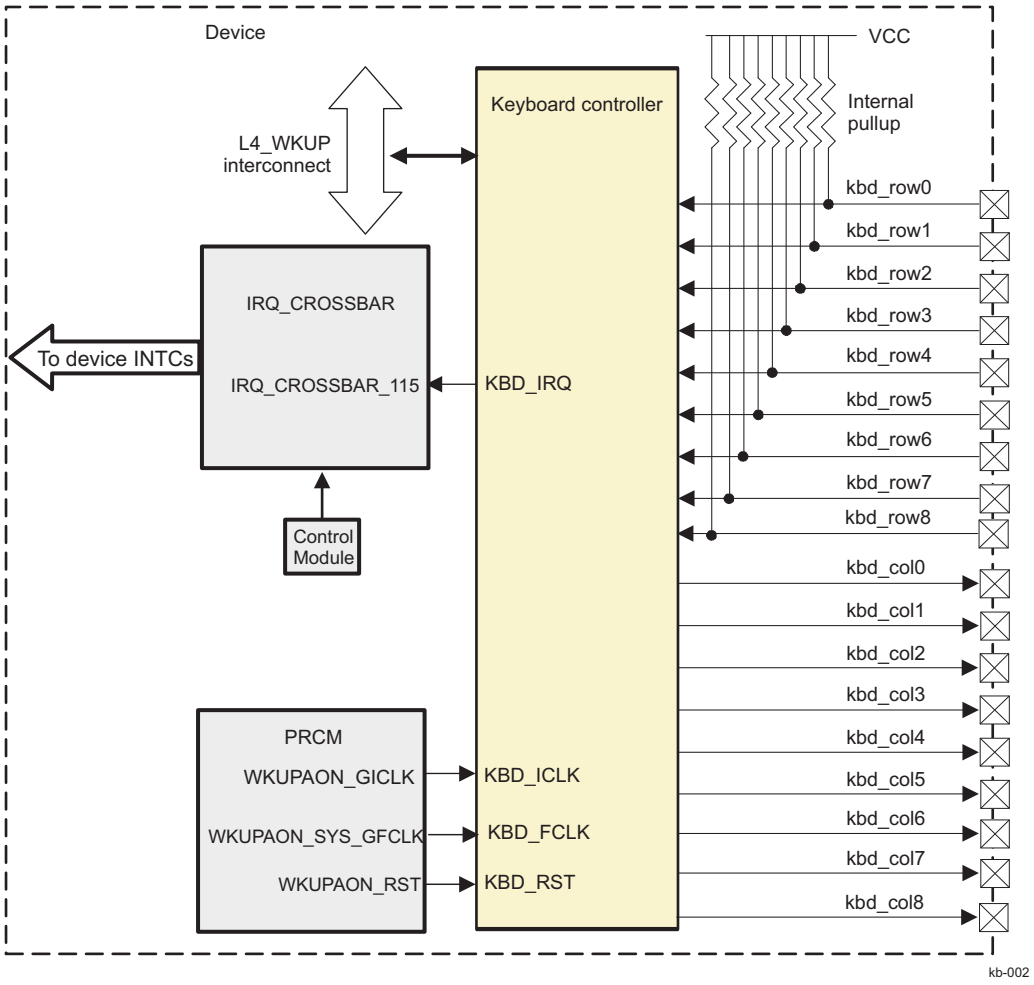
NOTE: When using the keyboard controller with a smaller keypad (for example, 5 × 5), unused rows must be tied high to prevent disturbing the scanning process. Normally, all rows must be pulled up internally at the I/O cells of the device.

Copyright © 2015–2017, Texas Instruments Incorporated

28.3 Keyboard Controller Integration

Figure 28-4 shows keyboard controller integration.

Figure 28-4. Keyboard Controller Integration



The control module must enable the internal pullups of the GPIO cells for all keypad rows (for more information about the configuration, see Chapter 18, *Control Module*).

Table 28-2 through Table 28-4 summarize the integration of the module in the device.

Table 28-2. Keyboard Controller Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
KBD	PD_WKUPAON	Yes	L4_WKUP

Table 28-3. Keyboard Controller Clocks and Resets

		Clocks		
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
KBD	KBD_FCLK	WKUPAON_SYS_GFCLK	PRCM	32-kHz functional clock. For information about PRCM clock gating and management, see Section 3.1.1.1.4, *Clock Domain-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

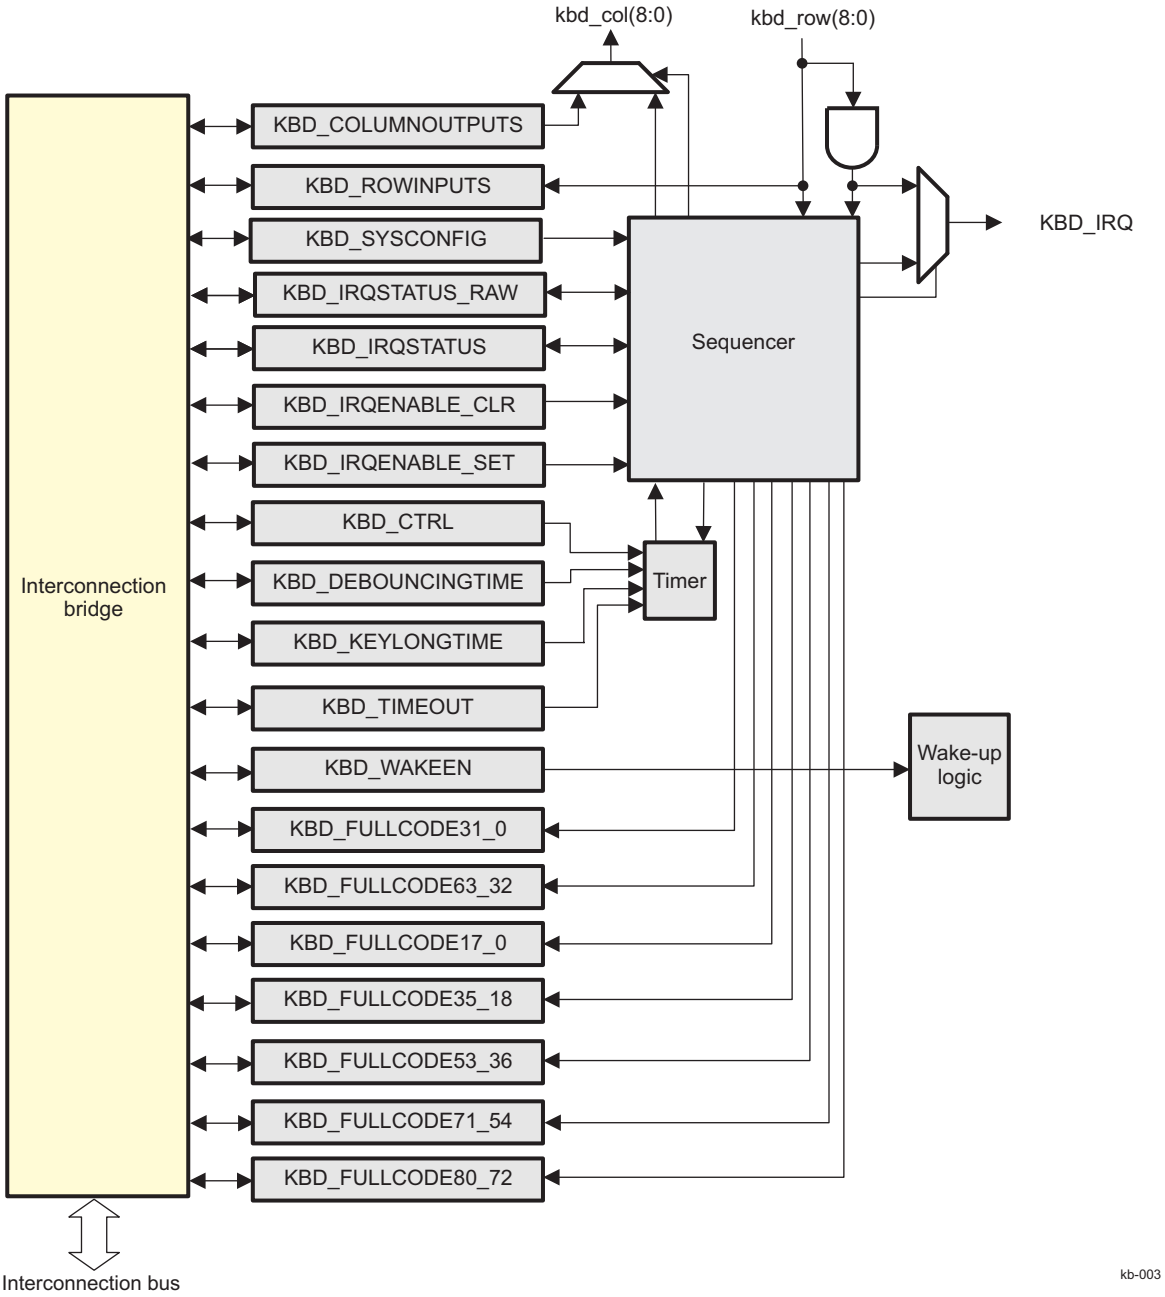
28.4 Keyboard Controller Functional Description

28.4.1 Keyboard Controller Block Diagram

Figure 28-5 shows the functional specification block diagram of the keyboard controller.

Figure 28-5. Keyboard Controller Block Diagram



The keyboard controller detects events issued on any key of the connected keyboard and generates an interrupt to alert the host processor. The built-in hardware-scan algorithm decodes the pressed keys, including multikey combinations.

To reduce MPU software overhead, the hardware performs detecting and decoding in the keyboard controller state-machine. However, hardware decoding can be deactivated so that software handles the scanning algorithm.

Copyright © 2015–2017, Texas Instruments Incorporated

The value of the columns output is determined in the KBD_COLUMNOUTPUTS[8:0] KBC_REG bit field. To activate a keypad row-column connection, the corresponding bit must be 0b0.

The following sections describe subfunctions and subfunction interactions (control and data paths).

28.4.2 Keyboard Controller Software Reset

To perform a software reset, set the KBD_SYSCONFIG[1] SOFTRESET bit to 1. When the software reset completes, the KBD_SYSCONFIG[1] SOFTRESET bit is automatically reset. Software must ensure that the software reset completes before performing mailbox operations.

28.4.3 Keyboard Controller Power Management

Table 28-5 describes the power-management features available for the keyboard controller.

NOTE: For information about source clock gating and a description of the sleep/wake-up transitions, see Section 3.1.1.1.4, *Clock Domain-Level Clock Management*, in , *Power, Reset, and Clock Management*.

Table 28-5. Local Power-Management Features

Feature	Registers	Description
Slave idle modes	KBD_SYSCONFIG[4:3] IDLEMODE	Force-idle, no-idle, and smart-idle modes are available.
Master standby modes	N/A	N/A
Wake-up sources enable	KBD_IRQWAKEEN	This register holds one active-high enable bit per event source able to generate a wake-up signal.

28.4.4 Keyboard Controller Interrupt Requests

Table 28-6 lists the event flags, and their mask, that can cause module interrupts.

Table 28-6. Events

Event Flag	Event Mask	Description
KBD_IRQSTATUS[3] MISS_EVENT	–	A miss event occurs.
KBD_IRQSTATUS[2] IT_TIMEOUT	KBD_IRQENABLE_SET/KBD_IRQENABLE_CLR [2] IT_TIMEOUT_EN	A time-out event is detected.
KBD_IRQSTATUS[1] IT_LONG_KEY	KBD_IRQENABLE_SET/KBD_IRQENABLE_CLR [1] IT_LONG_KEY_EN	A long-key event is detected.
KBD_IRQSTATUS[0] IT_EVENT	KBD_IRQENABLE_SET/KBD_IRQENABLE_CLR [0] IT_EVENT_EN	An event is detected.

28.4.5 Keyboard Controller Software Mode

The KBD_CTRL[1] NSOFTWARE_MODE bit selects software mode when it is set to 0.

In software mode, the keyboard controller internal sequencer, which performs automatic scanning and decoding, is disabled. Consequently, software must manually perform the scanning algorithm.

The scanning sequence is managed using the keyboard controller column outputs register (KBD_COLUMNOUTPUTS) and the keyboard controller row inputs register (KBD_ROWINPUTS). In this configuration, the keyboard interrupt is a logical ANDing of all bits of the KBD_ROWINPUTS register.

For more information about the software scan, see Section 28.5.1, *Keyboard Controller Low-Level Programming Model*.

Copyright © 2015–2017, Texas Instruments Incorporated

28.4.6 Keyboard Controller Hardware Decoding Modes

28.4.6.1 Functional Modes

When running in hardware (default) decoding mode (the KBD_CTRL[1] NSOFTWARE_ MODE bit is set to 1), the keyboard controller offers several functional modes; these modes are summarized in Table 28-7. The keyboard interrupt depends on the configuration in the keyboard controller interrupt-enable register (KBD_IRQENABLE_SET). If the event is enabled (bit 0 is set to 1), an interrupt is generated when the sequencer detects an event. Even if this interrupt is disabled, the flag status of the keyboard controller interrupt-status register (KBD_IRQSTATUS) is updated.

Table 28-7. Keyboard Controller Functional Modes

Functional Mode	Associated Interrupt	Associated Timer Value	Description	Control
Keyboard event	Event interrupt	Debouncing value	Occurs when a key is pressed or released Always enabled	KBD_CTRL[8:5] bits must be set to 0 to disable all the other features.
Long key	Long-key interrupt	Long-key value	Used to detect a key that is pressed for a long time Should be associated with the long-key time-out function or repeat mode	KBD_CTRL[5] LONG_KEY
Repeat key	Long-key interrupt	Long-key value	Generates an interrupt every long-key delay No time-out can be associated.	KBD_CTRL[8] REPEAT_MODE
Empty time-out	Time-out interrupt	Empty time-out value	Interrupt generated if no key is pressed during an empty time-out period.	KBD_CTRL[6] TIMEOUT_EMPTY
Long-key time-out	Time-out interrupt	Long-key time-out value	Associated with the long-key function Generated after a long-key interrupt if no event occurs during a long-key time-out period	KBD_CTRL[7] TIMEOUT_LONG_KEY

Each mode can be activated/deactivated by setting the corresponding bits (5, 6, 7, and 8) in the KBD_CTRL register with the appropriate values (for more information, see Section 28.6, *Keyboard Controller Register Manual*).

28.4.6.2 Keyboard Controller Timer

As described in the previous section, each functional mode is associated with a timer value. Depending on the selected mode, the keyboard controller timer is loaded with the corresponding value as set in the related registers:

- KBD_DEBOUNCINGTIME
- KBD_KEYLONGTIME
- KBD_TIMEOUT

Table 28-8 summarizes the values of the keyboard controller timer.

Table 28-8. Keyboard Controller Timer Values

Timer Value	Associated Register Field	Description
Debouncing time	KBD_DEBOUNCINGTIME[5:0] DEBOUNCING_VALUE	To remove the effects of glitches when an event occurs on the keyboard, the controller waits for a debouncing period before taking a snapshot of the current state on the keyboard matrix. The timer is loaded with the debouncing time value after each detected event on the keyboard matrix. An event interrupt is generated after this delay.

Copyright © 2015–2017, Texas Instruments Incorporated

Table 28-8. Keyboard Controller Timer Values (continued)

Timer Value	Associated Register Field	Description
Long-key time	KBD_KEYLONGTIME[11:0] LONG_KEY_VALUE	This is the delay before generating a long-key interrupt after an event interrupt. If the long-key mode is selected, the timer is loaded with the long-key time value after an event interrupt is generated. In repeat mode, the timer is reloaded with the same value after a long-key interrupt, and starts to count down again.
Long-key time-out	KBD_TIMEOUT[15:0] TIMEOUT_VALUE	The timer is loaded with the time-out value and then a long-key interrupt is generated and starts to count down. When it reaches 0, a time-out interrupt is generated and the keyboard controller returns to its IDLE state. This long-key time-out does not work in repeat mode.
Empty key time-out	KBD_TIMEOUT[15:0] TIMEOUT_VALUE	The time-out interrupt occurs if no key is pressed during this delay. The keyboard controller then returns to IDLE state.

The timer countdown period depends on three factors:

- The loaded value as set in:
  - KBD_DEBOUNCINGTIME
  - KBD_KEYLONGTIME
  - KBD_TIMEOUT
- The value of the prescale clock timer as set in the KBD_CTRL[4:2] PTV bit field. This programmable clock divider allows the reduction of the clock frequency used by the timer.
- The frequency of the keyboard controller functional clock (32 kHz). This clock is actually either 32K oscillator, or it is the SYSCLK1/610, depending on sysboot[9:8] state at power-on. For more information about sysboot states see Chapter 33, *Initialization*.

The period is calculated as follows:

$T_{period} = (T_{value} + 1) \times 2^{PTV + 1} \times T_{clk}$

Where:

T_{value} is the value stored in the KBD_DEBOUNCINGTIME, KBD_KEYLONGTIME, or KBD_TIMEOUT register.

PTV is the value of the KBD_CTRL[4:2] PTV bit field.

T_{clk} is the period of the 32-kHz functional clock; that is, 31.25 µs or other (depending wheather the 32K oscillator or the SYSCLK1/610 clock is selected as source).

The KBD_CTRL[4:2] PTV bit field determines the division factor of the timer clock. Table 28-9 lists the divider rates.

Table 28-9. Timer Prescale Values

KBD_CTRL[4:2] PTV Value	Divisor
0	2
1	4
2	8
3	16
4	32
5	64
6	128
7	256

NOTE: The timer minimum period is 62.5 µs; its maximum period is 524.288 seconds.

Copyright © 2015–2017, Texas Instruments Incorporated

CAUTION

To prevent undefined results, the KBD_CTRL[4:2] PTV bit field must not be changed when the timer is running.

The timer value registers (KBD_DEBOUNCINGTIME, KBD_KEYLONGTIME, and KBD_TIMEOUT) can be updated at any time, whether or not the timer is running. Nevertheless, the timer is updated only on the fly for the long-key time value. The new debouncing and time-out values are loaded only on the next load. Depending on the updated register, two cases can occur:

- The KBD_KEYLONGTIME register is updated; the new value stored in the KBD_KEYLONGTIME register is loaded into the timer when the register is written. If the timer is already counting down when KBD_KEYLONGTIME is updated, it counts down from the new value loaded in KBD_KEYLONGTIME.
- The KBD_DEBOUNCINGTIME or KBD_TIMEOUT register is updated; the new value is considered only when the next timer loads. If the timer is counting down when the registers are updated, the timer continues counting down from the previous value and is loaded with the new one on the next load.

Regardless of the timer state (stopped, counting down any of the values previously described, etc.), when a new event occurs on the keyboard, the timer is stopped and loaded with the debouncing time value. It then starts counting down.

28.4.6.3 State-Machine Status

To facilitate debugging, each state of the state-machine is coded in a register that indicates the current state of the machine. Table 28-10 lists the corresponding codes.

Table 28-10. State-Machine Values

KBD_STATEMACHINE[3:0] Value	Description
0x0	Idle
0x1	Scanning
0x2	Load timer debouncing
0x3	Test timer debouncing
0x4	Generated interrupt event
0x6	Load timer long key
0x7	Test timer long key
0x8	Generated interrupt long key
0x9	Load timer time-out
0xA	Test timer time-out
0xB	Generated interrupt time-out
0xF	Other

28.4.6.4 Keyboard Controller Interrupt Generation

28.4.6.4.1 Interrupt-Generation Scheme

The keyboard controller generates the KBD_IRQ interrupt signal connected to the IRQ_CROSSBAR_115 input. Each functional mode generates dedicated interrupt events (logged in the KBD_IRQSTATUS register) that can be masked using the KBD_IRQENABLE_CLR register or unmasked using the KBD_IRQENABLE_SET register.

The KBD_IRQSTATUS register is updated when the selected functional mode generates an interrupt event. However, the KBD_IRQ signal is asserted on the related event only if the corresponding bit is set to 0x1 in the KBD_IRQENABLE_SET register.

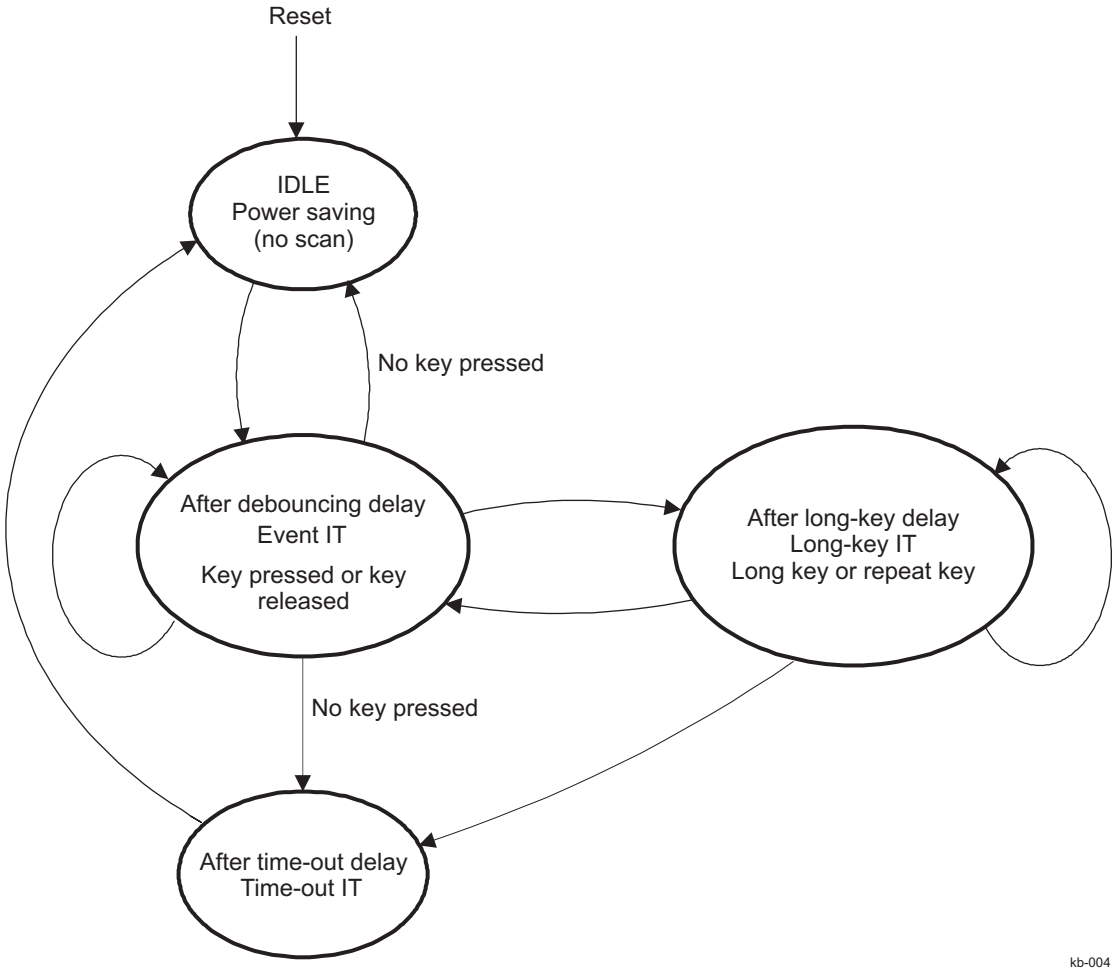
Copyright © 2015–2017, Texas Instruments Incorporated

NOTE: To reset the interrupt status bit, 1 must be written to the appropriate bit of the KBD_IRQSTATUS read/write register.

Figure 28-6 shows the different interrupt events generated in each keyboard controller functional mode and details the relationships between them.

NOTE: Depending on the selected mode, some interrupt events cannot be generated.

Figure 28-6. Functional Modes and Related Interrupt Events



While running in hardware-decoding mode, the keyboard controller performs automatic scans when not in IDLE state. When a key-press event occurs on the keyboard matrix, the keyboard controller leaves IDLE state and an interrupt event (the KBD_IRQSTATUS[0] IT_EVENT bit) is set after the timer counts down the debouncing delay. An IT_EVENT is generated when a key is pressed or released.

NOTE: An IT_EVENT is generated regardless of the selected functional mode. If no time-out is set and no more keys are pressed, the keyboard controller returns to IDLE state.

If long-key detection mode is set when the timer counts down the long-key delay, an interrupt long key (the KBD_IRQSTATUS[1] IT_LONG_KEY bit) is generated. If the repeat mode is set, the IT_LONG_KEY interrupt is generated periodically every long-key delay.

A time-out can also be set in event detection or long-key detection mode. In this case, a time-out interrupt (the KBD_IRQSTATUS[2] IT_TIMEOUT bit) is generated after the time-out delay timer expires. After such an interrupt, the keyboard controller always returns to IDLE state.

Copyright © 2015–2017, Texas Instruments Incorporated

NOTE: No time-out can be set in repeat mode. Only a keyboard event can stop the periodic interrupt generation.

28.4.6.4.2 Keyboard Buffer and Missed Events (Overrun Feature)

The keyboard controller has an overrun feature: A dedicated buffer allows the keyboard controller to memorize two successive events. If two successive events occur before a read is performed, the second event is stored and a second interrupt is generated when the first interrupt is cleared, allowing two consecutive key events to be received.

If a third event occurs before the first event is treated, a missed event interrupt (the KBD_IRQSTATUS[3] MISS_EVENT bit) is generated to report the lost event.

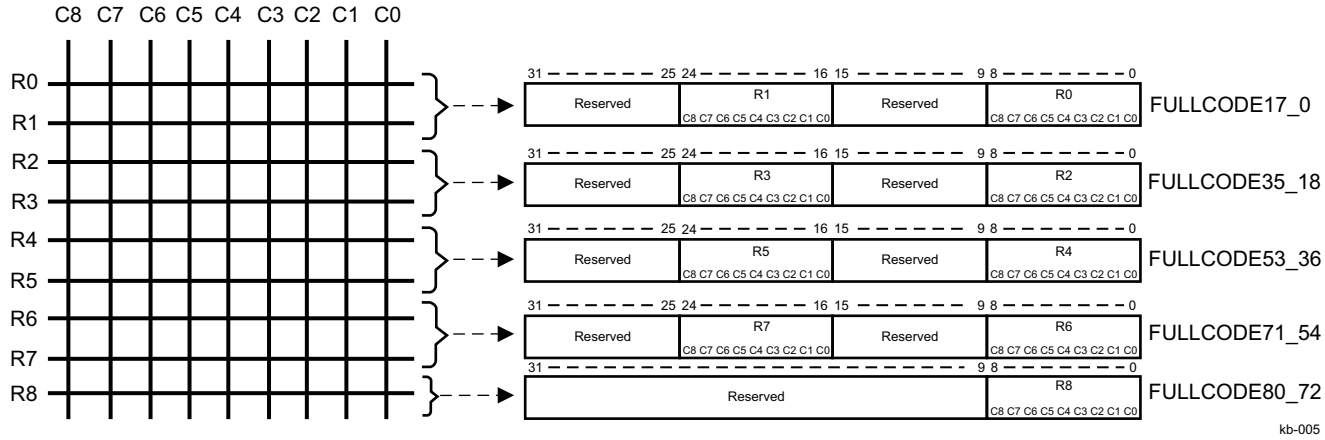
NOTE: The MISS_EVENT interrupt is not routed to the KBD_IRQ signal; software must check the KBD_IRQSTATUS[3] MISS_EVENT bit to detect any missed events.

28.4.7 Keyboard Controller Key Coding Registers

The keyboard controller matrix pressed keys state (indicating which columns/rows are connected) is reflected in the KBD_FULLCODE17_0 to KBD_FULLCODE80_72 registers, as shown in Figure 28-7. These registers are updated only when interrupt event status is inactive to prevent a lost event.

NOTE: The KBD_FULLCODE31_0 and KBD_FULLCODE63_32 registers, which are limited to supporting keyboards of a maximum 8 × 8 array size, can be used for back-to-back software compatibility.

Figure 28-7. Key Coding Registers



Each of the 9 × 9 keyboard size supporting registers (KBD_FULLCODE17_0 to KBD_FULLCODE71_54) stores the state of two keyboard rows. The KBD_FULLCODE80_72 register stores the state of the last row, R8:

- The KBD_FULLCODE17_0 register code rows 0, 1 (row 0 is coded between bits 0 and 8, row 1 is coded between bits 16 and 24)
- The KBD_FULLCODE35_18 register code rows 2, 3 (row 2 is coded between bits 0 and 8, row 3 is coded between bits 16 and 24)
- The KBD_FULLCODE53_36 register code rows 4, 5 (row 4 is coded between bits 0 and 8, row 5 is coded between bits 16 and 24)
- The KBD_FULLCODE71_54 register code rows 6, 7 (row 6 is coded between bits 0 and 8, row 7 is coded between bits 16 and 24)
- The KBD_FULLCODE80_72 register code row 8 (row 8 is coded between bits 0 and 8)

Copyright © 2015–2017, Texas Instruments Incorporated

In each of these registers (excluding KBD_FULLCODE80_72):

- Bit 0 corresponds to column(0) – row (i) key, … , bit 8 corresponds to column(8) – row (i) key.
- Bits from 9 to 15 are reserved.
- Bit 16 corresponds to column(0) – row (i + 1) key, … , bit 24 corresponds to column (8) – row (i + 1) key.
- Bits 31 to 25 are reserved, where i = 0, 2, 4, 6.

In the KBD_FULLCODE80_72 register, bit 0 corresponds to column (0) – row (8) key, …, the bit 8 corresponds to column (8) – row (8) key, and the remaining bits (from 9 to 31) are reserved.

Each of the 8 × 8-keyboard size supporting registers (KBD_FULLCODE31_0 and KBD_FULLCODE63_32) stores the state of four keyboard rows:

- The KBD_FULLCODE31_0 register code rows 0, 1, 2, and 3 (row 0 is coded between bits 0 and 7, row 1 is coded between bits 8 and 15, row 2 is coded between bits 16 and 23, and row 3 is coded between bits 24 and 31)
- The KBD_FULLCODE63_32 register code rows 4, 5, 6, and 7 (row 4 is coded between bits 0 and 7, row 5 is coded between bits 8 and 15, row 6 is coded between bits 16 and 23, and row 7 is coded between bits 24 and 31)

In these registers:

- KBD_FULLCODE31_0[0] corresponds to column (0) – row (0) key,…, KBD_FULLCODE31_0[7] corresponds to column (7) – row (0).
- KBD_FULLCODE31_0[8] corresponds to column (0) – row (1) key,..., KBD_FULLCODE31_0[15] corresponds to column (7) – row (1).
- KBD_FULLCODE31_0[16] corresponds to column (0) – row (2) key,..., KBD_FULLCODE31_0[23] corresponds to column (7) – row (2).
- KBD_FULLCODE31_0[24] corresponds to column (0) – row (3) key,..., KBD_FULLCODE31_0[31] corresponds to column (7) – row (3).
- KBD_FULLCODE63_32[0] corresponds to column (0) – row (4) key,..., KBD_FULLCODE63_32[7] corresponds to column (7) – row (4).
- KBD_FULLCODE63_32[8] corresponds to column (0) – row (5) key,..., KBD_FULLCODE63_32[15] corresponds to column (7) – row (5).
- KBD_FULLCODE63_32[16] corresponds to column (0) – row (6) key,..., KBD_FULLCODE63_32[23] corresponds to column (7) – row (6).
- KBD_FULLCODE63_32[24] corresponds to column (0) – row (7) key,..., KBD_FULLCODE63_32[31] corresponds to column (7) – row (7).

NOTE: The keyboard fullcode registers are not updated in software mode.

NOTE: When using a smaller keyboard (for example, 5 × 5 or 4 × 4), the bits of the unused columns/rows are not used.

28.4.8 Keyboard Controller Register Access

28.4.8.1 Write Registers Access

The keyboard module uses a posted-write scheme to update any internal registers. This means the write transaction is immediately acknowledged on the L4 interface, although the effective write operation occurs later due to a resynchronization in the functional clock domain. This has the advantage of not stalling the interconnect system or the CPU that requested the write transaction. For each functional register, a pending bit is provided that is set if there is a pending write access to this register. The pending bits are accessible in the keyboard pending write register (KBD_PENDING).

Copyright © 2015–2017, Texas Instruments Incorporated

In this mode, it is mandatory that the CPU checks the pending bits before any write access in the functional registers. If a write is attempted to a register with a previous access pending, the previous access is discarded without notice (this can also lead to unexpected results).

A register read following a posted write (on the same register) may not read the previous write value if the write posted process is not complete. Software synchronization must be used to avoid noncoherent read.

This posted period is defined as the interval between the posted write access request and the reset of the pending bit in the KBD_PENDING register, and can be quantified:

T (reset posted bit maximum) = 3 × Ticlk + 3 × Tfuncclk

The time it takes to accomplish the writing is:

T (write accomplish maximum) = 1 × Ticlk + 3 × Tfuncclk

where:

Ticlk is the L4 interface clock period, and Tfuncclk is the functional clock period.

28.4.8.2 Read Registers Access

The keyboard module uses a posted-read scheme for reading any internal register. The read transaction is immediately acknowledged on the L4 interface. The value of the functional register to be read must be previously synchronized. This has the advantage of not stalling the interconnect system or the CPU that requested the read transaction.

The posted-read scheme can be used only if Freq(KBD_FCLK) < Freq(KBD_ICLK)/4.

28.5 Keyboard Controller Programming Guide

28.5.1 Keyboard Controller Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

28.5.1.1 Global Initialization

28.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the keyboard module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the keyboard. For more information, see Section 28.2, *Keyboard Controller Environment,* and Section 28.3, *Keyboard Controller Integration*.

Table 28-11 describes the global initialization of surrounding modules.

Table 28-11. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled. See Chapter 3, *Power, Reset, and Clock Management*.
IRQ_CROSSBAR	IRQ_CROSSBAR configuration must be done to allow the keyboard controller IRQ to be mapped to certain device INTC line. For more information see Section 18.4.6.4, IRQ_CROSSBAR Module Functional Description, in Chapter 18, *Control Module*.
Interrupt controllers	Device INTCs must be configured to enable the interrupt request generation. For more information about enabling interrupts, see Chapter 17, Interrupt Controllers.
Control module	The pad configuration registers must be configured to map the keyboard interface signals to the device pads, to determine the signal directions and for all keyboard rows to enable the internal pull-ups of the associated IO cells . For more information about this configuration, see Section 18.4.6.1.1, *Pad Configuration Registers.*

28.5.1.1.2 Keyboard Controller Global Initialization

28.5.1.1.2.1 Main Sequence – Keyboard Controller Global Initialization

This procedure initializes the keyboard controller after a POR or software reset (see Table 28-12).

Table 28-12. Keyboard Controller Global Initialization

Step	Register/Bit Field/Programming Model	Value
Configure the debouncing time of filtering the glitches on pressing or releasing key.	KBD_DEBOUNCINGTIME[5:0] DEBOUNCING_VALUE	0x–
Configure the duration of a key press to allow shortcut detection (desired value of the long-key interrupt or repeat mode value).	KBD_KEYLONGTIME[11:0] LONG_KEY_VALUE	0x–
Configure the period of the long inactivity on the keyboard (desired value of the time-out interrupt).	KBD_TIMEOUT[15:0] TIMEOUT_VALUE	0x–
Define the logical value of the column outputs (KEYPAD configuration) (logical 0 bit = active column-row).	KBD_COLUMNOUTPUTS[8:0] KBC_REG	0x–
Perform the functional configuration of the keyboard module and the prescale clock timer value.	KBD_CTRL	0x00000–
Clear the interrupt-status register.	KBD_IRQSTATUS	0x0000000F
Enable (0b1)/disable (0b0) certain keyboard events for generating an interrupt request.	KBD_IRQENABLE_SET/KBD_IRQENABLE_CLR [2:0] IT_..._EN	0x–
Unmask (0b1)/mask (0b0) the expected source of wake-up event that generates a wake-up request.	KBD_IRQWAKEEN[2:0] WUP_..._ENA	0x–

Copyright © 2015–2017, Texas Instruments Incorporated

28.5.1.2 Operational Modes Configuration

28.5.1.2.1 Keyboard Controller in Hardware Decoding Mode (Default Mode)

28.5.1.2.1.1 Main Sequence – Keyboard Controller Hardware Mode

After reset, all available functional modes are disabled, except detect-event mode, which is always active. Table 28-13 describes the keyboard controller hardware mode.

Table 28-13. Keyboard Controller Hardware Mode

Step	Register/Bit Field/Programming Model	Value
Activate the internal keyboard controller sequencer by setting the bit.	KBD_CTRL[1] NSOFTWARE_MODE	0b1
Select the functional mode by setting its corresponding bit to 1.	KBD_CTRL[8:5]	0x–
Configure the duration of a key press to allow shortcut detection (desired value of the long-key interrupt or repeat mode value).	KBD_KEYLONGTIME[11:0] LONG_KEY_VALUE	0x–
Configure the period of the long inactivity on the keyboard (desired value of the time-out interrupt).	KBD_TIMEOUT[15:0] TIMEOUT_VALUE	0x–
Configure the debouncing time of filtering the glitches on pressing or releasing key.	KBD_DEBOUNCINGTIME[5:0] DEBOUNCING_VALUE	0x–
Clear the interrupt-status register.	KBD_IRQSTATUS	0x0000000F
Enable (by writing 1)/disable (by writing 0) certain keyboard event for generating an interrupt request	KBD_IRQENABLE_SET or KBD_IRQENABLE_CLR[2:0] IT_..._EN	0x–
Unmask (0b1)/mask (0b0) the expected source of wake-up event that generates a wake-up request.	KBD_IRQWAKEEN[2:0] WUP_..._ENA	0x–
Wait for the KBD_IRQ interrupt signal assertion.		
Read the interrupt-status register to determine which event caused the interrupt.	KBD_IRQSTATUS	
Read the KBD_FULLCODE17_0 to KBD_FULLCODE80_72 registers (or 8 × 8 keyboard-size-supporting KBD_FULLCODE31_0 and KBD_FULLCODE63_32 registers) to determine which key matrix combination was pressed.	KBD_FULLCODE17_0 [ROWi bits] (where i = 0 or 1) up to KBD_FULLCODE71_54 [ROWi bits] (where i = 6 or 7); KBD_FULLCODE80_72 [ROWi bits] (where i = 8); (or KBD_FULLCODE31_0[j] FULL_CODE_31_0 and KBD_FULLCODE63_32[k] FULL_CODE_63_32 bits (where j = 0 to 31, k = 32 to 63)	
Clear the corresponding bit(s) in the interrupt-status register by writing logical 1.	KBD_IRQSTATUS	0x1

NOTE: The long-key detection mode and the repeat mode cannot be used simultaneously, because they share the same interrupt status bit and are mutually exclusive. Software must ensure that only one of these modes at a time is selected.

NOTE: All interrupts are disabled on reset.

NOTE: When two events occur successively before the first event is read, the second interrupt is generated when the first interrupt is cleared. When more than two events in a row occur, the KBD_IRQSTATUS[3] MISS_EVENT bit is set. Software must check this bit, which is not reflected on the KBD_IRQ line.

Copyright © 2015–2017, Texas Instruments Incorporated

NOTE: The keyboard controller uses a posted-write scheme to update any internal register. Software must read the pending write status bits to ensure that the next write access is not discarded because of ongoing write synchronization. For more information, see Section 28.4.8.1, *Write Registers Access*.

28.5.1.2.2 Keyboard Controller Software Scanning Mode

28.5.1.2.2.1 Main Sequence – Keyboard Controller Software Mode

Table 28-14 describes the keyboard controller software mode.

Table 28-14. Keyboard Controller Software Mode

Step	Register/Bit Field/Programming Model	Value D
Deactivate the internal keyboard controller sequencer by clearing the bit.	KBD_CTRL[1] NSOFTWARE_MODE	0b0
Enable the interrupt event by setting the bit.	KBD_IRQENABLE_SET[0] IT_EVENT_EN	0b1
Wait for the KBD_IRQ interrupt signal assertion. Begin the software scan when the interrupt signal is asserted:		
1) Disable all columns to drive a logical 0 on the kbd_col[8:0] output by writing 0xFF. (logical 1 bit = inactive column-row)	KBD_COLUMNOUTPUTS[8:0] KBC_REG	0xFF
2) Drive kbd_col(i) output, (where i = 0 to 8), to 0 to capture a pressed-key-event, at the corresponding row input.	KBD_COLUMNOUTPUTS[i] KBC_REG (where i = 0 to 8)	0b0
3) Read the KBR_LATCH bit field of the KBD_ROWINPUTS register to determine which is the pressed key. IF: KBR_LATCH k-bit = 0 , where k = 0 to 8 Then, the corresponding k-row is connected to the column being enabled.	KBD_ROWINPUTS[8:0] KBR_LATCH	
END IF		
Repeat step 2) and step 3) for all existing columns.	KBD_IRQWAKEEN[2:0] WUP_..._ENA	0x–

NOTE: In software mode, during the manual keyboard scan, an interrupt is generated when a pressed key is detected.

28.5.1.2.3 Using the Timer

For information about programming the keyboard controller timer, see Section 28.4.6.2, *Keyboard Controller Timer*.

28.5.1.2.4 State-Machine Status Register

To see the state of the state-machine, see Section 28.4.6.3, *State-Machine Status*.

28.5.1.3 Keyboard Controller Events Servicing

Table 28-15 lists the keyboard controller event servicing.

Table 28-15. Keyboard Controller Event Servicing

Step	Register/Bit Field/Programming Model	Value
Clear all eventual previous indications of treated interrupts; write the IRQSTATUS register:	KBD_IRQSTATUS	0x0000000F
Enable the desired sources of interrupt by writing in:	KBD_IRQENABLE	0x0000000–

Copyright © 2015–2017, Texas Instruments Incorporated

Table 28-15. Keyboard Controller Event Servicing (continued)

Step	Register/Bit Field/Programming Model	Value
Unmask (enable) the desired sources of interrupt by writing logical 1 in the desired bit fields.	KBD_IRQWAKEEN	0x0000000–
When event occurs:		
Read the status register.	KBD_IRQSTATUS	
IF: KBD_IRQSTATUS[3] MISS_EVENT = 1	Start the interrupt handler for missed event.	
ELSIF: KBD_IRQSTATUS[2] IT_TIMEOUT = 1	Start the interrupt handler for timeout event.	
ELSIF: KBD_IRQSTATUS[1] IT_LONG_KEY = 1	Start the interrupt handler for long key pressed event.	
ELSIF: KBD_IRQSTATUS[0] IT_EVENT = 1	Start the interrupt handler for pressed key event.	
ENDIF		
Wait for the execution of the corresponding interrupt handler.	Interrupt controller of the MPU	
Clear the corresponding IRQ status register bits by writing 1 there.	KBD_IRQSTATUS	0x0000000–
Disable the corresponding sources of interrupt if needed by writing 0 at the corresponding bit fields.	KBD_IRQENABLE or KBD_IRQWAKEEN	0x0000000-
Read the status register.	KBD_IRQSTATUS	
IF :	KBD_IRQSTATUS[2] IT_TIMEOUT	=1
Handle the timeout event.		
Clear the corresponding status flag.	KBD_IRQSTATUS[2] IT_TIMEOUT	0x1
ELSE IF:	KBD_IRQSTATUS[1] IT_LONG_KEY	=1
Handle the long pressed key event.		
Clear the corresponding status flag.	KBD_IRQSTATUS[1] IT_LONG_KEY	0x1
ELSE IF:	KBD_IRQSTATUS[0] IT_EVENT	=1
Handle the pressed key event.		
Clear the corresponding status flag.	KBD_IRQSTATUS[0] IT_EVENT	0x1
ENDIF		
Disable the interrupts if needed.	KBD_IRQENABLE_CLR[2:0]	0x1

Pulse-Width Modulation Subsystem

This chapter describes the Pulse-Width Modulation (PWM) subsystem in the device.

Topic **Page**

29.1 PWM Subsystem Resources 6994
29.2 Enhanced PWM (ePWM) Module 7010
29.3 Enhanced Capture (eCAP) Module 7106
29.4 Enhanced Quadrature Encoder Pulse (eQEP) Module 7130

Copyright © 2015–2017, Texas Instruments Incorporated

29.1 PWM Subsystem Resources

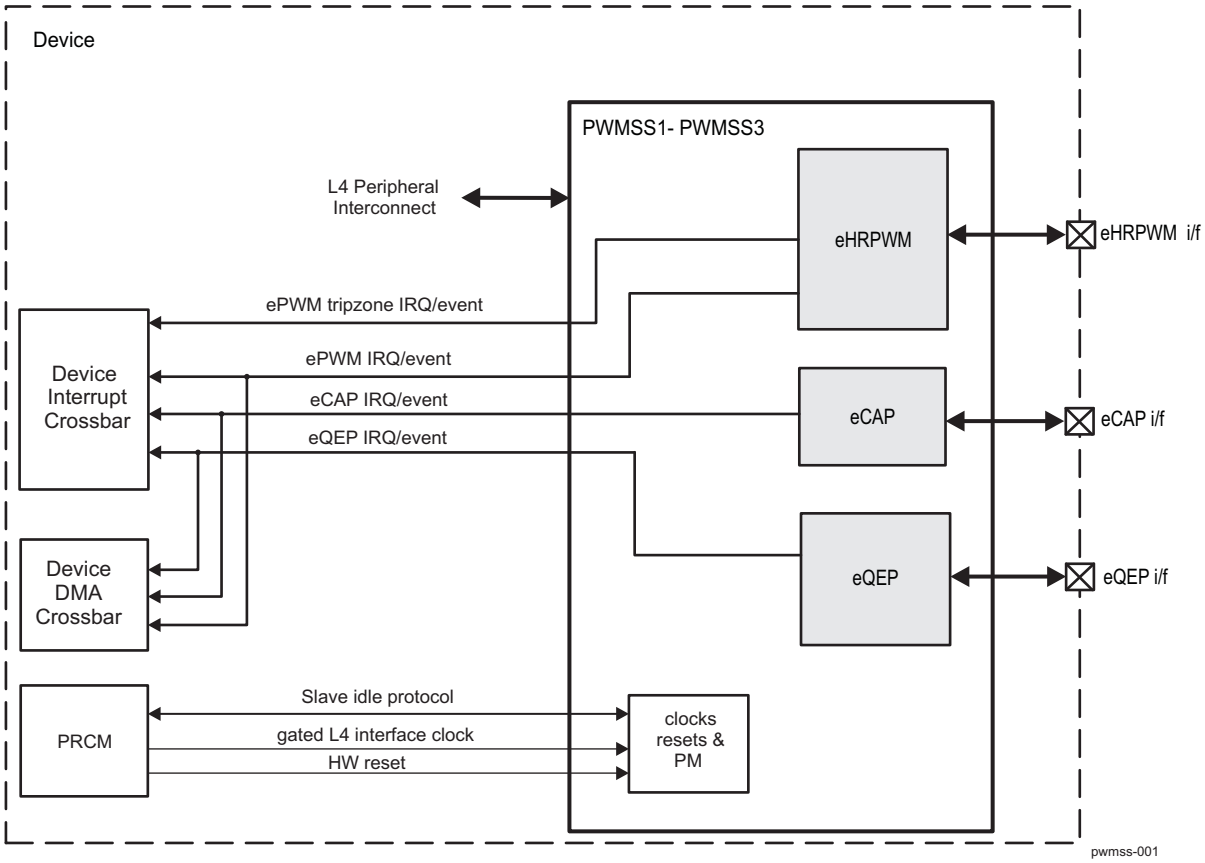
29.1.1 PWMSS Overview

The device has three embedded Pulse Width Modulation Subsystems (PWMSS1, PWMSS2 and PWMSS3). Each PWMSS includes one instance of :

- Enhanced High Resolution Pulse Width Modulator (eHRPWM)
- Enhanced Capture (eCAP)
- Enhanced Quadrature Encoded Pulse (eQEP)

Figure 29-1 shows an overview of each of the 3 available on the device PWM-subsystems.

Figure 29-1. PWMSS Block Diagram



29.1.1.1 PWMSS Key Features

The supported features by the device PWMSS-s are:

eHRPWM

- Dedicated 16 bit time-base with Period/Frequency control
- Can support 2 independent PWM outputs with Single edge operation
- Can support 2 independent PWM outputs with Dual edge symmetric operation
- Can support 1 independent PWM output with Dual edge asymmetric operation
- Supports Dead-band generation with independent Rising and Falling edge delay control
- Provides asynchronous over-ride control of PWM signals during fault conditions
- Supports “trip zone” allocation of both latched and un-latched fault conditions
- Allows events to trigger both CPU interrupts and start of ADC conversions

Copyright © 2015–2017, Texas Instruments Incorporated

- Support PWM chopping by high frequency carrier signal, used for pulse transformer gate drives.
- High-resolution module with programmable delay line:
  - Programmable on a per PWM period basis
  - Can be inserted either on the rising edge or falling edge of the PWM pulse or both or not at all

eCAP

- Dedicated input Capture pin
- 32 bit Time Base (counter)
- 4 x 32 bit Time-stamp Capture registers (PWMSS_ECAP_CAP1 - PWMSS_ECAP_CAP4)
- 4 stage sequencer (Mod4 counter) which is synchronized to external events (ECAPx pin edges)
- Independent Edge polarity (Rising/Falling edge) selection for all 4 events
- Input Capture signal pre-scaling (from 1 to 16)
- One-shot compare register (2 bits) to freeze captures after 1 to 4 Time-stamp events
- Control for continuous Time-stamp captures using a 4 deep circular buffer (PWMSS_ECAP_CAP1 - PWMSS_ECAP_CAP4) scheme
- Interrupt capabilities on any of the 4 capture events

eQEP

- Input Synchronization
- Three Stage/Six Stage Digital Noise Filter
- Quadrature Decoder Unit
- Position Counter and Control unit for position measurement
- Quadrature Edge Capture unit for low speed measurement
- Unit Time base for speed/frequency measurement
- Watchdog Timer for detecting stalls

At a PWMSS system level :

- each of the three PWMSS generates 2x eHRPWM, 1x eCAP and 1x eQEP event mapped to both the device IRQ crossbar.
- Three of the interrupt events (excluding ePWM tripzone event) are also mapped as DMA requests to the device DMA crossbar.
- The different PWMSS - ePWM/eHRPWM and eCAP modules have their synchronization input /output signals coupled in a daisy chain implemented between PWMSS1, PWMSS2 and PWMSS3 within the device.

29.1.1.2 PWMSS Unsupported Fetaures

The PWMSS limitations in the device are :

- No ePWM inputs are pinned-out (available at the off-chip boundary)
- Only one ePWM tripzone input is pinned-out
- No ePWM digital comparator inputs are pinned-out
- Only input signals of QEP are pinned-out.

Table 29-1. PWMSS Unsupported Features

Feature	Reason
ePWM inputs	Not pinned out
ePWM tripzone 1-5 inputs	Only Tripzone0 is pinned out
ePWM digital comparators	Inputs not connected
eQEP quadrature outputs	Only input signals are connected

Copyright © 2015–2017, Texas Instruments Incorporated

29.1.2 PWMSS Environment

29.1.2.1 PWMSS I/O Interface

Table 29-2 shows the device integrated PWMSS subsystems interface signals to external devices.

Table 29-2. PWM Subsystems I/O Signals

PWMSS Modules Level Signal Name	Device Level Signal Name	I/O Type[1]	Description	Module Pin Reset Value

EQEP3_STROBE	eQEP3_strobe	I/O	eQEP3 Strobe input/output	HiZ

[1] I = Input; O = Output

NOTE: The PWMSSn (where n=1 to 3 synchronization I/O signals which are NOT available at chip pad level are as follows:

- ePWM2SYNCI/SYNCO, ePWM3SYNCI/SYNCO
- eCAP1SYNCI/SYNCO, eCAP2SYNCI/SYNCO, eCAP3SYNCI/SYNCO

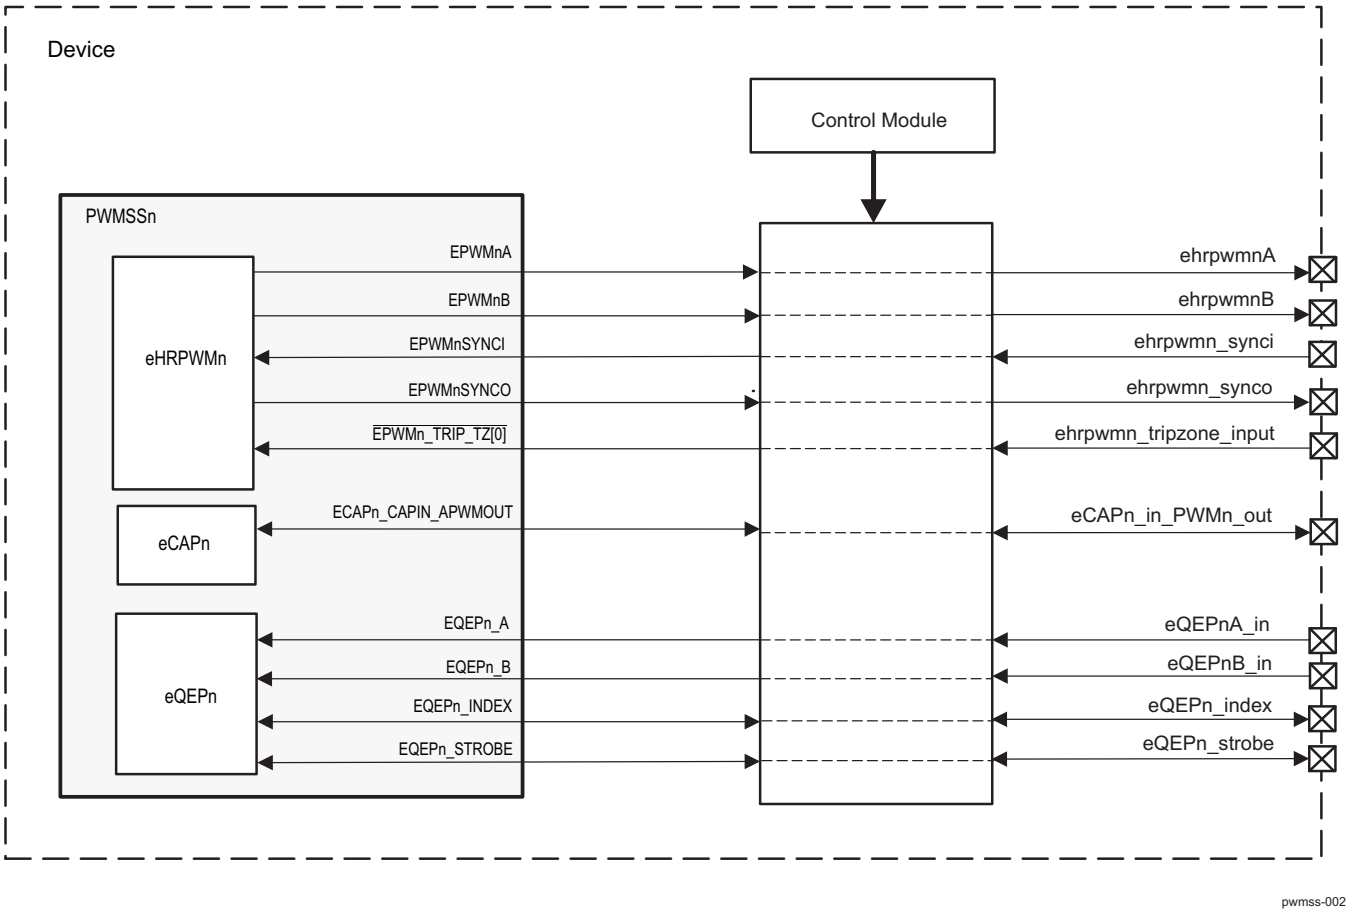
These signals are interconnected via a daisy chain implemented within the device. See also Section 29.1.3.1.2.

For more details on synchronization daisy-chain which exist between the PWMSS1, PWMSS2 and PWMSS3, refer to the Section 29.1.3.1.2 .

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 29-2 shows the external interface I/Os for the integrated modules in PWMSSn (where n=1 to 3) .

Figure 29-2. PWMSS External Interface I/Os



NOTE: The path from module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. For more information, refer to the Section 18.4.6.1.1, *Pad Configuration Registers*, in the chapter, *Control Module*.

Copyright © 2015–2017, Texas Instruments Incorporated

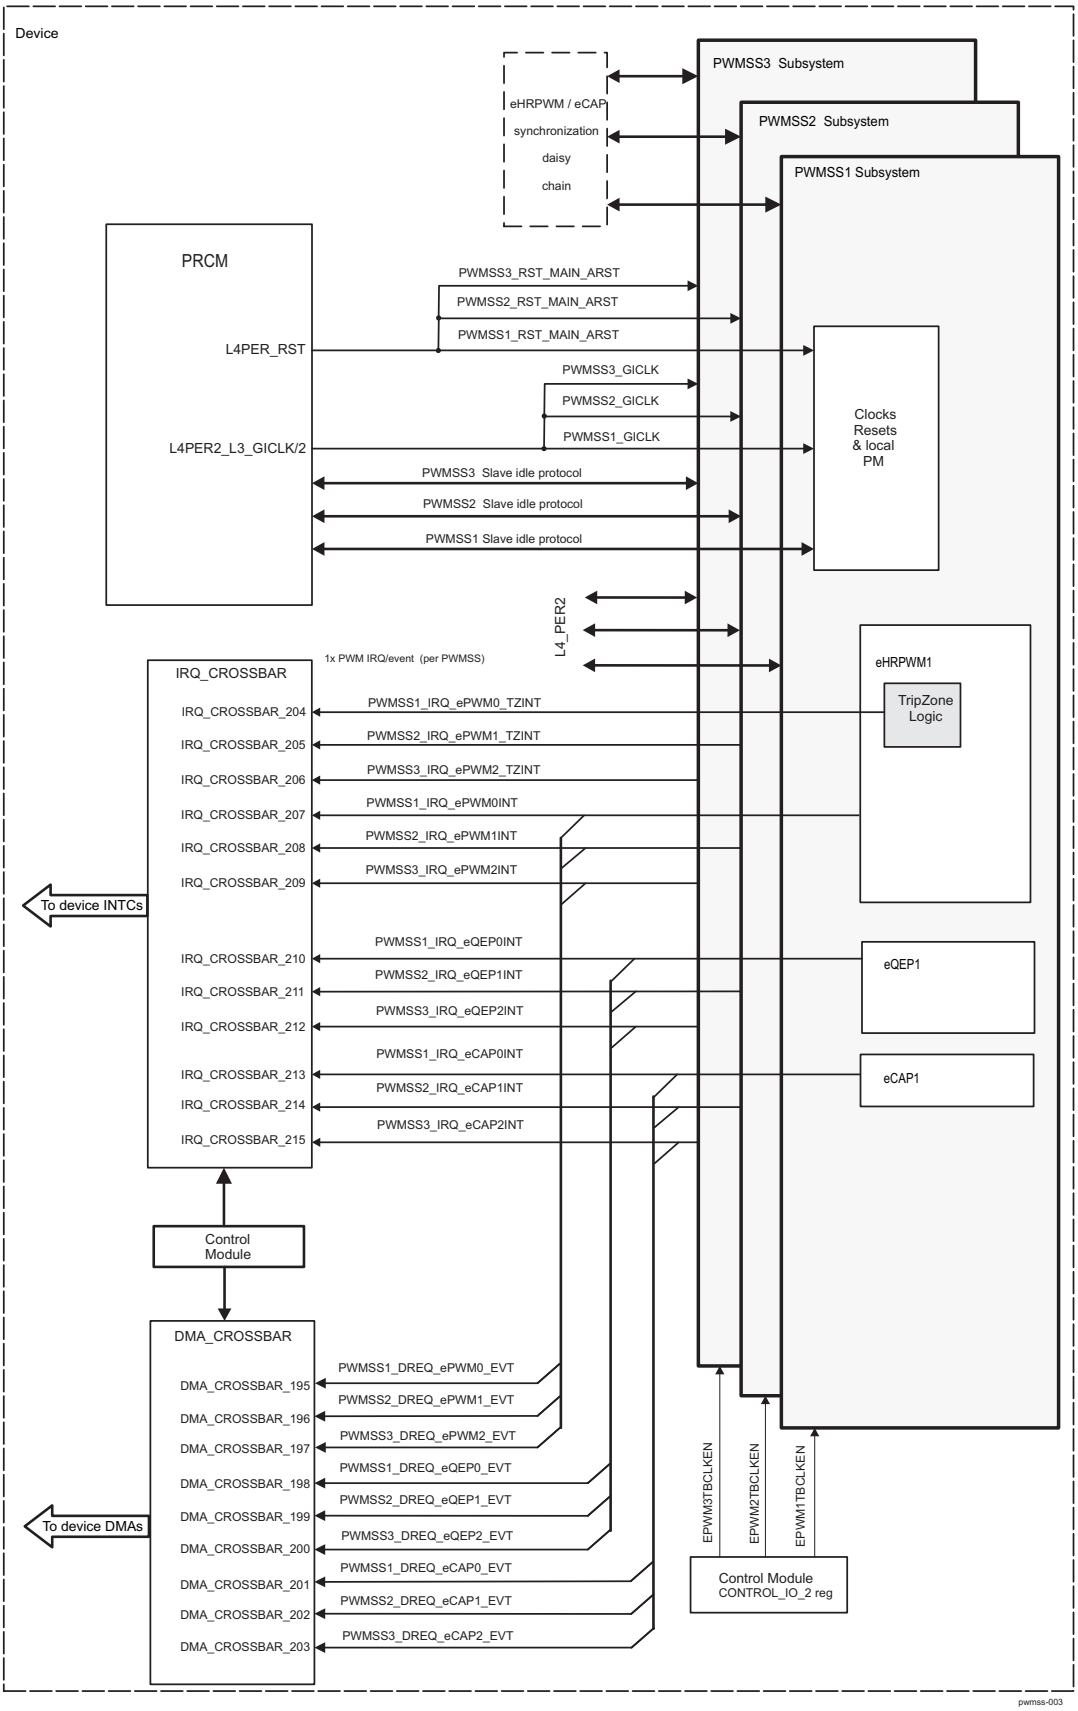
29.1.3 PWMSS Integration

There are three instances of the PWMSS integrated in the device. Each of the the Pulse Width Modulation Subsystems (PWMSS) includes a single instance of one pulse width modulator (ePWM) including an Enhanced High Resolution Modulator (eHRPWM), one Enhanced Capture (eCAP), and one Enhanced Quadrature Encoded Pulse (eQEP) modules.

NOTE: Let's assume that the letter "x" is used to denote the number of a PWMSS submodule (ePWM/eCAP and eQEP) within the device, and NOT within the PWMSSn itself. Because there is only one ePWM/eCAP and eQEP per device PWMSS, device point of view, the index - "x" of a module matches the PWMSS index "n". Therefore the ePWM1/eHRPWM1, eCAP1 and eQEP1 correspond to PWMSS1; ePWM2/eHRPWM2/eCAP2 and eQEP2 correspond to PWMSS2; ePWM3/eHRPWM3/eCAP3 and eQEP3 correspond to PWMSS3, i.e. x=n.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 29-3. PWMSS Integration



Copyright © 2015–2017, Texas Instruments Incorporated

At system level the PWMSS1 through PWMSS3 integration features:

- A 32-bit slave configuration port on the L4_PER2 interconnect.
- A single gateable interface and functional clock from PRCM shared between the 3 PWMSS.
- A slave idle protocol with the device PRCM
- A "non-wakeup capable Smart Idle" mode supported

NOTE: For more information about the slave idle protocol, see Section 3.1.1.1.2, *Module Level Clock Management* in Chapter 3, *Power, Reset, and Clock Management*.

- A non-retention hardware reset from PRCM to all 3 PWMSS simultaneously
- A PWMSS global level software reset which imapcts all registers of a PWMSS at the same time
- 4 hardware events per PWMSS, i.e. a total of 12 events. From these events each PWMSS :
  - generates 4 interrupts to the device IRQ_CROSSBAR
  - generates 3 DMA requests, mapped to the device DMA_CROSSBAR
- A synchronization input/output daisy chain-like connection exists between the PWMSS1,PWMSS2 and PWMSS3. For more details, refer to Section 29.1.3.1.2.

Table 29-3 through Table 29-5 summarize the integration of the module in the device.

Table 29-3. PWMSS Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
PWMSS1	PD_COREAON	L4_PER2

PWMSS1	PWMSS1_IRQ_ePWM0_TZINT	IRQ_CROSSBAR_204	-	eHRPWM1 tripzone event/interrupt.
	PWMSS1_IRQ_ePWM0INT	IRQ_CROSSBAR_207	-	eHRPWM1 event/interrupt.
	PWMSS1_IRQ_eQEP0INT	IRQ_CROSSBAR_210	-	eQEP1 event/interrupt.
	PWMSS1_IRQ_eCAP0INT	IRQ_CROSSBAR_213	-	eCAP1 event/interrupt.
PWMSS2	PWMSS2_IRQ_ePWM1_TZINT	IRQ_CROSSBAR_205	-	eHRPWM2 tripzone event/interrupt.
	PWMSS2_IRQ_ePWM1INT	IRQ_CROSSBAR_208	-	eHRPWM2 event/interrupt.
	PWMSS2_IRQ_eQEP1INT	IRQ_CROSSBAR_211	-	eQEP2 event/interrupt.
	PWMSS2_IRQ_eCAP1INT	IRQ_CROSSBAR_214	-	eCAP2 event/interrupt.
PWMSS3	PWMSS3_IRQ_ePWM2_TZINT	IRQ_CROSSBAR_206	-	eHRPWM3 tripzone event/interrupt.
	PWMSS3_IRQ_ePWM2INT	IRQ_CROSSBAR_209	-	eHRPWM3 event/interrupt.
	PWMSS3_IRQ_eQEP2INT	IRQ_CROSSBAR_212	-	eQEP3 event/interrupt.
	PWMSS3_IRQ_eCAP2INT	IRQ_CROSSBAR_215	-	eCAP3 event/interrupt.
DMA Requests				
Module Instance	**Source Signal Name**	**Destination DMA_CROSSBAR Input**	**Default Mapping**	**Description**
PWMSS1	PWMSS1_DREQ_ePWM0_EVT	DMA_CROSSBAR_195	-	eHRPWM1 event DMA request.
	PWMSS1_DREQ_eQEP0_EVT	DMA_CROSSBAR_198	-	eQEP1 event DMA request.
	PWMSS1_DREQ_eCAP0_EVT	DMA_CROSSBAR_201	-	eCAP1 event DMA request.
PWMSS2	PWMSS2_DREQ_ePWM1_EVT	DMA_CROSSBAR_196	-	eHRPWM2 event DMA request.
	PWMSS2_DREQ_eQEP1_EVT	DMA_CROSSBAR_199	-	eQEP2 event DMA request.
	PWMSS2_DREQ_eCAP1_EVT	DMA_CROSSBAR_202	-	eCAP2 event DMA request.
PWMSS3	PWMSS3_DREQ_ePWM2_EVT	DMA_CROSSBAR_197	-	eHRPWM3 event DMA request.
	PWMSS3_DREQ_eQEP2_EVT	DMA_CROSSBAR_200	-	eQEP3 event DMA request.
	PWMSS3_DREQ_eCAP2_EVT	DMA_CROSSBAR_203	-	eCAP3 event DMA request.

NOTE: The “Default Mapping” column inTable 29-5,*PWMSS Hardware Requests* shows the default mapping of module IRQ and DREQ source signals. These module IRQ and DREQ source signals can also be mapped to other lines of each device Interrupt or DMA controller through the IRQ_CROSSBAR and DMA_CROSSBAR modules, respectively.

For more information about the IRQ_CROSSBAR module, see Section 18.4.6.4, *IRQ_CROSSBAR Module Functional Description*, in Chapter 18, *Control Module*.

For more information about the DMA_CROSSBAR module, see Section 18.4.6.5, *DMA_CROSSBAR Module Functional Description*, in Chapter 18, *Control Module*.

For more information about the device interrupt controllers, see Chapter 17, *Interrupt Controllers*.

For more information about the device DMA_SYSTEM module, see Section 16.1, *System DMA*.

For more information about the device EDMA module, see Section 16.2, *Enhanced DMA*.

29.1.3.1 PWMSS Module Interfaces Implementation

This section describes how the different PWMSSn (where n=1 to 3 for the device) submodules - ePWM/eHRPWM, eQEP and eCAP can be used in terms of their functional interfaces considering PWMSS **device specific integration**.

Copyright © 2015–2017, Texas Instruments Incorporated

29.1.3.1.1 Device Specific PWMSS Features

A High-Resolution PWM (HRPWM) modulator is added to the ePWM module in each of the device PWMSS subsystems, hence the device ePWMs are signified as eHRPWMs.

NOTE: The HR PWM option applies only to the ePWMxA output channel of the PWMSSn (ehre n=1 to 3 for the device). The PWMSSn ePWMxB channel has conventional capabilities. For more details on HRPWM features of ePWM modules refer to the Section 29.2.2.10.

While the eCAP functionalities are fully implemented in the device, the eHRPWM and eQEP module interface have some restrictions in functionality. The eHRPWM and eQEP restrictions which are common between the PWMSS1, PWMSS2 and PWMSS3 subsystems are, as follows:

- For ePWM comparators - only the outputs (ehrpwmxA and ehrpwmxB) are available at chip level
- Only one tripzone input pin - EPWMx_TRIP_TZ[0] of ePWM/eHRPWM is available to user at chip level
- Only QEP inputs (A/ B/INDEX and STROBE) are available to user at chip level

The eHRPWM and eQEP functional interface signals which are NOT available to user for the PWMSS1, PWMSS2 and PWMSS3 are summarized in Table 29-6.

Table 29-6. Device Limitations for the eHRPWM and eQEP Functional Interfaces of PWMSSn

Module Interface	Signal	Description	Comment
PWMSSn eHRPWM (where n= 1 to 3)	EPWM_COMP_EPWMDCMAH	ePWM Comparator A input (HIGH)	Not available at chip boundary (can not be used)
	EPWM_COMP_EPWMDCMAL	ePWM Comparator A input (LOW)	
	EPWM_COMP_EPWMDCMBH	ePWM Comparator B input (HIGH)	
	EPWM_COMP_EPWMDCMBL	ePWM Comparator B input (LOW)	
	EPWM_EPWMA_i	ePWM A input	
	EPWM_EPWMB_i	ePWM B input	
	EPWM_TRIP_TZ[5:1]	ePWM Tripzone inputs [5:1]	
	EPWM_ADC_SOCA	ePWM Start of ADC conversion A output	
	EPWM_ADC_SOCB	ePWM Start of ADC conversion B output	
	EPWM_TRIP_TZ_O[5:0]	ePWM Tripzone outputs	
PWMSSn eQEP (where n= 1 to 3)	EQEP_ERR_PHASE_ERR	eQEP phase error output	Not available at chip boundary (can not be used)
	EQEP_EQEPA_O	eQEP quadrature A output	
	EQEP_EQEPB_O	eQEP quadrature B output	

NOTE: Only for the device eHRPWM1 module, the SYNCI input and SYNCO output signals are available at chip-level – these are the signals ehrpwm1_synci and ehrpwm1_synco, respectively. The eHRPWM2 and eHRPWM3 SYNCi and SYNCO signals are not available on device pads. For more information, see section, PWMSS Environment.

29.1.3.1.2 Daisy-Chain Connectivity between PWMSS Modules

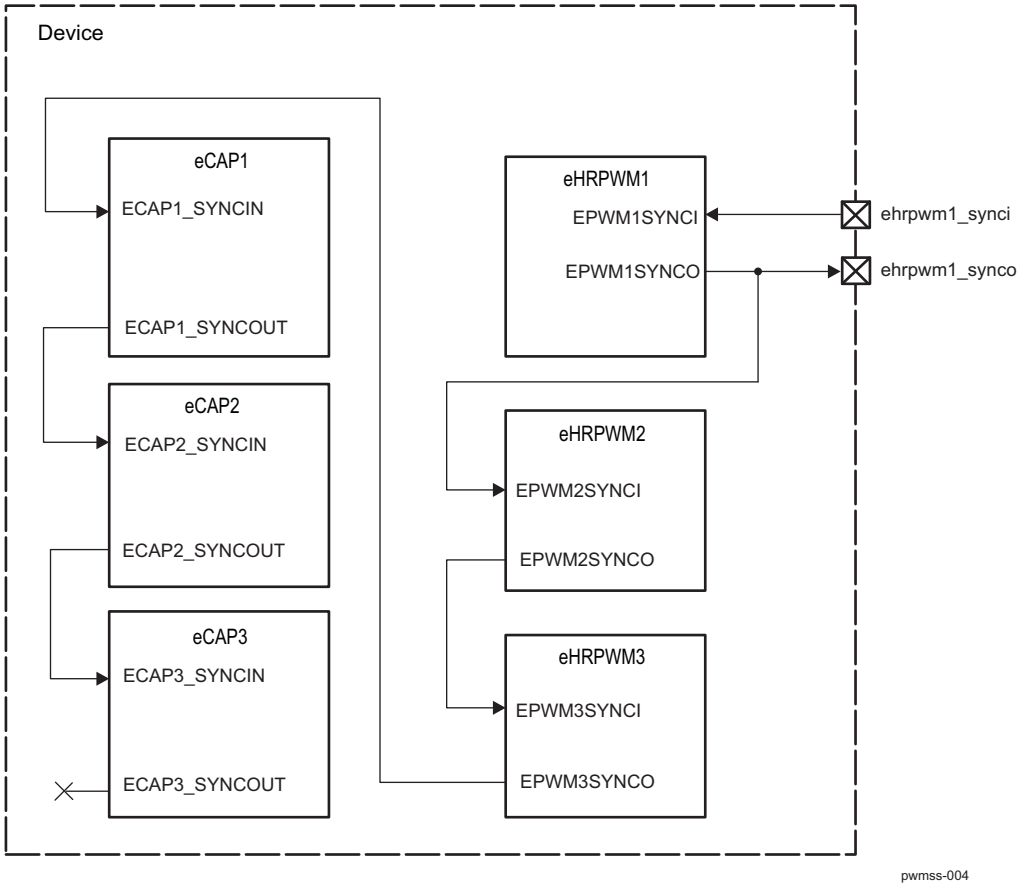
The PWM (eHRPWM) and capture (eCAP) components of the PWMSSn (where n= 1 through 3 for the device) provide synchronization signals to allow them to be synchronized to other modules or events. In the device, these signals are connected in a daisy-chain fashion as shown in Figure 29-4. Only the PWMSS1 eHRPWM input synchronization signal is terminated at a device pad (ehrpwm1_synci signal), such that device external sync events can be directly applied only to the PWMSS1 eHRPWM (eHRPWM1) submodule. A synchronization output from device PWMSS is available only from the eHRPWM1 on the ehrpwm1_synco output pin. The PWMSS2 and PWMSS3 rely on synchronization signals from its neighbour PWM subsystem within device ,as shown in Figure 29-4.

Copyright © 2015–2017, Texas Instruments Incorporated

NOTE: The PWMSS1.EPWM1SYNCI signal (device ehrpwm1_synci input signal) triggers the event of the eHRPWM1 Phase Register being loaded into the Counter register (TBCNT -> TBPHS). This event is synchronous to the PWMSS1 eHRPWM **time-base clock** (TBCLK).

The PWMSS1 EPWM1SYNCO (device ehrpwm1_synco output signal) is implicitly synchronous to the time-base clock, as this signal has a programmable source of event (in EPWM_TBCTL[5:4] SYNCOSEL) triggered synchronously to the eHRPWM1 TBCLK.

Figure 29-4. Synchronization between PWMSS1, PWMSS2 and PWMSS3



29.1.3.1.3 eHRPWM Modules Time Base Clock Gating

Each PWMSSn ePWM/eHRPWM module has an EPWMTBCLKEN module input used to individually enable/disable its ePWM time-base clock. For each PWMSSn (where n=1 to 3), the ePWM/eHRPWM time-base clock enable input comes from the device core control module register - CTRL_CORE_CONTROL_IO_2, as follows:

- PWMSS1 ePWM -> CTRL_CORE_CONTROL_IO_2[22] PWMSS3_TBCLKEN bit
- PWMSS2 ePWM -> CTRL_CORE_CONTROL_IO_2[21] PWMSS2_TBCLKEN bit
- PWMSS3 ePWM -> CTRL_CORE_CONTROL_IO_2[20] PWMSS1_TBCLKEN bit

This individual TBCLKEN control can be used to align the ePWM time base clock between the three device PWMSS subsystems. PWMSSn_TBCLKEN bit set to 0b0, holds the TBCLK generation counter in its reset state. When PWMSSn_TBCLKEN is set to 0b1, then the TBCLK generation counter is allowed to count.

For more details on the CTRL_CORE_CONTROL_IO_2, refer to the Section 18.5, *Control Module Register Manual*, in the chapter *Control Module*.

29.1.4 PWMSS Subsystem Power, Reset and Clock Configuration

29.1.4.1 PWMSS Local Clock Management

The system configuration register - PWMSS_SYSCONFIG is used to configure the local clock management of a PWMSSn slave configuration port on the device L4_PER2 interconnect. Note that this register impacts the behaviour of the root interface and functional clock PWMSSn_GICLK inside PWMSSn (n=1 to 3) shared between the ePWM/eHRPWM, eQEP and eCAP modules within a subsystem. An idle handashake protocol is supported between PWMSSn and the device PRCM.

NOTE: For more information about the slave idle protocol, see Section 3.1.1.1.2, *Module Level Clock Management* in Chapter 3, *Power, Reset, and Clock Management*.

Table 29-7. Local IDLE Clock Management Features

Feature	Register bitfield	Description
Slave idle mode	PWMSS_SYSCONFIG[3:2] IDLEMODE	The available modes are: Force-idle, no-idle, and smart-idle (non-wakeup capable) modes.

NOTE: The device PWM subsystems are part of the CD_L4_PER2 clock domain. For more details on the PWM subsystems top level clock-management modes and control, refer to the Section 3.6.4.1.4, *Clock Domain Module Attributes*, in the Chapter 3, *Power, Reset, and Clock Management*.

29.1.4.2 PWMSS Modules Local Clock Gating

NOTE: PWMSS Modules Local Clock Gating feature is not supported in this family of devices.

In addition to PWMSS level IDLE clock management, described above, a clock configuration register - PWMSS_CLKCONFIG is used to individually gate (stop) or enable interface and functional clock to the ePWM/eHRPWM, eCAP and eQEP modules. By default, the interface/functional clocks are enabled to all modules.

The clock status register - PWMSS_CLKSTATUS is used in the PWMSS submodule to indicated acknowledgement of a clock stop or clock enable request.

The PWMSS_CLKCONFIG and PWMSS_CLKSTATUS role is described in Table 29-8.

Table 29-8. Local Module Clock Control and Status Features

Clock Control/Status Feature	PWMSSn Module	Register bit
Request "stop interface and functional clock" to module	ePWM/eHRPWM	PWMSS_CLKCONFIG[9] EPWM_CLKSTOP_REQ
	eQEP	PWMSS_CLKCONFIG[5] EQEP_CLKSTOP_REQ
	eCAP	PWMSS_CLKCONFIG[1] ECAP_CLKSTOP_REQ
"Stop module interface and functional clock" acknowledged status	ePWM/eHRPWM	PWMSS_CLKSTATUS[9] EPWM_CLKSTOP_ACK
	eQEP	PWMSS_CLKSTATUS[5] EQEP_CLKSTOP_ACK
	eCAP	PWMSS_CLKSTATUS[1] ECAP_CLKSTOP_ACK
Request "enable interface and functional clock" to module	ePWM/eHRPWM	PWMSS_CLKCONFIG[8] EPWM_CLK_EN
	eQEP	PWMSS_CLKCONFIG[4] EQEP_CLK_EN
	eCAP	PWMSS_CLKCONFIG[0] ECAP_CLK_EN
"Enable module Interface and functional clock" acknowledged status	ePWM/eHRPWM	PWMSS_CLKSTATUS[8] EPWM_CLK_EN_ACK
	eQEP	PWMSS_CLKSTATUS[4] EQEP_CLK_EN_ACK
	eCAP	PWMSS_CLKSTATUS[0] ECAP_CLK_EN_ACK

Copyright © 2015–2017, Texas Instruments Incorporated

NOTE: In order for PWMSSn to enter "Idle state", all PWMSSn submodules must have acknowledged a stop clock request, i.e. the PWMSS_CLKSTATUS bits EPWM_CLKSTOP_ACK, ECAP_CLKSTOP_ACK and EQEP_CLKSTOP_ACK must be raised 'HIGH'.

29.1.4.3 PWMSS Software Reset

The PWMSS_SYSCONFIG[0] SOFTRESET bit can be used to exert a "PWMSS" software reset impacting ePWM/eHRPWM, eCAP and eQEP modules of PWMSSn at the same time. The software has to poll the same bit until it is deasserted by HW, to insure software reset of all modules is completed.

29.1.5 PWMSS_CFG Register Manual

This section provides description of the PWM subsystem (top) level functional registers.

29.2 Enhanced PWM (ePWM) Module

29.2.1 ePWM Overview

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention. It needs to be highly programmable and very flexible while being easy to understand and use. The ePWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross coupling or sharing of resources has been avoided; instead, the ePWM is built up from smaller single channel modules with separate resources and that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand its operation quickly.

As already described in Section 29.1.3, the letter x within a signal or module name is used to indicate a generic ePWM instance on a device. For example, output signals EPWMxA and EPWMxB refer to the output signals from the ePWMx instance. Thus, EPWM1A and EPWM1B belong to ePWM1, EPWM2A and EPWM2B belong to ePWM2, etc.

The ePWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB. A given ePWM module functionality can be extended with the so called **High-Resolution Pulse Width modulator**. Refer to the Section 29.1.3, to determine which ePWM instances include the HRPWM feature. The HRPWM functionalities are described in Section 29.2.2.10. Each ePWM module is indicated by a numerical value starting with 1. For example ePWM1 is the first instance, the ePWM2 is the second instance in the device, etc. The ePWMx indicates any instance.

As also described in Section 29.1.3.1.2, the ePWM modules are chained together via a clock synchronization scheme that allows them to operate as a single system when required. Additionally, the PWMSSn integration allows this synchronization scheme to be extended to the capture peripheral modules (eCAP). The number of modules is device-dependent and based on target application needs. Modules can also operate stand-alone.

Each ePWM module supports the following features:

- **Dedicated 16-bit time-base counter with period and frequency control**
- **Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations:**
  - Two independent PWM outputs with single-edge operation
  - Two independent PWM outputs with dual-edge symmetric operation
  - One independent PWM output with dual-edge asymmetric operation
- **Asynchronous override control of PWM signals through software.**
- **Programmable phase-control support for lag or lead operation relative to other ePWM modules.**
- **Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis.**
- **Dead-band generation with independent rising and falling edge delay control.**
- **Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions.**
- **A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs.**
- **Programmable event prescaling minimizes CPU overhead on interrupts.**
- **PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives.**

Each ePWM module is connected to the input/output signals shown in Figure 29-5. The signals are described in detail in subsequent sections.

The order in which the ePWM modules are connected may differ from what is shown in Figure 29-5. See Section 29.1.3.1.2 for the actual synchronization scheme implemented in the device. Each ePWM module consists of seven submodules and is connected within a system via the signals shown in Figure 29-6.

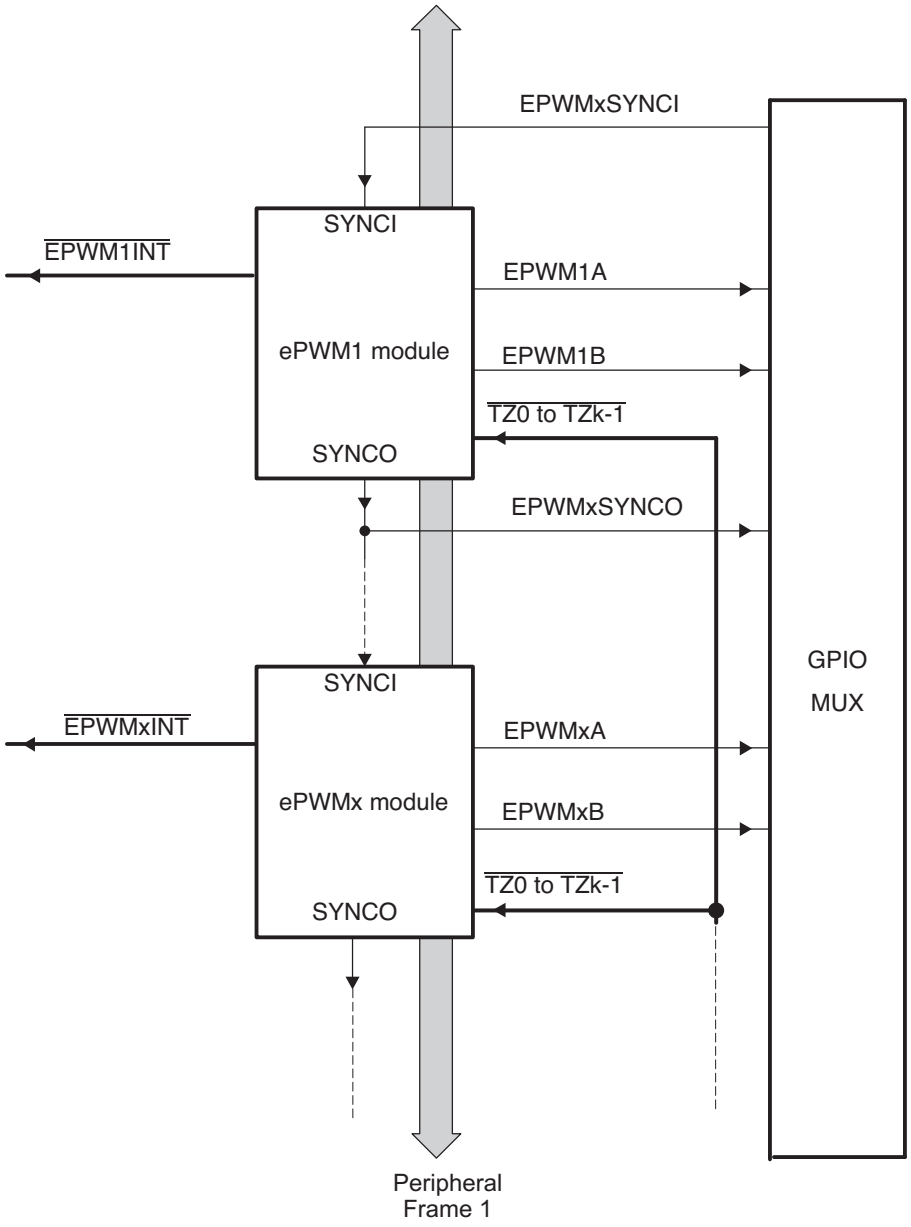
Figure 29-5. Multiple ePWM Modules



Copyright © 2015–2017, Texas Instruments Incorporated

Figure 29-6. Submodules and Signal Connections for an ePWM Module

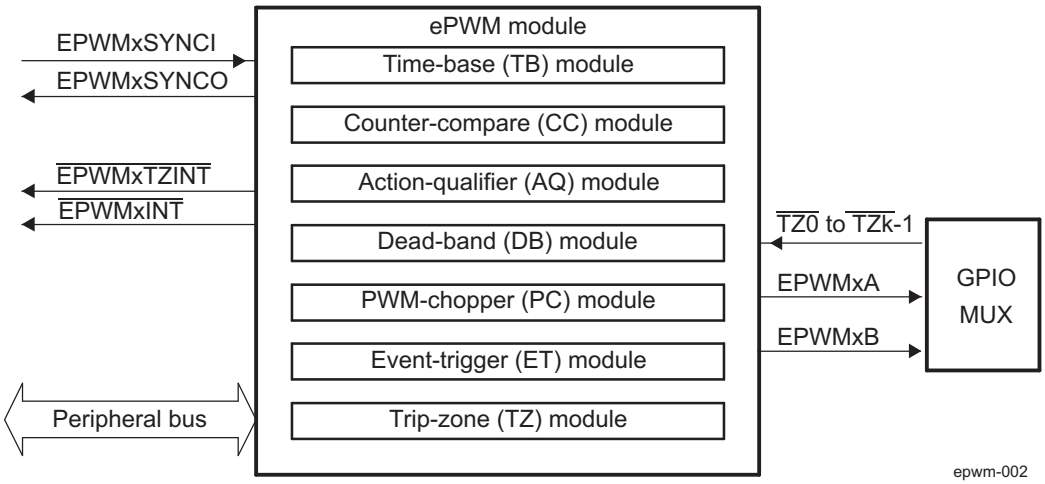


Figure 29-7 shows more internal details of a single ePWM module. The main signals used by the ePWM module are:

- **PWM output signals (EPWMxA and EPWMxB).** The PWM output signals are made available external to the device through the GPIO peripheral described in the system control and interrupts guide for your device.
- **Trip-zone signals ($\overline{\text{TZ0}}$ to $\overline{\text{TZk-1}}$).** These **k** input signals alert the ePWM module of an external fault condition. Each module on a device can be configured to either use or ignore any of the trip-zone signals. The trip-zone signal can be configured as an asynchronous input through the GPIO peripheral.

NOTE: According to the device ePWMx (where x= 1to 3) trip zone i/f implementation, the number of input signals implemented is k=1, which means **ONLY the ePWMx $\overline{\text{TZ0}}$ input is available at chip level**. Refer to the Section 29.1.3, for details on trip zone input implementation.

- **Time-base synchronization input (EPWMxSYNCI) and output (EPWMxSYNCO) signals.** The synchronization signals daisy chain the ePWM modules together. Each module can be configured to either use or ignore its synchronization input. The clock synchronization input and output signal are brought out to pins only for ePWM1 (ePWM module #1). **The synchronization output for ePWM3 (EPWM3SYNCO) is also connected to the eCAP1SYNCI of the first enhanced capture module (eCAP1).**
- **Peripheral Bus.** The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the ePWM register file.

Figure 29-7 also shows the key internal submodule interconnect signals. Each submodule is described in Section 29.2.2.

29.2.2 ePWM Functional Description

Seven submodules are included in each ePWM peripheral. There are some instances that include a high-resolution submodule that allows more precise control of the PWM outputs. Each of these submodules performs specific tasks that can be configured by software.

29.2.2.1 ePWM Submodule Features

Table 29-19 lists the eight key submodules together with a list of their main configuration parameters. For example, if you need to adjust or control the duty cycle of a PWM waveform, then you should see the counter-compare submodule in Section 29.2.2.4 for relevant details.

Table 29-19. Submodule Configuration Parameters

Submodule	Configuration Parameter or Option
Time-base (TB)	• Scale the time-base clock (TBCLK) relative to the system clock (SYSCLKOUT). • Configure the PWM time-base counter (TBCNT) frequency or period. • Set the mode for the time-base counter: – count-up mode: used for asymmetric PWM – count-down mode: used for asymmetric PWM – count-up-and-down mode: used for symmetric PWM • Configure the time-base phase relative to another ePWM module. • Synchronize the time-base counter between modules through hardware or software. • Configure the direction (up or down) of the time-base counter after a synchronization event. • Configure how the time-base counter will behave when the device is halted by an emulator. • Specify the source for the synchronization output of the ePWM module: – Synchronization input signal – Time-base counter equal to zero – Time-base counter equal to counter-compare B (CMPB) – No output synchronization signal generated.
Counter-compare (CC)	• Specify the PWM duty cycle for output EPWMxA and/or output EPWMxB • Specify the time at which switching events occur on the EPWMxA or EPWMxB output
Action-qualifier (AQ)	• Specify the type of action taken when a time-base or counter-compare submodule event occurs: – No action taken – Output EPWMxA and/or EPWMxB switched high – Output EPWMxA and/or EPWMxB switched low – Output EPWMxA and/or EPWMxB toggled • Force the PWM output state through software control • Configure and control the PWM dead-band through software
Dead-band (DB)	• Control of traditional complementary dead-band relationship between upper and lower switches • Specify the output rising-edge-delay value • Specify the output falling-edge delay value • Bypass the dead-band module entirely. In this case the PWM waveform is passed through without modification.
PWM-chopper (PC)	• Create a chopping (carrier) frequency. • Pulse width of the first pulse in the chopped pulse train. • Duty cycle of the second and subsequent pulses. • Bypass the PWM-chopper module entirely. In this case the PWM waveform is passed through without modification.

Table 29-19. Submodule Configuration Parameters (continued)

Submodule	Configuration Parameter or Option
Trip-zone (TZ)	• Configure the ePWM module to react to one, all, or none of the trip-zone pins. • Specify the tripping action taken when a fault occurs: – Force EPWMxA and/or EPWMxB high – Force EPWMxA and/or EPWMxB low – Force EPWMxA and/or EPWMxB to a high-impedance state – Configure EPWMxA and/or EPWMxB to ignore any trip condition. • Configure how often the ePWM will react to the trip-zone pin: – One-shot – Cycle-by-cycle • Enable the trip-zone to initiate an interrupt. • Bypass the trip-zone module entirely.
Event-trigger (ET)	• Enable the ePWM events that will trigger an interrupt. • Specify the rate at which events cause triggers (every occurrence or every second or third occurrence) • Poll, set, or clear event flags
High-Resolution PWM (HRPWM)	• Enable extended time resolution capabilities • Configure finer time granularity control or edge positioning

NOTE: The system clock - SYSCLKOUT is the ePWM functional clock derived from the PWMSSn gateable interface and functional clock PWMSSn_GICLK, described in the Section 29.1.3.

Code examples are provided in the remainder of this chapter that show how to implement various ePWM module configurations. These examples use the constant definitions shown in Example 29-1.

29.2.2.2 Proper ePWM Interrupt Initialization Procedure

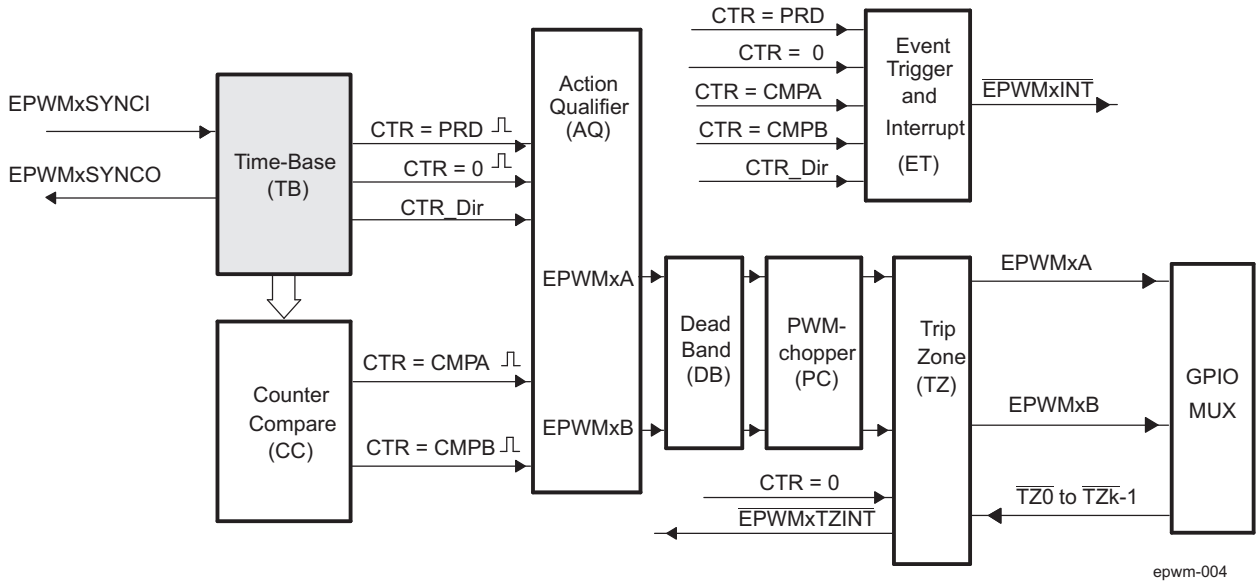
When the ePWM peripheral clock is enabled it may be possible that interrupt flags may be set due to spurious events due to the ePWM registers not being properly initialized. The proper procedure for initializing the ePWM peripheral is:

1. Disable global interrupts (CPU INTM flag)
2. Disable ePWM interrupts
3. Initialize peripheral registers
4. Clear any spurious ePWM flags
5. Enable ePWM interrupts
6. Enable global interrupts

29.2.2.3 ePWM Time-Base (TB) Submodule

Each ePWM module has its own time-base submodule that determines all of the event timing for the ePWM module. Built-in synchronization logic allows the time-base of multiple ePWM modules (ePWMx) to work together as a single system. Figure 29-8 illustrates the time-base module's place within the ePWM.

Figure 29-8. ePWM Time-Base Submodule Block Diagram



Copyright © 2015–2017, Texas Instruments Incorporated

29.2.2.3.1 Purpose of the ePWM Time-Base Submodule

You can configure the time-base submodule for the following:

- Specify the ePWMx time-base counter (TBCNT) frequency or period in the EPWM_TBCNT register to control how often events occur.
- Manage time-base synchronization with other ePWMx modules.
- Maintain a phase relationship with other ePWMx modules.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
  - TBCNT = PRD: Time-base counter (EPWM_TBCNT register) equal to the specified period in EPWM_TBPRD register (i.e. TBCNT = TBPRD) .
  - TBCNT = 0: Time-base counter equal to zero (TBCNT = 0000h).
- Configure the rate of the time-base clock; a prescaled version of the CPU system clock (SYSCLKOUT). This allows the time-base counter to increment/decrement at a slower rate.

29.2.2.3.2 Controlling and Monitoring the ePWM Time-Base Submodule

Table 29-20 lists the registers used to control and monitor the time-base submodule.

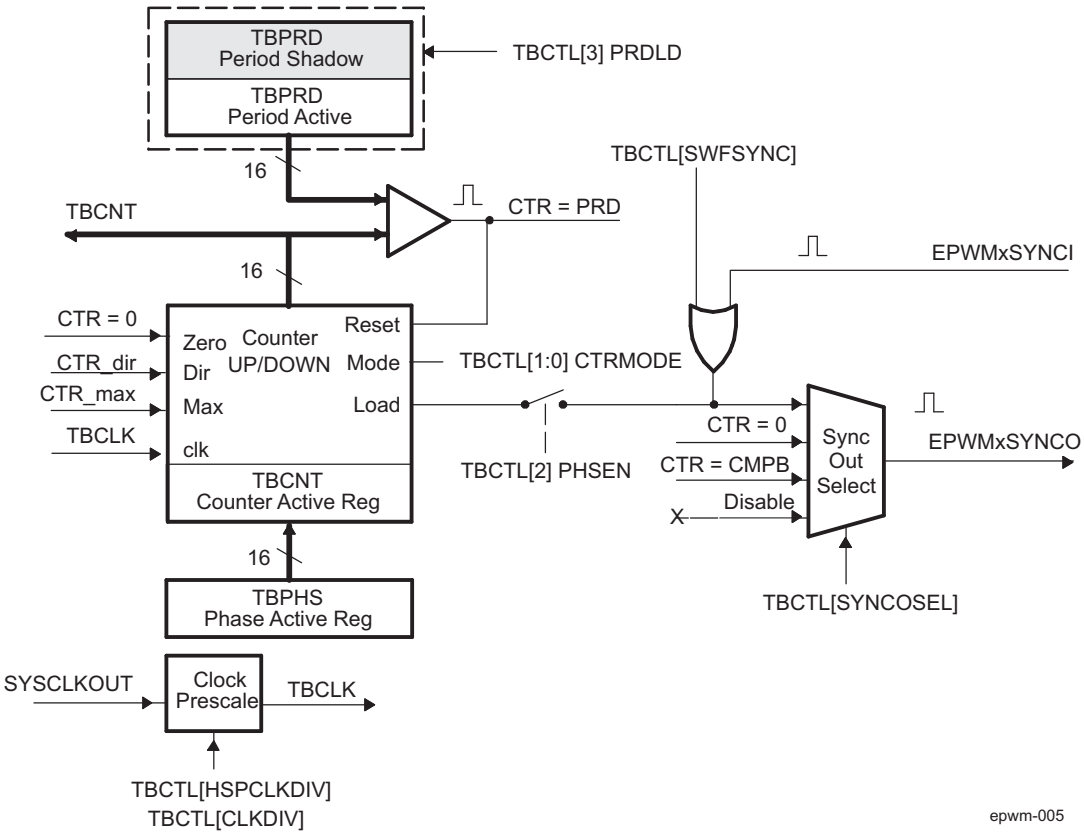
Table 29-20. ePWM Time-Base Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
EPWM_TBCTL	Time-Base Control Register	0h	No
EPWM_TBSTS	Time-Base Status Register	2h	No
HRPWM_TBPHSHR	HRPWM extension Phase Register (1)	4h	No
EPWM_TBPHS	Time-Base Phase Register	6h	No
EPWM_TBCNT	Time-Base Counter Register	8h	No
EPWM_TBPRD	Time-Base Period Register	Ah	Yes

(1) This register is available only on ePWM instances that include the high-resolution extension (HRPWM). On ePWM modules that do not include the HRPWM, this location is reserved. See Section 29.1.3 to determine which ePWM instances include this feature.

Figure 29-9 shows the critical signals and registers of the time-base submodule. Table 29-21 provides descriptions of the key signals associated with the time-base submodule.

Figure 29-9. ePWM Time-Base Submodule Signals and Registers



Copyright © 2015–2017, Texas Instruments Incorporated

Table 29-21. ePWM Key Time-Base Signals

Signal	Description
EPWMxSYNCI	Time-base synchronization input.
	Input pulse used to synchronize the time-base counter with the counter of ePWM module earlier in the synchronization chain. An ePWM peripheral can be configured to use or ignore this signal. For the first ePWM module (EPWM1) this signal comes from a device pin. For subsequent ePWM modules this signal is passed from another ePWM peripheral. For example, EPWM2SYNCI is generated by the ePWM1 peripheral and the EPWM3SYNCI is generated by ePWM2. See Section 29.2.2.3.3.2 for information on the synchronization order of a particular device.
EPWMxSYNCO	Time-base synchronization output.
	This output pulse is used to synchronize the counter of an ePWM module later in the synchronization chain. The ePWM module generates this signal from one of three event sources: 1. EPWMxSYNCI (Synchronization input pulse) 2. TBCNT = 0: The time-base counter (register EPWM_TBCNT) equal to zero (TBCNT = 0000h). 3. TBCNT = CMPB: The time-base counter (register EPWM_TBCNT) equal to the counter-compare B register - EPWM_CMPB (i.e. bitfield TBCNT = bitfield CMPB) .
TBCNT = PRD	Time-base counter equal to the specified period.
	This signal is generated whenever the counter value is equal to the active period register value. That is when TBCNT = TBPRD.
TBCNT = 0	Time-base counter equal to zero.
	This signal is generated whenever the counter value is zero. That is when TBCNT equals 0000h.
TBCNT = CMPB	Time-base counter equal to active counter-compare B register (TBCNT = CMPB).
	This event is generated by the counter-compare submodule and used by the synchronization out logic.
CTR_dir	Time-base counter direction.
	Indicates the current direction of the ePWM's time-base counter. This signal is high when the counter is increasing and low when it is decreasing.
CTR_max	Time-base counter equal max value. (TBCNT = FFFFh)
	Generated event when the EPWM_TBCNT value reaches its maximum value. This signal is only used only as a status bit.
TBCLK	Time-base clock.
	This is a prescaled version of the system clock - SYSCLKOUT(1) and is used by all submodules within the ePWMn. This clock determines the rate at which time-base counter increments or decrements.

(1) The system clock - SYSCLKOUT is the ePWM functional clock derived from the PWMSS n gateable interface and functional clock PWMSSn_GICLK, described in Section 29.1.3.

29.2.2.3.3 Calculating PWM Period and Frequency

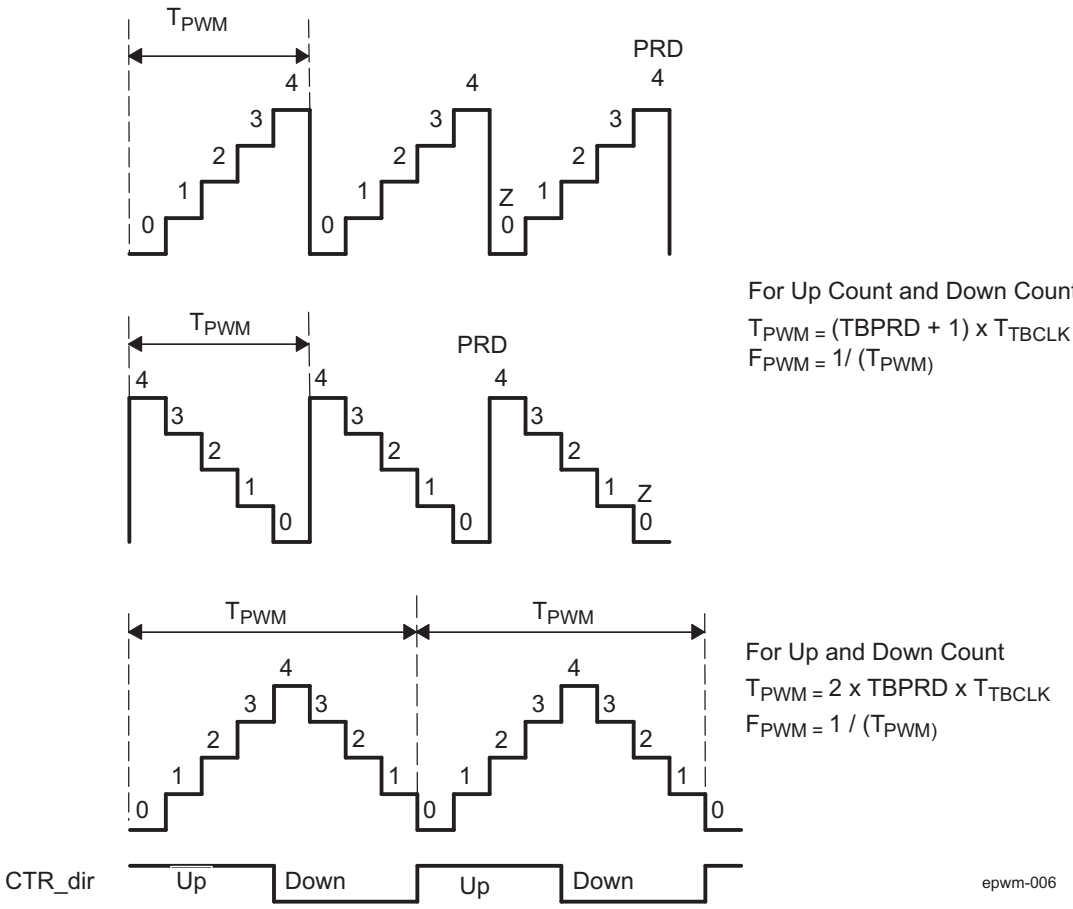
The frequency of PWM events is controlled by the time-base period (EPWM_TBPRD) register and the mode of the time-base counter. Figure 29-10 shows the period (T_{pwm}) and frequency (F_{pwm}) relationships for the up-count, down-count, and up-down-count time-base counter modes when when the period is set to 4 (EPWM_TBPRD register bitfield TBPRD = 0x4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the system clock (SYSCLKOUT).

The time-base counter has three modes of operation selected by the time-base control register (EPWM_TBCTL):

- **Up-Down-Count Mode:** In up-down-count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until it reaches zero. At this point the counter repeats the pattern and begins to increment.
- **Up-Count Mode:** In this mode, the time-base counter starts from zero and increments until it reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.
- **Down-Count Mode:** In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until it reaches zero. When it reaches zero, the time-base counter is reset to the period value and it begins to decrement once again.

Copyright © 2015–2017, Texas Instruments Incorporated

Figure 29-10. ePWM Time-Base Frequency and Period



29.2.2.3.3.1 ePWM Time-Base Period Shadow Register

The time-base period register (EPWM_TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the ePWM module:

- **Active Register:** The active register controls the hardware and is responsible for actions that the hardware causes or invokes.
- **Shadow Register:** The shadow register buffers or provides a temporary holding location for the active register. It has no direct effect on any control hardware. At a strategic point in time the shadow register's content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the EPWM_TBCTL[3] PRDLD bit. This bit enables and disables the EPWM_TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:** The EPWM_TBPRD shadow register is enabled when EPWM_TBCTL[3] PRDLD = 0. Reads from and writes to the EPWM_TBPRD memory address go to the shadow register. The shadow register contents are transferred to the active register (EPWM_TBPRD (Active) ← EPWM_TBPRD (shadow)) when the time-base counter (register (EPWM_TBCNT) equals zero (TBCNT = 0000h). By default the EPWM_TBPRD shadow register is enabled.
- **Time-Base Period Immediate Load Mode:** If immediate load mode is selected (EPWM_TBCTL[3] PRDLD = 1), then a read from or a write to the TBPRD memory address goes directly to the active

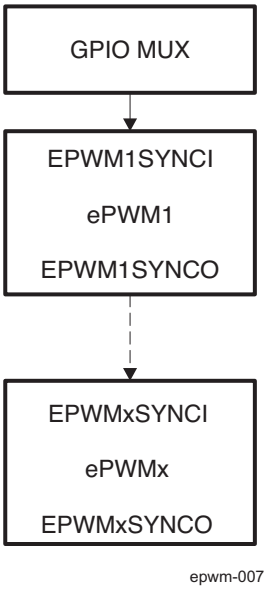
register.

29.2.2.3.3.2 ePWM Time-Base Counter Synchronization

A time-base synchronization scheme connects all of the ePWM modules on a device. Each ePWM module has a synchronization input (EPWMxSYNCI) and a synchronization output (EPWMxSYNCO). The input synchronization for the first instance (ePWM1) comes from an external pin. For the device ePWM environment sync pin details refer to the Section 29.1.2. The possible synchronization connections for the remaining ePWM modules is shown in Figure 29-11.

Figure 29-11. ePWM Time-Base Counter Synchronization Scheme 1



Copyright © 2015–2017, Texas Instruments Incorporated

Each ePWM module can be configured to use or ignore the synchronization input. If the EPWM_TBCTL[2] PHSEN bit is set, then the time-base counter (TBCNT) of the ePWM module (register EPWM_TBCNT) will be automatically loaded with the phase register (EPWM_TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCI: Synchronization Input Pulse:** The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (EPWM_TBPHS → EPWM_TBCNT). This operation occurs on the next valid time-base clock (TBCLK) edge.
- **Software Forced Synchronization Pulse:** Writing a 1 to the EPWM_TBCTL[6] SWFSYNC control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCI.

This feature enables the ePWM module to be automatically synchronized to the time base of another ePWM module. Lead or lag phase control can be added to the waveforms generated by different ePWM modules to synchronize them. In up-down-count mode, the EPWM_TBCTL[13] PHSDIR bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the synchronization event. The TBPHS bit is ignored in count-up or count-down modes. See Figure 29-12 through Figure 29-15 for examples.

Clearing the EPWM_TBCTL[2] PHSEN bit configures the ePWM to ignore the synchronization input pulse. The synchronization pulse can still be allowed to flow-through to the EPWMxSYNCO and be used to synchronize other ePWM modules. In this way, you can set up a master time-base (for example, ePWM1) and downstream modules (ePWM2 - ePWMx) may elect to run in synchronization with the master.

29.2.2.3.4 Phase Locking the Time-Base Clocks of Multiple ePWM Modules

As already described in the Section 29.1.3.1.3, PWMSS1_TBCLKEN through PWMSS3_TBCLKEN bits in the CTRL_CORE_CONTROL_IO_2 register of the device Core Control Module can be used to individually control or globally synchronize the time-base clocks of all enabled ePWM modules on a device. When all PWMSSN_TBCLKEN (where n = 1 to 3) bits are set to 0b0, the time-base clocks of all ePWMx (where x = 1 to 3) modules are stopped (default). When all PWMSSn_TBCLKEN bits are simultaneously set in SW to 0b1, all ePWMx modules (x = 1 to 3) time-base clocks are started with the rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescaler bits in the EPWM_TBCTL register of each ePWM module must be set identically. The proper procedure for enabling the ePWM clocks is as follows:

1. Enable the ePWM module clocks.
2. Set PWMSSn_TBCLKEN = 0. This will stop the time-base clock within any enabled ePWMx module.
3. Configure the prescaler values and desired ePWM modes per each involved ePWMx.
4. Simultaneously set bits PWMSSn_TBCLKEN to 0b1 (where n = 1 to 3) 1.

29.2.2.3.5 ePWM Time-Base Counter Modes and Timing Waveforms

The time-base counter operates in one of four modes:

- Up-count mode which is asymmetrical.
- Down-count mode which is asymmetrical.
- Up-down-count which is symmetrical.
- Frozen where the time-base counter is held constant at the current value.

To illustrate the operation of the first three modes, Figure 29-12 to Figure 29-15 show when events are generated and how the time-base responds to an EPWMxSYNCI signal.
