18.4 SerDes Memory Map/Register Definition

The table below lists the address, name, and a cross-reference to the complete description of each register. The offsets to the memory map table are defined for each SerDes module from 0x000 to 0xFFF (4 KB).

The SerDes module is programmed by control/status registers (CSRs). The CSRs are used for mode control, and to extract status information. All accesses to and from the registers must be made as 32-bit accesses. There is no support for accesses of sizes other than 32 bits. Writes to reserved register bits must always preserve the previous value; that is, the register should be programmed by reading the value, modifying appropriate fields,

and writing back the value. Unless otherwise specified, the read values of unmapped registers or reserved bits in mapped registers are not defined, and must not be assumed to be 0.

The registers described in this section include the superset used for all protocols supported by all instances of the SerDes module. However, each SerDes module implemented on this chip may not support all the protocols described. If a specific SerDes module instance does not support a given protocol, then the registers, fields, or settings specific to that protocol should be considered as reserved for that SerDes module. For more details on the protocols supported on each of the SerDes modules, please refer to The SerDes module as implemented on the chip.

SerDes memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
E_A000	SerDes PLLn Reset Control Register (SerDes1_PLL1RSTCTL)	32	R/W	See section	18.4.1/1202

18.4.1 SerDes PLLn Reset Control Register (SerDes*x*_PLL*n*RSTCTL)

PLLnRSTCTL contains control and status bits for the SerDes PLL n reset state machine.

This register should not be modified if RST_DONE=0 and RST_ERR=0.

Address: Base address + 0h offset + (32d × i), where i=0d to 1d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	RSTREQ	RST_DONE	RST_ERR	Reserved												
Reset	0	0	0	0	n	n	n	0	0	1	0	0	0	1	1	1

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Reserved								PLLRST_B	SDRST_B	SDEN	Reserved				
Reset	0	1	0	0	0	1	0	1	0	0	0	0	0	0	0	0

SerDes*x*_PLL*n*RSTCTL field descriptions

Field	Description
0 RSTREQ	PLL Reset Request - write 1 self-clearing. Software setting of 1 initiates a soft reset of SerDes PLL n, along with all lanes using PLL n. Hardware automatically clears this bit before reset is done. Note: Clearing this bit during the reset sequence has no effect. 0 Not requesting PLL soft reset. 1 Requesting PLL soft reset.
1 RST_DONE	PLL Reset Done from Control Block State Machine 0 PLL reset sequence in progress. 1 PLL reset sequence complete.

Table continues on the next page...

SerDes*x*_PLL*n*RSTCTL field descriptions (continued)

Field	Description
2 RST_ERR	No PLL Lock before counter time_out 0 Normal function 1 PLL lock didn't happen in the expected time period
3–23 -	This field is reserved. Reserved
24 PLLRST_B	PLL reset. Resets PLLn . Default value: 1 The SerDes reset state machine overrides this field to 0 in some states. Setting PLLRST_B=0 when RST_DONE=0 forces a SerDes PLL reset regardless of the reset state machine state, and may cause the reset state machine to time out and set RST_ERR=1. 0 Force PLL reset 1 Application Mode, unless RSTREQ=1
25 SDRST_B	SRDS group reset. Resets all logic in the group of lanes operating from PLLn The SerDes reset state machine overrides this field to 0 in some states. 0 Force SerDes group reset 1 Application Mode, unless RSTREQ=1
26 SDEN	SerDes enable. Enable the section of the SerDes module clocked by PLLn. Default value: 1 The SerDes reset state machine overrides this field to 0 in some states. Setting SDEN=0 when RST_DONE=0 forces a SerDes powerdown regardless of the reset state machine state, and may cause the reset state machine to time out and set RST_ERR=1. 0 Force SerDes power down 1 Application Mode, unless RSTREQ=1
27–31 -	This field is reserved. Reserved

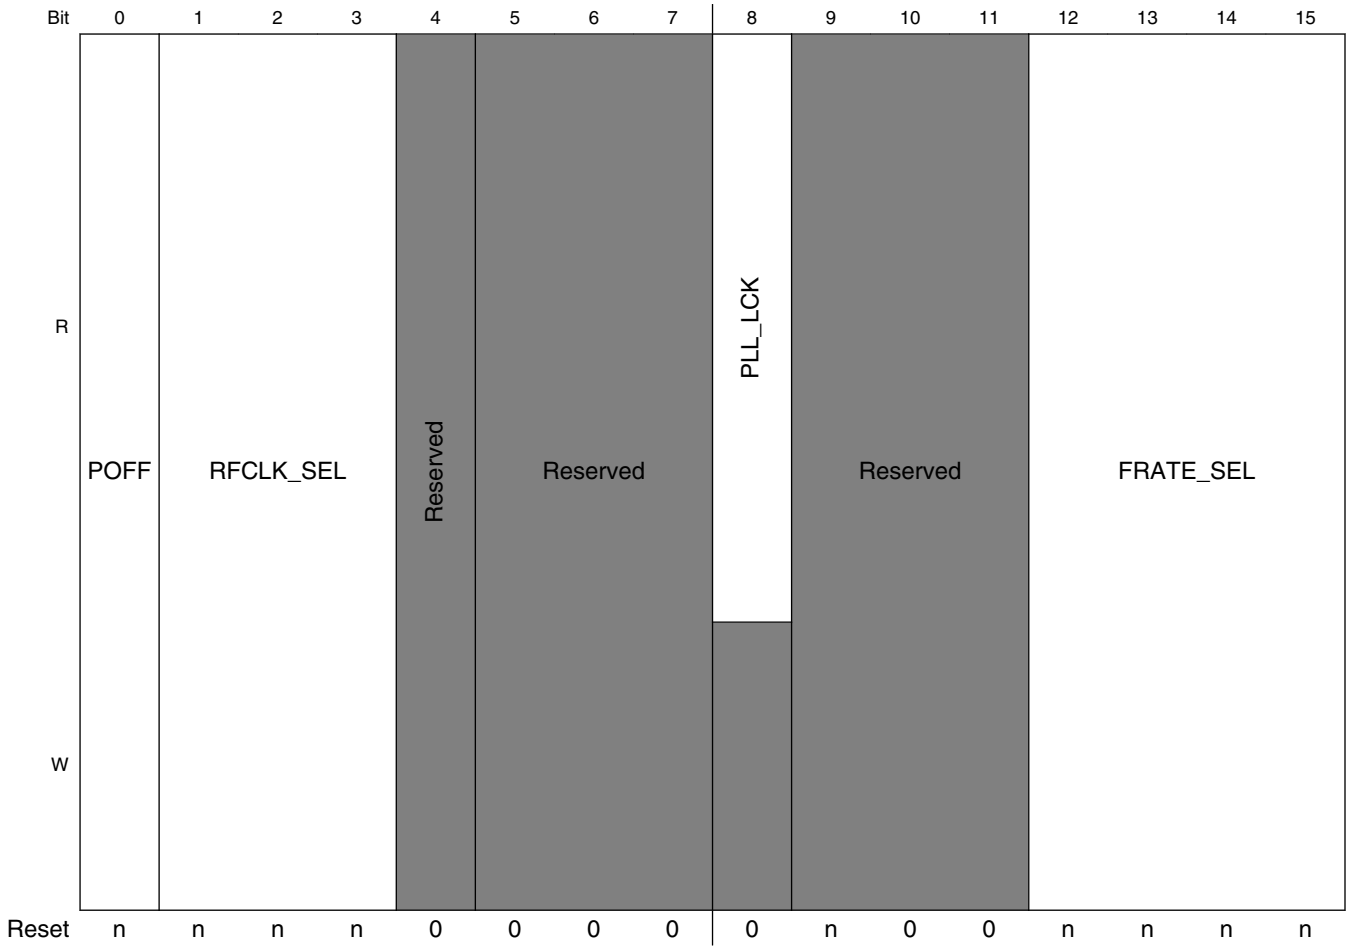
18.4.2 SerDes PLLn Control Register 0 (SerDes*x*_PLL*n*CR0)

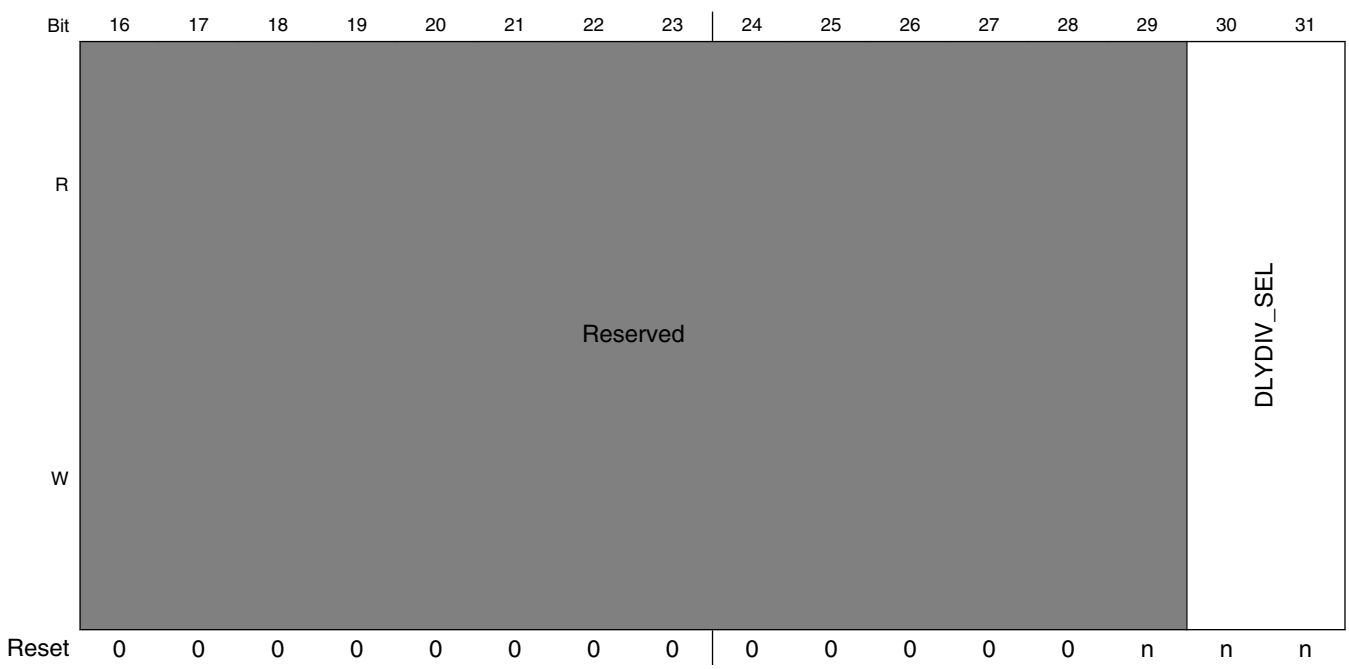
PLLnCR0 contains control and status bits for SerDes PLL n.

NOTE

This register may be automatically updated when PCI Express is active on the SerDes. Only write to this register when all associated PCI Express controllers are inactive.

Address: Base address + 4h offset + (32d × i), where i=0d to 1d





SerDesx_PLL*n*CR0 field descriptions

Field	Description
0 POFF	Power down an unused PLL Default value: 0 0 PLL on 1 PLL off. All lanes referencing this PLL must also be disabled.
1–3 RFCLK_SEL	Reference clock frequency select. Default value set by RCW configuration. Recommended setting per protocol: • SATA: 000, 001 or 011 • Interlaken @ 3.125, 6.25: 001 or 010 • PCIe: 000 or 001 • SRIO @ 3.125: 001 or 010 • SRIO @ 1.25, 2.5, 5: 000, 001 or 100 • Aurora @ 3.125: 001 or 010 • Aurora @ 2.5, 5: 000, 001 or 010 • SGMII @ 3.125: 001 or 010 • SGMII @ 1.25: 000, 001, or 010 • QSGMII: 000 or 001 • HiGig: 001 or 010 • HiGig2: 001 or 010 • XFI 010 or 100 All settings not shown are reserved 000 100 MHz 001 125 MHz 010 156.25MHz 011 150 MHz 100 161.1328125 MHz
4 -	This field is reserved. Reserved
5–7 -	This field is reserved. Reserved
8 PLL_LCK	Indicates PLL(n) has calibrated and locked Read-only status bit. 0 PLL is not locked 1 PLL is locked
9–11 -	This field is reserved. Reserved
12–15 FRATE_SEL	Select frequency of PLL VCO. All lanes within a group must operate at a multiple of this frequency and within specified limits of the protocol(s). All settings not shown are reserved Default value set by RCW configuration. Recommended settings per protocol: • PCIe: 0000 or 0111 (see Frequency Negotiation for details on PCIe speed negotiation) • SATA: 1010 • SRIO: 0000 or 1001 • Aurora: 0000 or 1001

Table continues on the next page...

SerDes*x*_PLL*n*CR0 field descriptions (continued)

Field	Description
	• SGMII-1G: 0000 • SGMII-2.5G: 1001 • QSGMII: 0000 • XAUI: 1001 • XFI: 0110 • HiGig: 1001 • HiGig2: 1001 or 0101 0000 5.00 GHz 0101 3.75 GHz 0110 5.15625 GHz 0111 4 GHz 1001 3.125 GHz 1010 3.0 GHz
16–29 -	This field is reserved. Reserved
30–31 DLYDIV_SEL	Select pllN_ex_dly_clk divider value: All values not shown are reserved 00 pllN_ex_dly_clk off

18.4.3 SerDes PLLn Control Register 1 (SerDes*x*_PLL*n*CR1)

PLLnCR1 contains control bits for SerDes PLL n.

Address: Base address + 8h offset + (32d × i), where i=0d to 1d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	Reserved				PLLBW_SEL	Reserved					VCO_EN	Reserved				
Reset	0	0	0	0	n	0	0	0	0	0	n	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Reserved															
Reset	0	1	0	0	0	0	0	1	0	0	0	0	0	0	0	0

SerDesx_PLLnCR1 field descriptions

Field	Description
0–3 -	This field is reserved. Reserved
4 PLLBW_SEL	Select Higher pll(n) bandwidth. Recommended setting per PLL: 1 0 Nominal PLL Bandwidth 1 PLL Bandwidth Setting
5–9 -	This field is reserved. Reserved
10 VCO_EN	Select VCO for use in PLLn Default value set by RCW configuration. Recommended settings per PLLnCR0[FRATE_SEL] and LNnGCR0[T/RRAT_SEL]: • 5.00 GHz: full/half/quarterspeed: 0 or 1 • 3.75 GHz full speed: 1 • 5.15625 GHz double speed: 0 • 4 GHz double speed: 0 • 3.125 GHz full/double speed: 1 • 3.0 GHz full/half speed: 1 0 Use LC VCO 1 Use ring VCO
11–31 -	This field is reserved. Reserved

18.4.4 SerDes Transmit Calibration Control Register (SerDesx_TCALCR)

TCALCR contains the control bits used for Transmit Calibration.

Address: Base address + 90h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	Reserved				CALRST_B	Reserved										
Reset	0	n	n	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SerDesx_TCALCR field descriptions

Field	Description
0–3 -	This field is reserved. Reserved
4 CALRST_B	Reset to the transmit calibration logic in the right endcap cell During POR (warm reset sequence) it is active and is released when first PLL comes out of reset 0 Reset 1 Application Mode
5–31 -	This field is reserved. Reserved

18.4.5 SerDes Receive Calibration Control Register (SerDesx_RCALCR)

RCALCR contains the control bits for Receive Calibration.

Address: Base address + A0h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	Reserved				CALRST_B	Reserved										
Reset	0	n	n	0	0	0	0	0	0	0	0	0	n	n	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

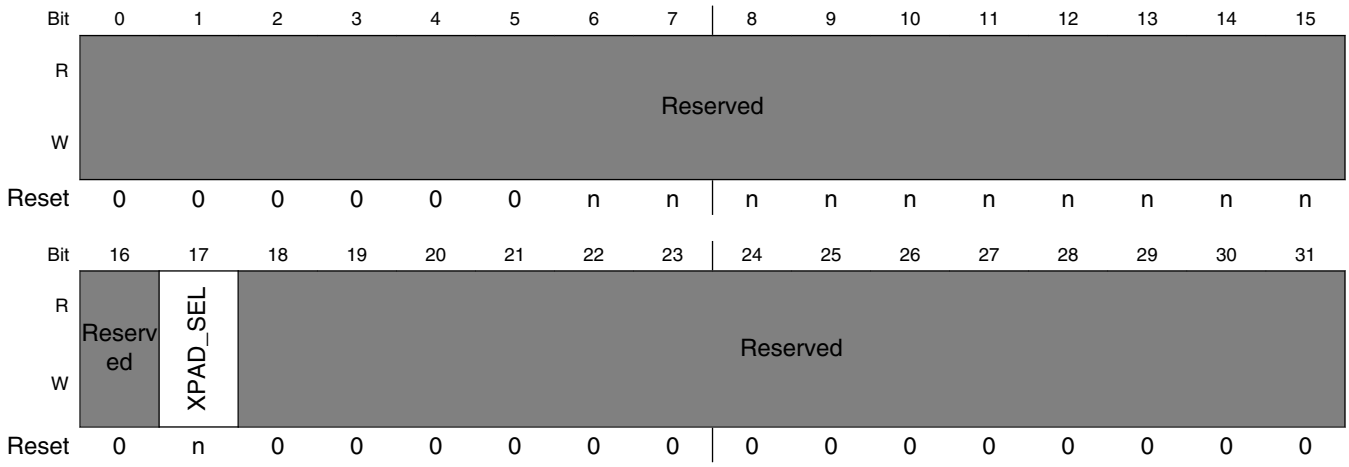
SerDesx_RCALCR field descriptions

Field	Description
0–3 -	This field is reserved. Reserved
4 CALRST_B	Reset to the receiver calibration logic in the left endcap cell 0 = Reset 1 = Application Mode During POR (warm reset sequence) it is active and is released when first PLL comes out of reset
5–31 -	This field is reserved. Reserved

18.4.6 SerDes General Control Register 0 (SerDesx_GR0)

GR0 contains general control/status bits for the SerDes.

Address: Base address + B0h offset



SerDesx_GR0 field descriptions

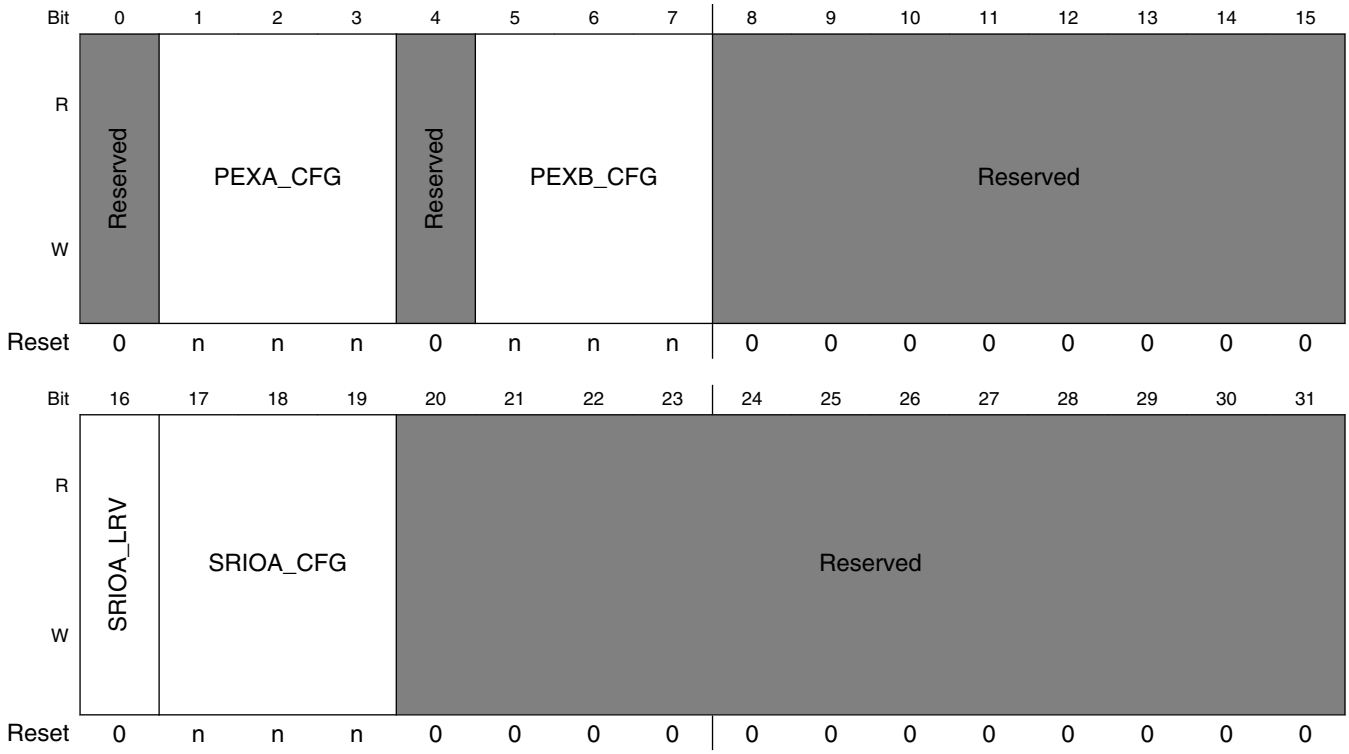
Field	Description
0–16 -	This field is reserved. Reserved
17 XPAD_SEL	Describes to the SerDes module the value of the power supply being used by the Serdes I/Os: 0 = High xpadvdd supply (nominal 1.5 V - see the voltage specifications in the datasheet for details) 1 = Low xpadvdd supply (nominal 1.35 V - see the voltage specifications in the datasheet for details) Full SerDes reset required after changing this value. Warning: Setting XPAD_SEL to low xpadvdd supply when the supply is > 1.35 V +5% may cause irreparable damage to the device.
18–31 -	This field is reserved. Reserved

18.4.7 SerDes Protocol Configuration Register 0 (SerDesx_PCCR0)

PCCR0 contains controls for protocol configuration for PCIe and SRIO.

This register is only valid for SerDes 3 and 4. All fields are reserved for the other SerDes instances.

Address: Base address + E0h offset



SerDesx_PCCR0 field descriptions

Field	Description
0 -	This field is reserved. Reserved
1–3 PEXA_CFG	PEXa Configuration: Default value set by RCW configuration. This field must be 0 for Serdes 1 & 2 All settings not shown are reserved. 000 disabled 100 x4 [3:0] on lanes [3:0] 111 x8 [7:0] on lanes [7:0]
4 -	This field is reserved. Reserved
5–7 PEXB_CFG	PEXb Configuration: Default value set by RCW configuration. This field must be 0 for Serdes 1 & 2 All settings not shown are reserved. 000 disabled 010 x2 [1:0] on lanes [5:4] 011 x4 [3:0] on lanes [7:4]
8–15 -	This field is reserved. Reserved

Table continues on the next page...

SerDesx_PCCR0 field descriptions (continued)

Field	Description
16 SRIOA_LRV	SRIOa Lane Reversal Note: the lane marked as lane 0 in SRIOA_CFG must remain powered up regardless of lane reversal. This field must be 0 for SerDes 1 & 2 0 Lanes mapped as in SRIOA_CFG x2 [0:1] on lanes [7:6] or x4 [0:3] on lanes [7:4] 1 Lanes mapped in the reverse order as SRIOA_CFG, if SRIOa enabled as x2 or x4. x2 [0:1] on lanes [6:7] or x4 [0:3] on lanes [4:7]
17–19 SRIOA_CFG	SRIOa Configuration: Default value set by RCW configuration. This field must be 0 for SerDes 1 & 2 All settings not shown are reserved 000 disabled 110 x2 [0:1] on lanes [7:6] 111 x4 [0:3] on lanes [7:4]
20–31 -	This field is reserved. Reserved

18.4.8 SerDes Protocol Configuration Register 1 (SerDesx_PCCR1)

PCCR1 contains the Protocol Configuration for SGMII and QSGMII.

This register is only valid for SerDes 1 and 2. All fields are reserved for the other SerDes instances.

Address: Base address + E4h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SerDesx_PCCR1 field descriptions

Field	Description
0–1 SGMIIA_CFG	SGMIIa Configuration: Default value set by RCW configuration. This field must be 0 for SerDes 3 & 4

Table continues on the next page...

SerDesx_PCCR1 field descriptions (continued)

Field	Description
	All settings not shown are reserved 00 disabled 10 x1 on Lane 4 to MAC 1
2–3 SGMIIB_CFG	SGMIIb Configuration: Default value set by RCW configuration. This field must be 0 for SerDes 3 & 4 All settings not shown are reserved 00 disabled 10 x1 on Lane 5 to MAC 2
4–5 SGMIIC_CFG	SGMIIc Configuration: Default value set by RCW configuration. This field must be 0 for SerDes 3 & 4 All settings not shown are reserved 00 disabled 10 x1 on Lane 6 to MAC 3
6–7 SGMIID_CFG	SGMIId Configuration: Default value set by RCW configuration. This field must be 0 for SerDes 3 & 4 All settings not shown are reserved 00 disabled 10 x1 on Lane 7 to MAC 4
8–9 SGMIIE_CFG	SGMIIe Configuration: Default value set by RCW configuration. This field must be 0 for Serdes 3 & 4 All settings not shown are reserved 00 disabled 01 x1 on Lane 0 to MAC 5
10–11 SGMIIF_CFG	SGMIIf Configuration: Default value set by RCW configuration. This field must be 0 for SerDes 3 & 4 All settings not shown are reserved 00 disabled 01 x1 on Lane 1 to MAC 6
12–13 SGMIIG_CFG	SGMIIg Configuration: Default value set by RCW configuration. This field must be 0 for Serdes 3 & 4 All settings not shown are reserved

Table continues on the next page...

SerDesx_PCCR1 field descriptions (continued)

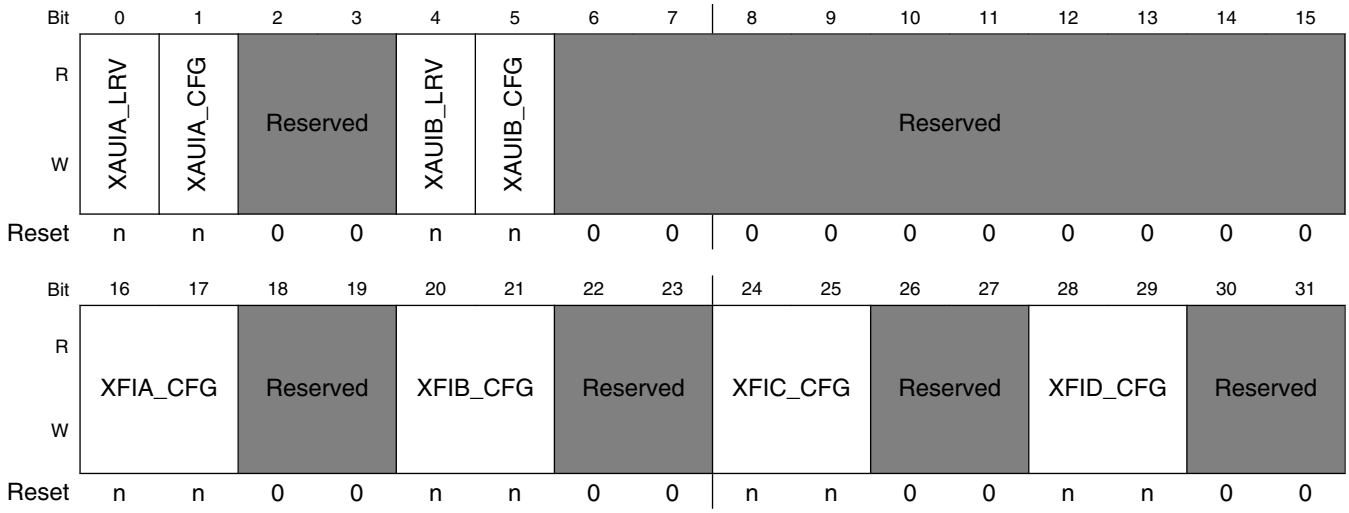
Field	Description
	00 disabled 01 x1 on Lane 3 to MAC 9
14–15 SGMIIH_CFG	SGMIIh Configuration: Default value set by RCW configuration. This field must be 0 for Serdes 3 & 4 All settings not shown are reserved 00 disabled 01 x1 on Lane 2 to MAC 10
16–23 -	This field is reserved. Reserved
24–25 QSGMA_CFG	QSGMIIa Configuration: Default value set by RCW configuration. This field must be 0 for SerDes 3 & 4 All settings not shown are reserved 00 disabled 01 x1 on Lane 6 to MACs 1-4
26–27 -	This field is reserved. Reserved
28–29 QSGMB_CFG	QSGMIIb Configuration: Default value set by RCW configuration. This field must be 0 for SerDes 3 & 4 All settings not shown are reserved 00 disabled 01 x1 on Lane 2 to MACs 5-6,9-10
30–31 -	This field is reserved. Reserved

18.4.9 SerDes Protocol Configuration Register 2 (SerDesx_PCCR2)

PCCR2 contains the Protocol Configuration for XAUI and XFI. Note that HiGig and HiGig2 use XAUI configuration.

This register is only valid for SerDes 1 and 2. All fields are reserved for the other SerDes instances.

Address: Base address + E8h offset



SerDesx_PCCR2 field descriptions

Field	Description
0 XAUIA_LRV	XAUIa Lane Reversal Note: the lane marked as lane 0 in XAUIA_CFG must remain powered up regardless of lane reversal. 0 Lanes mapped as in XAUIA_CFG x4 [3:0] on lanes [3:0] 1 Lanes mapped in the reverse order as XAUIA_CFG, if XAUIa enabled. x4 [3:0] on lanes [0:3]
1 XAUIA_CFG	XAUIa Configuration: Default value set by RCW configuration. This field must be 0 for SerDes 3 & 4 0 Disabled 1 x4 [3:0] on lanes [3:0] to MAC 9
2–3 -	This field is reserved. Reserved
4 XAUIB_LRV	XAUIb Lane Reversal Note: the lane marked as lane 0 in XAUIB_CFG must remain powered up regardless of lane reversal. 0 Lanes mapped as in XAUIB_CFG x4 [3:0] on lanes [7:4] 1 Lanes mapped in the reverse order as XAUIB_CFG, if XAUIb enabled. x4 [3:0] on lanes [4:7]
5 XAUIB_CFG	XAUIb Configuration: Default value set by RCW configuration. This field must be 0 for SerDes 3 & 4 0 Disabled 1 x4 [3:0] on lanes [7:4] to MAC 10

Table continues on the next page...

SerDesx_PCCR2 field descriptions (continued)

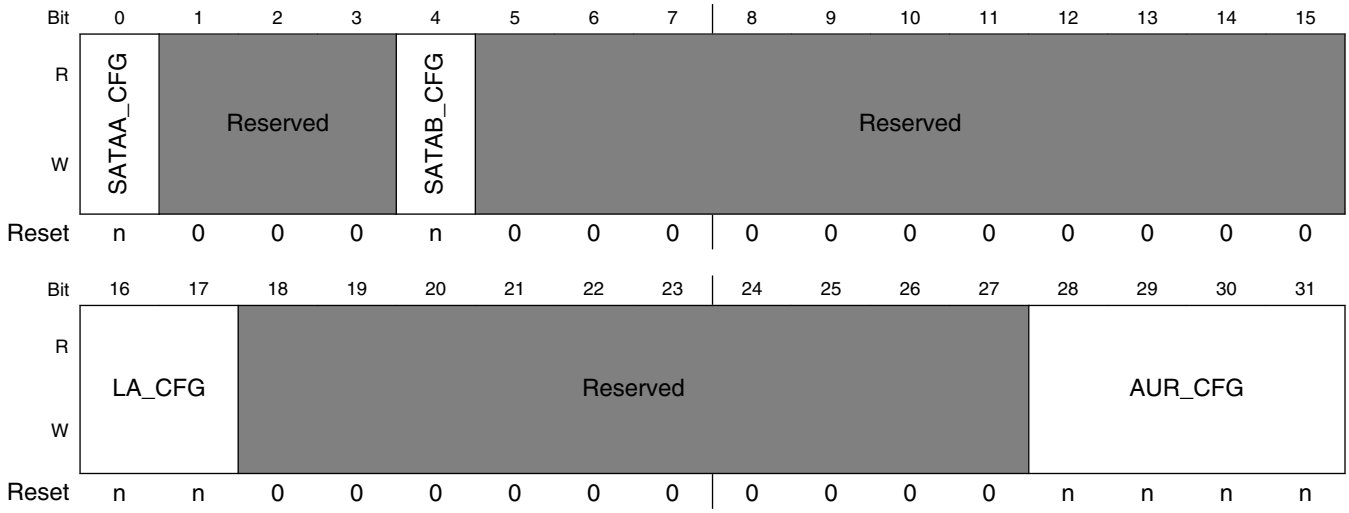
Field	Description
6–15 -	This field is reserved. Reserved
16–17 XFIA_CFG	XFIa Configuration: Default value set by RCW configuration. This field must be 0 for SerDes 3 & 4 All settings not shown are reserved 00 Disabled 01 x1 on Lane 3 to FM2 MAC 9
18–19 -	This field is reserved. Reserved
20–21 XFIB_CFG	XFIb Configuration: Default value set by RCW configuration. This field must be 0 for SerDes 3 & 4 All settings not shown are reserved 00 Disabled 01 x1 on Lane 2 to FM2 MAC 10
22–23 -	This field is reserved. Reserved
24–25 XFIC_CFG	XFIc Configuration: Default value set by RCW configuration. This field must be 0 for SerDes 3 & 4 All settings not shown are reserved 00 Disabled 01 x1 on Lane 0 to FM1 MAC 9
26–27 -	This field is reserved. Reserved
28–29 XFID_CFG	XFId Configuration: Default value set by RCW configuration. This field must be 0 for SerDes 3 & 4 All settings not shown are reserved 00 Disabled 01 x1 on Lane 1 to FM1 MAC 10
30–31 -	This field is reserved. Reserved

18.4.10 SerDes Protocol Configuration Register 4 (SerDesx_PCCR4)

PCCR4 contains the protocol configuration for:

- SATA
- Interlaken-LA
- Aurora

Address: Base address + F0h offset



SerDesx_PCCR4 field descriptions

Field	Description
0 SATAA_CFG	SATAa Configuration: Note: this field must be 0 for SerDes 1, 2, & 3. 0 Disabled 1 x1 on Lane 6
1–3 -	This field is reserved. Reserved
4 SATAB_CFG	SATAb Configuration: Note: this field must be 0 for SerDes 1, 2, & 3. 0 Disabled 1 x1 on Lane 7
5–15 -	This field is reserved. Reserved
16–17 LA_CFG	LA Configuration: All settings not shown are reserved Note: this field must be 0 for SerDes 1, 2, & 4. 00 Disabled 01 x4 [3:0] on lanes [3:0] 11 x8 [7:0] on lanes [7:0]
18–27 -	This field is reserved. Reserved
28–31 AUR_CFG	AURORA Configuration Note: this field must be 0 for SerDes 1, 2, & 3.

Table continues on the next page...

SerDesx_PCCR4 field descriptions (continued)

Field	Description
	All settings not shown are reserved. 0000 disabled 0110 x2 [1:0] on lanes [4:5] 1001 x4 [3:0] on lanes [4:7]

18.4.11 SerDes PCIe Equalization Configuration Register (SerDesx_PEXEQCR)

PEXEQCR (y=0-10) contains the PCIe gen3 Tx equalization configuration values.

Address: Base address + 300h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SerDesx_PEXEQCR field descriptions

Field	Description
0–19 -	This field is reserved. Reserved
20–25 FS	PCI Express FS value. This field determines the FS value advertised during 8.0 GT/s link equalization phase 1, and is also used to calculate the preset C(0). Default value = 0x30 This value applies to all PCIe links on
26–31 LF	PCI Express LF value. This field determines the LF value advertised during 8.0 GT/s link equalization phase 1. Default value =0x10 This value applies to all PCIe links on

18.4.12 SerDes PCIe Equalization Preset n Register (SerDesx_PEXEQP*n*CR)

PEXEQPyCR (y=0-10) contains the PCIe gen3 Tx equalization preset values. Note that C(0) is automatically calculated from C(-1), C(+1), and PEXEQCR[FS].

Address: Base address + 304h offset + (4d × i), where i=0d to 10d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

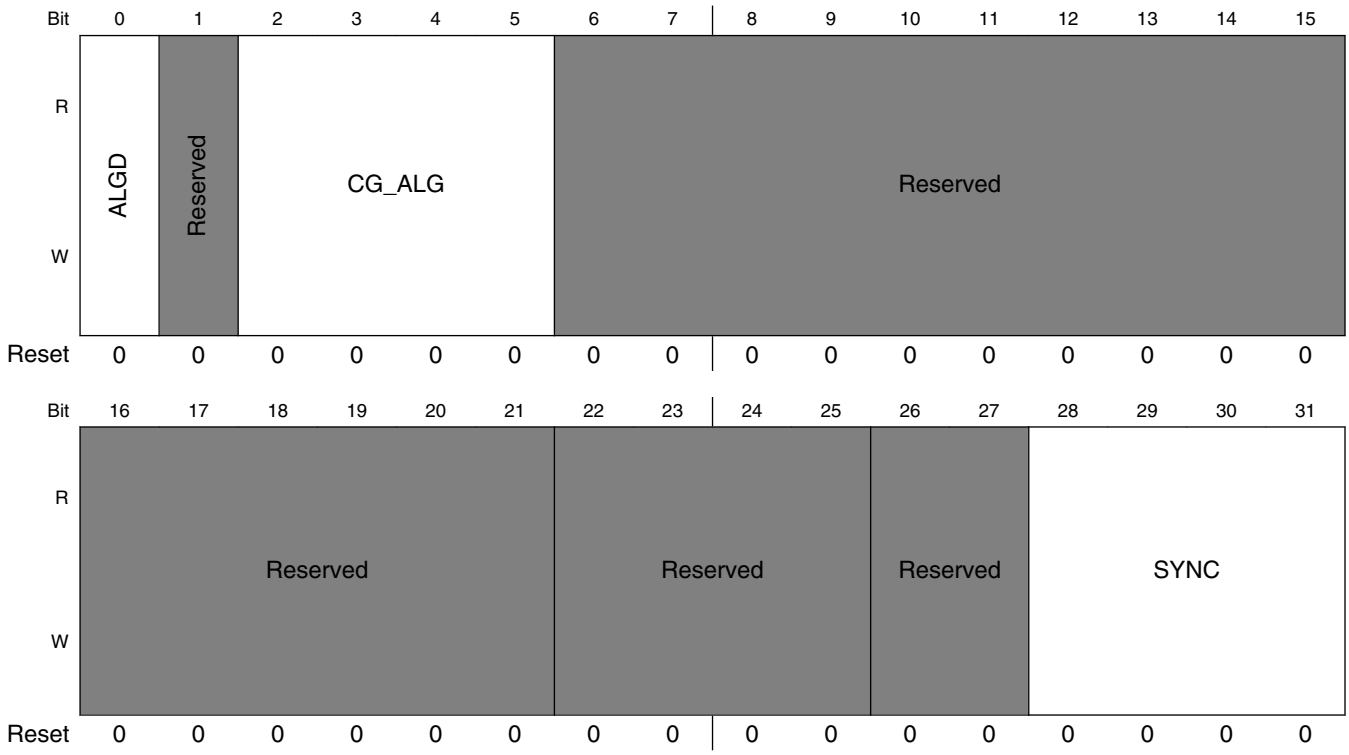
SerDesx_QSGMII*n*CR1 field descriptions

Field	Description
0–2 MDEV_PORT	Device port ID. Compared to upper 3 bits of MDIO_CTL[PHY ADDR] to accept a command. The lower 2 bits of PHY Address map the SGMII port within the SGMII PCS. Note: software must wait at least 3 platform clocks after changing this value before performing any MDIO accesses to the QSGMIIn PCS.
3–31 -	This field is reserved. Reserved

18.4.17 XAUIx Protocol Control Register 1 (SerDes*x*_XAUI*n*CR1)

XAUInCR1 contains control bits used for the XAUIn protocol logic.

Address: Base address + 6A4h offset + (16d × i), where i=0d to 1d



SerDes*x*_XAUI*n*CR1 field descriptions

Field	Description
0 ALGD	Lane alignment Status. Asserted to indicate that the lanes are correctly synchronized, deasserted when the lane synchronization is lost or not acquired.
1 -	This field is reserved. Reserved
2–5 CG_ALG	Core Group alignment indication. One signal per lane set to "1" to indicate that the code group align
6–21 -	This field is reserved. Reserved
22–25 -	This field is reserved. Reserved
26–27 -	This field is reserved. Reserved
28–31 SYNC	Lane Synchronization. One signal per lane, asserted to 1 to indicate that the lane is correctly synchronized.

18.4.18 XFIx Protocol Control Register 1 (SerDesx_XFInCR1)

XFInCR1 contains the control bits used for the XFIn Protocol Converter

Address: Base address + 6C4h offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SerDesx_XFInCR1 field descriptions

Field	Description
0–4 MDEV_PORT	MDIO bus port address. Compared to the MDIO_CTL[DEV_ADDR] to accept a command. Default value: 0 Note: software must wait at least 3 platform clocks after changing this value before performing any MDIO accesses to the XFIn PCS.
5–31 -	This field is reserved. Reserved

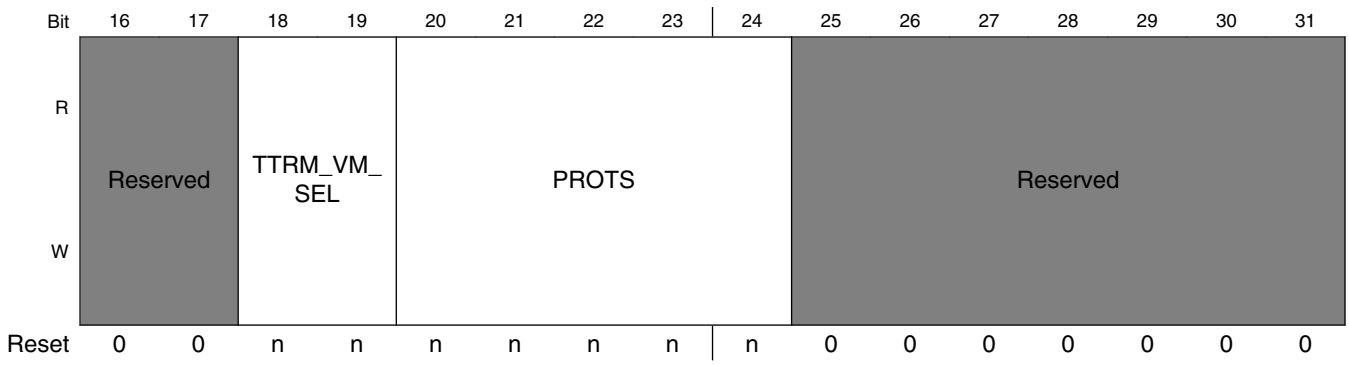
18.4.19 General Control Register 0 - Lane n (SerDesx_LNnGCR0)

LNnGCR0 contains functional control bits for SerDes lane n.

Special consideration must be taken when writing this register while PLLnRSTCTL[RST_DONE]=0. See RRST_B and TRST_B fields for details.

Address: Base address + 800h offset + (64d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	RPLL_LES	Reserved	RRAT_SEL		TPLL_LES	Reserved	TRAT_SEL		Reserved	RRST_B	TRST_B	RX_ PD	TX_ PD	IF20BIT_EN	Reserved	FIRST_LANE
Reset	n	0	n	n	n	0	n	n	0	n	n	n	n	n	0	n



SerDesx_LNnGCR0 field descriptions

Field	Description
0 RPLL_LES	Directs the RX portion of lane n to use the corresponding PLL. Default value set by reset configuration. Note: for m=0-1, PLL2 cannot be selected. PLL1 is used regardless of this setting. Note: must be set the same as TPLL_LES for normal function. See Lane Reset and Reconfiguration for details on the sequence required to change this setting. 0 If m=0-1, use PLL1; If m=2-7, use PLL2 1 If m=0-1, use PLL1; If m=2-7, use PLL1
1 -	This field is reserved. Reserved
2–3 RRAT_SEL	Receiver speed selection for lane m, relative to the corresponding PLLnCR0[FRATE_SEL], n as selected by LNnGCR0[RPLL_LES]: Default value set by reset configuration. Required setting per protocol: SGMII-1G: 10 (1.25 Gbaud) SGMII-2.5G: 00 (3.125 Gbaud) QSGMII: 00 XAUI: 00 XFI: 11 SRIO: 01 (2.5 Gbaud) SRIO: 00 (3.125/5 Gbaud) Aurora: 01 (2.5 Gbaud) Aurora: 00 (3.125/5 Gbaud) Interlaken: 11 (6.25 Gbaud) PCIe: N/A (receiver speed selection automatically selected by protocol) SATA: N/A (receiver speed selection automatically selected by protocol) This register value is overridden by the protocol logic when running in the following modes: • PCIe • SATA Note: must be set the same as TRAT_SEL for normal function.

Table continues on the next page...

SerDesx_LNnGCR0 field descriptions (continued)

Field	Description
	00 Same as FRATE_SEL 01 FRATE_SEL/2 10 FRATE_SEL/4 11 FRATE_SEL*2
4 TPLL_LES	Used to direct the TX portion of lane to use the corresponding PLL. Default value set by reset configuration. Note: for m=0-1, PLL2 cannot be selected. PLL1 is used regardless of this setting. Note: must be set the same as RPLL_LES for normal function. See Lane Reset and Reconfiguration for details on the sequence required to change this setting. 0 If m=0-1, use PLL1; If m=2-7, use PLL2 1 If m=0-1, use PLL1; If m=2-7, use PLL1
5 -	This field is reserved. Reserved
6–7 TRAT_SEL	Transmitter speed selection for lane n, relative to the corresponding PLLnCR0[FRATE_SEL], n as selected by LNnGCR0[TPLL_LES]: Default value set by reset configuration. Required setting per protocol: SGMII-1G: 10 (1.25 Gbaud) SGMII-2.5G: 00 (3.125 Gbaud) QSGMII: 00 XAUI: 00 XFI: 11 SRIO: 01 (2.5 Gbaud) SRIO: 00 (3.125/5 Gbaud) Aurora: 01 (2.5 Gbaud) Aurora: 00 (3.125/5 Gbaud) Interlaken: 11 (6.25 Gbaud) PCIe: N/A (receiver speed selection automatically selected by protocol) SATA: N/A (receiver speed selection automatically selected by protocol) This register value is overridden by the protocol logic when running in the following modes: • PCIe • SATA Note: must be set the same as RRAT_SEL for normal function. 00 Same as FRATE_SEL 01 FRATE_SEL/2 10 FRATE_SEL/4 11 FRATE_SEL*2
8 -	This field is reserved. Reserved

Table continues on the next page...

SerDesx_LNnGCR0 field descriptions (continued)

Field	Description
9 RRST_B	Resets receiver for lane n Recommended setting per protocol: 1, unless PLLnRSTCTL[RST_DONE]=0, then 0. This register value is automatically set to 1 after SerDes reset (POR or PLLnRSTCTL[RSTREQ]). This register is overridden when running in SATA or PCIe mode. Used in lane reset and reconfiguring procedures. See Lane Reset and Reconfiguration for details. 0 Reset 1 Application Mode
10 TRST_B	Resets transmitter for lane n Recommended setting per protocol: 1 This register value is automatically set to 1 after SerDes reset (POR or PLLnRSTCTL[RSTREQ]). This register is overridden when running in SATA or PCIe mode. Used in lane reset and reconfiguring procedures. See Lane Reset and Reconfiguration for details. 0 Reset 1 Application Mode
11 RX_PD	Lane powerdown for receiver on lane m Default value set by reset configuration. This register value is overridden by the protocol controls during SerDes reset (POR or PLLnRSTCTL[RSTREQ]). See Lane Enable After Powerdown for details on re-enabling powered down lanes. 0 Lane receiver active 1 Lane receiver powered down
12 TX_PD	Lane powerdown for transmitter on lane m Default value set by reset configuration. This register value is overridden by the protocol controls during SerDes reset (POR or PLLnRSTCTL[RSTREQ]). Note: the user must not assert TX_PD for the master clock lane (TX_CLK_1STLANE=1) of a multi-lane link during normal function. See Lane Enable After Powerdown for details on e-enabling powered down lanes. 0 Lane transmitter active 1 Lane transmitter powered down
13 IF20BIT_EN	20-bit interface enable Default value set by reset configuration. Required value per protocol: PCIe : 1 SRIO: 0 XFI: 1 XAUI: 0 SGMII: 0 QSGMII: 1

5–31 -	This field is reserved. Reserved

18.5 MDIO register spaces

The SerDes module also contains MDIO slave ports containing registers for each PCS module.

The PCS MDIO registers are accessed through an indirect method from the MDIO Ethernet management interface registers in the Ethernet MAC controllers. There are two methods used to access the PCS MDIO registers—dubbed Clause 45 and Clause 22 (from the IEEE 802.3 sub clauses that define them), depending on the protocol.

The Clause 45 protocols are subdivided into separate spaces selected by the device address. The following table shows the Clause 45 register spaces:

Table 18-11. Clause 45 register spaces

XFI MDIO registers			
Register space	**Device address**	**Notes**	**See**
XFI PMA/PMD registers	01h	Also used for 10GBase-KR	XFI PMA/PMD MDIO Memory Map/Register Definition
XFI PCS registers	03h	Also used for 10GBase-KR	XFI PCS MDIO Memory Map/ Register Definition
XFI Auto-Negotiation registers	07h	Also used for 10GBase-KR	XFI Auto-Negotiation MDIO Memory Map/Register Definition
XFI Vendor-Specific 1 registers	1Eh	Also used for 10GBase-KR	XFI Vendor-Specific 1 MDIO Memory Map/Register Definition

The following table shows the Clause 22 register spaces:

Table 18-12. Clause 22 registers

Registers	Notes	See
SGMII		SGMII MDIO Memory Map/Register Definition
QSGMII	For QSGMII, the most-significant 3 bits of MDIO_CTL[PHY_ADDR] are compared to QSGMIInCR1[MDEV_PORT]. The least-significant 2 bits are used to select the specific QSGMII PCS port (0, 1, 2, or 3).	QSGMII MDIO Memory Map/Register Definition

NOTE

Throughout the MDIO register sections:

- Each MDIO register is 16 bits.
- Register offsets are 16-bit offsets, not byte offsets.
- Addresses not listed are reserved.
- Read accesses to reserved addresses return 0x0000.

18.5.1 XFI PMA/PMD MDIO Memory Map/Register Definition

The XFI PMA/PMD register space is selected when the associated XFInCR1[MDEV_PORT] matches the Ethernet MAC port address (MDIO_CTL[PORT_ADDR]) and the device address (MDIO_CTL[DEV_ADDR]) is 01h.

MDIO memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

18.5.1.1 XFI PMD Control 1 (MDIO_XFI_PMD_CR1)

XFI PMD Control 1 register contains global controls for the XFI PMD module.

Address: 0h base + 0h offset = 0h

Bit	15	14	13	12	11	10	9	8
Read Write	Reserved							
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read Write	Reserved							PMD_ RESET
Reset	0	0	0	0	0	0	0	0

MDIO_XFI_PMD_CR1 field descriptions

Field	Description
15–1 -	This field is reserved. Reserved
0 PMD_RESET	PMD Reset Self-Clearing Reset Bit. When set to 1, resets the 10GBase-KR Link Training modules. The reset command clears all bits in the 10GBase-KR PMD control register

18.5.1.2 XFI 10GBASE-KR PMD Control Register (MDIO_XFI_10GKR_PMD_CR)

XFI 10GBASE-KR PMD Control Register contains global controls for the 10GBASE-KR.

Address: 0h base + 96h offset = 96h

Bit	15	14	13	12	11	10	9	8
Read Write	Reserved							
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read Write	Reserved						TRAIN_EN	RESTART_ TRAIN
Reset	0	0	0	0	0	0	0	0

MDIO_XFI_10GKR_PMD_CR field descriptions

Field	Description
15–2 -	This field is reserved. Reserved
1 TRAIN_EN	Training Enable 0 10GBase-KR startup protocol disabled 1 10GBase-KR startup protocol enabled Note: To safely disable link training, the RESTART_TRAIN bit should be written with 1 with TRAIN_ENABLE = 0 to force exit of the state machine from whatever state it is in. (see IEEE 802.3 Fig 72-5 Training State Diagram).
0 RESTART_ TRAIN	Restart Training Self Clearing Bit. When set to 1, resets the 10GBase-KR startup protocol and begins or ends its operation (depending on TRAIN_EN).

18.5.1.3 XFI 10GBASE-KR PMD Status Register (MDIO_XFI_10GKR_PMD_SR)

XFI 10GBASE-KR PMD Control Register contains status for the 10GBASE-KR

Address: 0h base + 97h offset = 97h

Bit	15	14	13	12	11	10	9	8
Read Write	Reserved							
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read Write	Reserved				TRAIN_FAIL	SUP_STAT	FRAME_ LOCK	RX_STAT
Reset	0	0	0	0	0	0	0	0

MDIO_XFI_10GKR_PMD_SR field descriptions

Field	Description
15–4 -	This field is reserved. Reserved
3 TRAIN_FAIL	Training Failure: 0 Training failure has not been detected 1 Training failure has been detected Note: when training failure occurs, the link is kept in an inoperable state (PCS is not allowed to lock). The application then must write the 10GBase-KR PMD Control register with the restart bit being set and the enable bit being cleared to exit this condition and allow the link to come up without link training.
2 SUP_STAT	Start-up Protocol Status 0 Startup protocol is completed (or not started) 1 Startup protocol is in progress
1 FRAME_LOCK	Frame Lock 0 Training frame delineation not detected 1 Training frame delineation detected
0 RX_STAT	Receiver Status 0 Receiver training is proceeding (or not started) 1 Receiver is trained and is ready to receive data Note: this bit is writeable, which differs from the corresponding notion in IEEE 802.3 Clause 45.2.1.77 for MMD register 1.151) as the application has to decide when the local device is trained. Writing this bit sets the mr_trained variable allowing the training statemachine to proceed (see IEEE 802.3 Clause 72.6.10.3.1)

18.5.1.4 XFI 10GBASE-KR LP Coefficient Update Register (MDIO_XFI_10GKR_LP_COEF_UPDATE)

XFI 10GBASE-KR LP Coefficient Update Register contains controls for the 10GBASE-KR Link Partner Coefficient Update. The fields in this register are read-only if XFI 10GBASE-KR PMD Control Register[TRAIN_EN]=1, but they are writeable if TRAIN_EN=0.

Address: 0h base + 98h offset = 98h

Bit	15	14	13	12	11	10	9	8

MDIO_XFI_10GKR_LD_COEF_UPDATE field descriptions

Field	Description
15–14 -	This field is reserved. Reserved
13 PRESET	Preset the transmitter coefficients 0 Normal operation 1 Preset the transmitter coefficients
12 INIT	Initialize the transmitter coefficients 0 Normal operation 1 Initialize the transmitter coefficients
11–6 -	This field is reserved. Reserved
5–4 COP1_UPD	Coefficient (+1) update: 11 reserved 10 decrement

Table continues on the next page...

MDIO_XFI_10GKR_LD_COEF_UPDATE field descriptions (continued)

Field	Description
	01 increment 00 hold
3–2 COZ_UPD	Coefficient (0) update: 11 reserved 10 decrement 01 increment 00 hold
COM1_UPD	Coefficient (-1) update: 11 reserved 10 decrement 01 increment 00 hold

18.5.1.7 XFI 10GBASE-KR LD Status Report Register (MDIO_XFI_10GKR_LD_SRR)

XFI 10GBASE-KR LD Coefficient Status Report Register contains the 10GBASE-KR Link Device Coefficient reported status

Address: 0h base + 9Bh offset = 9Bh

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	RX_ RDY	Reserved									COP1_STAT		COZ_STAT		COM1_STAT	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MDIO_XFI_10GKR_LD_SRR field descriptions

Field	Description
15 RX_RDY	Receiver Ready 0 The LD receiver is requesting that training continue 1: The LD receiver has determined that training is complete and is prepared to receive data.
14–6 -	This field is reserved. Reserved
5–4 COP1_STAT	Coefficient (+1) status: 11 maximum 10 minimum 01 updated 00 not updated

Table continues on the next page...

MDIO_XFI_10GKR_LD_SRR field descriptions (continued)

Field	Description
3–2 COZ_STAT	Coefficient (0) status: 11 maximum 10 minimum 01 updated 00 not updated
COM1_STAT	Coefficient (-1) status: 11 maximum 10 minimum 01 updated 00 not updated

18.5.1.8 XFI 10GBASE-R FEC Ability (MDIO_XFI_10GR_FEC_ABIL)

XFI 10GBASE-R FEC Ability Register contains the status bit showing the PCS FEC capability. Note that this device does not support FEC, so the FEC ability is a constant 0.

Address: 0h base + AAh offset = AAh

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	Reserved														FEC_ERR_ABIL	FEC_ABIL
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MDIO_XFI_10GR_FEC_ABIL field descriptions

Field	Description
15–2 -	This field is reserved. Reserved
1 FEC_ERR_ABIL	10GBASE-R FEC Error Indication Ability Set to 0 since this PCS does not implement the FEC functions
0 FEC_ABIL	10GBase-R FEC Ability Set to 0 to indicate this PCS does not implement the FEC functions

18.5.1.9 XFI Number of PRBS Sequence Errors Lower (MDIO_XFI_10GKR_NPRBS_ERR_CNT_LO)

The XFI Number of PRBS Sequence Errors Lower Register contains the lower half of the 32-bit counter for tracking number of link training frame PRBS Sequence Errors

Address: 0h base + 8001h offset = 8001h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	NPRBS_ERR_CNT_L															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MDIO_XFI_10GKR_NPRBS_ERR_CNT_LO field descriptions

Field	Description
NPRBS_ERR_CNT_L	Number of Link Training Frame PRBS Sequence Error, lower 16 Bits. Reset to 0 when a read is performed on the counter upper register, the counter does not roll over to 0 when the value 0xFFFFFFFF is reached.

18.5.1.10 XFI Number of PRBS Sequence Errors Upper (MDIO_XFI_10GKR_NPRBS_ERR_CNT_HI)

The XFI Number of PRBS Sequence Errors Upper Register contains the upper half of the 32-bit counter for tracking number of link training frame PRBS Sequence Errors

Address: 0h base + 8002h offset = 8002h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	NPRBS_ERR_CNT_H															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MDIO_XFI_10GKR_NPRBS_ERR_CNT_HI field descriptions

Field	Description
NPRBS_ERR_CNT_H	Number of Link Training Frame PRBS Sequence Error, upper 16 Bits. Reset to 0 when a read is performed on the counter upper register, the counter does not roll over to 0 when the value 0xFFFFFFFF is reached.

18.5.2 XFI PCS MDIO Memory Map/Register Definition

The XFI PCS register space is selected when the associated XFInCR1[MDEV_PORT] matches the Ethernet MAC port address (MDIO_CTL[PORT_ADDR]) and the device address (MDIO_CTL[DEV_ADDR]) is 03h.

MDIO memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

Write								
Reset	0	0	0	0	0	0	1	0

MDIO_XFI_PCS_SR1 field descriptions

Field	Description
15–12 -	This field is reserved. Reserved
11 TX_LPI	Once set, stays set until register read Note: for this device Tx LPI state does not Transmit LPI 0 normal operation. 1 transmit is or was in LPI (EEE)
10 RX_LPI	Receive LPI Once set, stays set until register read 0 normal operation. 1 receive is or was in LPI state (EEE)
9 TX_LPI_ACTIVE	Transmit LPI Active 0 normal operation 1 transmit is currently in LPI state (EEE)
8 RX_LPI_ACTIVE	Receive LPI Active 0 normal operation 1 receive is currently in LPI state (EEE).
7 FAULT	Fault 0 no fault condition detected 1 fault condition detected
6 LPI_CLK_STP_CAP	Clock Stop Capable: 0 MAC is not capable of stopping the clock during LPI
5–3 -	This field is reserved. Reserved
2 PCS_RX_LNK_STAT	PCS Receive Link Status Once cleared, stays cleared until register read 0 indicates that the PCS receive link is or was down 1 indicates that the PCS receive link is up.
1 LPWR_ABIL	Low Power Ability 1 The PCS implements a low power mode, meaning bit setting 11 of PCS Control register 1 register is supported and allows to place the PCS is a reset state.
0 -	This field is reserved. Reserved

18.5.2.3 XFI PCS Device Identifier Upper (MDIO_XFI_PCS_DEV_ID_H)

The XFI PCS Device Identifier Upper Register contains the upper half of the PCS Device Identifier

Address: 0h base + 2h offset = 2h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	PCS_DEV_ID_U															
Write																
Reset	0	0	0	0	0	0	0	0	1	0	0	0	0	0	1	1

MDIO_XFI_PCS_DEV_ID_H field descriptions

Field	Description
PCS_DEV_ID_U	PCS Device ID Upper: 15:0 - OIU[3:18]

18.5.2.4 XFI PCS Device Identifier Lower (MDIO_XFI_PCS_DEV_ID_L)

The XFI PCS Device Identifier Lower Register contains the lower half half of the PCS Device Identifier

Address: 0h base + 3h offset = 3h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	PCS_DEV_ID_L															
Write																
Reset	1	1	1	0	0	1	0	0	0	0	0	0	0	0	0	0

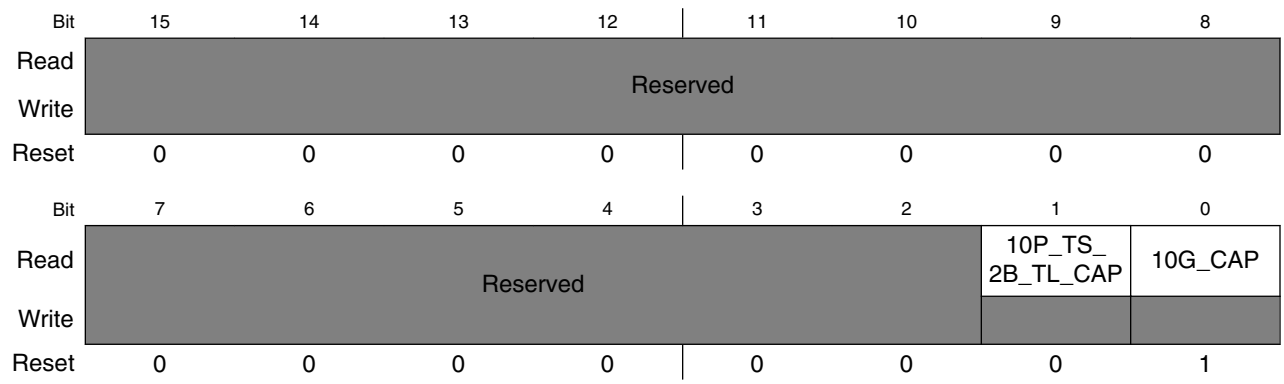
MDIO_XFI_PCS_DEV_ID_L field descriptions

Field	Description
PCS_DEV_ID_L	PCS Device ID Lower: 15:10 - OIU[19:24] 9:4 - Manufacturer's Model Number 3:0 - Revision Number

18.5.2.5 XFI PCS Speed Ability (MDIO_XFI_PCS_SPEED_ABIL)

The XFI PCS Speed Ability Register contains ability bits for the 10GBASE-R PCS

Address: 0h base + 4h offset = 4h



MDIO_XFI_PCS_SPEED_ABIL field descriptions

Field	Description
15–2 -	This field is reserved. Reserved
1 10P_TS_2B_TL_CAP	10PASS-TS/2BASE-TL Capable 0 The PCS is not capable of operating as the 10P/2B PCS
0 10G_CAP	10G Capable 1 PCS is capable of operating at 10Gbps.

18.5.2.6 XFI PCS Devices In Package 0 (MDIO_XFI_PCS_DEV_PRES0)

The XFI PCS Devices in Package 0 Register contains half of the devices present status

Address: 0h base + 5h offset = 5h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	Reserved								AN_PRES	TC_PRES	DTE_XS_PRES	PHY_XS_PRES	PCS_PRES	WIS_PRES	PMD_PMA_RES	C22_REG_PRES
Write																
Reset	0	0	0	0	0	0	0	0	1	0	0	0	1	0	1	0

MDIO_XFI_PCS_DEV_PRES0 field descriptions

Field	Description
15–8 -	This field is reserved. Reserved
7 AN_PRES	Auto-negotiation Present 1 the PCS implements the Auto-Negotiation function
6 TC_PRES	TC Present 0 the PCS does not implement TC functions
5 DTE_XS_PRES	DTE XS Present 0 the PCS does not implement DTE XS functions
4 PHY_XS_PRES	PHY XS Present 0 the PCS does not implement PHY XS functions.
3 PCS_PRES	PCS Present 1 the PCS implements PCS functions
2 WIS_PRES	WIS Present 0 the PCS does not implement a WIS function.
1 PMD_PMA_RES	PMD/PMA Present 1 the PCS implements PMD/PMA functions (Link Training)
0 C22_REG_PRES	Clause 22 Registers Present 0 the PCS does not implement the Clause 22 Registers.

18.5.2.7 XFI PCS Devices in Package 1 (MDIO_XFI_PCS_DEV_PRES1)

The XFI PCS Devices in Package 1 Register contains half of the devices present status

Address: 0h base + 6h offset = 6h

MDIO_XFI_PCS_DEV_PRES1 field descriptions

Field	Description
15 VEND_SPEC_ DEV2_PRES	Vendor Specific Device 2 Present 0 the PCS does not implement any vendor specific device.
14 VEND_SPEC_ DEV1_PRES	Vendor Specific Device 1 Present 0 the PCS does not implement any vendor specific device.
13 CLAUSE22_ EXT_PRES	Clause 22 Extension Present 0 the PCS does not implement Clause 22 extensions.
-	This field is reserved. Reserved

18.5.2.8 XFI 10G PCS Control 2 (MDIO_XFI_PCS_CR2)

The XFI 10G PCS Control 2 Register contains control bits for the 10G PCS

Address: 0h base + 7h offset = 7h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	Reserved													PCS_TYP_SEL		
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1	1

MDIO_XFI_PCS_CR2 field descriptions

Field	Description
15–3 -	This field is reserved. Reserved
PCS_TYP_SEL	PCS Type Selection Read-only field, as this PCS only supports 10GBase-R functions. Note that the value of this field does not match the 802.3 encoding for 10GBase-R.

18.5.2.9 XFI 10G PCS Status 2 (MDIO_XFI_PCS_SR2)

The XFI 10G PCS Status 2 Register contains status bits for the 10G PCS

Address: 0h base + 8h offset = 8h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	DEV_PRES		Reserved		TX_FAULT	RX_FAULT	Reserved						10GBASET_CAP	10GBASEW_CAP	10GBASEX_CAP	10GBASER_CAP
Write																
Reset	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

MDIO_XFI_PCS_SR2 field descriptions

Field	Description
15–14 DEV_PRES	Device Present 10 device responding at this address
13–12 -	This field is reserved. Reserved
11 TX_FAULT	Transmit Fault 0 no fault condition on transmit path 1 fault condition on transmit path
10 RX_FAULT	Receive Fault 0 no fault condition on receive path 1 fault condition on receive path
9–4 -	This field is reserved. Reserved
3 10GBASET_CAP	10GBase-T Capable 0 PCS is not able to support 10GBase-T PCS type
2 10GBASEW_ CAP	10GBase-W Capable 0 PCS is not able to support 10GBase-W PCS type
1 10GBASEX_CAP	10GBase-X Capable 0 PCS is not able to support 10GBase-X PCS type
0 10GBASER_CAP	10GBase-R Capable 1 PCS is able to support 10GBase-R PCS type

18.5.2.10 XFI PCS Package Identifier Upper (MDIO_XFI_PCS_PKG_ID_H)

The XFI PCS Package Identifier Upper Register contains the upper half of a 32-bit unique identifier for a particular type of package that the PCS is instantiated within

Address: 0h base + Eh offset = Eh

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	PCS_PKG_ID_U															
Write																
Reset	0	0	0	0	0	0	0	0	1	0	0	0	0	0	1	1

MDIO_XFI_PCS_PKG_ID_H field descriptions

Field	Description
PCS_PKG_ID_U	PCS Package ID Upper: 15:0 - OIU[3:18]

18.5.2.11 XFI PCS Package Identifier Lower (MDIO_XFI_PCS_PKG_ID_L)

The XFI PCS Package Identifier Lower Register contains the lower half of a 32-bit unique identifier for a particular type of package that the PCS is instantiated within.

Address: 0h base + Fh offset = Fh

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	PCS_PKG_ID_L															
Write																
Reset	1	1	1	0	0	1	0	0	0	0	0	0	0	0	0	0

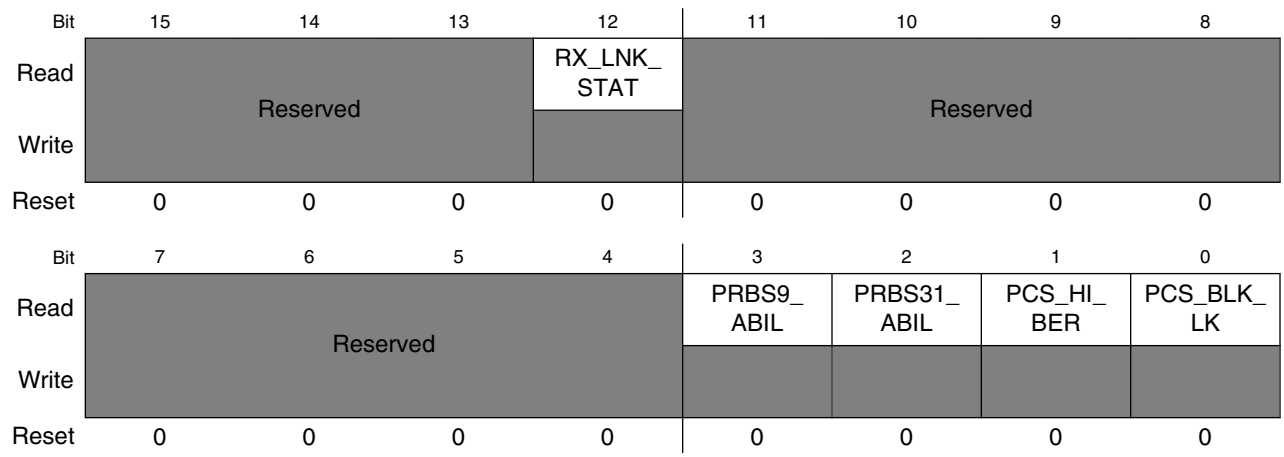
18.5.2.12 XFI 10GBASE-R PCS Status 1 (MDIO_XFI_PCS_10GR_SR1)

The XFI 10GBASE-R PCS Status 1 Register contains 10GBase-R PCS status.

Address: 0h base + 20h offset = 20h



MDIO_XFI_PCS_10GR_SR1 field descriptions

Field	Description
15–13 -	This field is reserved. Reserved
12 RX_LNK_STAT	10GBase-R Receive Link Status 0 10GBase-R PCS receive link is down 1 10GBase-R PCS receive link is up
11–4 -	This field is reserved. Reserved
3 PRBS9_ABIL	PRBS9 Pattern Testing Ability 0 the PCS does not support PRBS9 pattern testing
2 PRBS31_ABIL	PRBS31 Pattern Testing Ability 0 the PCS does not support PRBS31 pattern testing
1 PCS_HI_BER	10GBase-R PCS high BER 0 PCS not reporting a high BER 1 PCS reporting a high BER
0 PCS_BLK_LK	10GBase-R PCS block lock 0 PCS not locked to receive blocks 1 PCS locked to receive blocks

18.5.2.13 XFI 10GBASE-R PCS Status 2 (MDIO_XFI_PCS_10GR_SR2)

XFI 10GBASE-R PCS Status 2 Register contains PCS status bits.

Address: 0h base + 21h offset = 21h

Bit	15	14	13	12	11	10	9	8
Read	L_BLK_LK	LH_BER	BER					
Write								
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read	ERR_BLKS							
Write								
Reset	0	0	0	0	0	0	0	0

MDIO_XFI_PCS_10GR_SR2 field descriptions

Field	Description
15 L_BLK_LK	Latched Block Lock When cleared, stays cleared until register read0: PCS does not have block lock 1 PCS has block lock
14 LH_BER	Latched high BER When set, stays set until register read 0 PCS has not reported a high BER 1 PCS has reported a high BER
13–8 BER	BER Counter Does not roll over from 0x3F to 0x00 Cleared on register read or PCS reset
ERR_BLKS	Errored Blocks Counter Does not roll over from 0xFF to 0x00 Cleared on register read or PCS reset

18.5.2.14 XFI 10GBASE-R PCS Test Pattern Seed A 0 (MDIO_XFI_PCS_TP_SEED_A0)

The XFI 10GBASE-R PCS Test Pattern Seed A Register 0 contains bits 15:0 of Test Pattern Seed A.

Address: 0h base + 22h offset = 22h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	1

MDIO_SGMII_SR field descriptions

Field	Description
15 100BASET4	Read Only bit set to 0 to indicate that the PCS does not support 100Base-T4 operation
14 100BASEX_FD	Read Only bit set to 0 to indicate that the PCS does not support 100Base-X operation
13 100BASEX_HD	Read Only bit set to 0 to indicate that the PCS does not support 100Base-X operation
12 10MBPS_FD	Read Only bit set to 0 to indicate that the PCS does not support 10Mbps operation
11 10MBPS_HD	Read Only bit set to 0 to indicate that the PCS does not support 10Mbps operation
10 100BASET2_FD	Read Only bit set to 0 to indicate that the PCS does not support 100Base-T2 operation.
9 100BASET2_HD	Read Only bit set to 0 to indicate that the PCS does not support 100Base-T2 operation.
8 EXT_STAT	Read Only bit always set to 0 to indicate that the PCS does not implement an extended status register.

Table continues on the next page...

MDIO_SGMII_SR field descriptions (continued)

Field	Description
7–6 -	This field is reserved. Reserved
5 AN_COMP	Auto-negotiation complete. Read Only Bit 0 The Auto Negotiation process is not completed or Auto Negotiation is disabled 1 The Auto Negotiation process is completed and that the Auto Negotiation control registers are valid.
4 REM_FAULT	Read Only Bit always set to 0. The PCS does not implement a PHY specific remote fault detection optional function.
3 AN_ABIL	Auto Negotiation Ability. Read Only Bit set to „1. to indicate that the PCS supports Auto-Negotiation.
2 LINK_STAT	Link Status 0 The link is not valid. If the link synchronization is lost a 0 is latched which is cleared only after a register read access 1 This link is valid.
1 JAB_DET	Read Only bit always set to 0, the Core does not support the optional Jabber detection function
0 EXT_CAP	Read Only bit set to „1. to indicate that the Core supports extended registers

18.5.5.3 SGMII PHY Identifier Upper (MDIO_SGMII_PHY_ID_H)

The SGMII PHY Identifier Upper Register contains the upper half of the 32-bit PHY Identifier.

Address: 0h base + 2h offset = 2h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	PHY_IDENTIFIER_U															
Write																
Reset	0	0	0	0	0	0	0	0	1	0	0	0	0	0	1	1

MDIO_SGMII_PHY_ID_H field descriptions

Field	Description
PHY_ IDENTIFIER_U	PHY Identifier Upper: OUI[3:18]

18.5.5.4 SGMII PHY Identifier Lower (MDIO_SGMII_PHY_ID_L)

The SGMII PHY Identifier Lower Register contains the lower half of the 32-bit PHY Identifier.

Address: 0h base + 3h offset = 3h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	PHY_IDENTIFIER_L															
Write																
Reset	1	1	1	0	0	1	0	0	0	0	0	0	0	0	0	0

MDIO_SGMII_PHY_ID_L field descriptions

Field	Description
PHY_ IDENTIFIER_L	PHY Identifier Lower: 15:10 OUI[19:24] 9:4 Manufacturer's Model Number 3:0 Revision Number

18.5.5.5 SGMII Device Ability for SGMII (MDIO_SGMII_DEV_ABIL_SGMII)

The SGMII Device Ability Register contains the control bits used to advertise the device abilities to the Link Partner during auto-negotiation for SGMII mode.

Address: 0h base + 4h offset = 4h

Bit	15	14	13	12	11	10	9	8
Read Write	Reserved	ACK	Reserved					EEE_CLK_ STP_EN
Reset	0	0	0	0	0	0	0	1

Bit	7	6	5	4	3	2	1	0
Read Write	Reserved							SGMII
Reset	1	0	1	0	0	0	0	0

MDIO_SGMII_DEV_ABIL_SGMII field descriptions

Field	Description
15 -	This field is reserved. Reserved
14 ACK	Read only bit set to 1 when device has received three consecutive matching ability values from the link partner
13–9 -	This field is reserved. Reserved. Should be set to 0
8 EEE_CLK_STP_EN	EEE Clock Stop Enable Should be set to 0 before SGMII Auto-Negotiation enable/restart, as this device does not support EEE clock stop. 0 EEE Clock Stop Disabled 1 EEE Clock Stop Enabled
7–1 -	This field is reserved. Reserved. Should be set to 0
0 SGMII	SGMII mode. Should be set to 1.

18.5.5.6 SGMII Partner Ability for SGMII (MDIO_SGMII_LP_DEV_ABIL_SGMII)

The SGMII Partner Ability Register contains the capability status of the SGMII link partner.

Address: 0h base + 5h offset = 5h

Bit	15	14	13	12	11	10	9	8
Read	COP_LNK_STAT	ACK	-	COP_DUPL	COP_SPD		EEE_CAP	EEE_CLK_STOP_CAP
Write								
Reset	0	0	0	0	0	0	0	0

Read Write	Reserved							
Reset	0	0	0	0	0	0	0	0

MDIO_SGMII_LP_DEV_ABIL_SGMII field descriptions

Field	Description
15 COP_LNK_STAT	Read only bit, used by the SGMII PHY to advertise the Link Partner Copper status:

Table continues on the next page...

MDIO_SGMII_LP_DEV_ABIL_SGMII field descriptions (continued)

Field	Description
	1 Copper interface link is up 0 Copper interface link is down
14 ACK	Read only bit set to 1. when the Link Partner Copper Interface advertises that it has that received three consecutive matching ability values from the device
13 -	Always 0
12 COP_DUPL	Read only bit, used by the SGMII PHY to advertise the Link Copper duplex capability: 0 Copper Interface resolved to Half-Duplex 1 Copper Interface resolved to Full-Duplex
11–10 COP_SPD	Read only bits, used by the SGMII PHY to advertise the Link Partner Copper interface speed 00 Copper Interface Speed is 10Mbps 01 Copper Interface Speed is 100Mbps 10 Copper Interface Speed is Gigabit 11 Reserved
9 EEE_CAP	EEE Capability 0 EEE not supported 1 EEE supported
8 EEE_CLK_ STOP_CAP	EEE Clock Stop Capability 0 EEE Clock Stop not supported 1 EEE Clock Stop supported
-	This field is reserved. Reserved

18.5.5.7 SGMII AN Expansion (MDIO_SGMII_AN_EXP)

The SGMII AN Expansion Register contains status bits indicating the PCS next page auto-negotiation capability and status.

Address: 0h base + 6h offset = 6h

Bit	15	14	13	12	11	10	9	8
Read Write	Reserved							
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read	Reserved					NP_ABLE	PG_RCV	Reserved
Write								
Reset	0	0	0	0	0	1	0	0

MDIO_SGMII_AN_EXP field descriptions

Field	Description
15–3 -	This field is reserved. Reserved
2 NP_ABLE	Read Only bit set to 1 to indicate the PCS does support the Next Page function
1 PG_RCV	Set to 1 to indicate that a new page has been received with new partner ability available in the PCS register PARTNER_ABILITY. The bit is set to 0 (Reset value) when the system management agent performs a read access.
0 -	This field is reserved. Reserved

18.5.5.8 SGMII Next Page Transmit (MDIO_SGMII_NP_TX)

The SGMII NP TX Register contains next page data to transfer to the remote devide. Writing to this register initiates a next page exchange (sets mr_np_loaded variable).

Address: 0h base + 7h offset = 7h

Bit	15	14	13	12	11	10	9	8
Read Write	NP	ACK	MP	ACK2	TOGGLE	DATA		
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read Write	DATA							
Reset	0	0	0	0	0	0	0	0

MDIO_SGMII_NP_TX field descriptions

Field	Description
15 NP	Next page indication. Indicates if additional next pages will follow (1) or this is the last page (0).
14 ACK	Acknowledge bit used by the autoneg function during message transfer. It has no meaning to the application and should be written with 0 always and ignored on read.
13 MP	Message page (1) or unformatted page (0) format.
12 ACK2	Application level acknowledge to indicate acceptance of a message. Use is defined by application layer.
11 TOGGLE	The toggle bit is used by the auto-negotiation function to keep track of message exchange. It has no meaning to the application and should be written with 0 always and ignored on read.
DATA	11 bits of data which can either be a message-id (if MP bit 13=1) or unformatted data (if MP bit 13=0). See IEEE 802.3 Annex 28C for message page encodings

18.5.5.9 SGMII LP Next Page Receive (MDIO_SGMII_NP_RX)

The SGMII NP RX Register contains the next page data received from the remote device during the latest next page exchange. The value is overridden with every new next page. Next page transfers are controlled by the application.

Address: 0h base + 8h offset = 8h

Bit	15	14	13	12	11	10	9	8
Read	NP	ACK	MP	ACK2	TOGGLE	DATA		
Write								
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read	DATA							
Write								
Reset	0	0	0	0	0	0	0	0

MDIO_SGMII_NP_RX field descriptions

Field	Description
15 NP	Next page indication. Indicates if additional next pages will follow (1) or this is the last page (0).
14 ACK	Acknowledge bit used by the autoneg function during message transfer. It has no meaning to the application and should be written with 0 always and ignored on read.
13 MP	Message page (1) or unformatted page (0) format.
12 ACK2	Application level acknowledge to indicate acceptance of a message. Use is defined by application layer.
11 TOGGLE	The toggle bit is used by the auto-negotiation function to keep track of message exchange. It has no meaning to the application and should be written with 0 always and ignored on read.
DATA	11 bits of data which can either be a message-id (if MP bit 13=1) or unformatted data (if MP bit 13=0). See IEEE 802.3 Annex 28C for message page encodings

18.5.5.10 SGMII Extended Status (MDIO_SGMII_XTND_STAT)

The SGMII Extended Status Register is reserved, as this device does not implement the optional extended status registers.

Address: 0h base + Fh offset = Fh

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MDIO_SGMII_XTND_STAT field descriptions

Field	Description
-	This field is reserved. Reserved. Always 0

18.5.5.11 SGMII Scratch (MDIO_SGMII_SCRATCH)

The SGMII Scratch Register provides a memory location available to test register read and write operations.

Address: 0h base + 10h offset = 10h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	SCRATCH															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MDIO_SGMII_SCRATCH field descriptions

Field	Description
SCRATCH	Scratch field.

18.5.5.12 SGMII Design Revision (MDIO_SGMII_REV)

The SGMII Revision Register contains revision information for the PCS.

Address: 0h base + 11h offset = 11h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	Reserved								IP_MJ				IP_MN			
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

MDIO_SGMII_REV field descriptions

Field	Description
15–8 -	This field is reserved. Reserved
7–4 IP_MJ	Major revision
IP_MN	Minor revision

18.5.5.13 SGMII Link Timer Lower (MDIO_SGMII_LINK_TMR_L)

The SGMII Link Timer Register Lower contains bits 15:1 of the link timer value.

Address: 0h base + 12h offset = 12h

Bit	15	14	13	12	11	10	9	8
Read Write	LINK_TMR_L							
Reset	0	0	0	1	0	0	1	0

Bit	7	6	5	4	3	2	1	0
Read Write	LINK_TMR_L							Reserved
Reset	1	1	0	1	0	0	0	0

MDIO_SGMII_LINK_TMR_L field descriptions

Field	Description
15–1 LINK_TMR_L	Link timer[15:1]
0 -	This field is reserved. Reserved

18.5.5.14 SGMII Link Timer Upper (MDIO_SGMII_LINK_TMR_H)

The SGMII Link Timer Register Upper contains bits 20:16 of the link timer value.

Address: 0h base + 13h offset = 13h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	Reserved											LINK_TMR_U				
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	1	1

MDIO_SGMII_LINK_TMR_H field descriptions

Field	Description
15–5 -	This field is reserved. Reserved
LINK_TMR_U	Link timer[20:16]

18.5.5.15 SGMII IF Mode (MDIO_SGMII_IF_MODE)

The SGMII IF Mode Register contains control bits to set the interface mode.

Address: 0h base + 14h offset = 14h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	Reserved											SGMII_DUPLEX	SGMII_SPEED		USE_SGMII_AN	SGMII_EN
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MDIO_SGMII_IF_MODE field descriptions

Field	Description
15–5 -	This field is reserved. Reserved
4 SGMII_DUPLEX	SGMII Halfduplex Mode: Bit ignored when SGMII_EN is set to 0 or USE_SGMII_AN is set to 1. 0 Full duplex enabled (default) 1 Half duplex enabled
3–2 SGMII_SPEED	SGMII Speed. When the PCS operates in SGMII mode (SGMII_EN set to 1) and is programmed not to be automatically configured (USE_SGMII_AN set to 0), sets the PCS speed of operation:

Table continues on the next page...

MDIO_SGMII_IF_MODE field descriptions (continued)

Field	Description
	Bits ignored when SGMII_EN is set to 0 or USE_SGMII_AN is set to 1. 00 10Mbps 01 100Mbps 10 Gigabit 11 Reserved
1 USE_SGMII_AN	Use the SGMII Auto-Negotiation Results to Program the PCS Speed. When set to 0 (Reset Value), the PCS operation should be programmed with the register bit SGMII_SPEED and SGMII_DUPLEX. When set to 1, the PCS operation is automatically programmed with the Partner abilities advertised during Auto-Negotiation. Ignored when SGMII_EN is set to 0.
0 SGMII_EN	SGMII Mode Enable. When set to '0' (Reset Value), the PCS operates in standard 1000Base-X Gigabit mode, when set to '1', the PCS operates in SGMII Mode

18.5.6 QSGMII MDIO Memory Map/Register Definition

The QSGMII MDIO register space is selected when the associated QSGMIInCR1[MDEV_PORT] matches the most-significant 3 bits of the Ethernet MAC PHY address (MDIO_CTL[PHY_ADDR]). The least significant 2 bits of the PHY address are used to select the specific QSGMII PCS port (0, 1, 2, or 3).

MDIO memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	QSGMII Control (MDIO_QSGMII_CR)	16	R/W	1140h	18.5.6.1/ 1326

18.5.6.1 QSGMII Control (MDIO_QSGMII_CR)

The QSGMII Control Register contains control bits used to enable/disable functions in the PCS, and to initiate commands such as reset.

Address: 0h base + 0h offset = 0h

Bit	15	14	13	12	11	10	9	8
Read	RST	LPBK	SPEED_ SEL0	AN_EN	PD	ISOLATE	RESTART_ AN	FD
Write								
Reset	0	0	0	1	0	0	0	1

Bit	7	6	5	4	3	2	1	0
Read	COL_TEST	SPEED_ SEL1	Reserved					
Write								
Reset	0	1	0	0	0	0	0	0

MDIO_QSGMII_CR field descriptions

Field	Description
15 RST	Self-Clearing Read / Write Reset Command Register. When set to 1, a synchronous reset pulse is generated which resets all the PCS state machines, the Comma detection function and the 8b/10b coder / decoder. Should be set to 0 (default) for normal operation.
14 LPBK	Loopback Command. 0 Normal operation 1 Reserved

Table continues on the next page...

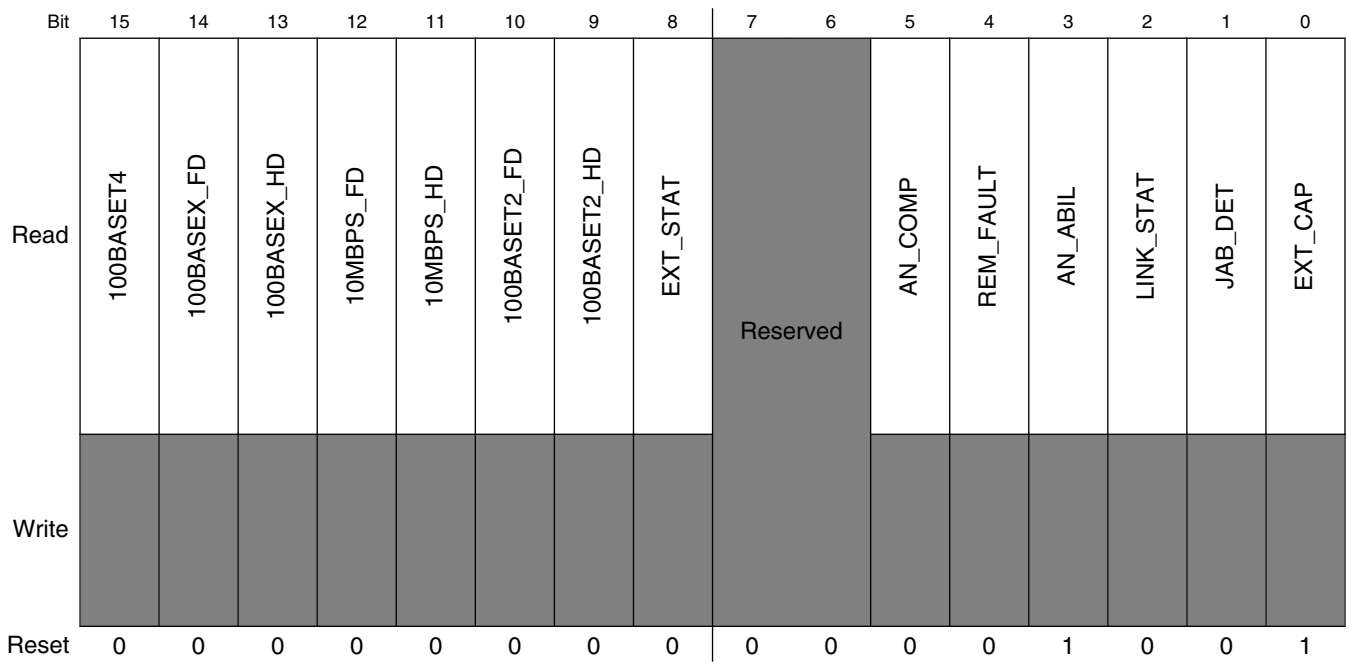
MDIO_QSGMII_CR field descriptions (continued)

Field	Description
13 SPEED_SEL0	Speed selection (LSB) All others reserved Note: SGMII speed is controlled with the IF Mode register MSB,LSB 10 1000 Mb/s
12 AN_EN	Auto-negotiation enable 0 Disable auto-negotiation 1 Enable auto-negotiation
11 PD	Power down 0 Normal operation 1 Power down PCS. The PCS is held in internal soft reset until the bit is cleared again.
10 ISOLATE	Isolate 0 Normal operation 1 Reserved
9 RESTART_AN	Restart auto-negotiation This bit is self-clearing 0 Normal operation 1 Restart auto-negotiation
8 FD	Duplex mode. Read-only 0 Reserved 1 Full duplex
7 COL_TEST	Collision test. Read-only 0 Disable COL signal test 1 Reserved
6 SPEED_SEL1	Speed selection (MSB) See SPEED_SEL0
-	This field is reserved. Reserved

18.5.6.2 QSGMII Status (MDIO_QSGMII_SR)

The QSGMII Status Register contains status bits on the operation of the PCS.

Address: 0h base + 1h offset = 1h



MDIO_QSGMII_SR field descriptions

Field	Description
15 100BASET4	Read Only bit set to 0 to indicate that the PCS does not support 100Base-T4 operation
14 100BASEX_FD	Read Only bit set to 0 to indicate that the PCS does not support 100Base-X operation
13 100BASEX_HD	Read Only bit set to 0 to indicate that the PCS does not support 100Base-X operation
12 10MBPS_FD	Read Only bit set to 0 to indicate that the PCS does not support 10Mbps operation
11 10MBPS_HD	Read Only bit set to 0 to indicate that the PCS does not support 10Mbps operation
10 100BASET2_FD	Read Only bit set to 0 to indicate that the PCS does not support 100Base-T2 operation.
9 100BASET2_HD	Read Only bit set to 0 to indicate that the PCS does not support 100Base-T2 operation.
8 EXT_STAT	Read Only bit always set to 0 to indicate that the PCS does not implement an extended status register.

Table continues on the next page...

MDIO_QSGMII_SR field descriptions (continued)

Field	Description
7–6 -	This field is reserved. Reserved
5 AN_COMP	Auto-negotiation complete. Read Only Bit 0 The Auto Negotiation process is not completed or Auto Negotiation is disabled 1 The Auto Negotiation process is completed and that the Auto Negotiation control registers are valid.
4 REM_FAULT	Read Only Bit always set to 0. The PCS does not implement a PHY specific remote fault detection optional function.
3 AN_ABIL	Auto Negotiation Ability. Read Only Bit set to „1. to indicate that the PCS supports Auto-Negotiation.
2 LINK_STAT	Link Status 0 The link is not valid. If the link synchronization is lost a 0 is latched which is cleared only after a register read access 1 This link is valid.
1 JAB_DET	Read Only bit always set to 0, the Core does not support the optional Jabber detection function
0 EXT_CAP	Read Only bit set to „1. to indicate that the Core supports extended registers

18.5.6.3 QSGMII PHY Identifier Upper (MDIO_QSGMII_PHY_ID_H)

The QSGMII PHY Identifier Upper Register contains the upper half of the 32-bit PHY Identifier.

Address: 0h base + 2h offset = 2h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	PHY_IDENTIFIER_U															
Write																
Reset	0	0	0	0	0	0	0	0	1	0	0	0	0	0	1	1

MDIO_QSGMII_PHY_ID_H field descriptions

Field	Description
PHY_ IDENTIFIER_U	PHY Identifier Upper: OUI[3:18]

18.5.6.4 QSGMII PHY Identifier Lower (MDIO_QSGMII_PHY_ID_L)

The QSGMII PHY Identifier Lower Register contains the lower half of the 32-bit PHY Identifier.

Address: 0h base + 3h offset = 3h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	PHY_IDENTIFIER_L															
Write																
Reset	1	1	1	0	0	1	0	0	0	0	0	0	0	0	0	0

MDIO_QSGMII_PHY_ID_L field descriptions

Field	Description
PHY_ IDENTIFIER_L	PHY Identifier Lower: 15:10 OUI[19:24] 9:4 Manufacturer's Model Number 3:0 Revision Number

18.5.6.5 QSGMII Device Ability for SGMII (MDIO_QSGMII_DEV_ABIL_SGMII)

The QSGMII Device Ability Register contains the control bits used to advertise the device abilities to the Link Partner during auto-negotiation for SGMII mode.

Address: 0h base + 4h offset = 4h

Bit	15	14	13	12	11	10	9	8
Read Write	Reserved	ACK	Reserved					EEE_CLK_ STP_EN
Reset	0	0	0	0	0	0	0	1

Bit	7	6	5	4	3	2	1	0

18.5.6.7 QSGMII AN Expansion (MDIO_QSGMII_AN_EXP)

The QSGMII AN Expansion Register contains status bits indicating the PCS next page auto-negotiation capability and status.

Address: 0h base + 6h offset = 6h

Bit	15	14	13	12	11	10	9	8
Read Write	Reserved							
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read	Reserved					NP_ABLE	PG_RCV	Reserved
Write								
Reset	0	0	0	0	0	1	0	0

MDIO_QSGMII_AN_EXP field descriptions

Field	Description
15–3 -	This field is reserved. Reserved
2 NP_ABLE	Read Only bit set to 1 to indicate the PCS does support the Next Page function
1 PG_RCV	Set to 1 to indicate that a new page has been received with new partner ability available in the PCS register PARTNER_ABILITY. The bit is set to 0 (Reset value) when the system management agent performs a read access.
0 -	This field is reserved. Reserved

18.5.6.8 QSGMII Next Page Transmit (MDIO_QSGMII_NP_TX)

The QSGMII NP TX Register contains next page data to transfer to the remote devide. Writing to this register initiates a next page exchange (sets mr_np_loaded variable).

Address: 0h base + 7h offset = 7h

Bit	15	14	13	12	11	10	9	8
Read Write	NP	ACK	MP	ACK2	TOGGLE	DATA		
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read Write	DATA							
Reset	0	0	0	0	0	0	0	0

MDIO_QSGMII_NP_TX field descriptions

Field	Description
15 NP	Next page indication. Indicates if additional next pages will follow (1) or this is the last page (0).
14 ACK	Acknowledge bit used by the autoneg function during message transfer. It has no meaning to the application and should be written with 0 always and ignored on read.
13 MP	Message page (1) or unformatted page (0) format.
12 ACK2	Application level acknowledge to indicate acceptance of a message. Use is defined by application layer.
11 TOGGLE	The toggle bit is used by the auto-negotiation function to keep track of message exchange. It has no meaning to the application and should be written with 0 always and ignored on read.
DATA	11 bits of data which can either be a message-id (if MP bit 13=1) or unformatted data (if MP bit 13=0). See IEEE 802.3 Annex 28C for message page encodings

18.5.6.9 QSGMII LP Next Page Receive (MDIO_QSGMII_NP_RX)

The QSGMII NP RX Register contains the next page data received from the remote device during the latest next page exchange. The value is overridden with every new next page. Next page transfers are controlled by the application.

Address: 0h base + 8h offset = 8h

Bit	15	14	13	12	11	10	9	8
Read	NP	ACK	MP	ACK2	TOGGLE	DATA		
Write								
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read	DATA							
Write								
Reset	0	0	0	0	0	0	0	0

MDIO_QSGMII_NP_RX field descriptions

Field	Description
15 NP	Next page indication. Indicates if additional next pages will follow (1) or this is the last page (0).
14 ACK	Acknowledge bit used by the autoneg function during message transfer. It has no meaning to the application and should be written with 0 always and ignored on read.
13 MP	Message page (1) or unformatted page (0) format.
12 ACK2	Application level acknowledge to indicate acceptance of a message. Use is defined by application layer.
11 TOGGLE	The toggle bit is used by the auto-negotiation function to keep track of message exchange. It has no meaning to the application and should be written with 0 always and ignored on read.
DATA	11 bits of data which can either be a message-id (if MP bit 13=1) or unformatted data (if MP bit 13=0). See IEEE 802.3 Annex 28C for message page encodings

18.5.6.10 QSGMII Extended Status (MDIO_QSGMII_XTND_STAT)

The QSGMII Extended Status Register is reserved, as this device does not implement the optional extended status registers.

Address: 0h base + Fh offset = Fh

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MDIO_QSGMII_XTND_STAT field descriptions

Field	Description
-	This field is reserved. Reserved. Always 0

18.5.6.11 QSGMII Scratch (MDIO_QSGMII_SCRATCH)

The QSGMII Scratch Register provides a memory location available to test register read and write operations.

Address: 0h base + 10h offset = 10h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	SCRATCH															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MDIO_QSGMII_SCRATCH field descriptions

Field	Description
SCRATCH	Scratch field.

18.5.6.12 QSGMII Design Revision (MDIO_QSGMII_REV)

The QSGMII Revision Register contains revision information for the PCS.

Address: 0h base + 11h offset = 11h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	Reserved								IP_MJ				IP_MN			
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

MDIO_QSGMII_REV field descriptions

Field	Description
15–8 -	This field is reserved. Reserved
7–4 IP_MJ	Major revision
IP_MN	Minor revision

18.5.6.13 QSGMII Link Timer Lower (MDIO_QSGMII_LINK_TMR_L)

The QSGMII Link Timer Register Lower contains bits 15:1 of the link timer value.

Address: 0h base + 12h offset = 12h

Bit	15	14	13	12	11	10	9	8
Read Write	LINK_TMR_L							
Reset	0	0	0	1	0	0	1	0

Bit	7	6	5	4	3	2	1	0
Read Write	LINK_TMR_L							Reserved
Reset	1	1	0	1	0	0	0	0

MDIO_QSGMII_LINK_TMR_L field descriptions

Field	Description
15–1 LINK_TMR_L	Link timer[15:1]
0 -	This field is reserved. Reserved

18.5.6.14 QSGMII Link Timer Upper (MDIO_QSGMII_LINK_TMR_H)

The QSGMII Link Timer Register Upper contains bits 20:16 of the link timer value.

Address: 0h base + 13h offset = 13h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	Reserved											LINK_TMR_U				
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	1	1

MDIO_QSGMII_LINK_TMR_H field descriptions

Field	Description
15–5 -	This field is reserved. Reserved
LINK_TMR_U	Link timer[20:16]

18.5.6.15 QSGMII IF Mode (MDIO_QSGMII_IF_MODE)

The QSGMII IF Mode Register contains control bits to set the interface mode.

Address: 0h base + 14h offset = 14h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	Reserved											SGMII_DUPLEX	SGMII_SPEED		USE_SGMII_AN	SGMII_EN
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MDIO_QSGMII_IF_MODE field descriptions

Field	Description
15–5 -	This field is reserved. Reserved
4 SGMII_DUPLEX	SGMII Halfduplex Mode: Bit ignored when SGMII_EN is set to 0 or USE_SGMII_AN is set to 1. 0 Full duplex enabled (default) 1 Half duplex enabled
3–2 SGMII_SPEED	SGMII Speed. When the PCS operates in SGMII mode (SGMII_EN set to 1) and is programmed not to be automatically configured (USE_SGMII_AN set to 0), sets the PCS speed of operation:

Table continues on the next page...

MDIO_QSGMII_IF_MODE field descriptions (continued)

Field	Description
	Bits ignored when SGMII_EN is set to 0 or USE_SGMII_AN is set to 1. 00 10Mbps 01 100Mbps 10 Gigabit 11 Reserved
1 USE_SGMII_AN	Use the SGMII Auto-Negotiation Results to Program the PCS Speed. When set to 0 (Reset Value), the PCS operation should be programmed with the register bit SGMII_SPEED and SGMII_DUPLEX. When set to 1, the PCS operation is automatically programmed with the Partner abilities advertised during Auto-Negotiation. Ignored when SGMII_EN is set to 0.
0 SGMII_EN	SGMII Mode Enable. When set to '0' (Reset Value), the PCS operates in standard 1000Base-X Gigabit mode, when set to '1', the PCS operates in SGMII Mode

18.6 Initialization/Application Information

18.6.1 Initialization

All initialization necessary for the SerDes module to start operation is done automatically based on RCW , with the exception of the following protocols:

18.6.1.1 SGMII

After initializing the MAC, and prior to initiating any SGMII traffic, perform the following SGMII protocol initialization:

1. SGMII IF Mode register:
   - SGMII_EN=1
   - USE_SGMII_AN=1 if SGMII auto-negotiation is desired
   - SGMII_SPEED (if USE_SGMII_AN=0)
   - SGMII_DUPLEX (if USE_SGMII_AN=0)
2. SGMII Device Ability Register:
   - EEE_CLK_STP_EN=0
   - SGMII=1

To enable SGMII auto-negotiation, perform the following sequence:

1. SGMII Link Timer Register Upper:
   - LINK_TMR_U=0h03
2. SGMII Link Timer Register Lower:
   - LINK_TMR_L=0h06A0

3. SGMII Control Register:
   - AN_EN=1
   - RESTART_AN=1

NOTE

Half duplex is not supported for PCSs connected to FM MAC.

NOTE

Auto-negotiation is not supported for 2.5G SGMII

18.6.1.2 QSGMII

After initializing the MACs, and prior to initiating any QSGMII traffic, perform the following per-port SGMII protocol initialization in each corresponding register in the QSGMII PCS (4 per PCS):

1. QSGMII IF Mode register:
   - SGMII_EN=1
   - USE_SGMII_AN=1 if SGMII auto-negotiation is desired
   - SGMII_SPEED (if USE_SGMII_AN=0)
   - SGMII_DUPLEX (if USE_SGMII_AN=0)
2. QSGMII Device Ability Register:
   - SGMII=1
3. QSGMII Link Timer Register Upper:
   - SGMII: LINK_TMR_U=0h03
4. QSGMII Link Timer Register Lower:
   - SGMII: LINK_TMR_L=0h06A0
5. QSGMII Control Register:
   - RESTART_EN=1

To initialize QSGMII with auto-negotiation disabled, instead of steps 2-4 above, do:

1. QSGMII Control Register:
   - AN_EN=0

18.6.1.3 XFI/10GBase-KR

All default SerDes settings are for XFI. For 10GBase-KR, the following settings need to be modified, following the procedure in Lane Reset and Reconfiguration:

- SerDesx_LNmTECR0[TEQ_TYPE]
- SerDesx_LNmTECR0[SGN_PREQ]

- SerDesx_LNmTECR0[RATIO_PREQ]
- SerDesx_LNmTECR0[RATIO_PST1Q]
- SerDesx_LNmTECR0[AMP_RED]

See Transmit Equalization Control Register 0 - Lane n (SerDes_LN*n*TECR0) for details.

18.6.1.4 SRIO Long Reach

The default SerDes settings for SRIO are for short reach.

For long reach, the following settings need to be updated following the procedure in Lane Reset and Reconfiguration :

- SerDesx_LNmTECR0[AMP_RED]

See Transmit Equalization Control Register 0 - Lane n (SerDes_LN*n*TECR0) for details.

18.6.1.5 Interlaken Long Reach

The default SerDes settings for Interlaken are for short reach. For long reach, the following settings need to be updated , following the procedure in Lane Reset and Reconfiguration

- SRDSx_LNmTECR0[RATIO_PST1Q]
- SRDSx_LNmTECR0[AMP_RED]

See Transmit Equalization Control Register 0 - Lane n (SerDes_LN*n*TECR0) for details.

18.6.2 Unused Lanes

Unused lanes should be powered down to save power and avoid noise on adjacent lanes.

Power down the Rx portion of the lanes by setting SerDesx_LNmGCR0[RX_PD]=1 and SerDesx_LNmGCR0[RRST_B]=0.

Power down the Tx portion of the lanes by setting SerDesx_LNmGCR0[TX_PD]=1 and SerDesx_LNmGCR0[TRST_B]=0.

The Rx and Tx portions of the lanes may be independently powered down for uni-directional lanes or links (e.g. Tx-only Aurora lanes).

18.6.3 Frequency Negotiation

SATA and PCI Express auto-negotiate frequency in hardware. For SATA, and PCIe 2.5/5 Gbaud, auto-negotiation involves overriding the by-n rate select function of the SerDes lane.

For PCIe 8 Gbaud, the auto-negotiation also involves a combination of switching PLL selects, and/or reconfiguring a PLL. The current state of the by-n rate selects and PLL select per lane are reflected in SerDesx_LNnGCR0, as defined in General Control Register 0 - Lane n (SerDes_LN*n*GCR0). The current state of the PLL full-rate frequency select is reflected in SRDSx_112, as defined in SerDes PLLn Control Register 0 (SerDes_PLL*n*CR0).

Note: SGMII can operate at 10 Mbps, 100 Mbps, 1000 Mbps or 2500 Mbps , but the frequency of operation of the serial link is 1.25 GHz for 10/100/1000 , and 3.125 GHz for 2500 . The lower effective data rates on SGMII 10/100 are implemented by replicating symbols 10 or 100 times.

Other protocols either have a static frequency configuration, or change frequencies via a software reconfiguring sequence. See Lane Reset and Reconfiguration and PLL Reset and Reconfiguration for details on the software reconfiguring sequences.

18.6.4 Soft Reset and Reconfiguring Procedures

18.6.4.1 Lane Reset and Reconfiguration

To reconfigure a lane (change settings including clock divider or PLL select), perform the following sequence:

1. Put the lane(s) into reset by setting SerDesx_LNmGCR0[TRST_B]=0 and SerDesx_LNmGCR0[RRST_B]=0.
2. Wait at least 50 ns
3. Change the desired per-lane settings
4. Wait at least 120 ns
5. Take the lane(s) out of reset by setting SerDesx_LNmGCR0[TRST_B]=1 and SerDesx_LNmGCR0[RRST_B]=1

Note that if the lanes being reconfigured are grouped for multi-lane or synchronous mode, then the master source clock lane for the group must have TRST_B set to 1 after all the other lanes in the group. The master source clock lane of the group is indicated by SerDesx_LNmGCR0[1STLANE]=1. All lanes either to the left (if SerDesx_LNpGCR1[TRSTDIR]=0) or to the right (if

SerDesx_LNpGCR1[TRSTDIR]=1) of the master source clock lane until the next lane with SerDesx_LNmGCR0[1STLANE]=1, or the end of the SerDes, are grouped with the master source clock lane.

It is recommended to disable any controller connected to a lane being reconfigured prior to starting the reconfiguration sequence.

18.6.4.2 Lane Enable After Powerdown

To enable a previously powered down lane, set SerDesx_LNmGCR0[nX_PD]=0 (n=R or T), wait 15 us, then set SerDesx_LNmGCR0[nRST]=1.

Note that if a Tx lane m with SerDesx_LNmGCR0[1STLANE]=1 (master Tx clock lane) is powered down or reset, all Tx lanes to the left of it (p<m) with SerDesx_LNpGCR1[TRSTDIR]=0, or all Tx lanes to the right of it (p>m) with SerDesx_LNpGCR1[TRSTDIR]=1, cannot be used.

18.6.4.3 XAUI lane alignment recovery

Unused lanes should be powered down to save power and avoid noise on adjacent lanes.

When the XAUI lane synchronization is lost or not acquired, perform the steps below to recover:

1. If XAUInCR1[ALGD] = 0, perform a Rx lane reset in LNnGCR0
   - Clear RRST_B for lanes 0:3 (XAUIA) or lanes 4:7 (XAUIB)
   - Read back LNnGCR0 to ensure write is complete
   - Wait at least 120ns
   - Set RRST_B for lanes 0:3 (XAUIA) or lanes 4:7 (XAUIB)
2. Check if XAUInCR1[ALGD]. If ALGD=0 (not aligned)
   - Write 0x00000000 to register at SerDes + offset 0x6A0 (XAUIA) or SerDes + offset 0x6B0 (XAUIB) to clear RST_XAU=0
   - Read SerDes + offset 0x6A0/0x6B0 to ensure write is complete
   - Write 0x80000000 to SerDes register + offset 0x6A0/0x6B0 to set RST_XAU=1

18.6.4.4 PLL Reset and Reconfiguration

To reconfigure a PLL, perform the following sequence:

1. Disable all lanes using the PLL to be reconfigured by setting SerDesx_PLLnRSTCTL[SDRST_B]=0

2. Wait at least 50 ns
3. Disable the PLL by setting SerDesx_PLLnRSTCTL[SDEN]=0 and SerDesx_PLLnRSTCTL[PLLRST_B]=0
4. Wait at least 100 ns
5. Change the desired per-PLL settings
6. Reset the PLL by setting SerDesx_PLLnRSTCTL[RSTREQ]=1 and wait no longer than 0.5 µsecs before going to step 7.
7. Set SerDesx_PLLnRSTCTL[SDEN]=1, SerDesx_PLLnRSTCTL[PLLRST_B]=1, and SerDesx_PLLnRSTCTL[SDRST_B]=1
    - Note this step is not to be combined with setting RSTREQ=1

Note: lane reconfiguration may also be performed while the PLL is disabled by following the first three steps of the lane reset sequence in Lane Reset and Reconfiguration after changing the per-PLL settings, before setting RSTREQ=1, and the last step of the lane reset sequence after the last step of the above PLL reset sequence.

It is recommended to disable any controller connected to a lane selecting the PLL being reconfigured prior to starting the reconfiguration sequence. In the case of PCI Express, the controllers must be disabled to prevent auto-negotiation to 8Gbaud, which can include autonomous PLL reset and reconfiguration.

18.6.5 Quiesce Sequences for System Sleep

To quiece the SerDes module in preparation for System Sleep, the user must first quiesce all controllers and disable transmission/reception of packets.

Chapter 19
PCI Express Interface Controller

19.1 Introduction

The PCI Express interface is compatible with the *PCI Express™ Base Specification, Revision* 3.0 (available from http://www.pcisig.org). It is beyond the scope of this manual to document the intricacies of the PCI Express protocol. This chapter describes the PCI Express controller of this device and provides a basic description of the PCI Express protocol. The specific emphasis is directed at how the device implements the PCI Express specification. Designers of systems incorporating PCI Express devices should refer to the specification for a thorough description of PCI Express.

NOTE

Much of the available PCI Express literature refers to a 16-bit quantity as a WORD and a 32-bit quantity as a DWORD. Note that this is inconsistent with the terminology in the rest of this manual where the terms 'word' and 'double word' refer to a 32-bit and 64-bit quantity, respectively. Where necessary to avoid confusion, the precise number of bits or bytes is specified.

19.1.1 Overview

The PCI Express controller connects the internal platform to a serial interface.

As both an initiator and a target device, the PCI Express interface is capable of high-bandwidth data transfer and is designed to support next generation I/O devices. Upon coming out of reset, the PCI Express interface performs link width negotiation and exchanges flow control credits with its link partner. Once link autonegotiation is successful, the controller is in operation.

Internally, the design contains queues to keep track of inbound and outbound transactions. There is control logic that handles buffer management, bus protocol, transaction spawning and tag generation. In addition, there are memory blocks used to store inbound and outbound data.

The PCI Express controller can be configured to operate as either a PCI Express root complex (RC) or endpoint (EP) device. An RC device connects the host CPU/memory subsystem to I/O devices while an EP device typically denotes a peripheral or I/O device. In RC mode, a PCI Express type 1 configuration header is used; in EP mode, a PCI Express type 0 configuration header is used.

This figure shows a high-level block diagram of the PCI Express controller.

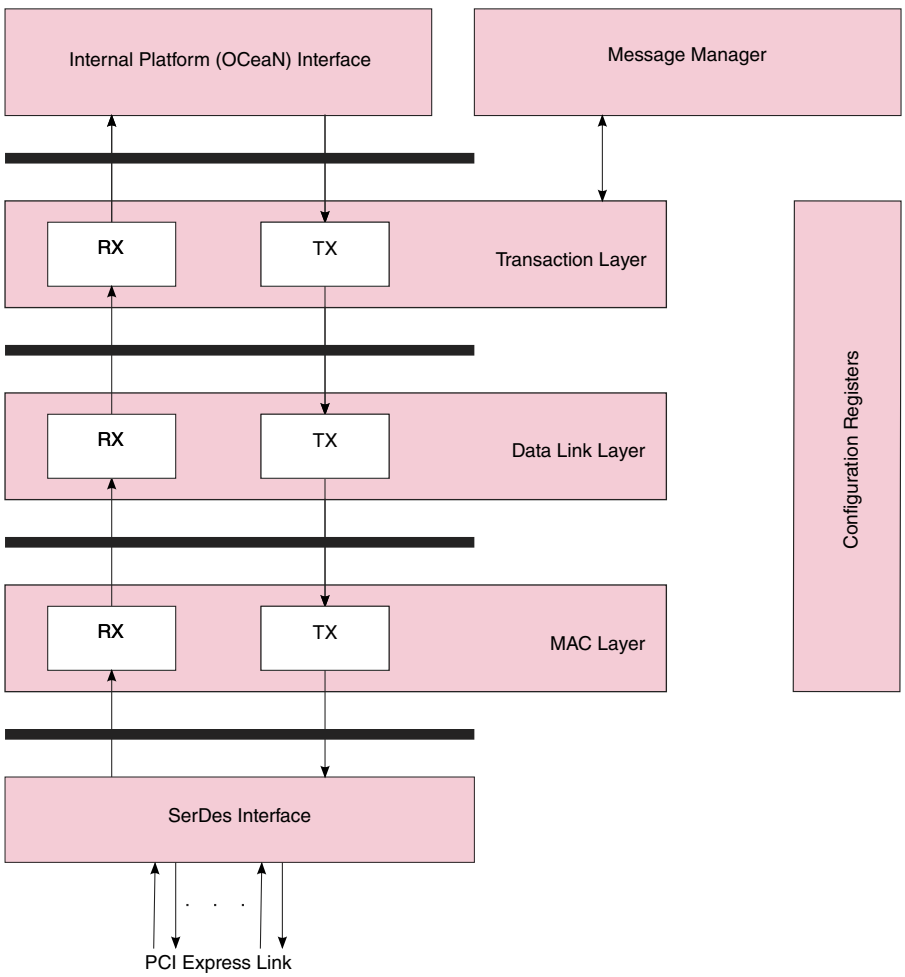

Figure 19-1. PCI Express Controller Block Diagram

As an initiator, the PCI Express controller supports memory read and write operations. In addition, configuration and I/O transactions are supported if the PCI Express controller is in RC mode. As a target interface, the PCI Express controller accepts read and write operations to local memory space. When configured as an EP device, the PCI Express

controller accepts configuration transactions to the internal PCI Express configuration registers. Message generation and acceptance are supported in both RC and EP modes. Locked transactions and inbound I/O transactions are not supported.

19.1.1.1 PCI Express

Each of the chip's PCI Express controllers is compatible with the PCI Express Base Specification Revision 3.0. Key features of each PCI Express controller include the following:

- Power-on reset configuration options allow root complex or endpoint functionality.
- The physical layer operates at up to 8 GT/s data rate per lane
  - x4, x2, and x1 link widths supported on all controllers at 2.5, 5, or 8 GT/s
  - x8 link width supported on two controllers at 2.5 or 5 GT/s
- Both 32- and 64-bit addressing
- 256-byte maximum payload size
- Full 64-bit decode with 40-bit wide windows
- Inbound INTx transactions
- Message signaled interrupt (MSI) transactions
- One PCI Express controller supports end-point SR-IOV
  - Two physical functions, each with 64 virtual functions
  - Eight MSI-X per virtual function

19.1.1.2 The PCI Express controller as implemented on the chip

This section provides details about how the PCI Express controller is integrated into this chip.

The following table describes the PCI Express controller integration into this chip:

Table 19-1. PCI Express controller integration

Controller	Base address	Maximum number of lanes	Supports SR-IOV
PEX1	24_0000h	8 (at 2.5 or 5 GT/s)	Yes
PEX2	25_0000h	4	No
PEX3	26_0000h	8 (at 2.5 or 5 GT/s)	No
PEX4	27_0000h	4	No

The remainder of this chapter refers to a single PCI Express controller with SR-IOV offering up to a x8 link interface. Notes are included to indicate variations for multiple instantiations.

19.1.1.3 Outbound Transactions

Outbound internal platform transactions to PCI Express are first mapped to a translation window to determine what PCI Express transactions are to be issued. A transaction from the internal platform can become a PCI Express Memory, I/O,Message, or Configuration transaction depending on the window attributes.

A transaction may be broken up into smaller sized transactions depending on the original request size, transaction type, and either the PCI Express Device Control register [MAX_PAYLOAD_SIZE] field for write requests or the PCI Express Device Control register [MAX_READ_SIZE] field for read requests. The controller performs PCI Express ordering rule checking to determine which transaction is to be sent on the PCI Express link.

In general, transactions are serviced in the order that they are received from the internal platform . Only when there is a stalled condition does the controller apply PCI Express ordering rules to outstanding transactions. For posted write transactions, once all data has been received from the internal platform , the data is forwarded to the PCI Express link and the transaction is considered as done. For non-posted write transactions, the controller waits for the completion packets to return before considering the transaction finished. For non-posted read transactions, the controller waits for all completion packets to return and then forwards all data back to the internal platform before terminating the transaction.

Note that after reset or when recovering from a link down condition, external transactions should not be attempted until the link has successfully trained. Software can poll the LTSSM state status in PEX_CSR0 to check the status of link training before issuing external requests.

19.1.1.4 Inbound Transactions

Inbound PCI Express transactions to internal platform are first mapped to a translation window to determine what internal platform transactions are to be issued.

A transaction may be broken up into smaller sized transactions when sending to the internal platform depending on the original request size, byte enables and starting/ending addresses. The controller performs PCI Express ordering rule checking to determine what transaction is to be sent next to the internal platform.

In general, transactions are serviced in the order that they are received from the PCI Express link. Only when there is a stalled condition does the controller apply PCI Express ordering to outstanding transactions. For posted write transactions, once all data

has been received from the PCI Express link, the data is forwarded to the internal platform and the transaction is considered as done. For non-posted read transactions, the controller forwards internal platform data back to the PCI Express link.

Note that the controller splits transactions at the crossing of every 256-byte-aligned boundary when sending data back to the PCI Express link.

19.1.2 Features

The following is a list of features supported by the PCI Express controller:

- Compatible with the *PCI Express™ Base Specification, Revision 3.0*
- Supports root complex (RC) and endpoint (EP) configurations
- 32-bit PCI Express address support
- 40-bit internal platform address support
- x8, x4, x2, and x1 link support
- Supports accesses to all PCI Express memory and I/O address spaces (requestor only)
- Supports posting of processor-to-PCI Express and PCI Express-to-memory writes
- Supports strong and relaxed transaction ordering rules
- Enforces outbound PCI Express ordering rules and inbound internal platform priority
- PCI Express configuration registers (type 0 in EP mode, type 1 in RC mode)
- Baseline and advanced error reporting support
- One virtual channel (VC0)
- 256-byte maximum payload size (MAX_PAYLOAD_SIZE)
- Supports three inbound general-purpose translation windows, one 64-bit MSI window (RC only), and one configuration window which can be alternately configured as a general purpose window.
- Supports 32- or 64-bit MSI interrupts
- Supports four outbound translation windows and one default window
- Supports twelve non-posted and eight posted PCI Express inbound transactions
- Supports up to ten internal platform transactions
- Credit-based flow control management handled by PCI Express core.
- Supports PCI Express messages and interrupts
- Accepts up to 256-byte transactions from the internal platform
- Supports memory protection on a per transaction basis (inbound) using LIODN
- Supports separate LIODN base register for Inbound MSI ATMU hit.
- Supports SR-IOV 1.1 spec version with 2 PFs and 64 VFs per PF (total of 128 VFs)
- SR-IOV-only: Supports Functional Level Reset (FLR)
- SR-IOV-only: Supports Alternative Routing ID (ARI)
- SR-IOV-only: Supports MSI-X

    - Eight MSI-X vectors per PF or VF
- SR-IOV-only: Supports MSI-X trap operation.

19.1.3 Modes of Operation

Several parameters that affect the PCI Express controller modes of operation are determined at power-on reset (POR) by reset configuration word (RCW) fields configured depending on SoC product.

Table 19-2. POR Parameters for PCI Express Controller

RCW Parameter	Description	Section/Page
Host/Agent HOST_AGT_PEX	Selects between root complex (RC) and endpoint (EP) modes	
SerDes Protocol Select SRDS_PRTCL_Sn	Determines the link width	

19.1.3.1 Root Complex/Endpoint Modes

The PCI Express controller can function as either a root complex (RC) or an endpoint (EP) on the PCI Express link. The host/agent configuration field, RCW[HOST_AGT_PEX], determines the RC/EP mode.

19.1.3.2 Link Width

The initial link width is determined by the SerDes protocol configuration field (RCW[SRDS_PRTCL_Sn]). See Reset Configuration Word (RCW) for more information. The specific configurations are detailed in SerDes Lane Assignments and Multiplexing.

19.1.3.3 Link Speed

The initial link speed is determined by the SerDes frequency divider for PCI Express field (RCW[SRDS_DIV_PEX_Sn]).

See RCW Field Definitions for more information. The specific configurations are detailed in Reference Clocks for SerDes Protocols.

19.1.3.4 LIODN

Logical I/O Device Number (LIODN) is a mechanism where the memory subsystem identifies the LIODN that is assigned to an inbound PCI Express memory transaction based on its transaction ID (that is, RID), looks up its memory access permissions in a table, and performs the appropriate actions based on the outcome of the table look-up.

19.1.3.5 EP SR-IOV

Single Root I/O Virtualization (SR-IOV) allows for different software images to share IO resources that exist on an EP device. With SR-IOV supported in EP, different devices or different software tasks can share IO resources such as Gigabit Ethernet controllers with minimum code modifications. Additional benefits include savings in hardware cost for additional and/or dedicated IO resources, space and power consumption.

A total of two PFs and 128 VFs are supported. Each PF will have its own dedicated 8-Kbyte memory-mapped register space. Unless stated otherwise, all memory-mapped registers, except inbound and outbound ATMUs, are shared among the PFs.

19.1.3.6 MSI-X (SR-IOV-only)

MSI-X allows the Physical or Virtual functions (as supported by the EP SR-IOV) to send independent message interrupts to the RC device.

Each PF or VF will have eight MSI-X vectors allocated with a total of 256 total MSI-X vectors supported.

19.2 External Signal Descriptions

The PCI Express specification defines the connection between two devices as a link, which can be composed of a single or multiple lanes. Each lane consists of a differential pair for transmitting (TX[n]_P and TX[n]_N) and a differential pair for receiving (RX[n]_P and RX[n]_N) with an embedded data clock.

Table 19-3. PCI Express Interface Signals—Detailed Signal Descriptions

Signal	I/O	Description
SD_RX[n]_P	I	Receive data, positive. The receive data signals carry PCI Express packet information.

Table continues on the next page...

Table 19-3. PCI Express Interface Signals—Detailed Signal Descriptions (continued)

Signal	I/O	Description	
		State Meaning	Asserted/Negated—Represents data being received from the PCI Express interface.
		Timing	Assertion/Negation—As described in the *PCI Express Base Specification, Revision 3.0*.
SD_RX[n]_N	I	Receive data, negative. The receive data signals carry PCI Express packet information.	
		State Meaning	Asserted/Negated—Represents the inverse of data being received from the PCI Express interface.
		Timing	Assertion/Negation—As described in the *PCI Express Base Specification, Revision 3.0*.
SD_TX[n]_P	O	Transmit data, positive. The transmit data signals carry PCI Express packet information.	
		State Meaning	Asserted/Negated—Represents data being transmitted to the PCI Express interface.
		Timing	Assertion/Negation—As described in the *PCI Express Base Specification, Revision 3.0*.
SD_TX[n]_N	O	Transmit data, negative. The transmit data signals carry PCI Express packet information.	
		State Meaning	Asserted/Negated—Represents the inverse of data being transmitted to the PCI Express interface.
		Timing	Assertion/Negation—As described in the *PCI Express Base Specification, Revision 3.0*.

19.3 Memory map/register overview

The PCI Express interface supports the following register types:

- Memory-mapped registers—these registers control PCI Express address translation, PCI error management, and PCI Express configuration register access. These registers are described in the following sections. The memory mapped registers are accessed by reading and writing to an address comprised of the base address (specified in CCSRBAR) plus the block base address, plus the offset of the specific register to be accessed. Note that all memory-mapped registers must only be accessed as 32-bit quantities. Each PF in EP occupies an 8-Kbyte CCSR register space. The block base addresses in EP are as follows:
  - PF0 starts at 0x0000 address offset
  - PF1 starts at 0x2000 address offset
- PCI Express configuration registers contained within the PCI Express configuration space—these registers are specified by the PCI Express specification for every PCI Express device. These registers are described in PCI Express configuration-space registers and its subsections. SR-IOV-only: Each PF/VF will have its own configuration registers as specified by the PCI Express SR-IOV specification.

19.4 PEX Register Descriptions

The PCI Express memory mapped registers are accessed by reading and writing to an address comprised of the base address (specified in the CCSRBAR on the local side or the PEXCSRBAR on the PCI Express side) plus the block base address, plus the offset of the specific register to be accessed. Note that all memory-mapped registers (except the PCI Express configuration data register, PEX_CONFIG_DATA) must only be accessed as 32-bit quantities.

The following table lists the memory-mapped registers.

19.4.1 PEX Memory Map

Offset	Register	Width (In bits)	Access	Reset value
0h	PCI Express configuration address register (CONFIG_ADDR)	32	RW	00000000h
0h	PCI Express configuration address register [SR-IOV] (CONFIG_ADDR_S)	32	RW	00000000h
4h	PCI Express configuration data register (CONFIG_DATA)	32	RW	00000000h
Ch	PCI Express outbound completion timeout register (OTB_CPL_TOR)	32	RW	0013FFFFh
10h	PCI Express configuration retry timeout register (CONF_RTY_TOR)	32	RW	0400FFFFh
14h	PCI Express configuration register (CONFIG)	32	RW	00000028h
18h	PCI Express interrupt status register (INT_STAT)	32	RO	00000000h
20h	PCI Express PME message detect (PF0_PME_MES_DR)	32	W1C	00000000h
24h	PCI Express PME & message disable register (PF0_PME_MES_DISR)	32	RW	00000000h
28h	PCI Express PME & message interrupt enable register (PF0_PME_MES_IER)	32	RW	00000000h
2Ch	PCI Express power management command register (PF0_PMCR)	32	RW	00000000h
40h	PCI Express LIODN base register (LBR)	32	RW	00000000h
44h	PCI Express MSI LIODN base register (PEXMSI_LBR)	32	RW	00000000h
50h	PCI Express address offset register (AOR)	32	RW	00000000h
58h	PCI Express upper data register (UDR)	32	RW	00000000h
5Ch	PCI Express lower data register (LDR)	32	RW	00000000h
BF8h	IP block revision register 1 (IP_BLK_REV1)	32	RO	02080300h
BFCh	IP block revision register 2 (IP_BLK_REV2)	32	RO	00000000h
C00h	PCI Express outbound translation address register n (PF0_PEXOTAR0)	32	RW	00000000h

Table continues on the next page...

Offset	Register	Width (In bits)	Access	Reset value
C04h	PCI Express outbound translation extended address register n (PF0_PEXOTEAR0)	32	RW	00000000h
C10h	PCI Express outbound window attributes register n (PF0_PEXOWAR0)	32	RW	00044027h

19.4.2 PCI Express configuration address register (CONFIG_ADDR)

19.4.2.1 Offset

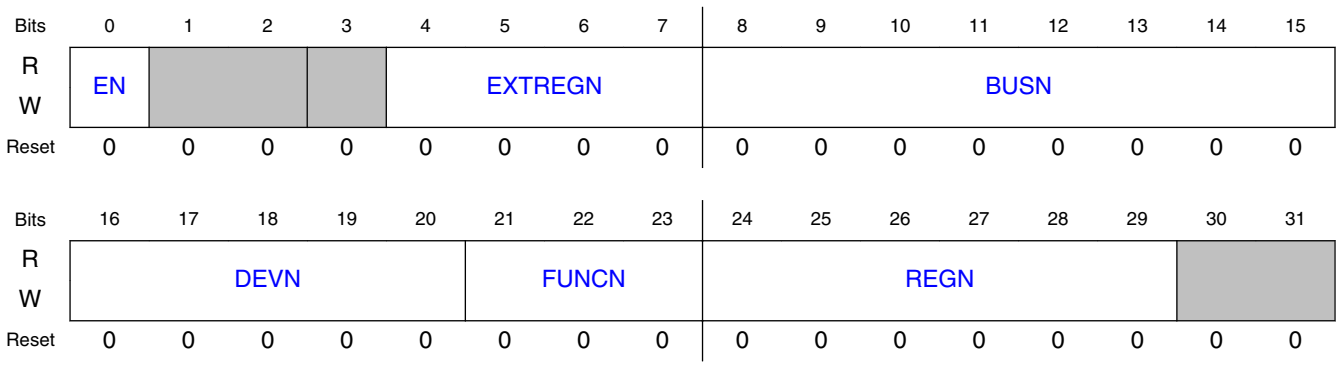
Register	Offset
CONFIG_ADDR	0h

19.4.2.2 Function

The PCI Express configuration address register contains address information for accesses to PCI Express internal and external configuration registers for Root Complex (RC), or End Point (EP) without SR-IOV.

Root complex (RC) and End Point (EP without SR-IOV) configuration headers contain 4096 bytes of address space. To access a register within the header, both the extended register number and the register number fields are concatenated to form the 4-byte aligned address of the register. That is, the register address is extended register number || register number || 0b00.

19.4.2.3 Diagram



19.4.2.4 Fields

Field	Function
0 EN	Enable. This bit allows a PCI Express configuration access when PEX_CONFIG_DATA is accessed. If this bit is cleared, writing to PEX_CONFIG_DATA has no effect and reading PEX_CONFIG_DATA returns unknown data.
1-2 —	Reserved
3 —	Reserved
4-7 EXTREGN	Extended register number. This field allows access to extended PCI Express configuration space (that is, the registers in the offset range from 0x100 to 0xFFF).
8-15 BUSN	Bus number. PCI bus number to access
16-20 DEVN	Device number. Device number to access on specified bus
21-23 FUNCN	Physical Function number. Function to access within specified device
24-29 REGN	Register number. 32-bit register to access within specified device
30-31 —	Reserved

19.4.3 PCI Express configuration address register [SR-IOV] (CONFIG_ADDR_S)

19.4.3.1 Offset

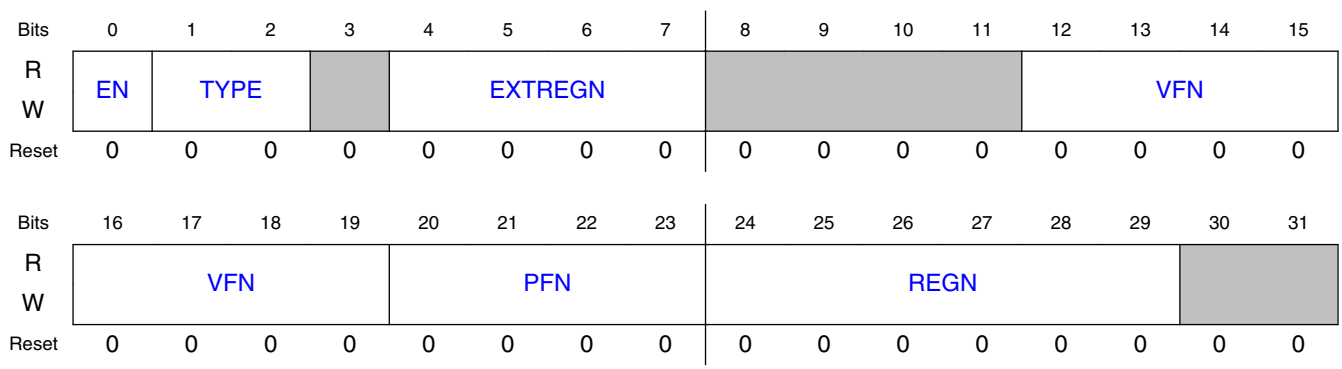
Register	Offset
CONFIG_ADDR_S	0h

19.4.3.2 Function

SR-IOV-only: The PCI Express configuration address register contains address information for accesses to PCI Express internal and external configuration registers for End Point (EP) with SR-IOV.

End Point (EP without SR-IOV) configuration headers contain 4096 bytes of address space for each PF. Access Type (TYPE), Physical Function (PF) number and Virtual Function (VF) number are required for the PCI-Express core to differentiate accesses to PF and VF configuration registers. To access a register within the header, both the extended register number and the register number fields are concatenated to form the 4-byte aligned address of the register. That is, the register address is extended register number || register number || 0b00.

19.4.3.3 Diagram



19.4.3.4 Fields

Field	Function
0 EN	Enable. This bit allows a PCI Express configuration access when PEX_CONFIG_DATA is accessed. If this bit is cleared, writing to PEX_CONFIG_DATA has no effect and reading PEX_CONFIG_DATA returns unknown data.
1-2 TYPE	00, Configuration Register Accesses for RC and EP without SR-IOV 01, Configuration Register Accesses to PF registers for EP with SR-IOV 10, Reserved 11, Configuration Register Accesses to VF registers for EP with SR-IOV
3 —	Reserved
4-7 EXTREGN	Extended register number. This field allows access to extended PCI Express configuration space (that is, the registers in the offset range from 0x100 to 0xFFF).
8-11 —	Reserved
12-19 VFN	Virtual Function number minus 1. 64-255 is reserved.
20-23 PFN	Physical Function number minus 1. 2-15 is reserved.
24-29 REGN	Register number. 32-bit register to access within specified device
30-31 —	Reserved

19.4.4 PCI Express configuration data register (CONFIG_DATA)

19.4.4.1 Offset

Register	Offset
CONFIG_DATA	4h

19.4.4.2 Function

The PCI Express configuration data register is a 32-bit port for internal and external configuration access. Note that accesses of 1, 2, or 4 bytes to the PCI Express configuration data register are allowed. Also note that accesses to the little-endian PCI Express configuration space must be properly formatted. See Byte order for configuration transactions for more information.

19.4.4.3 Diagram

Bits	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	Data															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Data															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

19.4.4.4 Fields

Field	Function
0-31 Data	A read or write to this register starts a PCI Express configuration cycle if the PEX_CONFIG_ADDR enable bit is set (PEX_CONFIG_ADDR[EN] = 1).

19.4.5 PCI Express outbound completion timeout register (OTB_CPL_TOR)

19.4.5.1 Offset

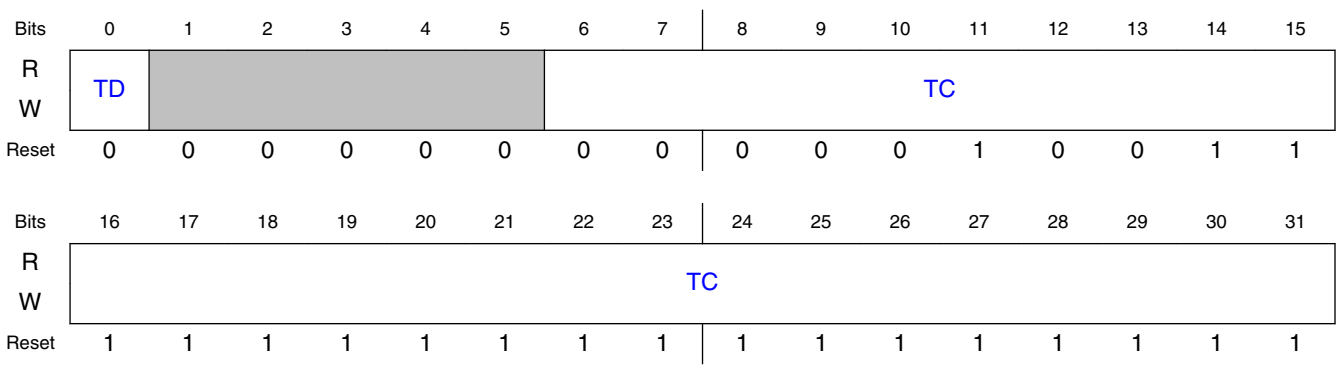
Register	Offset
OTB_CPL_TOR	Ch

19.4.5.2 Function

The PCI Express outbound completion timeout register contains the maximum wait time for a response to come back as a result of an outbound non-posted request before a timeout condition occurs. This timeout register is also used to timeout requests that were not acknowledged (PEX_ERR_DET[PAT]) which is a fatal error.

- Timeout value = (0x10FFFF) × 3 ns = 3.34 ms.
- Total timeout value = 8 × 3.34 ms = 26.72 ms.

19.4.5.3 Diagram



19.4.5.4 Fields

Field	Function
0 TD	Timeout disable. This bit controls the enabling/disabling of the timeout function. 0b - Enable completion timeout 1b - Disable completion timeout
1-5 —	Reserved
6-31 TC	Timeout counter. This is the value that is used to load the response counter of the completion timeout. The completion timeout is determined by TC and the setting of the completion timeout disable bit (CPL_TOD) in Device Control 2 Register per PF. When Device Control 2[CPL_TOD] is cleared, one TC unit is 8x the PCI Express controller clock period; that is, one TC unit is 20 ns at 400 MHz, and 30 ns at 266.66 MHz. The following are examples of timeout periods based on different TC settings: 0x00_0000 Reserved 0x10_FFFF 22.28 ms at 400 MHz controller clock; 33.34 ms at 266.66 MHz controller clock 0xFF_FFFF 335.54 ms at 400 MHz controller clock; 503.31 ms at 266.66 MHz controller clock

Field	Function
	0x3FF_FFFF 1.34 s at 400 MHz controller clock; 2.01 s at 266.66 MHz controller clock When Device Control 2[CPL_TOD] is set, the timeout value is based on TC and Device Control 2[CPL_TO_VAL]. When completion timeout value (CPL_TO_VAL) is: 0000 the timeout value is TC 0001 the timeout value is TC/64 0010 the timeout value is TC/4 0101 the timeout value is TC 0110 the timeout value is TCx4 1001 the timeout value is TCx16 1010 the timeout value is TCx64 For all other values of completion timeout the timeout value is TC. **NOTE:** The maximum computed timeout value based on TC can not exceed 1.34s at 400 MHz and 2.01s at 266.66 MHz.

19.4.6 PCI Express configuration retry timeout register (CONF_ RTY_TOR)

19.4.6.1 Offset

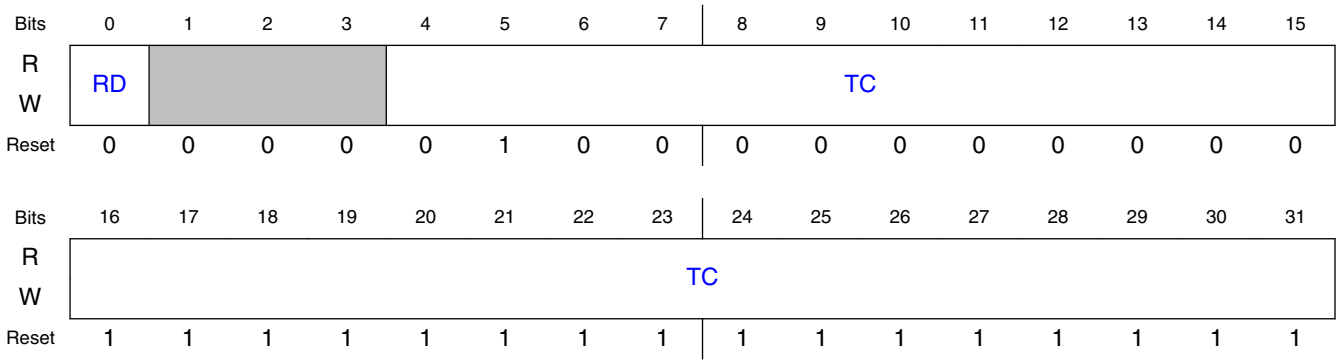
Register	Offset
CONF_RTY_TOR	10h

19.4.6.2 Function

The PCI Express configuration retry timeout register contains the maximum time period during which retries of configuration transactions which resulted in a CRS response occur.

- Timeout value = (0x400_FFFF) × 3 ns = 201.5 ms
- Total timeout value = 8 × 201.5 ms = 1.612 s

19.4.6.3 Diagram



19.4.6.4 Fields

Field	Function
0 RD	Retry disable. This bit disables the retry of a configuration transaction that receives a CRS status response packet. 0b - Enable retry of a configuration transaction in response to receiving a CRS status response until the timeout counter (defined by the PEX_CONF_RTY_TOR[TC] field) has expired. 1b - Disable retry of a configuration transaction regardless of receiving a CRS status response.
1-3 —	Reserved
4-31 TC	Timeout counter. This is the value that is used to load the CRS response counter. One TC unit is 8x the PCI Express controller clock period; that is, one TC unit is 20 ns at 400 MHz and 30 ns at 266.66 MHz. Timeout period based on different TC settings: 00000000000000000000000000000b - Reserved 01000000000011111111111111111b - 1.34 s at 400 MHz controller clock, 2.02 s at 266.66 MHz controller clock 11111111111111111111111111111b - 5.37 s at 400 MHz controller clock, 8.05 s at 266.66 MHz controller clock

19.4.7 PCI Express configuration register (CONFIG)

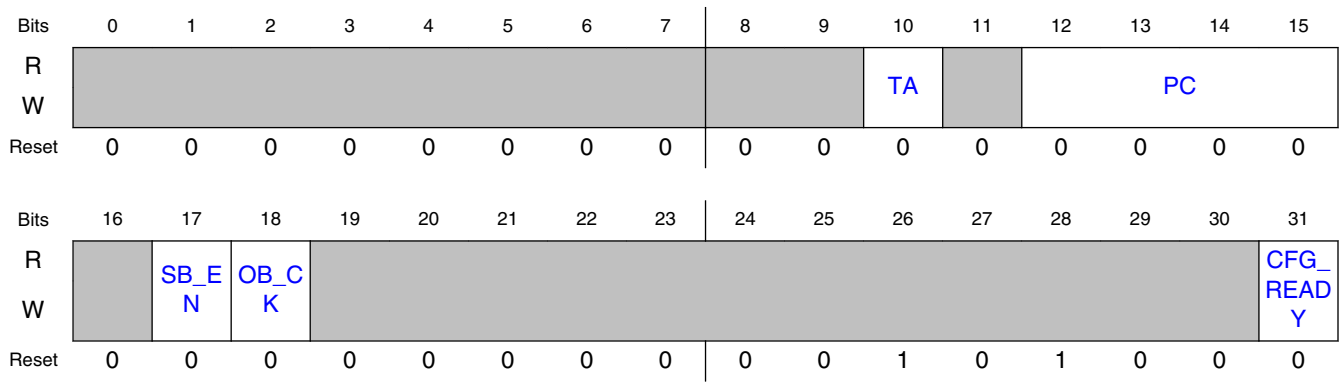
19.4.7.1 Offset

Register	Offset
CONFIG	14h

19.4.7.2 Function

The PCI Express configuration register contains various control switches for the controller.

19.4.7.3 Diagram



19.4.7.4 Fields

Field	Function
0-7 —	Reserved
8-9 —	Reserved
10 TA	SR-IOV: Tx Abort: When set allows logic to terminate any outbound transactions that is targeted to a device that does not set its bus master enable bit or its D-state is non zero.When not set will make logic hold on to outbound transaction that is targeted to a device that does not set its bus master enable bit or its D-state is non zero. Non-SR-IOV: This bit is reserved.
11 —	Reserved
12-15 PC	Reserved. Default value may be non-zeros. Do not alter default value.
16 —	Reserved

Table continues on the next page...

Field	Function
17 SB_EN	Southbridge enable. Enables the ability to operate with certain southbridge devices that require being configured on bus 0. Note that this bit is for use in RC mode only; this bit must be cleared in EP mode. This bit should also be set for configuring devices that are ARI capable. 0b - Configuration transactions targeting bus 0 are handled internally and are not allowed to pass to the external link. 1b - Configuration transactions targeting bus 0 are allowed to pass to the external link.
18 OB_CK	Outbound transaction address checking enable. 0b - Disable checking for all outbound transaction addresses (memory and I/O) against the base/limit registers. There is no checking of outbound addresses. This setting is compatible with the previous generation PCI Express controller behavior. 1b - Enable checking for all outbound addresses (memory and I/O) against the base/limit registers. If an outbound transaction address does not hit into the base/limit registers, it will cause an error.
19-30 —	Reserved. (Some bits may be set by default. Software is required to preserve the setting of reserved bits)
31 CFG_READY	Configuration ready. Only applicable when in EP mode. Default setting is SOC driven . Modification of this bit by software requires a read-modify-write operation. 1b - Allow all inbound configuration transactions to be processed normally 0b - Retry al inbound configuration transaction

19.4.8 PCI Express interrupt status register (INT_STAT)

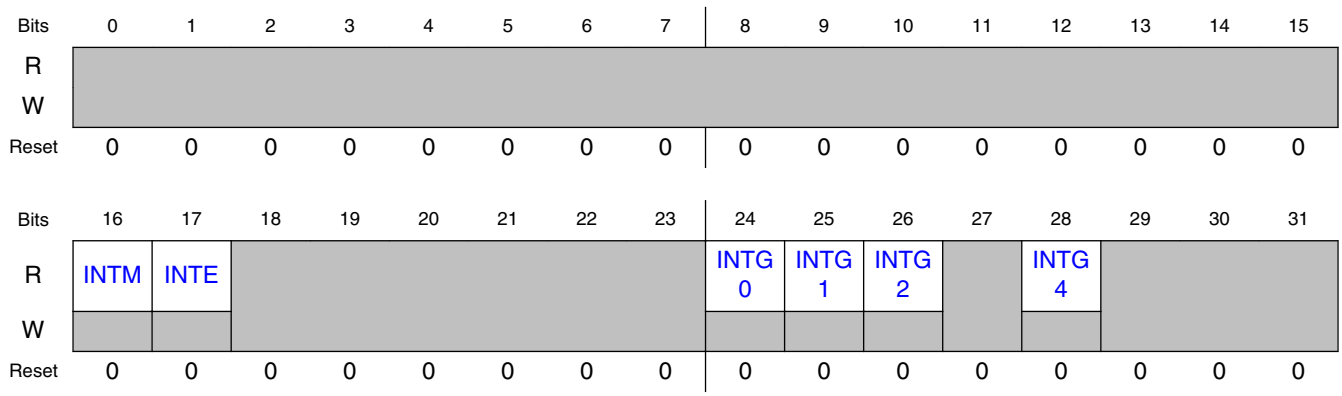
19.4.8.1 Offset

Register	Offset
INT_STAT	18h

19.4.8.2 Function

The PCI Express interrupt status register shows the current interrupt sources that are raising an interrupt to the core. This register is a read only register. Clearing the interrupt source will clear the corresponding bit in the interrupt status register.

19.4.8.3 Diagram



19.4.8.4 Fields

Field	Function
0-15 —	Reserved
16 INTM	Interrupt from PEX_PME_MES_DR register. 1b - Interrupt is pending 0b - No interrupt
17 INTE	Interrupt from PEX_ERR_DR register. 1b - Interrupt is pending 0b - No interrupt
18-23 —	Reserved
24 INTG0	Interrupt from group 0. This includes interrupt generated by: The INTx assertion disable bit in the Command register is 0 and the PME interrupt enable bit in the Root Control register is set to 1 and the PME Status bit in the Root Status register is set to 1. 1b - Interrupt is pending 0b - No interrupt
25 INTG1	Interrupt from group 1. This includes interrupts generated when a reported error condition causes a bit to be set in the Root Error Status register and the associated error message reporting enable bit is set in the Root Error Command register. 1b - Interrupt is pending 0b - No interrupt
26 INTG2	Interrupt from group 2. This includes interrupts generated from Command Status Register (Master Abort, Target Abort, etc..) 1b - Interrupt is pending 0b - No interrupt
27	Reserved

Table continues on the next page...

Field	Function
—	
28 INTG4	Interrupt from group 4. This includes interrupts generated when the Link Autonomous Bandwidth Status register (Link Status register bit 15) is updated and the Link Autonomous Bandwidth Interrupt Enable (Link Control register bit 11) is set or the Link Bandwidth Management Status register (Link Status register bit 14) is updated and the Link Bandwidth Management Interrupt Enable (Link Control register bit 10) is set or the Link Equalization Request bit in the Link Status 2 Register has been set. 1b - Interrupt is pending 0b - No interrupt
29-31 —	Reserved

19.4.9 PCI Express PME message detect (PFa_PME_MES_DR)

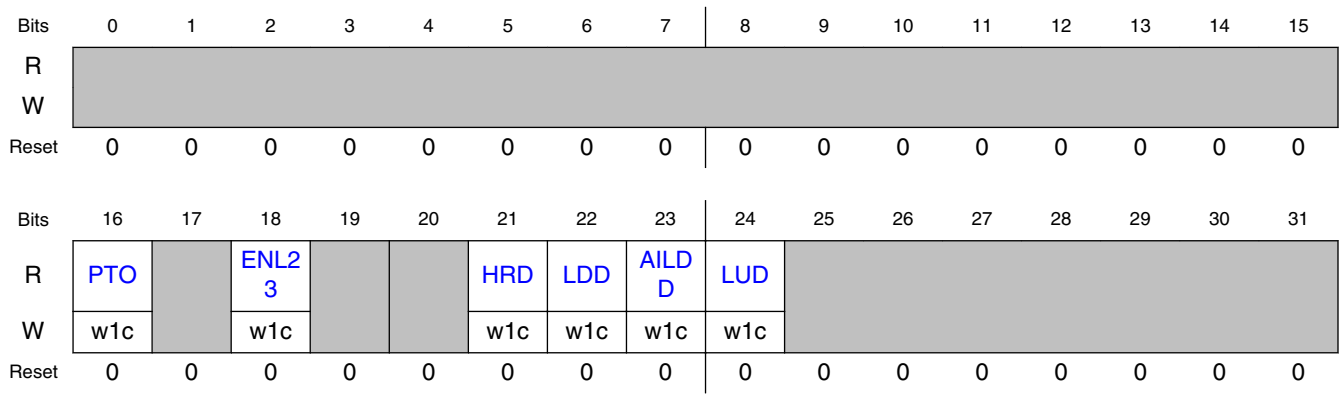
19.4.9.1 Offset

Register	Offset
PF0_PME_MES_DR	20h
PF1_PME_MES_DR	2020h

19.4.9.2 Function

The PCI Express PME and message detect register logs inbound messages and PME events that are detected by the PCI Express controller. This register is a write-1-to-clear type register.

19.4.9.3 Diagram



19.4.9.4 Fields

Field	Function
0-15 —	Reserved
16 PTO	PME turn off. This bit indicates the detection of a PME_Turn_Off message. This bit is only valid in EP mode. 1b - A PME_Turn_Off_message is detected 0b - No PME_Turn_Off message detected
17 —	Reserved. Note that during normal operation, this bit may be set (falsely). The bit may be ignored and cleared (w1c) without consequence.
18 ENL23	Entered L2/L3 ready state. This bit indicates that the PCI Express controller has entered L2/L3 state. This is only valid in RC mode. 1b - L2/L3 ready state has been entered 0b - L2/L3 ready state has not been entered
19 —	Reserved.
20 —	Reserved. Note that during normal operation, this bit may be set (falsely). The bit may be ignored and cleared (w1c) without consequence.
21 HRD	Hot reset detected. This bit indicates that the PCI Express controller has detected a hot reset condition on the link. The controller is reset and cleans up all outstanding transactions. Link retraining takes place once hot reset state is exited. This is valid only in EP mode. 1b - Hot reset request has been detected 0b - Hot reset request not detected
22 LDD	Link down detected. This bit indicates that a link down condition has been detected. The controller is reset and then cleans up all outstanding transactions. Link retraining takes place once the controller has cleaned itself up. Note that for EP, this bit and HRD are typically set when a hot reset event is detected. 1b - Link down has been detected 0b - Link down not detected

Table continues on the next page...

Field	Function
23 AILDD	Ack-timeout induced link down detected. This bit indicates that a link down condition has been detected due to an internal timeout condition. The controller is reset and then cleans up all outstanding transactions. Link retraining takes place once the controller has cleaned itself up. No LDD will be set if this bit is set. 1b - Ack timeout link down has been detected 0b - Ack timeout link down not detected
24 LUD	Link up detected. This bit indicates that a link up condition has been detected. It means that link training has been successful. 1b - Link up detected 0b - Link up not detected
25-31 —	Reserved. Note that during normal operation, these bits may be set (falsely). The bits may be ignored and cleared (w1c) without consequence.

19.4.10 PCI Express PME & message disable register (PFa_PME_MES_DISR)

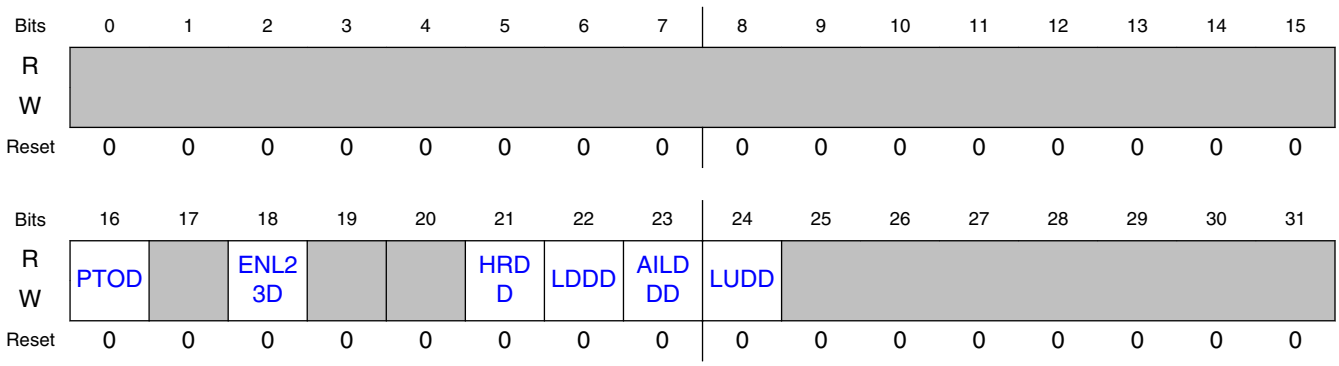
19.4.10.1 Offset

Register	Offset
PF0_PME_MES_DISR	24h
PF1_PME_MES_DISR	2024h

19.4.10.2 Function

The PCI Express PME and message disable register, when set, prevents the detection of the corresponding bits in the PCI Express PME and message detect register.

19.4.10.3 Diagram



19.4.10.4 Fields

Field	Function
0-15 —	Reserved
16 PTOD	PME turn off disable. When set, this bit disables the setting of PEX_PME_MES_DR[PTO] bit. 1b - Disable PME_Turn_Off_message detection 0b - Enable PME_Turn_Off message detection
17 —	Reserved
18 ENL23D	Entered_L2/L3 ready disable. When set, this bit disables the setting of PEX_PME_MES_DR[ENL23] bit. 1b - Disable Entered_L2/L3 ready state detection 0b - Enable Entered_L2/L3 ready state detection
19 —	Reserved.
20 —	Reserved
21 HRDD	Hot reset detected disable. When set, this bit disables the setting of PEX_PME_MES_DR[HRD] bit. 1b - Disable hot reset state detection 0b - Enable hot reset state detection
22 LDDD	Link down detected disable. When set, this bit disables the setting of PEX_PME_MES_DR[LDD] bit. 1b - Disable link down state detection 0b - Enable link down state detection
23 AILDDD	Ack time-out induced link down detected disable. When set, this bit disables the setting of PEX_PME_MES_DR[AILDD] bit. 1b - Disable ack time-out link down state detection 0b - Enable ack time-out link down state detection
24 LUDD	Link up detected disable. When set, this bit disables the setting of PEX_PME_MES_DR[LUD] bit. 1b - Disable link up detection

Table continues on the next page...

Field	Function
	0b - Enable link up detection
25-31 —	Reserved

19.4.11 PCI Express PME & message interrupt enable register (PFa_PME_MES_IER)

19.4.11.1 Offset

Register	Offset
PF0_PME_MES_IER	28h
PF1_PME_MES_IER	2028h

19.4.11.2 Function

The PCI Express PME and message interrupt enable register allows for the detection of a message or a PME event to generate an interrupt, provided that the corresponding bit in the PCI Express PME and message detect register is set.

19.4.11.3 Diagram

Bits	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

19.4.11.4 Fields

Field	Function
0-15 —	Reserved
16 PTOIE	PME turn off interrupt enable. When set and PEX_PME_MES_DR[PTO]=1 generates an interrupt. 1b - Enable PME_Turn_Off_message interrupt generation 0b - Disable PME_Turn_Off message interrupt generation
17 —	Reserved
18 ENL23IE	Entered L2/L3 ready interrupt enable. When set and PEX_PME_MES_DR[ENL23]=1 generates an interrupt. 1b - Enable Entered_L2/L3 ready state interrupt generation 0b - Disable Entered_L2/L3 ready state interrupt generation
19 —	Reserved.
20 —	Reserved
21 HRDIE	Hot reset detected interrupt enable. When set and PEX_PME_MES_DR[HRD]=1 generates an interrupt. 1b - Enable hot reset state interrupt generation 0b - Disable hot reset state interrupt generation
22 LDDIE	Link down detected interrupt enable. When set and PEX_PME_MES_DR[LDD]=1 generates an interrupt. 1b - Enable link down state interrupt generation 0b - Disable link down state interrupt generation
23 AILDDIE	Ack time-out induced link down detected interrupt enable. When set and PEX_PME_MES_DR[AILDD]=1 generates an interrupt. 1b - Enable ack time-out link down state interrupt generation 0b - Disable ack time-out link down state interrupt generation
24 LUDIE	Link up detected interrupt enable. When set and PEX_PME_MES_DR[LUD]=1 generates an interrupt. 1b - Enable link up detected interrupt generation 0b - Disable link up detected interrupt generation
25-31 —	Reserved

19.4.12 PCI Express power management command register (PFa_PMCR)

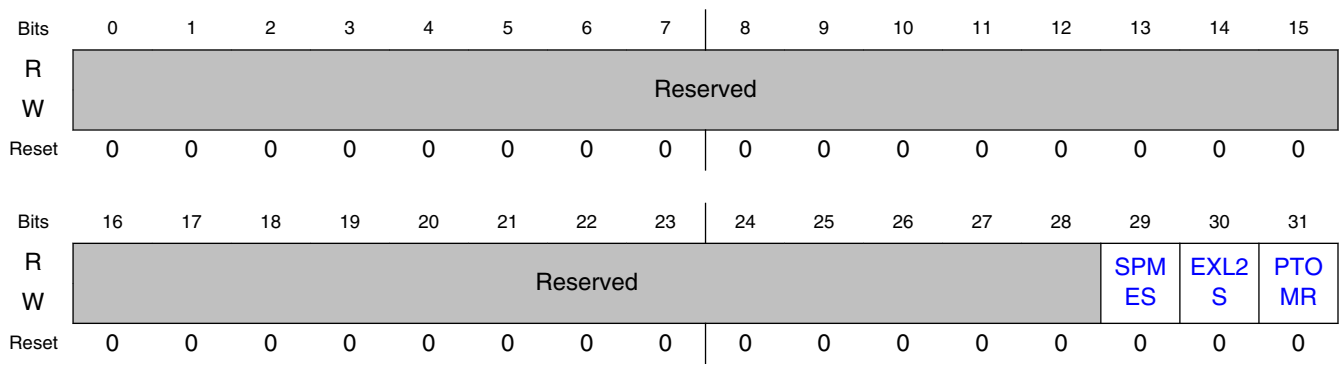
19.4.12.1 Offset

Register	Offset
PF0_PMCR	2Ch
PF1_PMCR	202Ch

19.4.12.2 Function

The PCI Express power management command register provides software a mechanism to allow the PCI Express controller to get back to L0 link state.

19.4.12.3 Diagram



19.4.12.4 Fields

Field	Function
0-28 Reserved	Reserved
29 SPMES	Set PME status. This sets the PME status bit and if PME is enabled (see Power Management Status and Control Register for more information) it transmits a PM_PME message upstream. This bit should not be used when in RC mode. This bit is self-clearing.
30 EXL2S	Exit L2 state. When set exits the link state out of L2/L3 ready state in order to send new requests. The request is only made when entered_L2/L3 ready state is active. This bit is self-clearing. When the link has exited L2/L3 ready state, the status bit Exit_L2/L3 ready state is set. This bit should not be used when in EP mode. This bit is shared among PFs. In RC mode, Exit L2 clears both sticky and non-sticky register bits.
31 PTOMR	PME_Turn_Off message request. When set broadcasts a PME turn_off message. This bit should not be used when in EP mode. This bit is self-clearing. This bit is unique to each PF (that is, per PF).

19.4.13 PCI Express LIODN base register (LBR)

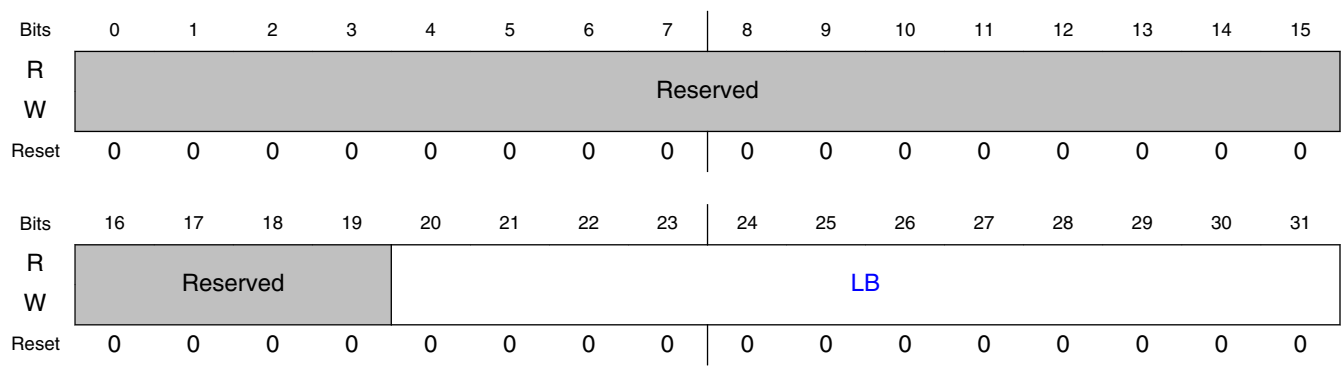
19.4.13.1 Offset

Register	Offset
LBR	40h

19.4.13.2 Function

The PCI Express LIODN base register provides the base LIODN that all transactions to memory (except for Inbound MSI window hits) must use. The actual LIODN that is associated with a transaction sent to memory is PEX_LBR + LIODN offset that is derived from the LIODN permission table. See LIODN Permission Table for more information.

19.4.13.3 Diagram



19.4.13.4 Fields

Field	Function
0-19 Reserved	Reserved

Table continues on the next page...

Field	Function
20-31 LB	LIODN Base. This field contains the 12-bit LIODN base that is used for permission identification for all inbound transactions toward mermory.

19.4.14 PCI Express MSI LIODN base register (PEXMSI_LBR)

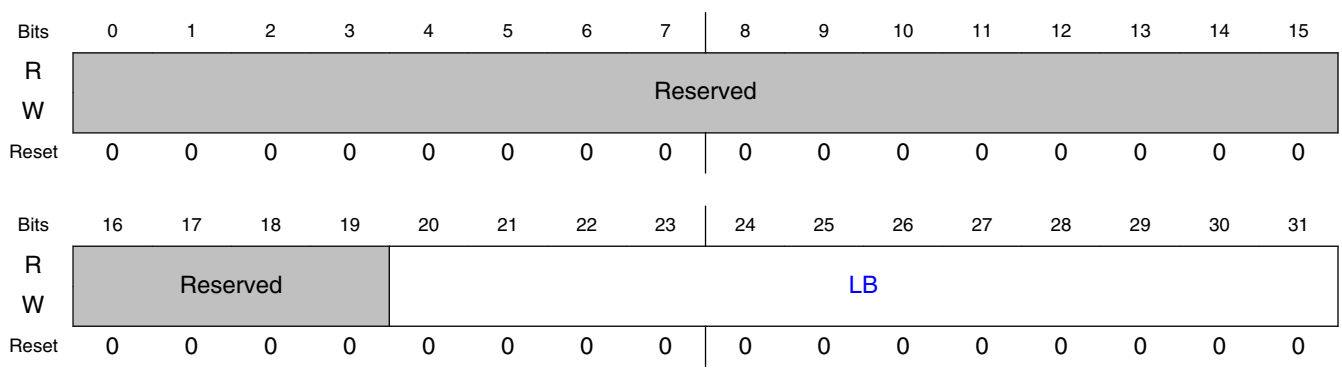
19.4.14.1 Offset

Register	Offset
PEXMSI_LBR	44h

19.4.14.2 Function

The PCI Express MSI LIODN base register provides the base LIODN that Inbound MSI transactions to memory must use. The actual LIODN that is associated with a Inbound MSI transaction sent to memory is PEXMSI_LBR + LIODN offset that is derived from the LIODN permission table. See LIODN Permission Table for more information.

19.4.14.3 Diagram



19.4.14.4 Fields

Field	Function
0-19 Reserved	Reserved
20-31 LB	LIODN Base. This field contains the 12-bit LIODN base that is used for permission identification for all inbound transactions toward mermory.

19.4.15 PCI Express address offset register (AOR)

19.4.15.1 Offset

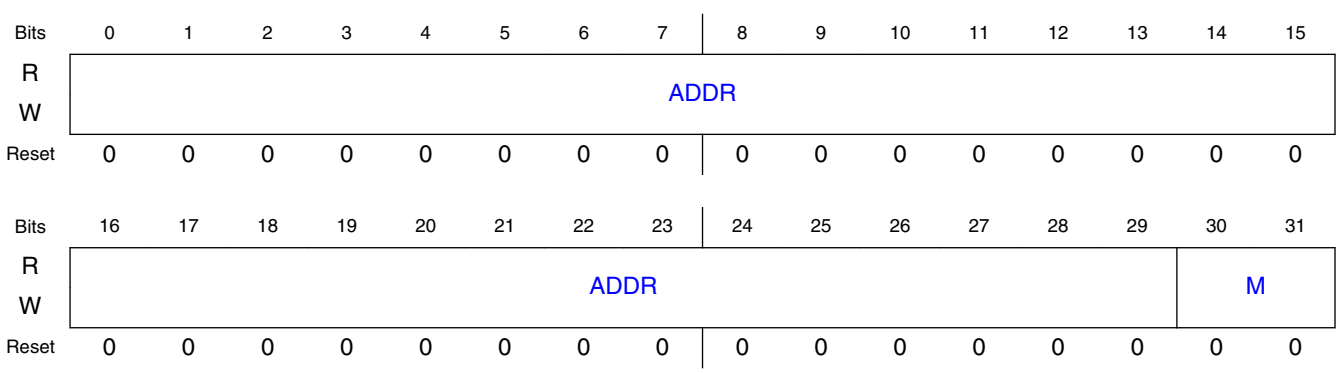
Register	Offset
AOR	50h

19.4.15.2 Function

The PCI Express address offset register provides address index into the LIODN permission table or MSI-X/PBA table.

The layout of bits 0-29 depends on the setting of the Mode field (M).

19.4.15.3 Diagram



19.4.15.4 Fields

Field	Function
0-29 ADDR	Address. This field takes on different meanings depending on the setting of M (Mode) field.
30-31 M	Mode. Depending on setting will take on different meaning. 00b - Reserved 01b - LIODN. Part of the ADDR fields is used to access LIODN permission table. See LIODN Permission Table. 10b - SR-IOV-only: MSI-X Vector Table. Part of the ADDR field is used to access MSI-X table structure. See MSI-X Operations (SR-IOV-only). 11b - SR-IOV-only: MSI-X PBA Array. Part of the ADDR field is used to access MSI-X PBA structure. See MSI-X Operations (SR-IOV-only).

19.4.16 PCI Express upper data register (UDR)

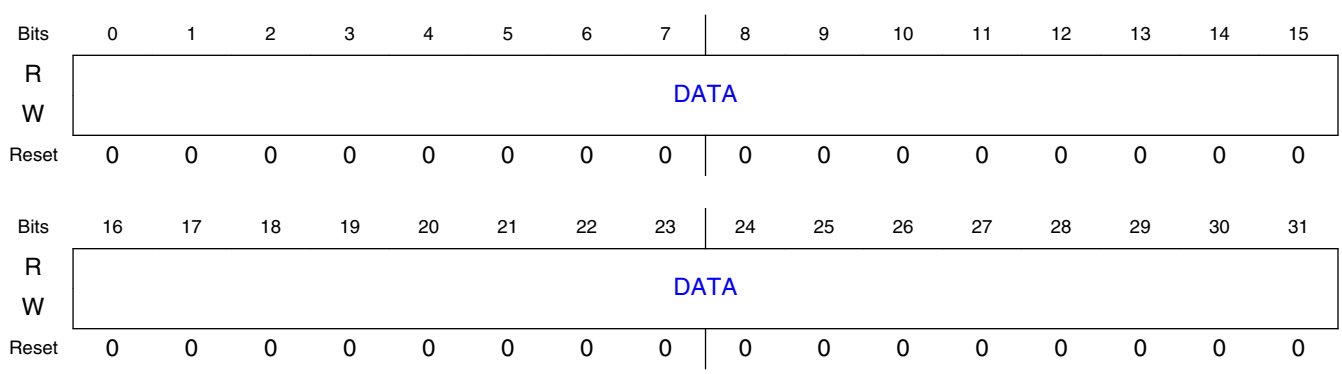
19.4.16.1 Offset

Register	Offset
UDR	58h

19.4.16.2 Function

The PCI Express upper data register allows software to read/write into the upper 32-bit of the LIODN permission table's entry.

19.4.16.3 Diagram



19.4.16.4 Fields

Field	Function
0-31 DATA	PEX_AOR[M] = 01, upper 32-bit entity of the LIODN permission table's entry. PEX_AOR[M] = 00, 10, 11 are reserved.

19.4.17 PCI Express lower data register (LDR)

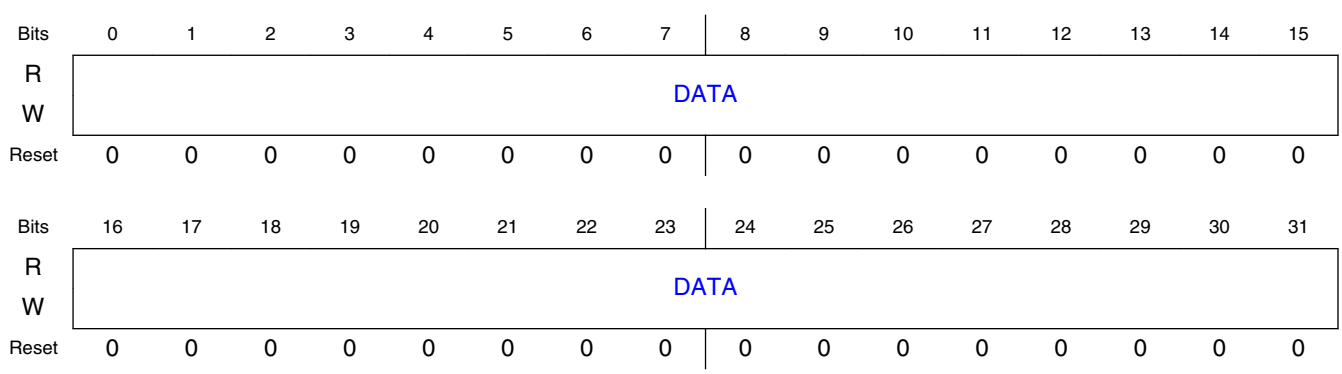
19.4.17.1 Offset

Register	Offset
LDR	5Ch

19.4.17.2 Function

The PCI Express lower data register allows software to read/write into the lower 32-bits of the LIODN permission table's entry or MSI-X vector/PBA table's entry.

19.4.17.3 Diagram



19.4.17.4 Fields

Field	Function
0-31 DATA	PEX_AOR[M] = 00, reserved. PEX_AOR[M] = 01, lower 32-bit entity of the LIODN permission table's entry. PEX_AOR[M] = 10, 4-byte data of the MSI-X vector corresponding to PEX_AOR[ADDR] field. PEX_AOR[M] = 11, 4-byte data of the MSI-X PBA data corresponding to PEX_AOR[ADDR] field.

19.4.20 PCI Express outbound translation address register n (PFa_PEXOTARb)

19.4.20.1 Offset

For a = 0 to 1:

For b = 0 to 4:

Register	Offset
PFa_PEXOTARb	C00h + (a × 2000h) + (b × 20h)

19.4.20.2 Function

The PCI Express outbound translation address registers select the starting addresses in the system address space for window hits within the PCI Express outbound address translation windows. The new translated address is created by concatenating the transaction offset to this translation address. PEXOTAR0 exists in RC mode or for PF0-only in EP mode. PEXOTAR1-4 are unique per PF.

19.4.20.3 Diagram

19.4.20.4 Fields

Field	Function
0-11 TEA	Translation extended address. System address which indicates the starting point of the outbound translated address. The translation address must be aligned based on the size field. Corresponds to PCI Express address bits [43:32] (bit 32 is the lsb).
12-31 TA	Translation address. System address which indicates the starting point of the outbound translated address. The translation address must be aligned based on the size field. This corresponds to PCI Express address bits [31:12].

19.4.21 PCI Express outbound translation extended address register n (PFa_PEXOTEARb)

19.4.21.1 Offset

For a = 0 to 1:

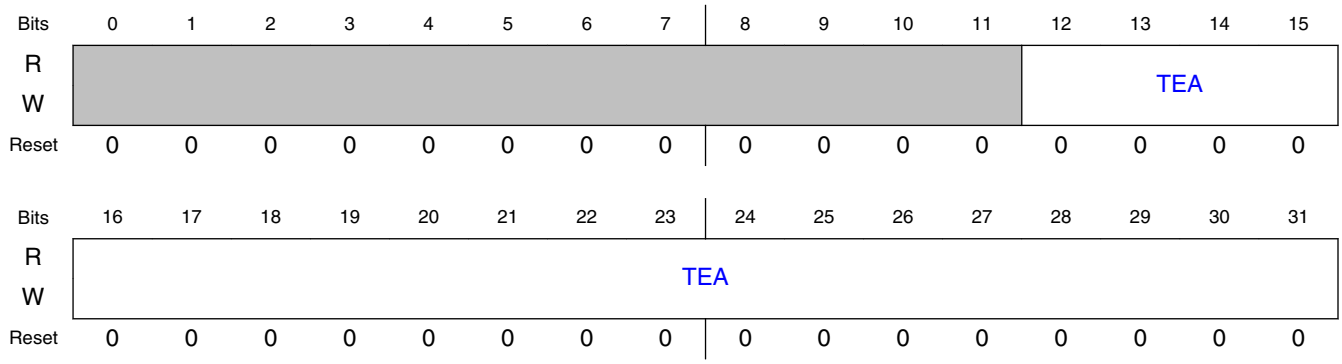
For b = 0 to 4:

Register	Offset
PFa_PEXOTEARb	C04h + (a × 2000h) + (b × 20h)

19.4.21.2 Function

The PCI Express outbound translation extended address registers contain the most-significant bits of a 64 bit translation address. PEXOTEAR0 exists in RC mode or for for PF0-only in EP mode. PEXOTEAR1-4 are unique per PF.

19.4.21.3 Diagram



19.4.21.4 Fields

Field	Function
0-11 —	Reserved
12-31 TEA	Translation extended address. System address which indicates the starting point of the outbound translated address. The translation address must be aligned based on the size field. Corresponds to PCI Express address bits [63:44].

19.4.22 PCI Express outbound window attributes register n (PFa_PEXOWARb)

19.4.22.1 Offset

For a = 0 to 1:

For b = 0 to 4:

Register	Offset
PFa_PEXOWARb	C10h + (a × 2000h) + (b × 20h)

19.4.22.2 Function

The PCI Express outbound window attributes registers define the window sizes to translate and other attributes for the translations. 1 Tbyte is the largest window size allowed. PEXOWAR0 only exists for PF0. In order to properly update the fields of this register, there should not be back-to-back writes. At least 2 pipe clocks delay are needed in between write accesses when changing fields of this register.

NOTE

PEXOWAR0[EN] is read only and set to 1.

19.4.22.3 Diagram

19.4.22.4 Fields

Field	Function
0 EN	Enable. This bit enables this address translation window. For the default window (window 0), this bit is read-only and always hardwired to 1. 0b - Disable outbound translation window 1b - Enable outbound translation window
1 DIEN	Data invariance enable. This bit controls the data ordering policy of all outbound transactions passing through this window. See Byte Ordering for more information. **NOTE:** The data invariance feature is only supported for use with specific interface cards that require this non-default byte ordering policy. 0b - Disable data invariance mode. Outbound transactions use address invariance ordering. 1b - Enable data invariance mode. Outbound transactions use data invariance ordering.
2 —	Reserved
3 ROE	Relaxed ordering enable. This bit when set and the PCI Express device control register[Enable Relaxed] bit is set enables the Relaxed Ordering bit for the packet. This bit only applies to memory transactions.

Table continues on the next page...

Field	Function
	0b - Default ordering 1b - Relaxed ordering
4 NS	No snoop enable. This bit when set and the PCI Express device control register[Enable No Snoop] bit is set enables the no snoop bit for the packet. This bit only applies to memory transactions. 0b - Snoopable 1b - No snoop
5-7 —	Reserved
8-10 TC	Traffic class. This field indicates the traffic class of the outbound packet. This field only applies to memory transaction. All other transaction types should set the TC field to 0. **NOTE:** Traffic class settings are passed through to the PCI Express link, but no specific actions are taken in the device based on traffic class. 000b - TC0 001b - TC1 010b - TC2 011b - TC3 100b - TC4 101b - TC5 110b - TC6 111b - TC7
11 —	Reserved
12-15 RTT	Read transaction type. Read transaction type to run on the PCI Express link Settings not shown are reserved. 0010b - Configuration read. Supported only when in RC mode and size of less than or equal to 4 bytes and not crossing 4-byte address boundary. 0100b - Memory read 1000b - IO read. Supported only when in RC mode and size of less than or equal to 4 bytes and not crossing 4-byte address boundary.
16-19 WTT	Write transaction type. Write transaction type to run on the PCI Express link. Settings not shown are reserved. 0010b - Configuration write. Supported only when in RC mode and size of less than or equal to 4 bytes and not crossing 4-byte address boundary. 0100b - Memory write 0101b - Message write. Only support 4-byte size access on a 4-byte address boundary. 1000b - IO Write. Supported only when in RC mode and size of less than or equal to 4 bytes and not crossing 4-byte address boundary.
20-25 —	Reserved
26-31 OWS	Outbound window size. Outbound translation window size N which is the encoded $2^{(N + 1)}$-byte window size. The smallest window size is 4 Kbytes. Note that for the default window (window 0), the outbound window size may be programmed less than the 1-Tbyte maximum. However, accesses that miss all other windows and hit outside the default window is aliased to the default window. 000000b - Reserved 001011b - 4-Kbyte window size 001100b - 8-Kbyte window size 011111b - 4-Gbyte window size 100000b - 8-Gbyte window size

Field	Function
	100001b - 16-Gbyte window size 100010b - 32-Gbyte window size 100011b - 64-Gbyte window size 100111b - 1-Tbyte window size 111111b - Reserved

19.4.23 PCI Express outbound window base address register (PFa_PEXOWBARb)

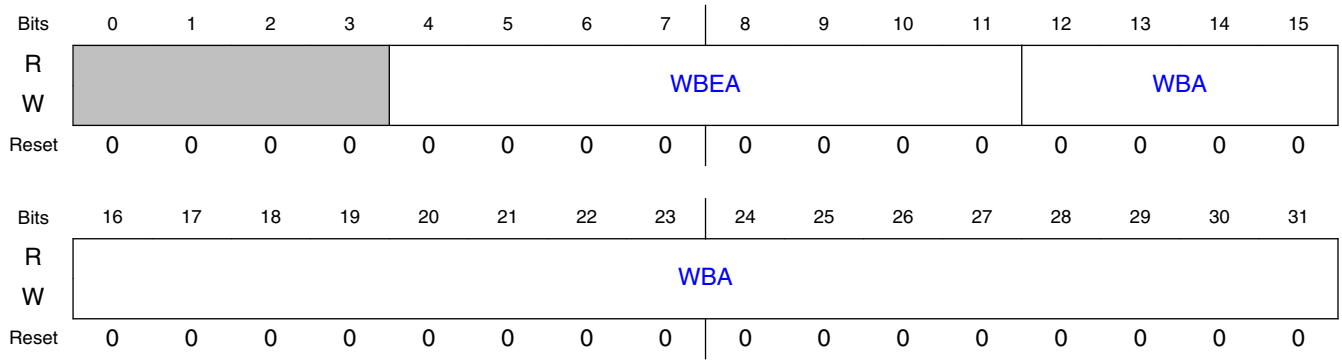
19.4.23.1 Offset

Register	Offset
PF0_PEXOWBAR1	C28h
PF0_PEXOWBAR2	C48h
PF0_PEXOWBAR3	C68h
PF0_PEXOWBAR4	C88h
PF1_PEXOWBAR1	2C28h
PF1_PEXOWBAR2	2C48h
PF1_PEXOWBAR3	2C68h
PF1_PEXOWBAR4	2C88h

19.4.23.2 Function

The PCI Express outbound window base address registers select the base address for the windows which are translated to the external address space. Addresses for outbound transactions are compared to these windows. If such a transaction does not fall within one of these spaces the transaction is forwarded through a default register set. These registers are unique per PF.

19.4.23.3 Diagram



19.4.23.4 Fields

Field	Function
0-3 —	Reserved
4-11 WBEA	Window base extended address. Source address which is the starting point for the outbound translation window. The window must be aligned based on the size selected in the window size bits. Correspond to internal platform address bits [0:7]. (where 0 is the msb of the internal platform address)
12-31 WBA	Window base address. Source address which is the starting point for the outbound translation window. The window must be aligned based on the size selected in the window size bits. This corresponds to internal platform address bits [8:27].

19.4.24 PCI Express MSIX trap outbound window base address register (PFa_PEXMSIX_TPOWBAR)

19.4.24.1 Offset

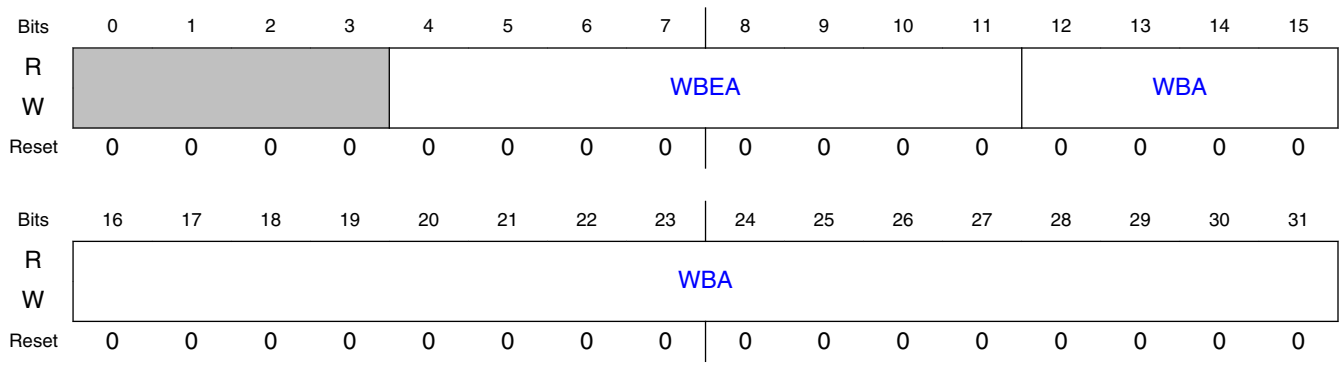
Register	Offset
PF0_PEXMSIX_TPOWBAR	CC8h
PF1_PEXMSIX_TPOWBAR	2CC8h

19.4.24.2 Function

This register is supported only for EP mode.

The PCI Express MSI-X trap outbound window base address register provides address offset for MSI-X trap operation. When MSI-X trap operation is enabled and a 4-byte write transaction falls into the MSI-X trap window starting address, hardware converts the write transaction to a MSI-X operation. The MSI-X vector information is included in the write data.

19.4.24.3 Diagram



19.4.24.4 Fields

Field	Function
0-3 —	Reserved
4-11 WBEA	Window base extended address. Source address which is the starting point for the outbound translation window. The window must be aligned based on the size selected in the window size bits. Correspond to internal platform address bits [0:7]. (where 0 is the msb of the internal platform address)
12-31 WBA	Window base address. Source address which is the starting point for the outbound translation window. The window must be aligned based on the size selected in the window size bits. This corresponds to internal platform address bits [8:27].

19.4.25 PCI Express MSIX trap outbound window attribute register (PFa_PEXMSIX_TPOWAR)

19.4.25.1 Offset

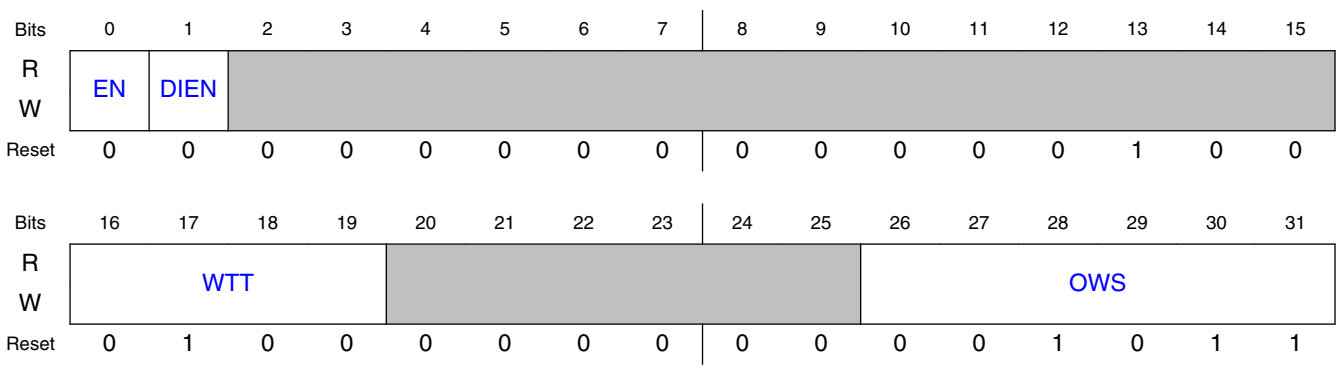
Register	Offset
PF0_PEXMSIX_TPOWAR	CD0h
PF1_PEXMSIX_TPOWAR	2CD0h

19.4.25.2 Function

This register is supported only for EP mode.

The PCI Express MSI-X trap outbound window attribute register, provides controls for MSI-X trap operation. These registers are unique per PF.

19.4.25.3 Diagram



19.4.25.4 Fields

Field	Function
0 EN	Enable. This bit enables this address translation window. For the default window, this bit is read-only and always hardwired to 1. 0b - Disable outbound translation window 1b - Enable outbound translation window
1 DIEN	Data invariance enable. This bit controls the data ordering policy of all outbound transactions passing through this window. See Byte Ordering for more information. **NOTE:** The data invariance feature is only supported for use with specific interface cards that require this non-default byte ordering policy.

Table continues on the next page...

Field	Function
	0b - Disable data invariance mode. Outbound transactions use address invariance ordering. 1b - Enable data invariance mode. Outbound transactions use data invariance ordering.

19.4.26 PCI Express Expansion ROM inbound translation address register (PFa_PEXEPROMITAR)

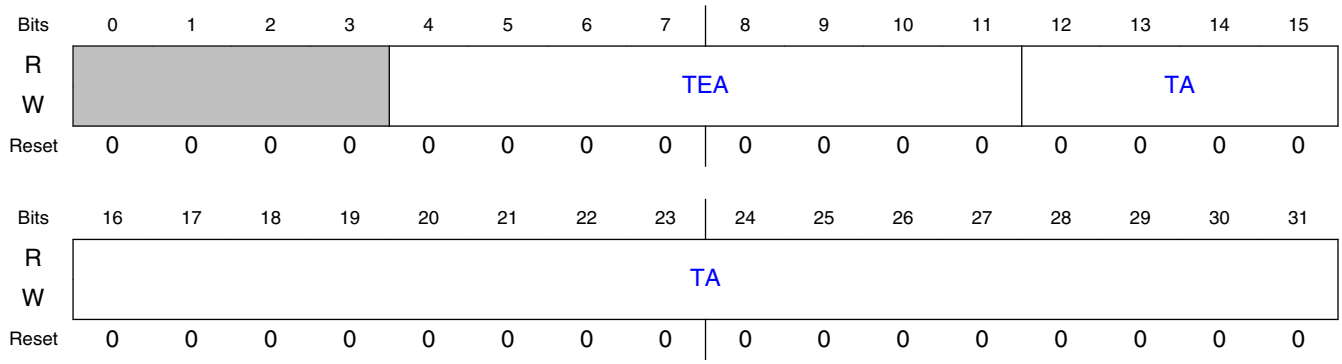
19.4.26.1 Offset

Register	Offset
PF0_PEXEPROMITAR	CE0h
PF1_PEXEPROMITAR	2CE0h

19.4.26.2 Function

The PCI Express Expansion ROM inbound translation address register contains the translated internal platform address to be used for Expansion ROM. The base of the Expansion ROM window is defined in the PCI Express Expansion ROM Base Address Register (Expansion ROM BAR) in the PCI Compatible Configuration Headers. The expansion ROM translation address should be initialized to an appropriate value by the pre-boot loader.

19.4.26.3 Diagram



19.4.26.4 Fields

Field	Function
0-3 —	Reserved
4-11 TEA	Translation extended address. Target address which indicates the starting point of the inbound translated address. The translation address must be aligned based on the size field. Corresponds to internal platform address bits [0:7] where bit 0 is the msb of the internal platform address.
12-31 TA	Translation address. Target address which indicates the starting point of the inbound translated address. The translation address must be aligned based on the size field. Corresponds to internal platform address bits [8:27]

19.4.27 PCI Express Expansion ROM inbound window attribute register (PFa_PEXEPROMIWAR)

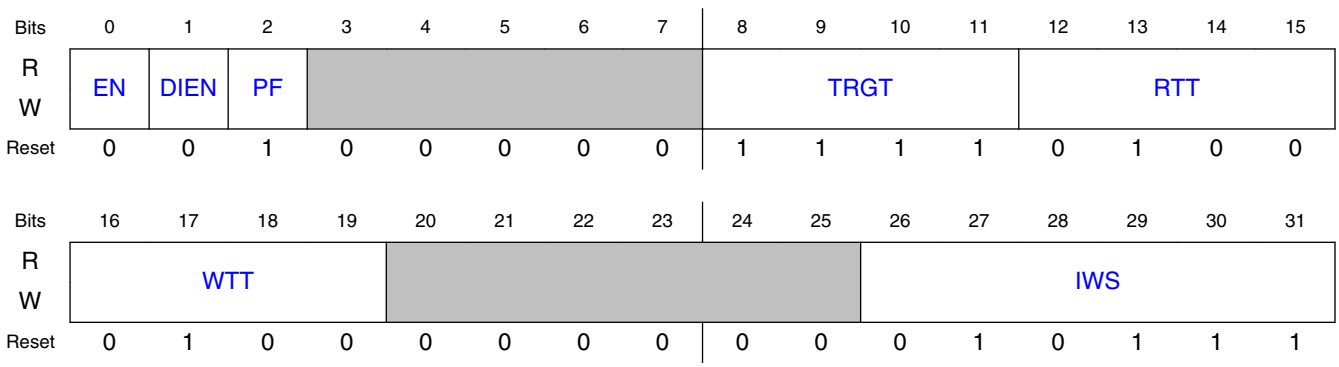
19.4.27.1 Offset

Register	Offset
PF0_PEXEPROMIWAR	CF0h
PF1_PEXEPROMIWAR	2CF0h

19.4.27.2 Function

The PCI Express Expansion ROM inbound window attributes register defines the window attributes for the translations. The enable (EN) and inbound window size (IWS) attributes of the window are shadow copies of what is programmed in the Expansion ROM BAR Mask register in the SPEX core. The Expansion ROM window is limited to the lower 4-Gbyte space with maximim size of 16-Mbytes. The default window size is 16 Mbytes. It is expected that the pre-boot loader will program the PEXEPROMIWAR[EN], and PEXEPROMIWAR[IWS] fields and the Expansion ROM Bar Mask Register (at config offset 0x30) to have matching values prior to using the window.

19.4.27.3 Diagram



19.4.27.4 Fields

Field	Function
0 EN	Enable. This bit controls the enabling/disabling of the Expansion ROM translation window. Note that bit 0 of the Expansion ROM Base Address register in the PCI Express PCI-Compatible Configuration Header needs to be programmed with the same value as this enable bit. 0b - Disable inbound window translation 1b - Enable inbound window translation
1 DIEN	Data invariance enable. This bit controls the data ordering policy of all inbound transactions passing through this window. See Byte Ordering for more information. 0b - Disable data invariance mode. Inbound transactions use address invariance ordering. 1b - Enable data invariance mode. Inbound transactions use data invariance ordering.
2 PF	Prefetchable. This bit indicates that the address space is prefetchable. This bit corresponds to the prefetchable bit in the BAR in the PCI Express type 0 header. This bit drives the BAR's prefetchable bit in EP mode. 0b - Not prefetchable 1b - Prefetchable

Table continues on the next page...

Field	Function
3-7 —	Reserved
8-11 TRGT	Target interface. 1111b - Local memory space
12-15 RTT	Read transaction type. Read transaction type to send to target interface. If the transaction is not going to local memory space 0000 Reserved ... 0100 Read 0101 Reserved 0110 Reserved 0111 Reserved 1000 Reserved ... 1111 Reserved If the transaction is going to local memory space 0000 Reserved ... 0100 Read, do not snoop local processor 0101 Read, snoop local processor 0110 Reserved 0111 Read, snoop local processor, unlock L2 cache line 1000 Reserved ... 1111 Reserved

26-31 IWS	Inbound window size. Inbound translation window size N which is the encoded $2^{(N + 1)}$-bytes window size. The smallest window size is 4 Kbytes. For EP mode, this field directly controls the size of the BARs. Note that IWS needs to match the Expansion ROM BAR mask register at configuration offset 0x30 and PEX_CSR1[CS2] needs to be set when programming the Expansion ROM BAR mask register. 000000b - Reserved 001010b - Reserved 001011b - 4-Kbyte window size 001100b - 8-Kbyte window size 010111b - 16-Mbyte window size 111000b - Reserved 111111b - Reserved

19.4.28 PCI Express MSI inbound translation address register (PEXMSIITAR)

19.4.28.1 Offset

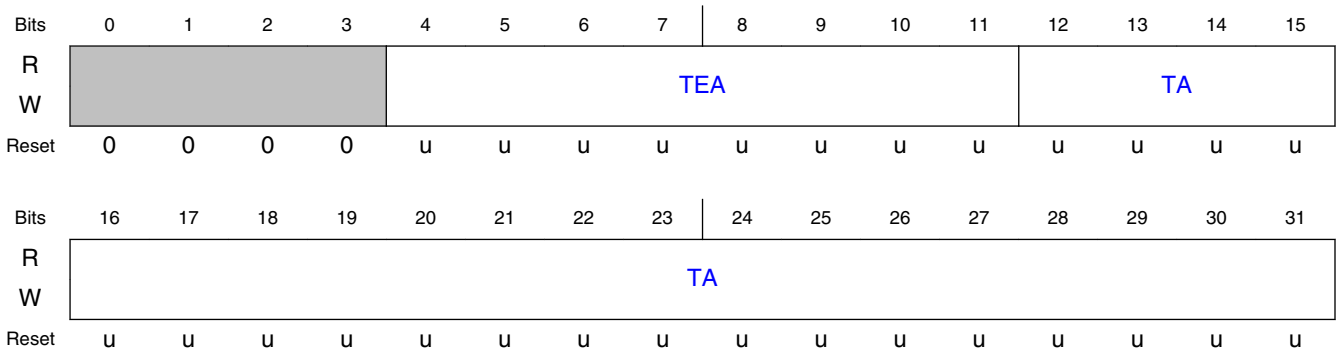
Register	Offset
PEXMSIITAR	D00h

19.4.28.2 Function

This register is supported only for RC mode.

The PCI Express MSI inbound translation address register contains the translated internal platform address to be used. The translated address is always mapped to CCSRBAR space similarly to PEXITAR0.

19.4.28.3 Diagram



19.4.28.4 Fields

Field	Function
0-3 —	Reserved
4-11 TEA	Translation extended address. Target address which indicates the starting point of the inbound translated address. The translation address must be aligned based on the size field. Corresponds to internal platform address bits [0:7] where bit 0 is the msb of the internal platform address. Mapped to CCSRBAR. .
12-31 TA	Translation address. Target address which indicates the starting point of the inbound translated address. The translation address must be aligned based on the size field. Corresponds to internal platform address bits [8:27]. Mapped to CCSRBAR.

19.4.29 PCI Express MSI inbound window base address register (PEXMSIIWBAR)

19.4.29.1 Offset

Register	Offset
PEXMSIIWBAR	D08h

19.4.29.2 Function

This register is supported only for RC mode.

The PCI Express MSI inbound window base address register selects the base address for the windows which are translated to an alternate target address space. In root complex (RC) mode, addresses for the 64-bit MSI inbound transactions are compared to this window.

19.4.29.3 Diagram

19.4.29.4 Fields

Field	Function
0-11 WBEA	Window base extended address. This field corresponds to PCI Express address bits [43:32].
12-31 WBA	Window base address. Source address which is the starting point for the inbound translation window. The window must be aligned based on the size selected in the window size bits. This corresponds to PCI Express address bits [31:12].

19.4.30 PCI Express MSI inbound window base extended address register (PEXMSIIWBEAR)

19.4.30.1 Offset

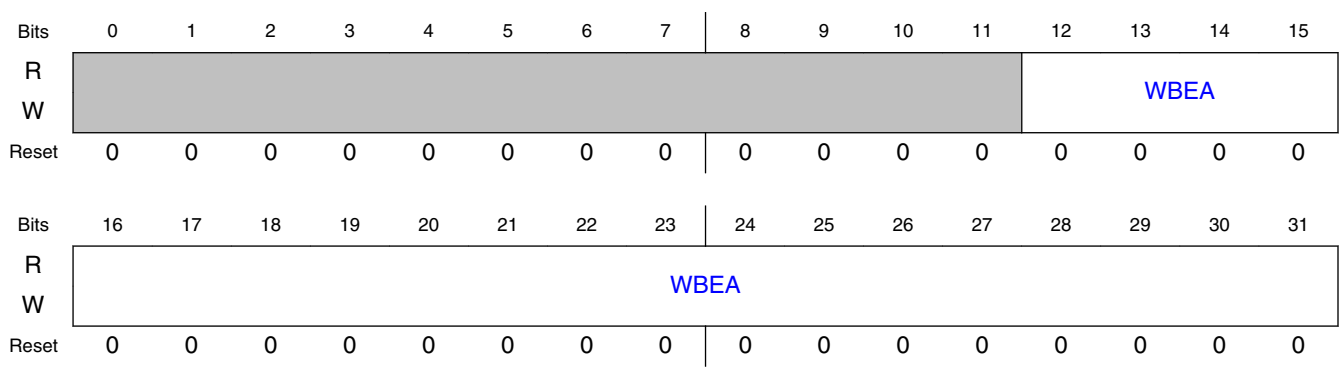
Register	Offset
PEXMSIIWBEAR	D0Ch

19.4.30.2 Function

This register is supported only for RC mode.

The PCI Express MSI inbound window base extended address register contains the most-significant bits of a 64-bit MSI base address.

19.4.30.3 Diagram



19.4.30.4 Fields

Field	Function
0-11 —	Reserved
12-31 WBEA	Window base extended address. This field corresponds to PCI Express address bits [63:44]

19.4.31 PCI Express MSI inbound window attributes register (PEXMSIIWAR)

19.4.31.1 Offset

Register	Offset
PEXMSIIWAR	D10h

19.4.31.2 Function

This register is supported only for RC mode.

The PCI Express MSI inbound window attributes register defines the window sizes to translate and other attributes for the translations. The size is fixed at 16-M window.

19.4.31.3 Diagram

19.4.32 PCI Express inbound translation address (PFa_PEXITARb)

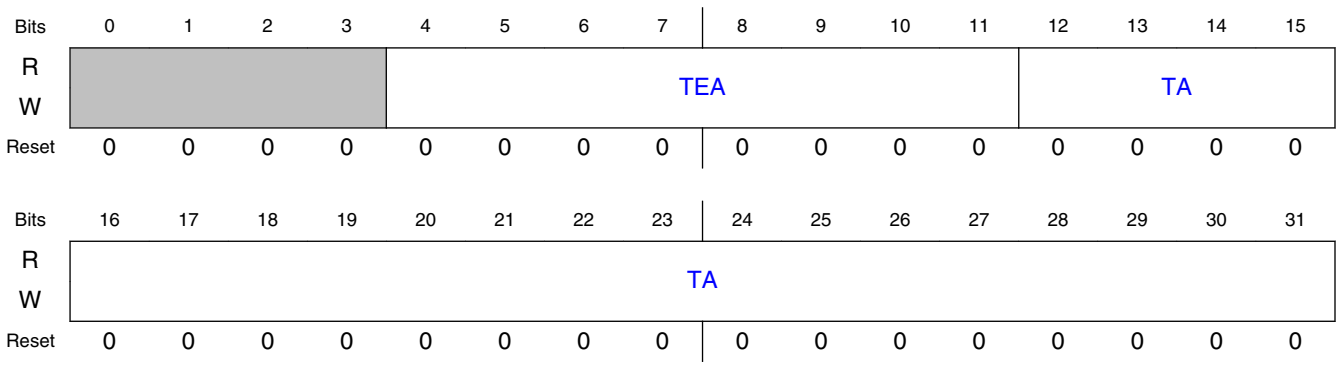
19.4.32.1 Offset

Register	Offset
PF0_PEXITAR3	D80h
PF0_PEXITAR2	DA0h
PF0_PEXITAR1	DC0h
PF0_PEXITAR0	DE0h
PF1_PEXITAR3	2D80h
PF1_PEXITAR2	2DA0h
PF1_PEXITAR1	2DC0h
PF1_PEXITAR0	2DE0h

19.4.32.2 Function

The PCI Express inbound translation address registers contain the translated internal platform address to be used. These registers are unique per PF.

19.4.32.3 Diagram



19.4.32.4 Fields

Field	Function
0-3 —	Reserved
4-11 TEA	Translation extended address. Target address which indicates the starting point of the inbound translated address. The translation address must be aligned based on the size field. Corresponds to internal platform address bits [0:7] where bit 0 is the msb of the internal platform address. When PEXIWARn[TRGT] field is set for CCSRBAR, this field becomes CCSRBAR address. Otherwise, it takes on the current programmed value.
12-31 TA	Translation address. Target address which indicates the starting point of the inbound translated address. The translation address must be aligned based on the size field. Corresponds to internal platform address bits [8:27]. When PEXIWARn[TRGT] field is set for CCSRBAR, this field becomes CCSRBAR address. Otherwise, it takes on the current programmed value.

19.4.33 PCI Express inbound window base address (PFa_PEXIWBARb)

19.4.33.1 Offset

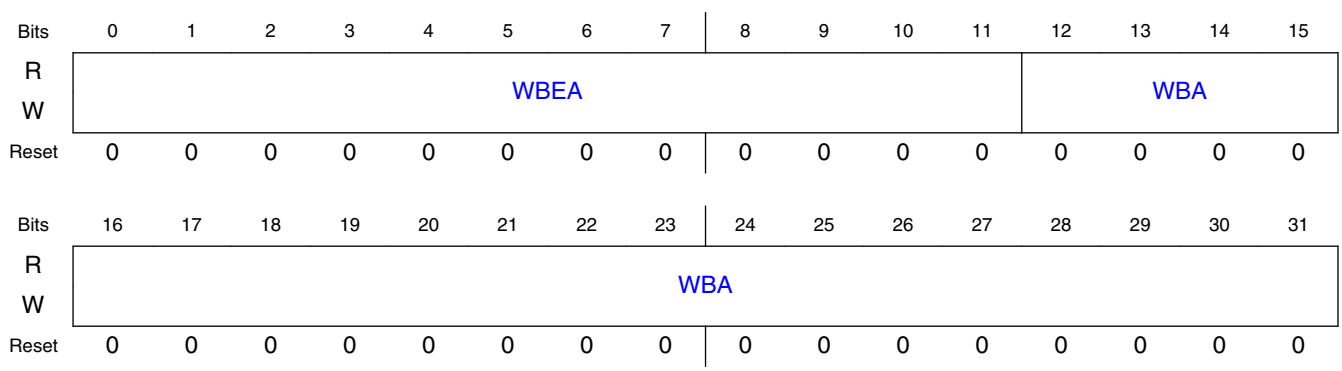
Register	Offset
PF0_PEXIWBAR3	D88h
PF0_PEXIWBAR2	DA8h
PF0_PEXIWBAR1	DC8h
PF1_PEXIWBAR3	2D88h
PF1_PEXIWBAR2	2DA8h
PF1_PEXIWBAR1	2DC8h

19.4.33.2 Function

These registers are supported only for RC mode.

The PCI Express inbound window base address registers select the base address for the windows which are translated to an alternate target address space. In root complex (RC) mode, addresses for inbound transactions are compared to these windows. In RC mode, PEXIWBAR0 is located in the PCI Express type 1 configuration header space and PEXIWBAR[1-3] registers are implemented as described in this section. In endpoint (EP) mode, these registers are not implemented in the memory-mapped space. Reading these registers in EP mode returns all zeros and writing to these offsets has no consequences. All base address registers in EP are located in the PCI Express type 0 configuration header space. Note that PEXIWBAR1 only supports 32-bit PCI Express address space. These registers are unique per PF.

19.4.33.3 Diagram



19.4.33.4 Fields

Field	Function
0-11 WBEA	Window base extended address. This field corresponds to PCI Express address bits [43:32]. Note that the extended address is supported for windows 2 and 3 only; for PEXIWBAR1, these bits are reserved and must be 0.
12-31 WBA	Window base address. Source address which is the starting point for the inbound translation window. The window must be aligned based on the size selected in the window size bits. This corresponds to PCI Express address bits [31:12].

19.4.34 PCI Express inbound window base extended address (PFa_PEXIWBEARb)

19.4.34.1 Offset

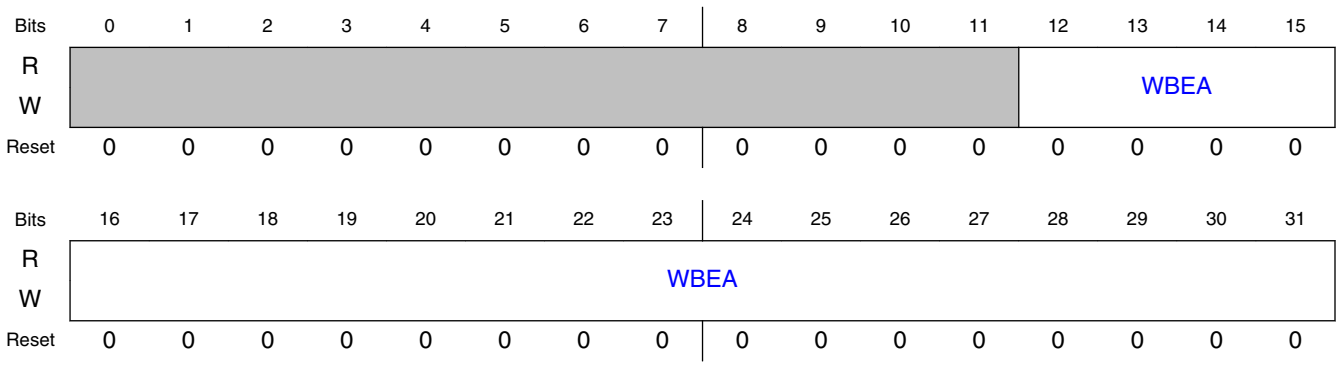
Register	Offset
PF0_PEXIWBEAR3	D8Ch
PF0_PEXIWBEAR2	DACh
PF1_PEXIWBEAR3	2D8Ch
PF1_PEXIWBEAR2	2DACh

19.4.34.2 Function

These registers are supported only for RC mode.

The PCI Express inbound window base extended address registers contain the most-significant bits of a 64 bit base address. This register is only available in RC mode. These registers are unique per PF.

19.4.34.3 Diagram



19.4.34.4 Fields

Field	Function
0-11 —	Reserved
12-31 WBEA	Window base extended address. This field corresponds to PCI Express address bits [63:44]

19.4.35 PCI Express inbound window attributes (PFa_PEXIWARb)

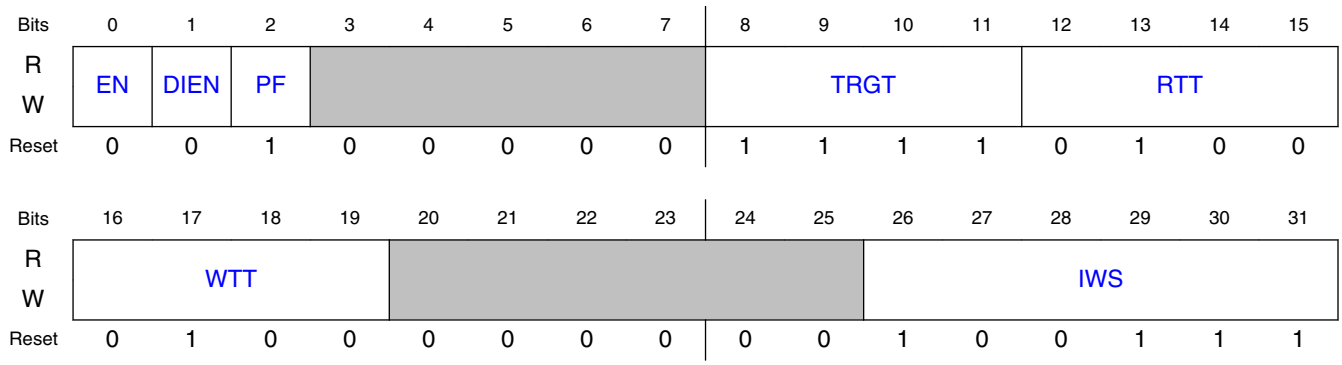
19.4.35.1 Offset

Register	Offset
PF0_PEXIWAR3	D90h
PF0_PEXIWAR2	DB0h
PF0_PEXIWAR1	DD0h
PF0_PEXIWAR0	DF0h
PF1_PEXIWAR3	2D90h
PF1_PEXIWAR2	2DB0h
PF1_PEXIWAR1	2DD0h
PF1_PEXIWAR0	2DF0h

19.4.35.2 Function

The PCI Express inbound window attributes registers define the window sizes to translate and other attributes for the translations. 1 Tbyte is the largest window size allowed. These registers are unique per PF.

19.4.35.3 Diagram



19.4.35.4 Fields

Field	Function
0 EN	Enable. This bit controls the enabling/disabling of the translation window. This field defaults to 1 for window 0. 0b - Disable inbound window translation 1b - Enable inbound window translation
1 DIEN	Data invariance enable. This bit controls the data ordering policy of all inbound transactions passing through this window. See Byte Ordering for more information. **NOTE:** The data invariance feature is only supported for use with specific interface cards that require this non-default byte ordering policy. 0b - Disable data invariance mode. Inbound transactions use address invariance ordering. 1b - Enable data invariance mode. Inbound transactions use data invariance ordering.
2 PF	Prefetchable. This bit indicates that the address space is prefetchable. This bit corresponds to the prefetchable bit in the BAR in the PCI Express type 0 header. This bit drives the BAR's prefetchable bit in EP mode.When PEXIWARn[TRGT] field is set for CCSRBAR, this field is set to 0. Otherwise, it takes on current programmed value. 0b - Not prefetchable 1b - Prefetchable
3-7 —	Reserved
8-11 TRGT	Target interface. This field defaults to CCSRBAR for window 0.

26-31 IWS	Inbound window size. Inbound translation window size N which is the encoded $2^{(N + 1)}$-bytes window size. The smallest window size is 4 Kbytes. For EP mode, this field directly controls the size of the BARs. When PEXIWARn[TRGT] field is set for CCSRBAR, this field can be either 1M or 16M. Otherwise, it takes on current programmed value. For PEXIWAR1 in EP mode with SR-IOV, this field should be set to 8-Kbyte window size. 000000b - Reserved 001010b - Reserved 001011b - 4-Kbyte window size 001100b - 8-Kbyte window size 011111b - 4-Gbyte window size 100000b - 8-Gbyte window size 100001b - 16-Gbyte window size 100010b - 32-Gbyte window size 100011b - 64-Gbyte window size 100111b - 1-Tbyte window size 111111b - Reserved

19.4.36 PCI Express error detect register (ERR_DR)

19.4.36.1 Offset

Register	Offset
ERR_DR	E00h

19.4.36.2 Function

The PCI Express error detect register contains error status bits that are detected by hardware.The detected error bits are write-1-to-clear type registers. Reading from these registers occurs normally; however, write operations can clear but not set bits. A bit is cleared whenever the register is written, and the data in the corresponding bit location is a

1. For example, to clear bit 6 and not affect any other bits in the register, the value 0b0200_0000 is written to the register. When an error is detected the appropriate error bit is set. Subsequent errors sets the appropriate error bits in the error detection registers, but only the first error for a particular unit have any relevant information captured. The interrupt enable bits are used to allow or block the error reporting to the interrupt mechanism while the disable bits are used to prevent or allow the setting of the status bits.

19.4.36.4 Fields

Field	Function
0 ME	Multiple errors. Detecting multiple errors of the same type. An error is considered as multiple error when its detect bit is set and the same error is occurring again. Note that this bit does not track the ordering of when the error occurs. 1b - Multiple errors were detected. 0b - Multiple errors were not detected.
1-7 —	Reserved
8 PCT	PCI Express completion time-out. A completion time-out condition was detected for a non-posted, outbound PCI Express transaction. An error response is sent back to the requestor. Note that a completion timeout counter only starts when the non-posted request was able to send to the link partner. 1b - A completion time-out on the PCI Express link was detected. Note that a completion timeout error is a fatal error. If a completion timeout error is detected, the system has become unstable. Hot reset is recommended to restore stability of the system. 0b - No completion time-out on the PCI Express link detected.

Table continues on the next page...

Field	Function
9 PAT	PCI Express Ack time-out. An internal request timeout was seen. This is considered as a internal fatal error. Once this bit is set, all outstanding transactions will be canceled. No new transactions will be accepted until this bit is clear. It is expected that software needs to perform the proper clean-up operation (that is, hot reset) to get the link to function again before clearing this bit. 1b - An Ack time-out on the PCI Express link was detected. 0b - No Ack time-out on the PCI Express link detected.
10 PCAC	PCI Express completer abort (CA) completion. A completion with CA status was received. 1b - A completion with CA status was detected. 0b - No completion with CA status detected.
11 PNM	PCI Express no map. An inbound transaction that is not mapped to any inbound windows was detected. In RC mode, a posted transaction will be dropped silently and this bit will be set. A nonposted transaction will return a completion without data (Cpl) packet with a UR completion status to the requester and this bit is set. For EP mode, a Cpl packet with a UR completion status is sent back to the requester but does not set this bit.This bit is also set when an IO Write or IO Read transaction is received in RC mode and the transaction is not hitting into IO Base/Limit registers. 1b - A no-map transaction was detected in RC mode. 0b - No no-map transaction detected.
12 CDNSC	Completion with data not successful. A completion with data packet was received with a non successful status (that is, UR, CA or CRS status). 1b - Completion with data non successful packet was detected. 0b - No completion with data non successful packet detected.
13 CRSNC	CRS non configuration. A completion was detected for a non configuration cycle and with CRS status. See PCI Express Configuration Access Register Mechanism for more information. 1b - CRS non configuration packet was detected. 0b - No CRS non configuration packet detected.
14 ICCA	Invalid PEX_CONFIG_ADDR/PEX_CONFIG_DATA configuration access. Access to an illegal configuration space from PEX_CONFIG_ADDR/PEX_CONFIG_DATA was detected. 1b - Invalid CONFIG_ADDR/PEX_CONFIG_DATA access detected 0b - No invalid PEX_CONFIG_ADDR/PEX_CONFIG_DATA access detected
15 IACA	Invalid ATMU configuration access. Access to an illegal configuration space from an ATMU window was detected. 1b - Invalid ATMU configuration access was detected 0b - No invalid ATMU configuration access detected
16 CRST	CRS thresholded. An outbound configuration transaction was retried and thresholded due to a CRS completion status. An error response is sent back to the requestor. See CONF_RTY_TOR for more information. 1b - A CRS threshold condition was detected for an outbound configuration transaction 0b - No CRS threshold condition detected
17 MIS	Message invalid size. An outbound message transaction that is greater than 4 bytes or crosses a 4-byte boundary was detected. See Outbound ATMU Message Generation for more information. 1b - An invalid size outbound message transaction was detected 0b - No invalid size outbound message transaction detected
18 IOIS	I/O invalid size. An outbound I/O transaction that is greater than 4 bytes or crosses a 4-byte boundary was detected. 1b - An invalid size outbound I/O transaction was detected 0b - No invalid size outbound I/O transaction detected
19 CIS	Configuration invalid size. An outbound configuration transaction that is greater than 4 bytes or crosses a 4-byte boundary was detected.

Table continues on the next page...

Field	Function
	1b - An invalid size outbound configuration transaction was detected 0b - No invalid size outbound configuration transaction detected
20 CIEP	Configuration invalid EP. An outbound ATMU configuration transaction request was seen when in EP mode. 1b - An outbound configuration transaction while in EP was detected 0b - No outbound configuration transaction in EP detected
21 IOIEP	I/O invalid EP. An outbound I/O transaction request was seen when in EP mode. 1b - An outbound I/O transaction while in EP was detected 0b - No outbound I/O transaction in EP detected
22 OAC	Outbound ATMU crossing. An outbound crossing ATMU transaction was detected. SR-IOV only: Does not detect crossing if transaction is hitting into a VF window. In addition, behavior is undefined if address is crossing 40-bit boundary. 1b - An outbound transaction that hits in one window and crosses overing it was detected 0b - No outbound ATMU crossing condition detected
23 IOIA	I/O invalid address. An outbound I/O transaction with a translated address of greater than 4 Gbytes was detected. 1b - A greater than 4-Gbyte I/O address was detected 0b - No greater than 4-Gbyte I/O address detected
24 IMBA	Invalid memory base address. An outbound memory transaction with a translated address not hitting into the Memory Base/Limit register or Prefetchable Memory Base/Limit register. Only valid in RC mode. This feature is enabled by setting PEX_CONFIG[OB_CK]. 1b - Invalid memory base address was detected 0b - No invalid memory base address detected
25 IIOBA	Invalid I/O base address. An outbound I/O transaction with a translated address not hitting into the IO Base/Limit register or IO Upper Base/Limit register. Only valid in RC mode. This feature is enabled by setting PEX_CONFIG[OB_CK]. 1b - Invalid I/O base address was detected 0b - No invalid I/O base address detected
26 LDDE	Link down data error. An outbound read transaction was issued through an ATMU window when the link was down. 1b - Link down data error detected 0b - No Link down data error detected
27 LME	LIODN mapping error. An inbound transaction was not mapped to an LIODN entry in the LIODN permission table. 1b - LIODN mapping error detected 0b - No LIODN mapping error detected
28 FLRDE	SR-IOV-only: FLR data error. A nonposted transaction was issued toward a PF/VF that has FLR event active. 1b - Nonposted transaction issued while FLR event active detected 0b - No nonposted transaction issued during FLR event
29 UREP	PCI Express Unsupported Request completion in EP. A completion with UR status was detected when in EP mode. 1b - A completion with UR status was detected while in EP mode 0b - No completion with UR status while in EP mode detected
30 TAE	SR-IOV-only: Tx Abort error. A nonposted transaction was issued to a device that does not have its bus master enable bit set (EP mode only) or its D-state non-zero (EP/RC). 1b - Nonposted transaction issued to devices that are not enabled or in low power state.

Table continues on the next page...

Field	Function
	0b - No nonposted transaction issued to devices that are not enabled or in low power state.

19.4.39 PCI Express error capture status register (ERR_CAP_STAT)

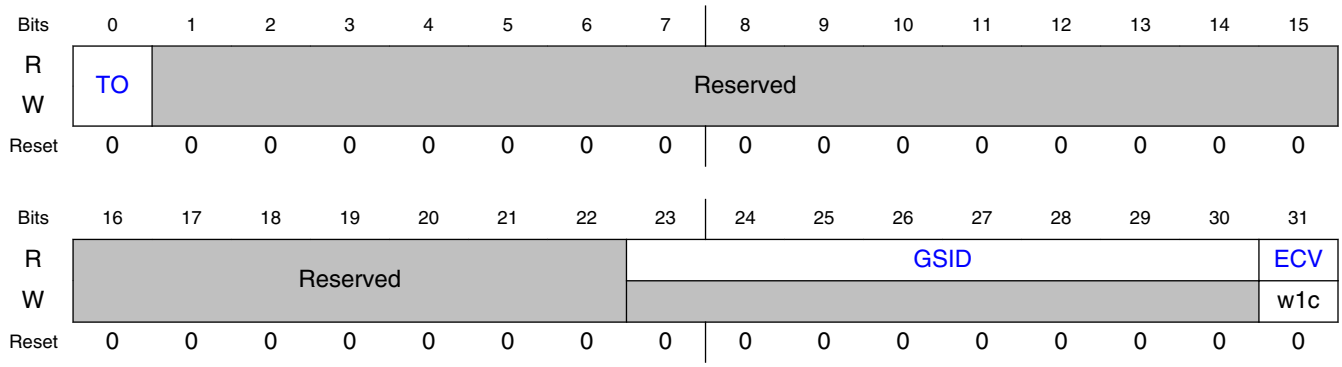
19.4.39.1 Offset

Register	Offset
ERR_CAP_STAT	E20h

19.4.39.2 Function

The PCI Express error capture status register allows vital error information to be captured when an error occurs. Note that no further error capturing is performed until the ECV bit is cleared.

19.4.39.3 Diagram



19.4.39.4 Fields

Field	Function
0 TO	Transaction originator. This field Indicates whether the originator of the transaction is from PEX_CONFIG_ADDR/PEX_CONFIG_DATA. 1 Transaction originated from PEX_CONFIG_ADDR/PEX_CONFIG_DATA. 0 Transaction not originated from PEX_CONFIG_ADDR/PEX_CONFIG_DATA.
1-22 Reserved	Reserved
23-30 GSID	Global source ID. This field indicates the internal platform global source ID that the error transaction originates. This field only applies to non PEX_CONFIG_ADDR/PEX_CONFIG_DATA transactions. TBD
31 ECV	Error capture valid. This bit indicates that the capture registers 0-3 contain valid info. This bit when set indicates that the captured registers contain valid capturing information. No new capturing is done unless this bit is cleared by writing a 1 to it.

19.4.40 PCI Express error capture register n (ERR_CAP_Ra)

19.4.40.1 Offset

Register	Offset
ERR_CAP_R0	E28h
ERR_CAP_R1	E2Ch

Table continues on the next page...

Register	Offset
ERR_CAP_R2	E30h
ERR_CAP_R3	E34h

19.4.40.2 Function

PEX_ERR_CAP_Rn allow vital error information to be captured when an error occurs. Different error information is reported depending on whether the error source is from an outbound transaction from an internal source or from an inbound transaction from an external source; the source of the captured error is reflected in PEX_ERR_CAP_STAT[GSID]. Note that after the initial error is captured, no further capturing is performed until the PEX_ERR_CAP_STAT[ECV] bit is clear.

See Error capture registers for further details.

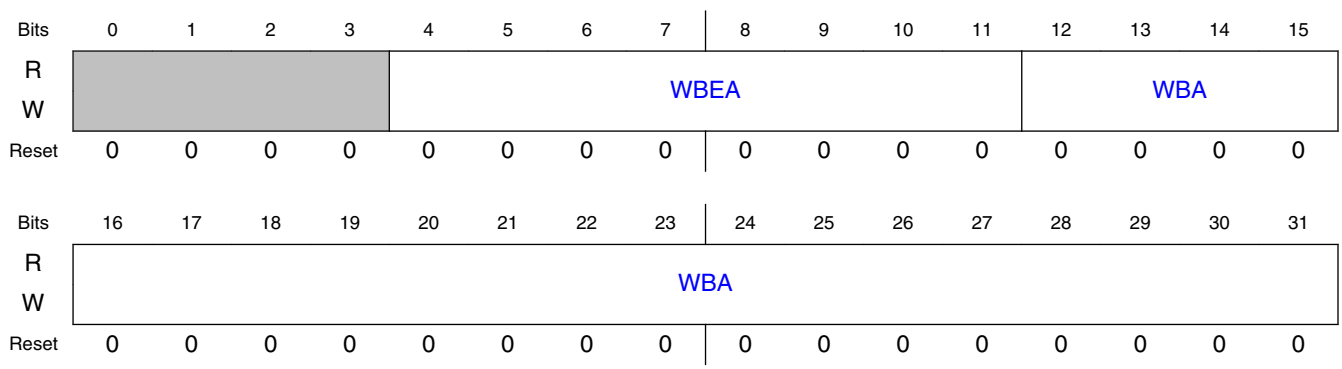
PEX_PF1VFOWBAR3	3048h
PEX_PF1VFOWBAR4	3068h

19.4.43.2 Function

This register is supported only for EP mode.

The PCI Express VF outbound window base address registers select the base address for the windows which are translated to the external address space. Addresses for outbound transactions are compared to these windows. If such a transaction does not fall within one of these spaces the transaction is forwarded through a default register set. These registers are unique per PF.

19.4.43.3 Diagram



19.4.43.4 Fields

Field	Function
0-3 —	Reserved
4-11 WBEA	Window base extended address. Source address which is the starting point for the outbound translation window. The window must be aligned based on the total VF window size calculated from the window size (PEXVFOWARn[OWS] x number of VFs). Correspond to internal platform address bits [0:7]. (where 0 is the msb of the internal platform address)

Table continues on the next page...

Field	Function
12-31 WBA	Window base address. Source address which is the starting point for the outbound translation window. The window must be aligned based on the total VF window size calculated from the window size bits. This corresponds to internal platform address bits [8:27].

19.4.44 PCI Express VF outbound window attributes register n (PEX_PFaVFOWARb)

19.4.44.1 Offset

Register	Offset
PEX_PF0VFOWAR1	1010h

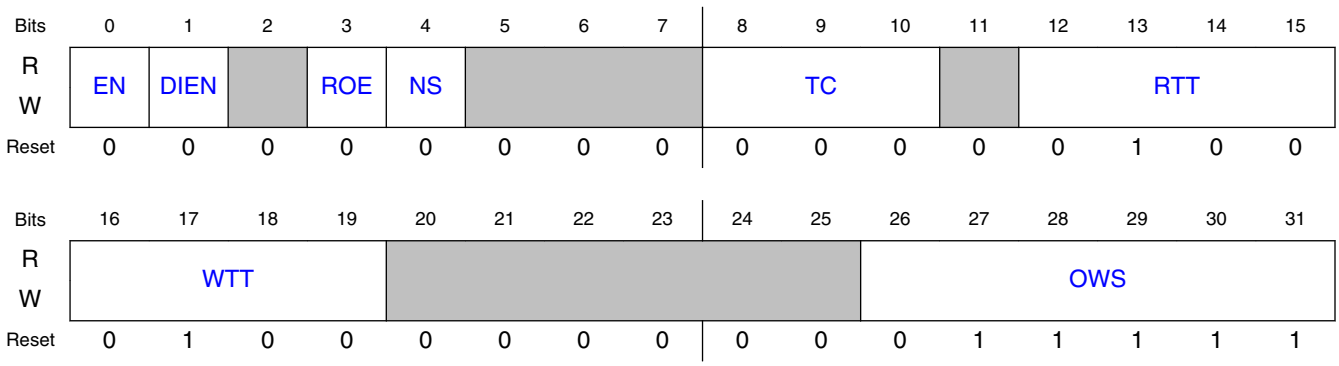
PEX_PF1VFOWAR2	3030h
PEX_PF1VFOWAR3	3050h
PEX_PF1VFOWAR4	3070h

19.4.44.2 Function

This register is supported only for EP mode.

The PCI Express VF outbound window attributes registers define the window sizes to translate and other attributes for the translations. These registers are unique per PF.

19.4.44.3 Diagram



19.4.44.4 Fields

Field	Function
0 EN	Enable. This bit enables this address translation window. For the default window, this bit is read-only and always hardwired to 1. 0b - Disable outbound translation window 1b - Enable outbound translation window
1 DIEN	Data invariance enable. This bit controls the data ordering policy of all outbound transactions passing through this window. See Byte Ordering for more information. **NOTE:** The data invariance feature is only supported for use with specific interface cards that require this non-default byte ordering policy. 0b - Disable data invariance mode. Outbound transactions use address invariance ordering. 1b - Enable data invariance mode. Outbound transactions use data invariance ordering.
2 —	Reserved
3 ROE	Relaxed ordering enable. This bit when set and the PCI Express device control register[Enable Relaxed] bit is set enables the Relaxed Ordering bit for the packet. This bit only applies to memory transactions. 0b - Default ordering 1b - Relaxed ordering
4 NS	No snoop enable. This bit when set and the PCI Express device control register[Enable No Snoop] bit is set enables the no snoop bit for the packet. This bit only applies to memory transactions. 0b - Snoopable 1b - No snoop
5-7 —	Reserved
8-10 TC	Traffic class. This field indicates the traffic class of the outbound packet. This field only applies to memory transaction. All other transaction types should set the TC field to 0. **NOTE:** Traffic class settings are passed through to the PCI Express link, but no specific actions are taken in the device based on traffic class. 000b - TC0

Table continues on the next page...

Field	Function
	001b - TC1 010b - TC2 011b - TC3 100b - TC4 101b - TC5 110b - TC6 111b - TC7
11 —	Reserved
12-15 RTT	Read transaction type. Read transaction type to run on the PCI Express link All other settings reserved 0100b - Memory read
16-19 WTT	Write transaction type. Write transaction type to run on the PCI Express link. All other settings reserved 0100b - Memory write
20-25 —	Reserved
26-31 OWS	Outbound window size. Outbound translation window size N which is the encoded $2^{(N + 1)}$-byte window size. The smallest window size is 4 Kbytes. The window size represents the size of one VF in a PF. To determine the total VF size per PF, it is OWS*total num VF active in a PF. 000000b - Reserved 001011b - 4-Kbyte window size 001100b - 8-Kbyte window size 011111b - 4-Gbyte window size 100000b - 8-Gbyte window size 100001b - 16-Gbyte window size 100010b - 32-Gbyte window size 100011b - 64-Gbyte window size 100111b - 1-Tbyte window size 101000b - Reserved 111111b - Reserved

19.4.45 PCI Express VF inbound window translation address register n (PEX_PFaVFIWTARb)

19.4.45.1 Offset

Register	Offset
PEX_PF0VFIWTAR3	1080h
PEX_PF0VFIWTAR2	10A0h
PEX_PF0VFIWTAR1	10C0h

Table continues on the next page...

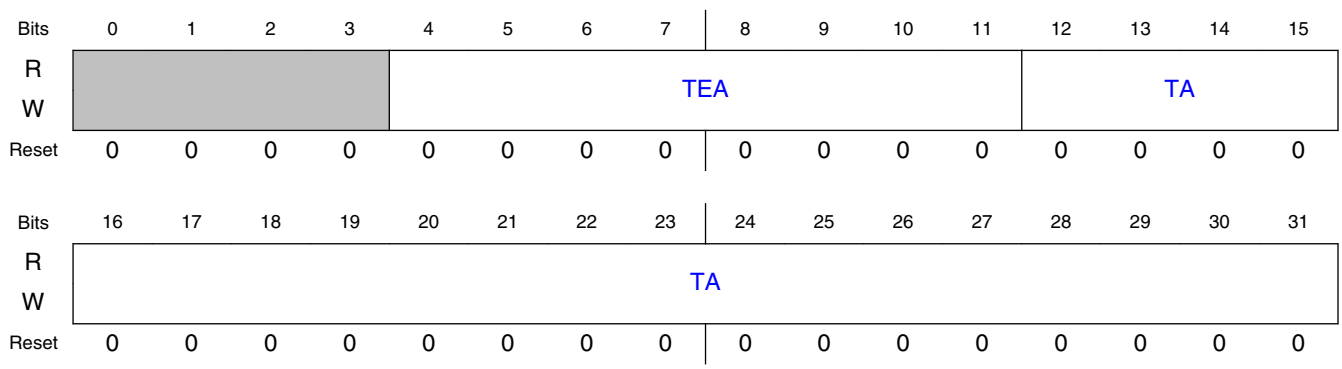
Register	Offset
PEX_PF0VFIWTAR0	10E0h
PEX_PF1VFIWTAR3	3080h
PEX_PF1VFIWTAR2	30A0h
PEX_PF1VFIWTAR1	30C0h
PEX_PF1VFIWTAR0	30E0h

19.4.45.2 Function

This register is supported only for EP mode.

The PCI Express VF inbound translation address registers contain the translated internal platform address to be used for transactions that are hitting into VF space. n indicates the Inbound Window number. The aperture of the size of the VF translated address region is the same as the size of the VF base address region. These registers are unique per PF.

19.4.45.3 Diagram



19.4.45.4 Fields

Field	Function
0-3 —	Reserved
4-11 TEA	Translation extended address. Target address which indicates the starting point of the inbound translated address. The translation address must be aligned based on the total VF size calculated from PEXVFIWARn[IWS] x the number of VFs. Corresponds to internal platform address bits [0:7] where bit 0 is the msb of the internal platform address. When PEXVFIWARn[TRGT] field is set for CCSRBAR, this field becomes CCSRBAR address. Otherwise, it takes on current programmed value.

Table continues on the next page...

Field	Function
12-31 TA	Translation address. Target address which indicates the starting point of the inbound translated address. The translation address must be aligned based on the total VF size calculated from the size field. This corresponds to internal platform address bits [8:27]. When PEXVFIWnARw[TRGT] field is set for CCSRBAR, this field becomes CCSRBAR address. Otherwise, it takes on current programmed value.

19.4.46 PCI Express VF inbound window attributes register n (PEX_PFaVFIWARb)

19.4.46.1 Offset

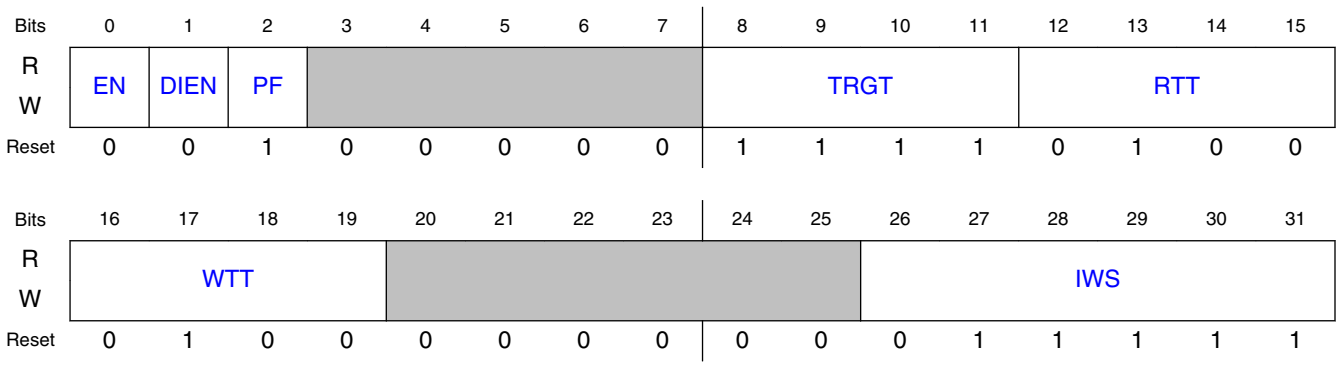
Register	Offset
PEX_PF0VFIWAR3	1090h
PEX_PF0VFIWAR2	10B0h
PEX_PF0VFIWAR1	10D0h
PEX_PF0VFIWAR0	10F0h
PEX_PF1VFIWAR3	3090h
PEX_PF1VFIWAR2	30B0h
PEX_PF1VFIWAR1	30D0h
PEX_PF1VFIWAR0	30F0h

19.4.46.2 Function

This register is supported only for EP mode.

The PCI Express VF inbound window attributes registers define the window size of a single VF to translate and other attributes for the translations. The total window size is determine by the number of VF supported x IWS. Total window size must not exceed 1 Tbyte. These registers are unique per PF.

19.4.46.3 Diagram



19.4.46.4 Fields

Field	Function
0 EN	Enable. This bit controls the enabling/disabling of the translation window. This field defaults to 1 for window 0. 0b - Disable inbound window translation 1b - Enable inbound window translation
1 DIEN	Data invariance enable. This bit controls the data ordering policy of all inbound transactions passing through this window. See Byte Ordering for more information. **NOTE:** The data invariance feature is only supported for use with specific interface cards that require this non-default byte ordering policy. 0b - Disable data invariance mode. Inbound transactions use address invariance ordering. 1b - Enable data invariance mode. Inbound transactions use data invariance ordering.
2 PF	Prefetchable. This bit indicates that the address space is prefetchable. This bit corresponds to the prefetchable bit in the BAR in the PCI Express type 0 header. This bit drives the BAR's prefetchable bit in EP mode. When PEXVFIWARn[TRGT] field is set for CCSRBAR, this field is set to 0. Otherwise, it takes on current programmed value. 0b - Not prefetchable 1b - Prefetchable
3-7 —	Reserved
8-11 TRGT	Target interface. This field defaults to CCSRBAR for window 0. Target interface. If this field is set to anything other than local memory space, the attributes for the transaction must be assigned in a corresponding outbound window at the target. 1111b - Local memory space
12-15 RTT	Read transaction type. Read transaction type to send to target interface. When PEXVFIWARn[TRGT] field is set for CCSRBAR, this field is set to 4. Otherwise, it takes on current programmed value. If the transaction is not going to local memory space 0000 Reserved

Field	Function
	1111 Reserved
20-25 —	Reserved
26-31 IWS	Inbound window size. Inbound translation window size N which is the encoded $2^{(N + 1)}$-bytes window size for a single VF. The total window size is determined by number of VF * IWS. The smallest window size is 4 Kbytes. For EP mode, this field directly controls the size of the BARs. When PEXVFIWARn[TRGT] field is set for CCSRBAR, this field can be either 1M or 16M. Otherwise, it takes on current programmed value. Care must be taken such that VFxIWS does not exceed the maximum memory size (1Tbyte) supported and is not in conflict with any other memory region. For PEXVFIWAR1 in EP mode with SR-IOV, this field should be set to 8-Kbyte window size. 000000b - Reserved 001010b - Reserved 001011b - 4-Kbyte window size 001100b - 8-Kbyte window size 011111b - 4-Gbyte window size 100000b - 8-Gbyte window size 100001b - 16-Gbyte window size 100010b - See requirement above 111111b - Reserved

19.4.47 PCI Express VF outbound window a translation address register b (PEX_PFaVFOWbTARc)

19.4.47.1 Offset

For a = 0 to 1:

For b = 0 to 3 (i = 1 to 4):

For c = 0 to 63 (i = 1 to 64):

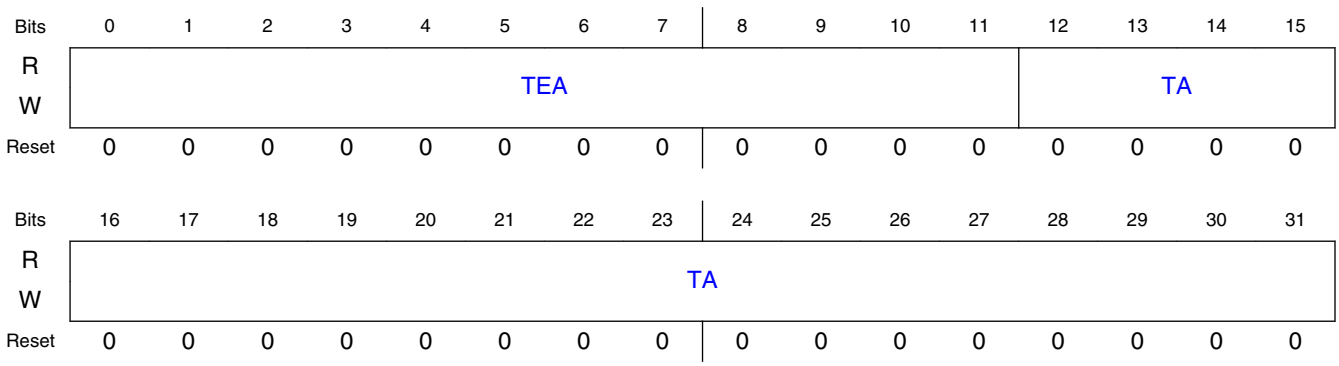
Register	Offset
PEX_PFaVFOWbTARc	1800h + (a × 2000h) + (j × 200h) + (k × 8h)

19.4.47.2 Function

This register is supported only for EP mode.

The PCI Express VF outbound translation address registers select the starting addresses in the system address space for window hits within the PCI Express outbound address translation windows. The new translated address is created by concatenating the transaction offset to this translation address. a indicates the Outbound Window number and b indicates the Virtual Function number.

19.4.47.3 Diagram



19.4.47.4 Fields

Field	Function
0-11 TEA	Translation extended address. System address which indicates the starting point of the outbound translated address. The translation address must be aligned based on the total VF size calculated from the size field. Corresponds to PCI Express address bits [43:32] (bit 32 is the lsb).
12-31 TA	Translation address. System address which indicates the starting point of the outbound translated address. The translation address must be aligned based on the total VF size calculated from the size field. This corresponds to PCI Express address bits [31:12].

19.4.48 PCI Express VF outbound window a extended translation address register b (PEX_PFaVFOWbTEARc)

19.4.48.1 Offset

For a = 0 to 1:

For b = 0 to 3 (i = 1 to 4):

For c = 0 to 63 (i = 1 to 64):

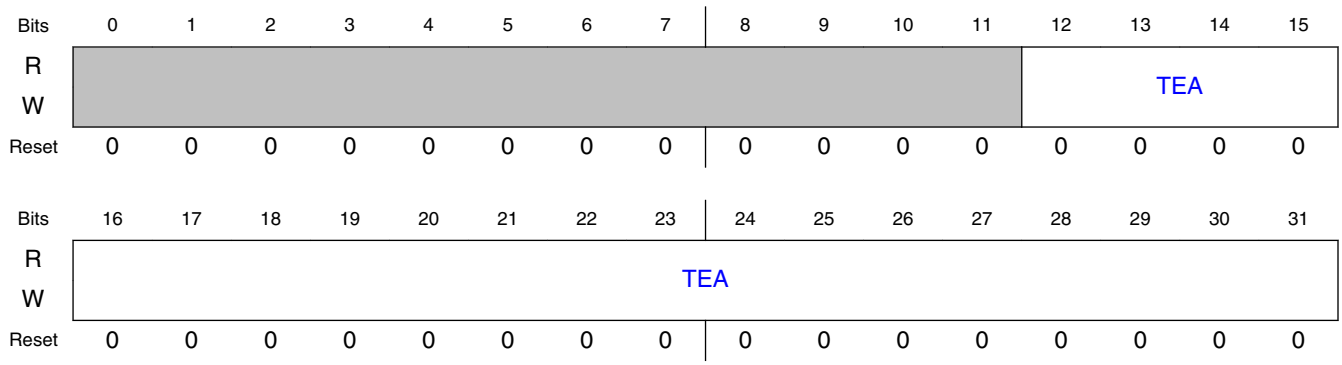
Register	Offset
PEX_PFaVFOWbTEARc	1804h + (a × 2000h) + (j × 200h) + (k × 8h)

19.4.48.2 Function

This register is supported only for EP mode.

The PCI Express VF outbound translation extended address registers contain the most-significant bits of a 64 bit translation address.

19.4.48.3 Diagram



19.4.48.4 Fields

Field	Function
0-11 —	Reserved
12-31 TEA	Translation extended address. System address which indicates the starting point of the outbound translated address. The translation address must be aligned based on the total VF size calculated from the size field. Corresponds to PCI Express address bits [63:44].

19.5 PCI Express configuration-space registers

This table lists the PCI Express configuration-space registers.

Table 19-4. PCI Express configuration-space registers

	PEX1: Root Complex		PEX1 PF0: SR-IOV Endpoint		PEX1 PF1: SR-IOV Endpoint		PEX2, PEX3, PEX4: RC or EP

19.5.1 PCI Compatible Configuration Headers

The first 64 bytes of the 256-byte PCI compatible configuration space consists of a predefined header that every PCI device must support. The first 16 bytes of the predefined header are defined the same for all PCI Express devices. These common registers are shown in the figure below.

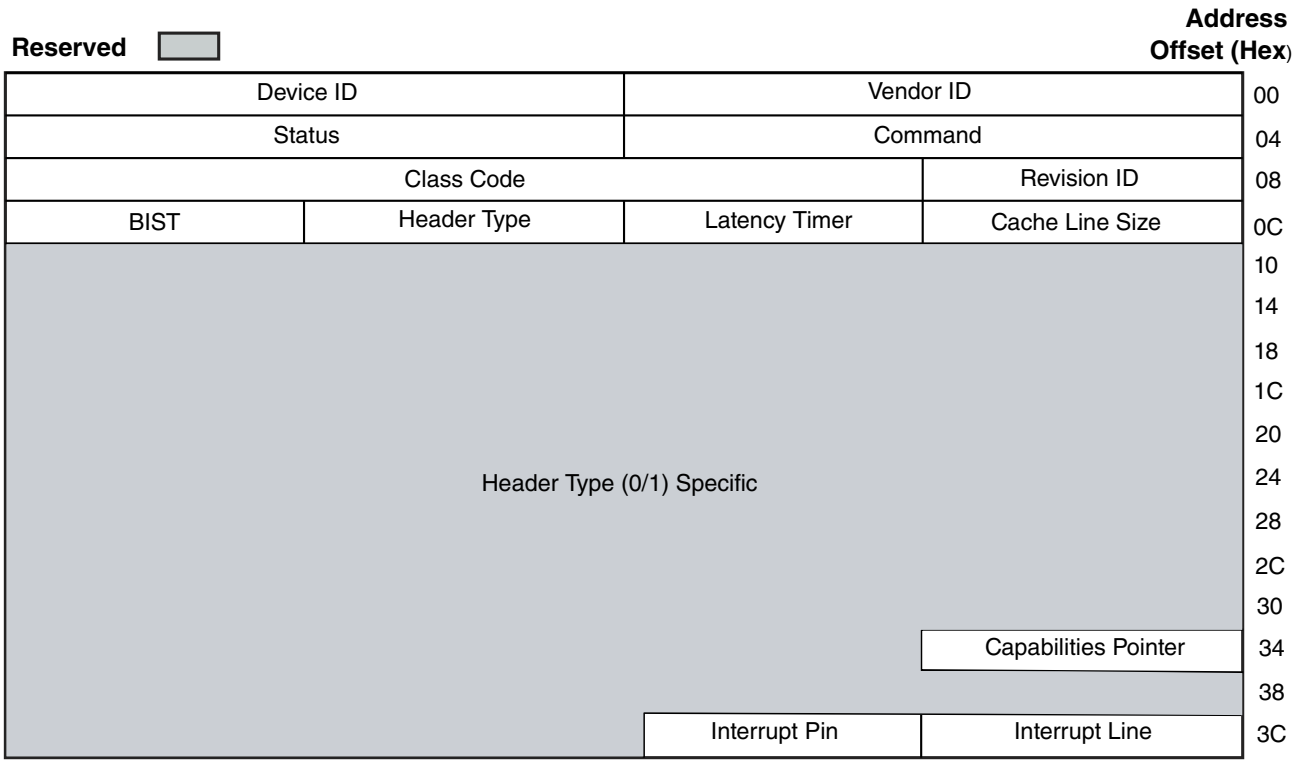

Figure 19-2. PCI Express PCI-compatible configuration header common registers

The remaining 48 bytes of the header may have differing layouts depending on the function of the device. There are two header types applicable to PCI Express. Type 0 headers are typically used by endpoints; Type 1 headers are used by root complexes and switches/bridges.

19.5.1.1 Type 0 configuration header

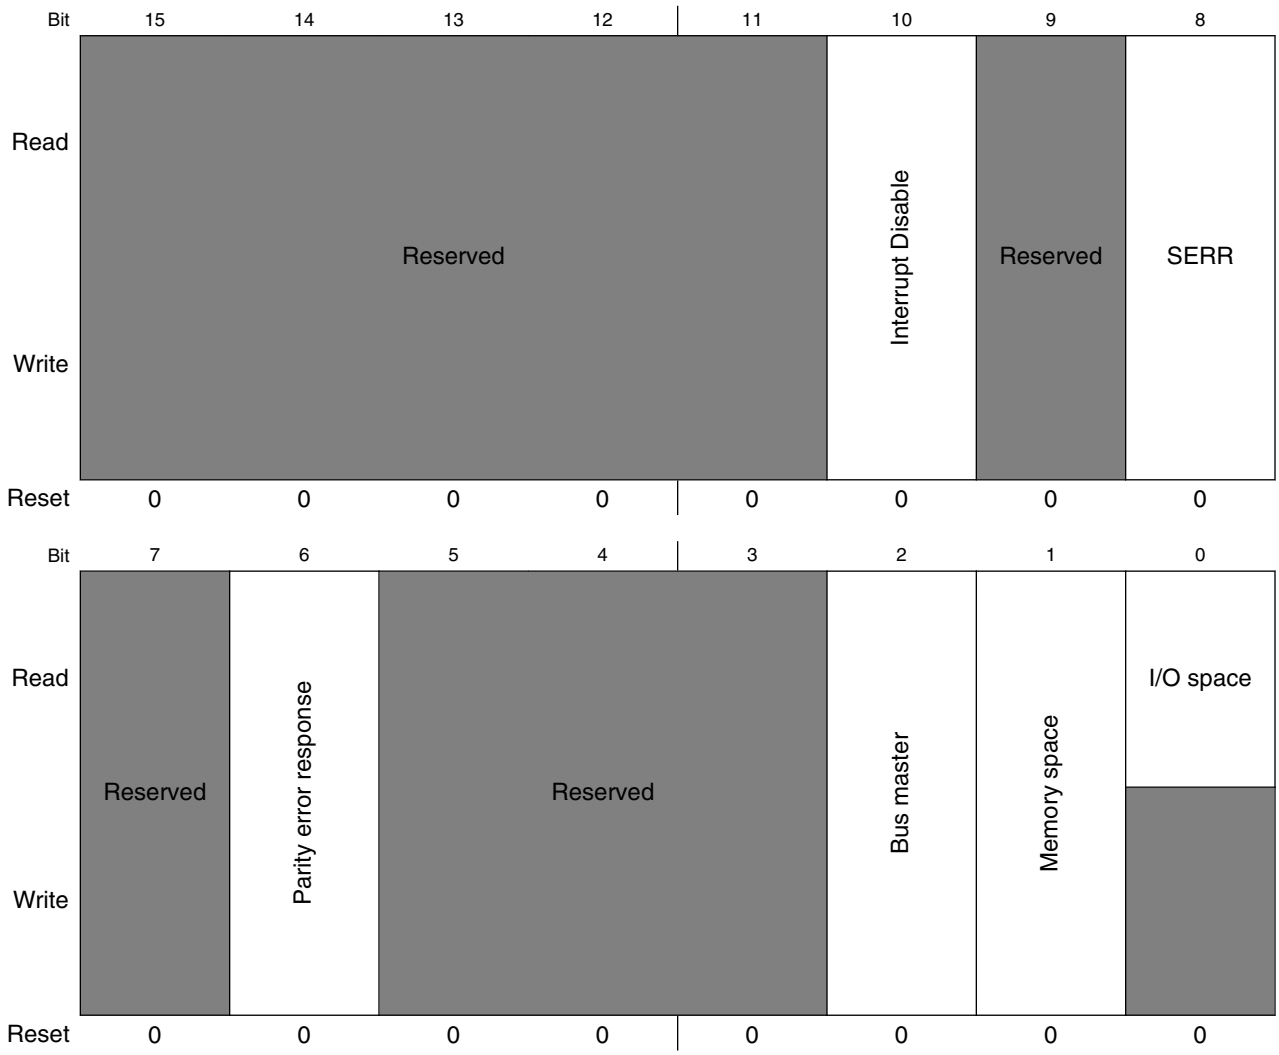
	0x044A	T4080 with security
	0x044B	T4080 without security

19.5.1.1.3 PCI Express Command Register (Command Register)

The command register provides control over the ability to generate and respond to PCI Express cycles.

Address: 0h base + 4h offset = 4h



Command Register field descriptions

Field	Description
15–11 -	This field is reserved. Reserved
10 Interrupt Disable	Controls the ability to generate INTx interrupt messages. Any INTx emulation interrupts already asserted by this device must be deasserted when this bit is set. 0 Enables INTx interrupt messages 1 Disables INTx interrupt messages
9 -	This field is reserved. Reserved
8 SERR	Controls the reporting of fatal and non-fatal errors detected by the device to the root complex. **NOTE:** The error control and status bits in the command and status registers control PCI-compatible error reporting. PCI Express advanced error reporting is controlled by the PCI

Table continues on the next page...

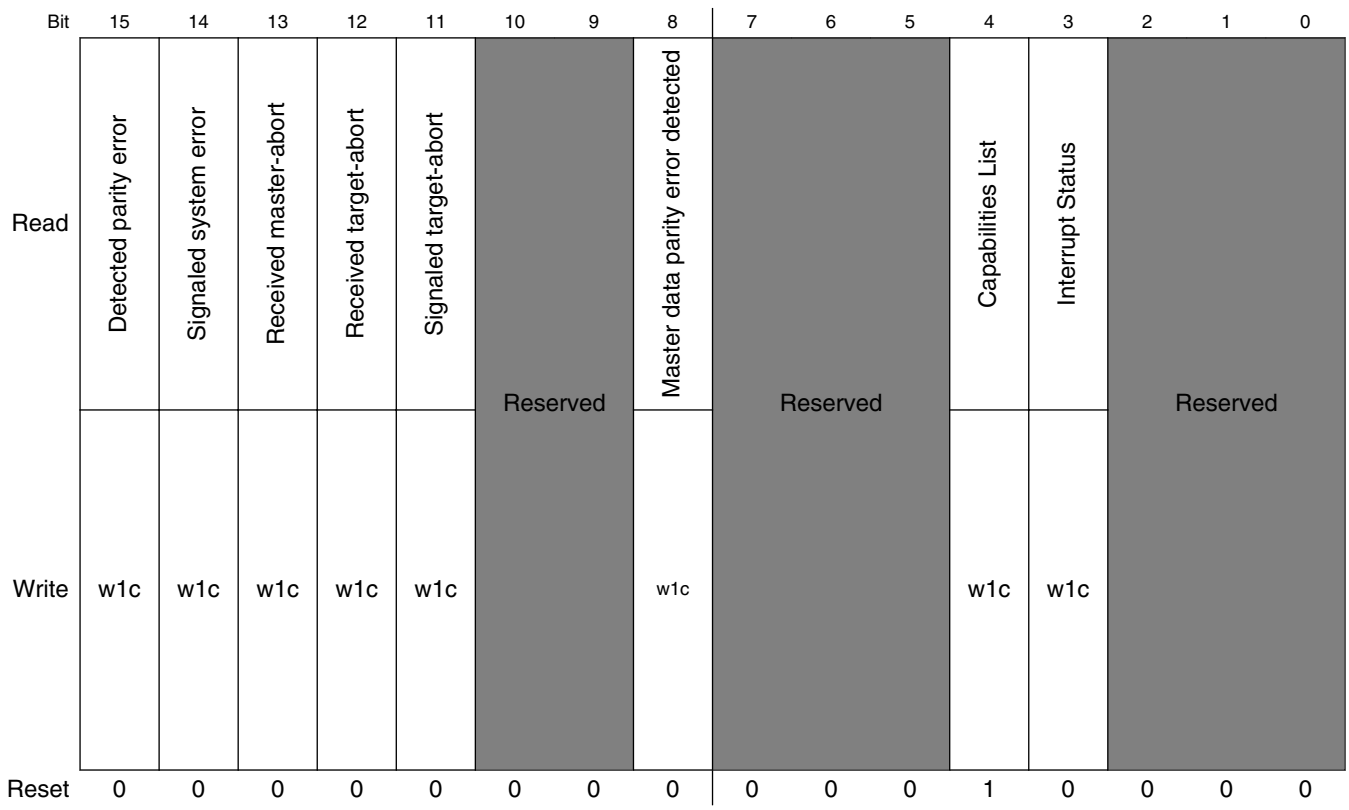
Command Register field descriptions (continued)

Field	Description
	Express device control register described in PCI Express Device Control Register (Device Control Register) and the advanced error reporting capability structure described in Advanced error reporting capability structure. 0 Disables reporting 1 Enables reporting
7 - Reserved	This field is reserved.
6 Parity error response	Controls whether this PCI Express controller responds to parity errors. **NOTE:** The error control and status bits in the command and status registers control PCI-compatible error reporting. PCI Express advanced error reporting is controlled by the PCI Express device control register described in PCI Express Device Control Register (Device Control Register) and the advanced error reporting capability structure described in Advanced error reporting capability structure. 0 Parity errors are ignored and normal operation continues. 1 Parity errors cause the appropriate bit in the PCI Express status register to be set. However, note that errors are reported based on the values set in the PCI Express error enable and detection registers.
5–3 - Reserved	This field is reserved.
2 Bus master	Indicates whether this PCI Express device is configured as a master. EP mode: Clearing this bit prevent the device from issuing any memory or I/O transactions. Because MSI interrupts are effectively memory writes, clearing this bit also disables the ability of the device to issue MSI interrupts. RC mode: Clearing this bit disables the ability of the device to forward memory transactions upstream. This causes any inbound memory transaction to be treated as an unsupported request. 0 Disables the ability to generate PCI Express accesses 1 Enables this PCI Express controller to behave as a PCI Express bus master
1 Memory space	Controls whether this PCI Express device (as a target) responds to memory accesses. EP mode: Clearing this bit prevents the device from accepting any memory transaction. RC mode: This bit is ignored. It does not affect outbound memory transaction 0 This PCI Express device does not respond to PCI Express memory space accesses. 1 This PCI Express device responds to PCI Express memory space accesses.
0 I/O space	I/O space. EP mode: Clearing this bit prevents the device from accepting any IO transaction. Note that this bit is a don't care in EP mode since the device does not support IO transaction. RC mode: This bit is ignored. It does not affect outbound IO transaction. 0 This PCI Express device (as a target) does not respond to PCI Express I/O space accesses. 1 This PCI Express device (as a target) does respond to PCI Express I/O space accesses.

19.5.1.1.4 PCI Express Status Register (Status Register)

The status register is used to record status information for PCI Express related events.

Address: 0h base + 6h offset = 6h



Status Register field descriptions

Field	Description
15 Detected parity error	Set whenever a device receives a poisoned TLP regardless of the state of bit 6 in the command register.[1]
14 Signaled system error	Set whenever a device sends a ERR_FATAL or ERR_NONFATAL message and the SERR enable bit in the command register is set.[1]
13 Received master-abort	Set whenever a requestor receives a completion with unsupported request completion status.[1]
12 Received target-abort	Set whenever a device receives a completion with completer abort completion status.[1]
11 Signaled target-abort	Set whenever a device completes a request using completer abort completion status.[1]
10–9 -	This field is reserved. Reserved
8 Master data parity error detected	Set by the requestor (primary side for Type1 headers) when either the requestor receives a completion marked poisoned or the requestor poisons a write request.

Table continues on the next page...

Status Register field descriptions (continued)

Field	Description
	Note that the parity error enable bit (bit 6) in the command register must be set for this bit to be set.[1]
7–5 -	This field is reserved. Reserved
4 Capabilities List	All PCI Express devices are required to implement the PCI Express capability structure.
3 Interrupt Status	Set when an INTx interrupt message is pending internally to the device. Note that this bit is associated with INTx messages and not Message Signaled Interrupts.
-	This field is reserved. Reserved

1. The error control and status bits in the command and status registers control PCI-compatible error reporting. PCI Express advanced error reporting is controlled by the PCI Express device control register described in PCI Express Device Control Register (Device Control Register) and the advanced error reporting capability structure described in Advanced error reporting capability structure.

19.5.1.1.5 PCI Express Revision ID Register (Revision ID Register)

The revision ID register is used to identify the revision of the device.

NOTE

This register is writeable using internal PEX_CONFIG_ADDR/ PEX_CONFIG_DATA accesses, but is read-only from inbound configuration accesses by an external host.

Address: 0h base + 8h offset = 8h

Bit	7	6	5	4	3	2	1	0
Read	Revision ID							
Write								
Reset	n	n	n	n	n	n	n	n

Revision ID Register field descriptions

Field	Description
Revision ID	Revision specific.

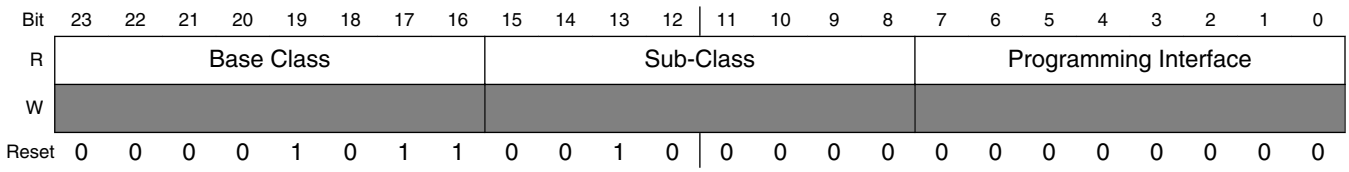
19.5.1.1.6 PCI Express Class Code Register (Class Code Register)

The class code register is comprised of three single-byte fields-base class (offset 0x0B), sub-class (offset 0x0A), and programming interface (offset 0x09)-that indicate the basic functionality of the function.

NOTE

This register is writeable using internal PEX_CONFIG_ADDR/ PEX_CONFIG_DATA accesses, but is read-only from inbound configuration accesses by an external host.

Address: 0h base + 9h offset = 9h



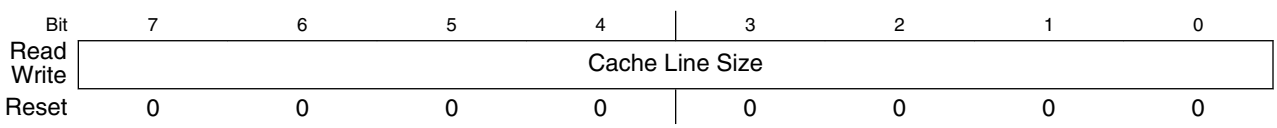
Class Code Register field descriptions

Field	Description
23–16 Base Class	0x0B-Processor
15–8 Sub-Class	0x20-PowerPC
Programming Interface	0x00 —

19.5.1.1.7 PCI Express Cache Line Size Register (Cache Line Size Register)

The cache line size register is provided for legacy compatibility purposes (PCI 2.3); it is not used for PCI Express device functionality.

Address: 0h base + Ch offset = Ch



Cache Line Size Register field descriptions

Field	Description
Cache Line Size	Represents the cache line size of the processor in terms of 32-bit words (8 32-bit words = 32 bytes). Note that for PCI Express operation this register is ignored.

19.5.1.1.8 PCI Express Latency Timer Register (Latency Timer Register)

The latency timer register is provided for legacy compatibility purposes (PCI 2.3); it is not used for PCI Express device functionality.

Address: 0h base + Dh offset = Dh

Bit	7	6	5	4	3	2	1	0
Read	Latency Timer							
Write								
Reset	0	0	0	0	0	0	0	0

Latency Timer Register field descriptions

Field	Description
Latency Timer	Note that for PCI Express operation this register is ignored.

19.5.1.1.9 PCI Express Header Type Register (Header Type Register)

The PCI Express header type register is used to identify the layout of the PCI compatible header.

Address: 0h base + Eh offset = Eh

Bit	7	6	5	4	3	2	1	0
Read	Multifunction	Header Layout						
Write								
Reset	n	0	0	0	0	0	0	n

Header Type Register field descriptions

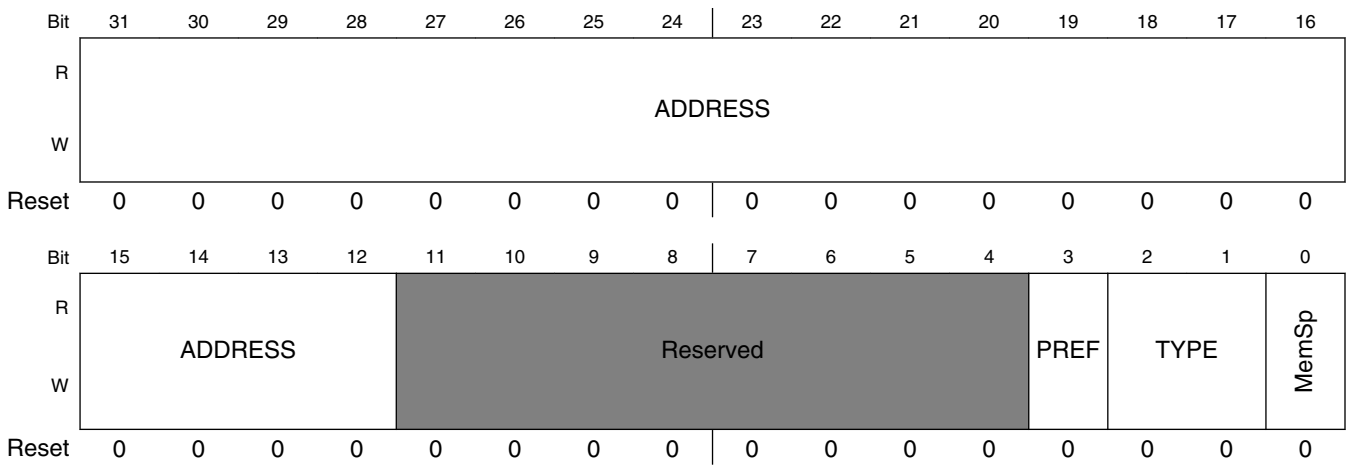
Field	Description
7 Multifunction	Identifies whether a device supports multiple functions 0 Single function device 1 Multiple function device
Header Layout	All other encodings reserved. 0x00 Endpoint. See Type 0 configuration header for type 0 layout. 0x01 Root Complex. See Type 1 configuration header for type 1 layout.

19.5.1.1.10 PCI Express Base Address Register 0 (PEXCSRBAR)

The PCI Express base address registers (BARs) point to the beginning of distinct address ranges which the device should claim. In EP mode, the device supports a configuration space BAR, a 32-bit memory space BAR, and two 64-bit memory space BARs. In RC mode, the device only supports the configuration space BAR in the header; the other memory spaces are defined by the inbound ATMUs. Refer to PCI Express Inbound ATMU Registers for more information.

Base address register 0 at offset 0x10 is a special fixed 16M or general purpose window that is used for inbound configuration or memory accesses. This window is called the PCI Express configuration and status register base address register (PEXCSRBAR) or window 0. Note that PEXCSRBAR cannot be updated through the inbound ATMU registers.

Address: 0h base + 10h offset = 10h



PEXCSRBAR field descriptions

Field	Description
31–12 ADDRESS	Indicates the base address of the inbound configuration window or the general purpose inbound memory window. If used as an inbound configuration window, the base address must be aligned to the 16-Mbyte CCSR space and the the size of the window in the inbound window attributes register (PEXIWAR0) must be 16-Mbytes. If the window is used as a general purpose inbound memory window, then the number of upper bits that the device allows to be writable is selected through the inbound window size in the inbound window attributes register (PEXIWAR0).
11–4 -	This field is reserved. Reserved
3 PREF	Prefetchable
2–1 TYPE	Type. 00 Locate anywhere in 32-bit address space.
0 MemSp	Memory space indicator

19.5.1.1.11 PCI Express Base Address Register 1 (BAR1)

This register is supported only for EP mode.

Base address register 1 at offset 0x14 is used to define the inbound memory window in the 32-bit memory space.

Address: 0h base + 14h offset = 14h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDRESS				Reserved								PREF	TYPE		MemSp
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	1

BAR1 field descriptions

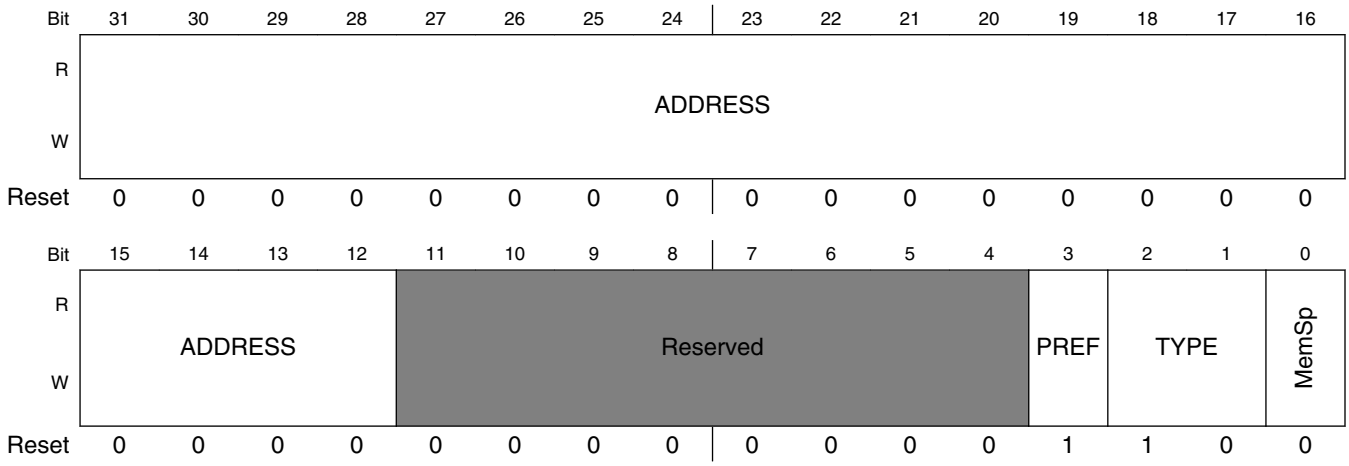
Field	Description
31–12 ADDRESS	Indicates the base address where the inbound memory window begins. The number of upper bits that the device allows to be writable is selected through the inbound window size in the inbound window attributes register (PEXIWAR1).
11–4 -	This field is reserved. Reserved. The device allows a 4 Kbyte window minimum.
3 PREF	Prefetchable. This bit is determined by PEXIWAR1[PF].
2–1 TYPE	Type. 00 Locate anywhere in 32-bit address space.
0 MemSp	Memory space indicator.

19.5.1.1.12 PCI Express Base Address Register 2 (BAR2)

This register is supported only for EP mode.

Base address register 2 at offset 0x18 and base address register 4 at offset 0x20 are used to define the lower portion of the 64-bit inbound memory windows.

Address: 0h base + 18h offset = 18h



BAR2 field descriptions

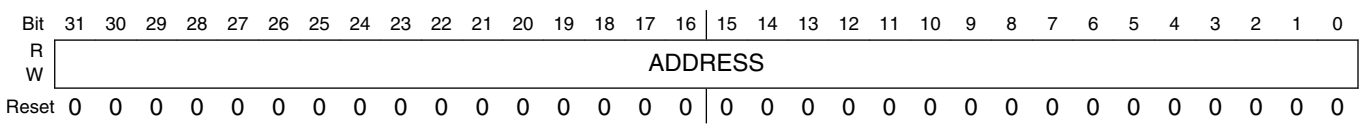
Field	Description
31–12 ADDRESS	Indicates the lower portion of the base address where the inbound memory window begins. The number of bits that the device allows to be writable is selected through the inbound window size in the inbound window attributes registers (PEXIWAR2 for offset 0x18 and PEXIWAR3 for offset 0x20).
11–4 -	This field is reserved. Reserved. The device allows a 4 Kbyte window minimum.
3 PREF	Prefetchable. This bit is determined by PEXIWARn[2].
2–1 TYPE	Type. 0b10 Locate anywhere in 64-bit address space.
0 MemSp	Memory space indicator

19.5.1.1.13 PCI Express Base Address Register 3 (BAR3)

This register is supported only for EP mode.

Base address register 3 at offset 0x1C and base address register 5 at offset 0x24 are used to define the upper portion of the 64-bit inbound memory windows.

Address: 0h base + 1Ch offset = 1Ch



BAR3 field descriptions

Field	Description
ADDRESS	Indicates the upper portion of the base address where the inbound memory window begins. The number of bits that the device allows to be writable is selected through the inbound window size in the inbound

BAR3 field descriptions (continued)

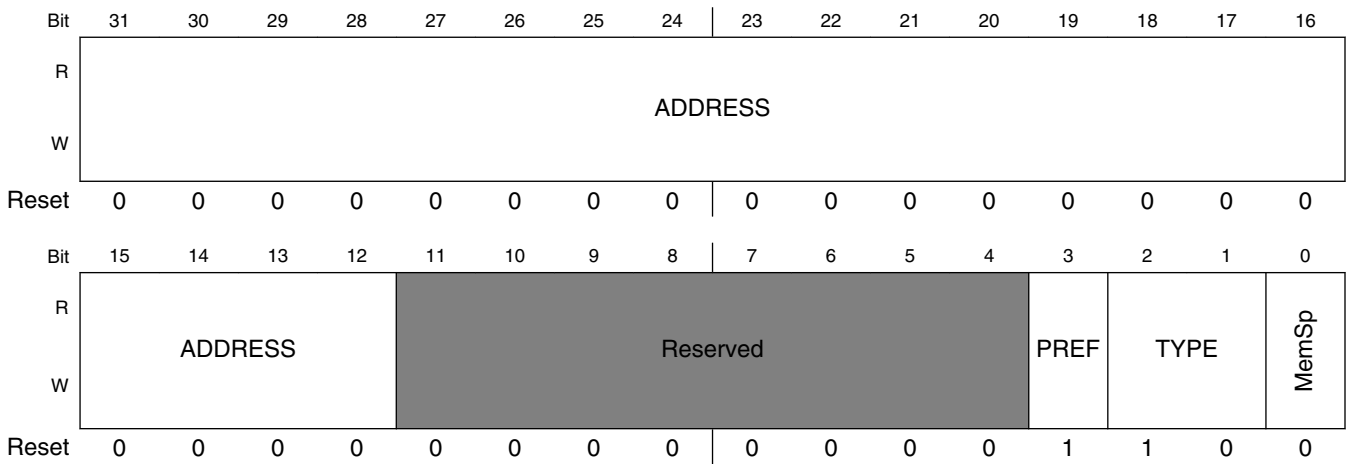
Field	Description
	window attributes registers (PEXIWAR2 for offset 0x1C and PEXIWAR3 for offset 0x24). If no access to local memory is to be permitted by external requesters, then all bits are programmed.

19.5.1.1.14 PCI Express Base Address Register 4 (BAR4)

This register is supported only for EP mode.

Base address register 2 at offset 0x18 and base address register 4 at offset 0x20 are used to define the lower portion of the 64-bit inbound memory windows.

Address: 0h base + 20h offset = 20h



BAR4 field descriptions

Field	Description
31–12 ADDRESS	Indicates the lower portion of the base address where the inbound memory window begins. The number of bits that the device allows to be writable is selected through the inbound window size in the inbound window attributes registers (PEXIWAR2 for offset 0x18 and PEXIWAR3 for offset 0x20).
11–4 -	This field is reserved. Reserved. The device allows a 4 Kbyte window minimum.
3 PREF	Prefetchable. This bit is determined by PEXIWARn[2].
2–1 TYPE	Type. 0b10 Locate anywhere in 64-bit address space.
0 MemSp	Memory space indicator

19.5.1.1.15 PCI Express Base Address Register 5 (BAR5)

This register is supported only for EP mode.

Base address register 3 at offset 0x1C and base address register 5 at offset 0x24 are used to define the upper portion of the 64-bit inbound memory windows.

Address: 0h base + 24h offset = 24h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDRESS																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

BAR5 field descriptions

Field	Description
ADDRESS	Indicates the upper portion of the base address where the inbound memory window begins. The number of bits that the device allows to be writable is selected through the inbound window size in the inbound window attributes registers (PEXIWAR2 for offset 0x1C and PEXIWAR3 for offset 0x24). If no access to local memory is to be permitted by external requestors, then all bits are programmed.

19.5.1.1.16 PCI Express Subsystem Vendor ID Register (Subsystem Vendor ID Register)

This register is supported only for EP mode.

The PCI Express subsystem vendor ID register is used to identify the subsystem.

Address: 0h base + 2Ch offset = 2Ch

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	Subsystem Vendor ID															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Subsystem Vendor ID Register field descriptions

Field	Description
Subsystem Vendor ID	Subsystem Vendor ID

19.5.1.1.17 PCI Express Subsystem ID Register (Subsystem ID Register)

This register is supported only for EP mode.

The PCI Express subsystem ID register is used to identify the subsystem.

Address: 0h base + 2Eh offset = 2Eh

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	Subsystem ID															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

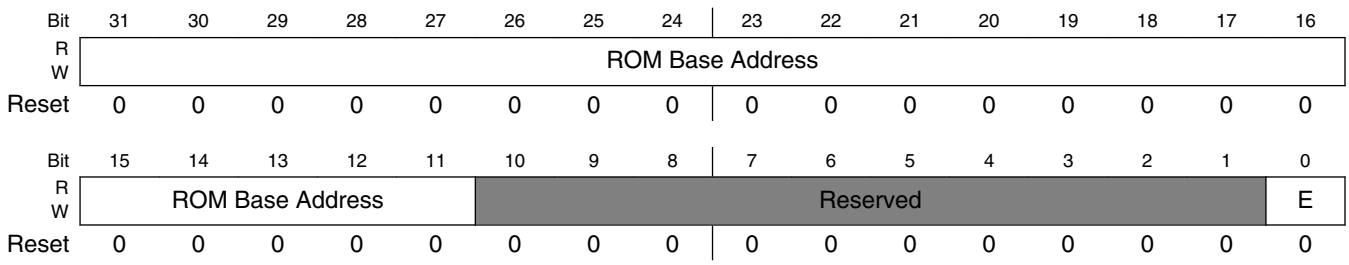
Subsystem ID Register field descriptions

Field	Description
Subsystem ID	Subsystem ID

19.5.1.1.18 PCI Express Expansion ROM Base Address Register (Expansion ROM BAR)

The register at offset 0x30 has a different function depending on the value in PEX_CSR1[CS2]. When PEX_CSR1[CS2] = 0, the register functions as the PCI Express expansion ROM base address register.

Address: 0h base + 30h offset = 30h



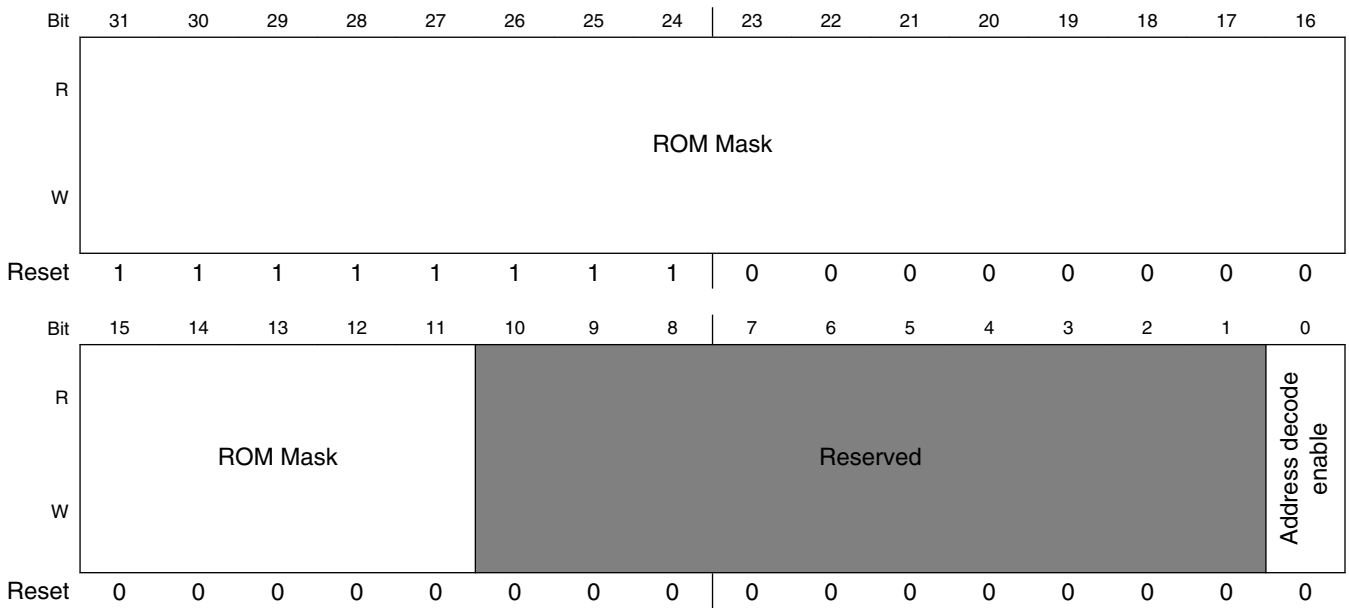
Expansion ROM BAR field descriptions

Field	Description
31–11 ROM Base Address	Specifies bits 31:11 of the non-prefetchable expansion ROM space start address. Typically used for specifying memory-mapped I/O space. The default size is 16M.
10–1 -	This field is reserved. Reserved
0 E	Address decode enable

19.5.1.1.19 PCI Express Expansion ROM BAR Mask Register (Expansion ROM BAR Mask Register)

The register at offset 0x30 has a different function depending on the value in PEX_CSR1[CS2]. When PEX_CSR1[CS2] = 1, the register functions as the PCI Express expansion ROM BAR mask register.

Address: 0h base + 30h offset = 30h



Expansion ROM BAR Mask Register field descriptions

Field	Description
31–11 ROM Mask	The default mask is 0xFF00000 which is 16 M.
10–1 -	This field is reserved. Reserved
0 Address decode enable	E

19.5.1.1.20 Capabilities Pointer Register (Capabilities Pointer Register)

The capabilities pointer identifies additional functionality supported by the device.

Address: 0h base + 34h offset = 34h

Bit	7	6	5	4	3	2	1	0
Read	Capabilities Pointer							
Write								
Reset	0	1	0	0	0	0	0	0

Capabilities Pointer Register field descriptions

Field	Description
Capabilities Pointer	The capabilities pointer provides the offset for additional PCI-compatible registers above the common 64-byte header.

19.5.1.1.21 PCI Express Interrupt Line Register (Interrupt Line Register)

The interrupt line register is used by device drivers and OS software to communicate interrupt line routing information. Values in this register are programmed by system software and are system specific.

Address: 0h base + 3Ch offset = 3Ch

Bit	7	6	5	4	3	2	1	0
Read Write	Interrupt Line							
Reset	0	0	0	0	0	0	0	0

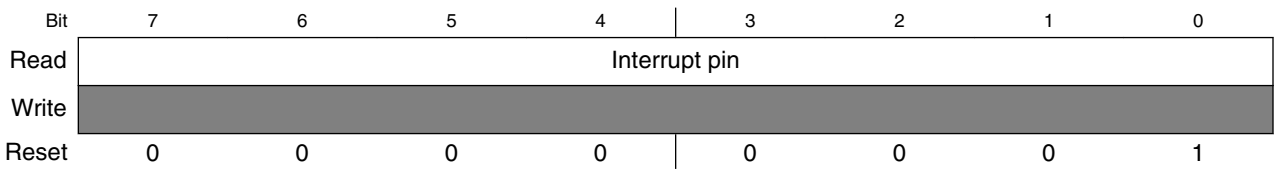
Interrupt Line Register field descriptions

Field	Description
Interrupt Line	Used to communicate interrupt line routing information.

19.5.1.1.22 PCI Express Interrupt Pin Register (Interrupt Pin Register)

The interrupt pin register identifies the legacy interrupt (INTx) messages the device (or function) uses.

Address: 0h base + 3Dh offset = 3Dh



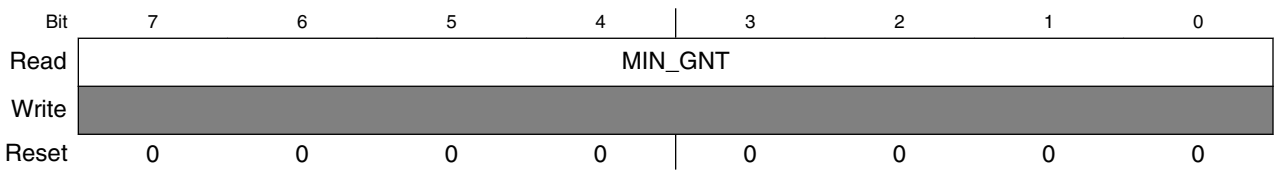
Interrupt Pin Register field descriptions

Field	Description
Interrupt pin	Legacy INTx message used by this device. All others settings are reserved. 0x00 This device does not use legacy interrupt (INTx) messages. 0x01 INTA 0x02 INTB 0x03 INTC 0x04 INTD

19.5.1.1.23 PCI Express Minimum Grant Register (Minimum Grant Register)

This register does not apply to PCI Express. It is present for legacy purposes.

Address: 0h base + 3Eh offset = 3Eh



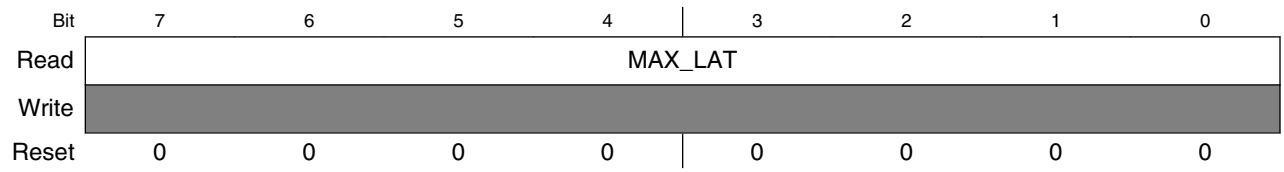
Minimum Grant Register field descriptions

Field	Description
MIN_GNT	Does not apply for PCI Express.

19.5.1.1.24 PCI Express Maximum Latency Register (Maximum Latency Register)

This register does not apply to PCI Express. It is present for legacy purposes.

Address: 0h base + 3Fh offset = 3Fh



Maximum Latency Register field descriptions

Field	Description
MAX_LAT	Does not apply for PCI Express.

19.5.1.2 Type 1 configuration header

19.5.1.2.1 PCI Express Vendor ID Register (Vendor ID Register)

The vendor ID register is used to identify the manufacturer of the device.

NOTE

This register is writeable using internal PEX_CONFIG_ADDR/ PEX_CONFIG_DATA accesses, but is read-only from inbound configuration accesses by an external host.

Address: 0h base + 0h offset = 0h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	Vendor ID															
Write																
Reset	0	0	0	1	1	0	0	1	0	1	0	1	0	1	1	1

Vendor ID Register field descriptions

Field	Description
Vendor ID	0x1957 (Freescale)

19.5.1.2.2 PCI Express Device ID Register (Device ID Register)

The device ID register is used to identify the device.

NOTE

This register is writeable using internal PEX_CONFIG_ADDR/ PEX_CONFIG_DATA accesses, but is read-only from inbound configuration accesses by an external host.

Address: 0h base + 2h offset = 2h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	Device ID															
Write

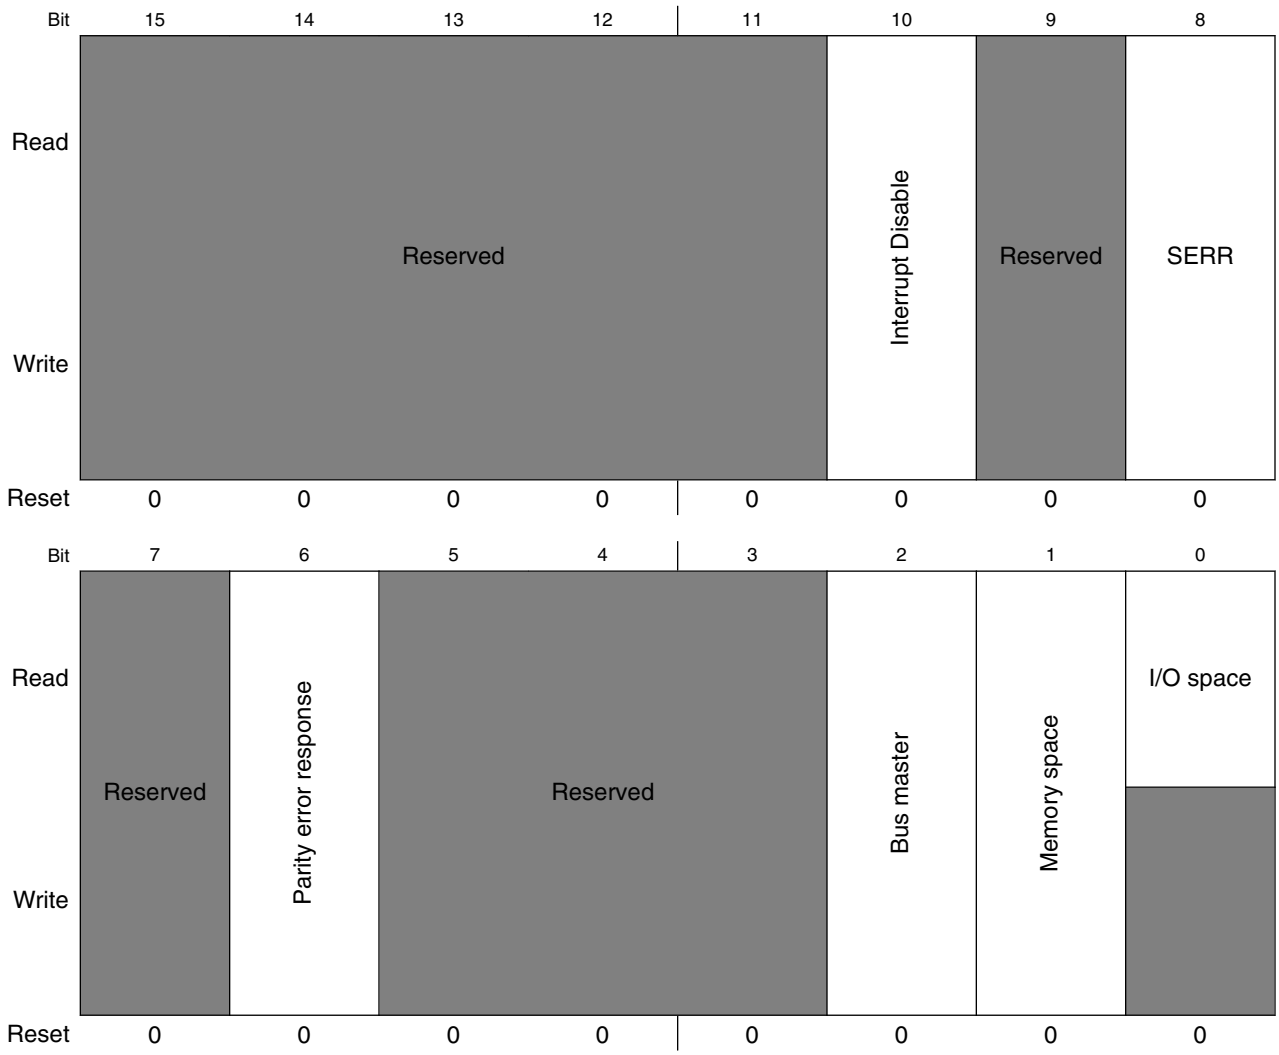
Device ID Register field descriptions

Field	Description	
Device ID	0x0440	T4240 with security
	0x0441	T4240 without security
	0x0442	T4160 with security
	0x0443	T4160 without security
	0x044A	T4080 with security
	0x044B	T4080 without security

19.5.1.2.3 PCI Express Command Register (Command Register)

The command register provides control over the ability to generate and respond to PCI Express cycles.

Address: 0h base + 4h offset = 4h



Command Register field descriptions

Field	Description
15–11 -	This field is reserved. Reserved
10 Interrupt Disable	Controls the ability to generate INTx interrupt messages. Any INTx emulation interrupts already asserted by this device must be deasserted when this bit is set. 0 Enables INTx interrupt messages 1 Disables INTx interrupt messages
9 -	This field is reserved. Reserved
8 SERR	Controls the reporting of fatal and non-fatal errors detected by the device to the root complex. **NOTE:** The error control and status bits in the command and status registers control PCI-compatible error reporting. PCI Express advanced error reporting is controlled by the PCI

Table continues on the next page...

Command Register field descriptions (continued)

Field	Description
	Express device control register described in PCI Express Device Control Register (Device Control Register) and the advanced error reporting capability structure described in Advanced error reporting capability structure. 0 Disables reporting 1 Enables reporting
7 - Reserved	This field is reserved.
6 Parity error response	Controls whether this PCI Express controller responds to parity errors. **NOTE:** The error control and status bits in the command and status registers control PCI-compatible error reporting. PCI Express advanced error reporting is controlled by the PCI Express device control register described in PCI Express Device Control Register (Device Control Register) and the advanced error reporting capability structure described in Advanced error reporting capability structure. 0 Parity errors are ignored and normal operation continues. 1 Parity errors cause the appropriate bit in the PCI Express status register to be set. However, note that errors are reported based on the values set in the PCI Express error enable and detection registers.
5–3 - Reserved	This field is reserved.
2 Bus master	Indicates whether this PCI Express device is configured as a master. EP mode: Clearing this bit prevent the device from issuing any memory or I/O transactions. Because MSI interrupts are effectively memory writes, clearing this bit also disables the ability of the device to issue MSI interrupts. RC mode: Clearing this bit disables the ability of the device to forward memory transactions upstream. This causes any inbound memory transaction to be treated as an unsupported request. 0 Disables the ability to generate PCI Express accesses 1 Enables this PCI Express controller to behave as a PCI Express bus master
1 Memory space	Controls whether this PCI Express device (as a target) responds to memory accesses. EP mode: Clearing this bit prevents the device from accepting any memory transaction. RC mode: This bit is ignored. It does not affect outbound memory transaction 0 This PCI Express device does not respond to PCI Express memory space accesses. 1 This PCI Express device responds to PCI Express memory space accesses.
0 I/O space	I/O space. EP mode: Clearing this bit prevents the device from accepting any IO transaction. Note that this bit is a don't care in EP mode since the device does not support IO transaction. RC mode: This bit is ignored. It does not affect outbound IO transaction. 0 This PCI Express device (as a target) does not respond to PCI Express I/O space accesses. 1 This PCI Express device (as a target) does respond to PCI Express I/O space accesses.

19.5.1.2.4 PCI Express Status Register (Status Register)

The status register is used to record status information for PCI Express related events.

Address: 0h base + 6h offset = 6h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	Detected parity error	Signaled system error	Received master-abort	Received target-abort	Signaled target-abort	Reserved		Master data parity error detected	Reserved			Capabilities List	Interrupt Status	Reserved		
Write	w1c	w1c	w1c	w1c	w1c			w1c				w1c	w1c			
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Status Register field descriptions

Field	Description
15 Detected parity error	Set whenever a device receives a poisoned TLP regardless of the state of bit 6 in the command register.[1]
14 Signaled system error	Set whenever a device sends a ERR_FATAL or ERR_NONFATAL message and the SERR enable bit in the command register is set.[1]
13 Received master-abort	Set whenever a requestor receives a completion with unsupported request completion status.[1]
12 Received target-abort	Set whenever a device receives a completion with completer abort completion status.[1]
11 Signaled target-abort	Set whenever a device completes a request using completer abort completion status.[1]
10–9 -	This field is reserved. Reserved
8 Master data parity error detected	Set by the requestor (primary side for Type1 headers) when either the requestor receives a completion marked poisoned or the requestor poisons a write request.

Table continues on the next page...

Status Register field descriptions (continued)

Field	Description
	Note that the parity error enable bit (bit 6) in the command register must be set for this bit to be set.[1]
7–5 -	This field is reserved. Reserved
4 Capabilities List	All PCI Express devices are required to implement the PCI Express capability structure.
3 Interrupt Status	Set when an INTx interrupt message is pending internally to the device. Note that this bit is associated with INTx messages and not Message Signaled Interrupts.
-	This field is reserved. Reserved

1. The error control and status bits in the command and status registers control PCI-compatible error reporting. PCI Express advanced error reporting is controlled by the PCI Express device control register described in PCI Express Device Control Register (Device Control Register) and the advanced error reporting capability structure described in Advanced error reporting capability structure.

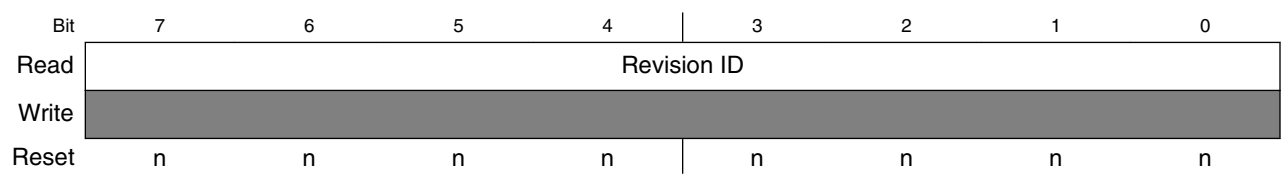
19.5.1.2.5 PCI Express Revision ID Register (Revision ID Register)

The revision ID register is used to identify the revision of the device.

NOTE

This register is writeable using internal PEX_CONFIG_ADDR/ PEX_CONFIG_DATA accesses, but is read-only from inbound configuration accesses by an external host.

Address: 0h base + 8h offset = 8h



Revision ID Register field descriptions

Field	Description
Revision ID	Revision specific.

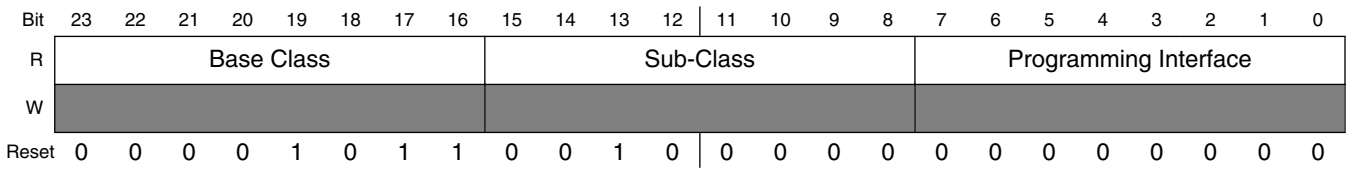
19.5.1.2.6 PCI Express Class Code Register (Class Code Register)

The class code register is comprised of three single-byte fields-base class (offset 0x0B), sub-class (offset 0x0A), and programming interface (offset 0x09)-that indicate the basic functionality of the function.

NOTE

This register is writeable using internal PEX_CONFIG_ADDR/ PEX_CONFIG_DATA accesses, but is read-only from inbound configuration accesses by an external host.

Address: 0h base + 9h offset = 9h



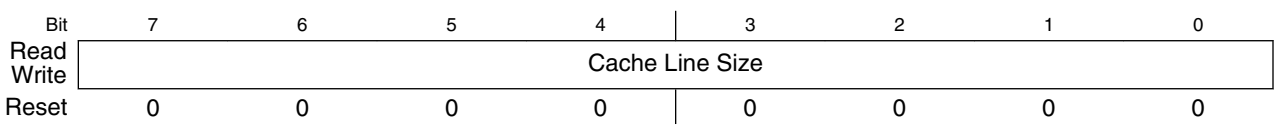
Class Code Register field descriptions

Field	Description
23–16 Base Class	0x0B—Processor
15–8 Sub-Class	0x20—Power Architecture
Programming Interface	0x00

19.5.1.2.7 PCI Express Cache Line Size Register (Cache Line Size Register)

The cache line size register is provided for legacy compatibility purposes (PCI 2.3); it is not used for PCI Express device functionality.

Address: 0h base + Ch offset = Ch



Cache Line Size Register field descriptions

Field	Description
Cache Line Size	Represents the cache line size of the processor in terms of 32-bit words (8 32-bit words = 32 bytes). Note that for PCI Express operation this register is ignored.

19.5.1.2.8 PCI Express Latency Timer Register (Latency Timer Register)

The latency timer register is provided for legacy compatibility purposes (PCI 2.3); it is not used for PCI Express device functionality.

Address: 0h base + Dh offset = Dh

Bit	7	6	5	4	3	2	1	0
Read	Latency Timer							
Write								
Reset	0	0	0	0	0	0	0	0

Latency Timer Register field descriptions

Field	Description
Latency Timer	Note that for PCI Express operation this register is ignored.

19.5.1.2.9 PCI Express Header Type Register (Header Type Register)

The PCI Express header type register is used to identify the layout of the PCI compatible header.

Address: 0h base + Eh offset = Eh

Bit	7	6	5	4	3	2	1	0
Read	Multifunction	Header Layout						
Write								
Reset	n	0	0	0	0	0	0	n

Header Type Register field descriptions

Field	Description
7 Multifunction	Identifies whether a device supports multiple functions 0 Single function device 1 Multiple function device
Header Layout	All other encodings reserved. 0x00 Endpoint. See Type 0 configuration header for type 0 layout. 0x01 Root Complex. See Type 1 configuration header for type 1 layout.

19.5.1.2.10 PCI Express Base Address Register 0 (PEXCSRBAR)

Base address register 0 at offset 0x10 is a special fixed 16-Mbyte window that is used for inbound configuration accesses. This window is called the PCI Express configuration and status register base address register (PEXCSRBAR). Note that PEXCSRBAR cannot be updated through the inbound ATMU registers.

Address: 0h base + 10h offset = 10h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDRESS				Reserved								PREF	TYPE		MemSp
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PEXCSRBAR field descriptions

Field	Description
31–12 ADDRESS	Indicates the base address that the inbound configuration window occupies. This window is fixed at 16 Mbyte.
11–4 -	This field is reserved. Reserved
3 PREF	Prefetchable
2–1 TYPE	Type. 00 Locate anywhere in 32-bit address space.
0 MemSp	Memory space indicator

19.5.1.2.11 PCI Express Primary Bus Number Register (Primary Bus Number Register)

Address: 0h base + 18h offset = 18h

Bit	7	6	5	4	3	2	1	0
Read Write	Primary Bus Number							
Reset	0	0	0	0	0	0	0	0

Primary Bus Number Register field descriptions

Field	Description
Primary Bus Number	Bus that is connected to the upstream interface. Note that this register is programmed during system enumeration; in RC mode this register should remain 0x00.

19.5.1.2.12 PCI Express Secondary Bus Number Register (Secondary Bus Number Register)

Address: 0h base + 19h offset = 19h

Bit	7	6	5	4	3	2	1	0
Read Write	Secondary Bus Number							
Reset	0	0	0	0	0	0	0	0

Secondary Bus Number Register field descriptions

Field	Description
Secondary Bus Number	Bus that is directly connected to the downstream interface. Note that this register is programmed during system enumeration; in RC mode, this register is typically programmed to 0x01.

19.5.1.2.13 PCI Express Subordinate Bus Number Register (Subordinate Bus Number Register)

Address: 0h base + 1Ah offset = 1Ah

Bit	7	6	5	4	3	2	1	0
Read Write	Subordinate Bus Number							
Reset	0	0	0	0	0	0	0	0

Subordinate Bus Number Register field descriptions

Field	Description
Subordinate Bus Number	Highest bus number that is on the downstream interface.

19.5.1.2.14 PCI Express I/O Base Register (I/O Base Register)

Note that this device does not support inbound I/O transactions.

Address: 0h base + 1Ch offset = 1Ch

Bit	7	6	5	4	3	2	1	0
Read	I/O Start Address				Address Decode Type			
Write								
Reset	0	0	0	0	0	0	0	1

I/O Base Register field descriptions

Field	Description
7–4 I/O Start Address	Specifies bits 15:12 of the I/O space start address
Address Decode Type	Specifies the number of I/O address bits. All other settings are reserved. 0x00 16-bit I/O address decode 0x01 32-bit I/O address decode

19.5.1.2.15 PCI Express I/O Limit Register (I/O Limit Register)

Note that this device does not support inbound I/O transactions.

Address: 0h base + 1Dh offset = 1Dh

Bit	7	6	5	4	3	2	1	0
Read	I/O Limit Address				Address Decode Type			
Write								
Reset	0	0	0	0	0	0	0	1

I/O Limit Register field descriptions

Field	Description
7–4 I/O Limit Address	Specifies bits 15:12 of the I/O space ending address
Address Decode Type	Specifies the number of I/O address bits. All other settings are reserved. 0x00 16-bit I/O address decode 0x01 32-bit I/O address decode

19.5.1.2.16 PCI Express Secondary Status Register (Secondary Status Register)

Address: 0h base + 1Eh offset = 1Eh

Bit	15	14	13	12	11	10	9	8
Read	DPE	SSE	RMA	RTA	STA	Reserved		MDPE
Write	w1c	w1c	w1c	w1c	w1c			w1c
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read Write	Reserved							
Reset	0	0	0	0	0	0	0	0

Secondary Status Register field descriptions

Field	Description
15 DPE	Detected parity error. This bit is set whenever the secondary side receives a poisoned TLP regardless of the state of the parity error response bit.
14 SSE	Signaled system error. This bit is set when a device sends a ERR_FATAL or ERR_NONFATAL message, provided the SERR enable bit in the command register is set to enable reporting.
13 RMA	Received master abort. This bit is set when the secondary side receives an unsupported request (UR) completion.
12 RTA	Received target abort. This bit is set when the secondary side receives a completer abort (CA) completion.
11 STA	Signaled target abort. This bit is set when the secondary side issues a CA completion.
10–9 -	This field is reserved. Reserved
8 MDPE	Master data parity error. This bit is set when the parity error response bit is set and the secondary side requester receives a poisoned completion or poisons a write request. If the parity error response bit is cleared, this bit is never set.
-	This field is reserved. Reserved

19.5.1.2.17 PCI Express Memory Base Register (Memory Base Register)

Address: 0h base + 20h offset = 20h

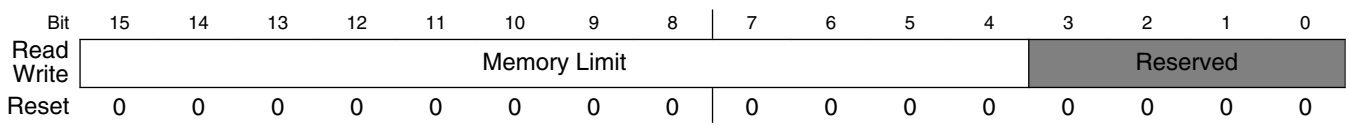
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	Memory Base												Reserved			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Memory Base Register field descriptions

Field	Description
15–4 Memory Base	Specifies bits 31:20 of the non-prefetchable memory space start address. Typically used for specifying memory-mapped I/O space. **NOTE:** Inbound posted transactions hitting into the mem base/limit range are ignored; inbound non-posted transactions hitting into the mem base/limit range results in an unsupported request response.
- Reserved	This field is reserved.

19.5.1.2.18 PCI Express Memory Limit Register (Memory Limit Register)

Address: 0h base + 22h offset = 22h

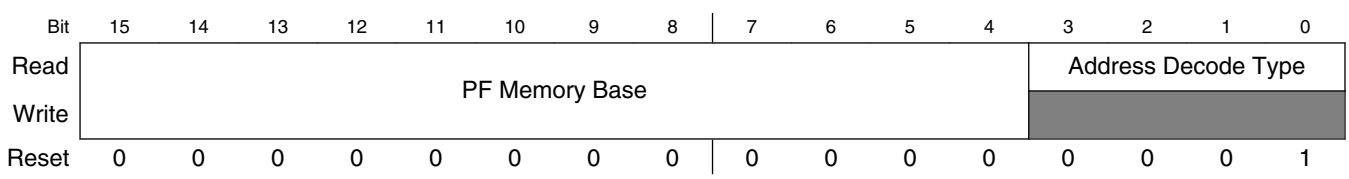


Memory Limit Register field descriptions

Field	Description
15–4 Memory Limit	Specifies bits 31:20 of the non-prefetchable memory space ending address. Typically used for specifying memory-mapped I/O space. **NOTE:** Inbound posted transactions hitting into the mem base/limit range are ignored; inbound non-posted transactions hitting into the mem base/limit range results in unsupported request response.
- Reserved	This field is reserved.

19.5.1.2.19 PCI Express Prefetchable Memory Base Register (Prefetchable Memory Base Register)

Address: 0h base + 24h offset = 24h



Prefetchable Memory Base Register field descriptions

Field	Description
15–4 PF Memory Base	Specifies bits 31:20 of the prefetchable memory space start address.
Address Decode Type	Specifies the number of prefetchable memory address bits. All other settings reserved.

Table continues on the next page...

Prefetchable Memory Base Register field descriptions (continued)

Field	Description
	0x00 32-bit memory address decode 0x01 64-bit memory address decode

19.5.1.2.20 PCI Express Prefetchable Memory Limit Register (Prefetchable Memory Limit Register)

Address: 0h base + 26h offset = 26h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	PF Memory Limit												Address Decode Type			
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Prefetchable Memory Limit Register field descriptions

Field	Description
15–4 PF Memory Limit	Specifies bits 31:20 of the prefetchable memory space ending address.
Address Decode Type	Specifies the number of prefetchable memory address bits. All other settings reserved. 0x00 32-bit memory address decode 0x01 64-bit memory address decode

19.5.1.2.21 PCI Express Prefetchable Base Upper 32 Bits Register (Prefetchable Base Upper 32 Bits Register)

Address: 0h base + 28h offset = 28h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	PF Base Upper 32 Bits																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Prefetchable Base Upper 32 Bits Register field descriptions

Field	Description
PF Base Upper 32 Bits	Specifies bits 64:32 of the prefetchable memory space start address when the address decode type field in the prefetchable memory base register is 0x01.

19.5.1.2.22 PCI Express Prefetchable Limit Upper 32 Bits Register (Prefetchable Limit Upper 32 Bits Register)

Address: 0h base + 2Ch offset = 2Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	PF Limit Upper 32 Bits																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Prefetchable Limit Upper 32 Bits Register field descriptions

Field	Description
PF Limit Upper 32 Bits	Specifies bits 64-32 of the prefetchable memory space ending address when the address decode type field in the prefetchable memory limit register is 0x01.

19.5.1.2.23 PCI Express I/O Base Upper 16 Bits Register (I/O Base Upper 16 Bits Register)

Note that this device does not support inbound I/O transactions.

Address: 0h base + 30h offset = 30h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	I/O Base Upper 16 Bits															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

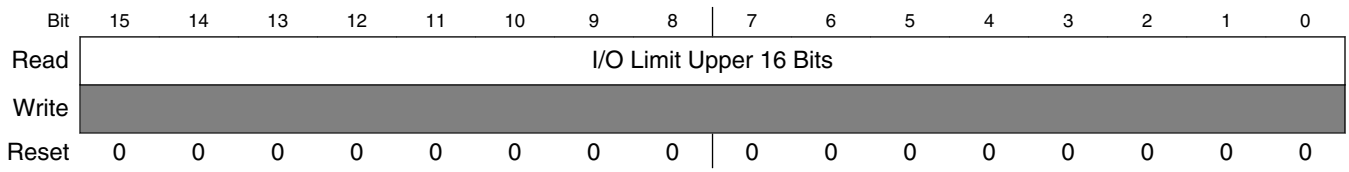
I/O Base Upper 16 Bits Register field descriptions

Field	Description
I/O Base Upper 16 Bits	Specifies bits 31-16 of the I/O space start address when the address decode type field in the I/O base register is 0x01.

19.5.1.2.24 PCI Express I/O Limit Upper 16 Bits Register (I/O Limit Upper 16 Bits Register)

Note that this device does not support inbound I/O transactions.

Address: 0h base + 32h offset = 32h



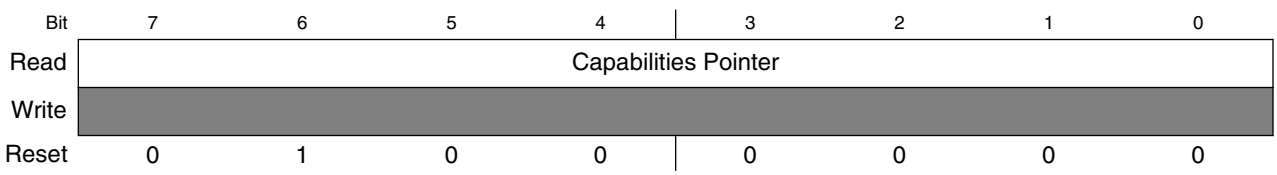
I/O Limit Upper 16 Bits Register field descriptions

Field	Description
I/O Limit Upper 16 Bits	Specifies bits 31-16 of the I/O space ending address when the address decode type field in the I/O limit register is 0x01.

19.5.1.2.25 Capabilities Pointer Register (Capabilities Pointer Register)

The capabilities pointer identifies additional functionality supported by the device.

Address: 0h base + 34h offset = 34h

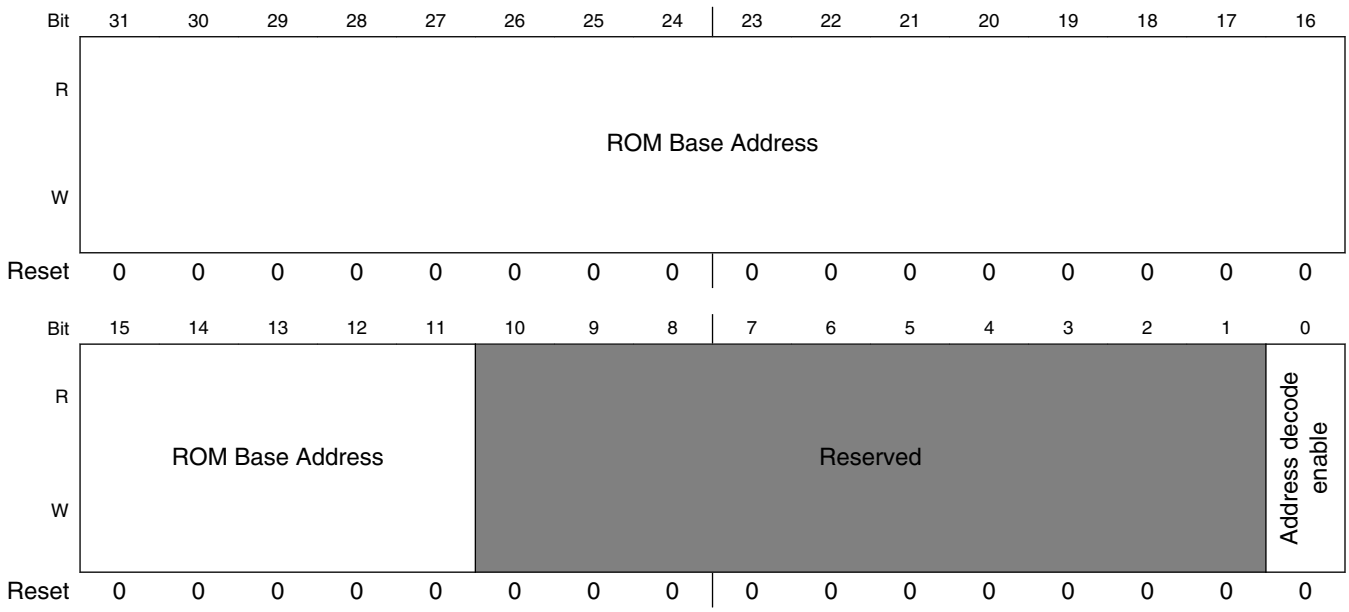


Capabilities Pointer Register field descriptions

Field	Description
Capabilities Pointer	The capabilities pointer provides the offset for additional PCI-compatible registers above the common 64-byte header.

19.5.1.2.26 PCI Express Expansion ROM Base Address Register (Expansion ROM BAR)

Address: 0h base + 38h offset = 38h



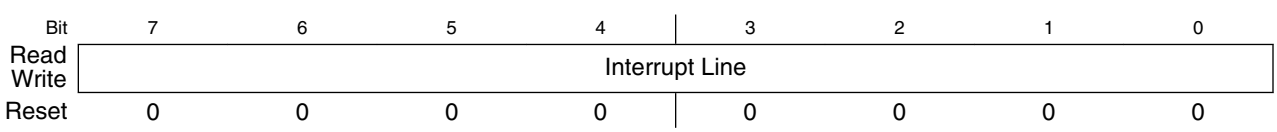
Expansion ROM BAR field descriptions

Field	Description
31–11 ROM Base Address	Specifies bits 31:11 of the non-prefetchable expansion ROM space start address. Typically used for specifying memory-mapped I/O space. The default size is 16M.
10–1 -	This field is reserved. Reserved
0 Address decode enable	Address Decode enable

19.5.1.2.27 PCI Express Interrupt Line Register (Interrupt Line Register)

The interrupt line register is used by device drivers and OS software to communicate interrupt line routing information. Values in this register are programmed by system software and are system specific.

Address: 0h base + 3Ch offset = 3Ch



Interrupt Line Register field descriptions

Field	Description
Interrupt Line	Used to communicate interrupt line routing information.

19.5.1.2.28 PCI Express Interrupt Pin Register (Interrupt Pin Register)

The interrupt pin register identifies the legacy interrupt (INTx) messages the device (or function) uses.

Address: 0h base + 3Dh offset = 3Dh

Bit	7	6	5	4	3	2	1	0
Read	Interrupt pin							
Write								
Reset	0	0	0	0	0	0	0	0

Interrupt Pin Register field descriptions

Field	Description
Interrupt pin	Legacy INTx message used by this device. All other settings reserved. 0x00 This device does not use legacy interrupt (INTx) messages. 0x01 INTA 0x02 INTB 0x03 INTC 0x04 INTD

19.5.1.2.29 PCI Express Bridge Control Register (Bridge Control Register)

Address: 0h base + 3Eh offset = 3Eh

Bit	15	14	13	12	11	10	9	8
Read Write	Reserved							
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read Write	Reserved	Scnd_RST	Reserved		VGA_EN	ISA_EN	SERR_EN	PER
Reset	0	0	0	0	0	0	0	0

Bridge Control Register field descriptions

Field	Description
15–7 -	This field is reserved. Reserved
6 Scnd_RST	Secondary bus reset
5–4 -	This field is reserved. Reserved
3 VGA_EN	VGA enable
2 ISA_EN	ISA enable
1 SERR_EN	SERR enable. This bit controls the propagation of ERR_COR, ERR_NONFATAL, and ERR_FATAL responses received on the secondary side.
0 PER	Parity error response.

19.5.2 Power management capability structure

memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
40	PCI Express Power Management Capability ID Register (Power Management Capability ID Register)	8	R	01h	19.5.2.1/ 1519
42	PCI Express Power Management Capabilities Register (Power Management Capabilities Register)	16	R	See section	19.5.2.2/ 1520
44	PCI Express Power Management Status and Control Register (Power Management Status and Control Register)	16	R/W	0000h	19.5.2.3/ 1521
47	PCI Express Power Management Data Register (Power Management Data Register)	8	R	00h	19.5.2.4/ 1521

19.5.2.1 PCI Express Power Management Capability ID Register (Power Management Capability ID Register)

Address: 40h base + 0h offset = 40h

Bit	7	6	5	4	3	2	1	0
Read	Power Mgmt Capability ID							
Write								
Reset	0	0	0	0	0	0	0	1

Power Management Capability ID Register field descriptions

Field	Description
Power Mgmt Capability ID	Power Management = 0x01

19.5.2.2 PCI Express Power Management Capabilities Register (Power Management Capabilities Register)

Address: 40h base + 2h offset = 42h

Bit	15	14	13	12	11	10	9	8
Read	PME Support					D2	D1	AUX Curr
Write								
Reset	n*	n*	n*	n*	n*	1	1	0

Bit	7	6	5	4	3	2	1	0
Read	AUX Curr		DSI	Reserved	PME CLK	Version		
Write								
Reset	0	0	0	0	0	0	1	0

* Notes:
- PME Support field: Reset value is 11111 in RC mode and 01111 in EP mode

Power Management Capabilities Register field descriptions

Field	Description
15–11 PME Support	Indicates the power states that this device supports
10 D2	D2 Support
9 D1	D1 Support
8–6 AUX Curr	AUX Current
5 DSI	Device Specific Initialization
4 -	This field is reserved. Reserved
3 PME CLK	Does not apply to PCI Express.
Version	Set to 0x2 for this version of the specification.

19.5.2.3 PCI Express Power Management Status and Control Register (Power Management Status and Control Register)

Address: 40h base + 4h offset = 44h

Bit	15	14	13	12	11	10	9	8
Read	PME_STAT	Data Scale			Data Select			PME_EN
Write	w1c							
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read	Reserved						Power State	
Write								
Reset	0	0	0	0	0	0	0	0

Power Management Status and Control Register field descriptions

Field	Description
15 PME_STAT	PME Status
14–13 Data Scale	Obtained directly from the PCI Express base specification.
12–9 Data Select	Obtained directly from the PCI Express base specification.
8 PME_EN	PME Enable **NOTE:** Bitfield access is sticky.
7–2 -	This field is reserved. Reserved
Power State	Power state. Indicates the current power state of the function. 0x00 D0 0x01 D1 0x02 D2 0x03 D3

19.5.2.4 PCI Express Power Management Data Register (Power Management Data Register)

Address: 40h base + 7h offset = 47h

Bit	7	6	5	4	3	2	1	0
Read	Data							
Write								
Reset	0	0	0	0	0	0	0	0

Power Management Data Register field descriptions

Field	Description
Data	Obtained from the PCI Express base specification.

19.5.3 MSI message capability structure

memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
50	PCI Express MSI Message Capability ID Register (MSI Message Capability ID Register)	8	R	05h	19.5.3.1/ 1522

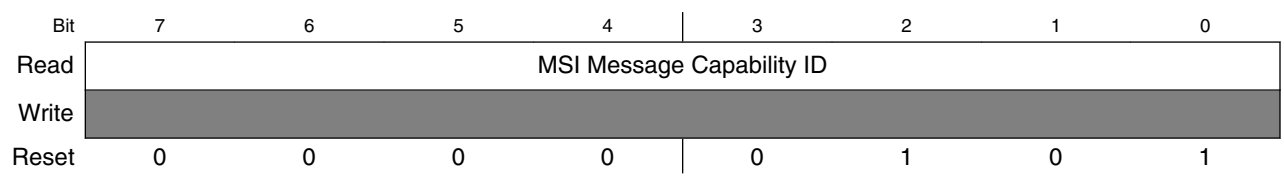
19.5.3.1 PCI Express MSI Message Capability ID Register (MSI Message Capability ID Register)

This register is supported only for EP mode.

Address: 50h base + 0h offset = 50h



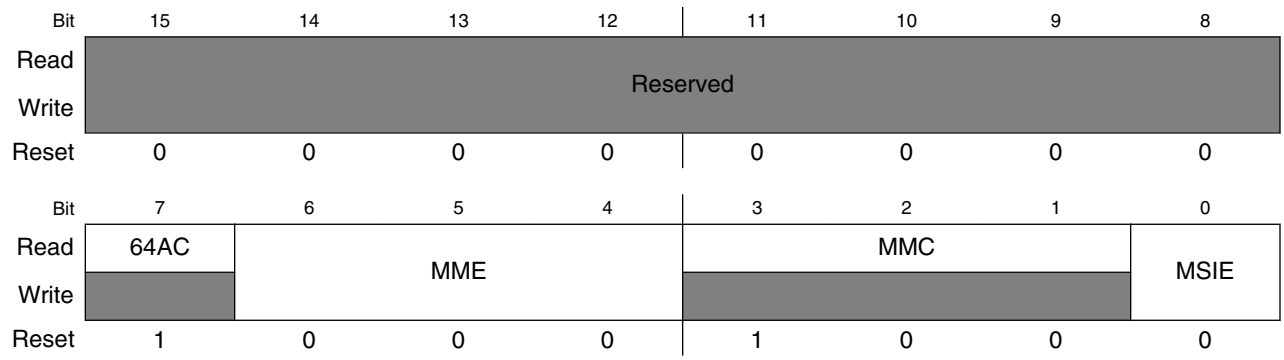
MSI Message Capability ID Register field descriptions

Field	Description
MSI Message Capability ID	MSI Message = 0x05

19.5.3.2 PCI Express MSI Message Control Register (MSI Message Control Register)

This register is supported only for EP mode.

Address: 50h base + 2h offset = 52h



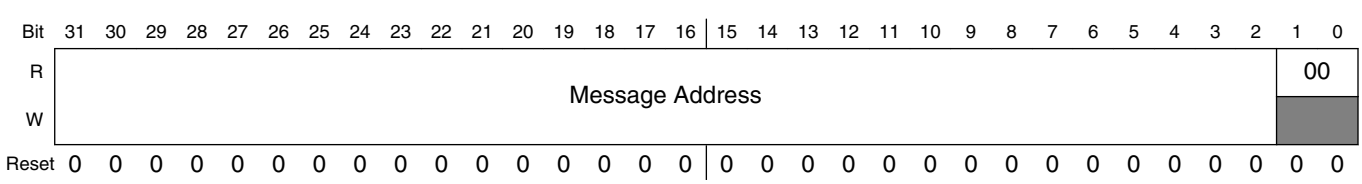
MSI Message Control Register field descriptions

Field	Description
15–8 -	This field is reserved. Reserved
7 64AC	64-bit address capable.
6–4 MME	Multiple message enable.
3–1 MMC	Multiple message capable.
0 MSIE	MSI enable.

19.5.3.3 PCI Express MSI Message Address Register (MSI Message Address Register)

This register is supported only for EP mode.

Address: 50h base + 4h offset = 54h



MSI Message Address Register field descriptions

Field	Description
31–2 Message Address	System-specified message address
00	Always returns 00 on reads; write operations have no effect.

19.5.3.4 PCI Express MSI Message Upper Address Register (MSI Message Upper Address Register)

This register is supported only for EP mode.

Address: 50h base + 8h offset = 58h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Message Upper Address

Bit	7	6	5	4	3	2	1	0
Read	PCI Express Capability ID							
Write								
Reset	0	0	0	1	0	0	0	0

Capability ID Register field descriptions

Field	Description
PCI Express Capability ID	PCI Express = 0x10

19.5.4.2 PCI Express Capabilities Register (Capabilities Register)

Address: 70h base + 2h offset = 72h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	Reserved		Interrupt Message Number					Slot	Device/Port Type				Capability Version			
Write																
Reset	0	0	0	0	0	0	0	0	0	n	0	0	0	0	1	0

Capabilities Register field descriptions

Field	Description
15–14 -	This field is reserved. Reserved
13–9 Interrupt Message Number	If this function is allocated more than one MSI interrupt number, then this register is required to contain the offset between the base Message Data and the MSI Message that is generated when any of the status bits in either the Slot Status register or the Root Port Status register, of this capability structure, are set.
8 Slot	Slot Implemented (RC mode only)
7–4 Device/Port Type	0100 (RC mode) 0000 (EP mode)
Capability Version	Indicates the defined PCI Express capability structure version number.

19.5.4.3 PCI Express Device Capabilities Register (Device Capabilities Register)

Address: 70h base + 4h offset = 74h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved			FLRC	CSPLS		CSPLV								Reserved	
W																
Reset	0	0	0	n	0	0	n	n	n	n	n	n	n	n	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RBER	PIP	AIP	ABP	EP_L1_LAT			EP_L0s_LAT			ET	PHAN_FCT		MAX_PL_SIZE_SUP		
W																
Reset	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Device Capabilities Register field descriptions

Field	Description
31–29 -	This field is reserved. Reserved
28 FLRC	Functional level reset capability. For RC mode, the reset value for this bit is 0; for EP mode, the reset value is 1.
27–26 CSPLS	Captured Slot Power Limit Scale
25–18 CSPLV	Captured Slot Power Limit Value For RC mode, the reset value for this field is 00h; for EP mode, the value is determined by received Set_Slot_Power_Limit messages.
17–16 -	This field is reserved. Reserved
15 RBER	Role based error reporting
14 PIP	Power Indicator Present
13 AIP	Attention Indicator Present
12 ABP	Attention Button Present
11–9 EP_L1_LAT	Endpoint L1 Acceptable Latency
8–6 EP_L0s_LAT	Endpoint L0s Acceptable Latency
5 ET	Extended Tag Field Supported
4–3 PHAN_FCT	Phantom Functions Supported
MAX_PL_SIZE_ SUP	Maximum payload size supported. 001 = 256-bytes

19.5.4.4 PCI Express Device Control Register (Device Control Register)

Address: 70h base + 8h offset = 78h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	IFLR	MAX_READ_SIZE			NSE	APE	PFE	ETE	MAX_PAYLOAD_ SIZE			RO	URR	FER	NFER	CER
Reset	0	0	1	0	1	0	0	0	0	0	0	1	0	0	0	0

Device Control Register field descriptions

Field	Description
15 IFLR	Initiate functional level reset.
14–12 MAX_READ_ SIZE	Maximum read request size
11 NSE	No snoop enable
10 APE	AUX power PM enable
9 PFE	Phantom functions enable
8 ETE	Extended tag field enable
7–5 MAX_ PAYLOAD_SIZE	Maximum payload size
4 RO	Relaxed ordering
3 URR	Unsupported request reporting
2 FER	Fatal error reporting
1 NFER	Non-fatal error reporting
0 CER	Correctable error reporting

19.5.4.5 PCI Express Device Status Register (Device Status Register)

Address: 70h base + Ah offset = 7Ah

Bit	15	14	13	12	11	10	9	8
Read Write	Reserved							
Reset	0	0	0	0	0	0	0	0

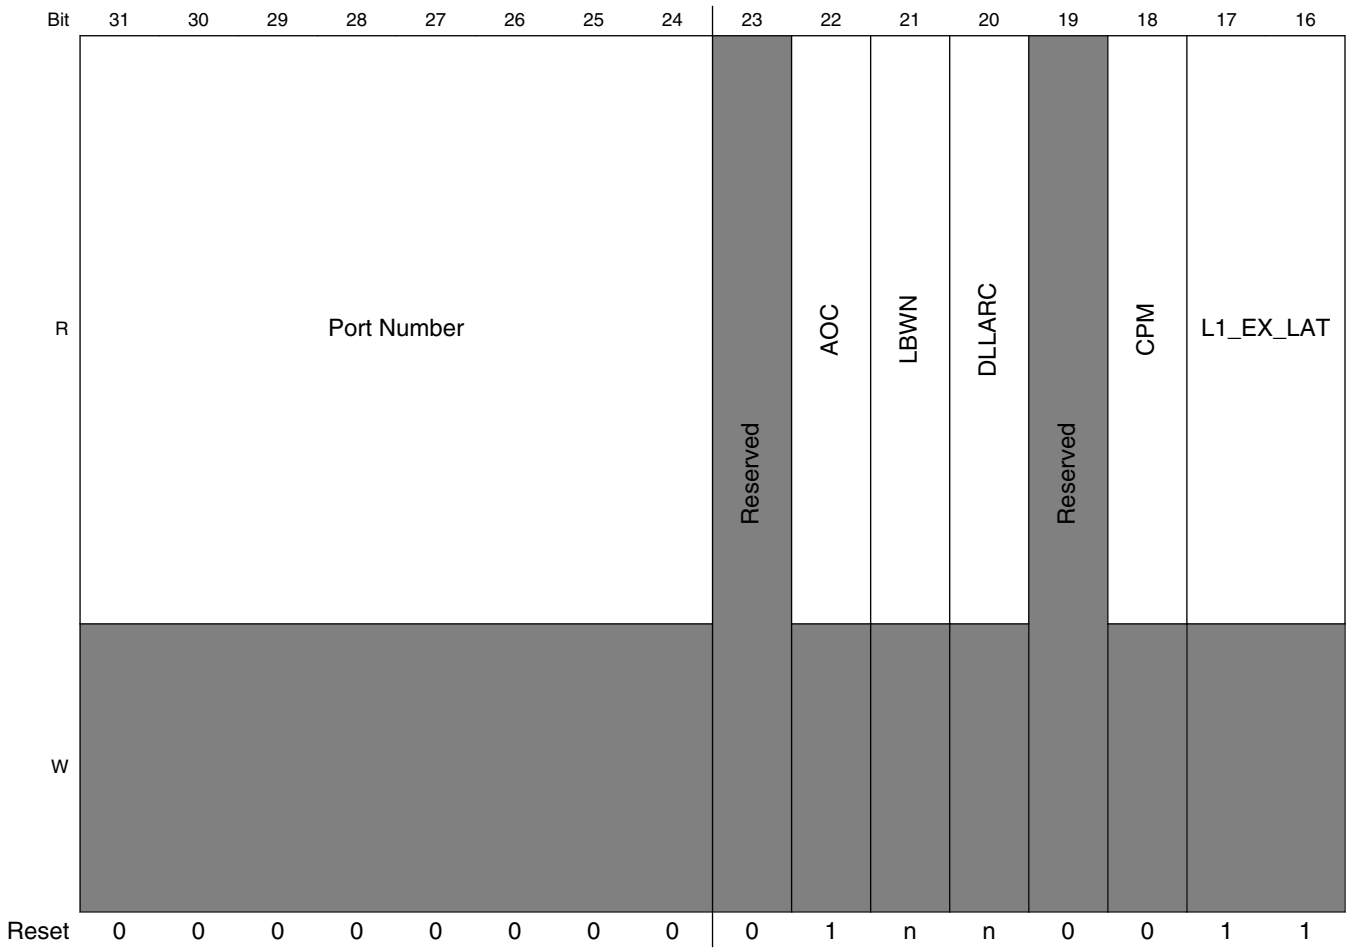
Bit	7	6	5	4	3	2	1	0
Read	Reserved		TP	APD	URD	FED	NFED	CED
Write					w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0

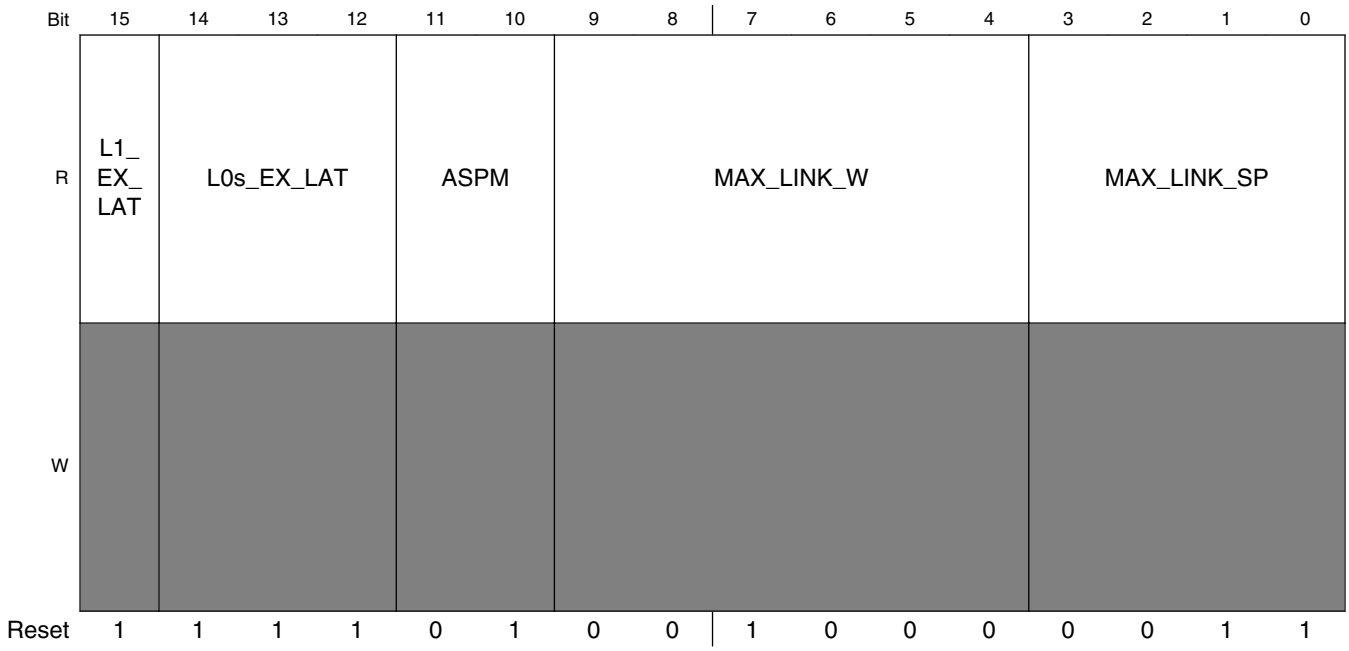
Device Status Register field descriptions

Field	Description
15–6 -	This field is reserved. Reserved
5 TP	Transactions pending
4 APD	AUX power detected. Note that this bit is always zero for VF.
3 URD	Unsupported request detected
2 FED	Fatal error detected
1 NFED	Non-fatal error detected
0 CED	Correctable error detected

19.5.4.6 PCI Express Link Capabilities Register (Link Capabilities Register)

Address: 70h base + Ch offset = 7Ch





Link Capabilities Register field descriptions

Field	Description
31–24 Port Number	-
23 -	This field is reserved. Reserved
22 AOC	ASPM Optionality Compliance Software is permitted to use the value of this bit to help determine whether to enable ASPM or whether to run ASPM compliance tests.
21 LBWN	Link bandwidth notification capable. In EP-mode, this bit is hardwired to 0. In RC-mode this bit is hardwired to 1.
20 DLLARC	Data link layer active reporting capable Set to 1 when in RC-mode. Set to 0 when in EP-mode.
19 -	This field is reserved. Reserved
18 CPM	Clock power management
17–15 L1_EX_LAT	L1 exit latency
14–12 L0s_EX_LAT	L0s exit latency
11–10 ASPM	Active state power management (ASPM) Support
9–4 MAX_LINK_W	Maximum link width
MAX_LINK_SP	Maximum link speed 0011 8.0 GT/s

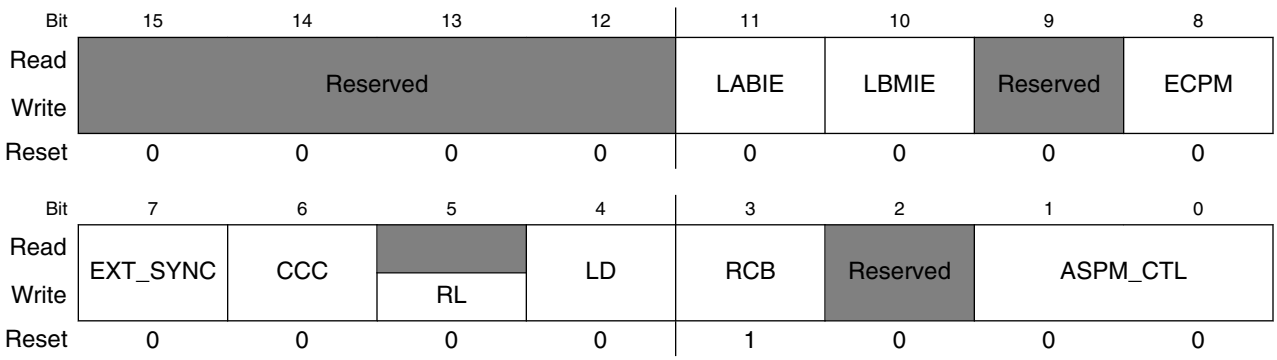
Table continues on the next page...

Link Capabilities Register field descriptions (continued)

Field	Description
	0010 5.0 GT/s 0001 2.5 GT/s link

19.5.4.7 PCI Express Link Control Register (Link Control Register)

Address: 70h base + 10h offset = 80h



Link Control Register field descriptions

Field	Description
15–12 -	This field is reserved. Reserved
11 LABIE	Link autonomous bandwidth interrupt enable
10 LBMIE	Link bandwidth management interrupt enable
9 -	This field is reserved. Reserved
8 ECPM	Enable clock power management.
7 EXT_SYNC	Extended synch
6 CCC	Common clock configuration
5 RL	Retrain link (Reserved for EP devices). In RC mode, setting this bit initiates link retraining by directing the Physical Layer LTSSM to the Recovery state; reads of this bit always return 0.
4 LD	Link disable (Reserved for EP devices)
3 RCB	Read completion boundary
2 -	This field is reserved. Reserved
ASPM_CTL	Active state power management (ASPM) control

19.5.4.8 PCI Express Link Status Register (Link Status Register)

Address: 70h base + 12h offset = 82h

Bit	15	14	13	12	11	10	9	8
Read	LABS	LBMS	Reserved	SCC	LT	Reserved	NEG_LINK_W	
Write								
Reset	0	0	0	1	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read	NEG_LINK_W				LINK_SP			
Write								
Reset	n	n	n	n	0	0	n	n

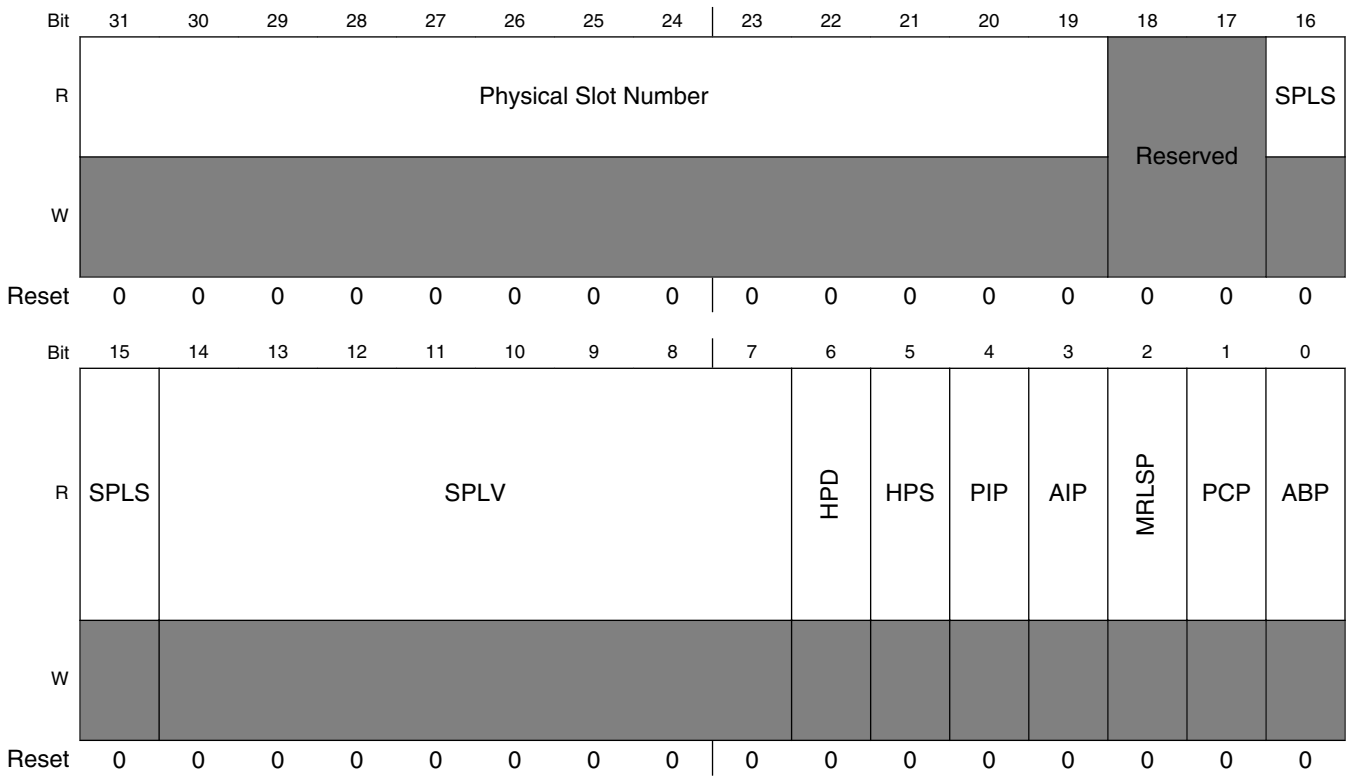
Link Status Register field descriptions

Field	Description
15 LABS	Link autonomous bandwidth status. **NOTE:** This bit is write-1-clear in RC mode; it is read-only in EP mode
14 LBMS	Link bandwidth management status. **NOTE:** This bit is write-1-clear in RC mode; it is read-only in EP mode.
13 -	This field is reserved. Reserved
12 SCC	Slot clock configuration
11 LT	Link training
10 -	This field is reserved. Reserved.
9–4 NEG_LINK_W	Negotiated link width
LINK_SP	Negotiated link speed. 0001 2.5 GT/s 0010 5.0 GT/s 0011 8.0 GT/s

19.5.4.9 PCI Express Slot Capabilities Register (Slot Capabilities Register)

This register is supported only for RC mode.

Address: 70h base + 14h offset = 84h



Slot Capabilities Register field descriptions

Field	Description
31–19 Physical Slot Number	This hardware initialized field indicates the physical slot number attached to this Port. This field must be hardware initialized to a value that assigns a slot number that is globally unique within the chassis. These registers should be initialized to 0 for Ports connected to devices that are either integrated on the system board or integrated within the same silicon as the Switch device or Root Port.
18–17 -	This field is reserved. Reserved
16–15 SPLS	Slot power limit scale.
14–7 SPLV	Slot power limit value.
6 HPD	Hot plug capable. **NOTE:** This chip does not support hot-plug capabilities.

Table continues on the next page...

Slot Capabilities Register field descriptions (continued)

Field	Description
5 HPS	Hot plug surprise. **NOTE:** This chip does not support hot-plug capabilities.
4 PIP	Power indicator present. **NOTE:** This chip does not support hot-plug capabilities.
3 AIP	Attention indicator present. **NOTE:** This chip does not support hot-plug capabilities.
2 MRLSP	MRL sensor present. **NOTE:** This chip does not support hot-plug capabilities.
1 PCP	Power controller present. **NOTE:** This chip does not support hot-plug capabilities.
0 ABP	Attention button present. **NOTE:** This chip does not support hot-plug capabilities.

19.5.4.10 PCI Express Slot Control Register (Slot Control Register)

This register is supported only for RC mode.

Address: 70h base + 18h offset = 88h

Bit	15	14	13	12	11	10	9	8
Read Write	Reserved					PCC	PIC	
Reset	0	0	0	0	0	0	1	1

Bit	7	6	5	4	3	2	1	0
Read Write	AIC		HPIE	CCIE	PDCE	MRLSCE	PFDE	ABPE
Reset	1	1	0	0	0	0	0	0

Slot Control Register field descriptions

Field	Description
15–11 -	This field is reserved. Reserved
10 PCC	Power controller control. **NOTE:** This chip does not support hot-plug capabilities.
9–8 PIC	Power indicator control. **NOTE:** This chip does not support hot-plug capabilities. Defined encodings are:

Table continues on the next page...

Slot Control Register field descriptions (continued)

Field	Description
7–6 AIC	Attention indicator control. **NOTE:** This chip does not support hot-plug capabilities. Defined encodings are:
5 HPIE	Hot plug interrupt enable. **NOTE:** This chip does not support hot-plug capabilities.
4 CCIE	Command completed interrupt enable. **NOTE:** This chip does not support hot-plug capabilities.
3 PDCE	Presence detect changed enable. **NOTE:** This chip does not support hot-plug capabilities.
2 MRLSCE	MRL sensor changed enable. **NOTE:** This chip does not support hot-plug capabilities.
1 PFDE	Power fault detected enable. **NOTE:** This chip does not support hot-plug capabilities.
0 ABPE	Attention button pressed enable. **NOTE:** This chip does not support hot-plug capabilities.

19.5.4.11 PCI Express Slot Status Register (Slot Status Register)

This register is supported only for RC mode.

Address: 70h base + 1Ah offset = 8Ah

Bit	15	14	13	12	11	10	9	8
Read Write	Reserved							
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read	Reserved	PDS	MRLSS	CC	PDC	MRLSC	PFD	ABP
Write				w1c	w1c	w1c	w1c	w1c
Reset	0	1	0	0	1	0	0	0

Slot Status Register field descriptions

Field	Description
15–7 -	This field is reserved. Reserved

Table continues on the next page...

Slot Status Register field descriptions (continued)

Field	Description
6 PDS	This bit indicates the presence of an adapter in the slot, reflected by the logical OR of the Physical Layer in-band presence detect mechanism and, if present, any out-of-band presence detect mechanism defined for the slotâs corresponding form factor. Note that the in-band presence detect mechanism requires that power be applied to an adapter for its presence to be detected. This register must be implemented on all Downstream Ports that implement slots. For Downstream Ports not connected to slots (where the Slot Implemented bit of the PCI Express Capabilities register is 0b), this bit must return 1b. Defined encodings are: 0 Slot Empty 1 Card Present in slot
5 MRLSS	MRL sensor state. 0 MRL closed 1 MRL open
4 CC	Command completed.
3 PDC	Presence detect changed.
2 MRLSC	MRL sensor changed.
1 PFD	Power fault detected.
0 ABP	Attention button pressed.

19.5.4.12 PCI Express Root Control Register (Root Control Register)

This register is supported only for RC mode.

Address: 70h base + 1Ch offset = 8Ch

Bit	15	14	13	12	11	10	9	8
Read Write	Reserved							
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read Write	Reserved				PMEIE	SEFEE	SENFEE	SECEE
Reset	0	0	0	0	0	0	0	0

Root Control Register field descriptions

Field	Description
15–4 -	This field is reserved. Reserved
3 PMEIE	PME interrupt enable.
2 SEFEE	System error on fatal error enable.
1 SENFEE	System error on non-fatal error enable.
0 SECEE	System error on correctable error enable.

19.5.4.13 PCI Express Root Capabilities Register (Root Capabilities Register)

This register is supported only for RC mode.

Address: 70h base + 1Eh offset = 8Eh

Bit	15	14	13	12	11	10	9	8
Read Write	Reserved							
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read Write	Reserved							CRSSWV
Reset	0	0	0	0	0	0	0	0

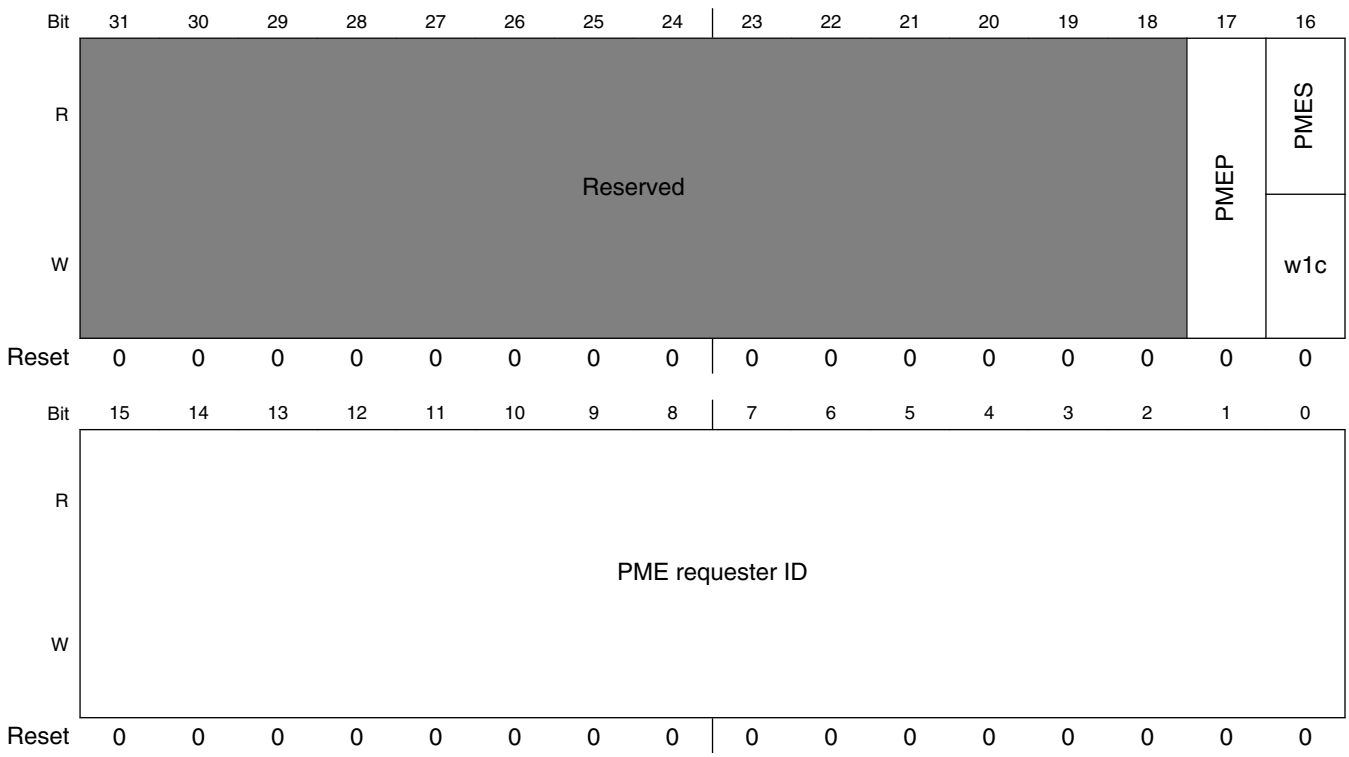
Root Capabilities Register field descriptions

Field	Description
15–1 -	This field is reserved. Reserved
0 CRSSWV	CRS Software Visability.

19.5.4.14 PCI Express Root Status Register (Root Status Register)

This register is supported only for RC mode.

Address: 70h base + 20h offset = 90h

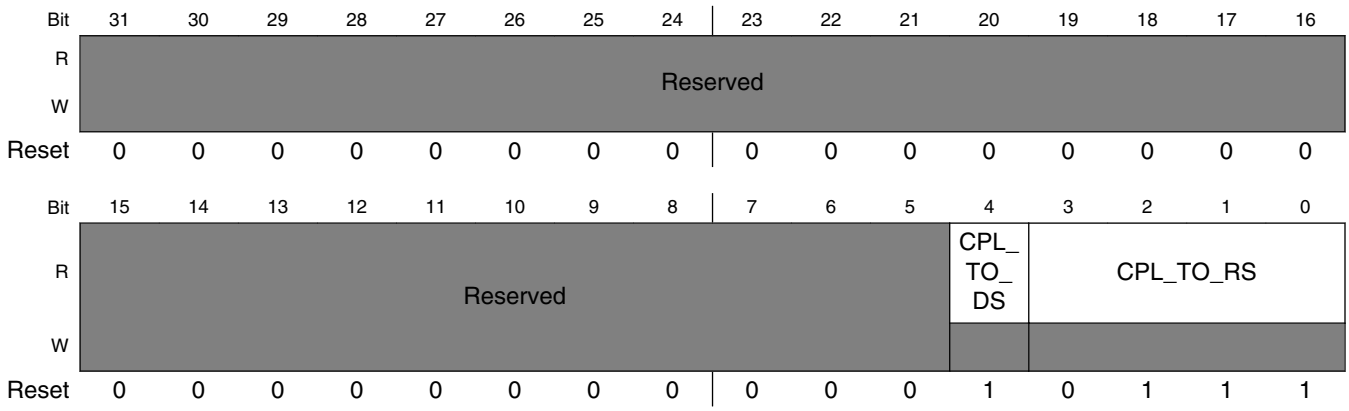


Root Status Register field descriptions

Field	Description
31–18 -	This field is reserved. Reserved
17 PMEP	PME pending.
16 PMES	PME status.
PME requester ID	PME requester ID.

19.5.4.15 PCI Express Device Capabilities 2 Register (Device Capabilities 2 Register)

Address: 70h base + 24h offset = 94h

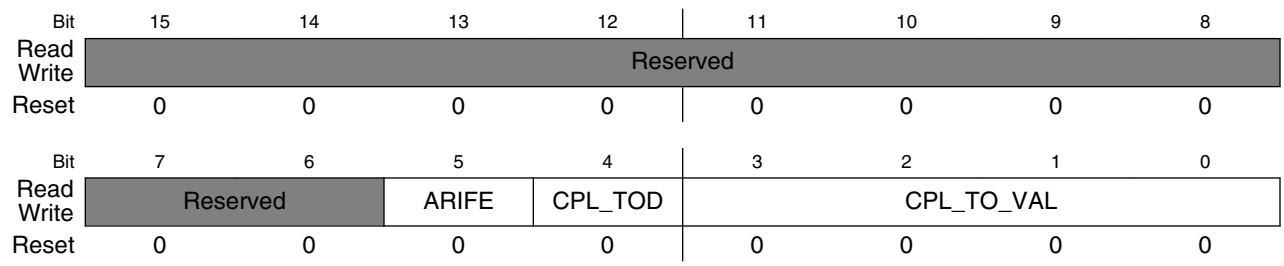


Device Capabilities 2 Register field descriptions

Field	Description
31–5 -	This field is reserved. Reserved
4 CPL_TO_DS	Completion timeout disable supported
CPL_TO_RS	Completion timeout ranges supported

19.5.4.16 PCI Express Device Control 2 Register (Device Control 2 Register)

Address: 70h base + 28h offset = 98h



Device Control 2 Register field descriptions

Field	Description
15–6 -	This field is reserved. Reserved

Table continues on the next page...

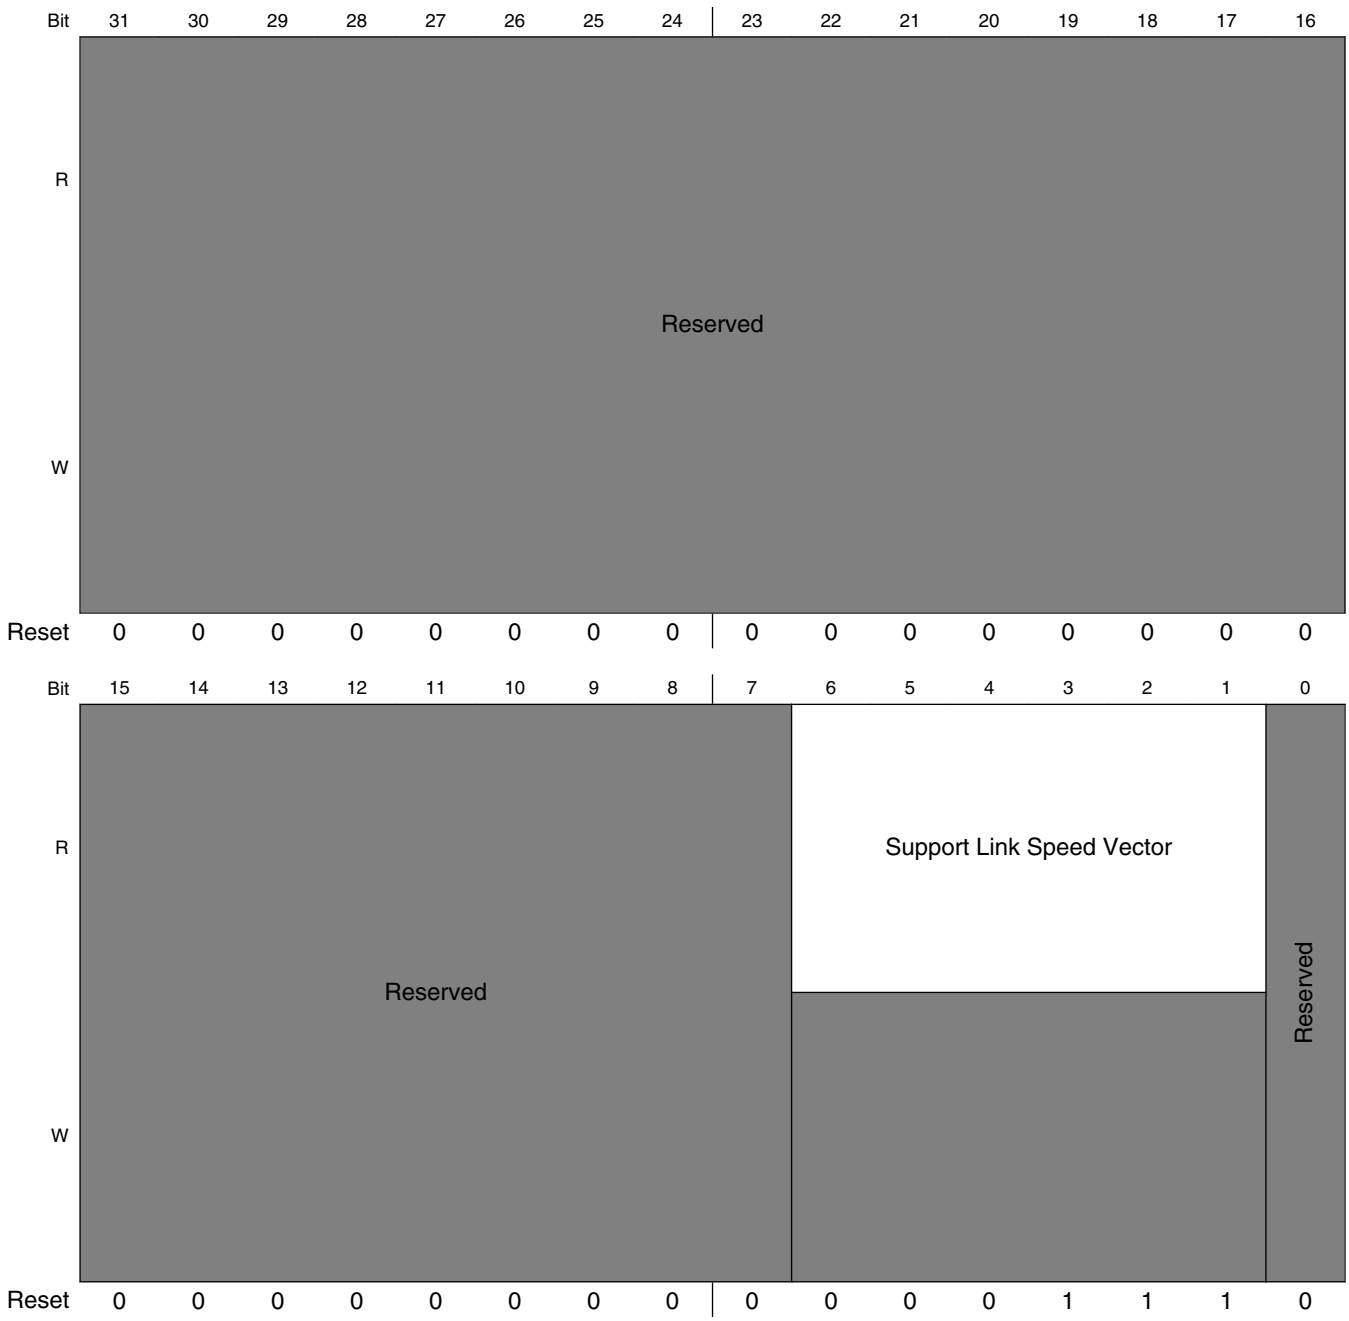
Device Control 2 Register field descriptions (continued)

Field	Description
5 ARIFE	ARI Forwarding Enable. Must be set when RC is communicating with ARI devices. When set will allow RC to issue configuration type 0 cycles with device number != 0.
4 CPL_TOD	Completion timeout disable
CPL_TO_VAL	Completion timeout value

19.5.4.17 PCI Express Link Capabilities 2 Register (Link Capabilities 2 Register)

The PCI Express link capability 2 register is shown below.

Address: 70h base + 2Ch offset = 9Ch



Link Capabilities 2 Register field descriptions

Field	Description
31–7 -	This field is reserved. Reserved
6–1 Support Link Speed Vector	This field indicates the supported Link speed(s) of the associated Port. For each bit, a value of 1 indicates that the corresponding Link speed is supported; otherwise, the Link speed is not supported. Bit definitions are: Bit 1 2.5 GT/s Bit 2 5.0 GT/s Bit 3 8.0 GT/s Other bits are reserved
0 -	This field is reserved. Reserved

19.5.4.18 PCI Express Link Control 2 Register (Link Control 2 Register)

Address: 70h base + 30h offset = A0h

Bit	15	14	13	12	11	10	9	8
Read Write	CDE				CSOS	EMC	TxM	
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read Write	TxM	SDE	HWASD	EC	T_LS			
Reset	0	0	0	0	0	0	1	1

Link Control 2 Register field descriptions

Field	Description
15–12 CDE	Compliance de-emphasis
11 CSOS	Compliance SOS
10 EMC	Enter modified compliance
9–7 TxM	Transmit margin
6 SDE	Selectable de-emphasis
5 HWASD	Hardware autonomous speed disable
4 EC	Enter compliance
T_LS	Target link speed

19.5.4.19 PCI Express Link Status 2 Register (Link Status 2 Register)

Address: 70h base + 32h offset = A2h

Bit	15	14	13	12	11	10	9	8
Read / Write	Reserved							
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read	Reserved		LER	EP3S	EP2S	EP1S	EC	DE_LVL
Write								
Reset	0	0	0	0	0	0	0	0

Link Status 2 Register field descriptions

Field	Description
15–6 -	This field is reserved. Reserved
5 LER	Link equalization request
4 EP3S	Equalization phase 3 complete
3 EP2S	Equalization phase 2 complete
2 EP1S	Equalization phase 1 complete
1 EC	Equalization complete
0 DE_LVL	Current de-emphasis level

Field	Description
31–21 -	This field is reserved. Reserved
20 UREM	Unsupported request error mask.
19 ECRCEM	ECRC error mask.
18 MTLPM	Malformed TLP mask.
17 RXOM	Receiver overflow mask.

Table continues on the next page...

Uncorrectable Error Mask Register field descriptions (continued)

Field	Description
16 UCM	Unexpected completion mask.
15 CAM	Completer abort mask.
14 CTOM	Completion timeout mask.
13 FCPEM	Flow control protocol error mask.
12 PTLPM	Poisoned TLP mask.
11–5 -	This field is reserved. Reserved
4 DLPEM	Data link protocol error mask.
3–1 -	This field is reserved. Reserved
0 TEM	Training error mask.

19.5.6.4 PCI Express Uncorrectable Error Severity Register (Uncorrectable Error Severity Register)

Address: 100h base + Ch offset = 10Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved											URES	ECRCES	MTLPS	RXOS	UCS
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CAS	CTOS	FCPES	PTLPS	Reserved							DLPES	Reserved			TES
Reset	0	0	1	0	0	0	0	0	0	0	0	1	0	0	0	1

Uncorrectable Error Severity Register field descriptions

Field	Description
31–21 -	This field is reserved. Reserved

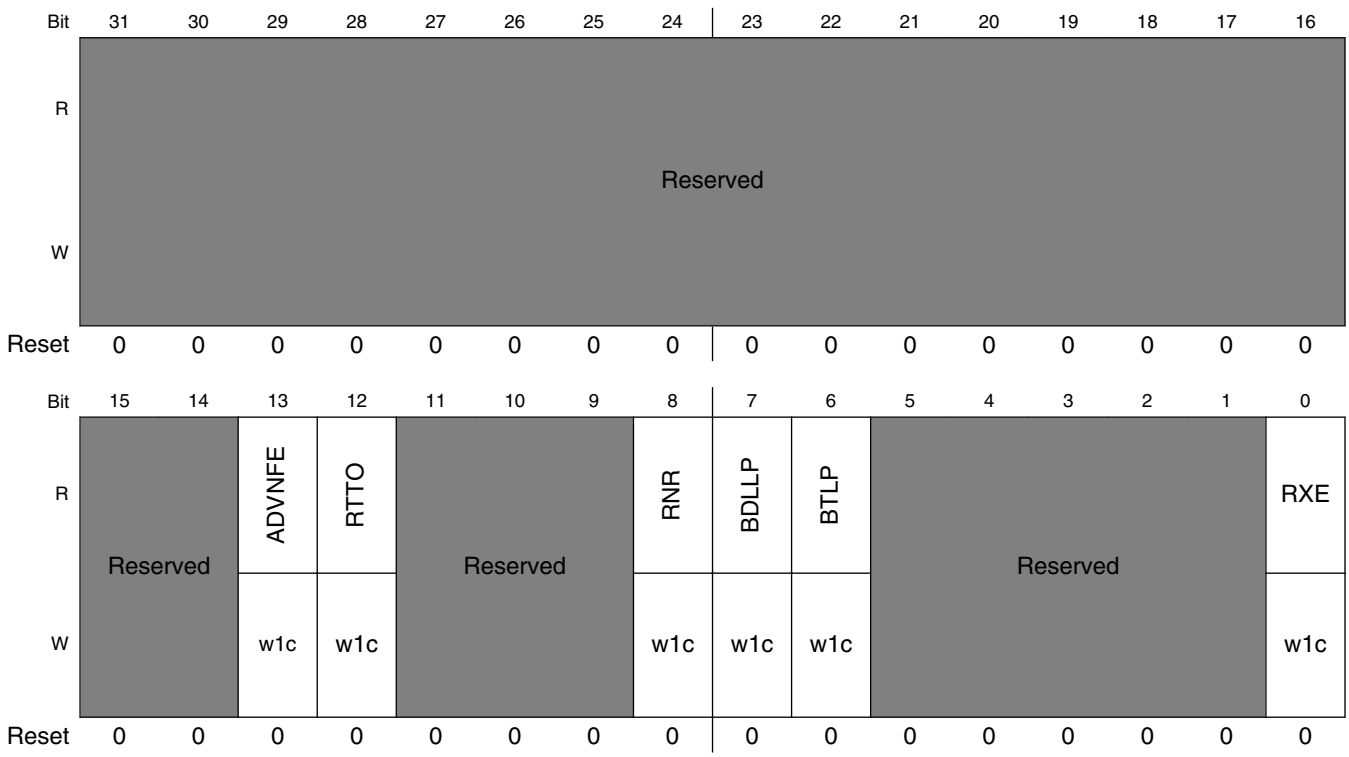
Table continues on the next page...

Uncorrectable Error Severity Register field descriptions (continued)

Field	Description
20 URES	Unsupported request error severity.
19 ECRCES	ECRC error severity.
18 MTLPS	Malformed TLP severity.
17 RXOS	Receiver overflow severity.
16 UCS	Unexpected completion severity.
15 CAS	Completer abort severity.
14 CTOS	Completion timeout severity.
13 FCPES	Flow control protocol error severity.
12 PTLPS	Poisoned TLP severity.
11–5 -	This field is reserved. Reserved
4 DLPES	Data link protocol error severity.
3–1 -	This field is reserved. Reserved
0 TES	Training error severity.

19.5.6.5 PCI Express Correctable Error Status Register (Correctable Error Status Register)

Address: 100h base + 10h offset = 110h



Correctable Error Status Register field descriptions

Field	Description
31–14 -	This field is reserved. Reserved
13 ADVNFE	Advisory Non-Fatal Error Status indicates the occurrence of the advisory error, and the Advisory Non-Fatal Error Mask bit in the PCI Express Correctable Error Mask Register (Correctable Error Mask Register) is checked to determine whether to proceed further with logging and signaling
12 RTTO	Replay timer timeout status
11–9 -	This field is reserved. Reserved
8 RNR	REPLAY_NUM Rollover status
7 BDLLP	Bad DLLP status
6 BTLP	Bad TLP status
5–1 -	This field is reserved. Reserved

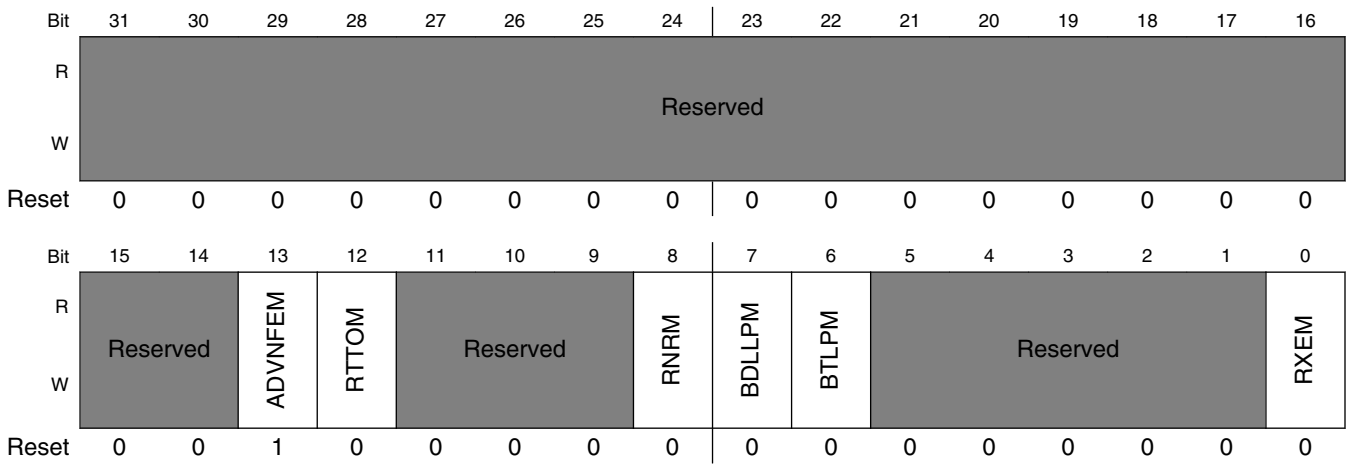
Table continues on the next page...

Correctable Error Status Register field descriptions (continued)

Field	Description
0 RXE	Receiver error status

19.5.6.6 PCI Express Correctable Error Mask Register (Correctable Error Mask Register)

Address: 100h base + 14h offset = 114h

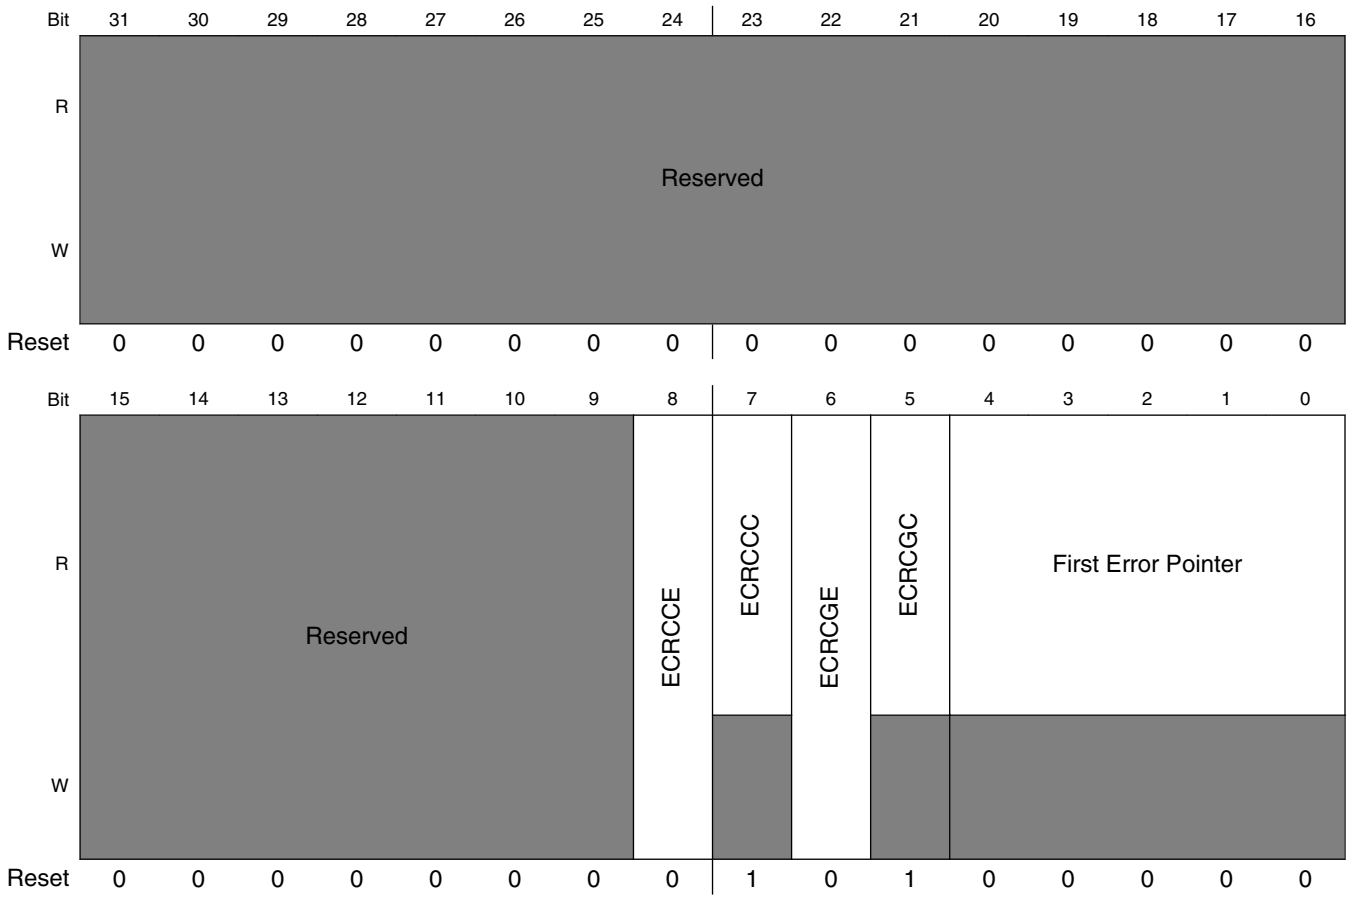


Correctable Error Mask Register field descriptions

Field	Description
31–14 -	This field is reserved. Reserved
13 ADVNFEM	Advisory non-fatal error mask. This bit is Set by default to enable compatibility with software that does not comprehend Role-Based Error Reporting
12 RTTOM	Replay timer timeout mask
11–9 -	This field is reserved. Reserved
8 RNRM	REPLAY_NUM Rollover mask
7 BDLLPM	Bad DLLP mask
6 BTLPM	Bad TLP mask
5–1 -	This field is reserved. Reserved
0 RXEM	Receiver error mask

19.5.6.7 PCI Express Advanced Error Capabilities and Control Register (Advanced Error Capabilities and Control Register)

Address: 100h base + 18h offset = 118h



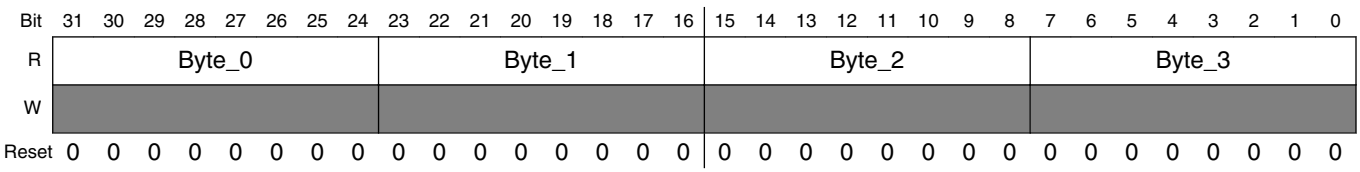
Advanced Error Capabilities and Control Register field descriptions

Field	Description
31–9 -	This field is reserved. Reserved
8 ECRCCE	ECRC checking enable.
7 ECRCCC	ECRC checking capable.
6 ECRCGE	ECRC generation enable.
5 ECRCGC	ECRC generation capable.
First Error Pointer	The First Error Pointer is a read-only register that identifies the bit position of the first error reported in the Uncorrectable Error Status register.

19.5.6.8 PCI Express Header Log Register 1 (Header_Log_Register_DWORD1)

The first DWORD of the PCI Express header log register is shown in the figure below.

Address: 100h base + 1Ch offset = 11Ch



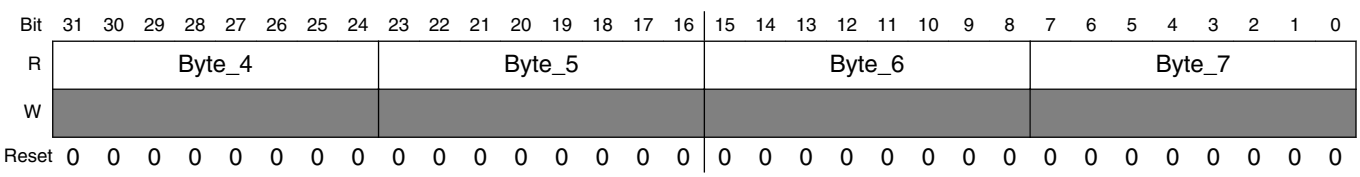
Header_Log_Register_DWORD1 field descriptions

Field	Description
31–24 Byte_0	Byte n of the TLP header associated with the error.
23–16 Byte_1	Byte n of the TLP header associated with the error.
15–8 Byte_2	Byte n of the TLP header associated with the error.
Byte_3	Byte n of the TLP header associated with the error.

19.5.6.9 PCI Express Header Log Register 2 (Header_Log_Register_DWORD2)

The second DWORD of the PCI Express header log register is shown in the figure below.

Address: 100h base + 20h offset = 120h



Header_Log_Register_DWORD2 field descriptions

Field	Description
31–24 Byte_4	Byte n of the TLP header associated with the error.

Table continues on the next page...

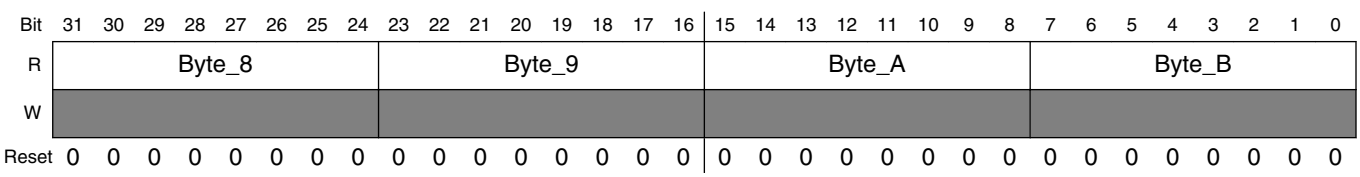
Header_Log_Register_DWORD2 field descriptions (continued)

Field	Description
23–16 Byte_5	Byte n of the TLP header associated with the error.
15–8 Byte_6	Byte n of the TLP header associated with the error.
Byte_7	Byte n of the TLP header associated with the error.

19.5.6.10 PCI Express Header Log Register 3 (Header_Log_Register_DWORD3)

The third DWORD of the PCI Express header log register is shown in the figure below.

Address: 100h base + 24h offset = 124h



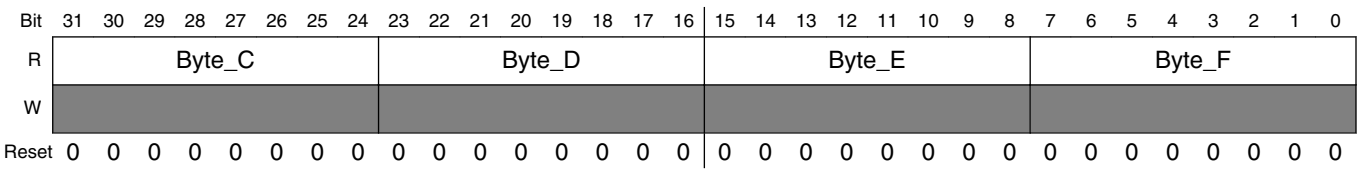
Header_Log_Register_DWORD3 field descriptions

Field	Description
31–24 Byte_8	Byte n of the TLP header associated with the error.
23–16 Byte_9	Byte n of the TLP header associated with the error.
15–8 Byte_A	Byte n of the TLP header associated with the error.
Byte_B	Byte n of the TLP header associated with the error.

19.5.6.11 PCI Express Header Log Register 4 (Header_Log_Register_DWORD4)

The fourth DWORD of the PCI Express header log register is shown in the figure below.

Address: 100h base + 28h offset = 128h



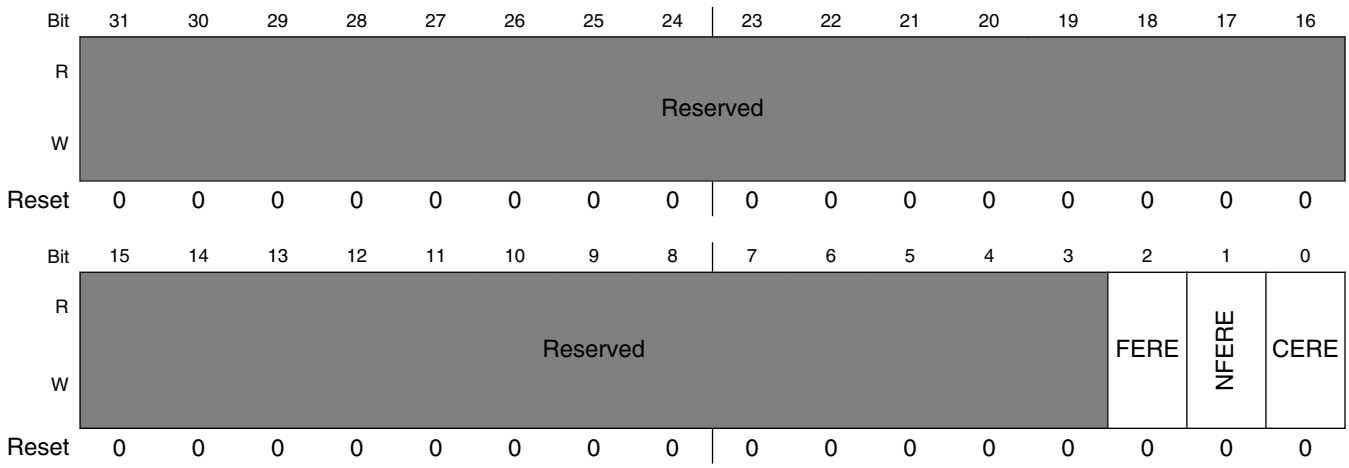
Header_Log_Register_DWORD4 field descriptions

Field	Description
31–24 Byte_C	Byte n of the TLP header associated with the error.
23–16 Byte_D	Byte n of the TLP header associated with the error.
15–8 Byte_E	Byte n of the TLP header associated with the error.
Byte_F	Byte n of the TLP header associated with the error.

19.5.6.12 PCI Express Root Error Command Register (Root Error Command Register)

This register is supported only for RC mode.

Address: 100h base + 2Ch offset = 12Ch



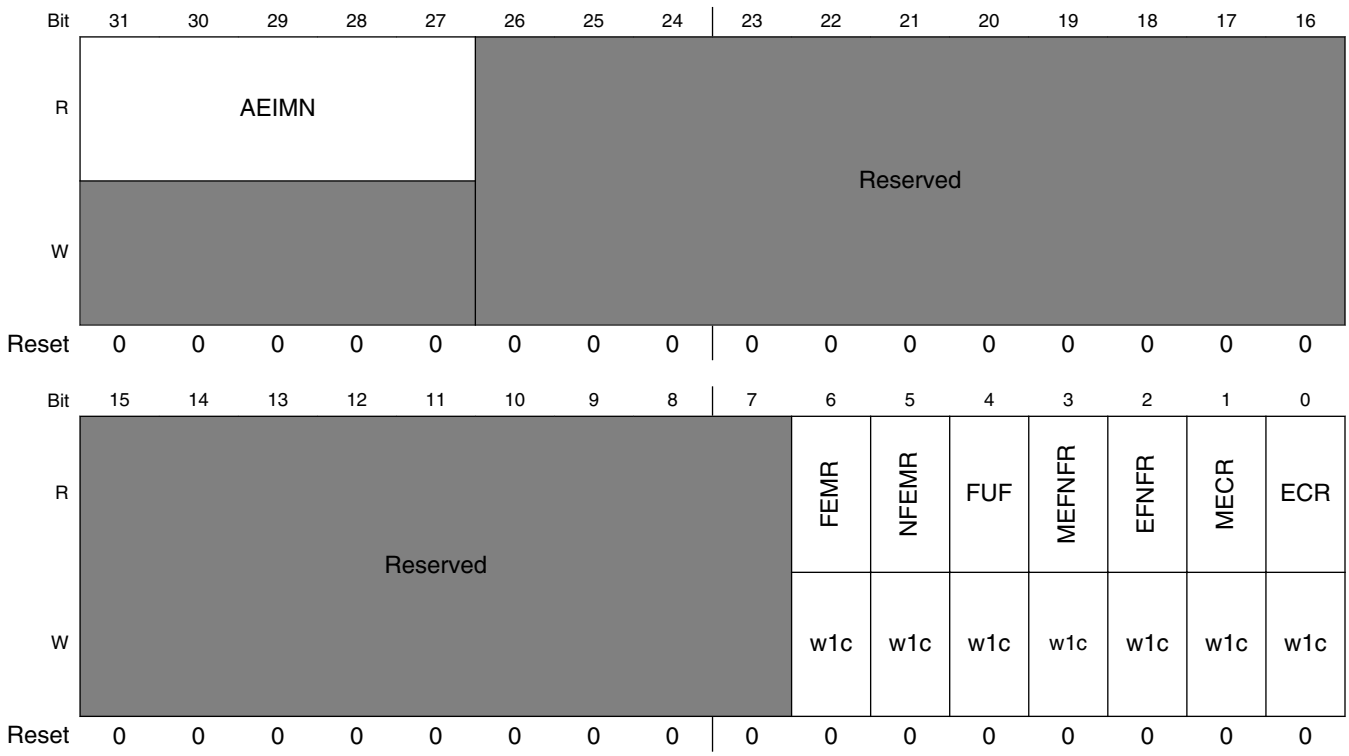
Root Error Command Register field descriptions

Field	Description
31–3 -	This field is reserved. Reserved
2 FERE	Fatal error reporting enable.
1 NFERE	Non-fatal error reporting enable
0 CERE	Correctable error reporting enable

19.5.6.13 PCI Express Root Error Status Register (Root Error Status Register)

This register is supported only for RC mode.

Address: 100h base + 30h offset = 130h



Root Error Status Register field descriptions

Field	Description
31–27 AEIMN	Advanced error interrupt message number.
26–7 -	This field is reserved. Reserved
6 FEMR	Fatal error messages received.
5 NFEMR	Non-fatal error messages received.
4 FUF	First uncorrectable fatal.
3 MEFNFR	Multiple ERR_FATAL/NONFATAL received.
2 EFNFR	ERR_FATAL/NONFATAL received.

Table continues on the next page...

Root Error Status Register field descriptions (continued)

Field	Description
1 MECR	Multiple ERR_COR received.
0 ECR	ERR_COR received.

19.5.6.14 PCI Express Correctable Error Source ID Register (Correctable Error Source ID Register)

Address: 100h base + 34h offset = 134h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	ERR_COR Source ID															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Correctable Error Source ID Register field descriptions

Field	Description
ERR_COR Source ID	Loaded with the requester ID indicated in the received ERR_COR Message when the ERR_COR Received register is not already set. Default value of this field is 0.

19.5.6.15 PCI Express Error Source ID Register (Error Source ID Register)

Address: 100h base + 36h offset = 136h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	Error Source ID															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Error Source ID Register field descriptions

Field	Description
Error Source ID	ERR_FATAL/NONFATAL source ID

19.5.7 Alternate routing ID capability structure (SR-IOV only)

memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
148	ARI Capability Header (ARI Capability Header)	32	R	See section	19.5.7.1/ 1562
14C	ARI Capability Register (ARI Capability Register)	16	R	0000h	19.5.7.2/ 1563
14E	ARI Control Register (ARI Control Register)	16	R	0000h	19.5.7.3/ 1564

19.5.7.1 ARI Capability Header (ARI Capability Header)

This register applies to SR-IOV-only.

Address: 148h base + 0h offset = 148h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	NEXT_OFFSET												CAP_VERSION			
W																
Reset	n	n	n	n	n	n	n	n	n	n	n	n	0	0	0	1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Extended Capability ID															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	0

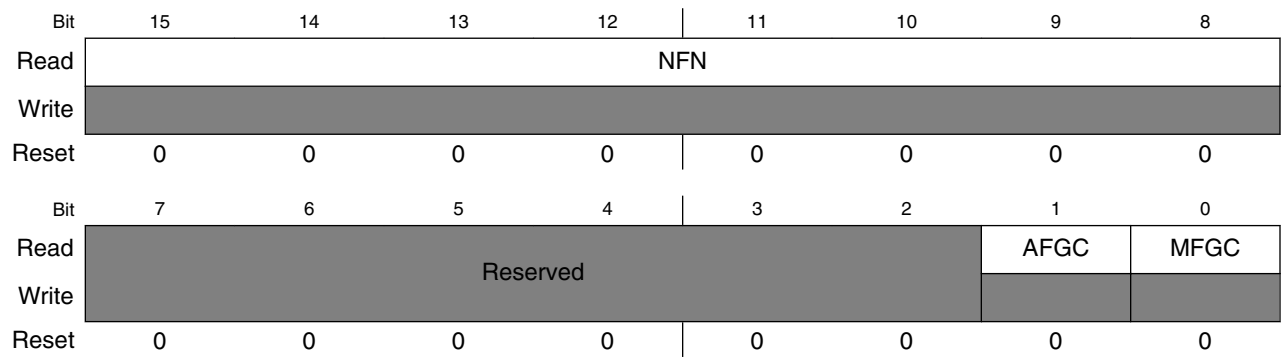
ARI Capability Header field descriptions

Field	Description
31–20 NEXT_OFFSET	This field is a pointer to the next capability structure. **NOTE:** The reset value of this field depends on the instantiation of the module. See PCI Express configuration-space registers for the specific values.
19–16 CAP_VERSION	Indicates the version of the Capability structure present.
Extended Capability ID	ARI extended capability = 0x000E

19.5.7.2 ARI Capability Register (ARI Capability Register)

This register applies to SR-IOV-only.

Address: 148h base + 4h offset = 14Ch



ARI Capability Register field descriptions

Field	Description
15–8 NFN	Next function number. This field indicates the Function Number of the next higher numbered Function in the Device, or 00h if there are no higher numbered Functions. Function 0 starts this linked list of Functions.
7–2 -	This field is reserved.
1 AFGC	ACS Function Groups Capability. Applicable only for Function 0; must be 0b for all other Functions. If 1b, indicates that the ARI Device supports Function Group level granularity for ACS P2P Egress Control via its ACS Capability structures.
0 MFGC	MFVC Function Groups Capability. Applicable only for Function 0; must be 0b for all other Functions. If 1b, indicates that the ARI Device supports Function Group level arbitration via its Multi-Function Virtual Channel (MFVC) Capability structure.

19.5.7.3 ARI Control Register (ARI Control Register)

This register applies to SR-IOV-only.

Address: 148h base + 6h offset = 14Eh

Bit	15	14	13	12	11	10	9	8
Read / Write	Reserved							
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read	Reserved	FG			Reserved		AFGE	MFGE
Write								
Reset	0	0	0	0	0	0	0	0

ARI Control Register field descriptions

Field	Description
15–7 -	This field is reserved.
6–4 FG	Function Group. Assigns a Function Group Number to this Function.
3–2 -	This field is reserved.
1 AFGE	ACS Function Groups Enable. Applicable only for Function 0; must be hardwired to 0b for all other Functions. When set, each Function in the ARI Device must associate bits within its Egress Control Vector with Function Group Numbers rather than Function Numbers. Default value of this field is 0b. Must be hardwired to 0b if the ACS Function Groups Capability bit is 0b.
0 MFGE	MFVC Function Groups Enable. Applicable only for Function 0; must be hardwired to 0b for all other Functions. When set, the ARI Device must interpret entries in its Function Arbitration Table as Function Group Numbers rather than Function Numbers. Default value of this field is 0b. Must be hardwired to 0b if the MFVC Function Groups Capability bit is 0b.

19.5.8 Secondary PCI Express capability structure (Non-SR-IOV)

NOTE

For PEX modules that do not support SR-IOV, the Secondary PCI Express Capability Stucture is located at offset 148h.

memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
148	Secondary PCIE Capability Header (SPCIE_CAP_HEADER_REG)	32	R	See section	19.5.8.1/ 1565

W																
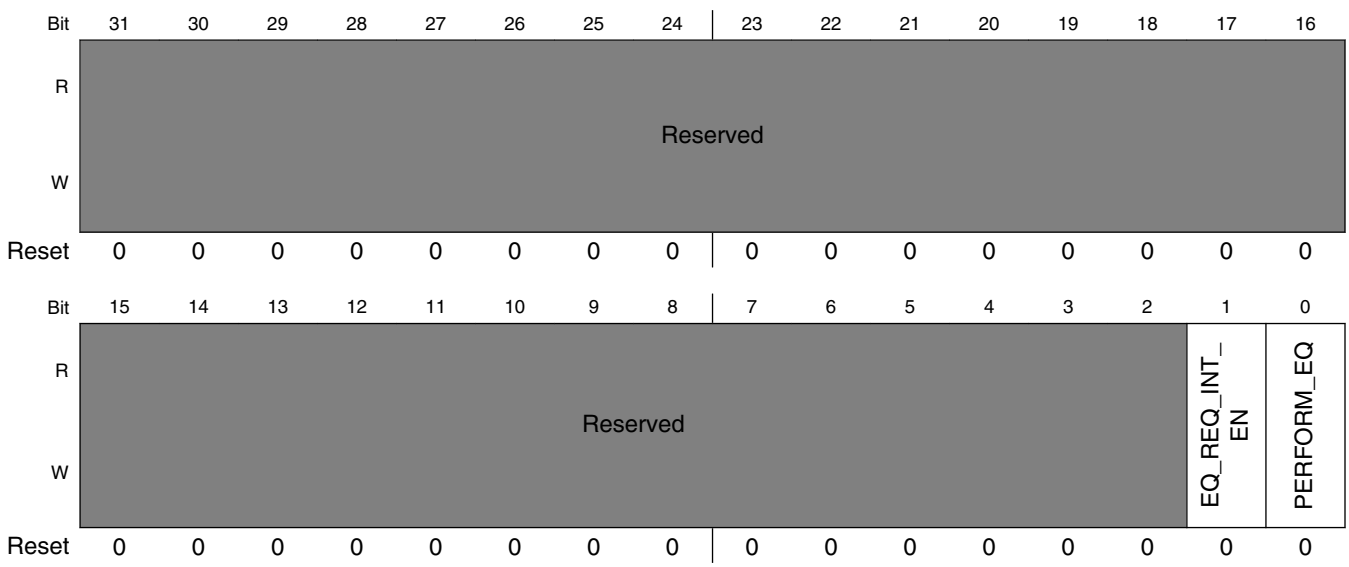
Reset	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	1

SPCIE_CAP_HEADER_REG field descriptions

Field	Description
31–20 NEXT_OFFSET	This field is a pointer to the next capability structure.
19–16 CAP_VERSION	Indicates the version of the Capability structure present.
EXTENDED_ CAP_ID	Secondary PCI Express capability = 0019h

19.5.8.2 Link Control 3 Register (LINK_CONTROL3_REG)

Address: 148h base + 4h offset = 14Ch



LINK_CONTROL3_REG field descriptions

Field	Description
31–2 -	This field is reserved. Reserved
1 EQ_REQ_INT_ EN	Link Equalization Request Interrupt Enable This bit is RW for Downstream Ports only.
0 PERFORM_EQ	Perform Equalization This bit is RW for Downstream Ports only.

19.5.8.3 Lane Error Status Register (LANE_ERR_STATUS_REG)

Address: 148h base + 8h offset = 150h

Bit	31–16	15–8	7–0
R	Reserved		LANE_ERR_STATUS
W			w1c
Reset	0	0	0

LANE_ERR_STATUS_REG field descriptions

Field	Description
31–8 -	This field is reserved. Reserved
LANE_ERR_ STATUS	Lane Error Status Bits—Each bit indicates if the corresponding Lane detected a Lane-based error.

19.5.8.4 Lane Equalization Control Register (LANE*n*_EQUALIZATION_CONTROL)

Address: 148h base + Ch offset + (2d × i), where i=0d to 7d

Bit	15	14–12	11–8
Read	Reserved	USP_RX_PRESET_HINT	USP_TX_PRESET
Write			
Reset	0	1 1 1	1 1 1 1

Bit	7	6–4	3–0
Read	Reserved	DSP_RX_PRESET_HINT	DSP_TX_PRESET
Write			
Reset	0	1 1 1	1 1 1 1

LANE*n*_EQUALIZATION_CONTROL field descriptions

Field	Description
15 -	This field is reserved. Reserved
14–12 USP_RX_ PRESET_HINT	Upstream Port Receiver Preset Hint
11–8 USP_TX_ PRESET	Upstream Port Transmitter Preset
7 -	This field is reserved. Reserved

Table continues on the next page...

LANE*n*_EQUALIZATION_CONTROL field descriptions (continued)

Field	Description
6–4 DSP_RX_ PRESET_HINT	Downstream Port Receiver Preset Hint
DSP_TX_ PRESET	Downstream Port Transmitter Preset.

19.5.9 Secondary PCI Express capability structure (SR-IOV)

NOTE

For PEX modules that support SR-IOV, the Secondary PCI Express Capability Stucture is located at offset 158h.

memory map

19.5.10.1 PCI Express SR-IOV Extended Capability ID Register (SR-IOV Extended Capability ID Register)

This register applies to SR-IOV-only.

Address: 178h base + 0h offset = 178h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	Extended Capability ID															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

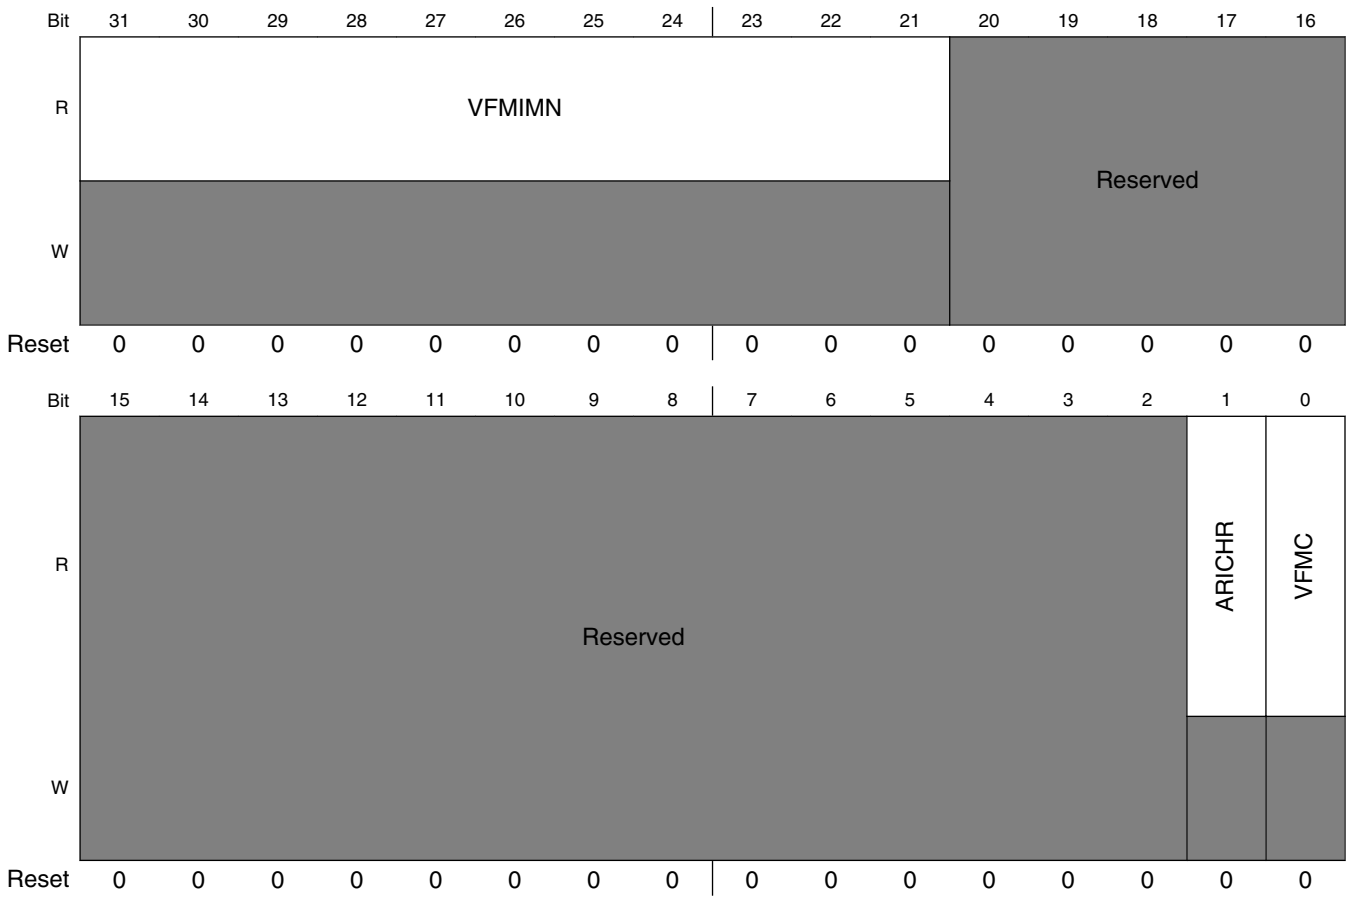
SR-IOV Extended Capability ID Register field descriptions

Field	Description
Extended Capability ID	SR-IOV extended capability = 0x0010

19.5.10.2 PCI Express SR-IOV Capabilities Register (SR-IOV Capabilities Register)

This register applies to SR-IOV-only.

Address: 178h base + 4h offset = 17Ch



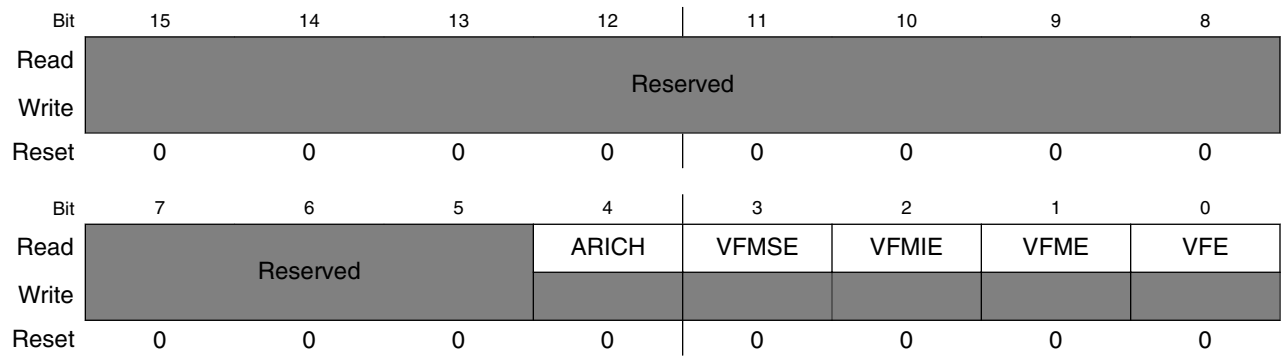
SR-IOV Capabilities Register field descriptions

Field	Description
31–21 VFMIMN	VF Migration Interrupt Message Number. Indicates the MSI/MSI-X vector used for migration interrupts. The value in this field is undefined if VF Migration Capable is clear.
20–2 -	This field is reserved.
1 ARICHR	ARI Capable Hierarchy Preserved. If set, the ARI Capable Hierarchy bit is preserved across certain power state transitions.
0 VFMC	VF Migration Capable. If set, the PF is Migration Capable and operating under a Migration Capable MR-PCIM.

19.5.10.3 PCI Express SR-IOV Control Register (SR-IOV Control Register)

This register applies to SR-IOV-only.

Address: 178h base + 8h offset = 180h



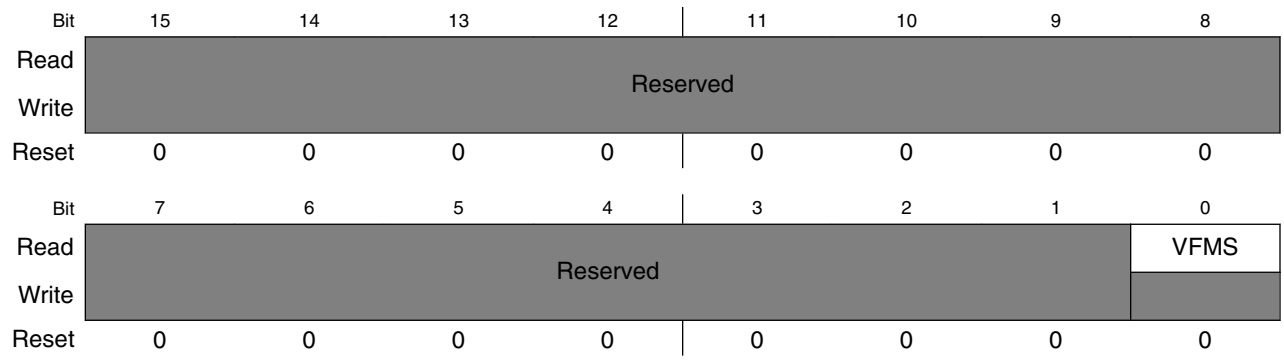
SR-IOV Control Register field descriptions

Field	Description
15–5 -	This field is reserved.
4 ARICH	ARI Capable Hierarchy PCI Express Endpoint: The device is permitted to locate VFs in Function numbers 8 to 255 of the captured Bus Number. Default value is 0. This field is RW in the lowest numbered PF of the Device and is Read Only Zero in all other PFs. Root Complex Integrated Endpoint: Not applicable. Must hardwire the bit to 0
3 VFMSE	VF MSE. Memory Space Enable for Virtual Functions.
2 VFMIE	VF Migration Interrupt Enable. Enables/Disables VF Migration State Change Interrupt. Default value is 0b.
1 VFME	VF Migration Enable. Enables/Disables VF Migration Support. Default value is 0b.
0 VFE	VF Enable. Enables/Disables VFs. Default value is 0.

19.5.10.4 PCI Express SR-IOV Status Register (SR-IOV Status Register)

This register applies to SR-IOV-only.

Address: 178h base + Ah offset = 182h



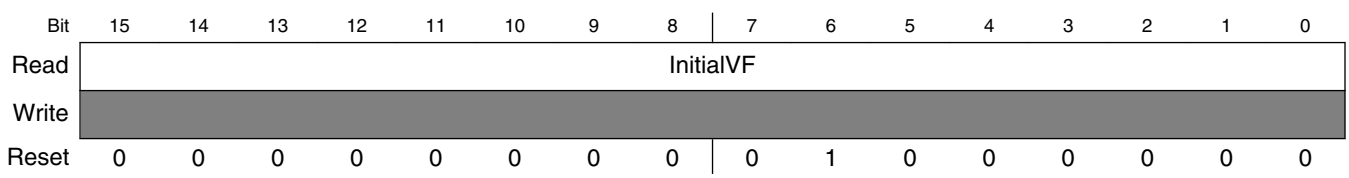
SR-IOV Status Register field descriptions

Field	Description
15–1 -	This field is reserved.
0 VFMS	VF Migration Status. Indicates a VF Migration In or Migration Out Request has been issued by MR-PCIM. To determine the cause of the event, software may scan the VF State Array. Default value is 0b.

19.5.10.5 PCI Express SR-IOV Initial VF Register (SR-IOV Initial VF Register)

This register applies to SR-IOV-only.

Address: 178h base + Ch offset = 184h



SR-IOV Initial VF Register field descriptions

Field	Description
InitialVF	Initial VF. Indicates to SR-PCIM the number of VFs that are initial associated with the PF.The minimum value of InitialVFs is 0.

19.5.10.6 PCI Express SR-IOV Total VF Register (SR-IOV Total VF Register)

This register applies to SR-IOV-only.

Address: 178h base + Eh offset = 186h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	TotalVF															
Write																
Reset	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

SR-IOV Total VF Register field descriptions

Field	Description
TotalVF	Total VF. indicates the maximum number of VFs that could be associated with the PF.The minimum value of TotalVFs is 0.

19.5.10.7 PCI Express SR-IOV Number VF Register (SR-IOV Number VF Register)

This register applies to SR-IOV-only.

Address: 178h base + 10h offset = 188h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	NumberVF															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SR-IOV Number VF Register field descriptions

Field	Description
NumberVF	Number of VF. Controls the number of VFs that are visible. Only supports a number that is a power of 2 (that is, 1, 2, 4, 8, 16...).

19.5.10.8 PCI Express SR-IOV Function Dependency Link Register (SR-IOV Function Dependency Link Register)

This register applies to SR-IOV-only.

Address: 178h base + 12h offset = 18Ah

Bit	7	6	5	4	3	2	1	0
Read Write	FDL							
Reset	0	0	0	0	0	0	0	0

SR-IOV Function Dependency Link Register field descriptions

Field	Description
FDL	Function Dependency Link. This field describes dependencies between PFs.

19.5.10.9 PCI Express SR-IOV First VF Offset Register (SR-IOV First VF Offset Register)

This register applies to SR-IOV-only.

Address: 178h base + 14h offset = 18Ch

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	FVFO															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SR-IOV First VF Offset Register field descriptions

Field	Description
FVFO	First VF Offset. Defines the Routing ID offset of the first VF that is associated with the PF that contains this Capability structure. For PF0, it is 0x0004. For PF1, it is 0x0100.

19.5.10.10 PCI Express SR-IOV VF Stride Register (SR-IOV VF Stride Register)

This register applies to SR-IOV-only.

Address: 178h base + 16h offset = 18Eh

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	VFS															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SR-IOV VF Stride Register field descriptions

Field	Description
VFS	VF Stride. Defines the Routing ID offset from one VF to the next one for all VFs associated with the PF that contains this Capability structure. For PF0, it is 0x0004. For PF1, it is 0x0100.

19.5.10.11 PCI Express SR-IOV Device ID Register (SR-IOV Device ID Register)

This register applies to SR-IOV-only.

Address: 178h base + 1Ah offset = 192h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	Device ID															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

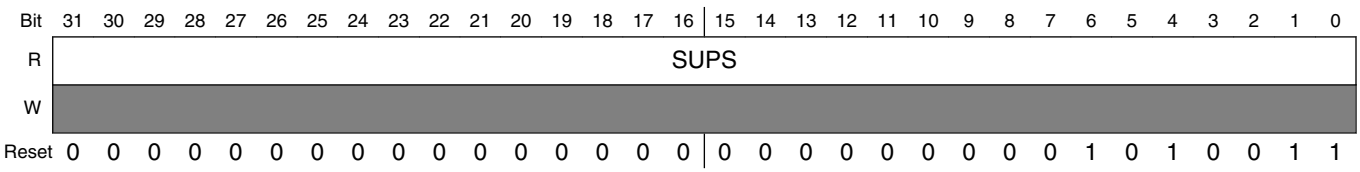
SR-IOV Device ID Register field descriptions

Field	Description
Device ID	Device ID.

19.5.10.12 PCI Express SR-IOV Supported Page Size Register (SR-IOV Supported Page Size Register)

This register applies to SR-IOV-only.

Address: 178h base + 1Ch offset = 194h



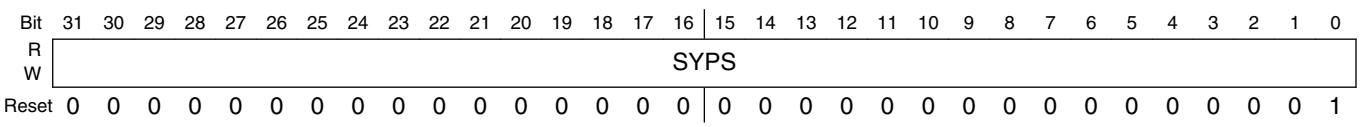
SR-IOV Supported Page Size Register field descriptions

Field	Description
SUPS	Supported Page Size.

19.5.10.13 PCI Express SR-IOV System Page Size Register (SR-IOV System Page Size Register)

This register applies to SR-IOV-only.

Address: 178h base + 20h offset = 198h



SR-IOV System Page Size Register field descriptions

Field	Description
SYPS	System Page Size. Defines the page size the system will use to map the VFs memory addresses.

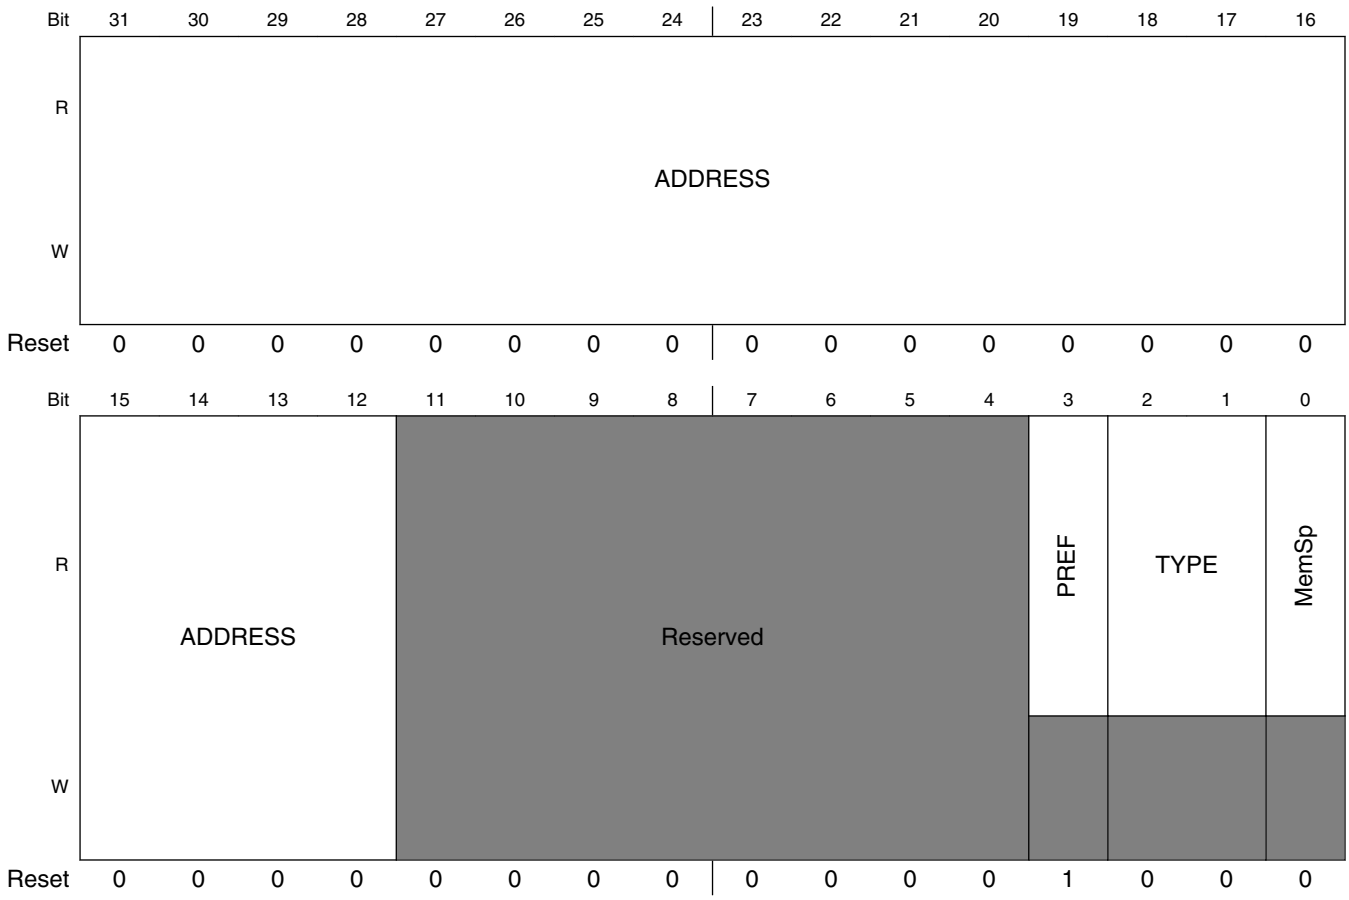
19.5.10.14 PCI Express SR-IOV VF Base Address Register 0 (VFBAR0)

This register applies to SR-IOV-only.

The PCI Express VF base address registers (VF BARs) point to the beginning of distinct address ranges which the device should claim. In EP mode, the device supports two 32-bit memory space BARs, and two 64-bit memory space BARs.

Base address register 0 at offset 0x174 and base address register 1 at offset 0x178 are used to define the inbound memory windows in the 32-bit memory space.

Address: 178h base + 24h offset = 19Ch



VFBAR0 field descriptions

Field	Description
31–12 ADDRESS	Indicates the base address where the inbound memory window begins. The number of upper bits that the device allows to be writable is selected through the inbound window size in the VF inbound window attributes register (PEXVFIWAR0,1).
11–4 -	This field is reserved. Reserved. The device allows a 4 Kbyte window minimum.
3 PREF	Prefetchable. This bit is determined by PEXVFIWAR0,1[PF].
2–1 TYPE	Type. 00 Locate anywhere in 32-bit address space.
0 MemSp	Memory space indicator.

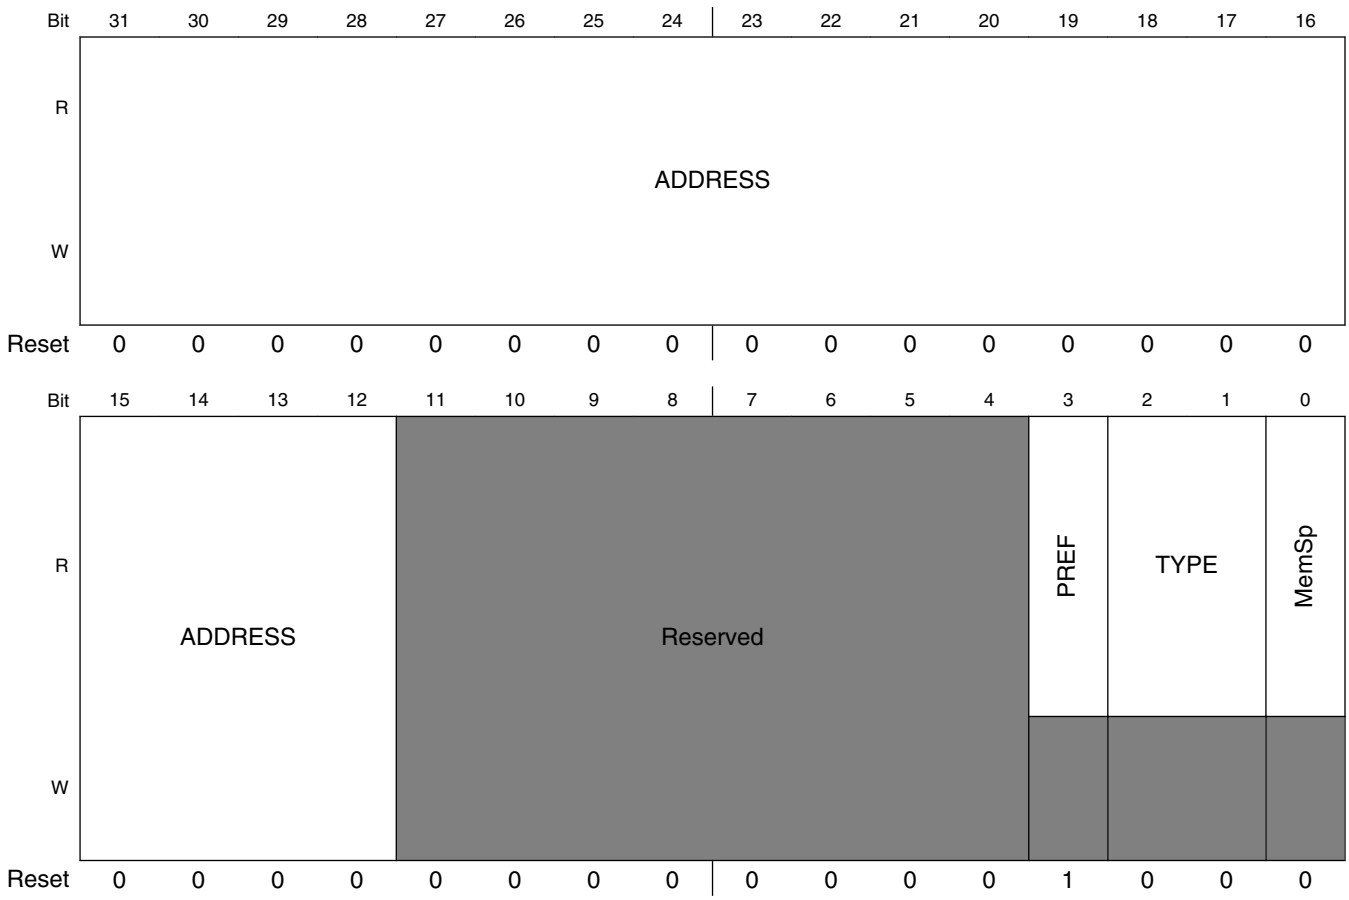
19.5.10.15 PCI Express SR-IOV VF Base Address Register 1 (VFBAR1)

This register applies to SR-IOV-only.

The PCI Express VF base address registers (VF BARs) point to the beginning of distinct address ranges which the device should claim. In EP mode, the device supports two 32-bit memory space BARs, and two 64-bit memory space BARs.

Base address register 0 at offset 0x174 and base address sregister 1 at offset 0x178 are used to define the inbound memory windows in the 32-bit memory space.

Address: 178h base + 28h offset = 1A0h



VFBAR1 field descriptions

Field	Description
31–12 ADDRESS	Indicates the base address where the inbound memory window begins. The number of upper bits that the device allows to be writable is selected through the inbound window size in the VF inbound window attributes register (PEXVFIWAR0,1).

Table continues on the next page...

VFBAR1 field descriptions (continued)

Field	Description
11–4 -	This field is reserved. Reserved. The device allows a 4 Kbyte window minimum.
3 PREF	Prefetchable. This bit is determined by PEXVFIWAR0,1[PF].
2–1 TYPE	Type. 00 Locate anywhere in 32-bit address space.
0 MemSp	Memory space indicator.

19.5.10.16 PCI Express SR-IOV VF Base Address Register 2 (VFBAR2)

This register applies to SR-IOV-only.

The PCI Express VF base address registers (VF BARs) point to the beginning of distinct address ranges which the device should claim. In EP mode, the device supports two 32-bit memory space BARs, and two 64-bit memory space BARs.

Base address register 2 at offset 0x17C and base address register 4 at offset 0x184 are used to define the lower portion of the 64-bit inbound memory windows.

Address: 178h base + 2Ch offset = 1A4h

VFBAR2 field descriptions

Field	Description
31–12 ADDRESS	Indicates the lower portion of the base address where the inbound memory window begins. The number of bits that the device allows to be writable is selected through the inbound window size in the inbound window attributes registers (PEXVFIWAR2 for VF BAR2 and PEXVFIWAR3 for VF BAR4).
11–4 -	This field is reserved. Reserved. The device allows a 4 Kbyte window minimum.
3 PREF	Prefetchable. This bit is determined by PEXVFIWAR2,3[2].
2–1 TYPE	Type. 0b10 Locate anywhere in 64-bit address space.
0 MemSp	Memory space indicator

19.5.10.17 PCI Express SR-IOV VF Base Address Register 3 (VFBAR3)

This register applies to SR-IOV-only.

The PCI Express VF base address registers (VF BARs) point to the beginning of distinct address ranges which the device should claim. In EP mode, the device supports two 32-bit memory space BARs, and two 64-bit memory space BARs.

Base address register 3 at offset 0x180 and base address register 5 at offset 0x188 are used to define the upper portion of the 64-bit inbound memory windows.

Address: 178h base + 30h offset = 1A8h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

VFBAR3 field descriptions

Field	Description
ADDRESS	Indicates the upper portion of the base address where the inbound memory window begins. The number of bits that the device allows to be writable is selected through the inbound window size in the inbound window attributes registers (PEXVFIWAR2 for VF BAR3 and PEXVFIWAR3 for VF BAR5). If no access to local memory is to be permitted by external requesters, then all bits are programmed.

19.5.10.18 PCI Express SR-IOV VF Base Address Register 4 (VFBAR4)

This register applies to SR-IOV-only.

The PCI Express VF base address registers (VF BARs) point to the beginning of distinct address ranges which the device should claim. In EP mode, the device supports two 32-bit memory space BARs, and two 64-bit memory space BARs.

Base address register 2 at offset 0x17C and base address register 4 at offset 0x184 are used to define the lower portion of the 64-bit inbound memory windows.

Address: 178h base + 34h offset = 1ACh

Field	Description

19.6 Functional Description

The PCI Express protocol relies on a requestor/completer relationship where one device requests that some desired action be performed by some target device and the target device completes the task and responds. Usually the requests and responses occur through a network of links, but to the requester and to the completer, the intermediate components are transparent.

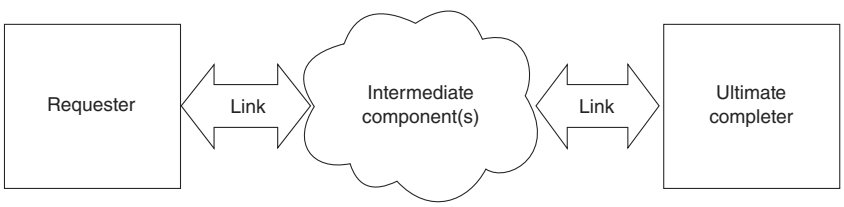

Figure 19-3. Requester/Completer Relationship

Each PCI Express device is divided into two halves—transmit (TX) and receive (RX), and each of these halves is further divided into three layers—transaction, data link, and physical, as shown in the following figure.

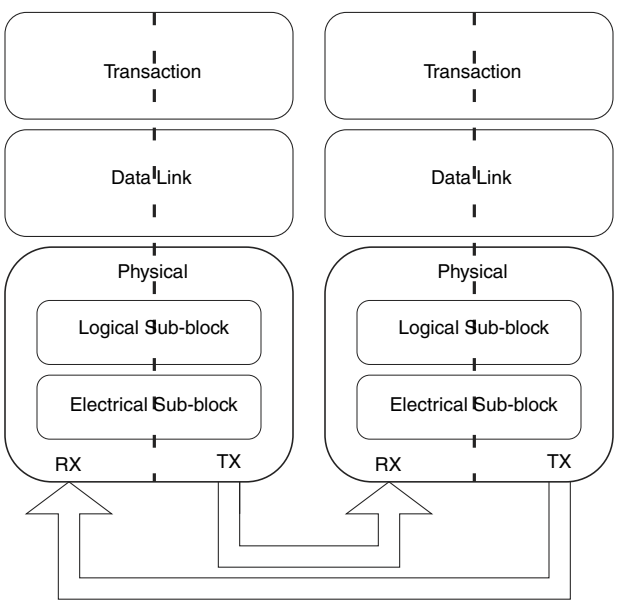

Figure 19-4. PCI Express High-Level Layering

Packets are formed in the transaction layer (TLPs) and data link layer (DLLPs), and each subsequent layer adds the necessary encodings and framing, as shown in the following figure. As packets are received, they are decoded and processed by the same layers but in reverse order, so they may be processed by the layer or by the device application software.

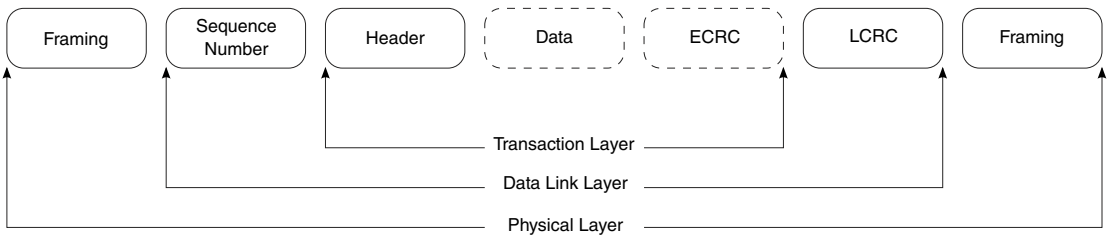

Figure 19-5. PCI Express Packet Flow

19.6.1 Architecture

This section describes implementation details of the PCI Express controller.

19.6.1.1 PCI Express Transactions

The following table contains the list of transactions that the PCI Express controller supports as an initiator and a target.

Table 19-5. PCI Express Transactions

PCI Express Transaction	Supported as an Initiator	Supported as a Target	Definition
Mrd	Yes	Yes	Memory Read Request
MRdLk	No	No	Memory Read Lock. As a target, CplLk with UR status is returned.
MWr	Yes	Yes	Memory Write Request to memory-mapped PCI-Express space
IORd	Yes (RC only)	No	I/O Read request. As a target, Cpl with UR status is returned.
IOWr	Yes (RC only)	No	I/O Write Request. As a target, Cpl with UR status is returned.
CfgRd0	Yes (RC only)	Yes (EP only)	Configuration Read Type 0.
CfgWr0	Yes (RC only)	Yes (EP only)	Configuration Write Type 0.
CfgRd1	Yes (RC only)	No	Configuration Read Type 1. As a target, Cpl with UR status is returned.
CfgWr1	Yes (RC only)	No	Configuration Write Type 1. As a target, Cpl with UR status is returned.
Msg	Yes	Yes	Message Request. Message without data is not forwarded to memory.
MsgD	Yes (RC only)	Yes (EP only)	Message Request with Data payload. Note that Set_Slot_Power_Limit is the only message with data that is supported and then only when the controller is an initiator and in RC mode or a target and in EP mode.

Table continues on the next page...

Table 19-5. PCI Express Transactions (continued)

PCI Express Transaction	Supported as an Initiator	Supported as a Target	Definition
Cpl	Yes	Yes	Completion without Data
CplD	Yes	Yes	Completion with Data
CplLk	No	Yes	Completion for Locked Memory Read without Data. The only time that CplLk is returned with UR status is when the controller receives a MRdLk command.
CplDLk	No	No	Completion for Locked Memory Read with Data

19.6.1.2 Byte Ordering

Whenever data must cross a bridge between two busses, the byte ordering of data on the source and destination buses must be considered. The internal platform bus of this device is inherently big endian and the PCI Express bus interface is inherently little endian.

There are two methods to handle ordering of data as it crosses a bridge-address invariance and data invariance. Address invariance preserves the addressing of bytes within a scalar data element, but not the relative significance of the bytes within that scalar. Conversely, data invariance preserves the relative significance of bytes within a scalar, but not the addressing of the individual bytes that make up a scalar.

This device uses address invariance as its default byte ordering policy, but it also may be configured to use a data invariance policy. The byte ordering policy is controlled by the ATMUs using the data invariance enable parameter in the inbound and outbound window attributes registers (PEXIWARn[DIEN] and PEXOWARn[DIEN]). Note that by using the ATMUs to control the byte ordering policy, it is possible to allow data invariance for certain devices or regions, while mapping other devices or regions using address invariance. However, in such cases, it is important that software keep track of which devices and regions use which byte ordering policy and access them accordingly.

19.6.1.2.1 Address invariance

As stated above, address invariance preserves the byte address of each byte on an I/O interface as it is placed in memory or moved into a register.

This policy can have the effect of reversing the significance order of bytes (most significant to least significant and vice versa), but it has the benefit of preserving the format of general data structures. Provided that software is aware of the endianness and format of the data structure, it can correctly interpret the data on either side of the bridge.

The following figure shows the transfer of a 4-byte scalar, 0x4142_4344, from a big endian source across an address invariant bridge to a little endian destination.

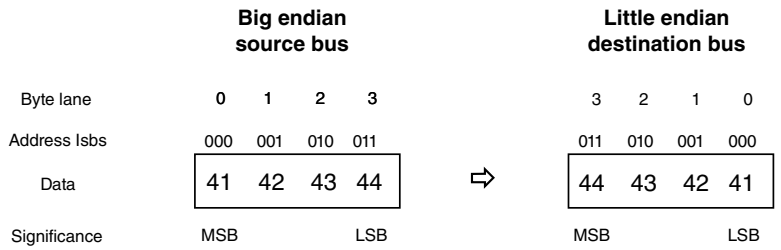

Figure 19-6. Address invariant byte ordering—4 bytes outbound

Note that although the significance of the bytes within the scalar have changed, the address of the individual bytes that make up the scalar have not changed. As long as software is aware that the source of the data used a big endian format, the data can be interpreted correctly.

The following figure shows data flowing the other way, from a little endian source to a big endian destination.

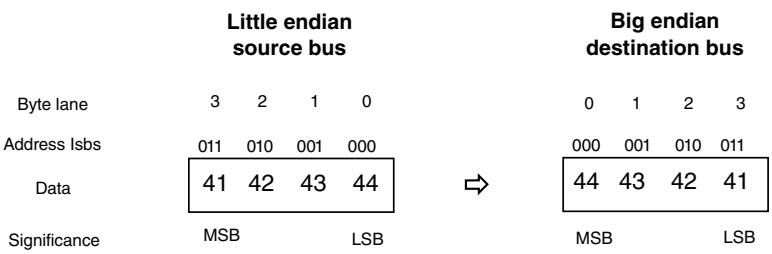

Figure 19-7. Address invariant byte ordering—4 bytes inbound

The following figure shows an outbound transfer of an 8-byte scalar, 0x5455_1617_CDCE_2728, using address invariance.

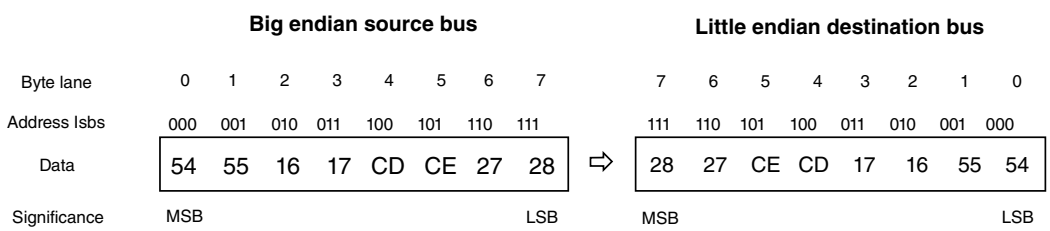

Figure 19-8. Address invariant byte ordering—8 bytes outbound

The following figure shows an inbound transfer of a 2-byte scalar, 0x5837, using address invariance.

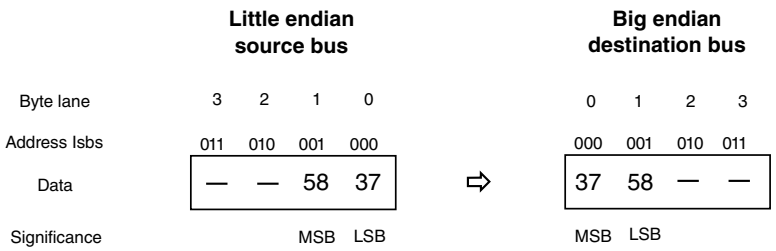

Figure 19-9. Address invariant byte ordering—2 bytes inbound

Note that in all of these examples, the original addresses of the individual bytes within the scalars (as created by the source) have been preserved.

19.6.1.2.2 Data invariance

The alternate policy of data invariance preserves the relative significance of data by translating the byte addressing within a given boundary.

The problem with data invariance is it can only preserve the significance of one size of data-in this device's case, 4-bytes. For scalars of different sizes or for data structures employing multiple sized scalars, it has the very undesirable effect of scrambling their addresses and formats. This puts a much greater burden on software to reconstruct non-homogeneous data structures that have passed through a data invariant bridge. It also requires knowledge of all potential paths that the data may have traversed and all the data invariance translations in each of those paths.

NXP provides the option of using data invariance on some of its devices to allow them to be used in systems employing external devices that require this policy. Note that the data invariance feature is only supported for use with specific interface cards that require this non-default byte ordering policy.

The following figure shows the transfer of a 4-byte scalar, 0x4142_4344, from a big endian source across a bridge to a little endian destination using a 4-byte data invariance policy.

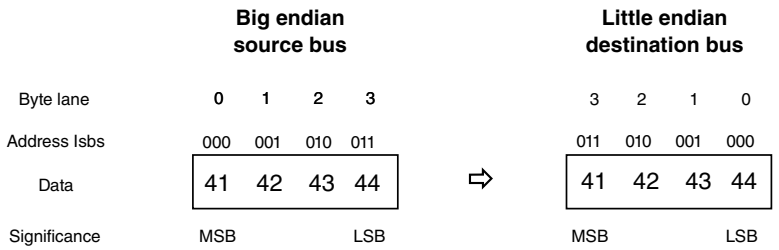

Figure 19-10. Data invariant byte ordering—4 bytes outbound

Note that the byte significance of the scalar has been preserved, even though the addresses of the individual bytes within the scalar have changed. This has effectively converted an aligned 4-byte big endian scalar to a 4-byte little endian scalar.

The following figure shows data flowing the other way, from a little endian source to a big endian destination.

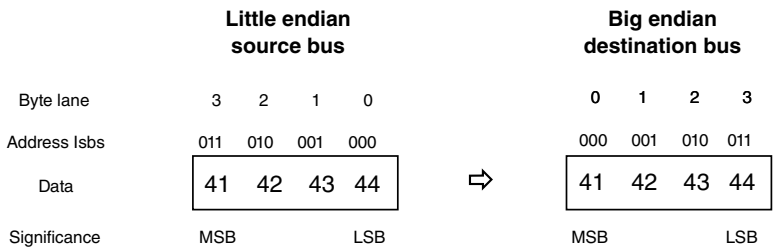

Figure 19-11. Data invariant byte ordering—4 bytes inbound

As before, the significance of the individual bytes has been preserved. It appears that the aligned 4-byte little endian scalar has been converted to a 4-byte big endian scalar. However, note what happens when a different size scalar is transferred across the bridge. The following figure shows an outbound transfer of an 8-byte scalar, 0x5455_1617_CDCE_2728, using a 4-byte data invariance policy.

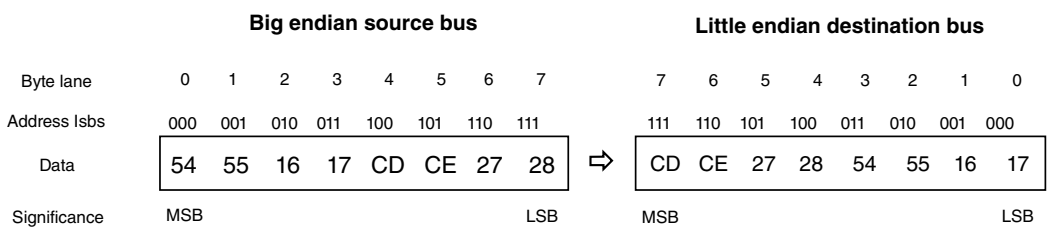

Figure 19-12. Data invariant byte ordering—8 bytes outbound

Here, the significance of bytes within the scalar has not been preserved. The data invariance has broken the scalar into halves at the 4-byte boundary. If a little endian device needs to access the 8-byte scalar, it will first need to reconstruct the data by rearranging the two halves.

The following figure shows an inbound transfer of a 2-byte scalar, 0x5837, using data invariance.

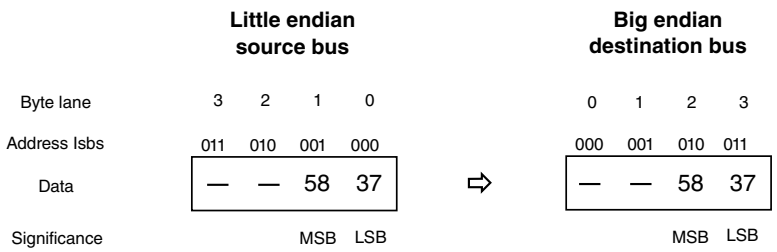

Figure 19-13. Data invariant byte ordering—2 bytes inbound

Again, the significance of the data has been preserved, but where the little endian device accesses the 2-byte scalar at an address offset 0, a big endian device will need to access it at an address offset by 2.

19.6.1.2.3 Byte order for configuration transactions

All internal memory-mapped registers in the CCSR space use big endian byte ordering. However, the PCI Express specification defines PCI Express configuration registers as little endian.

All accesses to the PCI Express configuration port, PEX_CONFIG_DATA, including the those targeting the internal PCI Express configuration registers, use the address invariance policy as shown in Figure 19-14. Therefore, software must access PEX_CONFIG_DATA with little-endian formatted data-either using the **lwbrx/stwbrx** instructions or by manipulating the data before writing to and after reading from PEX_CONFIG_DATA.

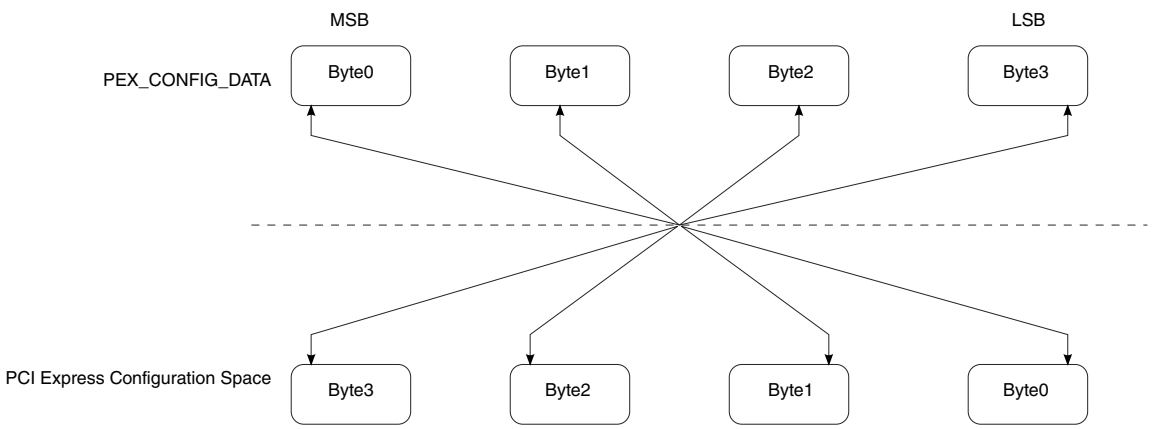

Figure 19-14. PEX_CONFIG_DATA byte ordering

19.6.1.3 Lane Reversal

PCI Express lane reversal is supported as part of the PCI Express training operations where the lanes are reversed between the two chips at the end of a PCI Express link. This can occur because of chip packaging, pinning or board placement. Lane reversal is performed automatically as part of the lane-numbering negotiation after the link-width negotiation is complete.

The following table describes the supported configurations.

Table 19-6. Lane assignment with and without lane reversal

Link configuration	Lane 0	Lane 1	Lane 2	Lane 3	Lane 4	Lane 5	Lane 6	Lane 7
x8 link without lane reversal	0	1	2	3	4	5	6	7
x4 link without lane reversal	0	1	2	3	—	—	—	—
x2 link without lane reversal	0	1	—	—	—	—	—	—
x1 link	0	—	—	—	—	—	—	—

Table continues on the next page...

Table 19-6. Lane assignment with and without lane reversal (continued)

Link configuration	Lane 0	Lane 1	Lane 2	Lane 3	Lane 4	Lane 5	Lane 6	Lane 7
x8 link with lane reversal	7	6	5	4	3	2	1	0
x4 link with lane reversal	3	2	1	0	—	—	—	—
x2 link with lane reversal	1	0	—	—	—	—	—	—

NOTE: The numbers shown in this table (0-7) are the lane numbers assigned to each lane as a result of link initialization and configuration. — indicates that the lane is not part of the configured link.

The lane reversal feature illustrated above can be achieved in one of the following ways:

- This PCI Express controller's Lane 0 is routed to the PCIe slot's Lane Number 7, 3 or 1 with PCB trace for x8, x4 or x2 lane reversal case respectively. In this case, the link partner is required to follow the lane reversal requirement of this PCI Express controller.
- The lanes of this PCI Express controller are still routed normally. However, the link partner reverses the lanes and wishes to negotiate the lane number with Lane 0 on PCIe slot's Lane Number 7, 3, or 1 for x8, x4 or x2 lane reversal case respectively. In this case, this PCI Express controller follows the lane reversal requirement of the link partner.

NOTE

The maximum number of lanes used in the lane reversal case cannot exceed the maximum number of lanes allocated for the PCI Express interface in use as determined by the SerDes options RCW settings (SRDS_PRTCL_Sn). For example, if an RCW SRDS_PRTCL_Sn setting only allocates two lanes for a PCI Express controller, the x4 or x8 lane reversal is invalid.

19.6.1.4 Transaction ordering rules

In general, transactions are serviced in the order that they are received.

However, transactions can be reordered as they are sent due to a stalled condition such as a full internal buffer. The following table describes the transaction ordering rules for this device.

Table 19-7. PCI Express controller TLP transaction ordering rules

Row pass column?		Posted request	Non-posted request		Completion	
		Memory write or message request (col 2)	Read request (Col 3)	I/O or Configuration write request (col 4)	Read completion (Col 5)	I/O or configuration write completion (col 6)
Posted request	Memory write or message request (row A)	a) No[1] b) No[1]	Yes	Yes	a) Yes[2] b) N/A[3]	a) Yes[2] b) N/A[3]
Non-posted request	Read request (row B)	No	No	No	a) No[4] b) Yes[5]	a) No[4] b)Yes[5]
	I/O or configuration write request (Row C)	No	No	No	a) No[4] b) Yes[5]	a) No[4] b) Yes[5]
Completion	Read completion (row D)	a) No[6] b) Yes[7]	Yes	Yes	a) No[8] b) No[8]	No
	I/O or configuration write completion (row E)	a) No[6] b) Yes[7]	Yes	Yes	No	No

1. Regardless of the setting of the relaxed ordering (RO) bit, a posted request cannot bypass another posted request.
2. Regardless of the setting of the relaxed ordering bit, a posted request can always bypass a completion.
3. N/A indicates that the original rules at these entries defined by the *PCI Express Base Specification* do not apply to RC or EP.
4. A non-posted request cannot bypass a completion if the relaxed ordering bit is cleared (that is, RO = 0).
5. A non-posted request can bypass a completion if the relaxed ordering bit is set (that is, RO = 1).
6. A read completion, I/O write completion, or configuration write completion cannot bypass a posted request if the relaxed ordering bit is cleared (that is, RO = 0).
7. A read completion, I/O write completion, or configuration write completion can bypass a posted request if the relaxed ordering bit is set (that is, RO = 1).
8. Regardless of the setting of the relaxed ordering bit, a read completion cannot bypass another read completion.

In general, the following points summarize the ordering rules for sending the next outstanding request:

- A posted request can bypass all other transactions except another posted request.
- A non-posted request cannot bypass posted or other non-posted requests, but it can bypass a completion if the relaxed ordering (RO) bit is set.(See Table 19-7).
- A completion can bypass posted requests if the relaxed ordering (RO) bit is set and can bypass non-posted transactions. However, a completion cannot bypass other completions.

19.6.1.5 PCI Express ATMU Registers

Software should initialize the appropriate PCI Express ATMU registers and associated configuration registers to allow inbound and outbound flow of traffic to be routed properly to and from memory. The table below describes the available programming options depending on whether the device is in RC or EP mode.

Table 19-8. ATMU and configuration registers—Non-SR_IOV Module

		RC	EP
Inbound	ATMU	• PEXITAR0-3 • PEXIBAR1-3 • PEXIBEAR2-3 • PEXIWAR0-3 • PEXMSIITAR • PEXMSIIWAR • PEXEPROMITAR • PEXEPROMIWAR	• PEXITAR0-3 • PEXIWAR0-3 • PEXEPROMITAR • PEXEPROMIWAR
	Configuration	• PEXCSRBAR (Type 1 header, offset 0x10) • PCI Express Memory Base Register (Type 1 header, offset 0x20) • PCI Express Memory Limit (Type 1 header, offset 0x22) • PCI Express Prefetchable Memory Base Register (Type 1 header, offset 0x24) • PCI Express Prefetchable Memory Limit Register (Type 1 header, offset 0x26) • PCI Express Expansion ROM Base Register (Type 1 header, offset 0x38)	• PEXCSRBAR (Type 0 header, offset 0x10) • PCI Express Memory Base Registers (Type 0 header, offset 0x14-0x24) • PCI Express Expansion ROM Base Reigister (Type 0 header, offset 0x30)
Outbound	ATMU	• PEXOBAR1-4 • PEXOTAR1-4 • PEXOTEAR1-4 • PEXOWAR1-4	• PEXOBAR1-4 • PEXOTAR1-4 • PEXOTEAR1-4 • PEXOWAR1-4
	Configuration	• PCI Express Memory Limit (Type 1 header, offset 0x22) • PCI Express Prefetchable Memory Base Register (Type 1 header, offset 0x24) • PCI Express Prefetchable Memory Limit Register (Type 1 header, offset 0x26) • PCI Express Expansion ROM Base Register (Type 1 header, offset 0x38)

19.6.1.5.1 PCI Express Outbound ATMU Registers

The outbound address translation windows must be aligned based on the granularity selected by the size fields. For SR-IOV VF windows, the base address must be aligned based on the total VF size calculated by multiplying the size field with the number of active VFs. Outbound transactions should hit into one of outbound address ranges defined by PEXOWARx/PEXVFOWWARx. Outbound window misses use the default outbound register set (outbound ATMU window 0). Overlapping outbound windows (1-4) are not supported and will cause undefined behavior. Note that for RC mode, all outbound transactions post ATMU must hit either into the memory base/limit range or the prefetchable memory base/limit range defined in the PCI Express type 1 header. For EP mode, there is no such requirement. There is also an MSI-X trap window which generates an MSI-X transaction when hit into. This window is only applicable for SR-IOV device operating in EP mode.

Note that in RC mode, when PEX_CONFIG[OB_CK] is set, the translated address of an outbound transaction must fall into either the memory base/limit range, the prefetchable memory base/limit range, or I/O base/limit range. The transaction will be terminated if the translated address does not fall within these ranges.

This figure shows the outbound transaction flow.

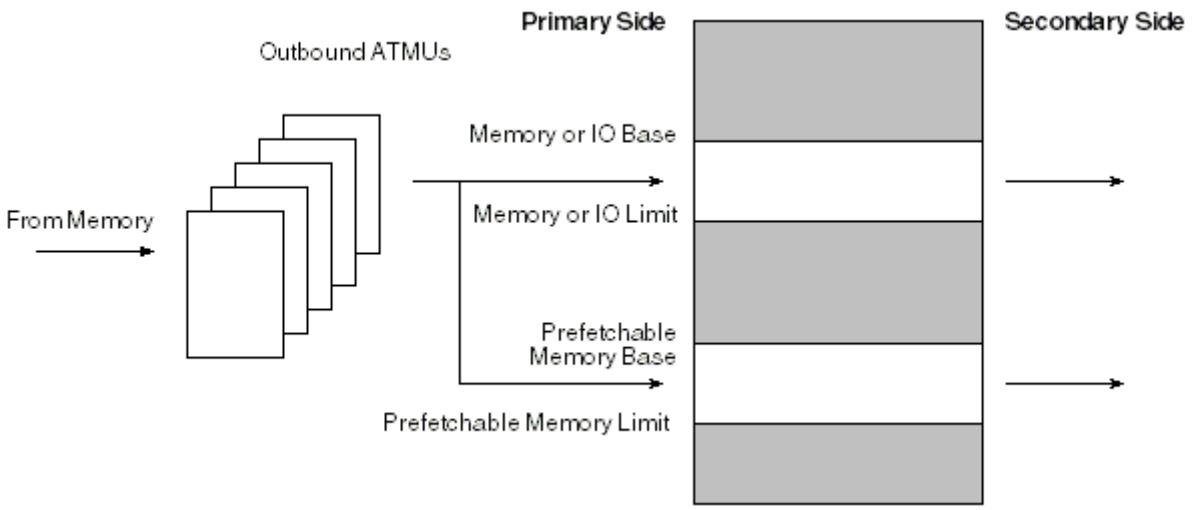

Figure 19-15. RC Outbound Transaction Flow

For SR-IOV implementation in EP mode, there needs to be a mechanism to map outbound addresses into a particular VF/PF space. This is done through the outbound ATMU translation windows. Each PF will have its own ATMU unit in separate 8K memory-mapped register regions. When an outbound transaction is passing through the ATMU windows, all ATMU units are compared. Depending on which ATMU region of address the outbound transaction is hitting into, a particular VF/PF is chosen. In case if no hit occurs, then the default outbound window that corresponds to PF 0 is chosen.

All outbound ATMU registers dedicated to PF address decode occupy memory-mapped offset 0xC00-0xCFC. Note that this condition only applies if in EP mode.

All the VFs in a PF share a set of the VF Outbound Window Base Address Register (PEXVFOWBAR1-4) and VF Outbound Window Attribute Register (PEXVFOWAR1-4) in each PF at memory-mapped offset 0x820-0x8FC.

However, each VF in a PF has its own VF Outbound Window Translation Address Registers (PEXVFOWnTAR1-64) and VF Outbound Window Extended Translation Address Registers (PEXVFOWnTEAR1-64).

Note that the size of a particular BAR for all the VFs in a PF is determined by PEXVFOWARn[OWS]. The total BAR memory size is determined by PEXVFOWARn[OWS] times the total number of VFs supported (i.e 64). For example, a VF bar 0 in PF 0 is configured to have a size of 4k and starting address is 0x0000_0000. Then the address mapping to a VF is done as follow.

- Address from 0x0000_0000 to 0x0000_0FFF maps to PF 0, VF 1, Bar0
- Address from 0x0000_1000 to 0x0000_1FFF maps to PF 0, VF 2, Bar0
- Address from 0x0000_2000 to 0x0000_2FFF maps to PF 0, VF 3, Bar0
- ...

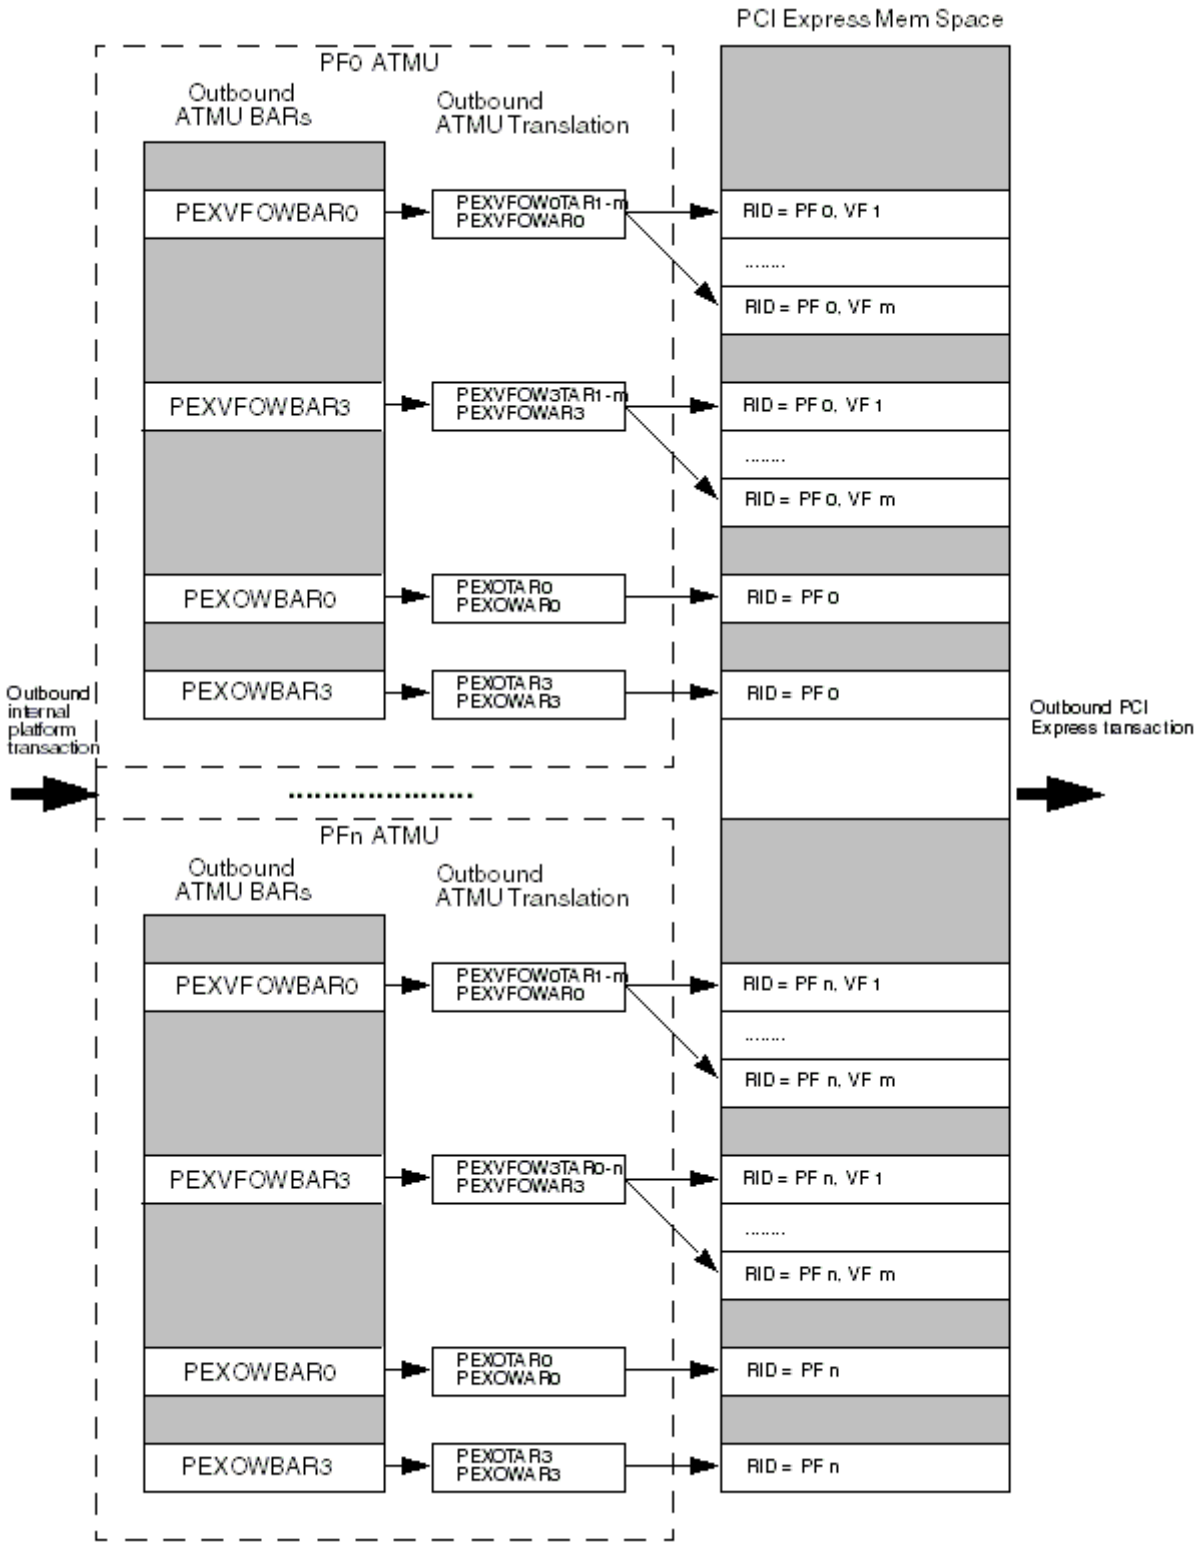

Figure 19-16. SR-IOV Outbound Transaction Flow - EP only

19.6.1.5.2 PCI Express Inbound ATMU Registers

There are differences between RC and EP implementations of inbound ATMU registers as described in the following sections.

NOTE

The inbound ATMU windows must be programmed and enabled before any inbound memory transaction can be handled.

19.6.1.5.2.1 EP Inbound ATMU Implementation

All base address registers (BARs) reside in the PCI Express type 0 configuration header space which is accessible through the PEX_CONFIG_ADDR/PEX_CONFIG_DATA mechanism. Note that host software must program these BAR using configuration type 0 cycles. There are 4 inbound BARs.

- Default inbound window BAR0 at configuration address 0x10 (32-bit). Also known as PEXCSRBAR. This is a fixed 16-Mbyte window used for inbound memory transactions that access memory-mapped registers. This window can also be used as either a fixed 16-Mbyte window used for inbound memory transactions that access memory-mapped registers or it can be programmed as a general purpose window for local memory access.
- Inbound window BAR1 at configuration address 0x14 (32-bit) This window is generic when not supporting MSI-X (that is, non SR-IOV device); this window is reserved for MSI-X table access for SR-IOV device.
- Inbound window BAR2 at configuration address 0x18-0x1c (64-bit)
- Inbound window BAR3 at configuration address 0x20-0x24 (64-bit)
- Inbound ROM BAR at configuration address 0x30

The PCI Express controller does not implement a shadow of the inbound BARs in the memory-mapped register set. However, when there is a hit to the BAR(s), the PCI Express controller uses the corresponding translation and attribute registers (PEXITARn and PEXIWARn) in the memory-mapped register set for the translation. If the transaction hits multiple BARs, then the lowest-numbered BAR is used.

For SR-IOV implementation in EP mode, there are 2 separate sets of inbound ATMU registers. One set is defined for PF translation and another is defined for VF translation.

All inbound ATMU registers that are dedicated to VF address decode occupy memory-mapped offset 0x1200-0x13FC. All inbound ATMU registers dedicated to PF address decode occupy memory-mapped offset 0xD00-DFC. Note that this condition only applies if in EP mode.

All PF BARs reside in the PCI Express type 0 config header space and all VF BARs reside in SR-IOV Capabilities structure which is accessible through the PEX_CONFIG_ADDR/PEX_CONFIG_DATA mechanism. There are 4 inbound VF BARs.

- Default inbound window VF BAR0 at configuration address SR-IOV Capabilities offset + 0x24 (32-bit). Also known as PEXCSRBAR. This window can also be used as either a fixed 1-Mbyte or 16-Mbyte window for inbound memory transactions that access memory-mapped registers or it can be programmed as a general purpose window for local memory access.
- Inbound window VF BAR1 at configuration address SR-IOV Capabilities offset + 0x28 (32-bit). Reserved for MSI-X table access.
- Inbound window VF BAR2 at configuration address SR-IOV Capabilities offset + 0x2c-0x30 (64-bit)
- Inbound window VF BAR3 at configuration address SR-IOV Capabilities offset + 0x34-0x38 (64-bit)

The PCI Express controller does not implement a shadow of the inbound VF BARs in the memory-mapped register set. However, when there is a hit to the VF BAR, the PCI Express controller uses the corresponding translation and attribute registers (PEXVFIWnTARm and PEXVFIWARn) in the memory-mapped register set for the translation. Similarly, when there is a hit to the PF BAR, the PCI Express controller uses the corresponding translation and attribute registers (PEXIWnTARm and PEXIWARn) in the memory-mapped register set for the translation.

Each VF BAR defines the size of a single memory aperture for the first VF. If there are multiple VFs, then the memory aperture for subsequent VFs lined up in subsequently memory addresses. The size of the memory aperture for each VF is defined in PEXVFIWAR[IWS]. The total BAR memory size is total of VF per PF (that is, 64) * PEXVFIWAR[IWS] size.

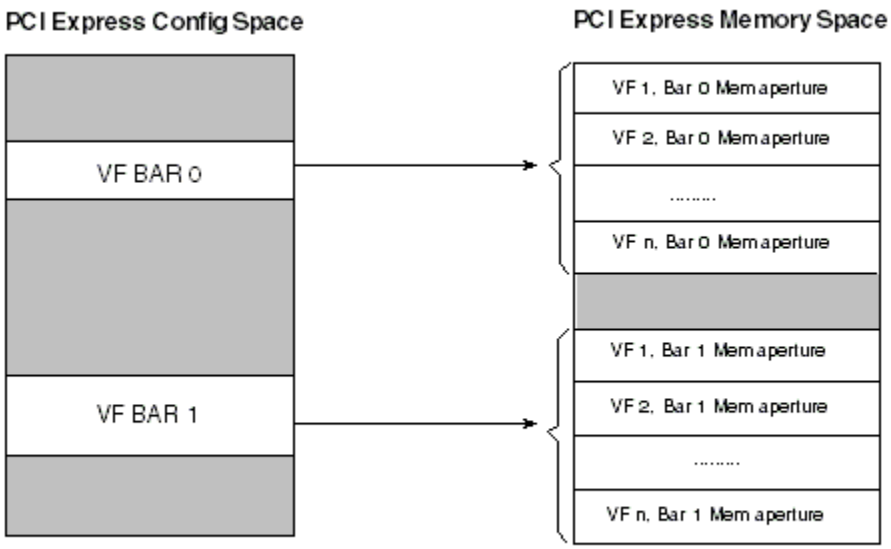

Figure 19-17. EP SR-IOV VF BARs Inbound Address - EP only

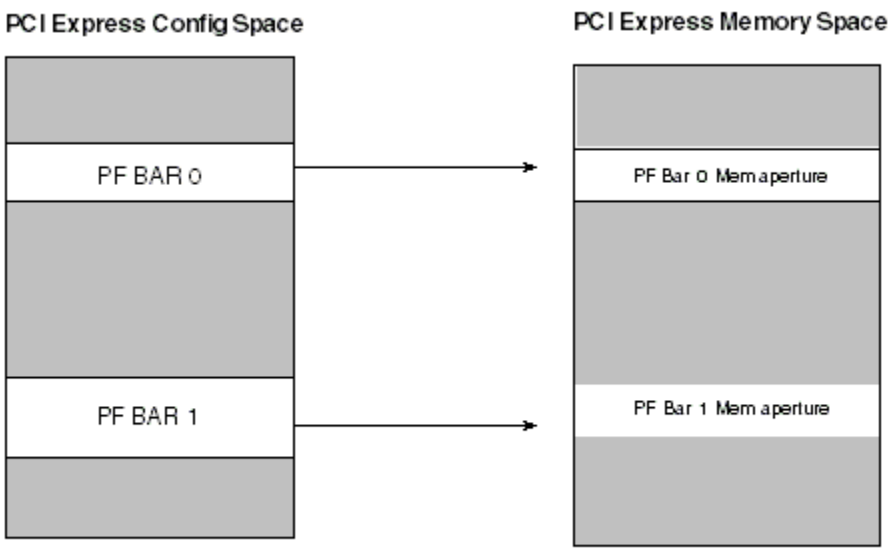

Figure 19-18. EP SR-IOV PF BARs Inbound Address

19.6.1.5.2.2 RC Inbound ATMU Implementation

In RC mode, the PEXIWBAR[1-3] registers reside outside of the type 1 header; PEXIWBAR0 resides in the Type 1 header (at offset 0x10). PEXIWBAR0 can be used as either a fixed 16-Mbyte window for inbound memory transactions that access memory-

mapped registers or it can be programmed as a general purpose window for local memory access. In addition, in RC mode, there is a 64-bit MSI BAR that decodes 64-bit MSI writes and an inbound expansion ROM base address in the type 1 header at offset 0x38.

If the transaction hits any window, the translation is performed and then the transaction is sent to memory. If there is no hit to any one of the BARs, then an UR completion is returned for non-posted transactions. All posted transactions with no BAR hit are ignored.

This figure shows the inbound transaction flow in RC mode.

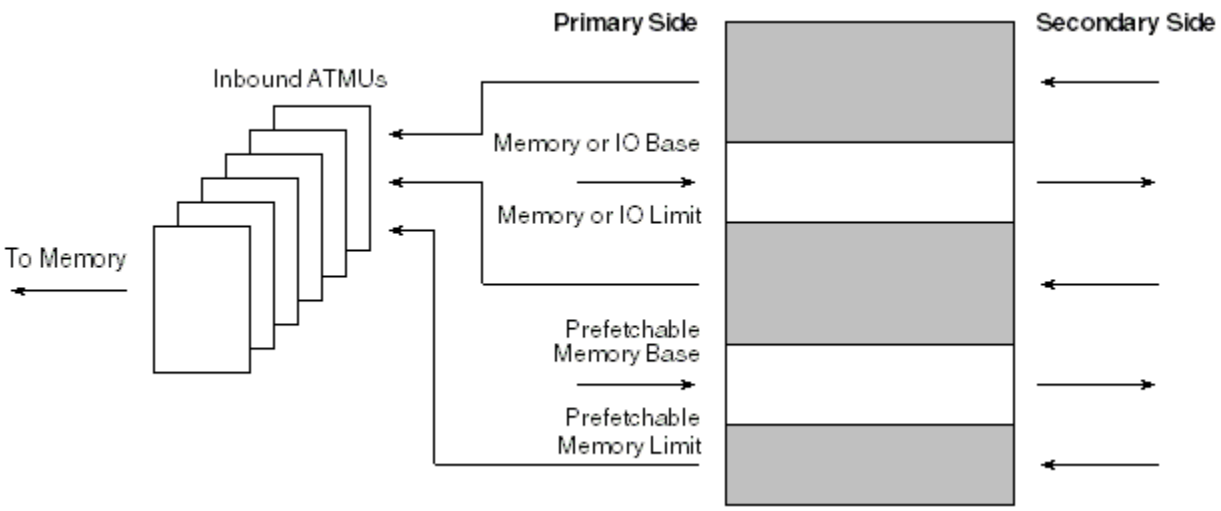

Figure 19-19. RC Inbound Transaction Flow

19.6.1.6 Memory Space Addressing

A PCI Express memory transaction can address a 32- or 64-bit memory space. The FMT[0] field in the PCI Express TLP header for a 32-bit address packet is 0; a 64-bit address packet has a FMT[0] = 1. The PCI Express TLP header for a memory read transaction has TYPE[4:0] = 00000 and FMT[1] = 0. A memory write transaction has TYPE[4:0] = 00000 and FMT[1] = 1. As an initiator, the controller is capable of sending 32- or 64-bit memory packets. Any transaction from the internal platform that (after passing through the translation mechanism) has a translated address greater than 4G is sent as a 64-bit memory packet. Otherwise, a 32-bit memory packet is sent. As a target device, the controller is capable of decoding 32- or 64-bit memory packets. This is done through two 32-bit inbound windows and two 64-bit inbound windows. All inbound addresses are translated to 40-bit internal platform addresses.

19.6.1.7 I/O Space Addressing

The controller does not support I/O transactions as a target. As an initiator, the controller can send I/O transactions in RC mode only. This can be done by programming one of the outbound translation window's attribute to send I/O transactions. All I/O transactions only access 32-bit address I/O space. The PCI Express TLP header for an I/O read transaction has TYPE[4:0] = 00010 and FMT[1] = 0. The PCI Express TLP header for an I/O write transaction has TYPE[4:0] = 00010 and FMT[1] = 1.

19.6.1.8 Configuration Space Addressing

As an initiator, the controller supports both type 0 and type 1 configuration cycles when configured in RC mode. There are two methods of generating a configuration transaction; refer to PCI Express Configuration Space Access for more information. A configuration transaction can hit into the controller's internal configuration space, it can be sent out on the PCI Express link, or it can be internally terminated. The PCI Express TLP header for a type 0 configuration read transaction has TYPE[4:0] = 00100 and FMT[1] = 0; the PCI Express TLP header for a type 0 configuration write transaction has TYPE[4:0] = 00100 and FMT[1] = 1. The PCI Express TLP header for a type 1 configuration read transaction has TYPE[4:0] = 00101 and FMT[1] = 0; the PCI Express TLP header for a type 1 configuration write transaction has TYPE[4:0] = 00101 and FMT[1] = 1. Note that all configuration transactions sent on PCI Express require a response, regardless whether they are read or a write configuration transactions.

The controller does not generate configuration transactions in EP mode. Only inbound configuration transactions are supported in EP mode.

19.6.1.9 PCI Express Configuration Space Access

There are two methods of accessing the PCI Express configuration header:

- PCI Express outbound ATMU window
- PCI Express configuration access registers (PEX_CONFIG_ADDR/ PEX_CONFIG_DATA)

19.6.1.9.1 RC Configuration Register Access

To access internal configuration space, software must rely on the PCI Express configuration access register (PEX_CONFIG_ADDR/ PEX_CONFIG_DATA) mechanism. To access external configuration space, software can either use configuration access registers or the outbound ATMU mechanism. For the configuration access register

method, a value must be written to the PEX_CONFIG_ADDR register that specifies the targeted PCI Express bus, the targeted device on that bus, the targeted function within the device, and the configuration register in that device that should be accessed. The PCI Express controller's bus number is obtained from the PCI Express configuration header (type 1). Then either a write or a read to the PEX_CONFIG_DATA register triggers the actual write or read cycle to the configuration space. Note that accesses to the little-endian PCI Express configuration space must be properly formatted. See Byte order for configuration transactions for more information.

Note that external configuration transactions should not be attempted until the link has successfully trained. Software can poll the LTSSM state status register (PEX_CSR0) to check the status of link training before issuing external configuration requests.

19.6.1.9.1.1 PCI Express Configuration Access Register Mechanism

There are two types of configuration transactions (Type 0 and Type 1) needed to support hierarchical bridges.

- If the targeted bus number, and targeted device number equal to the PCI Express controller's bus number and device number, and the targeted function number is zero, then an internal PCI Express configuration cycle access is performed.
- If the targeted bus number does not equal the PCI Express controller's bus number, but does equal the secondary bus number (from the type 1 header) and the targeted device number is 0, then a Type 0 configuration transaction is sent to the PCI Express link.
- If the targeted bus number does not equal the PCI Express controller's bus number, and does not equal the secondary bus number (from the type 1 header), and the targeted bus number is less than or equal to the subordinate bus number (from the type 1 header), then a Type 1 configuration transaction is sent to the PCI Express link.
- If none of the above conditions occur, then the PCI Express controller returns all 1s for reads and ignores writes. In this case, PEX_ERR_DR[ICCA] is set.

19.6.1.9.1.2 Outbound ATMU Configuration Mechanism (RC-Only)

Software can also program one of the outbound ATMU windows to perform a configuration access. This is accomplished by programming the ReadTType or WriteTType field of the desired PEXOWAR to 0x2. Software must only issue 4-byte or less access to the ATMU configuration window and the access cannot cross a 4-byte boundary. The targeted bus number, targeted device number, targeted function number, register, and targeted extended register number sent are decoded from the outbound translated PCI Express address.

- targeted bus number[7:0] = PCI Express address[27:20]
- targeted device number[4:0] = PCI Express address[19:15]
- targeted function number[2:0] = PCI Express address[14:12]
- targeted extended register number[3:0] = PCI Express address[11:8]
- targeted register number[5:0] = PCI Express address[7:2]

A Type 0 configuration cycle is sent to the link if the targeted bus number equals the secondary bus number (from the type 1 header) and targeted device number is 0. A Type 1 configuration cycle is sent to the link if targeted bus number does not equal primary bus and secondary bus numbers and it is less than or equal to the subordinate bus number (from the type 1 header). For all other cases, the PCI Express controller squashes the write and read results in a response with error returned. In this case, PEX_ERR_DR[IACA] is set.

Note that the PCI Express controller does not support access to its internal configuration registers using the outbound ATMU mechanism. That is, the outbound ATMU mechanism must not be used to program the internal registers.

19.6.1.9.2 EP Configuration Register Access

When the PCI Express controller is configured as an EP device it responds to remote host generated configuration cycles. This is indicated by decoding the configuration command along with type 0 access in the packet. A remote host can access all of the PCI Express configuration area except the PCI Express Controller Internal CSR registers in the extended PCI Express configuration space at offsets 0x400-0x6FF. The PCI Express Controller Internal CSR registers are not accessible by inbound PCI Express configuration transactions. Attempts to access these registers return all zeros.

While in EP mode, the PCI Express controller does not support generating configuration accesses as a master. All accesses to PEX_CONFIG_ADDR/PEX_CONFIG_DATA cause the device to access the internal configuration registers regardless of the targeted bus number or targeted device number programmed in the PEX_CONFIG_ADDR register. There is no configuration mechanism supported in EP mode using the ATMU window. If the outbound ATMU window is configured to issue a configuration transaction, all posted transactions hitting this window are ignored and all non-posted transactions get a response with an error.

19.6.1.10 Serialization of Configuration and I/O Writes

Configuration and I/O writes are serialized by the controller. The logic after issuing a configuration write or IO write does not issue any new transactions until the outstanding configuration or I/O write is finished. This means that an acknowledgement packet from

the link partner in the form of a CpL TLP packet must be seen or the transaction has timed out. If the CpL packet contains a CRS status, then the logic re-issues the configuration write transaction. It keeps retrying the request until either a status other than CRS is returned or the transaction times out.

Note that it is possible for outbound configuration read request to be requeued and be placed at the end of the request queue due to CRS condition.

19.6.1.11 Messages

Software message generation is supported in both RC and EP modes.

19.6.1.11.1 Outbound ATMU Message Generation

Software can choose to send a message by programming PEXOWARn[WTT] = 0x5. A message is sent by writing a 4-byte transaction in big-endian format that hits in an outbound window configured to send messages.

Part of the 4-byte data is used to store information such as message code and routing information. The data format is slightly different depending on whether data invariance mode is enabled. The table below describes the message data format in address invariance mode (PEXOWARn[DIEN] = 0).

Table 19-10. Internal Platform Message Data Format-Address Invariance Mode

Bits	Name	Reset Value	Description
0-15	-	-	Reserved
16-18	Routing	x	Routing mechanism. Contains the message's routing information
19-23	-	-	Reserved
24-31	Code	x	Message code. Contains the actual message type to be sent.

The table below describes the message data format in data invariance mode (PEXOWARn[DIEN] = 1).

Table 19-11. Internal Platform Message Data Format-Data Invariance Mode

Bits	Name	Reset Value	Description
0-7	Code	x	Message code. Contains the actual message type to be sent.
8-10	Routing	x	Routing mechanism. Contains the message's routing information
11-31	-	-	Reserved

In addition to the outbound ATMU, the power management command register (PFa_PMCR) also provides the capability to send PM_PME message or PME_Turn_Off message by setting SPMES (bit 29) or PTOMR (bit 31).

The following table provides a complete list of supported outbound messages depending on whether RC or EP is configured.

Table 19-12. PCI Express ATMU Outbound Messages

Name	Code[7:0]	Routing[2:0]	RC	EP	Description
PM_Active_State_Nak	0001 0100	100	Yes	N/A	Terminate at receiver
PM_PME	0001 1000	000	N/A	Yes	Sent Upstream by PME-requesting component
PME_Turn_Off	0001 1001	011	Yes	N/A	Broadcast Downstream
PM_TO_Ack	0001 1011	101	N/A	Yes	Sent Upstream by Endpoint
ERR_COR	0011 0000	000	N/A	Yes	Sent by component when it detects a correctable error
ERR_NONFATAL	0011 0001	000	N/A	Yes	Sent by component when it detects a Non-fatal, uncorrectable error
ERR_FATAL	0011 0011	000	N/A	Yes	Sent by component when it detects a Fatal, uncorrectable error
Unlock	0000 0000	011	No	N/A	Not supported
Set_Slot_Power_Limit	0101 0000	100	No	N/A	Set Slot Power Limit in Upstream Port Note that although it is not supported via ATMU, it can still be sent via PCI Express configuration register.
Vendor_Defined Type 0	0111 1110		No	No	Not supported
Vendor_Defined Type 1	0111 1111		No	No	Not supported

19.6.1.11.2 Inbound Messages

The following table provides a complete list of supported inbound messages in RC mode.

Table 19-13. PCI Express RC Inbound Message Handling

Name	Code[7:0]	Routing[2:0]	Action
Assert_INTA	0010 0000	100	Send to PIC
Assert_INTB	0010 0001	100	Send to PIC
Assert_INTC	0010 0010	100	Send to PIC

Unlock	0000 0000	000	No action taken
Set_Slot_Power_Limit	0101 0000	100	Update power value in PCI Express device capability register in configuration space.
Vendor_Defined Type 0	0111 1110		No action taken
Vendor_Defined Type 1	0111 1111		No action taken

19.6.1.12 Error Handling

The PCI Express specification classifies errors as correctable and uncorrectable. Correctable errors result in degraded performance, but uncorrectable errors generally result in functional failures. As shown in the figure below, uncorrectable errors can further be classified as fatal or non-fatal.

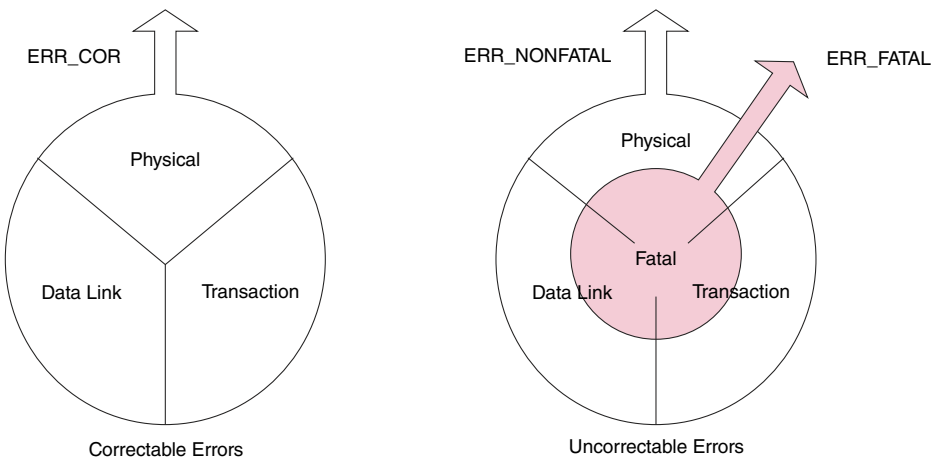

Figure 19-20. PCI Express Error Classification

19.6.1.12.1 PCI Express Error Logging and Signaling

The figure below shows the PCI Express-defined sequence of operations related to signaling and logging of errors detected by a device. Note that the PCI Express controller on this device supports the advanced error handling capabilities shown within the dotted lines.

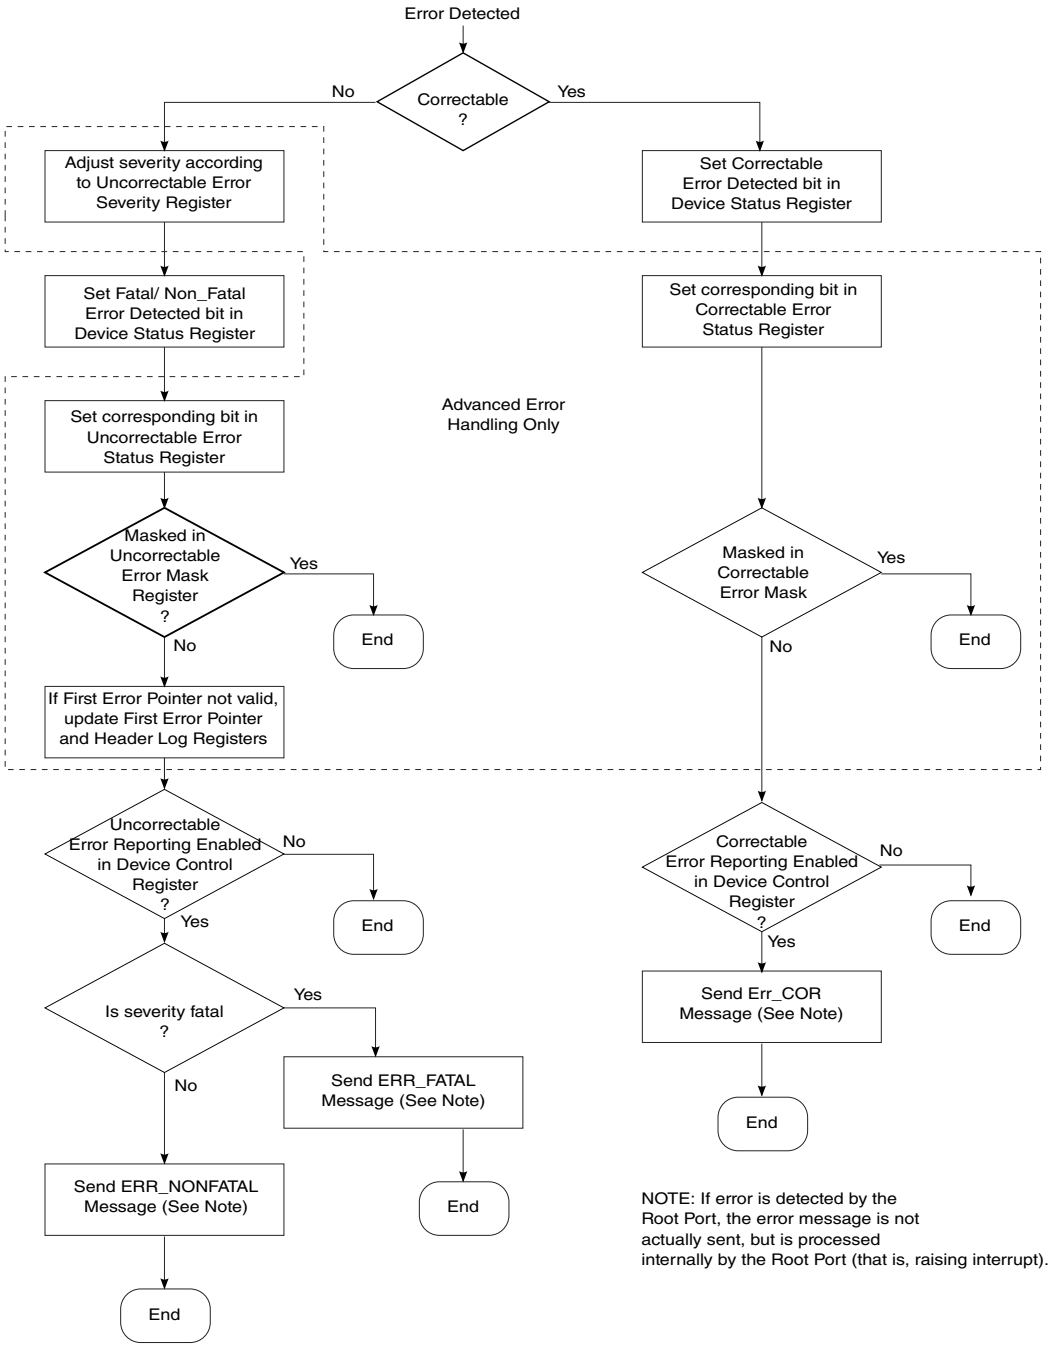

Figure 19-21. PCI Express Device Error Signaling Flowchart

19.6.1.12.2 PCI Express Controller Internal Interrupt Sources

This table describes the sources of the PCI Express controller internal interrupt to the PIC and the preconditions for signaling the interrupt.

Table 19-15. PCI Express Internal Controller Interrupt Sources

Status Register Bit	Preconditions
Any bit in PEX_PME_MES_DR set	The corresponding interrupt enable bits must be set in PEX_PME_MES_IER
Any bit in PEX_ERR_DR set	The corresponding interrupt enable bits must be set in PEX_ERR_EN.
PCI Express Root Status Register[16] (PME status) is set	The INTx Assertion Disable bit in the Command register is 0 and the PME Interrupt Enable bit in the Root Controlr egister is set to 1 and the PME Status bit in the Root Status register is set to 1.
Any bit in PCI Express Root Error Status Register set	A reported error condition causes a bit to be set in the Root Error Status register and the associated error message reporting enable bit is set in the Root Error Command register.
Any bit in PCI Express Secondary Status Register bit set	Any bits are set in the Secondary Status register.
Any bit in PCI Express Slot Status Register bit set	The INTx Assertion Disable bit in the Command register is 0 and Hot-Plug interrupts are enabled in the Slot Control register and any bit in the Slot Status register is equal to 1, and the associated event modification is enabled in the Slot Control register.
PCI Express Link Autonomous Bandwidth Status register (Link Status register bit 15) is set	Link Autonomous Bandwidth Status register (Link Status register bit 15) is updated and the Link Autonomous Bandwidth Interrupt Enable (Link Control register bit 11) is set.
Link Bandwidth Management Status register (Link Status register bit 14) is set	Link Bandwidth Management Status register (Link Status register bit 14) is updated and the Link Bandwidth Management Interrupt Enable (Link Control register bit 10) is set.
Link Equalization Request bit in the Link Status 2 register is set.	Link Equalization Request bit in the Link Status 2 register has been set.

19.6.1.12.3 Error Conditions

The following table describes specific error types and the action taken for various transaction types.

Table 19-16. Error Conditions

Transaction Type	Error Type	Action
Inbound response	PEX response time out. This case happens when the internal platform sends a non-posted request that did not get a response back after a specific amount of time specified in the outbound completion timeout register (PEX_OTB_CPL_TOR)	Log error (PEX_ERR_DR[PCT]) and send interrupt to PIC, if enabled.
Inbound response	Unexpected PEX response. This can happen if, after the response times out and the internal queue entry is deallocated, the response comes back.	Log unexpected completion error (PCI Express Uncorrectable Status Register[16]) and send interrupt to PIC, if enabled.
Inbound response	Unsupported request (UR) response status	Depending upon whether the initial internal request was broken up, the error is not sent until all responses come back for all portions of the internal request.

Table continues on the next page...

Table 19-16. Error Conditions (continued)

Transaction Type	Error Type	Action
		Log the error (PEX_ERR_DR[CDNSC] and PCI Express Uncorrectable Status Register[20]) and send interrupt to PIC, if enabled.
Inbound response	Completer abort (CA) response status	Depending upon whether the initial internal request was broken up, the error is not sent until all responses come back for all portions of the internal request. Log the error (PEX_ERR_DR[PCAC, CDNSC] and PCI Express Uncorrectable Status Register[15] and send interrupt to PIC, if enabled.
Inbound response	Unsupported Request (UR) response status in EP mode	Depending upon whether the initial internal request was broken up, the error is not sent until all responses come back for all portions of the internal request. Log the error (PEX_ERR_DR[UREP] and send interrupt to PIC, if enabled.
Inbound response	Poisoned TLP (EP=1)	Depending upon whether the initial internal request was broken up, the error is not sent until all responses come back for all portions of the internal request. Log the error (PCI Express Uncorrectable Status Register[12]) and send interrupt to PIC, if enabled.
Inbound response	ECRC error	Depending upon whether the initial internal request was broken up, the error is not sent until all responses come back for all portions of the internal request. Log the error (PCI Express Uncorrectable Status Register[19]) and send interrupt to PIC, if enabled.
Inbound response	Configuration Request Retry Status (CRS) timeout for a configuration transaction that originates from PEX_CONFIG_ADDR/ PEX_CONFIG_DATA	1.The controller always retries the transaction as soon as possible until a status other than CRS is returned. However, if a CRS status is returned after the configuration retry timeout (PEXCONF_RTY_TOR) timer expires, then the controller aborts the transaction and sends all 1s (0xFFFF_FFFF) data back to requester. 2. Log the error (PEX_ERR_DR[PCT]) and send interrupt to the PIC, if enabled.
Inbound response	UR response for configuration transaction that originates from PEX_CONFIG_ADDR/ PEX_CONFIG_DATA	1. Send back all 1s (0xFFFF_FFFF) data. 2. Log the error (PEX_ERR_DR[CDNSC] and PCI Express Uncorrectable Status Register[20]) and send interrupt to PIC, if enabled.
Inbound response	CA response for Configuration transaction that originates from PEX_CONFIG_ADDR/ PEX_CONFIG_DATA	1. Send back all 1s (0xFFFF_FFFF) data. 2. Log the error (PEX_ERR_DR[PCAC, CDNSC] and PCI Express Uncorrectable Status Register[15]) and send interrupt to PIC, if enabled.
Inbound response	Poisoned TLP (EP=1) response for Configuration transaction that originates from PEX_CONFIG_ADDR/ PEX_CONFIG_DATA	1. Send back all 1s (0xFFFF_FFFF) data. 2. Log the error (PCI Express Uncorrectable Status Register[12]) and send interrupt to PIC, if enabled.

Table continues on the next page...

Table 19-16. Error Conditions (continued)

Transaction Type	Error Type	Action
Inbound response	ECRC error response for Configuration transaction that originates from PEX_CONFIG_ADDR/ PEX_CONFIG_DATA	1. Send back all 1s (0xFFFF_FFFF) data. 2. Log the error (PCI Express Uncorrectable Status Register[19]) and send interrupt to PIC, if enabled.
Inbound response	Configuration Request Retry Status (CRS) response for Configuration transaction that originates from ATMU	1.The controller always retries the transaction as soon as possible until a status other than CRS is returned. However, if a CRS status is returned after the configuration retry timeout (PEXCONF_RTY_TOR) timer expires, then the controller aborts the transaction. 2. Log the error (PEX_ERR_DR[CRST]) and send interrupt to the PIC, if enabled.
Inbound response	UR response for Configuration transaction that originates from ATMU	Log the error (PEX_ERR_DR[CDNSC] and PCI Express Uncorrectable Status Register[20]) and send interrupt to PIC, if enabled.
Inbound response	CA response for Configuration transaction that originates from ATMU	Log the error (PEX_ERR_DR[PCAC, CDNSC] and PCI Express Uncorrectable Status Register[15]) and send interrupt to PIC, if enabled.
Inbound response	Malformed TLP response	PCI Express controller does not pass the response back to the core. Therefore, a completion timeout error eventually occurs.
Inbound request	Poisoned TLP (EP=1)	1. If it is a posted transaction, the controller drops it. 2. If it is a non-posted transaction, the controller returns a completion with UR status. 3. Release the proper credits
Inbound request	ECRC error	1. If it is a posted transaction, the controller drops it. 2. If it is a non-posted transaction, the controller returns a completion with UR status. 3. Release the proper credits
Inbound request	PCI Express nullified request	The packet is dropped.
Inbound request	No map	1. Log the error(PEX_ERR_DR[NM]) and send interrupt to PIC if enable. 2. If it is a non-posted transaction, the controller sends a completion with UR. If it is a posted transaction, the controller drops it.
Inbound request	LIODN mapping error	1. Set PEX_ERR_DR[LDDE] and send interrupt if enabled. 2. Transaction is dropped if posted and UR if non-posted.
Outbound request	Outbound ATMU crossing	Log the error (PEX_ERR_DR[OAC]). The transaction is not sent out on the link.
Outbound request	Illegal message size	Log the error (PEX_ERR_DR[MIS]). The transaction is not sent out on the link.
Outbound request	Illegal I/O size	Log the error (PEX_ERR_DR[IOIS]). The transaction is not sent out on the link.
Outbound request	Illegal I/O address	Log the error (PEX_ERR_DR[IOIA]). The transaction is not sent out on the link.
Outbound request	Illegal configuration size	Log the error (PEX_ERR_DR[CIS]). The transaction is not sent out on the link.

Table continues on the next page...

Table 19-16. Error Conditions (continued)

Transaction Type	Error Type	Action
Outbound request	Memory out of range	Log the error (PEX_ERR_DR[IMBA]). The transaction is not sent out on the link.
Outbound request	IO out of range	Log the error (PEX_ERR_DR[IIOBA]). The transaction is not sent out on the link.
Outbound request	Link down	Log the error (PEX_ERR_DR[LDDE]). The transaction is not sent out on the link.
Outbound request	FLR	Log the error (PEX_ERR_DR[FLRDE]). The transaction is not sent out on the link.
Outbound request	Tx Abort	Log the error (PEX_ERR_DR[TAE]). The transaction is not sent out on the link.
Outbound response	Internal platform response with error (for example, an ECC error on a DDR read or the transaction maps to unknown address space).	Send poisoned TLP (EP=1) completion(s) for data that are known bad. If the poison data happens in the middle of the packet, the rest of the response packet(s) is also poisoned.
Link speed change request	1. Auto request with Auto speed disable bit set or 2. Link partner incapable of 5.0 Gb/s and request speed is 5.0 Gb/s	Clear link speed request and set interrupt in PME Message Detect register. Additionally, log error in link speed status register.
Link width change request	1. Auto request with Auto width disable bit set or 2. Upconfiguration not capable and request was to size-up the width or 3. Not enough detected lanes for a given request	Clear link width request and set interrupt in PME Message Detect register. Additionally, log error in link width status register.

19.6.1.12.4 Error capture registers

The PCI Express error capture registers, PEX_ERR_CAP_R0 through PEX_ERR_CAP_R3, allow vital error information to be captured when an error occurs.

Different error information is reported depending on whether the error source is from an outbound transaction from an internal source or from an inbound transaction from an external source; the source of the captured error is reflected in PEX_ERR_CAP_STAT[GSID]. Note that after the initial error is captured, no further capturing is performed until the PEX_ERR_CAP_STAT[ECV] bit is clear.

19.6.1.12.4.1 Error capture registers (outbound error)

PEX_ERR_CAP_Rn for the case when the error is caused by an outbound transaction from an internal source and the error is due to timeout condition or PEX_CONFIG_ADDR/PEX_CONFIG_DATA access are shown in the following figure and tables.

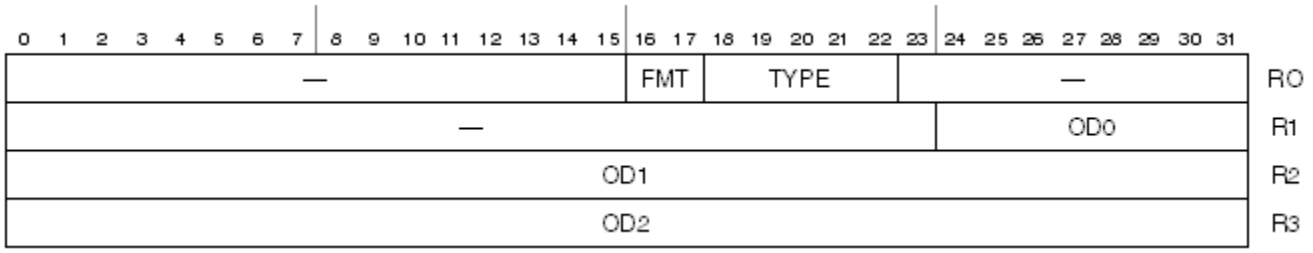

Figure 19-22. PCI Express error capture registers, outbound case

Table 19-17. PCI Express error capture register n field descriptions internal source, outbound transaction

ERR_CAP_n	Bits	Name	Description
R0	0-15	Reserved	-
	16-17	FMT	Header format
	18-22	TYPE	Transaction type
	23-31	Reserved	-
R1	0-23	Reserved	-
	24-31	OD0	Internal platform transaction information. Reserved for factory debug.
R2	0-31	OD1	Internal platform transaction information. Reserved for factory debug.
R3	0-31	OD2	Internal platform transaction information. Reserved for factory debug.

19.6.1.12.4.2 Error capture registers (inbound error)

PEX_ERR_CAP_Rn for the case when the error is caused by an inbound transaction from an external source are shown in the following figure and tables.

Inbound transactions that result in any af the following PEX_ERR_DR bits being set will result in PEX_ERR_CAP_STAT[GSID] indicating the controller itself was the source of the error:

- PEX_ERR_DR[PNM]
- PEX_ERR_DR[PCAC]
- PEX_ERR_DR[CDNSC]
- PEX_ERR_DR[CRSNC]
- PEX_ERR_DR[LME]
- PEX_ERR_DR[UREP]

19.6.2 Interrupts

Both INTx and message signaled interrupts (MSI) are supported; however there are differences depending on whether the PCI Express controller is configured as an RC or EP device.

19.6.2.1 EP Interrupt Generation

19.6.2.1.1 Hardware INTx Message Generation

Hardware INTx message generation is not supported in EP mode.

19.6.2.1.2 Hardware MSI Generation

In EP mode, the PCI Express controller can be configured to automatically generate MSI transactions to the root complex when an interrupt event occurs.

The PCI Express controller uses *sie1* (an internal signal) to trigger the generation of the MSI. To trigger the MSI, interrupt events must be routed to the appropriate *sie1* by setting the INTTGT field to 0xF1 in the associated Interrupt Level register in the MPIC. Note that sie1 is sent to all PCI Express controllers.

The remote root complex is expected set up the MSI capability structure of all endpoints at system initialization by filling the Message Address and Message Data registers with appropriate values and setting the MSIE bit in the MSI Message Control register.

With the PCI Express controller properly configured, when it detects the leading edge of *sie1* going active, it generates a PCI Express memory write transaction to the address specified in the MSI Message Address register (and MSI Message Upper Address register) with a data payload as specified in the MSI Message Data register (with leading zeros appended).

19.6.2.1.3 Software MSI Generation

Host software has to set up the MSI capability registers to enable MSI mode, and have the correct values for the MSI address and data register.

Then local software has to read the MSI address in the MSI capability register and configure the outbound ATMU window to map the translated address to the MSI address. Software has to determine the number of allocated messages in the MSI capability register and allocates the appropriate data values to use. A write to the ATMU window containing the MSI address with the appropriate data value generates the desired MSI transaction to the remote RC.

19.6.2.2 RC Handling of INTx Message and MSI Interrupts

19.6.2.2.1 INTx Message Handling

MSIs are the preferred interrupt signaling mechanism for PCI Express. However, in RC mode, the PCI Express controller supports the INTx virtual-wire interrupt signaling mechanism (as described in the PCI Express specification).

Whenever the controller receives an inbound INTx (INTA, INTB, INTC, or INTD) asserted or negated message, it asserts or negates an equivalent internal INTx signal (*inta*, *intb*, *intc*, or *intd*) to the interrupt controller (MPIC).

The internal INTx signals from the PCI Express controller may be logically combined with the external interrupt request (IRQn) signals so that they share the same interrupt controlled by the associated EIVPRn and EIDRn registers in the PIC. Refer to PCI Express INTx/External Interrupt IRQn Sharing for more information about sharing of PCI Express INTx interrupts and the IRQn signals.

If a PCI Express INTx interrupt is being used, then the MPIC must be configured so that external interrupts are level-sensitive (EIVPRn[S] = 1).

19.6.2.2.2 MSI Handling

An inbound MSI cycle must hit into the PEXCSRBAR window with the address offset that points to the MSIIR register in the PIC.

Note that it is the responsibility of the host software to configure each EP's MSI capability registers such that an MSI cycle generated from the EP device is routed to the MSIIR register in the PIC and for the appropriate interrupt to be generated to the core.

19.6.2.3 MSI-X Operations (SR-IOV-only)

MSI-X defines a separate optional extension to basic MSI functionality. Compared to MSI, MSI-X supports a larger maximum number of vectors per function, the ability for software to control aliasing when fewer vectors are allocated than requested, plus the ability for each vector to use an independent address and data value, specified by a MSI-X vector table that resides in PCI Express memory space.

PEX_AOR defines the MSI-X vector table address when PEX_AOR[M] = 10, as follows:

Offset 0x050 Access: Read/Write

	0	1–3	4–5	6–9	10–15	16–20	21–23	24–25	26–27	28–29	30–31
R	TYPE	-	PF	-	VF	-	IDX	-	EIDX	-	M
W											
Reset	All zeros										

Table 19-22. PEX_AOR Field Descriptions when M=10

Bits	Name	Description
0	TYPE	0, Access to PF MSI-X vector table for EP with SR-IOV. 1, Access to VF MSI-X vector table for EP with SR-IOV.
1-3	-	Reserved.
4-5	PF	Physical Function
6-9	-	Reserved.
10-15	VF	Virtual Function
16-20	-	Reserved.
21-23	IDX	MSI-X Entry Index in each VF.
24-25	-	Reserved.
26-27	EIDX	Extended index. This field provides which 4-byte entity within the MSI-X table entry to access. 00 First 4 bytes (lower 32-bit vector address) 01 Second 4 bytes (upper 32-bit vector address) 10 Third 4-bytes (vector data) 11 Fourth 4 bytes (vector control)
28-29	-	Reserved.
30-31	M	Mode=10

NOTE

Data will be byte-swapped.

To access a MSI-X vector table, the PF, VF, IDX, EIDX are concatenated to form the 4-byte aligned address of the register within the MSI-X vector table. That is, the register address is

PF || VF || IDX || EIDX || 0b00.

Eight MSI-X vectors are supported for each PF or VF. With two PF and 64 VF for each PF, there is a total of 16 MSI-X vectors for PF only (2 PFs x 8 vectors) and 1024 MSI-X vectors for VFs (64 VFs x 2 PFs x 8 vectors).

The MSI-X vector table structure is defined by the *PCI Express Base Specification, Revision 3.0*. Each MSI-X vector entry is 16 bytes long which consists of four bytes for vector control, four bytes for message data, and eight bytes for message address. The MSI-X vector table entry is summarized in the table below.

Table 19-23. MSI-X Vector Table Entry Definition

Byte	Bit	Field	Meaning
3:0		Message Address	System-specified PCI Express message address. For MSI-X messages, the contents of this field from an MSI-X Table entry specifies the lower portion of the DWORD-aligned address (AD[31::02]) for the memory write transaction. AD[1::0] must already be 0. This field is read/write.
7:4		Message Upper Address	System-specified message upper address bits. If this field is zero, Single Address Cycle (SAC) messages are used. If this field is non-zero, Dual Address Cycle (DAC) messages are used. This field is read/write.
11:8		Message Data	System-specified message data. For MSI-X messages, the contents of this field from an MSI-X Table entry specifies the data driven on AD[31::00] during the memory write transaction's data phase. C/BE[3::0]# are asserted during the data phase of the memory write transaction. In contrast to message data used for MSI messages, the low-order message data bits in MSI-X messages are not modified by the function. This field is read/write.
15:12	31:1	Reserved	After reset, the state of these bits must be 0.
	0	Mask Bit	When this bit is set, the function is prohibited from sending a message using this MSI-X Table entry. However, any other MSI-X Table entries programmed with the same vector will still be capable of sending an equivalent message unless they are also masked. This bit's state after reset is 1 (entry is masked). This bit is read/write.

The MSI-X PBA is also defined in the *PCI Express Base Specification, Revision 3.0*. Each PBA entry is with QWORD length corresponding to the pending status of 64 MSI-X vector interrupt.

PEX_AOR defines the MSI-X PBA structure address when PEX_AOR[M] = 11, as follows:

Offset 0x050 Access: Read/Write

	0	1–3	4	5	6–9	10–15	16–20	21–23	24–26	27	28	29–31
R	TYPE	-	PF		-	VF	-	IDX	-	EIDX		-	M
W													
Reset	All zeros												

Table 19-25. PEX_AOR Field Descriptions when M=11

Bits	Name	Description
0	TYPE	0, Access to PF MSI-X vector table for EP with SR-IOV. 1, Access to VF MSI-X vector table for EP with SR-IOV.
1-3	-	Reserved.
4-5	PF	Physical Function
6-9	-	Reserved.
10-15	VF	Virtual Function
16-20	-	Reserved.
21-23	IDX	MSI-X Entry Index in each VF.
24-25	-	Reserved.
26-27	EIDX	Extended index. This field provides which 4-Byte entity within the MSI-X PBA structure to access. 00 - PBA bits for 0-31 MSI-X vector of the function. 01 - PBA bits for 32-63 MSI-X vector of the function. 10 - PBA bits for 64-95 MSI-X vector of the fucnction. 11 - PBA bits for 96-127 MSI-X vector of the function.
28-29	-	Reserved.
30-31	M	Mode=11

NOTE

Note: Data will be byte-swapped.

To access a MSI-X PBA structure, the PF, VF, IDX, EIDXare concatenated to form the 4-byte aligned address of the register within the MSI-X PBA structure. That is, the register address is

PF || VF || IDX || EIDX || 0b00.

The 4-byte data returned is the pending bit status for 32 MSI-X vectors corresponding to the EIDX field.

Both MSI-X vector table and PBA structure can be accessed by the root complex through memory read/write transactions. By default, the BAR indicator register (BIR) in the MSI-X capability structure indicates BAR1 of each function is used to access the MSI-X vector table structure as well as the MSI-X pending bt array (PBA) structure as residing in PCI Express memory space. The PBA structure is right on top of the MSI-X vector table.

19.6.2.3.1 Enable MSI-X Operation

At reset, MSI-X is disabled with MSI-X enable bit in the MSI-X message control register cleared. System software can set the MSI-X enable bit to enable MSI-X operation. For each function, MSI and MSI-X operation can not be enabled at the same time.

When the PEX controller is configured in EP mode, either MSI or MSI-X operation is supported (but not both). When the PEX controller is configured in RC mode, only MSI operation is supported.

19.6.2.3.2 MSI-X Configuration

Depending upon system software policy, system software, device driver software, or each at different times or environments may configure a function's MSI-X capability and table structures with suitable vectors. Prior to enabling MSI-X operation, device driver needs to initialize the Table Offset and PBA Offset for all PFs. Recommended offset settings are shown in the following table:

Table 19-26. MSI-X Table/PBA Offset Assignment

PCI Express address assignment (lower 13-bit)	PF/VF assignment	Programmed Offset (lower 16-bit)
0x0000-0x0007F	Based on BAR1 hit (PF0,VF1:64, PF1,VF1:64)	Table Offset = 0x0000
0x1000-0x100F	Bsed on BAR1 hit (PF0,VF1:64, PF1,VF1:64)	PBA Offset = 0x0200

Note that the upper bit offset setting of Table/PBA should be programmed to match the BIR base address (BAR1). In addition, device driver also needs to program the PEXIWAR1[IWS]/PEXVFIWAR1 size to 8 Kbytes for accessing MSI-X vector/PBA tables. Note that there are only 8 vectors per PF/VF, accessing the lower 4K MSI-X vector/PBA table that do not fall within the 8 vector entries will alias.

Software reads the Table Size field from the Message Control register to determine the MSI-X Table size. Software calculates the base address of the MSI-X Table by reading the 32-bit value from the Table Offset/Table BIR register. Software calculates the base address of the MSI-X PBA using the same process with the PBA Offset/PBA BIR register. For each MSI-X Table entry that will be used, software fills in the MSI-X support Function Masking in MSI-X Message Control register.

When the MSI-X Function Mask bit is set, all of the function's entries must behave as being masked, regardless of the per-entry Mask bit states. "Per-vector masking" in MSI-X is controlled by a Mask bit in each MSI-X Table entry.

19.6.2.3.3 Send MSI-X Transaction

To request MSI-X Send service operation using a given MSI-X Table entry in an EP, Software performs a memory write to a designated MSI-X trap address window enabled by PEXMSIX_TOWAR[EN] register bit.

The MSI-X trap window is defined by a 4K address range, within which any of the 64-Byte aligned address offset can be written to initiate a MSI-X send operation. The MSI-X trap window is defined per PF. To send a VF MSI-X transaction, software should perform arbitration to ensure that the proper VF MSI-X message is being sent, especially when there are multiple threads involved.

When a 4-byte memory write transaction to any of the 64-byte aligned address offset with a specific transaction size within the MSI-X trap window is received by the PEX controller, it is interpreted as a MSI-X trap operation. Hardware will trigger scheduling of a MSI-X transaction for the corresponding MSI-X vector. The 4 bytes byte of the memory write data contains the MSI-X vector information to be used for the MSI-X transaction with the rest of the memory write data ignored by the PEX controller:

Table 19-27. PEXMSIX Trap Data (4-MSB Byte) Field Descriptions

Bits	Name	Description
0	TYPE	0, trigger MSI-X operation for PF of EP with SR-IOV 1, trigger MSI-X operation for VF of EP with SR-IOV
1-9	-	Reserved.
10-15	VF	Virtual Function Number.
16-20	-	Reserved.
21-23	IDX	MSI-X Entry Index in each PF or VF.
24-29	-	Reserved.
30-31	OP	00, trigger the Send operation for the corresponding MSI-X vector. 01, clear the Pending status bit for the corresponding MSI-X vector. This operation is used by local software to clear a pending transaction while a vector is masked. Clearing a Pending MSI-X transaction while the vector is unmasked has undefined results. 10-11, Reserved

A write transaction to MSI-X trap window will be undefined for any of the following conditions:

- PEXMSIX_TOWAR[EN] is cleared.
- The write data size is neither 4 bytes, 32 bytes, nor 64 bytes.
- The write address falls in the MSI-X trap window but is not 64-byte aligned.

Reading from a local physical address that hits in the MSI-X trap window is undefined regardless of the data size.

NOTE

Software is allowed to use cache flush instruction (i.e. DCBF) to optimize the performance of memory write operation to initiate MSI-X operation. Different address offsets are supported to trigger MSI-X operations to allow multiple cores

to independently initiate MSI-X operation with different Cache line resident in its private cache.

Undesired behavior could happen if the cache lines containing the MSI-X vector information were made coherent and different cores are accessing the cache line at the same time. Software is responsible to follow the convention of using different 64-byte address offset for triggering MSI-X operations for different physical core or threads.

Hardware keeps track of the MSI-X message request and will send a DW memory transaction with the message address and message data from the corresponding MSI-X vector if all the following conditions are met:

- MSI-X function masking is not set.
- Per-vector masking is not set.
- There is no other outstanding MSI-X transactions being sent.
- The current MSI-X request is the winning request among all the pending MSI-X requests to be sent subject to a Round-Robin priority selection as described in MSI-X Transaction Generation Prioritization.

If any of the above condition is not true and the current MSI-X transaction can not be sent immediately, hardware asserts Pending register bit in the PBA structure. If a MSI-X transaction is successfully sent, hardware clears its Pending register bit in the PBA structure. The Pending register bit status is available to local software via the PEX_AOR and PEX_LDR registers for the corresponding MSI-X vector of each function.

In the case when hardware is able to send a MSI-X transaction, the MSI-X transaction will be sent as a DWORD memory write transaction using the contents of the Message Data field entry for data, the contents of the Message Upper Address field for the upper 32 bits of address, and the contents of the Message Address field entry for the lower 32 bits of address for the corresponding MSI-X vector entry.

When software unmasks a vector whose associated Pending bit is set, hardware schedules sending the associated MSI-X message and clear the Pending bit as soon as the message has been sent. When software clears the MSI-X Function Mask bit, it could results in many messages to be sent and hardware scans through the PBA structure and send each MSI-X message as soon as possible per the prioritization rule described MSI-X Transaction Generation Prioritization.

NOTE

Host software can use the Masking bit in the MSI-X vector table to handle multiple MSI-X interrupt requests. A given vector's interrupt service routine on host can set the vector's Mask bit before it services any associated interrupting events

and clears the Mask bit after it has serviced all the events it knows about. Any occurrence of a new event while the Mask bit is set results in the Pending bit being set.

If a function sends messages with the same vector multiple times before being acknowledged by software, only one message is guaranteed to be serviced. Software is required to properly acknowledge the MSI-X message interrupts, typically by device driver handshake. Therefore, once a message is sent with Vector A, it can not send Vector A again until it is explicitly enabled to do so by its device driver.

Host software is allowed to mask one or more vectors indefinitely and service the associated interrupt events by polling their Pending bits in PBA structure. The Masking register bit in the Vector Control part of the MSI-X vector table is also made available to the local Software of a function.

19.6.2.3.4 MSI-X Transaction Generation Prioritization

SR-IOV-only: When there are any pending MSI-X transactions in PBA, hardware schedules MSI-X transaction using round-robin priority selection as described below:

- Hardware maintains one MSI-X vector index register in PEX controller.
- Hardware scans through from the index every time hardware is scheduling for new MSI-X transaction.
- When a MSI-X vector is selected, the vector number incremented by 1 is recorded by hardware as the index. 0 will be recorded if the selected vector number is the maximum vector number supported by the PEX controller.
- Hardware carries out the handshake with the PCI Express transaction layer to generate the MSI-X transaction for the corresponding MSI-X vector.
- The MSI-X vector index is initialized as 0 at reset.

19.6.3 Initial Credit Advertisement

To prevent overflowing of the receiver's buffers and for ordering compliance purposes, the transmitter cannot send transactions unless it has enough flow control (FC) credits to send. Each device maintains an FC credit pool. The FC information is conveyed between the two link partners by DLLPs during link training (initial credit advertisement). The transaction layer performs the FC accounting functions. One FC unit is four DWs (16-bytes) of data.

Table 19-28. Initial credit advertisement

Credit Type	Initial Credit Advertisement
PH (Memory Write, Message Write)	8
PD (Memory Write, Message Write)	128
NPH (Memory Read, IO Read, Cfg Read, Cfg Write)	12
NPD (IO Write, Cfg Write)	2
CPLH (Memory Read Completion, IO R/W Completion, Cfg R/W Completion)	Infinite
CPLD (Memory Read Completion, IO Read Completion, Cfg Read Completion)	Infinite

19.6.4 Power Management

All device power states are supported with the exception of D3cold. Only L0s ASPM mode is supported if enabled by configuring the Link Control register's bits 1-0 in configuration space. Note that there is no power saving in the controller when the device is put into a non-D0 state. The only power saving is the I/O drivers when the controller is put into a non-L0 link state.

Table 19-29. Power Management State Supported

Component D-State	Permissible Interconnect State	Action
D0	L0, L0s	In full operation.
D1	L0, L0s, L1	All outbound traffic is stalled. All inbound traffic is thrown away. The only exceptions are PME messages and configuration transactions. If the device is in RC mode, it is permissible to send a PM_Turn_Off message through the PEX Power Management Command register.
D2	L0, L0s, L1	All outbound traffic is stalled. All inbound traffic is thrown away. The only exceptions are PME messages and configuration transactions. If the device is in RC mode, it is permissible to send a PM_Turn_Off message through the PEX Power Management Command register.
D3hot	L0, L0s, L1, L2/L3 Ready	All outbound traffic is stalled. All inbound traffic is thrown away. The only exceptions are PME messages and configuration transactions. If the device is in RC mode, it is permissible to send a PM_Turn_Off message through the PEX Power Management Command register. Note that if a transition of D3hot to D0 occurs, a reset is performed to the controller's configuration space. In addition, link training restarts.
D3cold	L3	Completely off.

19.6.4.1 L2/L3 Ready Link State

The L2/L3 Ready link state is entered after the EP device is put into a D3hot state followed by a PME_Turn_Off/PME_TO_Ack message handshake protocol. Exiting this state requires a POR reset or a WAKE_B signal from the EP device. The PCI Express controller (in EP mode) does not support the generation of beacon; therefore, as an alternative, the device can use one of the GPIO signals as an enable to an external tristate buffer to generate a WAKE_B signal, as shown in the figure below.

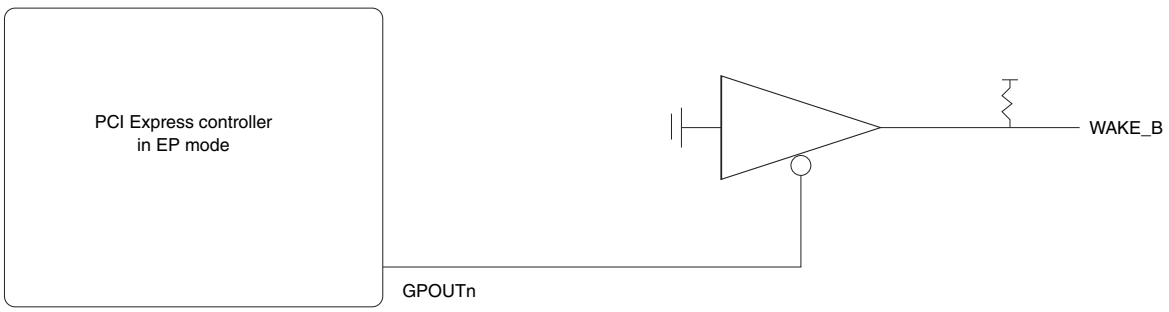

Figure 19-26. WAKE_B Generation Example

In RC mode, the WAKE_B signal from the EP device can be connected to one of the external interrupt inputs to service the WAKE_B request.

19.6.5 Hot Reset

When a hot reset condition occurs, the controller (in both RC and EP mode) initiates a clean-up of all outstanding transactions and returns to an idle state. All configuration register bits that are non-sticky are reset. Link training takes place subsequently. The device is permitted to generate a hot reset condition on the bus when it is configured as an RC device by setting the "Secondary Bus Reset" bit in the Bridge Control Register in the configuration space. As an EP device, it is not permitted to generate a hot reset condition; it can only detected a hot reset condition and initiates the clean-up procedure appropriately.

19.6.6 Alternative Routing ID (ARI, SR-IOV only)

ARI is not applicable to Root Complex; all other SR-IOV Capable Devices (Devices that include at least one PF) shall implement the ARI Capability in each Function. PF Routing IDs are determined based on the Next Function Number in the Alternative Routing ID Interpretation Extended Capability (ARI) register. VF Routing IDs are determined using the First VF Offset and the VF Stride configuration settings.

19.6.7 Functional Level Reset (FLR, SR-IOV only)

An FLR reset can be issued for a PF or VF by software by setting the IFLR bit in PCI Express device control register associated with the PF/VF. The controller will finish processing all outstanding transactions associated with the PF/VF and return to an idle state. Any new transactions targeted toward the PF or VF while the IFLR bit is set will be dropped (posted transactions) or errored out (outbound non-posted transactions) or returned UR (inbound non-posted transactions) until the IFLR bit is cleared by hardware. Traffic that are toward PF or VF without the IFLR bit set continue as before.

19.6.8 Link Down

Typically, a link down condition occurs after a hot reset event; however, it is possible for the link to go down unexpectedly without a hot reset event. When this occurs, a link down condition is detected (PEX_PME_MSG_DR[LDD]=1). Link down is treated similarly to a hot reset condition.

Subsequently, while the link is down, all new posted outbound transactions are discarded. All new non-posted ATMU transactions are errored out. Non-posted configuration transactions issued using PEX_CONFIG_ADDR/PEX_CONFIG_DATA toward the link returns 0xFFFF_FFFF (all 1s). As soon as the link is up again, the sending of transaction resumes.

A link down condition causes the controller to reset all non-sticky bits in its PCI Express configuration registers as if it had been hot reset.

19.6.9 LIODN Permission Table

The LIODN permission table assigns all inbound transactions toward memory with a 12-bit LIODN field that is used for the purpose of memory's access permission. At initialization, software is responsible for programming the LIODN permission table that maps RID (Routing ID of 16-bit if ARI is enabled or Transaction ID if ARI is not enabled) within a transaction to 10 bit LIODN offset. This 10-bit field is then added to PEX_LBR[LB] to form a 12-bit LIODN field that will identify the transaction as it is forwarded to memory.

Each entry in the LIODN permission table is 64-bit and has the following meaning:

Table 19-30. LIODN permission table entry definition

Bit	Meaning
0:15	RID. Routing ID of a transaction. Bit 0-7 identifies the bus # of a transaction.
16:31	Mask. Identify the bit position of RID to examine. 1 means that the bit should be ignored (ie always result in a match) and 0 means it should be compared.
32:33	Reserved
34:43	LIODN offset. This field identifies the 10-bit LIODN offset that is assigned to a transaction that matches the RID specified in bit 0:15.
61-62	Reserved
63	Enable. This field identifies the matching operation that will be done for the transaction that contains the RID specified in bit 0:15. 0 - disable. This entry is disable. 1 - match on RID & Mask.

The physical size of the LIODN permission table is 64-entry deep.

19.6.9.1 Programming the LIODN Permission Table

To access the LIODN table, software has to use the PEX_AOR/PEX_UDR/PEX_LDR registers in an indirect manner to program the table's entries to appropriate value. It is assumed that software is responsible for knowing the RIDs within a system and which permission (ie LIODN offset) is used for a particular RID. At startup, the default mode value of entry 0 is enable with a mask of ffff and the LIODN offset for entry 0 is 0.

PEX_AOR defines the LIODN permissions table address offset when PEX_AOR[M] = 01, as follows:

Offset 0x050 Access: Read/Write

	0	21	22	27	28	31
R W	-		ADDR		-	01
Reset	All zeros					

Table 19-32. PEX_AOR Field Descriptions when M=01

Bits	Name	Description
0-21	-	Reserved.
22-27	ADDR	Address. This field provides the address offset into the LIODN table. Each entry in the table is 64-bits.
28-29	-	Reserved.
30-31	M	Mode = 01

The following steps are used to determine an LIODN lookup table match:

- If RID matching operation is enabled, an inbound transaction RID is AND'ed with each entry's inverse MASK field.
- Each entry's RID field is AND'ed with the inverse MASK field.
- The results of items #1 and #2 are AND'ed with the entry's EN field and compared to determine if a match has been detected.
- A winning match will be determined by a valid match for the lowest entry.
- If Inbound Memory transaction hits Inbound MSI ATMU window, the resulting LIODN field is calculated from the following:
  - {4'b0000, PEXMSI_LBR[LBASE]} +
  - {6'b000000, winning entry's LOFFSET field}
- Otherwise, The resulting LIODN field is calculated from the following:
  - {4'b0000, PEX_LBR[LBASE]} +
  - {6'b000000, winning entry's LOFFSET field}

An inbound memory request that does not match any entry of the LIODN lookup table will be considered a logical inbound LIODN error and logged in PEX_ERR_DR[LDDE] register. Inbound Non-Posted memory transaction will return UR and Inbound Posted memory transaction will be dropped.

At startup, the default values of the LIODN permission table look like this:

Table 19-33. LIODN permission table default value

Entry#	Entry value	Meaning
0	0x0000_ffff_0000_0001	All memory transactions are accepted and LIODN offset of 0 is used if the address of the transaction is hitting into any PF or VF space.
1:63	0x0000_0000_0000_0000	Entry is disable.

Here is another example of how the LIODN permission table is programmed.

Table 19-34. LIODN permission table example

Entry#	Entry value	Meaning
0	0x1234_0000_0010_1001	All memory transactions with RID of 0x1234 are allowed to map to PF 0 space only. If the address of this transaction is hitting into PF 0's PF space, then LIODN offset of 1 is used for the transaction. Otherwise, for posted transaction, it will be dropped. For non-posted transaction, a UR is returned.
1	0x5678_0000_0029_8009	All memory transactions with RID of 0x5678 are allowed to map to PF 0, or PF 3, or PF 4 space only. If the address of this transaction is hitting into PF 0's VF 1 space, or PF 3's VF 1 space, or PF 4's VF 1 space, then LIODN offset of 2 is used for the transaction. Otherwise, for posted transaction, it will be dropped. For non-posted transaction, a UR is returned.
2	0x789A_00ff_0010_0019	All memory transactions with RID's bus # of 0x78 are allowed to map to PF 0 space only. If the address of this transaction is hitting into PF 0's VF 3 space, then LIODN offset of 3 is used for the transaction. Otherwise, for posted transaction, it will be dropped. For non-posted transaction, a UR is returned.

Table continues on the next page...

Table 19-34. LIODN permission table example (continued)

Entry#	Entry value	Meaning
3	0xXXXX_ffff_XXXX_xxx1	All memory transactions are accepted and LIODN offset of 0 is used if the address of the transaction is hitting into any PF or VF space. Otherwise, for posted transaction, it will be dropped. For non-posted transaction, a UR is returned.
4:63	0x0000_0000_0000_0000	Entry is disable.

19.7 Initialization/Application Information

19.7.1 Initial start-up programming guide

Depending on whether the device in in EP or RC mode, the table below shows the minimum registers that must be initialized after link training finishes successfully in order for proper system operation. Software is responsible for initializing the steps.

Table 19-35. Recommended Initialization Steps

RC	EP
1. Set PCI Express Device Control register's MAX_PAYLOAD_SIZE and MAX_READ_SIZE to appropriate values 2. Program ATMU registers. See PCI Express ATMU Registers for more information 3. Set PCI Express Command register's Bus Master and Memory Space bits 4. Begin operation	1. Set PCI Express Device Control register's MAX_PAYLOAD_SIZE and MAX_READ_SIZE to appropriate values 2. Program ATMU registers. See PCI Express ATMU Registers for more information 3. Set PEX_CONFIG's CFG_READY bit 4. Set PCI Express Command register's Bus Master and Memory Space bits 5. Begin operation

19.7.2 Boot Mode and Inbound Configuration Transactions

In normal boot mode, the core is allowed to boot and configure the device. During this time, the PCI Express interface retries all inbound PCI Express configuration transactions. When the core has configured the device to a state where it can accept inbound PCI Express configuration transactions, the boot code should set PEX_CONFIG[CFG_READY] = 1 using a read-modify-write operation after which inbound PCI Express configuration transactions are accepted.

In boot hold-off mode, the core is prevented from fetching its first instruction by withholding its internal bus grant. During this time, the PCI Express interface accepts all inbound PCI Express configuration transactions which allows an external host/RC to configure the device. When the external host/RC has configured the device to a state

where it can allow the core to fetch code from the boot vector, it reconfigures the PCI Express controller to not be in hold-off mode in order for the core to start fetching its first instruction.

19.7.3 Expansion ROM

PCI Express Expansion ROM is supported with shared inbound expansion ROM ATMU window registers (PEXEPROMITAR and PEXEPROMIWAR) across physical functions.

During pre-boot initialization, the PBL can configure the inbound expansion ROM ATMU window registers in the PCI Express controller. Accesses from a remote host to the expansion ROM address range are translated to internal platform accesses to non-volatile memories attached to the local physical space for boot operations.

19.7.4 SR-IOV RID examples

Based on the number of VFs and PFs, different RIDs should be used to ensure approriate accesses to the configuration space of each PF/VF. Please note for RID that has bus number not on the device's captured bus number, it can only be accessed using configuration Type 1 cycle. Please note that SR-IOV Control[ARICH] must always be enabled by RC and RC must also set Device Control 2 [ARI Forwarding Enable] to one.

Table 19-36. SR-IOV configuration

SR-IOV Field	PF0	PF1
NumVF	64	64
First VF Offset	4	4
VF Stride	4	4

Table 19-37. SR-IOV RID examples

Function number	Description	Note
0	VF1, 2	Use configuration type 0 access
1	PF1	Use configuration type 0 access
2	Function not present	
3	Function not present	
4	VF 0,1	Use configuration type 0 access
5	VF 1, 1	Use configuration type 0 access
6	VF not present	
7	VF not present	
8	VF 0, 2	Use configuration type 0 access

Table continues on the next page...

Table 19-37. SR-IOV RID examples (continued)

Function number	Description	Note
9	VF 1, 2	Use configuration type 0 access
10	VF not present	
11	VF not present	
...	...	...
256	VF 0, 64	Use configuration type 1 access
257	VF 1, 64	Use configuration type 1 access

19.7.5 Gen 3 Link Equalization

Link equalization allows components to adjust the transmitter and receiver setup of each lane to improve the signal quality and meet the requirements for operating at Gen 3 data rates. However, link equalization cannot be performd in loopback mode. Before attempting link training in loopback mode link equalization must be disabled by setting the "Equalization Disable" bit in the Gen3 Control Register at PCI Express extended configuration space offset 890h.

Chapter 20
Serial RapidIO Interface

20.1 SRIO Overview

The serial RapidIO interface provides a RapidIO port to communicate with other RapidIO devices. This figure shows the RapidIO port unit.

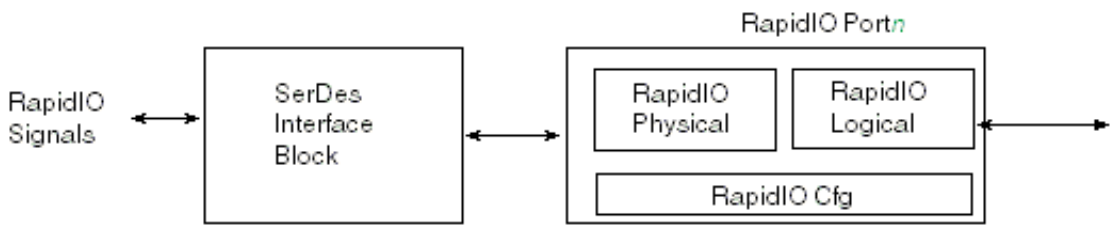

Figure 20-1. RapidIO Endpoint

20.2 SRIO Features Summary

The RapidIO port supports the following features of the RapidIO Interconnect Specification, Revision 2.1:

- Small or large size transport information field
- 34-bit addressing
- Up to 256-byte data payload
- Up to eight outstanding unacknowledged RapidIO transactions
- Hardware recovery only
- All transaction flows and all priorities
- Critical request flow (CRF) as described in the *RapidIO Interconnect Specification, Revision 1.3* Part 6: 1x/rx LP-Serial Physical Layer Specification.
- Register and register bit extensions as described in the *RapidIO Interconnect Specification, Revision 1.3*, *Part VIII: Error Management Extensions Specification*.
- Hot swap
- ATOMIC set/clr/inc/dec for read-modify-write operations

- IO_READ_HOME and FLUSH w/data for accessing cache-coherent data from a remote memory system
- Data streaming (type 9) and traffic management (type 9 extended) packet types as defined in the RapidIO Interconnect Specification, Revision 2.0.1, Part 10: Data Streaming Logical Specification
- Register and register bit extensions as described in the RapidIO Interconnect Specification, Revision 2.0.1, Part 10: Data Streaming Logical Specification
- Only supports receiver-controlled flow control
- Inbound transactions to the configuration registers are limited to 32-bit accesses only.
- Outbound maintenance transactions can be any valid size.

RapidIO endpoint supports the following user-defined features:

- Nine outbound ATMU windows with each window having up to 32 subwindows except the default window
- Five inbound ATMU windows
- Logical outbound packet time-to-live counter to prevent local processor from hanging when the RIO interface fails
- Accept-all mode of operation for failover support
- Pass-through mode of operation for RapidIO packets
- RapidIO random bit error injection
- Performance monitor interface

RapidIO endpoint does not support or has limited support of the following features of the *RapidIO Interconnect Specification, Revision 2.1*:

- No support for 50- and 66-bit addressing
- No support for software assisted error recovery
- No support for ATOMIC test-and-swap transaction
- No support for coherent (CC-NUMA) transactions with the exception of IO_READ_HOME and FLUSH w/data transactions
- No support for transmitter-controlled flow control
- No decrementing of a maintenance packet hop count (pass-through support does not imply switch functionality)
- No support for multicast event control symbols

RapidIO endpoint supports the following features of RapidIO LP-Serial:

- 1x, 2x, and 4x LP-Serial link interfaces
- Transmission rates of 2.5, 3.125, and 5 Gbaud (data rates of 2.0, 2.5, and 4.0 Gbps) per lane
- Auto detection of 1x, 2x, and 4x mode operation during port initialization
- Error detection for packets and control symbols
- Support for link initialization, synchronization, error recovery, and time-out

RapidIO endpoint does not support the following features of RapidIO LP-Serial:

- RapidIO endpoint cannot be configured as four 1x or two 2x ports

20.3 SRIO RapidIO Port Modes of Operation

The RapidIO port's primary operating modes include the following:

- 1x, 2x, or 4x LP-Serial link interfaces
- Transmission rates of 2.5, 3.125, or 5 Gbaud (data rates of 2.0, 2.5, or 4.0 Gbps) per lane
- Small or large size transport information field
- Accept-all mode of operation-all packets are accepted regardless of the target ID

20.4 LP-Serial Signal Descriptions

The high-speed interface signals used for the serial RapidIO interface are shared with other I/O ports and must be configured at power-on reset for use with the serial RapidIO controller

The following sections describe the serial RapidIO signal functionality. Refer to the *RapidIO Interconnect Specification,* Revision 2.0.1, Part 6: LP-Serial Physical Layer Specification, Chapter 8, Common Electrical Specifications, for electrical characteristic details.

20.4.1 Serial Rapid I/O Interface Overview

The serial Rapid I/O (SRIO) interface is compatible with the *RapidIO Interconnect Specification,* Revision 2.0.1, Part 6: LP-Serial Physical Layer Specification.

20.4.2 Serial Rapid I/O Interface Detailed Signal Descriptions

20.4.2.1 SD*n*_TX[*n*]/SD*n*_TX[*n*]_B-Outputs

These are the serial data outputs. They are differential pairs, one for each lane in 4x mode of operation. In the case of 2x mode of operation on the serial RapidIO interface, only the first and second lane may be used. In the case of 1x mode of operation on the serial RapidIO interface, only the first and third lanes may be used.

See *Part VI: Physical Layer 1x/4x LP-Serial Specification*, *RapidIO Interconnect Specification, Revision 2.1,* for complete details.

These outputs are asynchronous, as described in Part VI of the *RapidIO Interconnect Specification, Revision 2.1*. This implementation supports data rates of 2.5, 3.125, and 5 Gbaud.

20.4.2.2 SD*n*_RX[*n*]/SD*n*_RX[*n*]_B-Inputs

These are the serial data input pads. They are differential pairs, one for each lane in 4x mode of operation. In the case of 2x mode of operation on the serial RapidIO interface, only the first and second lane may be used. In the case of 1x mode of operation on the serial RapidIO interface, only the first lane is used.

See *Part VI: Physical Layer 1x/4x LP-Serial Specification*, *RapidIO Interconnect Specification, Revision 1.2.* for complete details.

These inputs are asynchronous, as described in Part VI of the *RapidIO Interconnect Specification, Revision 1.2*. This implementation supports data rates of 2.5, 3.125, and 5 Gbaud.

20.5 SRIO Memory Map/Register Definition

This table is the memory map of the RapidIO configuration registers.

SRIO memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
C_0000	Device identity capability register (SRIO_DIDCAR)	32	R	See section	20.5.1/1655
C_0004	Device information capability register (SRIO_DICAR)	32	R	0000_0000h	20.5.2/1656
C_0008	Assembly identity capability register (SRIO_AIDCAR)	32	R/W	0000_0000h	20.5.3/1656
C_000C	Assembly information capability register (SRIO_AICAR)	32	R/W	0000_0100h	20.5.4/1657

Table continues on the next page...

SRIO memory map (continued)

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
C_0010	Processing element features capability register (SRIO_PEFCAR)	32	R	See section	20.5.5/1657
C_0018	Source operations capability register (SRIO_SOCAR)	32	R	060C_FCF4h	20.5.6/1660
C_001C	Destination operations capability register (SRIO_DOCAR)	32	R	000C_FCF4h	20.5.7/1663
C_003C	Data streaming information capability register (SRIO_DSICAR)	32	R	0000_0018h	20.5.8/1666
C_0048	Data streaming logic layer command and status register (SRIO_DSLLCSR)	32	R	8000_0040h	20.5.9/1666
C_004C	Processing element logical layer control command and status register (SRIO_PELLCCSR)	32	R	0000_0001h	20.5.10/ 1667
C_005C	Local configuration space base address 1 command and status register (SRIO_LCSBA1CSR)	32	R/W	0000_0000h	20.5.11/ 1668
C_0060	Base device ID command and status register (SRIO_BDIDCSR)	32	R/W	See section	20.5.12/ 1669
C_0068	Host base device ID lock command and status register (SRIO_HBDIDLCSR)	32	R/W	0000_FFFFh	20.5.13/ 1670
C_006C	Component tag command and status register (SRIO_CTCSR)	32	R/W	0000_0000h	20.5.14/ 1670
C_0100	Port maintenance block header 0 (SRIO_PMBH0)	32	R	0600_0001h	20.5.15/ 1671
C_0120	Port link time-out control command and status register (SRIO_PLTOCCSR)	32	R/W	FFFF_FF00h	20.5.16/ 1671
C_0124	Port response time-out control command and status register (SRIO_PRTOCCSR)	32	R/W	FFFF_FF00h	20.5.17/ 1672
C_013C	Port General control command and status register (SRIO_GCCSR)	32	R/W	See section	20.5.18/ 1673
C_0140	Port 1 Link maintenance request command and status register (SRIO_P1LMREQCSR)	32	R/W	0000_0000h	20.5.19/ 1674
C_0144	Port 1 Link maintenance response command and status register (SRIO_P1LMRESPCSR)	32	R	0000_0000h	20.5.20/ 1675
C_0148	Port 1 Local ackID status command and status register (SRIO_P1LASCSR)	32	R/W	0000_0000h	20.5.21/ 1676
C_0158	Port 1 Error and status command and status register (SRIO_P1ESCSR)	32	R/W	0000_0001h	20.5.22/ 1677
C_015C	Port 1 Control command and status register (SRIO_P1CCSR)	32	R/W	D060_0001h	20.5.23/ 1679
C_0160	Port 2 Link maintenance request command and status register (SRIO_P2LMREQCSR)	32	R/W	0000_0000h	20.5.24/ 1681
C_0164	Port 2 Link maintenance response command and status register (SRIO_P2LMRESPCSR)	32	R	0000_0000h	20.5.25/ 1682
C_0168	Port 2 Local ackID status command and status register (SRIO_P2LASCSR)	32	R/W	0000_0000h	20.5.26/ 1683
C_0178	Port 2 Error and status command and status register (SRIO_P2ESCSR)	32	R/W	0000_0001h	20.5.27/ 1684

Table continues on the next page...

SRIO memory map (continued)

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
C_017C	Port 2 Control command and status register (SRIO_P2CCSR)	32	R/W	D060_0001h	20.5.28/ 1686
C_0600	Error reporting block header (SRIO_ERBH)	32	R	0000_0007h	20.5.29/ 1688

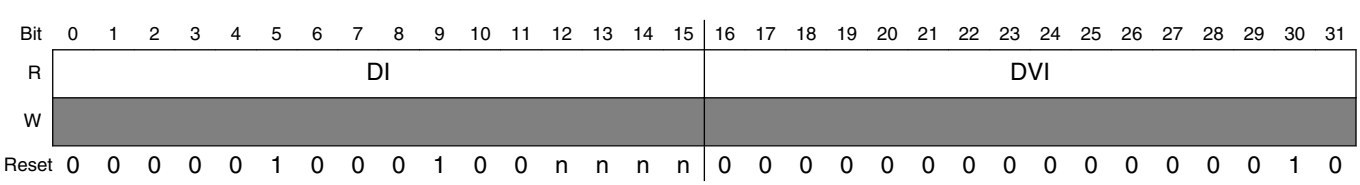
20.5.1 Device identity capability register (SRIO_DIDCAR)

The device vendor identity field (DVI) identifies the vendor that manufactured the device containing the processing element. A value for DVI is uniquely assigned to a device vendor by the registration authority of the RapidIO Trade Association.

The device identity field (DI) is intended to uniquely identify the type of device from the vendor specified by DVI. The values for DI are assigned and managed by the respective vendor.

Address: C_0000h base + 0h offset = C_0000h



SRIO_DIDCAR field descriptions

Field	Description
0–15 DI	Device identity 0x0440 (T4240 with security) 0x0441 (T4240 without security) 0x0442 (T4160 with security) 0x0443 (T4160 without security) 0x044A (T4080 with security) 0x044B (T4080 without security)
16–31 DVI	Device vendor identity 0x0002 (Freescale)

20.5.2 Device information capability register (SRIO_DICAR)

The device revision field (DR) is intended to identify the revision level of the device. The value for DR is assigned and managed by the vendor specified by DIDCAR[DVI]. DICAR represents a copy of the device's system version register (SVR). See Section SVR for more information.

Address: C_0000h base + 4h offset = C_0004h

SRIO_DICAR field descriptions

Field	Description
0–31 DR	Device revision. This is a copy of the device's system version register (SVR). See SVR for additional information.

20.5.3 Assembly identity capability register (SRIO_AIDCAR)

The assembly vendor identity field (AVI) identifies the vendor that manufactured the assembly or subsystem containing the device. A value for AVI is uniquely assigned to an assembly vendor by the registration authority of the RapidIO Trade Association.

The assembly identity field (AI) is intended to uniquely identify the type of assembly from the vendor specified by AVI. The values for AI are assigned and managed by the respective vendor.

Address: C_0000h base + 8h offset = C_0008h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SRIO_AICAR field descriptions

Field	Description
0–15 AR	AssyRev field (all zeros) **NOTE:** This field is write-able until boot completion.
16–31 EFP	ExtendedFeaturesPtr field (0x100)

20.5.5 Processing element features capability register (SRIO_PEFCAR)

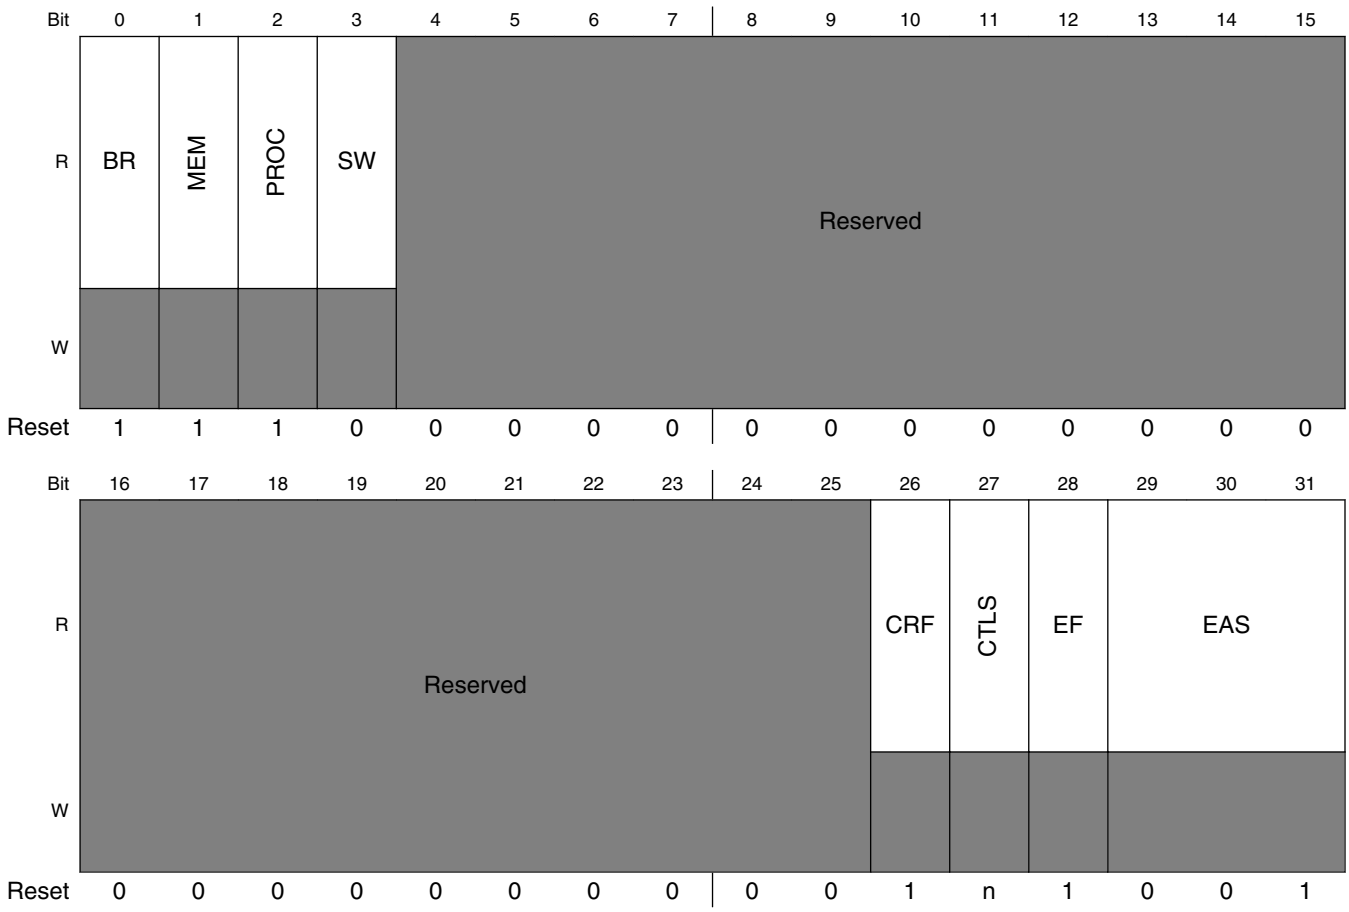
The processing element features capability register (PEFCAR), identifies the major functionality provided by the processing element. PEFCAR is a read-only register

NOTE

Values indicated with n are determined at power-on reset. See Section 4.4.3.12, "RapidIO System Size," for POR configuration details.

.

Address: C_0000h base + 10h offset = C_0010h



SRIO_PEFCAR field descriptions

Field	Description
0 BR	Bridge. PE can bridge to another interface. (BR = 1)
1 MEM	Memory. PE has physically addressable local address space and can be accessed as an endpoint through non-maintenance operations. (MEM = 1)
2 PROC	Processor. PE physically contains a local processor that executes code. (PROC = 1)
3 SW	Switch. PE does not bridge to another external RapidIO interface. (SW = 0)
4–25 -	This field is reserved. Reserved

Table continues on the next page...

SRIO_PEFCAR field descriptions (continued)

Field	Description
26 CRF	Critical request flow. PE supports the critical request flow (CRF) function. (CRF = 1)
27 CTLS	This bit reflects the selected RapidIO common transport system size. The RapidIO common transport system size is determined at power-on reset. 0 PE only supports common transport small systems (up to 256 devices). 1 PE supports common transport large systems (up to 65,536 devices).
28 EF	Extended features pointer is valid. (EF = 1)
29–31 EAS	Indicates the number of address bits supported by the PE both as a source and target of an operation. EAS = 001(34-bit addresses)

20.5.6 Source operations capability register (SRIO_SOCAR)

The source operations capability register (SOCAR), defines the set of RapidIO I/O logical operations that can be issued by this processing element. SOCAR is a read-only register. SOCAR settings are configurable via pins and can be modified. Must add note to NOT modify these bits to something other than their settings below.

Address: C_0000h base + 18h offset = C_0018h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

18 SW	PE supports an Swrite operation. (SW = 1)
19 NWR	PE supports a Nwrite_R operation. (NWR = 1)
20 M	PE supports a Message operation. (M = 1)
21 D	PE supports a Doorbell operation. (D = 1)
22 -	This field is reserved. Reserved
23 ATS	PE does not support an Atomic-Test-and-Swap operation. (ATS = 0)
24 AI	PE supports an Atomic-Inc operation. (AI = 1)
25 AD	PE supports an Atomic-Dec operation. (AD = 1)
26 AS	PE supports an Atomic-Set operation. (AS = 1)
27 AC	PE supports an Atomic-Clr operation. (AC = 1)
28 -	This field is reserved. Reserved
29 PW	PE supports a Port-Write operation. (PW = 1)
30–31 -	This field is reserved. Reserved

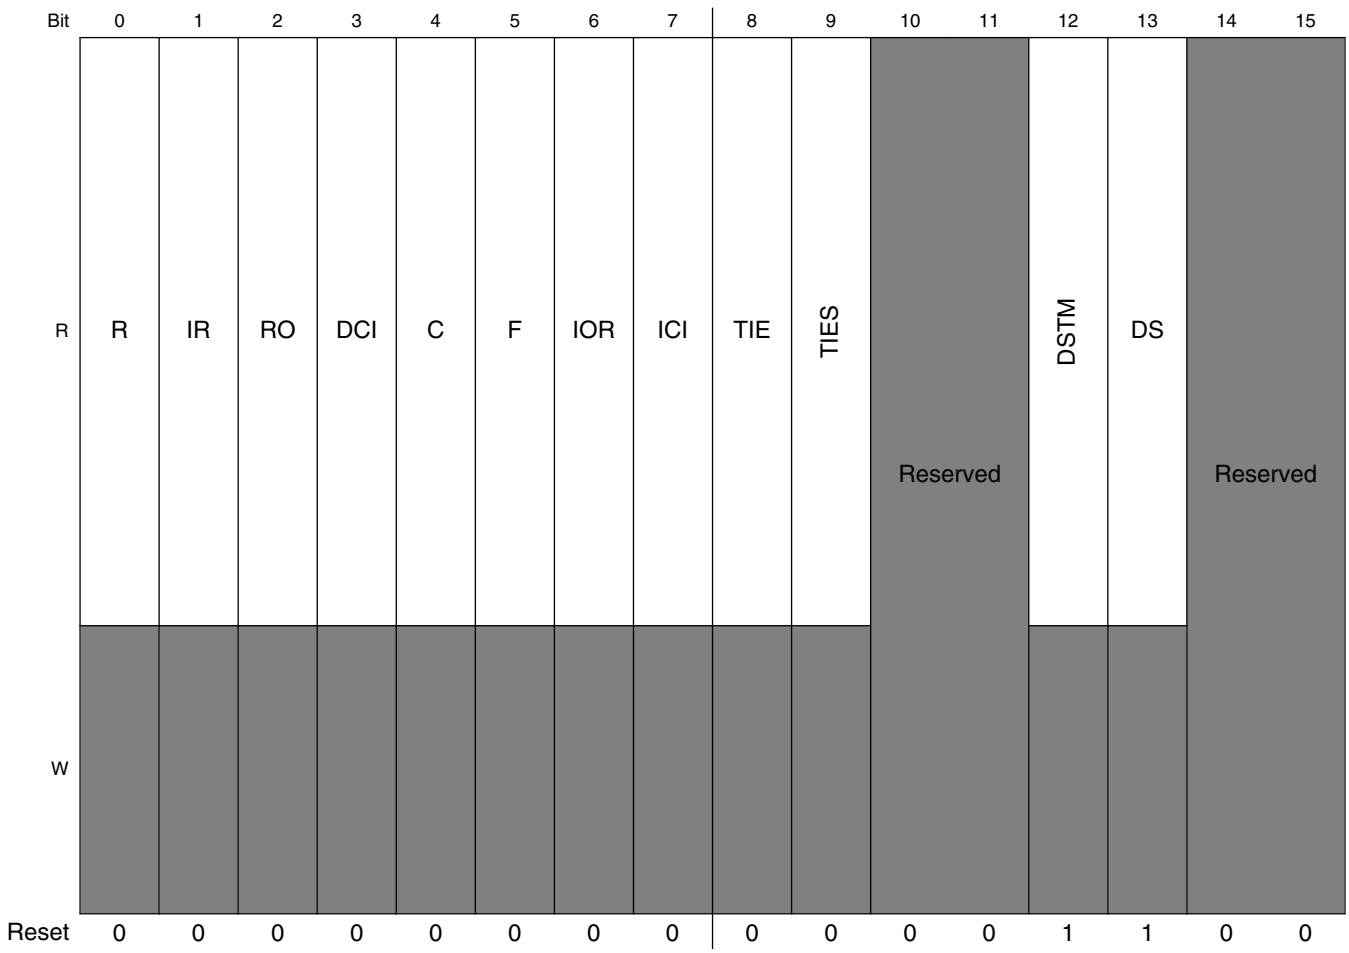
20.5.7 Destination operations capability register (SRIO_DOCAR)

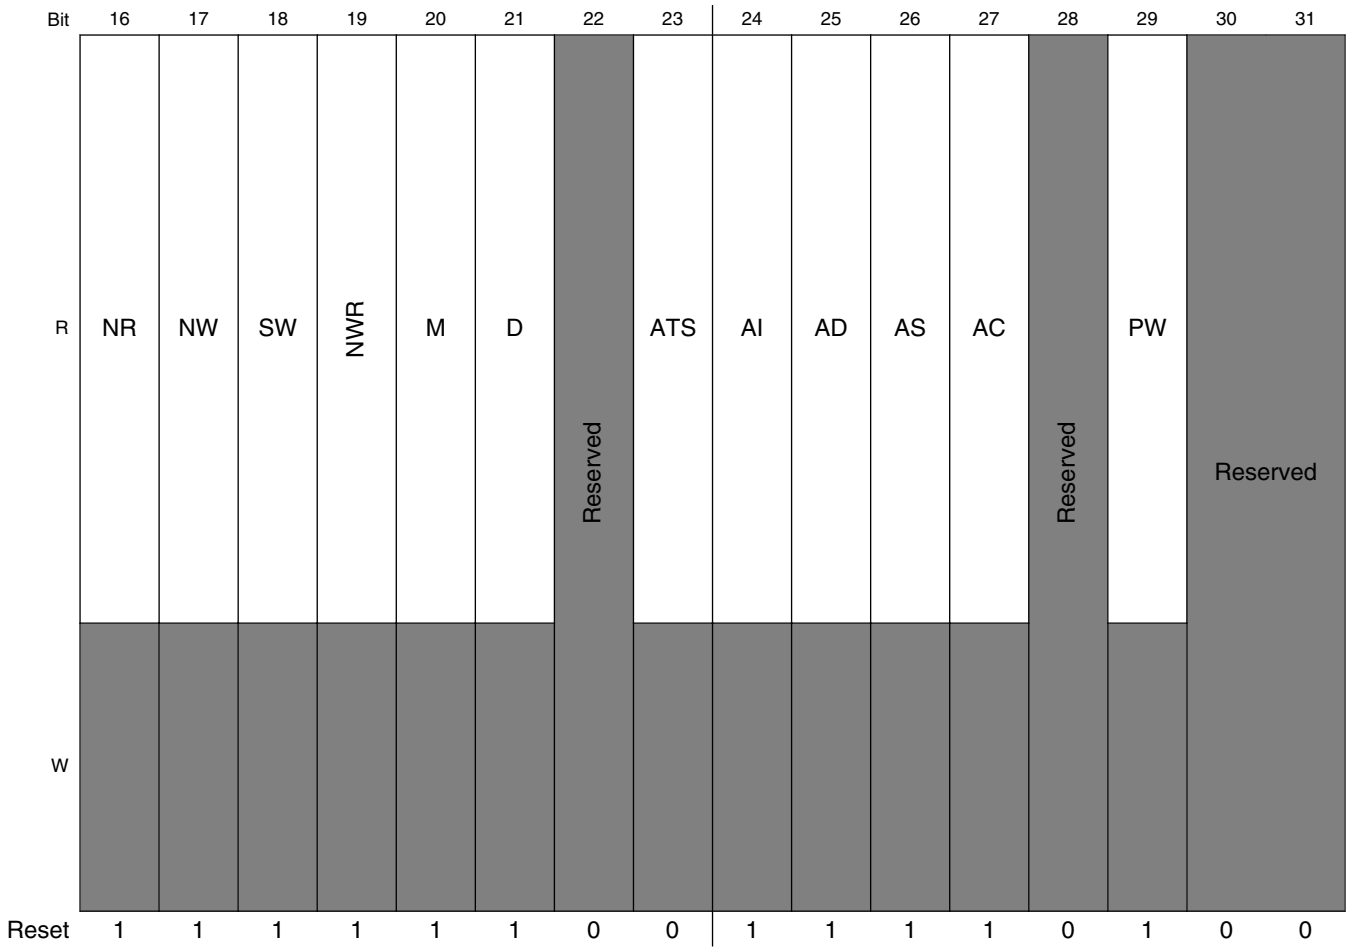
The destination operations capability register (DOCAR), defines the set of RapidIO I/O operations that can be supported by this processing element. DOCAR is a read-only register. DOCAR settings are configurable via pins and can be modified.

NOTE

Do not modify these bits to something other than the settings stated in Table 19-12, because unsupported transaction errors only apply to atomic transactions.

Address: C_0000h base + 1Ch offset = C_001Ch





SRIO_DOCAR field descriptions

Field	Description
0 R	PE does not support a Read operation. (R = 0)
1 IR	PE does not support an IRead operation. (IR = 0)

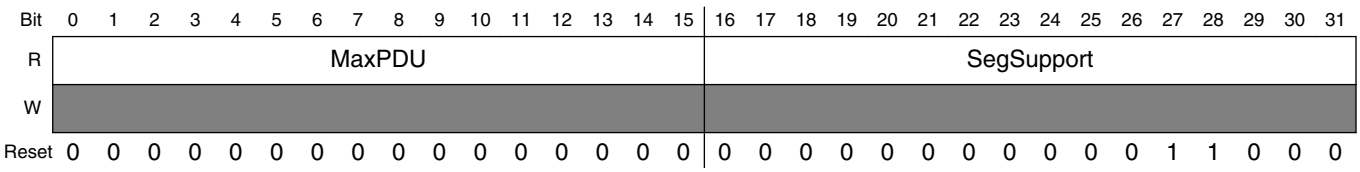
20.5.8 Data streaming information capability register (SRIO_DSICAR)

The data streaming information capability register (DSICAR), defines the data streaming capabilities of a processing element. It is required for destination end point devices. DSICAR is a read-only register.

Address: C_0000h base + 3Ch offset = C_003Ch



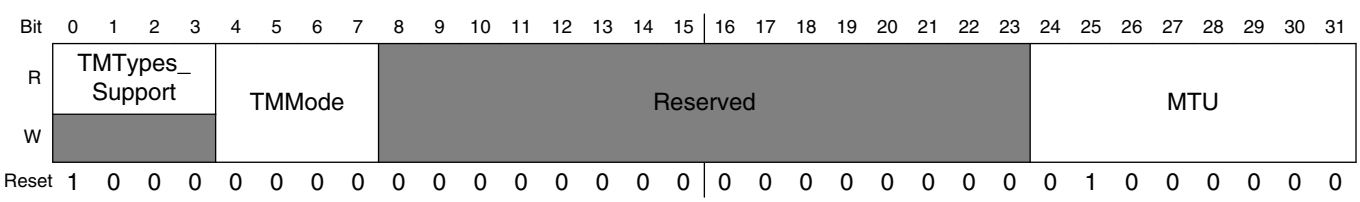
SRIO_DSICAR field descriptions

Field	Description
0–15 MaxPDU	Maximum PDU - The maximum PDU size in bytes supported by the destination end point (MaxPDU = 16'h0000). 0x0000 64 KBytes
16–31 SegSupport	Segment Support - The number of segmentation contexts supported by the destination end point (SegSupport = 16'h0018). 0x0018 24 segmentation contexts

20.5.9 Data streaming logic layer command and status register (SRIO_DSLLCSR)

The data streaming logic layer control command and status register (DSLLCCSR), is used for general command and status information for the logical interface.

Address: C_0000h base + 48h offset = C_0048h



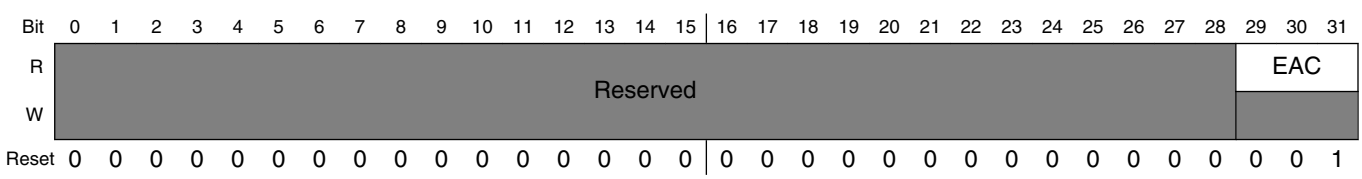
SRIO_DSLLCSR field descriptions

Field	Description
0–3 TMTypes_ Support	The traffic management types supported (this field is read-only). Only basic traffic management type is supported. 0x8 Basic type supported
4–7 TMMode	Traffic Management Mode of operation 0x0 Traffic management disabled 0x1 Basic 0x2 Reserved 0xF Reserved
8–23 -	This field is reserved. Reserved
24–31 MTU	Maximum Transmission Unit Controls the data payload size for segments of an encapsulated PDU. Only single segment PDUs and end segments are permitted to have a data payload that is less this value. The MTU can be specified in increments of 4 bytes. Support for the entire range is required.i 0x00 Reserved 0x07 Reserved 0x08 32 byte block size 0x09 36 byte block size 0x0A 40 byte block size 0x40 256 byte block size 0x41 Reserved 0xFF Reserved

20.5.10 Processing element logical layer control command and status register (SRIO_PELLCCSR)

The processing element logical layer control command and status register (PELLCCSR), controls the extended addressing abilities. The RapidIO endpoint only supports 34-bit addressing. PELLCCSR is a read-only register.

Address: C_0000h base + 4Ch offset = C_004Ch



SRIO_PELLCCSR field descriptions

Field	Description
0–28 -	This field is reserved. Reserved
29–31 EAC	Extended addressing control. Read-only value is 0b001.

20.5.11 Local configuration space base address 1 command and status register (SRIO_LCSBA1CSR)

The local configuration space base address 1 command and status register (LCSBA1CSR), specifies bits of the local physical address double-word offset for the processing element's configuration register space, allowing the configuration register space to be physically mapped in the processing element. This register allows configuration and maintenance of a processing element through regular read and write operations rather than maintenance operations. The double-word offset is right-justified in the register. This window has priority over all ATMU windows. As is the case with all registers, an external processor writing to LCSBA1CSR should not assume it has been written until a response has been received.

Address: C_0000h base + 5Ch offset = C_005Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SRIO_BDIDCSR field descriptions

Field	Description
0–7 -	This field is reserved. Reserved
8–15 BDID	Base device ID of the device in a small common transport system (RapidIO device ID). If RapidIO is configured as a host, BDID = {0b0000_0, RCW[RIO_DEVICE_ID](260-262)}. If RapidIO is configured as an agent, BDID = {0b1111_111, RCW[RIO_DEVICE_ID](262)}. See for details.)
16–31 LBDID	Large base device ID of the device in a large common transport system. This field is valid only if PEFCAR[CTLS] is set. If RapidIO is configured as a host, LBDID = {0b0000_0000_0000_0, RCW[RIO_DEVICE_ID](260-262)}. If RapidIO is configured as an agent, LBDID = {0b1111_1111_1111_111, RCW[RIO_DEVICE_ID](262)}. See for details.)

20.5.13 Host base device ID lock command and status register (SRIO_HBDIDLCSR)

The host base device ID lock command and status register (HBDIDLCSR) contains the base device ID value for the processing element in the system that is responsible for initializing this processing element. The HBDID field is a write-once/resettable field which provides a lock function. Once HBDID is written, all subsequent writes to the field are ignored, except in the case that the value written matches the value contained in the field. In this case, the register is re-initialized to 0xFFFF. After writing HBDID, a processing element must then read the host base device ID lock CSR to verify that it owns the lock before attempting to initialize this processing element.

Address: C_0000h base + 68h offset = C_0068h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SRIO_HBDIDLCSR field descriptions

Field	Description
0–15 -	This field is reserved. Reserved
16–31 HBDID	This is the host base device ID for the processing element that is responsible for initializing this device. Only the first write to this field is accepted; all other writes are ignored, except in the case that the value written matches the value contained in the field. In this case, the register is re-initialized to 0xFFFF.

20.5.14 Component tag command and status register (SRIO_CTCSR)

The component tag command and status register (CTCSR), contains a component tag value for the processing element and can be assigned by software when the device is initialized. It is unused internally in the RapidIO endpoint.

Address: C_0000h base + 6Ch offset = C_006Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SRIO_CTCSR field descriptions

Field	Description
0–31 CT	Component tag

20.5.15 Port maintenance block header 0 (SRIO_PMBH0)

The port maintenance block header 0 register (PMBH0), contains a pointer to the next EF_BLK (Extended Features Space, Error Management) and the EF_ID that identifies this as the generic end point port maintenance block header. Note that while registers defined by software-assisted error recovery are supported, software-assisted error recovery is not (these registers are included for hot insertion only); therefore, the RapidIO endpoint is defined here as not supporting software-assisted error recovery. PMBH0 is a read-only register.

Address: C_0000h base + 100h offset = C_0100h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SRIO_PMBH0 field descriptions

Field	Description
0–15 EF_PTR	Extended features pointer
16–31 EF_ID	Extended features ID

20.5.16 Port link time-out control command and status register (SRIO_PLTOCCSR)

The port link time-out control command and status register (PLTOCCSR), contains the link time-out value for all ports on a device. This time-out is for link events such as sending a packet to receiving the corresponding acknowledge and sending a link-request to receiving the corresponding link-response. The reset value is the maximum time-out interval. The timer resolution is specified between 178-298ns

.

The total delay will be

delay = decimal(SRIO_P1LOPTTLCR[TV])* 152/(platform frequency)

If the platform frequency ranges between 528Mhz and 800Mhz, then the delay resolution will range between 190ns and 288ns, thus the maximum time-out value will be between 3.19 and 4.83 seconds when using maximum TV field value, all ones.

Address: C_0000h base + 120h offset = C_0120h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SRIO_PLTOCCSR field descriptions

Field	Description
0–23 TV	Time-out value. Setting to all zeros disables the link time-out timer. This value is loaded each time the link time-out timer starts.
24–31 -	This field is reserved. Reserved

20.5.17 Port response time-out control command and status register (SRIO_PRTOCCSR)

The port response time-out control command and status register (PRTOCCSR), contains the time-out timer count for all ports on a device. This time-out is for sending a request packet to receiving the corresponding response packet.The reset value is the maximum time-out interval. The timer resolution is specified between 178-298ns. Note that this applies to the RapidIO endpoint and the messaging unit.

The total delay will be:

delay = decimal(SRIO_P1LOPTTLCR[TV])* 152/(platform frequency)

If the platform frequency ranges between 528Mhz and 800Mhz, then the delay resolution will range between 190ns and 288ns, thus the maximum time-out value will be between 3.19 and 4.83 seconds when using maximum TV field value, all ones.

Address: C_0000h base + 124h offset = C_0124h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SRIO_GCCSR field descriptions

Field	Description
0 H	Host. The reset value of this bit is assigned by the RCW fields HOST_AGT_B1, HOST_AGT_B3, which determine host/agent configuration for the device. See RCW Field Definitions for more information. A host device is a device that is responsible for system exploration, initialization, and maintenance. Agent or slave devices are initialized by host devices. (Note that although this status bit is Read/Write, manually changing its value does not affect logical operation.) 0 Agent device 1 Host device
1 M	Master. The reset value of this bit is assigned by the RCW fields HOST_AGT_B1, HOST_AGT_B3, which determine host/agent configuration for the device. See RCW Field Definitions for more information. This bit controls whether or not a device is allowed to issue requests into the system. If M = 0, the device may only respond to requests or send Type 9 Flow Control Packets. Software must ensure no requests are sent to the device by disabling any local access windows and disabling inbound ATMU windows from other devices targeting SRIO while M=0.

Table continues on the next page...

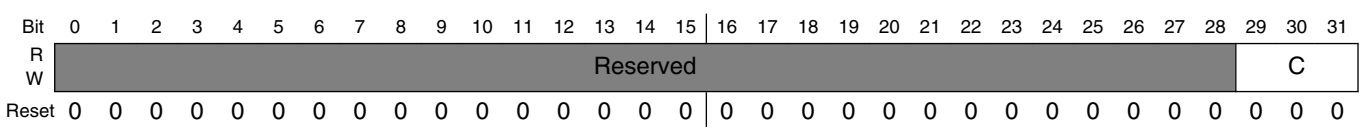
SRIO_GCCSR field descriptions (continued)

Field	Description
	0 Device is not enabled to issue requests into the system. 1 Device is enabled to issue requests into the system.
2 D	Discovered. The reset value of this bit is identical to PGCCSR[H] which is assigned by the RCW fields HOST_AGT_B1, HOST_AGT_B3, which determine host/agent configuration for the device. Master. The reset value of this bit is identical to PGCCSR[H] which is assigned by the RCW fields HOST_AGT_B1, HOST_AGT_B3, which determine host/agent configuration for the device. See for more information. This bit controls whether or not a device is allowed to issue requests into the system. If M = 0, the device may only respond to requests. Software must ensure no requests are sent to the device by disabling any local access windows and disabling inbound ATMU windows from other devices targeting SRIO while M=0. 0 Device is not enabled to issue requests into the system. This device has been located by the processing element responsible for system configuration. (Note that although this status bit is Read/Write, manually changing its value does not affect logical operation.) 0 Device has not been discovered by system host. 1 Device has been discovered by system host.
3–31 -	This field is reserved. Reserved

20.5.19 Port 1 Link maintenance request command and status register (SRIO_P1LMREQCSR)

The port 1 link maintenance request command and status register (P1LMREQCSR), is accessible both by the local processor and an external device. A write to this register generates a link-request control symbol on the RapidIO endpoint port 1 interface. Care should be taken when writing this register that it is only used for hot swap and not for software-assisted error recovery (which is not supported).

Address: C_0000h base + 140h offset = C_0140h



SRIO_P1LMREQCSR field descriptions

Field	Description
0–28 -	This field is reserved. Reserved
29–31 C	LINK_REQUEST command to send. If read, this field returns the last written value. If written with a value other than 0b011 (reset-device) or 0b100 (input-status), the resulting operation is undefined, as all other values are reserved in the RapidIO specification.

20.5.20 Port 1 Link maintenance response command and status register (SRIO_P1LMRESPCSR)

The port 1 link maintenance response command and status register (P1LMRESPCSR), is accessible both by the local processor and an external device. A read to this register returns the status received in a link-response control symbol. This register is read only.

Address: C_0000h base + 144h offset = C_0144h

SRIO_P1ESCSR field descriptions

Field	Description
0–4 -	This field is reserved. Reserved
5 OPD	Output Packet-dropped. Output port has discarded a packet. A packet is discarded if: • It is received while OFE is set and PnCCSR[DPE] (drop packet enable) is set and PnCCSR[SPF] (stop on port failed) is set. • It is received while PnPCR[OBDEN] (output buffer drain enable) is set. • It is not-accepted by the link-partner while PnERCSR[ERFTT] (error rate failed threshold trigger) is met or exceeded and PnCCSR[DPE] is set and PnCCSR[SPF] is not set (and link-response returns expected ackID). Once OPD is set, it remains set until written with a logic 1 to clear.

Table continues on the next page...

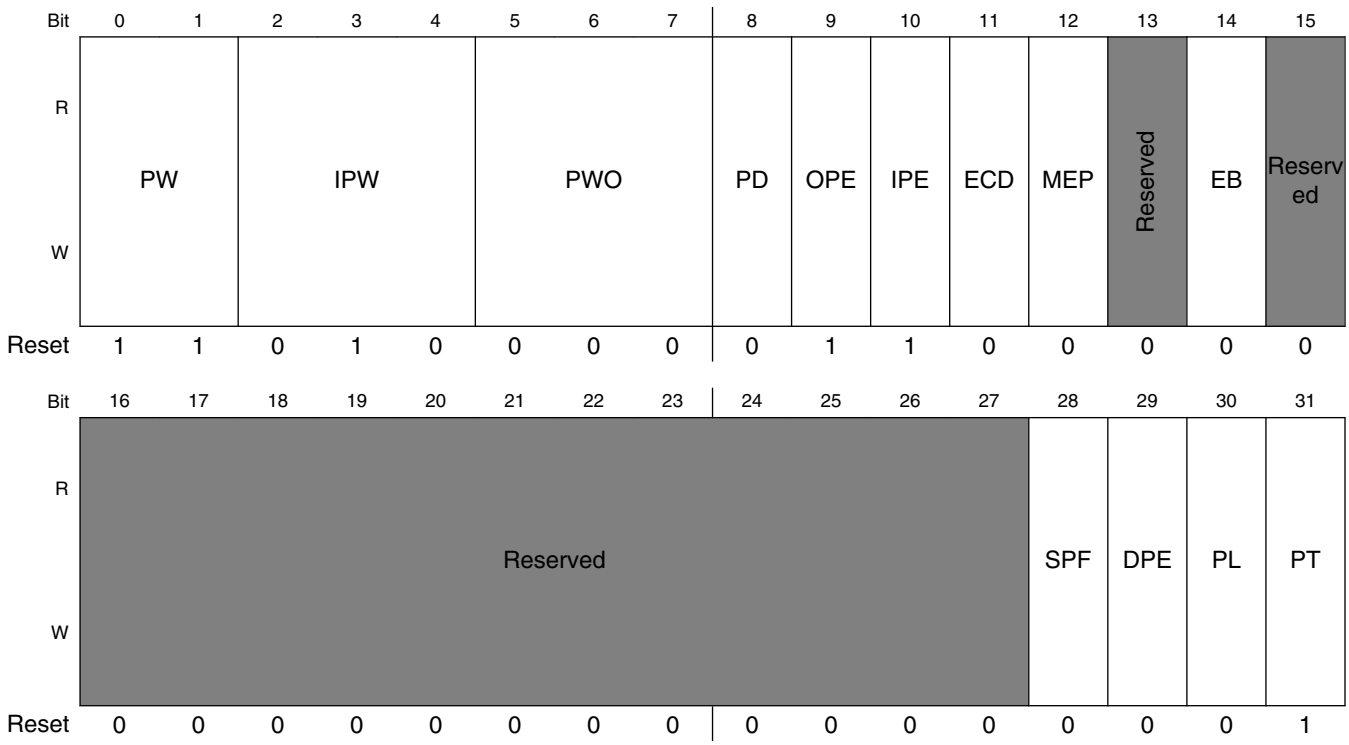
SRIO_P1ESCSR field descriptions (continued)

Field	Description
6 OFE	Output Failed-encountered. Output port has encountered a failed condition, meaning that the Error Rate Counter has met or exceeded the port's failed error threshold (ERFTT) Once set, remains set until written with a logic 1 to clear. Once cleared, does not assert again unless the Error Rate Counter dips below the port's failed error threshold and then meets or exceeds it again.
7 ODE	Output port has encountered a degraded condition, meaning that the Error Rate Counter has met or exceeded the port's degraded error threshold. Once set, remains set until written with a logic 1 to clear. Once cleared, does not assert again unless the Error Rate Counter dips below the port's degraded error threshold and then meets or exceeds it again.
8–10 -	This field is reserved. Reserved
11 ORE	Output port has encountered a retry condition. This bit is set when bit 13 is set. Once set, remains set until written with a logic 1 to clear.
12 OR	Output port has received a packet retry control symbol and cannot make forward progress. This bit is set when bit 13 is set and cleared when a packet-accepted or packet-not-accepted control symbol is received. (read only)
13 ORS	Output port is stopped due to a retry (read only)
14 OEE	Output port has encountered (and possibly recovered from) a transmission error. This bit is set when bit 15 is set. Once set, remains set until written with a logic 1 to clear.
15 OES	Output port is stopped due to a transmission error (read only)
16–20 -	This field is reserved. Reserved
21 IRS	Input port is stopped due to a retry (read only)
22 IEE	Input port has encountered (and possibly recovered from) a transmission error. This bit is set when bit 23 is set. Once set, remains set until written with a logic 1 to clear.
23 IES	Input port is stopped due to a transmission error (read-only)
24–26 -	This field is reserved. Reserved
27 PWP	Port has encountered a condition which required it to initiate a maintenance port-write operation. This bit is only valid if the device is capable of issuing an auto-generated maintenance port-write transaction. The RapidIO endpoint is not capable of issuing auto-generated port-writes. This bit is hardwired to 0.
28 -	This field is reserved. Reserved
29 PE	Input or output port has encountered an error from which hardware was unable to recover. Once set, remains set until written with a logic 1 to clear. This bit indicates that OFE is set while PnCCSR[SPF] is set; in other words, the failed threshold has been reached which has caused the output port to stop transmitting packets.
30 PO	The input and output ports are initialized and the port is exchanging error-free control symbols with the attached device. (read-only).
31 PU	Input and output ports are not initialized. This bit and bit 30 are mutually exclusive (read-only).

20.5.23 Port 1 Control command and status register (SRIO_P1CCSR)

The port 1 control command and status register (P1CCSR), contains control register bits for the RapidIO port.

Address: C_0000h base + 15Ch offset = C_015Ch



SRIO_P1CCSR field descriptions

Field	Description
0–1 PW	Indicates port width modes supported by the port (read-only). The bits of this field indicates the port width modes supported by the port in addition to 1x mode, which is required. 0x 4x mode not supported 1x 4x mode supported x0 2x mode not supported x1 2x mode supported
2–4 IPW	Width of the ports after initialized (read-only). 000 Single-lane port, lane 0 001 Single-lane port, lane R 010 Four-lane port, lanes 0-3 011 Two-lane port, lanes 0-1 100-111 Reserved

Table continues on the next page...

SRIO_P1CCSR field descriptions (continued)

Field	Description
5–7 PWO	Soft port configuration to control the width modes available for port initialization. The meaning of bits 6 and 7 depend on the value of bit 5. When bit [5] = 0b1, bit 6 controls the enabling of 4x mode, bit 7 controls the enabling of 2x mode, A change in the value of this field shall cause the port to re-initialize using the new field value. This field should be changed only when the port is uninitialized. To achieve this, first disable the RapidIO port. Then change PWO to any valid value. Finally, re-enable the RapidIO port. To achieve this, first set PnCCSR[PD] (port disabled). Then change PWO to any legal value. Finally, clear PnCCSR[PD] (enabled). 000 No override, all supported mode widths enabled. 001 Reserved 010 Force single lane, lane R not forced 011 Force single lane, force lane R 100 Reserved 101 2x mode enabled, 4x mode disabled 110 2x mode disabled, 4x mode enabled 111 2x mode enabled, 4x mode enabled
8 PD	Port disable. 0b0 - port receivers/drivers are enabled 0b1 - port receivers/drivers are disabled and are unable to receive/transmit If set, the output will congest if packets are sent to it.
9 OPE	Output port transmit enable. Initial value read from configuration pins. 0 Port is stopped and not enabled to issue any packets except to route or respond to I/O logical MAINTENANCE packets. Control symbols are not affected and are sent normally. 1 Port is enabled to issue any packets.
10 IPE	Input port receive enable. 0 Port is stopped and only enabled to route or respond to I/O logical MAINTENANCE packets. Other packets generate packet-not-accepted control symbols to force an error condition to be signaled by the sending device. Control symbols are not affected and are received and handled normally. 1 Port is enabled to respond to any packet.
11 ECD	Error checking disable. This bit is hardwired to 0. This bit disables all RapidIO transmission error checking This bit value must equal the value of the output port enable (OPE) bit in order for the RapidIO controller to function properly. Initial value read from configuration pins. 0 Error checking and recovery is enabled. 1 Error checking and recovery is disabled.

Table continues on the next page...

SRIO_P1CCSR field descriptions (continued)

Field	Description
12 MEP	Multicast-event participant. This bit is hard-wired to 0.
13 -	This field is reserved. Reserved
14 EB	Enumeration boundary. An enumeration boundary aware system enumeration algorithm shall honor this flag. The algorithm, on either the ingress or the egress port, shall not enumerate past a port with this bit set.
15–27 -	This field is reserved. Reserved
28 SPF	Stop on port failed-encountered enable. This bit is used with the Drop Packet Enable bit to force certain behavior when the Error Rate Failed Threshold has been met or exceeded.
29 DPE	Drop packet enable. This bit is used with the Stop on Port Failed-encountered Enable bit to force certain behavior when the Error Rate Failed Threshold has been met or exceeded.
30 PL	Port lockout. 0 The packets that may be received and issued are controlled by the state of the OPE and IPE bits. 1 This port is stopped and is not enabled to issue or receive any packets; the input port can still follow the training procedure and can still send and respond to link-requests; all received packets return packet-not-accepted control symbols to force an error condition to be signaled by the sending device.
31 PT	Port type (read-only). 0 Reserved 1 Serial port.

20.5.24 Port 2 Link maintenance request command and status register (SRIO_P2LMREQCSR)

The port 2 link maintenance request command and status register (P2LMREQCSR), is accessible both by the local processor and an external device. A write to this register generates a link-request control symbol on the RapidIO endpoint port 2 interface. Care should be taken when writing this register that it is only used for hot swap and not for software-assisted error recovery (which is not supported).

Address: C_0000h base + 160h offset = C_0160h

16–31 EF_ID	Extended features ID

20.5.30 Logical/Transport layer error detect command and status register (SRIO_LTLEDCSR)

This register indicates the error that was detected by the Logical or Transport logic layer. Software should write this register with all 0s to clear the detected error and unlock the capture registers.

Error information that corresponds to two or more different error events are not captured on the same clock cycle. However, one error event (such as a corrupted inbound packet) can cause multiple bits to be set. The priority of errors is PRT and all other errors. OACB error results in PRT. When PRT bit is set with OACB bit, error capture is for an internal platform transaction for which an Outbound ATMU window boundary was crossed or a segment or subsegment boundary was crossed.

An error that is not enabled will set the detect bit in this register as long as a capture has not yet occurred.

This register is shared among all ports. Error detect bits for each type of error are OR'd together with the upper port taking precedence.

Note that fields in this register can be set by writing to this register. This can be used to emulate a hardware error during software development. However, undefined results occur if fields in this register are set while an actual Logical/Transport Layer error is being detected. Also, note that this register can be written with an invalid combination of bits set and care should be taken to avoid this.

Address: C_0000h base + 608h offset = C_0608h

Field	Description
0 IER	IO error response. Received a response of ERROR for an IO logical layer request.
1 -	This field is reserved. Reserved
2 GER	GSM error response. Received a response of ERROR for a GSM logical layer request.
3 -	This field is reserved. Reserved
4 ITD	Illegal transaction decode. Received illegal fields in the request/response packet for a supported transaction (IO/GSM logical)
5 ITTE	Illegal transaction target error. Received a packet that contained a destination ID that is not defined for this end point when pass-through and accept-all are not enabled. Endpoints with multiple ports and a built-in switch function may not report this as an error (transport)
6 -	This field is reserved. Reserved
7 PRT	Packet response time-out. A required response has not been received within the specified time out interval (IO/GSM logical)
8 UR	Unsolicited response. An unsolicited/unexpected response packet was received (IO/GSM logical; only maintenance response for switches)
9 UT	Unsupported transaction. A transaction is received that is not supported in the destination operations CAR (IO/GSM logical; only maintenance port-write for switches)
10–21 -	This field is reserved. Reserved
22 ILE	Inbound LIODN error. An error occurred during the inbound RapidIO source ID to LIODN translation of a received request
23 -	This field is reserved. Reserved

Table continues on the next page...

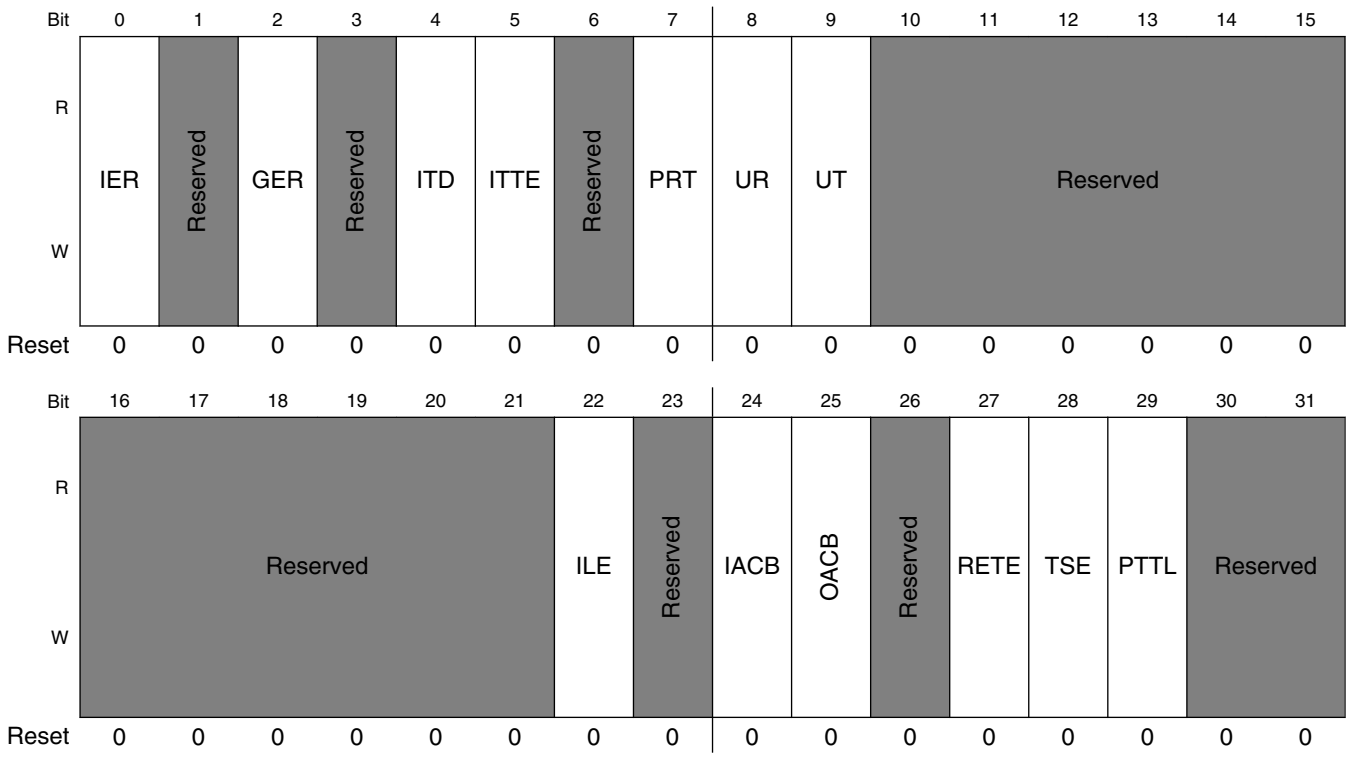
SRIO_LTLEDCSR field descriptions (continued)

Field	Description
24 IACB	Inbound ATMU crossed boundary. A transaction is received that crosses an inbound ATMU boundary.
25 OACB	Outbound ATMU crossed boundary. A transaction is being sent that crosses an outbound ATMU boundary, a segment boundary, or a subsegment boundary.
26 -	This field is reserved. Reserved
27 RETE	Retry error threshold exceeded. The allowed number of logical retries (given by LRETCR[RET] has been exceeded.
28 TSE	Transport size error. The tt field is not consistent with bit 27 of the processing element features CAR (that is, the tt value is reserved or indicates a common transport system that is unsupported by this device).
29 PTTL	Packet time-to-live error. A packet time-to-live error occurred (a packet could not be successfully transmitted before the packet time-to-live counter expired).
30–31 -	This field is reserved. Reserved

20.5.31 Logical/Transport layer error enable command and status register (SRIO_LTLEECSR)

This register contains the bits that control whether an error condition locks the logical/ transport layer error detect and capture registers and is reported to the system host.

Address: C_0000h base + 60Ch offset = C_060Ch



SRIO_LTLEECSR field descriptions

Field	Description
0 IER	IO error response enable.Enable reporting of an IO error response. Capture and lock the error.
1 -	This field is reserved. Reserved
2 GER	GSM error response enable. Enable reporting of a GSM error response. Capture and lock the error.
3 -	This field is reserved. Reserved
4 ITD	Illegal transaction decode enable. Enable reporting of an illegal transaction decode error. Capture and lock the error.
5 ITTE	Illegal transaction target error enable.

Table continues on the next page...

SRIO_LTLEECSR field descriptions (continued)

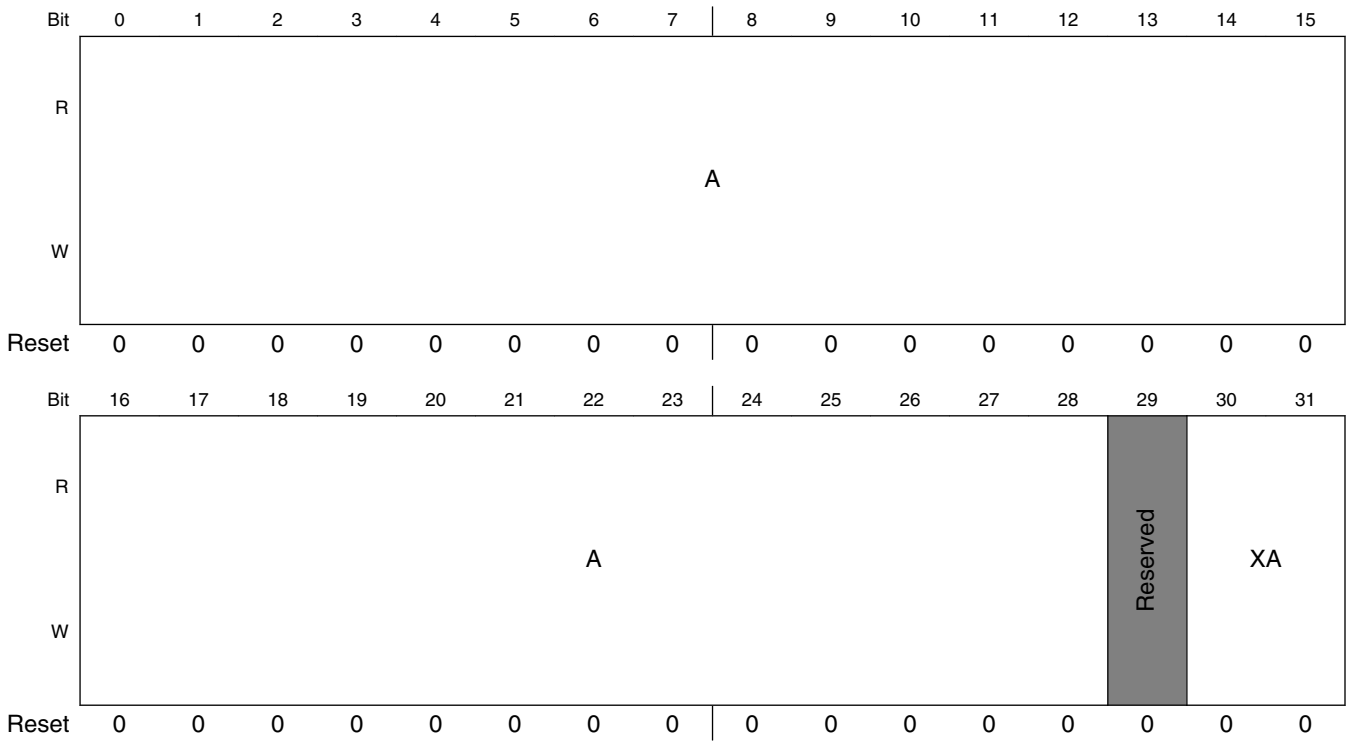
Field	Description
	Enable reporting of an illegal transaction target error. Capture and lock the error.
6 -	This field is reserved. Reserved
7 PRT	Packet response time-out error enable. Enable reporting of a packet response time-out error. Capture and lock the error.
8 UR	Unsolicited response error enable. Enable reporting of an unsolicited response error. Capture and lock the error.
9 UT	Unsupported transaction error enable. Enable reporting of an unsupported transaction error. Capture and lock the error.
10–21 -	This field is reserved. Reserved
22 ILE	Inbound LIODN error. An error occurred during the inbound RapidIO source ID to LIODN translation of a received request.
23 -	This field is reserved. Reserved
24 IACB	Inbound ATMU crossed boundary error enable. Enable reporting of a received transaction that crosses an inbound ATMU boundary. Capture and lock the error.
25 OACB	Outbound ATMU crossed boundary error enable. Enable reporting of a transaction that crosses an outbound ATMU boundary, a segment boundary, or a subsegment boundary. Capture and lock the error.
26 -	This field is reserved. Reserved
27 RETE	Retry error threshold exceeded. Enable error reporting when the allowed number of logical retries has been exceeded.
28 TSE	Transport size error. Enable error reporting when the tt field is not consistent with bit 27 of the Processing Element Features CAR (that is, the tt value is reserved or indicates a common transport system that is unsupported by this device).
29 PTTL	Packet time-to-live error. Enable reporting of a packet time-to-live time-out error. Capture and lock the error.
30–31 -	This field is reserved. Reserved

20.5.32 Logical/Transport layer address capture command and status register (SRIO_LTLACCSR)

The logical/transport layer address capture command and status register (LTLACCSR), provides error information. It is locked when a logical/transport error is detected, and the corresponding enable bit is set. Undefined results occur if this register is written while actual logical/transport layer errors are being detected by the port.

Note that fields in this register can be set by to writing this register. This can be used to emulate a hardware error during software development. However, undefined results occur if fields in this register are set while an actual logical/transport layer error is being detected.

Address: C_0000h base + 614h offset = C_0614h



SRIO_LTLACCSR field descriptions

Field	Description
0–28 A	Normally the least significant 29 bits of the address associated with the error (for requests, for responses if available). See Logical Layer Errors and Error Handling," for details.
29 -	This field is reserved. Reserved
30–31 XA	xamsbs. Normally the extended address bits of the address associated with the error (for requests, responses, if available). See Logical Layer Errors and Error Handling," for details.

20.5.33 Logical/Transport layer device ID capture command and status register (SRIO_LTLDIDCCSR)

The logical/transport layer device ID capture command and status register (LTLDIDCCSR), contains error information. It is locked when a logical/transport error is detected, and the corresponding enable bit is set. Undefined results occur if this register is written while actual logical/transport layer errors are being detected by the port.

Note that fields in this register can be set by writing to this register, in order to emulate a hardware error during software development. However, undefined results occur if fields in this register are set while an actual logical/transport layer error is being detected.

Address: C_0000h base + 618h offset = C_0618h

SRIO_LTLDIDCCSR field descriptions

Field	Description
0–7 DIDMSB	Normally the most significant byte of the destinationID associated with the error. This field is valid only if bit 27 of the Processing Element Features CAR is set (large transport systems only). See Logical Layer Errors and Error Handling," for details.
8–15 DID	Normally the destinationID (or least significant byte of the destination ID if large transport system) associated with the error. See Logical Layer Errors and Error Handling," for details.
16–23 SIDMSB	Normally the most significant byte of the sourceID associated with the error. This field is valid only if bit 27 of the Processing Element Features CAR is set (large transport systems only). See Logical Layer Errors and Error Handling," for details.
24–31 SID	Normally the sourceID (or least significant byte of the source ID if large transport system) associated with the error. See Logical Layer Errors and Error Handling," for details.

20.5.34 Logical/Transport layer control capture command and status register (SRIO_LTLCCCSR)

The logical/transport layer control capture command and status register (LTLCCCSR), contains error information. Undefined results occur if this register is written while actual logical/transport layer errors are being detected by the port.

Note that fields in this register can be set by writing to this register, in order to emulate a hardware error during software development. However, undefined results occur if fields in this register are set while an actual logical/transport layer error is being detected.

Address: C_0000h base + 61Ch offset = C_061Ch

SRIO_P1ERCSR field descriptions

Field	Description
0–7 ERB	These bits provide the error rate bias value. 0x00 Do not decrement the error rate counter 0x01 Decrement every 1 ms (±34%) 0x02 Decrement every 10 ms (±34%) 0x04 Decrement every 100 ms (±34%) 0x08 Decrement every 1 s (±34%) 0x10 Decrement every 10 s (±34%) 0x20 Decrement every 100 s (±34%) 0x40 Decrement every 1000 s (±34%) 0x80 Decrement every 10000 s (±34%) Other values are reserved and cause undefined operation.
8–13 -	This field is reserved. Reserved
14–15 ERR	These bits limit the incrementing of the error rate counter above the failed threshold trigger. 00 Only count 2 errors above 01 Only count 4 errors above 10 Only count 16 error above 11 Do not limit incrementing the error rate count Note that the Error Rate Counter never increments above 0xFF, even if the combination of the settings of ERR and the failed threshold trigger might imply that it might.

Table continues on the next page...

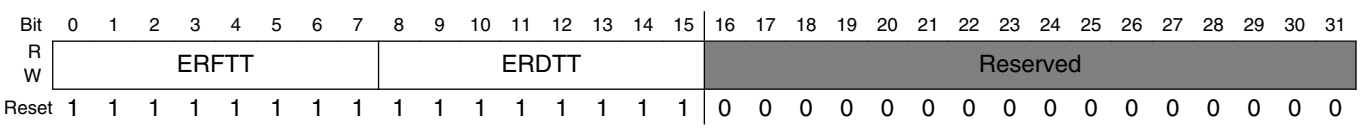
SRIO_P1ERCSR field descriptions (continued)

Field	Description
16–23 PER	Peak error rate. Contains the peak value attained by the error rate counter
24–31 ERC	Error rate counter. These bits maintain a count of the number of transmission errors that have been detected by the port, decremented by the Error Rate Bias mechanism, to create an indication of the link error rate. Software should not attempt to write this field to a value higher than failed threshold trigger plus the number of errors specified in the ERR field (the maximum ERC value).

20.5.43 Port 1 Error rate threshold command and status register (SRIO_P1ERTCSR)

The port 1 error rate threshold command and status register (P1ERTCSR), is a 32-bit register used to control the reporting of the link status to the system host.

Address: C_0000h base + 66Ch offset = C_066Ch



SRIO_P1ERTCSR field descriptions

Field	Description
0–7 ERFTT	Error rate failed threshold trigger. These bits provide the threshold value for reporting an error condition due to a possibly broken link. The PnESCSR[OFE] bit is not set if ERFTT is written to a value lower than or equal to the PnERCSR[ERC]. Please see Table 20-9 for more details. 0x00 Disable the Error Rate Failed Threshold Trigger. 0x01 Set the error reporting threshold to 1. 0x02 Set the error reporting threshold to 2. 0xFF Set the error reporting threshold to 255.
8–15 ERDTT	Error rate degraded threshold trigger. These bits provide the threshold value for reporting an error condition due to a degrading link. The PnESCSR[ODE] bit is not set if ERDTT is written to a value lower than or equal to the PnERCSR[ERC]. Please see Table 20-9 for more details. 0x00 Disable the Error Rate Degraded Threshold Trigger. 0x01 Set the error reporting threshold to 1.

Table continues on the next page...

SRIO_P1ERTCSR field descriptions (continued)

Field	Description
	0x02 Set the error reporting threshold to 2. 0xFF Set the error reporting threshold to 255.
16–31 -	This field is reserved. Reserved

20.5.44 Port 2 Error detect command and status register (SRIO_P2EDCSR)

The port 2 error detect command and status register (P2EDCSR), indicates transmission errors that are detected by the hardware. Software can write bits in this register with 1 to cause the Error Rate Counter to increment. Undefined results occur if this register is written while actual physical layer errors are being detected by the port.

Address: C_0000h base + 680h offset = C_0680h

SRIO_P2ERCSR field descriptions

Field	Description
0–7 ERB	These bits provide the error rate bias value. 0x00 Do not decrement the error rate counter 0x01 Decrement every 1 ms (±34%) 0x02 Decrement every 10 ms (±34%) 0x04 Decrement every 100 ms (±34%) 0x08 Decrement every 1 s (±34%) 0x10 Decrement every 10 s (±34%) 0x20 Decrement every 100 s (±34%) 0x40 Decrement every 1000 s (±34%) 0x80 Decrement every 10000 s (±34%) Other values are reserved and cause undefined operation.
8–13 -	This field is reserved. Reserved
14–15 ERR	These bits limit the incrementing of the error rate counter above the failed threshold trigger. 00 Only count 2 errors above 01 Only count 4 errors above 10 Only count 16 error above 11 Do not limit incrementing the error rate count Note that the Error Rate Counter never increments above 0xFF, even if the combination of the settings of ERR and the failed threshold trigger might imply that it might.

Table continues on the next page...

SRIO_P2ERCSR field descriptions (continued)

Field	Description
16–23 PER	Peak error rate. Contains the peak value attained by the error rate counter
24–31 ERC	Error rate counter. These bits maintain a count of the number of transmission errors that have been detected by the port, decremented by the Error Rate Bias mechanism, to create an indication of the link error rate. Software should not attempt to write this field to a value higher than failed threshold trigger plus the number of errors specified in the ERR field (the maximum ERC value).

20.5.52 Port 2 Error rate threshold command and status register (SRIO_P2ERTCSR)

The port 2 error rate threshold command and status register (P2ERTCSR), is a 32-bit register used to control the reporting of the link status to the system host.

Address: C_0000h base + 6ACh offset = C_06ACh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SRIO_P2ERTCSR field descriptions

Field	Description
0–7 ERFTT	Error rate failed threshold trigger. These bits provide the threshold value for reporting an error condition due to a possibly broken link. The P2ESCSR[OFE] bit is not set if ERFTT is written to a value lower than or equal to the P2ERCSR[ERC]. Please see Table 20-9 for more details. 0x00 Disable the Error Rate Failed Threshold Trigger. 0x01 Set the error reporting threshold to 1. 0x02 Set the error reporting threshold to 2. 0xFF Set the error reporting threshold to 255.
8–15 ERDTT	Error rate degraded threshold trigger. These bits provide the threshold value for reporting an error condition due to a degrading link. The P2ESCSR[ODE] bit is not set if ERDTT is written to a value lower than or equal to the P2ERCSR[ERC]. Please see Table 20-9 for more details. 0x00 Disable the Error Rate Degraded Threshold Trigger. 0x01 Set the error reporting threshold to 1.

Table continues on the next page...

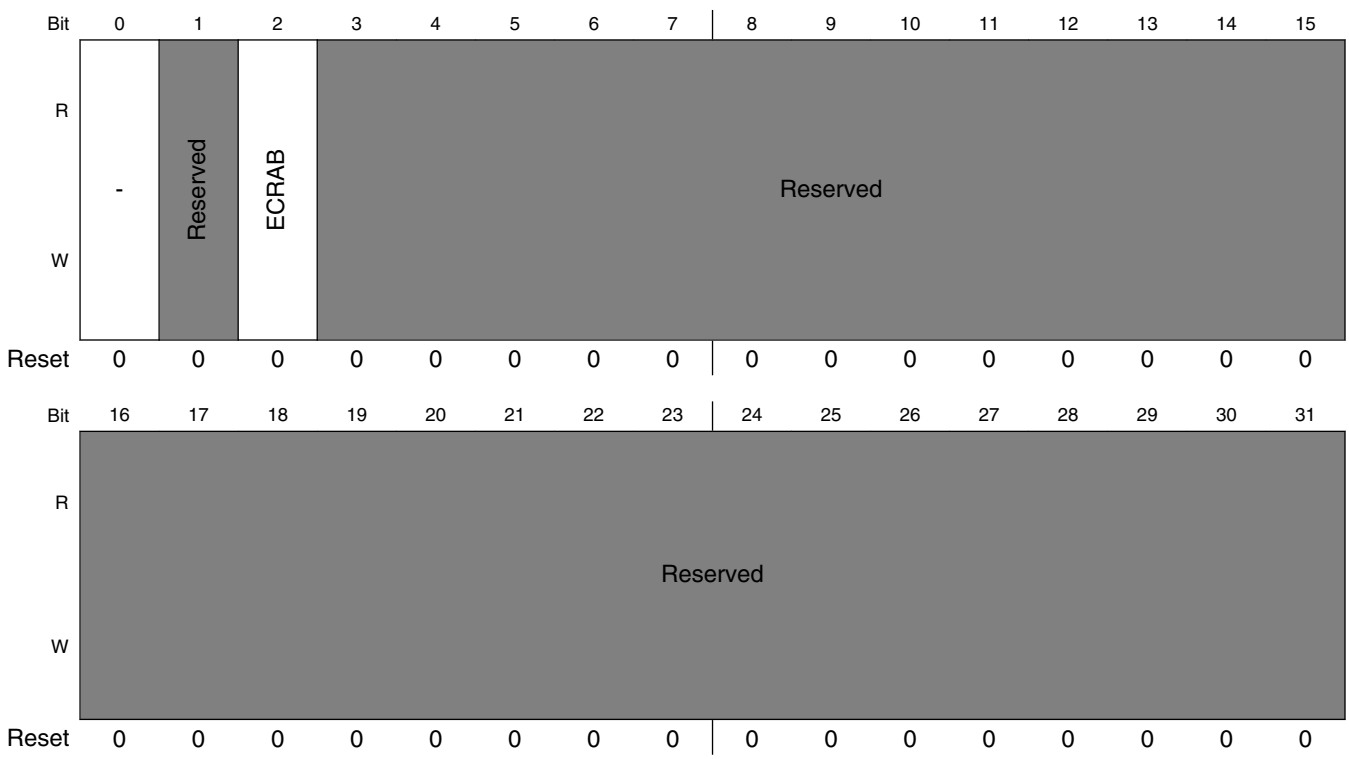
SRIO_P2ERTCSR field descriptions (continued)

Field	Description
	0x02 Set the error reporting threshold to 2. 0xFF Set the error reporting threshold to 255.
16–31 -	This field is reserved. Reserved

20.5.53 Logical layer configuration register (SRIO_LLCR)

The logical layer configuration register (LLCR), contains general port-common logical layer mode enables.

Address: C_0000h base + 1_0004h offset = D_0004h



SRIO_LLCR field descriptions

Field	Description
0 -	This bit is unused. It is readable and writable.
1 -	This field is reserved. Reserved

Table continues on the next page...

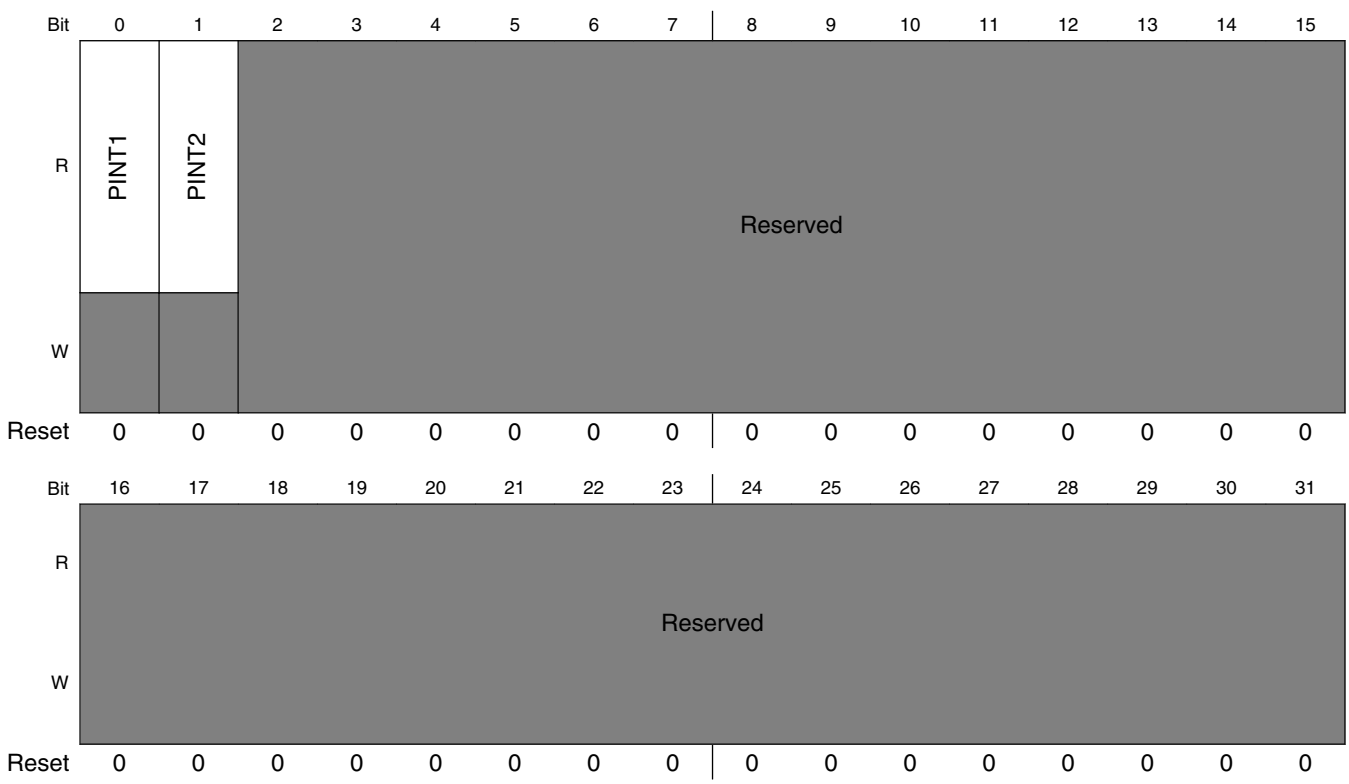
SRIO_LLCR field descriptions (continued)

Field	Description
2 ECRAB	External configuration register access block. When set, all maintenance requests and accesses that hit LCSBA1CSR are blocked; reads return all 0's, and writes are ignored (both return done response). When clear, any external RapidIO device can access registers.
3–31 -	This field is reserved. Reserved

20.5.54 Error / port-write interrupt status register (SRIO_EPWISR)

The error/port-write interrupt status register (EPWISR), contains status bits of the interrupts that have been generated by any port for physical or logical/transport layer errors. Because errors from all ports are reported to the core with one interrupt signal, this register provides the core with quick access to where the error occurred. This register is read only.

Address: C_0000h base + 1_0010h offset = D_0010h



SRIO_EPWISR field descriptions

Field	Description
0 PINT1	A physical or logical/transport error interrupt was generated for port 1.
1 PINT2	A physical or logical/transport error interrupt was generated for port 2.
2–31 -	This field is reserved. Reserved.

20.5.55 Logical retry error threshold configuration register (SRIO_LRETCR)

The logical retry error threshold configuration register (LRETCR), contains the retry error threshold for the logical layer. When the number of consecutive logical retries for a given packet is greater than to this value, an error interrupt is generated. Note that the number of retries must be greater than this value unlike other registers that define a retry threshold.

Address: C_0000h base + 1_0020h offset = D_0020h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

20.5.57 Port 1 Alternate device ID command and status register (SRIO_P1ADIDCSR)

The port 1 alternate device id CSR contains an alternate deviceID. This register should be used on a multi-port device to enable separate deviceIDs for each port. It is intended that this register, should be enabled before the master enabled bit of the PGCCSR is set, such that when it is enabled, all other devices in the RapidIO system (including switches) send packets to and receive packets from the deviceID contained in this register, instead of the deviceID contained in BDIDCSR.

When the alternate deviceID is enabled, the inbound RapidIO endpoint only accepts packets sent with the deviceID contained in P1ADIDCSR or with the deviceID contained in BDIDCSR (except during Accept All mode, during which the inbound RapidIO endpoint accepts packets using the same common transport system). In addition, the

outbound RapidIO endpoint only generates requests using the deviceID contained in P1ADIDCSR; it generates responses with the deviceID given in the original request packet (either from P1ADIDCSR or BDIDCSR).

Address: C_0000h base + 1_0100h offset = D_0100h

SRIO_P1AACR field descriptions

Field	Description
0–3 PTPN	Pass-through RapidIO port number. The RapidIO port to send pass-through packets to. Valid when PTE=1 and AA=0; otherwise unused. The RapidIO endpoint uses this to map the RapidIO port number (0-15) to OCN port number (0-63) 0 Refers to SRIO Port 1 1 Refers to SRIO port 2
4–29 -	This field is reserved. Reserved
30 PTE	Pass-through mode enable. 1 Packets whose target ID does not match this device's ID (base or alternate, if enabled) or whose transport size does not match this device's transport size (bit 27 of the processing element features CAR) will be sent out to another RapidIO Endpoint port, designated by PTPN, through OCN. 0 Packets whose target ID does not match this device's ID will not be sent out on the other RapidIO Endpoint port; error will occur if not in "accept all mode".
31 AA	Accept all 1 All packets are accepted without checking the target ID. However, the tt field must be consistent with the common transport system specified by bit 27 of the processing element features CAR. 0 Normal RapidIO acceptance based on target ID.

20.5.59 Port 1 Logical Outbound Packet time-to-live configuration register (SRIO_P1LOPTTLCR)

The port 1 logical outbound packet time-to-live configuration register (P1LOPTTLCR), contains the time-to-live count for all ports on a device. This packet time-to-live counter starts when a packet is ready to be transmitted. If the packet is not successfully transmitted before the timer expires, the packet is discarded. Successfully transmitted means that a packet accept was received for the packet on the RIO interface. If the packet requires a response, an internal error response is returned after the response time-out occurs (PRTOCCSR). The packet time-to-live counter prevents the local processor from being stalled when packets cannot be successfully transmitted (acknowledged with an accept by the link partner at the physical level). The value of this register should always be larger than the link time-out value (PLTOCCSR). By default, this time-out value is disabled (all zeros). The timer resolution is specified between 178-298ns.

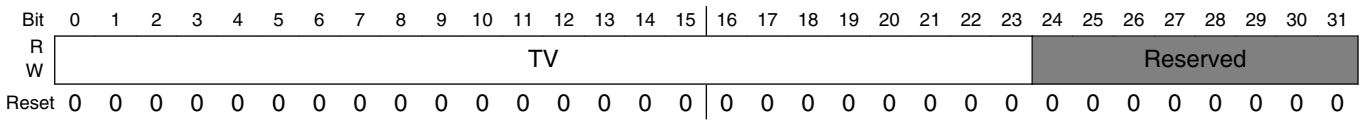
The total delay will be:

delay = decimal(SRIO_P1LOPTTLCR[TV])* 152/(platform frequency)

If the platform frequency ranges between 528Mhz and 800Mhz, then the delay resolution will range between 190ns and 288ns, thus the maximum time-out value will be between 3.19 and 4.83 seconds when using maximum TV field value, all ones.

When the packet time-to-live counter expires, PnPCR[OBDEN] is automatically set. PnPCR[OBDEN] must be cleared by software.

Address: C_0000h base + 1_0124h offset = D_0124h



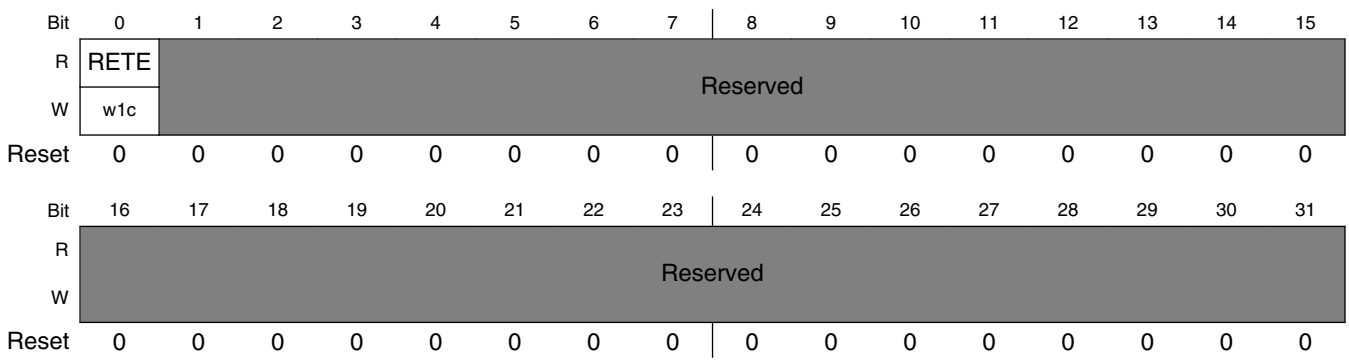
SRIO_P1LOPTTLCR field descriptions

Field	Description
0–23 TV	Time-out value. Setting to all zeros disables the time-to-live time-out timer. This value is loaded each time the time-to-live time-out timer starts.
24–31 -	This field is reserved. Reserved

20.5.60 Port 1 Implementation error command and status register (SRIO_P1IECSR)

The port 1 implementation error command and status register (PnIECSR), contains status bits that are asserted whenever an implementation-defined error occurs.

Address: C_0000h base + 1_0130h offset = D_0130h



SRIO_P1IECSR field descriptions

Field	Description
0 RETE	Retry error threshold exceeded. This bit is asserted when the number of consecutive retries has reached retry error threshold in the retry error threshold register. This bit is cleared by writing a 1 to it. This bit sets again if another retry is received and the number of consecutive retries continues to exceed the retry error threshold.
1–31 -	This field is reserved. Reserved

20.5.61 Port 1 Physical configuration register (SRIO_P1PCR)

The port 1 physical configuration register (PnPCR), contains general physical layer protocol and link mode enables.

Address: C_0000h base + 1_0140h offset = D_0140h

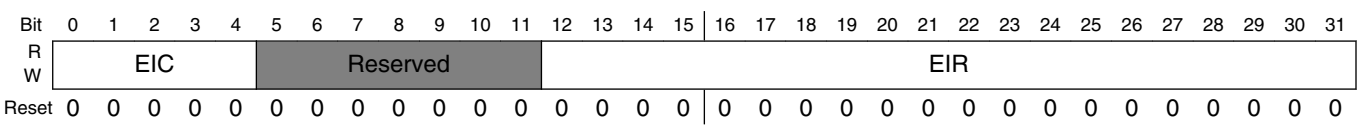
20.5.63 Port 1 Serial link error injection configuration register (SRIO_P1SLEICR)

The port 1 serial link error injection configuration register (PnSLEICR), is used to control the injection of bit errors into the transmit bit stream.

The P1SLEICR register is used to generate pseudo-random errors into the outbound serial RapidIO data stream. If the EIC field is any of the allowable non-zero values (as shown in the table above), then error injection is enabled for one lane or all four lanes, as selected by the EIC value. When enabled, at pseudo-random intervals, an error is injected by inverting a single bit in the outgoing data stream. This occurs only in the lane(s) that have error injection enabled. The range of the pseudo-random value (delay between injected errors) is controlled by the EIR field, as described above. That is, the value of EIR, multiplied by 32, determines the maximum number of character times between injected errors.

Address: C_0000h base + 1_0160h offset = D_0160h



SRIO_P1SLEICR field descriptions

Field	Description
0–4 EIC	Error injection control. Enables and controls serial link error injection as follows: 00000 Error injection is disabled. 10000 Error injection, lane 0 only 01000 Error injection, lane 1 only 00100 Error injection, lane 2 only 00010 Error injection, lane 3 only 11110 Error injection, all 4 lanes simultaneously 11111 Error injection, randomly distributed over all 4 lanes All other values are reserved.

Table continues on the next page...

SRIO_P1SLEICR field descriptions (continued)

Field	Description
5–11 -	This field is reserved. Reserved
12–31 EIR	Error injection range. The value of EIR x 32 determines the maximum value of the pseudo-random delay between errors. For example, a value of 0x1 would indicate a maximum delay of 32 character times. Value within this register should be right-justified.

20.5.64 Port 1 Arbitration 0 Tx Configuration Register (SRIO_P1A0TxCR)

The port 1 arbitration 0 Tx configuration register (PnA0TxCR), is used to control the arbitration of packets within the serial RapidIO controller's transmit logic (Tx), specifically at arbitration point '0'. Arbitration," for details on this register's use.

Address: C_0000h base + 1_0164h offset = D_0164h

20.5.70 Port 2 Alternate device ID command and status register (SRIO_P2ADIDCSR)

The port 2 alternate device id CSR contains an alternate deviceID. This register should be used on a multi-port device to enable separate deviceIDs for each port. It is intended that this register, should be enabled before the master enabled bit of the PGCCSR is set, such that when it is enabled, all other devices in the RapidIO system (including switches) send packets to and receive packets from the deviceID contained in this register, instead of the deviceID contained in BDIDCSR.

When the alternate deviceID is enabled, the inbound RapidIO endpoint only accepts packets sent with the deviceID contained in P2ADIDCSR or with the deviceID contained in BDIDCSR (except during Accept All mode, during which the inbound RapidIO endpoint accepts packets using the same common transport system). In addition, the outbound RapidIO endpoint only generates requests using the deviceID contained in P2ADIDCSR; it generates responses with the deviceID given in the original request packet (either from P2ADIDCSR or BDIDCSR).

Field	Description
	1 All packets are accepted without checking the target ID. However, the tt field must be consistent with the common transport system specified by bit 27 of the processing element features CAR. 0 Normal RapidIO acceptance based on target ID.

20.5.72 Port 2 Logical Outbound Packet time-to-live configuration register (SRIO_P2LOPTTLCR)

The port 2 logical outbound packet time-to-live configuration register (P2LOPTTLCR), contains the time-to-live count for all ports on a device. This packet time-to-live counter starts when a packet is ready to be transmitted. If the packet is not successfully transmitted before the timer expires, the packet is discarded. Successfully transmitted means that a packet accept was received for the packet on the RIO interface. If the packet requires a response, an internal error response is returned after the response time-out occurs (PRTOCCSR). The packet time-to-live counter prevents the local processor from being stalled when packets cannot be successfully transmitted (acknowledged with an accept by the link partner at the physical level). The value of this register should always be larger than the link time-out value (PLTOCCSR). By default, this time-out value is disabled (all zeros). The timer resolution is specified between 178-298ns.

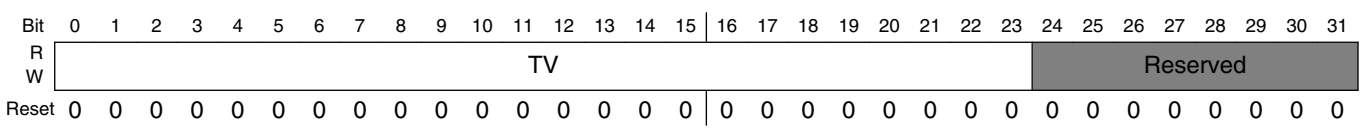
The total delay will be:

delay = decimal(SRIO_P1LOPTTLCR[TV])* 152/(platform frequency)

If the platform frequency ranges between 528Mhz and 800Mhz, then the delay resolution will range between 190ns and 288ns, thus the maximum time-out value will be between 3.19 and 4.83 seconds when using maximum TV field value, all ones.

When the packet time-to-live counter expires, PnPCR[OBDEN] is automatically set. PnPCR[OBDEN] must be cleared by software.

Address: C_0000h base + 1_01A4h offset = D_01A4h



SRIO_P2LOPTTLCR field descriptions

Field	Description
0–23 TV	Time-out value. Setting to all zeros disables the time-to-live time-out timer. This value is loaded each time the time-to-live time-out timer starts.
24–31 -	This field is reserved. Reserved

20.5.73 Port 2 Implementation error command and status register (SRIO_P2IECSR)

The port 2 implementation error command and status register (PnIECSR), contains status bits that are asserted whenever an implementation-defined error occurs.

Address: C_0000h base + 1_01B0h offset = D_01B0h

20.5.76 Port 2 Serial link error injection configuration register (SRIO_P2SLEICR)

The port 2 serial link error injection configuration register (PnSLEICR), is used to control the injection of bit errors into the transmit bit stream.

The P2SLEICR register is used to generate pseudo-random errors into the outbound serial RapidIO data stream. If the EIC field is any of the allowable non-zero values (as shown in the table above), then error injection is enabled for one lane or all four lanes, as selected by the EIC value. When enabled, at pseudo-random intervals, an error is injected by inverting a single bit in the outgoing data stream. This occurs only in the lane(s) that have error injection enabled. The range of the pseudo-random value (delay between injected errors) is controlled by the EIR field, as described above. That is, the value of EIR, multiplied by 32, determines the maximum number of character times between injected errors.

Address: C_0000h base + 1_01E0h offset = D_01E0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Field	Description
0–3 -	This field is reserved. Reserved
4–11 TREXAD	Translation extended address. Corresponds to bits 0-7 of the 40-bit internal platform translation address. TREXAD[6-7] are reserved for default window 0.
12–31 TRAD	Translation address. Target address which indicates the starting point of the inbound translated address. The translation address must be aligned based on the size field. This corresponds to bits 8-27 of the 40-bit internal platform translation address. TRAD is reserved for default window 0.

20.5.96 Port 1 RapidIO Inbound window base address register n (SRIO_P1RIWBAR*n*)

The port 1 RapidIO inbound window *n* base address registers select the base address for the windows which are translated to an alternate target address space. Addresses for inbound transactions are compared to these windows. If such a transaction does not fall within one of these spaces, then the transaction is forwarded to the interior of the chip using the default window. For transactions that cross more than one window, please see Window Boundary Crossing Errors-Inbound. Note that the LCSBA1CSR register Local configuration space base address 1 command and status register (SRIO_LCSBA1CSR) has priority over all ATMU windows if both are configured for the same address space.

Address: C_0000h base + 1_0D68h offset + (32d × i), where i=0d to 3d

SRIO_P2ROWTAR*n* field descriptions

Field	Description
0–1 LTGTID	LTGTID correspond to bits 6-7 of the target ID for a large transport system. This field is valid only if bit 27 of PEFCAR is set. Bits 0-5 of the target ID are specified in the window's port *n*RapidIO outbound window translation extended address register.
2–11 TREXAD	Translation extended address. TREXAD[0-7] correspond to the target ID for a small transport system or the least significant byte (bits 8-15) of the target ID for a large transport system. TREXAD[8-9] corresponds to bits [0-1] of a 34-bit RapidIO translation address. For maintenance transactions , TREXAD[8-9] is reserved.
12–31 TRAD	Translation address. System address which represents the starting point of the outbound translated address. The translation address must be aligned based on the size field. This corresponds to bits [2-21] of the 34-bit RapidIO translation address. For maintenance transactions, the hop count is formed from TRAD[0-7], and the upper 12 bits of the maintenance offset is formed from TRAD[8-19]; the rest of the maintenance offset is formed from the untranslated address. .

20.5.104 Port 2 RapidIO outbound window translation extended address register n (SRIO_P2ROWTEAR*n*)

The port 2 RapidIO outbound window translation extended address registers contain bits 0-5 of the target ID for a common transport large system.

Address: C_0000h base + 1_0E24h offset + (32d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

10–11 BEXAD	Base extended address. BEXAD represents bits 0-1 of the 34-bit RapidIO address.
12–31 BADD	Base address. System address which is the starting point for the inbound translation window. The window must be aligned based on the size selected in the window size bits. This corresponds to bits 2-21 of the 34-bit RapidIO base address.

20.5.112 Port 2 RapidIO inbound window attributes register n (SRIO_P2RIWAR*n*)

The port 2 RapidIO inbound window attributes registers define the window sizes to translate and other attributes for the translations. 16 Gbytes is the largest window size allowed. The RDTYP and WRTYP fields are used for attributes on the request, but do not actually change the transaction type of the transaction. In other words, PnRIWARn does not modify whether or not the request requires a response or if the request was atomic; this type of attribute remains unchanged on the request as it is translated through the ATMU.

20.5.113 Port 2 RapidIO inbound window translation address register 0 (SRIO_P2RIWTAR0)

The port 2 RapidIO inbound window translation address registers point to the starting addresses in local address space for window hits within the inbound translation windows. The new translated address is created by concatenating the transaction offset to this translation address.

Address: C_0000h base + 1_0FE0h offset = D_0FE0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

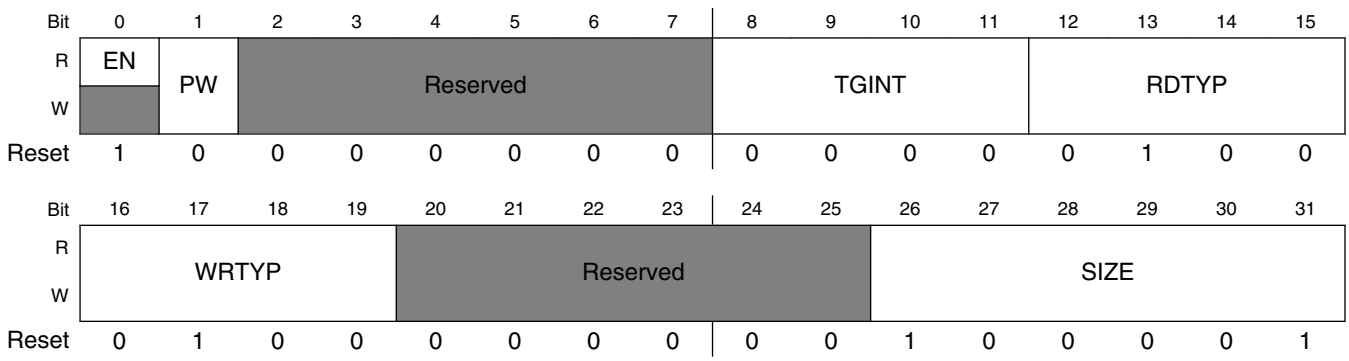
Field	Description
0–3 -	This field is reserved. Reserved
4–9 TREXAD	Translation extended address. Corresponds to bits 0-5 of the 40-bit internal platform translation address.
10–31 -	This field is reserved. Reserved

20.5.114 Port 2 RapidIO inbound window attributes register 0 (SRIO_P2RIWAR0)

The port 2 RapidIO inbound window attributes registers define the window sizes to translate and other attributes for the translations. 16 Gbytes is the largest window size allowed. The RDTYP and WRTYP fields are used for attributes on the request, but do not actually change the transaction type of the transaction. In other words, PnRIWARn does not modify whether or not the request requires a response or if the request was atomic; this type of attribute remains unchanged on the request as it is translated through the ATMU.

Address: C_0000h base + 1_0FF0h offset = D_0FF0h



SRIO_P2RIWAR0 field descriptions

Field	Description
0 EN	This bit enables this address translation. This field is set to 1 and read-only for default window 0.
1 PW	Protected Window. This bit indicates that this window is protected. Writes requiring response and reads to this window generate an error response. Writes not requiring response are silently discarded.
2–7 -	This field is reserved. Reserved
8–11 TGINT	Target interface. If this field is set to anything other than local address space, the attributes for the transaction must be assigned in a corresponding outbound window at the target. 0001 PCI Express 1 0011 PCI Express 2 0010 PCI Express 3 0101 PCI Express 4 0011 Serial RapidIO port 1 0100 Serial RapidIO port 2 1111 Local memory space

20.6 RapidIO Functional Description

20.6.1 RapidIO Implementation Space-ATMU Registers

ATMU registers are used for outbound and inbound transactions. Their purpose is to translate RapidIO packets to internal platform packets on inbound and to translate internal platform packets to RapidIO packets on outbound. ATMU window misses use the window 0 register set by default, and overlapping window hits results in the use of the lowest number window register set hit. For both inbound and outbound translation, the smallest window size is 4 Kbytes and the largest window size is 16G for inbound translation and 1T for outbound translation. The default window register set causes no translation of the transaction address for inbound transactions since the RapidIO address space has 34 bits and the internal platform address space has 40 bits. For outbound transactions, the default window maps each of the 64 16G chunks to the RapidIO 16-Gbyte address space. The inbound and outbound translation windows must be aligned based on the granularity selected by the size fields. The packet device ID fields are not used in the inbound translation process, only the address field.

The RapidIO endpoint implementation allows up to a 34-bit (0:33) RapidIO address and a 40-bit (0:39) internal platform address. As is the case with all registers, an external processor writing the ATMU registers should not assume that the write has completed until a response is received. A user must guarantee that the address tenures have stopped being initiated from those masters before starting to modify any ATMU settings and all traffic must be haulted during any reconfiguration of ATMU registers.

Note that when booting from serial RapidIO, outbound ATMU window 0 must be used.

20.6.1.1 Segmented Outbound Window Description

All outbound windows have the capability to have 2 or 4 segments, all of which are equal in size, numbered 0 and 1, or 0 through 3, respectively . Each segment assigns attributes and the target deviceID for an outbound transaction. All segments of a window translate to the same translation address in the target.

Additionally, each segment can be set up with 2, 4, or 8 subsegments, all of which are equal in size. These subsegments allow a single segment to target a number of numerically adjacent target device IDs, and, again, they all translate to the same translation address in the targets. For example, a segment with 8 subsegments can be configured to generate a transaction with the same set of attributes to target deviceIDs 0, 1, 2, 3, 4, 5, 6, or 7, depending on which subsegment is addressed.

Note that subsegments are only supported when multiple segments are chosen.

This allows a window to be configured so that aliases can be created to the same offset within the target device so that a single window can be used to generate different transaction types. Without segmented windows, achieving the equivalent behavior would require multiple windows. Figure 20-2 shows an example of this capability. A window is defined to be 4kB in size, and is defined to have 4 segments and no subsegments. Each segment is assigned to target deviceID 0x05, and each segment is given a different write transaction type attribute - segment 0 is assigned NWRITE, segment 1 is assigned SWRITE, segment 2 is assigned NWRITE_R, and segment 3 is assigned FLUSH. Since all of the segments are assigned to target the same device, by writing to the same offset in each segment, a different write transaction can be generated to the target to the same offset in the target.

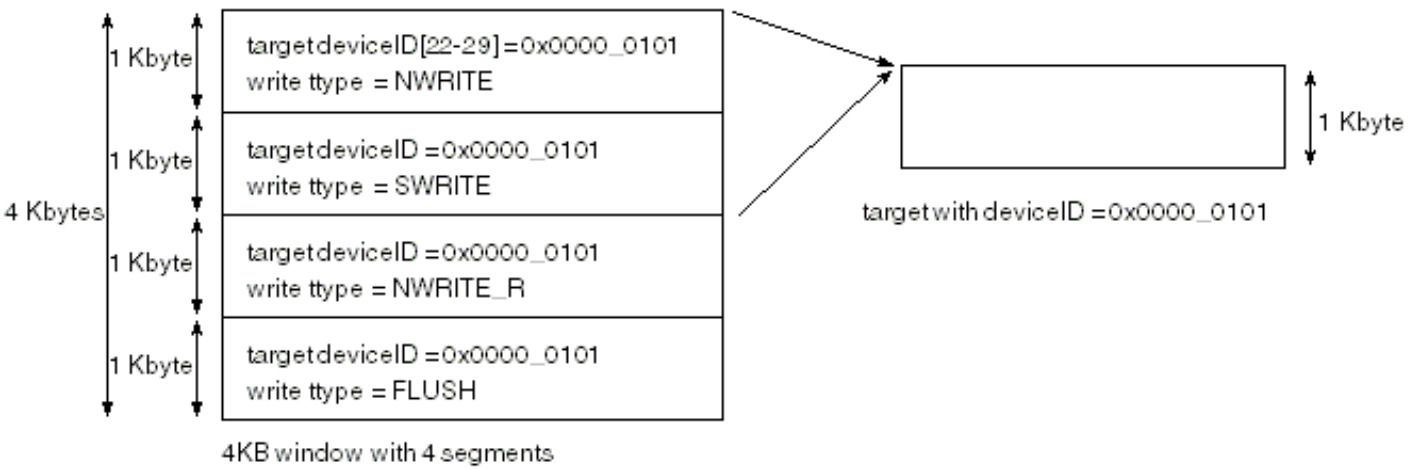

Figure 20-2. Example of Attribute Aliasing

So, writing to offset 0x0 in segment 0 is translated (as defined in the translation address registers) and generates a NWRITE transaction to offset 0x0 in a 1KB window in the target with deviceID = 0x05. A write to offset 0x0 in segment 2 is also translated, to the same offset in the target device as the write to segment 0, but this time a NWRITE_R transaction is generated.

Another use is that the same window can be used to target multiple devices with the same translation offset. Without segmented, (and subsegmented) windows, achieving the equivalent behavior would require multiple windows. Figure 20-3 shows an example of this multi-targeting. For example, a 4kB window is set up with 2 segments of 2 subsegments. Each segment is assigned a write ttype of NWRITE, but each segment and subsegment has a different target deviceID. Segments 0 and 1 are assigned target deviceIDs 4 and 5, and 8 and 9, respectively.

Figure 20-3. Example of Multi-Targeting

In this example, a write to offset 0x0 in segment 0 is translated as defined, and a NWRITE transaction is generated targeted to deviceID 4. A corresponding write to segment 1 to offset 0x400 is also translated but also using the assigned deviceID instead of the translation address bits [22-29]. The generated NWRITE transaction has the same target device offset as the write to segment 0, but is instead targeted to deviceID 9.

Combinations of aliasing and multi-targeting are also possible for a window.

20.6.2 RapidIO Transaction Summary

The RapidIO endpoint on this device supports all RapidIO I/O transactions, all RapidIO message passing transactions, and a few RapidIO GSM transactions.

This table summarizes the RapidIO I/O transactions that are supported by this RapidIO endpoint.

Table 20-1. RapidIO I/O Transactions

IO Transaction	ftype	ttype	Status	Description
NREAD	0010	0100	NA	Read
ATOMIC inc		1100		Read and post-increment with response
ATOMIC dec		1101		Read and post-decrement with response
ATOMIC set		1110		Read and set to all-1s with response

Table continues on the next page...

Table 20-1. RapidIO I/O Transactions (continued)

IO Transaction	ftype	ttype	Status	Description
ATOMIC clr		1111		Read and set to all-0s with response
NWRITE	0101	0100		Write with no response
NWRITE_R		0101		Write with response
SWRITE	0110	N/A		Streaming-Write
MAINT read	1000	0000		Maintenance read
MAINT write		0001		Maintenance write

			0011	GSM retry response
			0101	GSM done intervention response
			0111	GSM error response
RESPONSE with data		1000	0000	GSM done response
			0001	GSM data only response

1). Limited to RapidIO packet generation only

20.6.3 RapidIO Packet Format Summary

This table summarizes the small transport field packet formats for supported RapidIO transaction types for LP-Serial operation. Details of packet fields are located in the RapidIO Interconnect Specification, Revision 2.0.1.

Transaction ID (TID) source bits and sizes are defined as: rsv[0:2], doorbell type bit [3], source TID[4:7].

Note that this RapidIO endpoint limits configuration read and write requests to 32-bit data accesses.

Table 20-5. RapidIO Small Transport Field Packet Format

Transaction	Bits																
	32								32					16			64
	5	2	1	2	2	4	8	8	4	4	8	8	8	13	1	2

1. src TID[3] of [0:7] bus must be set to '1' for doorbell accesses.2 tar TID[3] of [0:7] bus must be set to '1' for doorbell responses.

The large transport field packet formats extends the destination and source IDs to 16-bits each.

20.6.4 RapidIO Control Symbol Summary.

This table summarizes the 1x/4x LP-Serial control symbols and their format. Refer to the *RapidIO Interconnect Specification, Revision 1.2, Part IV: Physical Layer 1x/4x LP-Serial Specifications*, *Chapter4, PCS and PMA Layers,* for 8B/10B data and special (/PD/, /SC/, idle, sync, skip, align) characters. The 32-bit LP-Serial control symbol is comprised of the eight bit special character and the 24-bit control symbol format.

Table 20-6. 1x/4x LP-Serial Control Symbol Format

Bits						Description
24						
stype0	param0	param1	stype1	cmd	CRC	
3	5	5	3	3	5	
000	pkt_ackID	buf_stat	-		crc	Packet accepted

20.6.5 Accessing Configuration Registers Using RapidIO Packets

20.6.5.1 Inbound Maintenance Accesses

There are two suggested methods by which RapidIO transactions can target RapidIO configuration register space in local memory.

The first method is based on RapidIO NREAD and NWRITE_R requests hitting a RapidIO address window defined by the local configuration space base address command and status register (LCSBACSR). See Local configuration space base address 1 command and status register (SRIO_LCSBA1CSR), for details.

If external configuration accesses are disabled (LLCR[ECRAB] = 1), any configuration access through the LCSBACSR window is denied. A 32-bit data payload of all zeros is returned for a non-maintenance configuration read.

The second method is based on a RapidIO MAINT requests. This method allows an external device limited access to local RapidIO configuration register space only. Any maintenance access beyond the first 64 Kbytes (lower 64KB contains RapidIO architecture registers; upper 64KB contains RapidIO implementation registers) of RapidIO configuration register space, is denied. A 32-bit data payload of all zeros is returned if for a read response.

A third method, though not suggested, would use an inbound ATMU window to translate RapidIO NREAD and NWRITE_R requests to configuration accesses. This method does not support the configuration access protection features offered by the LCSBACSR window and RapidIO MAINT requests.

20.6.5.2 Outbound Maintenance Accesses

Outbound internal platform NREAD_R or NWRITE requests can be translated to a RapidIO maintenance request if the internal platform address falls within the bounds of an outbound ATMU window that is setup for generating a maintenance request. The ATMU window specifies the configuration offset, hop count, source and destination ID, critical request flow, and priority for the outbound RapidIO packet.

20.6.6 Interaction with the Message Unit

The RapidIO controller is designed to interact with a message unit, which provides it with a message passing architecture.

There are both inbound (Rx) and outbound (Tx) interfaces with the message unit, in addition to the Rx and Tx interfaces with the system and link.

This figure shows RapidIO controller's interaction with the message unit.

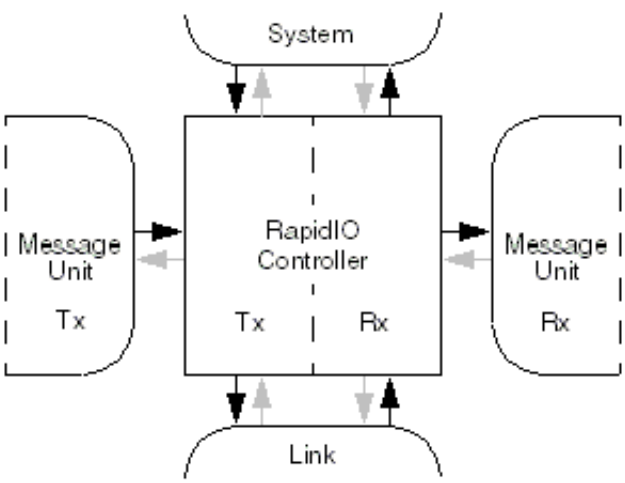

Figure 20-4. Interaction with the Message Unit

20.6.6.1 Inbound (Rx)

The inbound (Rx) interaction with the message unit is used receive message unit packets from the RapidIO link. The RapidIO link can receive message requests, responses, or flow control packets.

The inbound interaction directs incoming packets to either the message unit or the controller based upon various RapidIO fields. Inbound message packets will be buffered into either a request or response queue before being sent out to the message unit. A round robin arbitration scheme is used to select the next transaction out to the message unit.

20.6.6.2 Outbound (Tx)

The outbound (Tx) interaction with the message unit is used to transmit message unit packets to the RapidIO link. The message unit can transmit requests, responses, or flow control packets.

Tx message unit packets are bufferred within the RapidIO controller until they have been accepted on the link (received ack accepted). In addition, Tx message unit packets arbitrate with Tx system packets within the RapidIO controller before being transmitted to the link.

20.6.6.2.1 Buffer Allocation

The RapidIO controller contains buffers for Tx message unit packets.

The buffers are separated into two categories:

- Tx Message Unit Request Packets
- Tx Message Unit Response/Flow Control Packets

This figure shows the buffers for Tx message unit packets within the RapidIO controller.

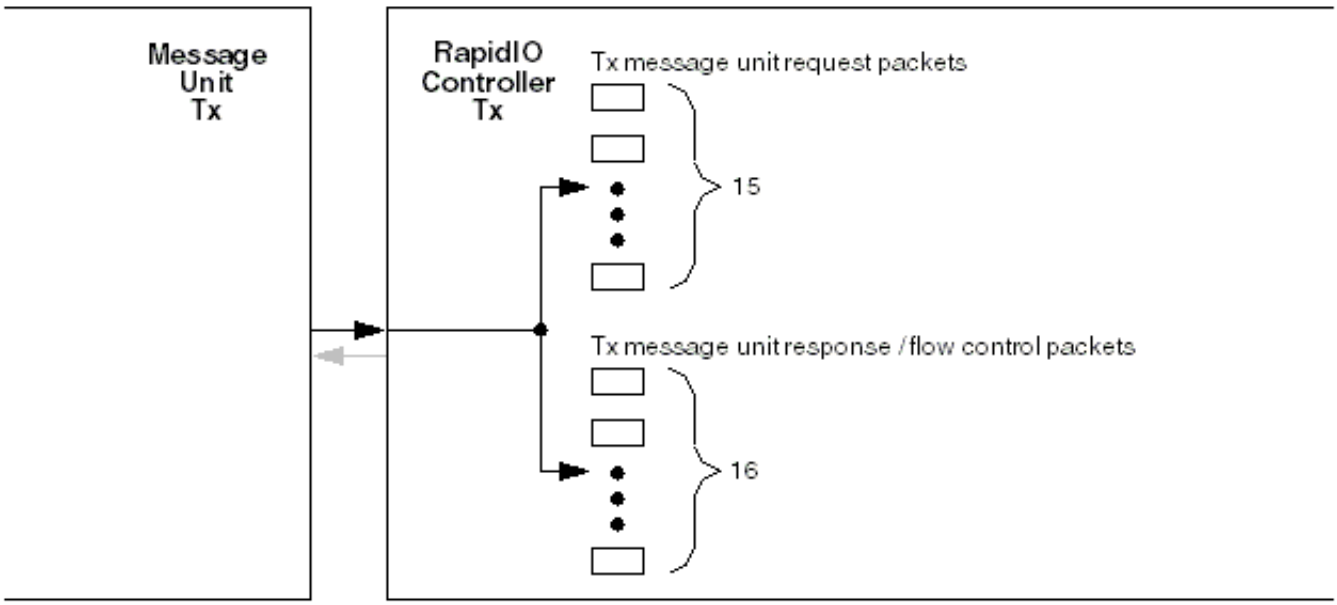

Figure 20-5. Tx Message Unit Packet Buffers

Within each category, there is dedicated and generic buffer allocation. Dedicated buffer allocation holds a specific type of message unit packet (within that category). Generic buffer allocation holds any type of message unit packet (within that category). Each buffer, regardless of its allocation (dedicated or generic), can only hold 1 message unit packet.

20.6.6.2.1.1 Tx Message Unit Request Packets

Tx mesage unit request packets are categorized according to an arbitration group (for example, arbitration group 0). Each arbitration group may have its own dedicated buffer allocation. In addition, there is also generic buffer allocation (holds any of the arbitration groups).

The number of dedicated and generic buffers for Tx message unit request packets is configurable with the following registers:

- Port 1 Message Request Tx Buffer Allocation Configuration Register 0 (SRIO_P1MReqTxBACR0) and Port 2 Message Request Tx Buffer Allocation Configuration Register 0 (SRIO_P2MReqTxBACR0)
- Port 1 Message Request Tx Buffer Allocation Configuration Register 2 (SRIO_P1MReqTxBACR2) and Port 2 Message Request Tx Buffer Allocation Configuration Register 2 (SRIO_P2MReqTxBACR2)

NOTE

There are only 15 buffers that hold message unit request packets. If the total value of the fields within the registers mentioned above exceeds 15 undefined behavior will result.

These registers are overwritten when the maximum arbitration group changes.

The new values support one dedicated buffer for each arbitration group up to the maximum, and the remaining buffers are generic. The total of all buffers (both dedicated and generic) should be 15.

For example, when the maximum arbitration group is set to 0, then DedAG0[3:0] is set to 4'h1 (one dedicated buffer for arbitration group 0) and GenAG[3:0] is set to 4'hE (the remaining 14 buffers are generic).

You can change these registers after the maximum arbitration group changes, and your new values are used. A subsequent change of the maximum arbitration group overwrites the values of these registers again.

20.6.6.2.1.2 Tx Message Unit Response/Flow Control Packets

There are two types of Tx message unit response/flow control packets:

- Tx message unit response packet
- Tx message unit flow control packet

Each type may have its own dedicated buffer allocation. In addition, there is also generic buffer allocation (holds any of the types mentioned above).

The number of dedicated and generic buffers for Tx message unit response/flow control packets is configurable with the following registers:

- Port 1 Message Response / Flow Control Tx Buffer Allocation Configuration Register (SRIO_P1MRspFcTxBACR) and Port 2 Message Response / Flow Control Tx Buffer Allocation Configuration Register (SRIO_P2MRspFcTxBACR)

NOTE

There are only 16 buffers that hold message unit response and flow control packets. The total value of the fields within the register mentioned above, must not exceed 16 (undefined behavior will result).

20.6.6.2.2 Arbitration

The RapidIO controller arbitrates amongst its Tx message unit packet buffers and an arbitration winner from the system packet buffers. Two main types of arbitration are used throughout: strict priority and weighted round robin.

Strict priority arbitration, with starvation avoidance selects a winner based on priority. Starvation avoidance, which may be disabled, elevates lower priority requestors to the highest priority. This can only occur when a starvation avoidance counter has expired. This counter only counts when a requestor has lost. A counter threshold of 0s will disable this feature. Note: disabling starvation avoidance may cause deadlocks.

Weighted round robin arbitration selects a winner based on round robin, but with weights. The weights delay moving to the next requestor until a number, equal to the corresponding weight, of winners has been chosen.

This figure shows the details of Tx message unit packet arbitration.

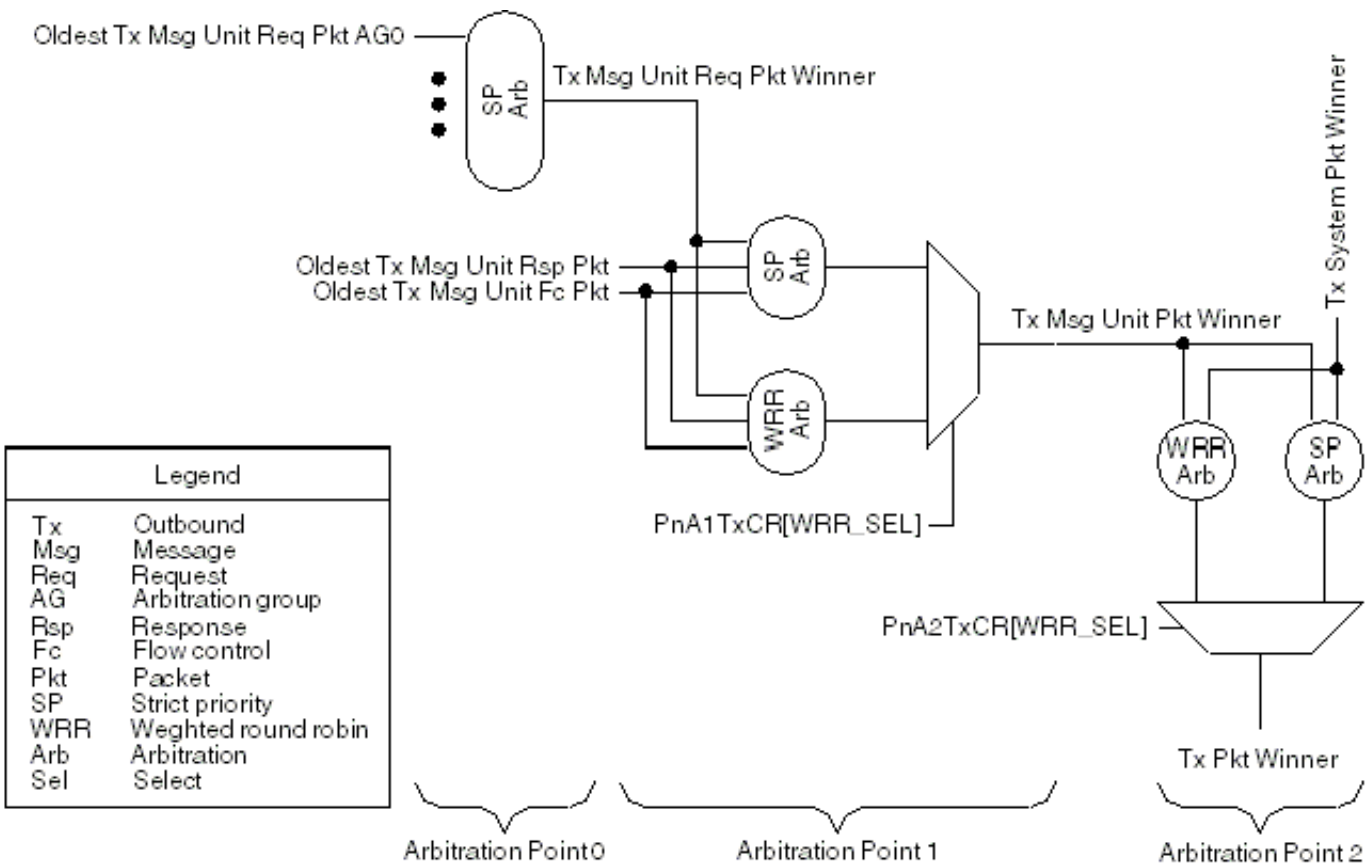

Figure 20-6. Tx Message Unit Packet Arbitration

20.6.6.2.2.1 Arbitration Point 0

Consider the following regarding arbitration point 0:

- It chooses a Tx message unit request packet winner. Only the oldest Tx message unit request packet of each arbitration group is eligible.
- Strict priority arbitration is used to select the winner.
- The priority of Tx message unit request packets is related to their arbitration group, with arbitration group 0 being the highest priority.
- It is configurable with Port 1 Arbitration 0 Tx Configuration Register (SRIO_P1A0TxCR) and Port 2 Arbitration 0 Tx Configuration Register (SRIO_P2A0TxCR).

20.6.6.2.2.2 Arbitration Point 1

Consider the following regarding arbitration point 1:

- It chooses a Tx message packet winner. Only the Tx message unit request packet winner (chosen from Arbitration Point 0), the oldest Tx message unit response packet, and the oldest Tx message unit flow control packet are eligible.
- Two types of arbitration are available:
  - Strict priority-If selected, the weighted round robin arbitration result is ignored. The RapidIO priorities (CRF and 2-bit priority field in the packet's header) of the three requestors (mentioned above) are compared. The packet with the highest RapidIO priority is chosen as the winner. In the case of a tie, round robin arbitration, based on past history, is used to select the winner.
  - Weighted round robin-if selected, the strict priority arbitration result is ignored. Each of the three requestors is considered based on its corresponding weight, and a winner is chosen.
- It is configurable with Port 1 Arbitration 1 Tx Configuration Register (SRIO_P1A1TxCR), Port 2 Arbitration 1 Tx Configuration Register (SRIO_P2A1TxCR).

20.6.6.2.2.3 Arbitration Point 2

Arbitration point 2 behaves the same as Arbitration Point 1, except it:

- Chooses the Tx message unit request packet winner from Arbitration Point 1
- Is configurable with Port 1 Arbitration 2 Tx Configuration Register (SRIO_P1A2TxCR), Port 2 Arbitration 2 Tx Configuration Register (SRIO_P2A2TxCR)

20.6.7 RapidIO Outbound ATMU

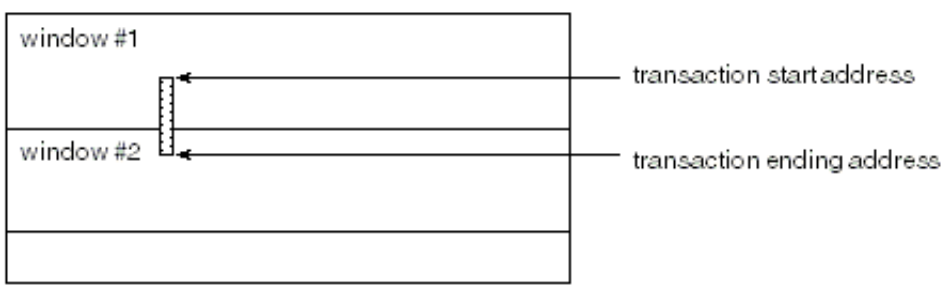
20.6.7.1 Valid Hits to Multiple ATMU Windows

If a request hits multiple ATMU windows, window 1 has the highest priority of the nine outbound ATMU windows (windows 1-8, default). Window 2 is given the next higher priority and is followed by windows 3 through 8. The default window has the lowest priority.

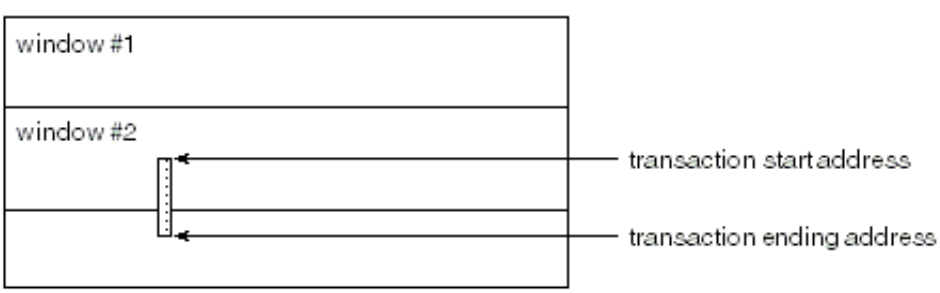
If a request hits (base address match) multiple ATMU windows and the transaction's end address is contained within the boundary of each hit window and does not extend into another ATMU window, the translation window is the highest priority window that is hit.

If a lower priority window is programmed to lie entirely within a higher priority window, then it is possible for a transaction to cross window boundaries. Although not a practical programming application, the RapidIO endpoint handles this as follows:

- If a request hits (base address match) an ATMU window (1-8) and the transaction's end address extends into another ATMU window with lower priority but is still contained within the boundary of the hit window, the translation window is the hit window.



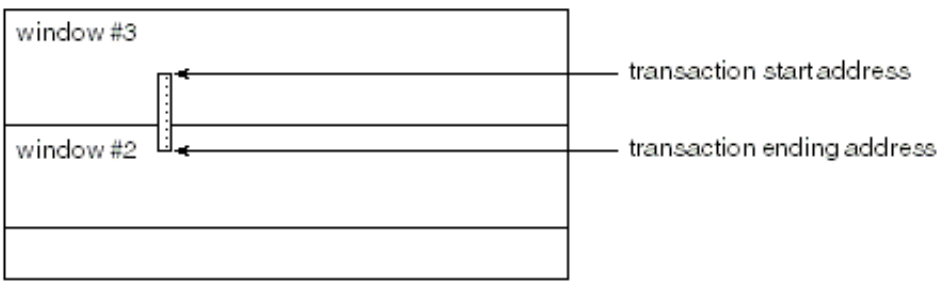
- If a request hits (base address match) multiple ATMU windows (1-8) and the transaction's end address extends beyond the boundary of a lower priority hit window but is still contained within the boundary of a higher priority hit window, the translation window is the highest priority window that is hit.



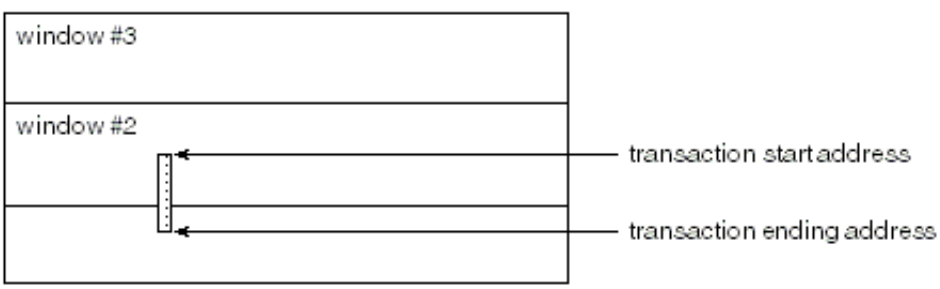
20.6.7.2 Window Boundary Crossing Errors-Outbound

If a higher priority window is programmed to lie entirely within a lower priority window, then it is possible for a transaction to cross window boundaries. The RapidIO endpoint handles this as follows:

- If a request hits (base address match) an ATMU window (1-8, default) and the transaction's end address extends into another ATMU window with higher priority, an ATMU crossed boundary error is generated and logged. The outbound request is discarded.

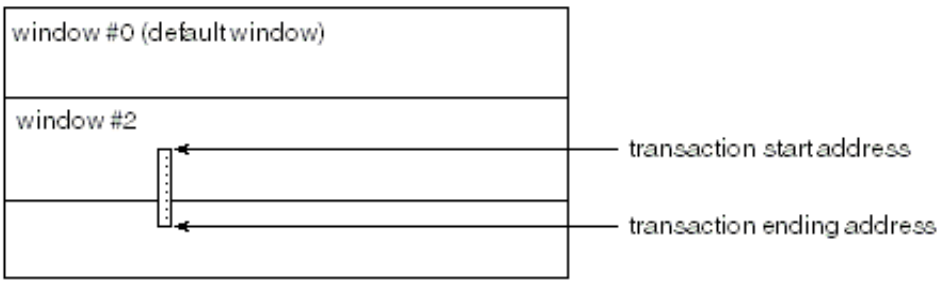


- If a request hits multiple ATMU windows (1-8, default) and transaction's end address extends beyond the boundary of a higher priority hit window, an outbound ATMU crossed boundary error is generated and logged. The outbound request is discarded.



Other window boundary crossing errors are:

- If a request hits (base address match) an ATMU window (1-8) and the transaction's end address exceeds the size of the window, an outbound ATMU crossed boundary error is generated and logged. The outbound request is discarded.



Boundary crossing errors (outbound ATMU boundary crossing, segment boundary crossing, and subsegment boundary crossing) are logged in the LTLEDCSR[OACB] configuration register field.

20.6.8 RapidIO Inbound ATMU

20.6.8.1 Hits to Multiple ATMU Windows

If a request hits multiple ATMU windows, window 1 has the highest priority of the five inbound ATMU windows (windows 1-4, default). Window 2 is given the next higher priority and is followed by windows 3 and 4. The default window has the lowest priority.

If a request hits (base address match) multiple ATMU windows and the transaction's end address is contained within the boundary of each hit window and does not extend into another ATMU window, the translation window is the highest priority window that is hit.

If a lower priority window is programmed to lie entirely within a higher priority window, then it is possible for a transaction to cross window boundaries. Although not a practical programming application, the RapidIO endpoint handles this as follows:

1. If a request hits (base address match) an ATMU window (1-4) and the transaction's end address extends into another ATMU window with lower priority but is still contained within the boundary of the hit window, the translation window is the hit window.
2. If a request hits (base address match) multiple ATMU windows (1-4) and transaction's end address extends beyond the boundary of a lower priority hit window but is still contained within the boundary of a higher priority hit window, the translation window is the highest priority window that is hit.

20.6.8.2 Window Boundary Crossing Errors-Inbound

If a higher priority window is programmed to lie entirely within a lower priority window, then it is possible for a transaction to cross window boundaries. The RapidIO endpoint handles this as follows:

1. If a request hits (base address match) an ATMU window (1-4, default) and the transaction's end address extends into another ATMU window with higher priority, an ATMU crossed boundary error is generated and logged.
2. If a request hits multiple ATMU windows (1-4, default) and transaction's end address extends beyond the boundary of a higher priority hit window, an inbound ATMU crossed boundary error is generated and logged.

Other window boundary crossing errors are:

1. If a request hits (base address match) an ATMU window (1-4) and the transaction's end address exceeds the size of the window, an inbound ATMU crossed boundary error is generated and logged.
2. If a NREAD/NWRITE_R/NWRITE/SWRITE request hits (base address match) an ATMU window (1-4, default) and the transaction's end address extends into the region defined as the local configuration space window, an inbound ATMU crossed boundary error is generated and logged.

A RapidIO error response is generated for RapidIO requests that require a response. RapidIO requests that do not require a response are dropped.

Inbound ATMU boundary crossing errors are logged in the LTLEDCSR[IACB] configuration register.

20.6.9 Inbound LIODN Translation

Inbound LIODN translation generates an internal LIODN value from an inbound request packet’s source ID. Inbound LIODN translation does not occur for inbound message type requests, pass-through packets and inbound responses; they do not generate an internal LIODN value. A base LIODN value, contained in SRIOPn_LBR, is added to a LIODN offset, contained in a matching entry of the LIODN lookup table, to create an LIODN value for the inbound request packet.

20.6.9.1 LIODN Lookup table

The LIODN lookup table is shown below.

Table 20-7. LIODN Lookup table

	Upper		Lower	
	SRCID	MASK	LOFFSET	EN
Entry 0	0x0000	0xFFFF	0x000	0x1
Entry 1	0x0000	0x0000	0x000	0x0
Entry 2	0x0000	0x0000	0x000	0x0
*				
*				

The default state of the LIODN lookup table will ensure a match to entry#0 and is defined as the following:

Entry 0

SRCID == 0x0000 MASK == 0xFFFF LOFFSET == 0x000 EN == 0x1.

Entry 1-63

SRCID == 0x0000 MASK == 0x0000 LOFFSET == 0x000 EN == 0x0.

20.6.9.1.1 Accessing the LIODN Lookup table

Software can program the LIODN lookup table using the following method:

1. Write the desired entry number into the SRIOPn_LAOR[ADDR] field.
2. Write the desired values for the SRCID and MASK fields within the SRIOPn_LUDR register.
3. Write the desired values for the LOFFSET and EN fields within the SRIOPn_LLDR register.
4. Repeat for other entries.

Each write to the SRIOPn_LUDR or SRIOPn_LLDR registers will initiate a write to the LIODN lookup table at the entry designated by SRIOPn_LAOR. Each read from the SRIOPn_LUDR or SRIOPn_LLDR registers will return data from the LIODN lookup table of the entry designated by SRIOPn_LAOR.

Care must be taken when programming the SRCIDs of the lookup table. All 16 bits of the SRCID are compared against the source ID field of a request packet. 8 bits of 0s are pre-pended to the source ID field of a small transport packet before comparison with SRCID. When the Serial RapidIO controller is configured in a small system (PEFCAR[CTLS]==0), the upper 8 bits of the SRCID field must be programmed with zeroes to match.

20.6.9.1.2 Translation

The following steps are used to determine an LIODN lookup table match:

1. An inbound request packet's source ID is AND'ed with each entry's inverse MASK field.
2. Each entry's SRCID field is AND'ed with the inverse MASK field.
3. The results of items #1 and #2 are AND'ed with the entry's EN field and compared to determine if a match has been detected.
4. A winning match will be determined by a valid match for that entry and no lower entry matches exist as well. For example multiple matches to entries #2, #6 and #24 will yield a winning match of entry #2.
5. The resulting LIODN field is calculated from the following:

   {4'b0000, SRIOPn_LBR[LBASE]} + {6'b000000, winning entry's LOFFSET field}

An inbound request that does not match any entry of the LIODN lookup table will be considered a logical inbound LIODN error and logged in the LTLEDCSR[ILE] error bit, along with any error capture information. Inbound requests requiring responses will return an ERROR response for a LIODN lookup table miss while inbound requests not requiring responses will be dropped. See hardware error tables in Logical Layer RapidIO Errors Detected Logical Layer RapidIO Errors Detected for more details.

20.6.10 Generating Link-Request/Reset-Device

20.6.10.1 LP-Serial Mode

In LP-Serial mode the link partner cannot be reliably reset using the link-request/reset-device control symbols since the input port receiver cannot be disabled independent of the output port driver. The input port driver needs to be disabled to prevent non idle control symbols from being transmitted between the four link-request/reset-device control symbols. For example, if a packet was received on the inbound side after one of the four link-request/reset-device control symbols was sent outbound, the required sequence of four link-request/reset-device symbols would be interrupted with the packet acknowledgement (packet accept, packet retry or packet not accept).

20.6.11 Outbound Drain Mode

- The RapidIO port is placed into Drain mode when one of the following occurs:
  - PnPCR[OBDEN] is set

    - the Failed Threshold has been encountered and the PnCCSR[SPF] and PnCCSR[DPE] are both set
    - the packet time-to-live counter expires causing P*n*PCR[OBDEN] to be set
- When the RapidIO port is placed into Drain mode, the RapidIO port discards all packets in the outgoing data stream. Since the data stream is invalid, the RapidIO port also puts its Outbound port back to normal state. Any received acknowledgements and link-responses are considered invalid during this period (since the RapidIO port has cleared out all acknowledgement history).
- The RapidIO port's outbound and outstanding ackID shows that all outstanding packets at the time Drain mode was entered were accepted, whether they truly were accepted or not. If the outbound ackID is not acceptable, then software should change it prior to taking the RapidIO port out of the Drain mode. Also, if the link-partner needs to be put back into inbound OK state, then software should send a link-request/input-status. The recommended sequence for recovering from Drain mode is given in Software Assisted Error Recovery Register Support.
- PnPCR[OBDEN] also causes any queued up packet acknowledgements to be discarded if the port is uninitialized (the RapidIO port lets them be transferred if the port is initialized). Drain mode due to failed threshold does not cause any packet acknowledgements to be dropped.
- If a discarded packet in the outgoing data stream requires a logical response, a packet response time-out occurs as long as the packet response timer is enabled (PRTOCCSR is non 0).

20.6.12 Input Port Disable Mode

- The RapidIO port is placed into Input Port Disable mode when PnCCSR[PD] is set.
- When the RapidIO port is placed in Input Port Disable mode, the RapidIO port discards all incoming data stream (obviously). Since the incoming stream is invalid, the RapidIO port also puts its inbound port back to normal state.
- When the RapidIO port is placed in input port disable mode, the RapidIO port also:
    - Ends any packet capture that was in progress.
    - Clears the link-request/reset-device count.
- The RapidIO port's inbound ackID shows that all packets successfully received by the RapidIO port at the time input port disable mode was entered were accepted. If output port disable mode was entered at the same time, some packet acknowledgements may be discarded by the RapidIO port. If the inbound ackID is not acceptable, then software should change it prior to taking the RapidIO port out of Input Port Disable mode.

20.6.13 Software Assisted Error Recovery Register Support

P*n*LMREQCSR is only supported for recovery from drain mode, including hot-swap support. Consistent with this statement, software should only write this register when the port is in Drain mode.

The proper sequence for recovering from Drain mode is as follows:

1. Software ensures that link activity is stopped. This should include the following:
   a. Software polls for Port OK bit to be set.
   b. Software waits longer than the link time-out value.
2. Software generates a link-request/input-status to obtain the link-partner's inbound ackID value.
3. Software changes the RapidIO port's outbound ackID to this value (if necessary).
4. If the link-partner was hot-inserted, software changes the RapidIO port's inbound ackID to zero. (Note that software needs to know when the link-partner was hot-inserted.)

NOTE

If software can guarantee that the link-partner does not attempt to forward any packets to this RapidIO port, then software may write the outbound ackID of the link-partner to match the inbound ackID of this RapidIO port. However, if the link-partner attempts to forward another packet while this write is still outstanding, and the ackIDs already happened to line-up, then the write actually causes the ackIDs to not match, and the link can not be recovered.

5. Software should cause the link-partner to send a link-request/input-status just to ensure that the RapidIO port's inbound port is in Normal operation.
6. Software clears the Failed Encountered bit or the Output Buffer Drain Enable bit; whichever one caused the Drain mode (thus clearing Drain mode).

Software is responsible for timing software generated link-requests. If the response valid bit is not set in some reasonable period of time, the software should write another request in the register.

When software writes P*n*LMREQCSR, software should make sure to successfully read P*n*LMRESPCSR set, otherwise, software may read a "stale" ackID status/link status later.

Note that when the RapidIO port's outbound ackID is written by software using P*n*LASCSR, the inbound ackID is also written. Care must be taken to ensure that the inbound ackID is not written to an incorrect value. For example, P*n*CCSR[PL] could be set to prevent the inbound ackID from changing before P*n*LASCSR is written.

20.6.14 Hot-Swap Support

The two basic hot-insertion approaches described in the RapidIO Error Management Extensions are supported although the second approach is only partially supported. Method one has a host bringing a field replacement unit (FRU) into the system. Method two has the FRU bringing itself into the system. Note that this RapidIO port is most likely the device being hot-inserted/extracted since typically this device would be connected to a switch but it could be the link partner of a device being hot-inserted/extracted.

20.6.14.1 Method 1

One possible sequence for when the host brings the FRU into the system is given. This RapidIO port can be either the device being hot-inserted/extracted or the link partner of the device being hot-inserted/extracted. The goal of this sequence is to bring the FRU into the system cleanly without generating errors.

20.6.14.1.1 Extraction Sequence (Method 1)

The extraction sequence using method 1 is as follows:

1. The host determines that the FRU has failed by getting a port response time-out when polling the port OK bit (PO bit in port n error and status CSR) of the FRU. Note that there are other ways to determine that the FRU has failed. This is one possible method to detect FRU failure.
2. The host must perform the following steps to the FRU link partner before hot insertion of the FRU occurs.
   a. Set the port lockout bit (PL = 1 in the port *n*control CSR) preventing packet reception and transmission
   b. Prevent any new packets from arriving to the FRU link partner RapidIO port by all other RapidIO devices and discard all pending packets destined for the FRU so that:
      - Congestion to this RapidIO port does not occur and cause other system problems
      - The FRU is not immediately flooded with old packets after insertion causing other errors like unsolicited responses
   c. Note that this RapidIO endpoint has a specific bit to enable the discard of pending packets (OBDEN in PnPCR). Also note that setting OBDEN in P*n*PCR forces the output state from error or retry to normal. In a switch, the time-to-live feature may be used to discard packets.

d. Force the input state to normal. In this RapidIO endpoint, this occurs by disabling the input port receiver.
e. Leave the input port receivers and output port drivers enabled so that initialization can complete when the FRU is inserted
f. Clear all errors pertaining to the extracted RapidIO port in the FRU link partner and any other RapidIO port that was affected by the FRU failing (port response time-outs)
g. If RapidIO endpoint, clear OBDEN in P*n*PCR for normal operation
h. Set the outbound and inbound ackID to 0x00 in the port *n*local ackID status CSR so that the ackID is correct and packets can be transmitted and received when the FRU is inserted

3. The host indicates that the FRU should be removed.
4. The FRU is removed from the system.

20.6.14.1.2 Insertion Sequence (Method 1)

The insertion sequence using method 1 is as follows:

1. The FRU is inserted into the system.
2. Link initialization occurs and initialization complete status is indicated (port OK bit in the port n error and status CSR) in both RapidIO ports.
3. The host determines that this link partner has been inserted by periodically polling the initialization complete status in the FRU link partner (PO bit = 1 in the port n error and status command and status register).
4. The host clears the output and input port enable bits and clears the port lockout bit in the port n control CSR in the FRU link partner allowing only maintenance transactions.
5. The host sets the master enabled and discovered bits in the FRU (M = 1 and D = 1 in the port general control CSR). Note that the master enable bit does not prevent the RapidIO endpoint from transmitting packets.
6. The host completes configuration of the FRU
7. The host sets the output and input port enable bits in the port n control CSR in the FRU link partner allowing transmission and reception of all packet types.
8. The host re-enables packets to be sent to this RapidIO port by other RapidIO devices.
9. System operation resumes.

20.6.14.2 Method 2 with RapidIO Port Hot-Swapped

One possible sequence for when the FRU brings itself into the system is given. This RapidIO Port can be either the device being hot-inserted/extracted or the link partner of the device being hot-inserted/extracted. The goal of this sequence is to bring the FRU into the system cleanly without generating errors.

20.6.14.2.1 Extraction Sequence (Method 2)

The extraction sequence using method 2 is as follows:

1. The FRU fails.
2. New packets are prevented from arriving to the FRU link partner by all other RapidIO devices and all pending packets destined for the FRU are discarded so that the following occur:
   a. Congestion to this RapidIO port does not occur and cause other system problems.
   b. The FRU is not immediately flooded with old packets after insertion causing other errors such as unsolicited responses.
3. This FRU link partner continues to have its drivers enabled.
4. The FRU link partner continues to allow the transmission and reception of all packet types since its output and input port enable bits are set and the port lockout bit is cleared in the port n control CSR.
5. The FRU is removed from the system.

20.6.14.2.2 Insertion Sequence (Method 2)

The insertion sequence using method 2 is as follows:

1. The FRU is inserted.
2. Link initialization occurs, initialization complete status is indicated in both RapidIO ports (PO bit = 1 in the port n error and status command and status register).
3. After initialization is complete, both devices set the port OK bit = 1 in the port n control CSR.
4. The FRU sets its port lockout bit in the port n control CSR.
5. The FRU generates a link-request/input-status to its link partner using the port n link maintenance request register. The FRU determines the link partner's inbound ackID by reading the port n link maintenance response register. The FRU then sets its outbound ackID in the port n local ackID status CSR.
6. The FRU only enables maintenance transactions by clearing its output and input port enable bits in the port n control CSR and by clearing its port lockout bit in the port n control CSR.

7. The FRU generates a maintenance write to its link partner's port n local ackID status CSR to set the link partner's outbound ackID value to 0. Upon receipt of the maintenance write, the link partner sets its outbound ackID value and generates the maintenance response using the new value. Note that if all packets intended for the link partner have not been discarded, or if any new packets intended for the link partner arrive, this step may fail (the RapidIO endpoint has no way to protect against this).
8. The FRU completes configuration.
9. The FRU enables all packets to be transmitted and received by setting its output and input port enable bits in the port n control CSR.
10. System operation resumes.

20.6.15 Software Re-Training

You can issue a software controlled re-training of the link in LP-Serial mode to update certain configurations by following these steps:

1. Software on the host must ensure that all RapidIO transactions have completed and link activity has stopped.
2. Set PnCCSR[PD] on the host to disable the port and force the initialization state machines to reset.
3. Set P*n*PCR[OBDEN] on the host to enable the discarding of any pending packets. (There should be none if proper steps were taken to ensure there was no link activity.)
4. Clear P*n*PCR[OBDEN] on the host.
5. Configure new operating width (via PnCCSR[PWO]) or any other new configurations.
6. Clear PnCCSR[PD] on the host to re-enable the drivers.
7. Poll PnESCSR[PO] on the host until it is set, which indicates the link has attained port and link initialization.
8. Poll PnESCSR[PO] on the agent until it is set, which indicates the link has attained port and link initialization.
9. Poll PnESCSR[OES] on the agent until it is clear, which indicates the link has completed the error recovery sequence initiated from the port disable.
10. Poll PnESCSR[OES] on the host until it is clear, which indicates the link has completed the error recovery sequence initiated from the port disable.
11. Clear the agent's error and status registers.
12. Clear the host's error and status registers.
13. Begin normal packet transfer.

20.6.16 Errors and Error Handling

This section describes how the logical and physical layers detect and react to RapidIO errors. The action of the core on notification of any of these errors is described minimally here. See *RapidIO Interconnect Specification, Revision 1.2* Part VII (Error Management Extensions Specifications) for more details on specific errors described below.

20.6.16.1 RapidIO Error Description

RapidIO errors are classified under three categories: recoverable errors, notification errors, and fatal errors.

Recoverable errors are non-fatal transmission errors (such as corrupt packet or control symbols, and general protocol errors) that RapidIO supports hardware detection of and a recovery mechanism for, as described in the *RapidIO Interconnect Specification, Revision 1.2*. In these cases, the appropriate bit is set in the port n error detect CSR. Only the packet containing the first detected recoverable error that is enabled for error capture (by port n error enable CSR) is captured in the port n error capture CSRs. No interrupt is generated or actions required for a recoverable error. Recoverable errors are detected in the physical layer only.

Notification errors are non-recoverable non-fatal errors detected by RapidIO (such as degraded threshold, port-write received, and all logical/transport layer (LTL) errors captured). Because they are non-recoverable (and in some cases have caused a packet to be dropped), notification by interrupt is available. However, because they are non-fatal, response to the interrupt is not crucial to port performance; that is, the port is still functional. When a notification error is detected, the appropriate bit is set in the error-specific register, an interrupt is generated, and in some cases, the error is captured. In all cases, the RapidIO port continues operating. Notification errors are detected in both the physical and logical layer. Note that to prevent processor stalls the P*n*LOPTTLCR registers must be initialized to a non-zero value.)

The RapidIO controller detects two fatal errors: exceeded failed threshold and exceeded consecutive retry threshold. In these cases, the port has failed because its recoverable error rate has exceeded a predefined failed threshold or because it has received too many packet retries in a row. In the first case, the controller sets the output failed-encountered bit in the port n error and status CSR; the RapidIO output hardware may or may not stop (based on stop-on-port-failed-encounter-enable and drop-packet-enable bits). In the second case, the controller sets the retry counter threshold trigger exceeded bit in the port n implementation error CSR; the RapidIO hardware continues to operate. In both cases,

an interrupt is generated, and while the port continues operating at least partially, a system-level fix (such as reset) is recommended to clean up the controller's internal queues and resume normal operation. Fatal errors are detected in the physical layer only.

20.6.16.2 Physical Layer RapidIO Errors Detected

This table lists all the RapidIO link errors detected by the RapidIO endpoint physical layer and the actions taken by the RapidIO endpoint. The error enable column lists the control bits that may disable the error checking associated with a particular error (if blank, error checking cannot be disabled). The cause field column indicates what cause field is used with the associated packet-not-accept control symbol for input error recovery. The EME error enable/detect column indicates which bit of the P*n*ERECSR allows the error to increment the error rate counter and lock the port n error capture registers, and likewise which bit of the P*n*EDCSR is set when the error has been detected.

Table 20-9 lists the RapidIO endpoint behavior after exceeding certain preset limits.

Table 20-8. Physical RapidIO Errors Detected

Level	Error	Error Enable	RapidIO Endpoint Action	Cause Field	EME Error Type	EME Error Enable / Detect
Recoverable Errors						
1a	Received character had a disparity error.	-	Enter Input Error Stopped. Enter Output Error Stopped.	5: Received invalid/illegal character	Delineation Error	DE
1a	Received an invalid character, or valid but illegal character	-	Enter Input Error Stopped. Enter Output Error Stopped.	5: Received invalid/illegal character		
1b	The four control character bits associated with the received symbol do not make sense (not 0000, 1000, 1111)	-	Enter Input Error Stopped. Enter Output Error Stopped.	5: Received invalid/illegal character		
1b	Control symbol does not begin with an /SC/ or /PD/ control character.	-	Enter Input Error Stopped. Enter Output Error Stopped.	5: Received invalid/illegal character		
1c	Received packet with embedded idles.	-	Enter Input Error Stopped.	5: Received invalid/illegal character		

Table continues on the next page...

Table 20-8. Physical RapidIO Errors Detected (continued)

Level	Error	Error Enable	RapidIO Endpoint Action	Cause Field	EME Error Type	EME Error Enable / Detect
1d	Received a control symbol with a bad CRC	PCR[CCC]enables detect.	Enter Input Error Stopped. Enter Output Error Stopped.	2: Received a control symbol with bad CRC	Received corrupt control symbol	CCS
1d	Missing start: Packet data received w/o previous SOP control symbol	-	Enter Input Error Stopped.	7/31: General error	Protocol Error (unexpected packet/control symbol received)	PE
1e	Received packet that is < 64 bits	-	Enter Input Error Stopped.	7/31: General error		
1e	Received an EOP control symbol when there is no packet being received.	-	Enter Input Error Stopped.	7/31: General error		
1e	Received a stomp control symbol when there is no packet being received.	-	Enter Input Error Stopped.	7/31: General error		
2a	Received a Restart-from-retry control symbol when in the "OK" state	-	Enter Input Error Stopped	7/31: General error	Protocol Error (unexpected packet/control symbol received)	PE
2a	Received packet with a bad CRC value.	PCR[CCP] enables detect.	Enter Input Error Stopped.	4: bad CRC on packet.	Received packet with bad CRC	CRC
2a	Received packet which exceeds the maximum allowed size by the RapidIO spec.	-	Enter Input Error Stopped.	7/31: General error	Received packet exceeds 276 Bytes	EM
2b	Received packet with unexpected ackID value (out-of-sequence ACKID)	-	Enter Input Error Stopped.	1: Received unexpected ACKID on packet	Received packet with unexpected ackID	UA
2c	Received a non-maintenance packet when non-maintenance packet reception is stopped	Non-maint. packet reception is stopped when 'Input Port Enable' = 0.	Enter Input Error Stopped.	3: Non-maintenance packet reception is stopped	Not Captured	-
2d	Any packet received while Port Lockout bit is set	All packet reception is stopped when Port Lockout bit is set.	Enter Input Error Stopped.	3: Non-maintenance packet reception is stopped	Not Captured	-

Table continues on the next page...

Table 20-8. Physical RapidIO Errors Detected (continued)

Level	Error	Error Enable	RapidIO Endpoint Action	Cause Field	EME Error Type	EME Error Enable / Detect
-	Received a Link request control symbol before servicing previous link request.	Not detected.				
2a	Received packet-not-accepted ACK control symbol.	-	Enter Output Error Stopped.	-	Received packet-not-accepted symbol	PNA
2b	Received an ACK (accepted, or retry) control symbol when there are no outstanding packets	-	Enter Output Error Stopped.	-	Unsolicited ACK symbol	UCS
2b	Received packet ACK (accepted) for a packet whose transmission has not finished	-	Enter Output Error Stopped.	-		
2b	Received a Link response control symbol when no outstanding request.	-	Enter Output Error Stopped.	-		
2c	Received an ACK (accepted or retry) control symbol with an unexpected ACKID.	-	Enter Output Error Stopped.	-	Received ack. control symbol with unexpected ackID	AUA
2c	Link_response received with an ackID that is not outstanding	-	Re-enter Output Error Stopped.	-	Non-outstanding ackID	NOA
2d	An ACK control symbol is not received within the specified time-out interval.	PLTOCCSR[TV] > 0 enables detect.	Enter Output Error Stopped.	-	Link time-out	LTO
2d	A Link response is not received within the specified time-out interval	PLTOCCSR[TV] > 0 enables detect.	(re-) Enter Output Error Stopped.	-		

This table lists the RapidIO endpoint behavior after exceeding certain preset limits (degraded threshold, failed threshold, retry threshold).

Table 20-9. Physical RapidIO Threshold Response

Error	Error Enable	RapidIO Endpoint Action	EME Error Type	Error Detect	Interrupt clear[1]
Notification Errors					
Error Rate Counter has met or exceeded the Degraded Threshold.	ERTCSR[ERDTT] > 0 & any bit in EECSR enables detect and interrupt generation.	Generate Interrupt. Continue to operate normally.	Degraded Threshold	ESCSR[ODE]	Write 1 to ESCSR[ODE]

Table continues on the next page...

Table 20-9. Physical RapidIO Threshold Response (continued)

Error	Error Enable	RapidIO Endpoint Action	EME Error Type	Error Detect	Interrupt clear[1]
Fatal Errors					
Consecutive Retry Counter has met or exceeded the Retry Counter Threshold Trigger	PRETCR[RET] > 0 enables detect and interrupt generation	Generate Interrupt. Port is in priority order.	Consecutive Retry Threshold	IECSR[RETE]	Write 1 to IECSR[RETE]
Error Rate Counter has met or exceeded the Failed Threshold.	ERTCSR[ERFTT] > 0 & any bit in EECSR enables detect and interrupt generation.	Generate Interrupt. Port behavior depends on CCSR[SPF] and CCSR[DPE] -- port can continue transmitting packets or can stop sending output packets, keeping or dropping them.	Failed Threshold	ESCSR[OFE]	Write 1 to ESCSR[OFE].

1. Information given here is minimal for clearing the interrupt. More detailed steps should be taken to find the cause of the interrupt.

20.6.16.3 Logical Layer Errors and Error Handling

This section describes how the logical layer detects and reacts to RapidIO errors. The action of the core on notification of any of these errors is described minimally here. Reference *RapidIO Interconnect Specification, Revision 1.2* Part VII (Error Management Extensions Specifications). Further details of message related errors are detailed in the RMan error management section for each each type.

20.6.16.3.1 Logical Layer RapidIO Errors Detected

The following tables list all the errors detected by the RapidIO endpoint logical layer and the actions taken by the RapidIO endpoint. Note that when the RapidIO endpoint action includes sending an error response to either the internal platform or RapidIO, an error response is only sent if the original transaction was a request that required a response. Otherwise, no error response is sent. When dealing with multiple errors, discard of packet has higher priority than error response.

For misaligned transactions, the error management extension registers are updated with each child.

All packet field positions are assumed to be in the mode (small or large transport) configured. For example, when configured for small transport mode with pass-through mode not enabled and a large transport mode NREAD packet is received, the transaction type field bit positions checked correspond to a small transport type NREAD packet.

Table 20-10. Hardware Errors For NRead Transaction

Error	Interrupt Generated	Status Bit Set	RapidIO Error Response Generated	Logical/Transport Layer Capture Register	Comments
Priority Priority of Read transaction is 3	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	Using the incoming RapidIO packet, for Small Transport type packet, LTLACCSR[XA] gets packet bits 78-79, LTLACCSR[A] gets packet bits 48-76, LTLDIDCCSR[DIDMSB] gets 0's, LTLDIDCCSR[DID] gets packet bits 16-23, LTLDIDCCSR[SIDMSB] gets 0's, LTLDIDCCSR[SID] gets packet bits 24-31, LTLCCCSR[FT] gets packet bits 12-15, LTLCCCSR[TT] gets packet bits 32-35, LTLCCCSR[MI] gets 0's For Large Transport type packets r. LTLACCSR[XA] gets packet bits 94-95, LTLACCSR[A] gets packet bits 64-92, LTLTLTLDIDCCSR[DIDMSB] gets 16-23, LTLDIDCCSR[DID] LTL gets packet bits 24-31, LTLDIDCCSR[SIDMSB] gets bits 32-39, LTLDIDCCSR[SID] gets bits 40-47, LTLCCCSR[FT] gets packet bits 12-15, LTLCCCSR[TT] gets packet bits 48-51, LTLCCCSR[MI] gets 0's	RapidIO packet is dropped.
Critical Request Flow Not Checked for error.	-	-	-	-	-
TransportType Received reserved TT	Yes if LTLEECSR[TSE] is set	LTLEDCSR[TSE]	No	Same as first entry	RapidIO packet is dropped

Table continues on the next page...

Table 20-10. Hardware Errors For NRead Transaction (continued)

Error	Interrupt Generated	Status Bit Set	RapidIO Error Response Generated	Logical/Transport Layer Capture Register	Comments
Received TT which is not enabled. - Error valid when pass_through is disabled and accept_all is disabled Or when accept_all is enabled.	Yes if LTLEECSR[TSE] is set	LTLEDCSR[TSE]	No	Same as first entry	RapidIO packet is dropped
DestID DestID does not match this port's DeviceID if Alternate DeviceID is disabled or DestId does not match either Alternate DeviceID or DeviceId if Alternate DeviceID is enabled. Error valid when (pass_through or accept_all) is false	Yes if LTLEECSR[ITTE] is set	LTLEDCSR[ITTE]	Yes	Same as first entry	Internal platform error response is generated to self
SourceID Not Checked for error.	-	-	-	-	-
TransactionType Received RapidIO packet with reserved TType for this ftype	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	Yes	Same as first entry	Internal platform error response is generated to self
RdSize Not Checked for error.	-	-	-	-	-
SrcTID Not Checked for error.	-	-	-	-	-
Address:WdPtr:Xambs Read request hits overlapping ATMU windows Refer to Window Boundary Crossing Errors-Inbound	Yes if LTLEECSR[IACB] is set	LTLEDCSR[IACB]	Yes	Same as first entry	Internal platform error response is generated to self
Address:WdPtr:Xambs Request hits a protected ATMU window	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	Yes	Same as first entry	Internal platform error response is generated to self
Address:WdPtr:Xambs Beginning address matches LCSBA1CSR with non 32 bit read request. Performed only when ttype == 4'b0100	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	Yes	Same as first entry	Internal platform error response is generated to self
Header Size	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	Yes	Same as first entry	Internal platform error

Table continues on the next page...

Table 20-10. Hardware Errors For NRead Transaction (continued)

Error	Interrupt Generated	Status Bit Set	RapidIO Error Response Generated	Logical/Transport Layer Capture Register	Comments
Header size is not 12 Bytes for small Transport packet or not 16 Bytes for Large Transport packet. Large Transport packet has 14 valid bytes and two bytes of padding of 0's. Padding of 0's is not checked.					response is generated to self
PayloadSize Not Applicable	-	-	-	-	-
LIODN: Lookup table miss	Yes if LTLEECSR[ILE] is set	LTLEDCSR[ILE]	Yes	Same as first entry	Internal platform error response is generated to self

Header Size Not unsupported Header size is not 12 Bytes for small Transport packet and not 16 Bytes for Large Transport packet Padding of 0's in last two bytes of Large Transport packet is not checked	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	Yes	Same as first entry	Error response is generated to self
LIODN: Lookup table miss	Yes if LTLEECSR[ILE] is set	LTLEDCSR[ILE]	Yes	Same as first entry	Internal platform error response is generated to self

Table 20-13. Hardware Errors For NWrite, NWrite_r, and Unsupported Atomic Test-and-Swap Transactions

Error	Interrupt Generated	Status Bit Set	RapidIO Error Response Generated	Logical/Transport Layer Capture Register	Comments
Priority Transaction priority is 3	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	Using the incoming RapidIO packet, for Small Transport type packets, LTLACCSR[XA] gets packet bits 78-79, LTLACCSR[A] gets packet bits 48-76, LTLDIDCCSR[DIDMSB] gets 0's, LTLDIDCCSR[DID] gets packet bits 16-23, LTLDIDCCSR[SIDMSB] gets 0's, LTLDIDCCSR[SID] gets packet bits 24-31, LTLCCCSR[FT] gets packet bits 12-15, LTLCCCSR[TT] gets packet bits 32-35, LTLCCCSR[MI] gets 0's For Large Transport type packets. LTLACCSR[XA] gets packet bits 94-95, LTLACCSR[A] gets packet bits 64-92, LTLTLTLDIDCCSR[DIDMSB]	RapidIO packet is dropped.

Table continues on the next page...

Table 20-13. Hardware Errors For NWrite, NWrite_r, and Unsupported Atomic Test-and-Swap Transactions (continued)

Error	Interrupt Generated	Status Bit Set	RapidIO Error Response Generated	Logical/Transport Layer Capture Register	Comments
				gets 16-23, LTLDIDCCSR[DID] gets packet bits 24-31,LTLDIDCCSR[SIDMSB] gets bits 32-39, LTLDIDCCSR[SID] gets bits 40-47, LTLCCCSR[FT] gets packet bits 12-15, LTLCCCSR[TT] gets packet bits 48-51, LTLCCCSR[MI] gets 0's	
Critical Request Flow Not Checked for error.	-	-	-	-	-
TransportType Received reserved TT	Yes	LTLEDCSR[TSE]	No	Same as first entry	RapidIO packet is dropped
Received TT which is not enabled. - Error valid when passthrough is disabled and accept_all is disabled Or when accept_all is enabled.	Yes if LTLEECSR[TSE] is set	LTLEDCSR[TSE]	No	Same as first entry	RapidIO packet is dropped
DestID DestID does not match this port's DeviceID if Alternate DeviceID is disabled or DestId does not match either Alternate DeviceID or DeviceId if Alternate DeviceID is enabled. Error valid when (passthrough or accept_all) is false	Yes if LTLEECSR[ITTE] is set	LTLEDCSR[ITTE]	Yes for Nwrite_r. No for Nwrite.	Same as first entry	Internal platform error response is generated to self for Nwrite_r. RapidIO packet is dropped for Nwrite
SourceID Not applicable	-	-	-	-	-
TransactionType Received RapidIO packet for Atomic test-and-swap transaction	Yes if LTLEECSR[UT] is set	LTLEDCSR[UT]	Yes	Same as first entry	Internal platform error response is generated to self
TransactionType Received RapidIO packet with reserved TType for this ftype Packet is treated as Nwrite Transaction	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	Same as first entry	RapidIO packet is dropped

Table continues on the next page...

Table 20-13. Hardware Errors For NWrite, NWrite_r, and Unsupported Atomic Test-and-Swap Transactions (continued)

Error	Interrupt Generated	Status Bit Set	RapidIO Error Response Generated	Logical/Transport Layer Capture Register	Comments
WrSize Not unsupported transaction WrSize request is for one of reserved sizes	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	Yes for Nwrite_r. No for Nwrite.	Same as first entry	Internal platform error response is generated to self for Nwrite_r. RapidIO packet is dropped for Nwrite
Address:WdPtr:Xambs Not unsupported transaction Nwrite request hits LCSBA1CSR	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No for Nwrite.	Same as first entry	RapidIO packet is dropped for Nwrite
Address:WdPtr:Xambs Not unsupported transaction Request hits a protected ATMU window	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	Yes for Nwrite_r. No for Nwrite.	Same as first entry	Internal platform error response is generated to self for Nwrite_r. RapidIO packet is dropped for Nwrite
Address:WdPtr:Xambs Write request hits overlapping ATMU windows Refer to Window Boundary Crossing Errors-Outbound	Yes if LTLEECSR[IACB] is set	LTLEDCSR[IACB]	Yes for Nwrite_r. No for Nwrite.	Same as first entry	Internal platform error response is generated to self for Nwrite_r. RapidIO packet is dropped for Nwrite
SrcTID Not Checked for error.	-	-	-	-	-
Address:WdPtr:Xambs Nwrite_r address matches LCSBA1CSR with non 32 bit read request. Performed only for Nwrite_r packet	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	Yes for Nwrite_r.	Same as first entry	Internal platform error response is generated to self

Table continues on the next page...

Table 20-13. Hardware Errors For NWrite, NWrite_r, and Unsupported Atomic Test-and-Swap Transactions (continued)

Error	Interrupt Generated	Status Bit Set	RapidIO Error Response Generated	Logical/Transport Layer Capture Register	Comments
Header Size Not unsupported transaction Header size is less than 12 bytes for small Transport packet or less than 16 bytes for Large Transport packet - that is, no payload present. Large Transport packet has 14 valid bytes and 2 bytes of padding of 0s. Padding of 0s is not checked.	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	Yes for Nwrite_r. No for Nwrite.	Same as first entry	Internal platform error response is generated to self for Nwrite_r. RapidIO packet is dropped for Nwrite
PayloadSize Not unsupported transaction Payload is greater than that indicated by {wdptr:wrsize} field, payload is not double word aligned or does not have any payload	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	Yes for Nwrite_r. No for Nwrite.	Same as first entry	Internal platform error response is generated to self for Nwrite_r. RapidIO packet is dropped for Nwrite
LIODN: Lookup table miss	Yes if LTLEECSR[ILE] is set	LTLEDCSR[ILE]	Yes for Nwrite_r. No for Nwrite.	Same as first entry	Internal platform error response is generated to self for Nwrite_r. RapidIO packet is dropped for Nwrite

Table 20-14. Hardware Errors For SWrite Transactions

Error	Interrupt Generated	Status Bit Set	Error Response Generated	Logical/Transport Layer Capture Register	Comments
Priority Swrite transaction priority is 3	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	Same as third entry	RapidIO packet is dropped
Critical Request Flow Not Checked for error.	-	-	-	-	-

Table continues on the next page...

Table 20-14. Hardware Errors For SWrite Transactions (continued)

Error	Interrupt Generated	Status Bit Set	Error Response Generated	Logical/Transport Layer Capture Register	Comments
TransportType Received reserved TT	Yes if LTLEECSR[TSE] is set	LTLEDCSR[TSE]	No	Using the incoming RapidIO packet, for Small Transport type packets, LTLACCSR[XA] gets packet bits 62-63, LTLACCSR[A] gets packet bits 32-60, LTLDIDCCSR[DIDMSB] gets 0's, LTLDIDCCSR[DID] gets packet bits 16-23, LTLDIDCCSR[SIDMSB] gets 0's, LTLDIDCCSR[SID] gets packet bits 24-31, LTLCCCSR[FT] gets packet bits 12-15, LTLCCCSR[TT] gets packet bits 32-35, LTLCCCSR[MI] gets 0's For Large Transport type packets. LTLACCSR[XA] gets packet bits 78-79, LTLACCSR[A] gets packet bits 48-76, LTLTLTLDIDCCSR[DIDMSB] gets 16-23, LTLDIDCCSR[DID] gets packet bits 24-31, LTLDIDCCSR[SIDMSB] gets bits 32-39, LTLDIDCCSR[SID] gets bits 40-47, LTLCCCSR[FT] gets packet bits 12-15, LTLCCCSR[TT] gets packet bits 48-51, LTLCCCSR[MI] gets 0's	RapidIO packet is dropped
Received TT which is not enabled. - Error valid when passthrough is disabled and accept_all is disabled Or when accept_all is enabled.	Yes if LTLEECSR[TSE] is set	LTLEDCSR[TSE]	No	Same as third entry	RapidIO packet is dropped
DestID DestID does not match this port's DeviceID if Alternate DeviceID is disabled or DestId does not match either Alternate DeviceID or DeviceId if Alternate DeviceID is enabled. Error valid when (passthrough or accept_all) is false	Yes if LTLEECSR[ITTE] is set	LTLEDCSR[ITTE]	No	Same as third entry	RapidIO packet is dropped
SourceID Not Checked for error.	-	-	-	-	-
Address:WdPtr:Xambs Swrite request hits overlapping ATMU windows. Refer to Window Boundary Crossing Errors-Outbound	Yes if LTLEECSR[IACB] is set	LTLEDCSR[IACB]	No	Same as third entry	RapidIO packet is dropped

Table continues on the next page...

Table 20-14. Hardware Errors For SWrite Transactions (continued)

Error	Interrupt Generated	Status Bit Set	Error Response Generated	Logical/Transport Layer Capture Register	Comments
Address:WdPtr:Xambs Request hits a protected ATMU window or the LCSBA1CSR	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	Same as third entry	RapidIO packet is dropped
PayloadSize Payload size is not in DWs, has exceeded 256 bytes or has no payload.	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	Same as third entry	RapidIO packet is dropped
LIODN: Lookup table miss	Yes if LTLEECSR[ILE] is set	LTLEDCSR[ILE]	No	Same as third entry	RapidIO packet is dropped

Table 20-15. Hardware Errors For Maintenance Response Transactions

Error	Interrupt Generated	Status Bit Set	Internal platform Error Response Generated	Logical/Transport Layer Capture Register	Comments
Priority Not UR Response priority is not higher than RapidIO maintenance request priority	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	Using the incoming RapidIO packet, for Small Transport type packets, LTLACCSR[XA] gets packet bits 78-79, LTLACCSR[A] gets packet bits 48-76, LTLDIDCCSR[DIDMSB] gets 0's, LTLDIDCCSR[DID] gets packet bits 16-23, LTLDIDCCSR[SIDMSB] gets 0's, LTLDIDCCSR[SID] gets packet bits 24-31, LTLCCCSR[FT] gets packet bits 12-15, LTLCCCSR[TT] gets packet bits 32-35, LTLCCCSR[MI] gets 0's For Large Transport type packets. LTLACCSR[XA] gets packet bits 94-95, LTLACCSR[A] gets packet bits 64-92, LTLTLTLDIDCCSR[DIDMSB] gets 16-23, LTLDIDCCSR[DID] gets packet bits 24-31, LTLDIDCCSR[SIDMSB] gets bits 32-39, LTLDIDCCSR[SID] gets bits 40-47, LTLCCCSR[FT] gets packet bits 12-15, LTLCCCSR[TT] gets packet bits 48-51, LTLCCCSR[MI] gets 0's	RapidIO packet is dropped and ignored
Critical Request Flow CRF field is set when corresponding request's CRF field was clear	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	Same as first entry	RapidIO packet is dropped and ignored.

Table continues on the next page...

Table 20-15. Hardware Errors For Maintenance Response Transactions (continued)

Error	Interrupt Generated	Status Bit Set	Internal platform Error Response Generated	Logical/Transport Layer Capture Register	Comments
TransportType Received reserved TT	Yes if LTLEECSR[TSE] is set	LTLEDCSR[TSE]	No	Same as first entry	RapidIO packet is dropped and ignored
Received TT which is not enabled. - Error valid when passthrough is disabled and accept_all is disabled Or when accept_all is enabled.	Yes if LTLEECSR[TSE] is set	LTLEDCSR[TSE]	No	Same as first entry	RapidIO packet is dropped and ignored
DestID DestID does not match this port's DeviceID if Alternate DeviceID is disabled or DestId does not match either Alternate DeviceID or DeviceId if Alternate DeviceID is enabled. Error valid when (passthrough or accept_all) is false	Yes if LTLEECSR[ITTE] is set	LTLEDCSR[ITTE]	No	Same as first entry	RapidIO packet is dropped and ignored
SourceID Does not match the request's DestID	Yes if LTLEECSR[UR] is set	LTLEDCSR[UR]	No	Same as first entry	RapidIO packet is dropped and ignored
TransactionType Not UR Received RapidIO packet with reserved TType for this ftype	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	Same as first entry	RapidIO packet is dropped and ignored
Not UR Maintenance read/write response does not correspond to an outstanding valid message read/write request.	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	Same as first entry	RapidIO packet is dropped and ignored
HopCount Not Checked for error.	-	-	-	-	-
Status Not UR Is not "Done" or "Error"	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	Same as first entry	RapidIO packet is dropped and ignored

Table continues on the next page...

Table 20-15. Hardware Errors For Maintenance Response Transactions (continued)

Error	Interrupt Generated	Status Bit Set	Internal platform Error Response Generated	Logical/Transport Layer Capture Register	Comments
Not "Done" status for "read_response" transaction type with payload					
Status Not UR Error Response with or without payload.	Yes if LTLEECSR[IER] is set	LTLEDCSR[IER]	Yes	Same as first entry except error capture is done from original request	Internal platform error response is generated to requestor.
TargetTID No outstanding transaction for this TargetTID	Yes if LTLEECSR[UR] is set	LTLEDCSR[UR]	No	Same as first entry	RapidIO packet is dropped and ignored
Header Size Not UR Maintenance Read response - total payload size with done status is not greater than 4 Bytes. Maintenance Write response - total header size is less than 12 Bytes for Small Transport packet or is less than 16 Bytes for Large Transport packet. Padding of 0's for Small or Large Transport packets is not verified.	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	Same as first entry	RapidIO packet is dropped and ignored
PayloadSize Not UR Maintenance write response has payload. Maintenance read response with done status and payload not matching valid request size, request size for the response is invalid or payload size is not dword aligned.	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	Same as first entry	RapidIO packet is dropped and ignored

Table continues on the next page...

Table 20-15. Hardware Errors For Maintenance Response Transactions (continued)

Error	Interrupt Generated	Status Bit Set	Internal platform Error Response Generated	Logical/Transport Layer Capture Register	Comments
Packet response time-out Response is not received by configured time	Yes if LTLEECSR[PRT] is set	LTLEDCSR[PRT]	Yes	Same as first entry except error capture is done from original request.	Internal platform error response is generated to requestor.

Table 20-16. Hardware Errors For IO/GSM Response Transactions (Not Maintenance)

Error	Interrupt Generated	Status Bit Set	Internal platform Error Response Generated	Logical/Transport Layer Capture Register	Comments
Priority Not UR Response priority is not higher than RapidIO request priority	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	Using the incoming RapidIO packet, for Small Transport type packets, LTLACCSR[XA] gets packet bits 78-79 (if available), LTLACCSR[A] gets packet bits 48-76 (if available), LTLDIDCCSR[DIDMSB] gets 0's, LTLDIDCCSR[DID] gets packet bits 16-23, LTLDIDCCSR[SIDMSB] gets 0's, LTLDIDCCSR[SID] gets packet bits 24-31, LTLCCCSR[FT] gets packet bits 12-15, LTLCCCSR[TT] gets packet bits 32-35, LTLCCCSR[MI] gets 0's For Large Transport type packets. LTLACCSR[XA] gets packet bits 94-95 (if available), LTLACCSR[A] gets packet bits 64-92 (if available), LTLTLTLDIDCCSR[DIDMSB] gets 16-23, LTLDIDCCSR[DID] gets packet bits 24-31, LTLDIDCCSR[SIDMSB] gets bits 32-39, LTLDIDCCSR[SID] gets bits 40-47, LTLCCCSR[FT] gets packet bits 12-15, LTLCCCSR[TT] gets packet bits 48-51, LTLCCCSR[MI] gets 0's	RapidIO packet is dropped and ignored
Critical Request Flow CRF field is set when corresponding request's CRF field was clear	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	Same as first entry	RapidIO packet is dropped and ignored.

Table continues on the next page...

Table 20-16. Hardware Errors For IO/GSM Response Transactions (Not Maintenance) (continued)

Error	Interrupt Generated	Status Bit Set	Internal platform Error Response Generated	Logical/Transport Layer Capture Register	Comments
TransportType Received reserved TT for this ftype	Yes if LTLEECSR[TSE] is set	LTLEDCSR[TSE]	No	Same as first entry	RapidIO packet is dropped and ignored
Received TT which is not enabled. - Error valid when passthrough is disabled and accept_all is disabled Or when accept_all is enabled.	Yes if LTLEECSR[TSE] is set	LTLEDCSR[TSE]	No	Same as first entry	RapidIO packet is dropped and ignored
DestID DestID does not match this port's DeviceID if Alternate DeviceID is disabled or DestId does not match either Alternate DeviceID or DeviceId if Alternate DeviceID is enabled. Error valid when (passthrough or accept_all) is false	Yes if LTLEECSR[ITTE] is set	LTLEDCSR[ITTE]	No	Same as first entry	RapidIO packet is dropped and ignored
SourceID Does not match the request's DestID	Yes if LTLEECSR[UR] is set	LTLEDCSR[UR]	No	Same as first entry	RapidIO packet is dropped and ignored
TransactionType Not UR Received RapidIO packet with reserved TType	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	Same as first entry	RapidIO packet is dropped and ignored
Not UR IO read response does not correspond to an outstanding valid IO/GSM read request. IO write response does not correspond to an outstanding valid IO/GSM write request.	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	Same as first entry	RapidIO packet is dropped and ignored
Status Not UR IO transaction - Is not "Done" or "Error" GSM transaction IO_Read_Home	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	Same as first entry	RapidIO packet is dropped and ignored.

Table continues on the next page...

Table 20-16. Hardware Errors For IO/GSM Response Transactions (Not Maintenance) (continued)

Error	Interrupt Generated	Status Bit Set	Internal platform Error Response Generated	Logical/Transport Layer Capture Register	Comments
Is not "Done - Data-Only", "Done - Done-Intervention", "Done", "Retry" or "Error". Flush_w_Data response is not "Done", "Retry" or "Error" Transaction type of "Response_with_data" and status is not done					
Status Not UR GSM Error response	Yes if LTLEECSR[GER] is set	LTLEDCSR[GER]	Yes if data is not received for this request.	Same as first entry except error capture is done from original request packet.	Internal platform error response is generated to requestor if data is not forwarded to it. Else the RapidIO packet is dropped.
Status Not UR IO Error Response	Yes if LTLEECSR[IER] is set	LTLEDCSR[IER]	Yes	Same as first entry except error capture is done from original request packet.	Internal platform error response is generated to requestor.
TargetTID No outstanding transaction for this TargetTID	Yes if LTLEECSR[UR] is set	LTLEDCSR[UR]	No	Same as first entry	RapidIO packet is dropped and ignored.
Packet Size Not UR (All non-maintenance and non-message) Write response - Header size is not 8 Bytes for Small Transport packet or not 12 Bytes for Large Transport packet	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	Same as first entry	RapidIO packet is dropped and ignored.

Table continues on the next page...

Table 20-16. Hardware Errors For IO/GSM Response Transactions (Not Maintenance) (continued)

Error	Interrupt Generated	Status Bit Set	Internal platform Error Response Generated	Logical/Transport Layer Capture Register	Comments
GSM - "Done" response packet size to "Flush" is not 8 Bytes for Small Transport packet or not 12 Bytes for Large Transport packet. "Done-Intervention" is not 8 Bytes for Small Transport and 12 Bytes for Large Transport field. Two byte padding of 0's in Large Transport field packet is not checked.					
Payload Size Not UR IO - Read Response - total payload is not of the size requested. "Done" or "Done-Data_Only" response to IO_Read_Home with incorrect payload size. Response with transaction type "response_with_no_data" has payload	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	Same as first entry	RapidIO packet is dropped and ignored.
Retry Not UR GSM request has had one more than configured number of retries for non misaligned request. The misaligned GSM request has had one to four (cumulative for the corresponding child requests) more than configured number of retries.	Yes if LTLEECSR[RETE] is set	LTLEDCSR[RETE]	Yes	Same as first entry except error capture is done from original request.	Internal platform error response is generated to requestor.
Packet response time-out Response is not received by configured time for packets requiring RapidIO response. "GSM - IO_Read_Home" - Done_With_Data is not received in configured time	Yes if LTLEECSR[PRT] is set	LTLEDCSR[PRT]	Yes	Same as first entry except error capture is done from original request.	Internal platform error response is generated to requestor.

Table continues on the next page...

Table 20-16. Hardware Errors For IO/GSM Response Transactions (Not Maintenance) (continued)

Error	Interrupt Generated	Status Bit Set	Internal platform Error Response Generated	Logical/Transport Layer Capture Register	Comments
when Done_Intervention is received for non misaligned request or last child of misaligned request. Done response is not received in configured time for non misaligned request or last child of misaligned request. EME capture occurs for each child packet response time-out.					
Packet response time-out Response is not received by configured time for packets requiring RapidIO response. "GSM - IO_Read_Home" - Done_Intervention is not received in configured time when Done_With_Data is received. This is true for both non misaligned or misaligned requests.	Yes if LTLEECSR[PRT] is set	LTLEDCSR[PRT]	No	Same as first entry except error capture is done from original request.	An Internal platform done response is generated when the Done_With_Data is received for non misaligned requests or the last child of a misaligned request. Therefore, an error response cannot be sent when the packet response time-out occurs.
GSM - IO_Read_Home Not UR Done response, Retry response, or Error response is after Done_Intervention response or Data_only is received.	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	Same as first entry	RapidIO packet is dropped and ignored.

Table continues on the next page...

Table 20-16. Hardware Errors For IO/GSM Response Transactions (Not Maintenance) (continued)

Error	Interrupt Generated	Status Bit Set	Internal platform Error Response Generated	Logical/Transport Layer Capture Register	Comments
Not UR Response for Internal platform packets not requiring response, but converted to "response" type packet by ATMU receives Error response. For example, NWrite converted to NWrite_r received "Error" response	Yes if LTLEECSR[IER]/ [GER]/ [RETE] is set	LTLEDCSR[IER]/ [GER]/ [RETE]	No	Same as first entry except error capture is done from original request.	RapidIO packet is dropped and ignored.
Response for Internal platform packets not requiring response, but converted to "response" type packet by ATMU is not received by configured time.	Yes if LTLEECSR[PRT] is set	LTLEDCSR[PRT]	No	Same as first entry except error capture is done from original request.	No error response is generated.

Table 20-17. Hardware Errors For Message Request Transactions

Error	Interrupt Generated	Status Bit Set	RapidIO Error Response Generated	Logical/Transport Layer Capture Register	Comments
Critical Request Flow Not Checked for error.	-	-	-	-	-
TransportType Received reserved TT	Yes if LTLEECSR[TSE] is set	LTLEDCSR[TSE]	No	Using the original request RapidIO packet, for small Transport type, LTLACCSR[XA] gets packet bits 78-79, LTLACCSR[A] gets packet bits 48-76, LTLDIDCCSR[DIDMSB] gets 0's, LTLDIDCCSR[DID] gets packet bits 16-23,LTLDIDCCSR[SIDMSB] gets 0's, LTLDIDCCSR[SID] gets packet bits 24-31, LTLCCCSR[FT] gets packet bits 12-15, LTLCCCSR[TT] gets packet bits 32-35, LTLCCCSR[MI] gets packet bits 40-47. For Large Transport type packets. LTLACCSR[XA] gets packet bits 94-95, LTLACCSR[A] gets packet bits 64-92, LTLTLTLDIDCCSR[DIDMSB] gets 16-23, LTLDIDCCSR[DID] LTL gets packet bits 24-31, LTLDIDCCSR[SIDMSB] gets bits 32-39, LTLDIDCCSR[SID] gets bits 40-47, LTLCCCSR[FT] gets packet bits 12-15, LTLCCCSR[TT] gets packet bits 48-51, LTLCCCSR[MI] gets packet bits 56-63.	RapidIO packet is dropped

Table continues on the next page...

Table 20-17. Hardware Errors For Message Request Transactions (continued)

Error	Interrupt Generated	Status Bit Set	RapidIO Error Response Generated	Logical/Transport Layer Capture Register	Comments
Received TT which is not enabled. - Error valid when passthrough is disabled and accept_all is disabled Or when accept_all is enabled.	Yes if LTLEECSR[TSE] is set	LTLEDCSR[TSE]	No	Same as third entry	RapidIO packet is dropped
DestID DestID does not match this port's DeviceID if Alternate DeviceID is disabled or DestId does not match either Alternate DeviceID or DeviceId if Alternate DeviceID is enabled. Error valid when (passthrough or accept_all) is false	Yes if LTLEECSR[ITTE] is set	LTLEDCSR[ITTE]	Yes if priority is not 3. Else packet is dropped	Same as third entry	Internal platform error response is sent to self if request priority is not 3. Else packet is dropped.
SourceID Not Checked for error.	-	-	-	-	-
MsgLen,Ssize,Ltr,Mbox, MsgSeg Not Checked for error.	-	-	-	-	-
Other Received Message request with SOCAR[M] disabled. Not Checked for error.	-	-	-	-	-

Refer to Window Boundary Crossing Errors-Outbound Packet checked as non Swrite packet					
Address:WdPtr:Xambs Not unsupported transaction Request hits a protected ATMU window or the LCSBA1CSR Packet checked as non Swrite packet	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	Same as first entry	RapidIO packet is dropped

Table 20-24. Hardware Errors for Outbound Transaction Crossed ATMU Boundary

Error	Interrupt Generated	Status Bit Set if corresponding bit is enabled		Logical/Transport Layer Capture Register	Comments
Internal platform Address and payload size Internal platform address range for Outbound RapidIO transaction hits multiple ATMU windows. Refer to Window Boundary Crossing Errors-Outbound	Yes if LTLEECSR[OACB] is set and/or LTLEECSR[PRT] is set	LTLEDCSR[OACB], LTLEDCSR[PRT]		Using the original request RapidIO packet send out by OB, for small Transport type, LTLACCSR[XA] gets packet bits 78-79, LTLACCSR[A] gets packet bits 48-76, LTLDIDCCSR[DIDMSB] gets 0's, LTLDIDCCSR[DID] gets packet bits 16-23, LTLDIDCCSR[SIDMSB] gets 0's, LTLDIDCCSR[SID] gets packet bits 24-31, LTLCCCSR[FT] gets packet bits 12-15, LTLCCCSR[TT] gets packet bits 32-35, LTLCCCSR[MI] gets 0's For Large Transport type packets, LTLACCSR[XA] gets packet bits 94-95, LTLACCSR[A] gets packet bits 64-92, LTLTLTLDIDCCSR[DIDMSB] gets 16-23, LTLDIDCCSR[DID] LTL gets packet bits 24-31, LTLDIDCCSR[SIDMSB] gets bits 32-39, LTLDIDCCSR[SID] gets bits 40-47, LTLCCCSR[FT] gets packet bits 12-15, LTLCCCSR[TT] gets packet bits 48-51, LTLCCCSR[MI] gets 0's	-

Table 20-25. Hardware Errors for Outbound Packet Time-to-live Errors

Error	Interrupt Generated	Status Bit Set if corresponding bit is enabled		Logical/Transport Layer Capture Register	Comments
Packet time-to-live error	Yes if LTLEECSR[PTTL] is set	LTLEDCSR[PTTL]		Using the RapidIO packet attempted to send outbound, if configured in small transport mode, LTLACCSR[XA] gets packet bits 78-79, LTLACCSR[A] gets packet bits 48-76,LTLDIDCCSR[DIDMSB] gets 0's, LTLDIDCCSR[DID] gets packet bits 16-23, LTLDIDCCSR[SIDMSB] gets 0's, LTLDIDCCSR[SID] gets packet bits 24-31, LTLCCCSR[FT] gets packet bits 12-15, LTLCCCSR[TT] gets packet bits 32-35, LTLCCCSR[MI] gets 0's For large transport mode, LTLACCSR[XA] gets packet bits 94-95, LTLACCSR[A] gets packet bits 64-92, LTLTLTLDIDCCSR[DIDMSB] gets 16-23, LTLDIDCCSR[DID] LTL gets packet bits 24-31, LTLDIDCCSR[SIDMSB] gets bits 32-39, LTLDIDCCSR[SID] gets bits 40-47, LTLCCCSR[FT] gets packet bits 12-15, LTLCCCSR[TT] gets packet bits 48-51, LTLCCCSR[MI] gets 0's	-

Chapter 21
Interlaken LA Controller (LAC)

21.1 LAC Introduction

The Interlaken is a narrow, high speed channelized chip-to-chip interface. To facilitate interoperablility between a data path device and a look-aside co-processor, the Interlaken Look-Aside protocol is defined for short transaction-related transfers. Although based on the Interlaken protocol, Interlaken Look-Aside is not directly compatible with Interlaken and can be considered a different operation mode.

21.1.1 LAC Overview

The Interlaken LA controller connects internal platform to Interlaken serial interface. It accepts LA command through software portals, which are system memory mapped 4KB spaces. The LA commands are then translated into the Interlaken control words and data words, which are sent on TX side to TCAM through Serdes lanes. When TCAM provides response through Interlaken serial interface, the LA control words and data words are received on RX side. The received control words and data words are then mapped to the corresponding software portal status and data register, which can be read through system memory accesses.

Internally, the design contains queues to keep track of inbound and outbound transactions. There is control logic that handles buffer management, bus protocol, transaction spawning and tag generation. In addition, there are memory blocks used to store inbound and outbound data.

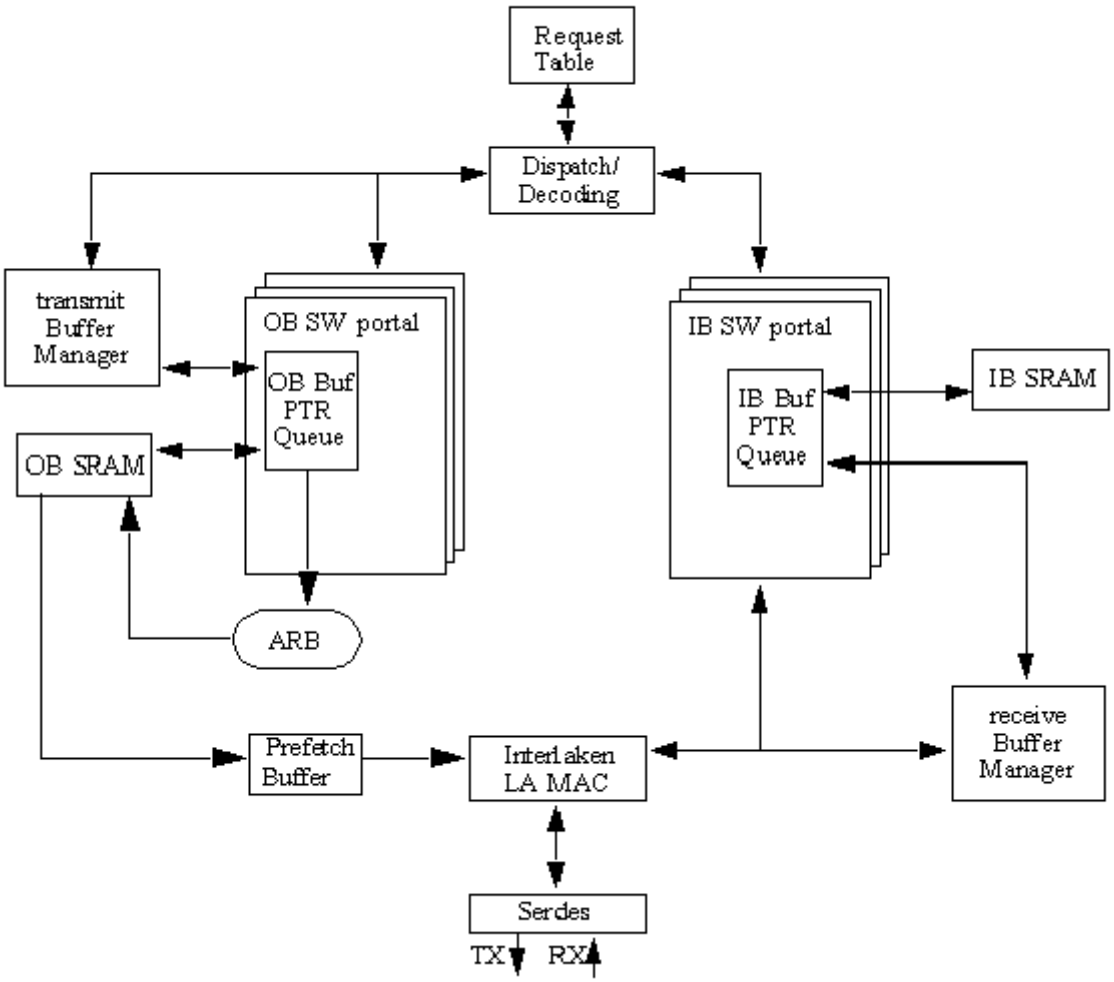

Figure 21-1. LAC Block Diagram

21.1.2 Features

The Interlaken LA controller features:

- Supports Interlaken Look-Aside Protocol definition, rev. 1.1
- Supports 24 partitioned software portals
- Supports inband per-channel flow control options, with a simple xon/xoff semantics.
- Ability to disable the connection to individual serdes lanes.
- A continuous Meta Frame of programmable frequency to guarantee lane alignment, synchronize the scrambler, perform clock compensation, and indicate lane health.
- 64B/67B data encoding and scrambling.
- Programmable BURSTSHORT parameter of 8 or 16 bytes
- Error detection illegal burst sizes, bad 64/67 word type and CRC-24 error.

- Error detection on Transmit command programming error
- Built in statistics counters and error counters.
- Dynamic powerdown of each software portal.

21.1.3 Mode of Operation

The LAC programming model is based on big endinan mode, meaning byte 0 on the most significant byte.

21.1.3.1 Stashing mode

When is LSRER[SEn] set, LAC stashes SWPnRSR value when all packet data is loaded into SWPnRDR registers. The 64 byte stashing data consists of 8 byte SWPnRSR, 8 byte 0's, and 48 most significant bytes of SWPnRDR0. This would reduce overall system traffic by avoiding most SWPnRSR going out of cores, it also reduces LAC transaction latency. When the response packet is no greater than 48 byte in size, stashing can provide additional advantage in that core can get both status and packet data through stashing.

When LSRER[SEn] is cleared, stashing mode is disabled, in which case, LAC does not stash, software has to issue dcbf each time it reads SWPnRSR and RDY bit is not set. This is to ensure software read from SWPnRSR get the updated value from LAC space instead of core caches.

21.2 External Signal Descriptions

Interlaken protocol defines a lane as a simplex serial link between two ICs. The protocol is designed to operate with any number of lanes, including only one, with no inherent maximum. Each lane consists of a differential pair for transmitting (TX and TXn) and a differential pair for receiving (RX and RXn) with an embedded data clock.

Table 21-1. Interlaken LA Interface Signals-Detailed Signal Descriptions (continued)

Signal	I/O	Description	
SD*n*_RX[7:0]	I	Receive data. The receive data signals carry Interlaken LA packet information.	
		State Meaning	Asserted/Negated-Represents data being received from the Interlaken interface.
		Timing	Assertion/Negation-
SD*n*_RX[7:0]_B	I	Receive data, inverted. SD*n*_RX[7:0]_Bare the inverted forms of the receive data signals SD*n*_RX[7:0].	
		State Meaning	Asserted/Negated-Represents the inverse of data being received from the Interlaken interface

Table continues on the next page...

Table 21-1. Interlaken LA Interface Signals-Detailed Signal Descriptions (continued) (continued)

Signal	I/O	Description	
		Timing	Assertion/Negation-
SDn_TX[7:0]	O	Transmit data. The transmit data signals carry Interlaken LA packet information.	
		State Meaning	Asserted/Negated-Represents data being transmitted to the Interlaken interface.
		Timing	Assertion/Negation-
SD*n*_TX[7:0]_B	O	Transmit data, inverted. SD*n*_TX[7:0]_Bare the inverted forms of the receive data signals SD*n*_TX[7:0].	
		State Meaning	Asserted/Negated-Represents the inverse of data being transmitted to the Interlaken interface.
		Timing	Assertion/Negation-

21.3 LAC Memory Map/Register Definition

This section provides a detailed description of all accessible LAC memory and registers.

Note that the full register address is comprised of the programmable CCSRBAR together with the fixed LAC block base address and the offset. In these tables and in the register figures and field descriptions, the following access definitions apply:

- Reserved fields are always ignored for the purposes of determining access type
- R/W, R, and W(read/write, read only, and write only) indicate that all the non-reserved fields in a register have the same access type.
- w1c indicates that all of the non-reserved fields in a register are cleared by writing ones to them.

There are two 4KB space in the global register memory map, hypervisor space 0x0000-0x0FFF, and managing core space 0x1000-0x1FFF. With the exception of hypervisor exclusive resgiters, LSRER, LBARE, LBAR, LLIODNRn, all other registers are accessible through both hypervisor space and managing core space. The offsets to hypervisor exclusive registers are treated as reserved space in managing core space. This is to be in compliant with trusted architecture so that access to any resgiter setting up address window or LIODN is restricted to hypervisor space only while still leave all the other registers that may be necessary to managing core to setup LAC.

LAC memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
22_8000	LAC mode register (LAC_LMR)	32	R/W	0000_0000h	21.3.1/1870

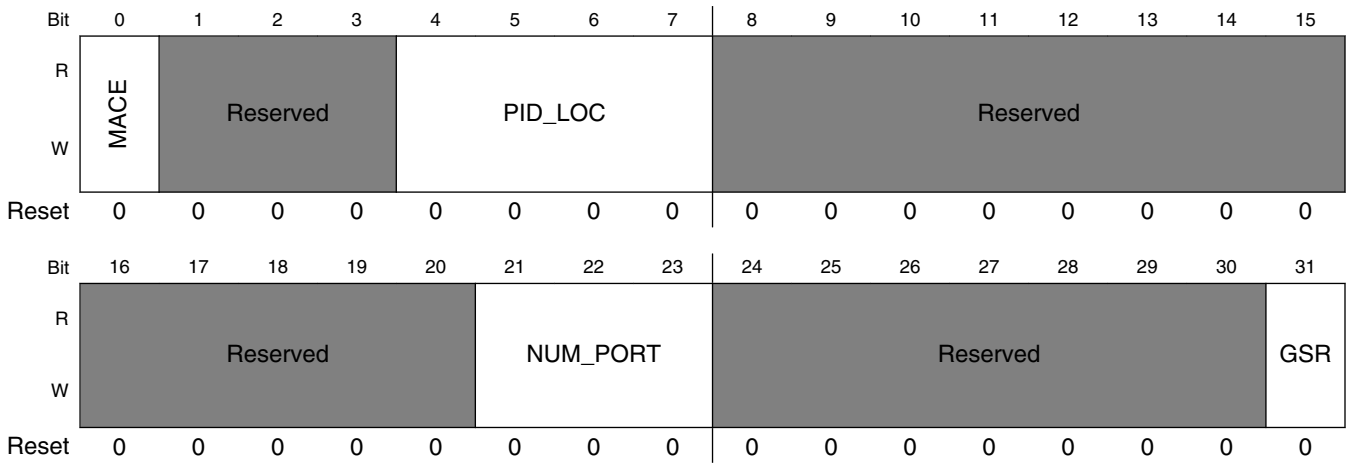
21.3.1 LAC mode register (LAC_LMR)

Address: 22_8000h base + 0h offset = 22_8000h



LAC_LMR field descriptions

Field	Description
0 MACE	Interlaken LA MAC enable. Note that all memory mapped configuration registers except LMR need to be set prior to setting MACE. 0 MAC transmit block disabled 1 MAC transmit block enabled
1–3 -	This field is reserved. Reserved
4–7 PID_LOC	Portal ID location. Indicates which bits in SWPnTCR[AppData0] and SWPnRSR[AppData0] are reserved as portal ID. all other encodings are reserved 0000 - bit 0 to 5 of AppData0 are reserved as portal ID 0001 - bit 1 to 6 of AppData0 are reserved as portal ID 0010 - bit 2 to 7 of AppData0 are reserved as portal ID 0011 - bit 3 to 8 of AppData0 are reserved as portal ID 0100 - bit 4 to 9 of AppData0 are reserved as portal ID 0101 - bit 5 to 10 of AppData0 are reserved as portal ID 0110 - bit 6 to 11 of AppData0 are reserved as portal ID 0111 - bit 7 to 12 of AppData0 are reserved as portal ID 1000 - bit 8 to 13 of AppData0 are reserved as portal ID, this encoding is reserved in LA 4-channel mode (TXCFG[NLAC]=0 and/or RXCFG[NLAC]=0) 1001 - bit 9 to 14 of AppData0 are reserved as portal ID, this encoding is reserved in LA 4-channel mode (TXCFG[NLAC]=0 and/or RXCFG[NLAC]=0)
8–20 -	This field is reserved. Reserved
21–23 NUM_PORT	Number of portals enabled Not that if one portal is not enabled, the corresponding 4K software portal space is treated as reserved space, i.e. reads return 0, writes are dropped.

Table continues on the next page...

LAC_LMR field descriptions (continued)

Field	Description
	all other encodings are reserved 000 all 24 portals are enabled 001 portal 0 is enabled 010 portal 0 to 1 are enabled 011 portal 0 to 3 are enabled 100 portal 0 to 7 are enabled 101 portal 0 to 11 are enabled 110 portal 0 to 15 are enabled
24–30 -	This field is reserved. Reserved
31 GSR	Global softreset, setting this bit clears all internal transaction queues and state machines. It also clears TX_EN and RX_EN, resetting MAC. This bit is cleared by the software when software has reset the extern device that is connected through the Interlaken links. **NOTE:** Global soft reset will not affect the SWPnTER register. After a GSR, the SWPnTER register needs to be manually cleared if errors were detected prior to the assertion of GSR.

21.3.2 LAC software portal soft reset register (LAC_LSWPSRR)

This register is used by software to softreset each individual software portal. When a SRn is set, the corresponding SWPnRSR[SR] will be set. LA controller drops all received packets to this portal, while the outstanding packet number is still being decremented for each dropped packet. LSWPSRR[SRn] is cleared by hardware when the corresponding SWPnRSR[OPC] outstanding packet counter becomes 0.

Address: 22_8000h base + 8h offset = 22_8008h

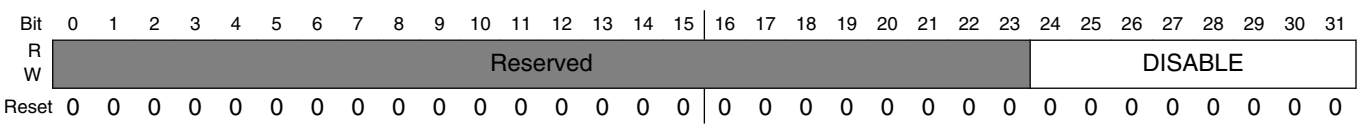
20–31 LIODN	LIODN used for LAC RSR stashing access for software portal n

21.3.7 TX lane disable register (LAC_TXLDR)

This register sets which, if any, serdes lanes are disabled. The value should be set before releasing the transmitter from reset and then remain unchanged. The DISABLE bits of this register are used to enable/disable the logic for the corresponding serdes lane. The reset value enables all available serdes lanes. This register should not be changed after initialization.

Address: 22_8000h base + 408h offset = 22_8408h



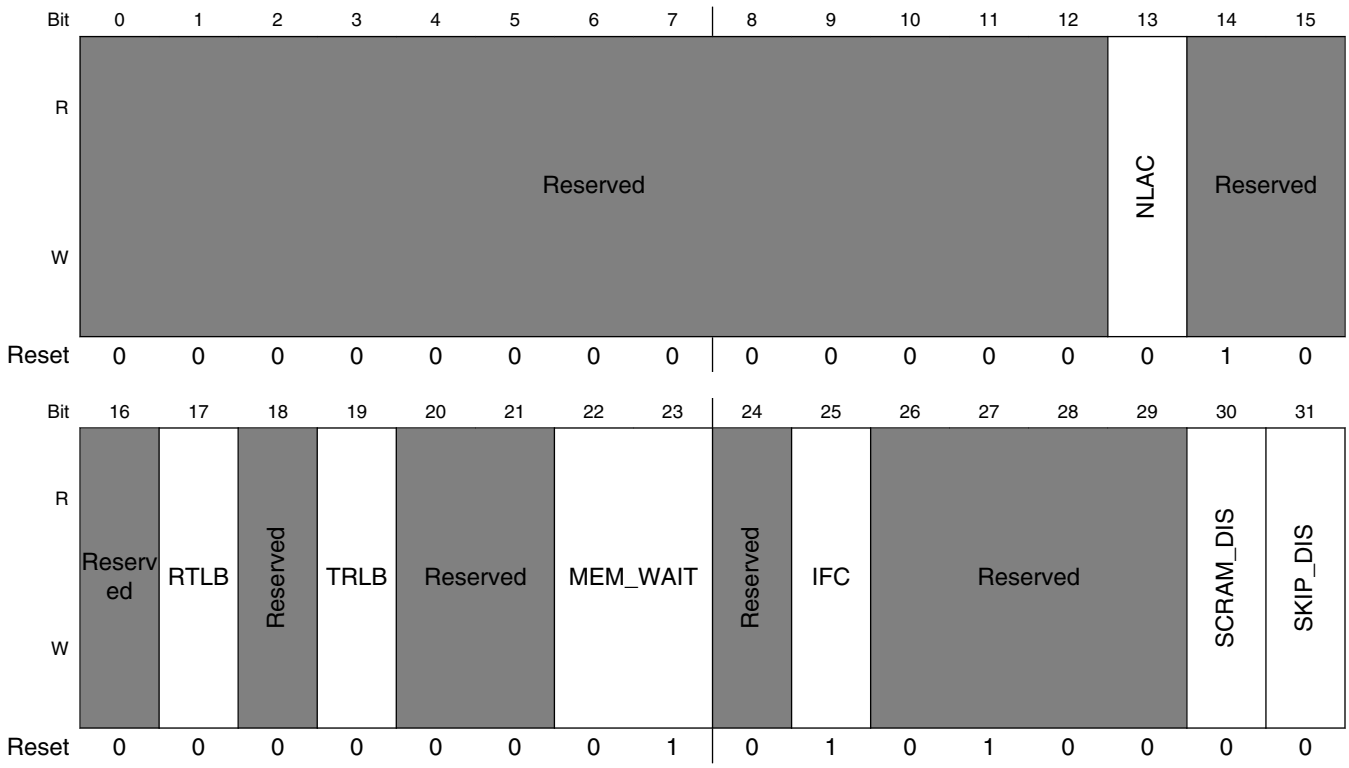
LAC_TXLDR field descriptions

Field	Description
0–23 -	This field is reserved. Reserved
24–31 DISABLE	When set to 1, the logic driving the corresponding serdes lane is disabled. When set to 0, the logic for the corresponding serdes lane is enabled, if it exists. Bit 31 controls serdes lane 0, and so on

21.3.8 TX block config register (LAC_TXCFGR)

This register configures basic functions of the transmitter. These values should be set before releasing the transmitter from reset and then remain unchanged. This register should not be changed after initialization.

Address: 22_8000h base + 410h offset = 22_8410h



LAC_TXCFGR field descriptions

Field	Description
0–12 -	This field is reserved. Reserved
13 NLAC	The number of LA channels 0 - 2 channels 1 - 4 channels
14–16 -	This field is reserved. Reserved
17 RTLB	Enable rx-to-tx loopback data path (external data loopback)
18 -	This field is reserved. Reserved

Table continues on the next page...

LAC_TXCFGR field descriptions (continued)

Field	Description
19 TRLB	Enable tx-to-rx loopback data path (internal data loopback)
20–21 -	This field is reserved. Reserved
22–23 MEM_WAIT	The number of wait states to assume when accessing the memory for the statistics counters. 0 = Read data on the cycle following read enable/address 1 = Read data two cycles after read eanble/address
24 -	This field is reserved. Reserved
25 IFC	This bit must be always set to one.
26–29 -	This field is reserved. Reserved
30 SCRAM_DIS	When 1, the scrambler of the 64/67 code is disabled.
31 SKIP_DIS	In the TX, when set to 1, the generation of skip words in the metaframe is disabled.

21.3.9 TX SERDES FIFO watermark register (LAC_TXSFWMR)

This register contains the watermarks interface for fifos that are used for the serdes interface in data paths and for clock domain crossing at the serdes interface and in out-of -band flow control paths. The reset values are chosen based on the characteristics of the internal logic and generally should only be changed for latency critical applications.

Using a larger value for DATA_HIGH and DATA_LOW will reduce the amount of data stored in the fifos and therefore reduce latency of the design. The DATA_HIGH value should typically be one less than the DATA_LOW value. When too large a value is used for DATA_LOW, the fifo may underflow, corrupting the serdes data. Because of the wide range of possible clock speeds and other factors, Open-Silicon does not provide any further guidance or support for setting these registers to values other than their default.

Address: 22_8000h base + 428h offset = 22_8428h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

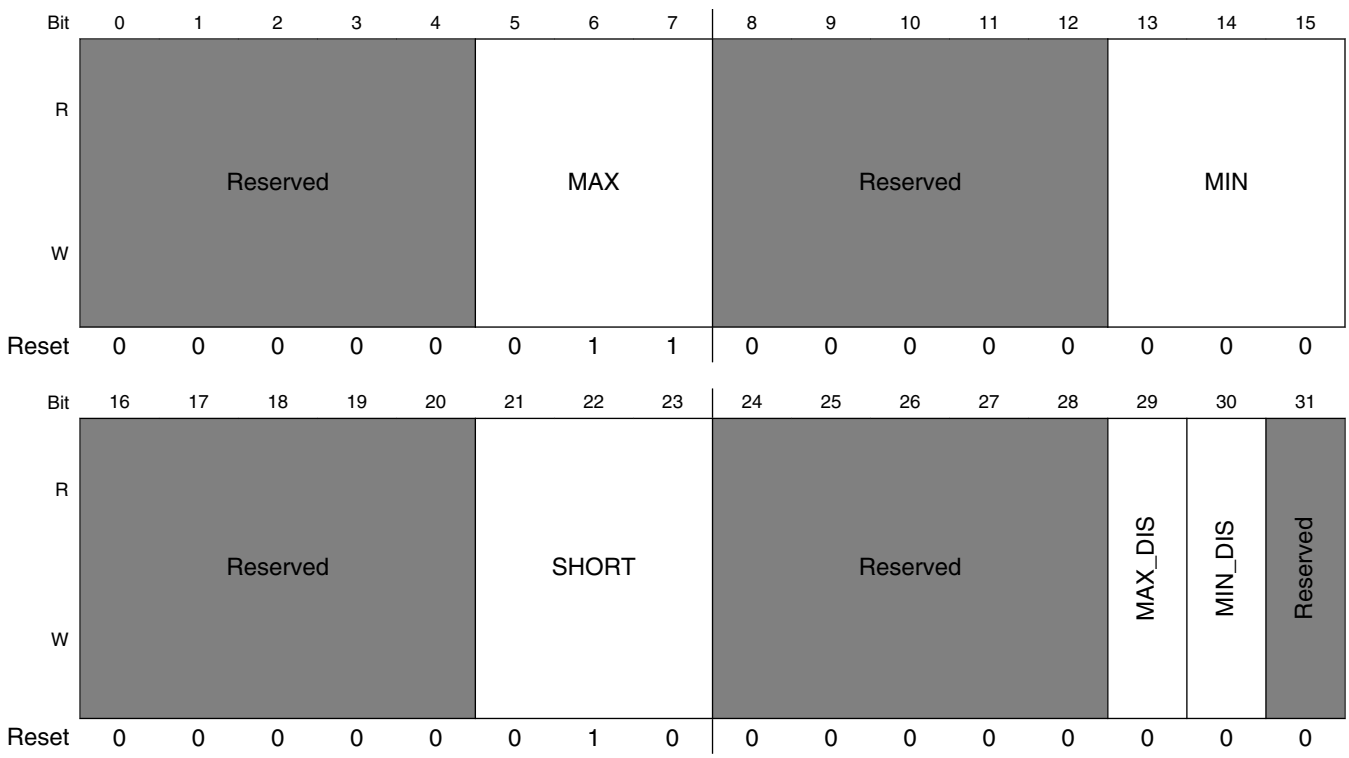
21–23 DATA_HIGH	The high watermark for the datapath's serdes interface fifo
24–28 -	This field is reserved. Reserved
29–31 DATA_LOW	The low watermark for the datapath's serdes interface fifo

21.3.10 TX Burst control register (LAC_TXBCR)

This register sets the Interlaken BURSTMAX, BURSTMIN, and BURSTSHORT parameters and enables the functions that use these parameters. This MMR should not be changed after initialization. Note : Short packets that are smaller than BURSTMIN, but are transferred entirely within one burst are not considered to fail the BurstMin check.

Address: 22_8000h base + 430h offset = 22_8430h



LAC_TXBCR field descriptions

Field	Description
0–4 -	This field is reserved. Reserved
5–7 MAX	BURSTMAX parameter. Data burst are checked on both the RX and TX to see that they are not larger than BURSTMAX. 011 = 256 bytes 111 = 512 bytes all other encodings are reserved
8–12 -	This field is reserved. Reserved
13–15 MIN	BURSTMIN parameter. Data bursts are checked on both the RX and TX to see that they are greater than or equal to BURSTMIN. Must be greater than or equal to BURSTSHORT and less than or equal to half of the BURSTMAX (in bytes). 000 = 32 bytes 100 = 160 bytes 001 = 64 bytes 101 = 192 bytes 010 = 96 bytes 110 = 224 bytes 011 = 128 bytes 111 = 256 bytes
16–20 -	This field is reserved. Reserved
21–23 SHORT	BURSTSHORT parameter. Unused in RX. TX data is padded with idles to ensure that this minimum burst size is met. To provide firmware compatibility with older designs, the field is decoded as follows: All other encodings are reserved. 000 = 32 bytes 001 = 64 bytes 010 = 16 bytes 100 = 24 bytes 111 = 8 bytes
24–28 -	This field is reserved. Reserved
29 MAX_DIS	When set to 1, checking against burstmax is disabled.
30 MIN_DIS	When set to 1, checking against burstmin is disabled
31 -	This field is reserved. Reserved

21.3.11 TX MetaFrame synchronization register (LAC_TXMSR)

This register contains the MetaFramePeriod timer used to transmit Synchronization Words. One unit of the timer corresponds to 67 bits on the serial lane (64 bits data plus 3 bits framing). The default value corresponds to an interval of 16Kbytes (not including the 3 bits framing). This register should not be changed after initialization.

Address: 22_8000h base + 434h offset = 22_8434h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Reserved																PERIOD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0

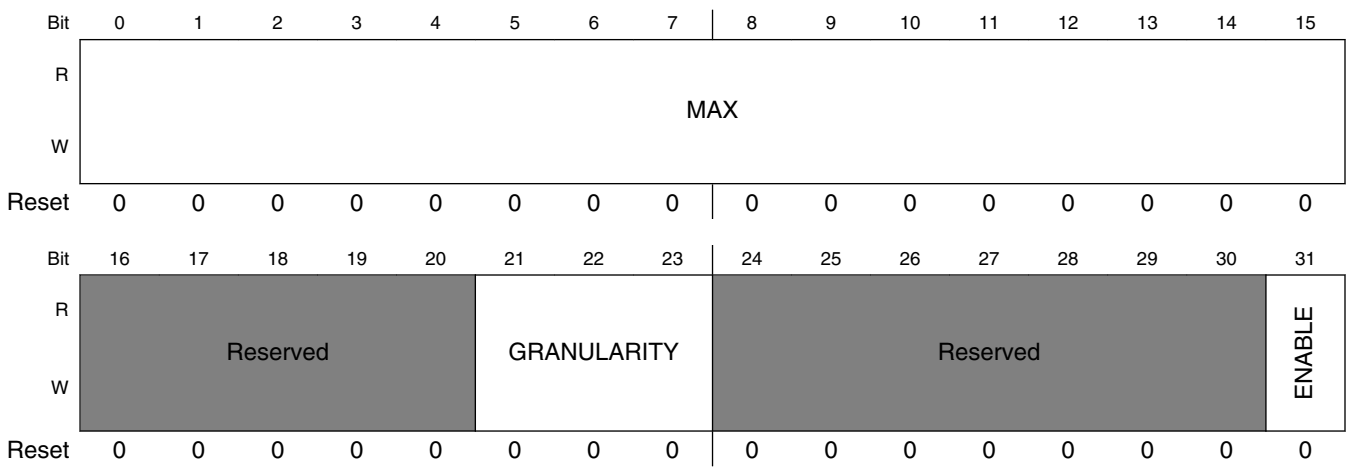
LAC_TXMSR field descriptions

Field	Description
0–15 -	This field is reserved. Reserved
16–31 PERIOD	Timer value. One unit of the timer corresponds to 67 bits on the serial lane (64 bits data plus 3 bits framing). Setting the timer to zero in the TX disables the generation of alignment frames. This value must be set the same in both the RX and TX. The minimum value is 64 (decimal).

21.3.12 TX transmit rate limiter register 0 (LAC_TXTRLR0)

The Interlaken mandatory rate matching function is implemented with a credit counter primarily controlled by four parameters. One credit corresponds to one byte. Whenever bytes are transmitted, credits get subtracted from the credit counter subject to the GRANULARITY parameter. The maximum number of credits is specified by the MAX parameter. A background timer which is set by the Transmit Rate Limit Regiser 1, counts down from the TIME parameter. Whenever the timer expires, additional credits from the TXTRLR1 [DELTA] parameter are added to the credit counter. Whenever the credit counter goes negative, packet data will not be transmitted.This register should not be changed after initialization.

Address: 22_8000h base + 438h offset = 22_8438h



LAC_TXTRLR0 field descriptions

Field	Description
0–15 MAX	The maximum number of credits allowed for the rate matching function. One credit equals one byte. This is similar to the BurstLimit Parameter described in the Interlaken Protocol Definition Specification. The difference between this field and BURSTLIMIT is the number of bytes that the user may send before i_tx_eob (BURSTMAX) plus an additional 96 bytes of reaction time. Once our rate matching logic decides that it is time to shut off, the transmitter needs to continue to send data until it gets to the end of a burst plus an additional 96 bytes for reaction time. For example; if BURSTLIMIT is set to 512 bytes, and BURSTMAX is set to 256 bytes, then RATEMAX equal 160 bytes, 512-256-96 = 160 bytes. Note: The TXTRLR1 [DELTA] field should be set less than or equal to the MAX field of register 0x038.
16–20 -	This field is reserved. Reserved
21–23 GRANULARITY	Counter decrement granularity in case of packet EOP. 6, 7 reserved 0 = 1 byte

Table continues on the next page...

LAC_TXTRLR0 field descriptions (continued)

Field	Description
	1 = 2 bytes 2 = 4 bytes 3 = 8 bytes 4 = 16 bytes 5 = 32 bytes
24–30 -	This field is reserved. Reserved
31 ENABLE	When set to 1, the rate limit function is enableds

21.3.13 TX transmit rate limiter register 1 (LAC_TXTRLR1)

The two values in this register, along with knowledge of the speed of the core clk input, determine the RateLimit parameter described in the Interlaken Protocol Definition Specification. For example, if core clk is running 400 MHz (2.5 ns cycle time), the TIME field is set to decimal 400, and the delta parameter is set to decimal 1500, the transmitted bandwidth will be approximately 1500 / (400 * 2.5) = 1.5 GBytes/s = 12 Gbps.This register should not be changed after initialization.

Address: 22_8000h base + 43Ch offset = 22_843Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	TIME																DELTA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

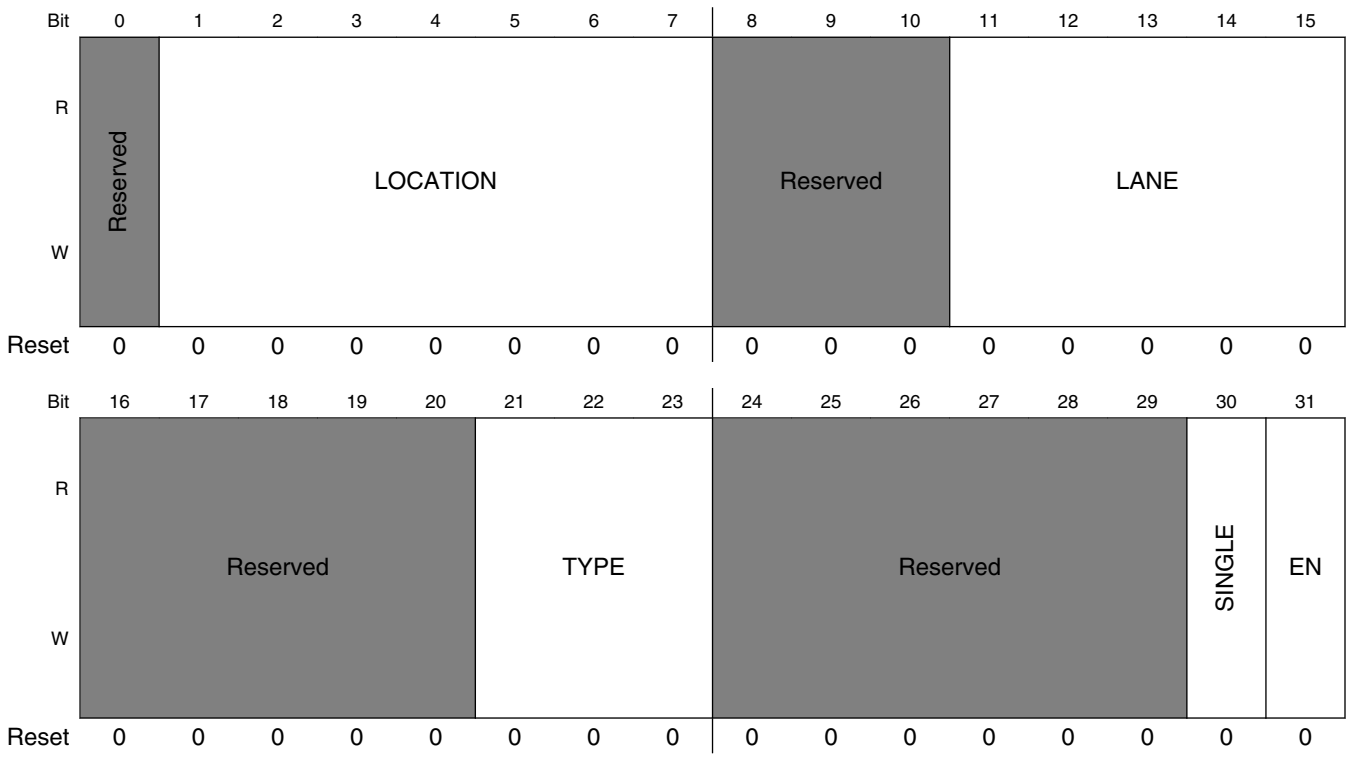
LAC_TXTRLR1 field descriptions

Field	Description
0–15 TIME	How often the rate limit credit counter should get DELTA bytes added to it.
16–31 DELTA	How many credits/bytes are added to the credit counter when the timer expires. Note: The DELTA field should be set less than or equal to the MAX field of TXRLR0.

21.3.14 TX transmit error injection register n (LAC_TXERRINJ*n*)

There are four registers that can be used to specify four different error injections on the transmitter.

Address: 22_8000h base + 450h offset + (4d × i), where i=0d to 3d



LAC_TXERRINJ*n* field descriptions

Field	Description
0 -	This field is reserved. Reserved
1–7 LOCATION	Which bit of the 67bit word should get flipped
8–10 -	This field is reserved. Reserved
11–15 LANE	Which serdes lane to inject the error on
16–20 -	This field is reserved. Reserved
21–23 TYPE	The type of word to inject the error on 000 = Data Word 001 = Idle/Burst Control Word

Table continues on the next page...

LAC_TXERRINJ*n* field descriptions (continued)

Field	Description
	010 = Invalid, Reserved value 011 = Any Word 100 = Diagnostic Word 101 = Synchronization Word 110 = Scrambler State Word 111 = Skip Word
24–29 -	This field is reserved. Reserved
30 SINGLE	When 1, inject the specified error once then quit. When 0, continue to inject the specified error
31 EN	Enable the error injection. When doing a series of single error injections, the EN bit must be set low in between each desired error.

21.3.15 TX statistic counter access register (LAC_TXSCAR)

This register provides access to the statistics counters. For counter values that are wider than a single access, the addressing is done big-endian, e.g. address offset 'h250 holds the upper portion of the byte counter while address offset 'h254 holds the lower portion of the byte counter.

For a write access, first the statistics write data registers are loaded with the desired write data, then a write command is issued here. For a read access, the read command is issued here, then the read data can be read from the statistics read data registers. For the per-channel counters, a read or write command accesses the byte, packet, and error counters simultaneously.

Address: 22_8000h base + 474h offset = 22_8474h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table continues on the next page...

LAC_TXSCAR field descriptions (continued)

Field	Description
	100 = Run reset state machine to clear all counters of the specificed TYPE. For TYPE = 0000 counters this process takes up to 2*MAX_CHAN clock cycles to complete, and other accesses to TYPE = 0000 counters will be ignored. For other counter types the clear happens immediately. 101 = Clear ECC/Parity Error flags for selected counter 110 = Reserved 111 = Read modify write access with parity bits taken from registers 0x298, 0x498 instead of being calculated. (Used to force parity errors in stats memory). Only valid with TYPE=0000 counters.
8–11 -	This field is reserved. Reserved
12–15 TYPE	Most of the counter type names match exactly with the recommended statistics from the Interlaken Protocol Definition TX counter types: 0000 = TX_Packets, TX_Bytes, and TX_Bad_Packets, ADDR field indicates which channel number 0001 = RX_FC_Error. The number of out of band Flow Control Errors, either framing or CRC4 errors Other = Unused RX counter types: 0000 = RX_Packets, RX_Bytes, and RX_Bad_Packets ADDR field indicates which channel number 0001 = In band Flow Control Framing Error 0010 = RX_CRC_Error. Number of Burst CRC24 Errors 0011 = RX_BurstMax_Error. Number of Bursts larger than the BurstMax parameter, if checking is enabled. 0100 = BurstMin Error. Number of Bursts smaller than the BurstMin parameter, if checking is enabled. 0101 = RX_Burst_Error. Number of times a protocol error occurs on the datapath related to burst delineation logic. 0110 = RX_Alignment_Error. Number of alignment sequences received in error. 0111 = RX_Alignment_Failure. Number of times alignment was lost (after consecutive RX_Alignment_Errors) 1000 = RX_Word_Sync_Error counter ADDR field indicates which Serdes lane 1001 = RX_CDR_Error counter, based on i_rx_serdes_valid input dropping. ADDR field indicates which Serdes lane 1010 = RX_Lane_CRC_Error counter. ADDR field indicates which Serdes lane 1011 = Unused 1100 = Unused 1101 = RX_Bad_Control_Error. Control word was not one of the recognized types. ADDR field indicates which Serdes lane 1110 = Unused 1111 = Unused
16–23 -	This field is reserved. Reserved
24–31 ADDR	When TYPE field = 0000 then ADDR[7:0] represent channel number When TYPE field = 1000, 1001, 1010, and 1101 then ADDR[7:0] represent serdes lane

Table continues on the next page...

LAC_TXSCAR field descriptions (continued)

Field	Description
	All other combinations of TYPE does not represent anything and therefore should be set to zeros.

21.3.16 TX statistic counter fill register (LAC_TXSCFR)

This register holds the address of a statistics counter that is half full or has overflowed. If multiple counters are half full or overflowed, reading this register will cause a different counter to be displayed here. Also, if the counter displayed here is cleared and is no longer half full or overflowed, a different counter will be displayed. The order in which counters are displayed is not specified.

Only the per channel statistics counters (type 0000) are reported here. The status for other counter types can be seen directly in interrupt and status registers. When in Single Channel Stats mode the return value for the ADDR field will always be zero.

Address: 22_8000h base + 478h offset = 22_8478h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

0 BO	The byte counter overflowed and started again from zero
1 PO	The packet counter overflowed and started again from zero
2 EO	The error counter overflowed and started again from zero
3 BH	The byte counter is over half full
4 PH	The packet counter is over half full
5 EH	The error counter is over half full
6–11 -	This field is reserved. Reserved

Table continues on the next page...

LAC_TXSCFR field descriptions (continued)

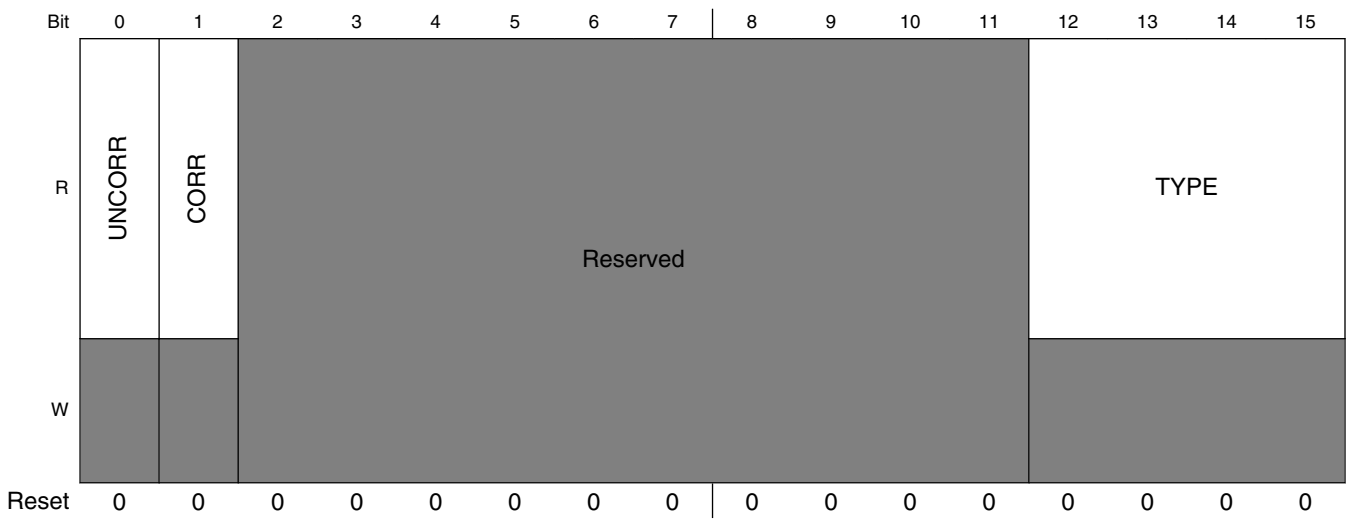
Field	Description
12–15 TYPE	The type of statistics counter being reported as described in the TXSCAR/RXSCAR register description. Only the per channel statistics counters are use this register, so the TYPE field will always be 0000
16–23 -	This field is reserved. Reserved
24–31 ADDR	The address of a statistics counter that is half full or has overflowed. When in Single Channel Stats mode the return value if the ADDR field will always be zero.

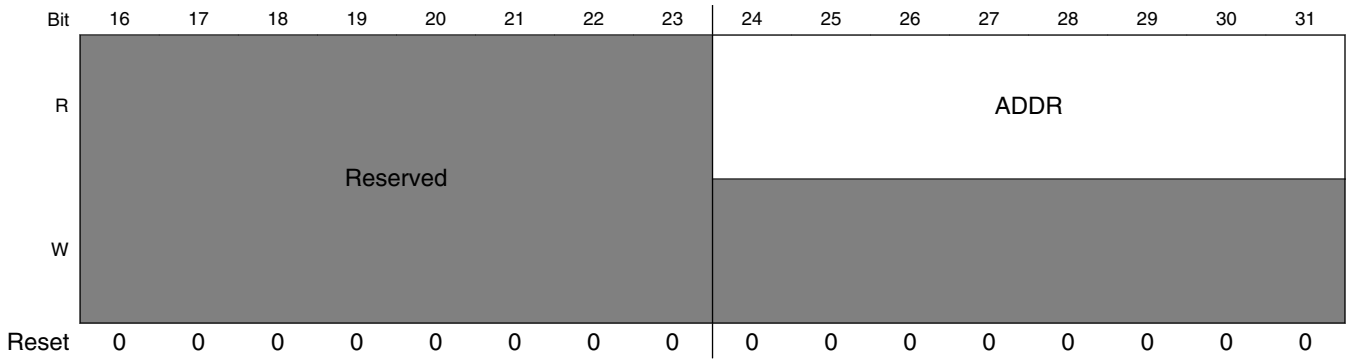
21.3.17 TX statistic counter parity register (LAC_TXSCPR)

By default the statistics counter memory is parity protected. This register holds the address of a statistics counter that had a parity error. If multiple counters have had parity errors, reading this register will cause a different counter to be displayed here. The parity error flags are cleared through the statistics counter access register. For future enhancements that may protect the memory with ECC, a flag is provided to indicate when a correctable ECC error has occurred.

When in Single Channel Stats mode the return value for the ADDR field will always be zero.

Address: 22_8000h base + 47Ch offset = 22_847Ch





LAC_TXSCPR field descriptions

Field	Description
0 UNCORR	Specifies whether any of the counters had a parity (or uncorrectable ECC) error.
1 CORR	Specifies whether any of the counters had a correctable ECC error.
2–11 -	This field is reserved. Reserved
12–15 TYPE	The type of statistics counter being reported as described in the TXSCAR/RXSCAR register description. Only the per channel statistics counters are use this register, so the TYPE field will always be 0000
16–23 -	This field is reserved. Reserved
24–31 ADDR	The address of a statistics counter that is half full or has overflowed. When in Single Channel Stats mode the return value if the ADDR field will always be zero.

21.3.18 TX statistic counter write byte counter high register (LAC_TXSCWBCHR)

This register holds the write data that will be written into the byte counter when the access type given in the Statistics Counter Access register is write or read/write. Note, even if some of the bits of the associated statistic counter are unused (specified by the STATS_BYTE_CNT_WIDTH parameter) all the bits of this register still exist and have the indicated access type.

Address: 22_8000h base + 480h offset = 22_8480h

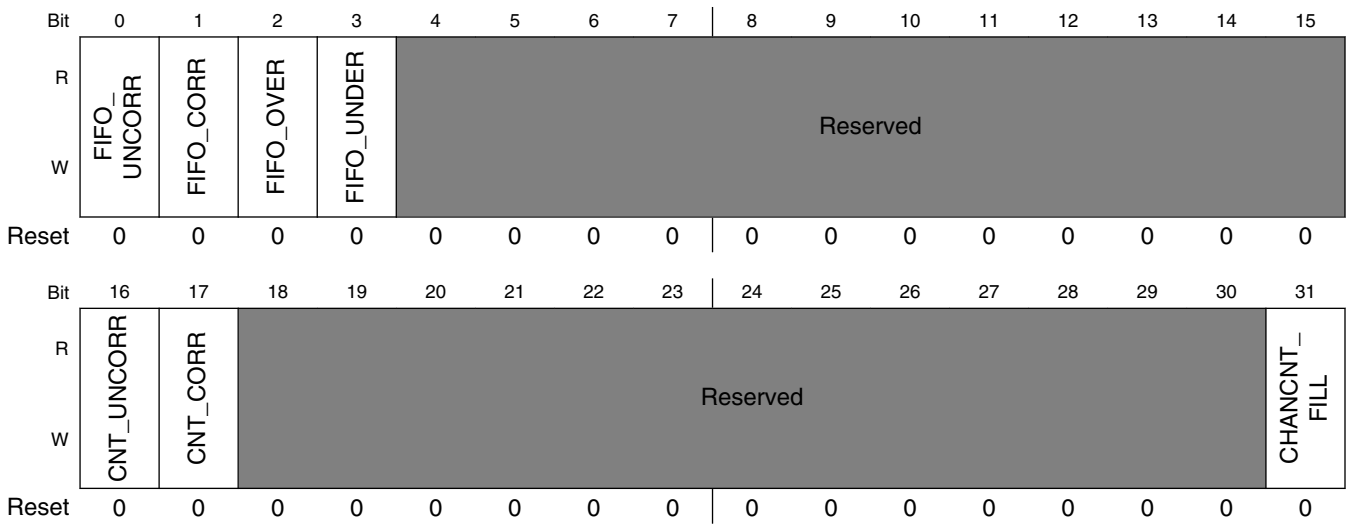
21.3.34 TX interrupt register n (LAC_TXINTR*n*)

This register holds the various interrupts available. Each bit in this register has an associated mask bit in the Interrupt Mask Register. The bits in this register will set regardless of the value of their associated mask. The Mask Register determines which bits of this register are OR'd together to create the interrupt outputs. Two separate interrupt outputs are provided, o_m_tx_int and o_m_tx_int_2nd. This may be used, for example, if firmware wants to differentiate between high priority and low priority interrupts. Each of the interrupt outputs has its own interrupt and interrupt mask registers. When the hardware sets an interrupt, it gets set in both of the interrupt registers. However, when firmare clears an interrupt it is only cleared in the register that is written.

Address: 22_8000h base + 580h offset + (8d × i), where i=0d to 1d



LAC_TXINTR*n* field descriptions

Field	Description
0 FIFO_UNCORR	The transmitter's input fifo had an uncorrectable parity or ECC error
1 FIFO_CORR	The transmitter's input fifo had an correctable ECC error
2 FIFO_OVER	The transmitter's input fifo overflowed. This should not happen if the high watermark in register TXFCR is set properly given the latency required for the user to respond to stall
3 FIFO_UNDER	The transmitter's input fifo went empty not on a burst boundary. To try to prevent Interlaken protocol errors a burst boundary was forced. This condition should not happen if the user sends data in complete bursts and the low watermark in register FIXME is set properly given the latency required for the user to respond to stall
4–15 -	This field is reserved. Reserved

Table continues on the next page...

LAC_TXINTR*n* field descriptions (continued)

Field	Description
16 CNT_UNCORR	One of the statistics counters had an uncorrectable parity or ECC error. Each channel in the design has a flag that sets when an uncorrectable parity or ECC error has been seen.
17 CNT_CORR	One of the statistics counters had an correctable ECC error. Each channel in the design has a flag that sets when an correctable ECC error has been seen.
18–30 -	This field is reserved. Reserved
31 CHANCNT_FILL	One or more per channel statistics counters (TX_Bytes, TX_Packets, and/or TX_Bad_Packets) are half full or overflowed

21.3.35 TX interrupt mask register n (LAC_TXINTMRn*n*)

These registers masks the individual bits of their respective Interrupt Registers from being included in the interrupt output. Coming out of reset, all interrupts are masked by default.

Address: 22_8000h base + 584h offset + (8d × i), where i=0d to 1d

31 -	This field is reserved. Reserved

21.3.39 RX SERDES FIFO watermark register (LAC_RXSFWMR)

This register contains the watermarks interface for fifos that are used for the serdes interface in data paths and for clock domain crossing at the serdes interface and in out-of -band flow control paths. The reset values are chosen based on the characteristics of the internal logic and generally should only be changed for latency critical applications.

Using a larger value for DATA_HIGH and DATA_LOW will reduce the amount of data stored in the fifos and therefore reduce latency of the design. The DATA_HIGH value should typically be one less than the DATA_LOW value. When too large a value is used for DATA_LOW, the fifo may underflow, corrupting the serdes data. Because of the wide range of possible clock speeds and other factors, Open-Silicon does not provide any further guidance or support for setting these registers to values other than their default.

Address: 22_8000h base + 628h offset = 22_8628h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

21.3.41 RX MetaFrame synchronization register (LAC_RXMSR)

This register contains the MetaFramePeriod timer used to transmit Synchronization Words. One unit of the timer corresponds to 67 bits on the serial lane (64 bits data plus 3 bits framing). The default value corresponds to an interval of 16Kbytes (not including the 3 bits framing). This register should not be changed after initialization.

Address: 22_8000h base + 634h offset = 22_8634h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

LAC_RXMSR field descriptions

Field	Description
0–15 -	This field is reserved. Reserved
16–31 PERIOD	Timer value. One unit of the timer corresponds to 67 bits on the serial lane (64 bits data plus 3 bits framing). Setting the timer to zero in the TX disables the generation of alignment frames. This value must be set the same in both the RX and TX. The minimum value is 64 (decimal).

21.3.42 RX statistic counter access register (LAC_RXSCAR)

This register provides access to the statistics counters. For counter values that are wider than a single access, the addressing is done big-endian, e.g. address offset 'h250 holds the upper portion of the byte counter while address offset 'h254 holds the lower portion of the byte counter.

For a write access, first the statistics write data registers are loaded with the desired write data, then a write command is issued here. For a read access, the read command is issued here, then the read data can be read from the statistics read data registers. For the per-channel counters, a read or write command accesses the byte, packet, and error counters simultaneously.

Address: 22_8000h base + 674h offset = 22_8674h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

LAC_RXSCAR field descriptions

Field	Description
0–4 -	This field is reserved. Reserved
5–7 CMD	Type of access to do. 000 = Single Channel Stats 001 = Read Access 010 = Write Access 011 = Read Modify Write Access 100 = Run reset state machine to clear all counters of the specificed TYPE. For TYPE = 0000 counters this process takes up to 2*MAX_CHAN clock cycles to complete, and other accesses to TYPE = 0000 counters will be ignored. For other counter types the clear happens immediately. 101 = Clear ECC/Parity Error flags for selected counter 110 = Reserved 111 = Read modify write access with parity bits taken from registers 0x298, 0x498 instead of being calculated. (Used to force parity errors in stats memory). Only valid with TYPE=0000 counters.

Table continues on the next page...

LAC_RXSCAR field descriptions (continued)

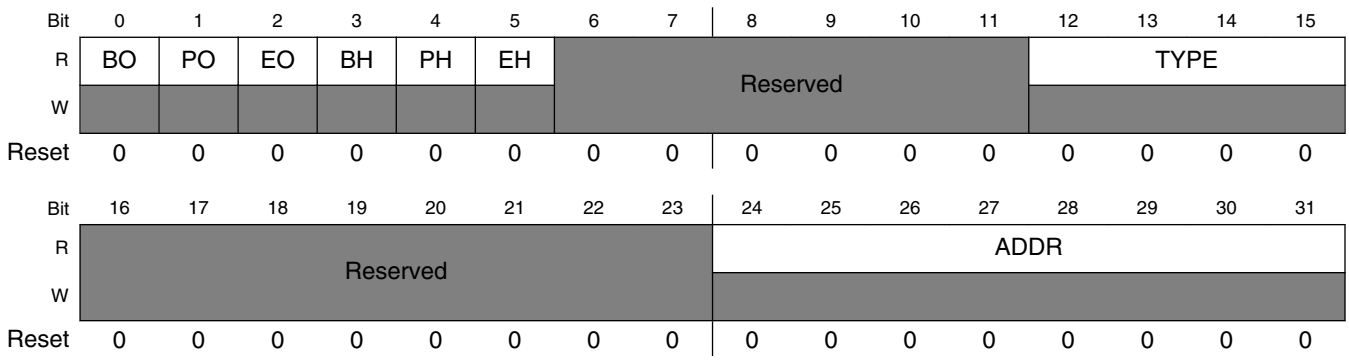
Field	Description
8–11 -	This field is reserved. Reserved
12–15 TYPE	Most of the counter type names match exactly with the recommended statistics from the Interlaken Protocol Definition TX counter types: 0000 = TX_Packets, TX_Bytes, and TX_Bad_Packets, ADDR field indicates which channel number 0001 = RX_FC_Error. The number of out of band Flow Control Errors, either framing or CRC4 errors Other = Unused RX counter types: 0000 = RX_Packets, RX_Bytes, and RX_Bad_Packets ADDR field indicates which channel number 0001 = In band Flow Control Framing Error 0010 = RX_CRC_Error. Number of Burst CRC24 Errors 0011 = RX_BurstMax_Error. Number of Bursts larger than the BurstMax parameter, if checking is enabled. 0100 = BurstMin Error. Number of Bursts smaller than the BurstMin parameter, if checking is enabled. 0101 = RX_Burst_Error. Number of times a protocol error occurs on the datapath related to burst delineation logic. 0110 = RX_Alignment_Error. Number of alignment sequences received in error. 0111 = RX_Alignment_Failure. Number of times alignment was lost (after consecutive RX_Alignment_Errors) 1000 = RX_Word_Sync_Error counter ADDR field indicates which Serdes lane 1001 = RX_CDR_Error counter, based on i_rx_serdes_valid input dropping. ADDR field indicates which Serdes lane 1010 = RX_Lane_CRC_Error counter. ADDR field indicates which Serdes lane 1011 = Unused 1100 = Unused 1101 = RX_Bad_Control_Error. Control word was not one of the recognized types. ADDR field indicates which Serdes lane 1110 = Unused 1111 = Unused
16–23 -	This field is reserved. Reserved
24–31 ADDR	When TYPE field = 0000 then ADDR[7:0] represent channel number When TYPE field = 1000, 1001, 1010, and 1101 then ADDR[7:0] represent serdes lane All other combinations of TYPE does not represent anything and therefore should be set to zeros.

21.3.43 RX statistic counter fill register (LAC_RXSCFR)

This register holds the address of a statistics counter that is half full or has overflowed. If multiple counters are half full or overflowed, reading this register will cause a different counter to be displayed here. Also, if the counter displayed here is cleared and is no longer half full or overflowed, a different counter will be displayed. The order in which counters are displayed is not specified.

Only the per channel statistics counters (type 0000) are reported here. The status for other counter types can be seen directly in interrupt and status registers. When in Single Channel Stats mode the return value for the ADDR field will always be zero.

Address: 22_8000h base + 678h offset = 22_8678h



LAC_RXSCFR field descriptions

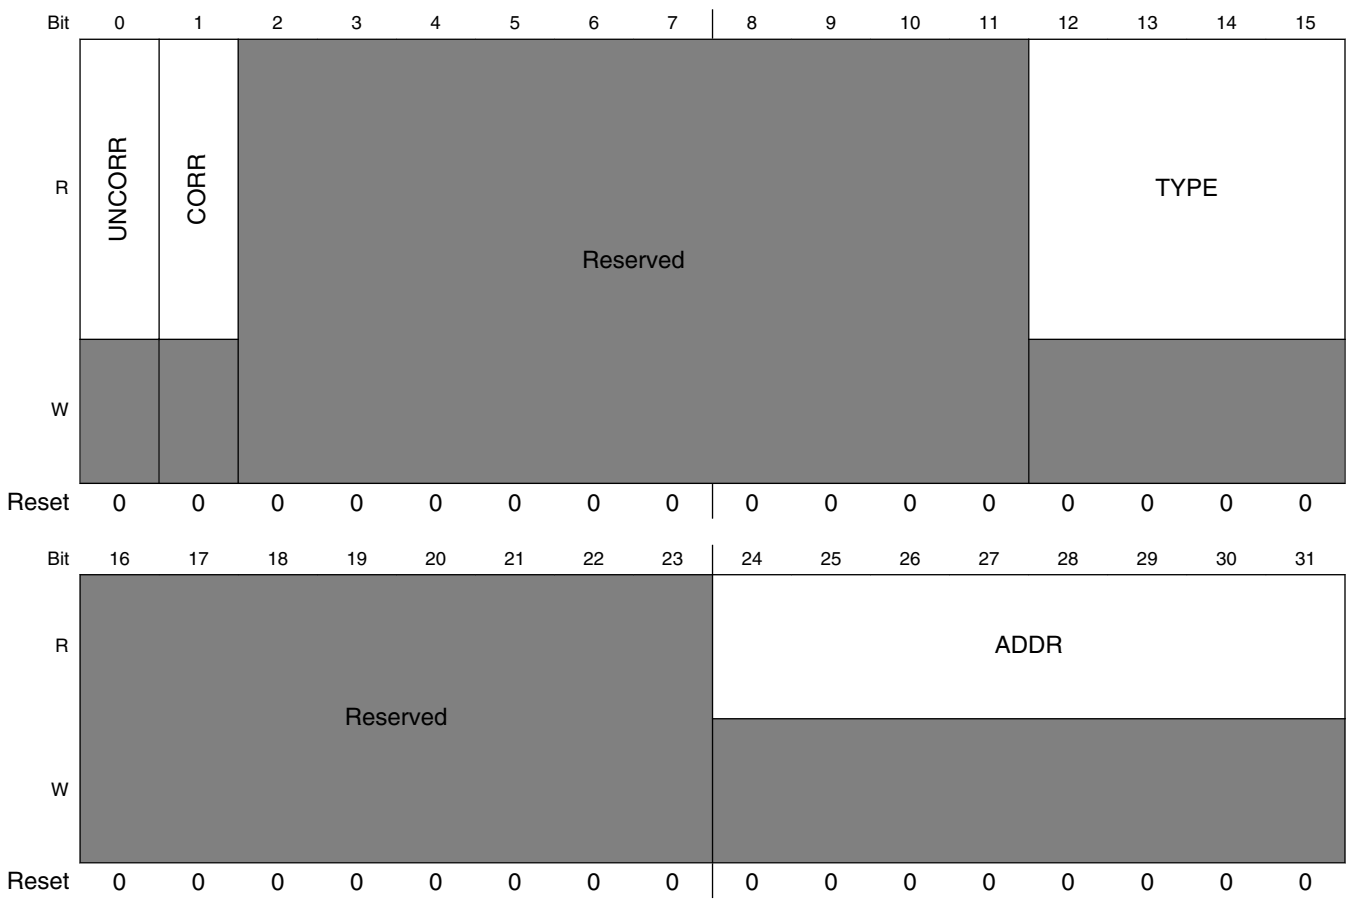
Field	Description
0 BO	The byte counter overflowed and started again from zero
1 PO	The packet counter overflowed and started again from zero
2 EO	The error counter overflowed and started again from zero
3 BH	The byte counter is over half full
4 PH	The packet counter is over half full
5 EH	The error counter is over half full
6–11 -	This field is reserved. Reserved
12–15 TYPE	The type of statistics counter being reported as described in the TXSCAR/RXSCAR register description. Only the per channel statistics counters are use this register, so the TYPE field will always be 0000
16–23 -	This field is reserved. Reserved
24–31 ADDR	The address of a statistics counter that is half full or has overflowed. When in Single Channel Stats mode the return value if the ADDR field will always be zero.

21.3.44 RX statistic counter parity register (LAC_RXSCPR)

By default the statistics counter memory is parity protected. This register holds the address of a statistics counter that had a parity error. If multiple counters have had parity errors, reading this register will cause a different counter to be displayed here. The parity error flags are cleared through the statistics counter access register. For future enhancements that may protect the memory with ECC, a flag is provided to indicate when a correctable ECC error has occurred.

When in Single Channel Stats mode the return value for the ADDR field will always be zero.

Address: 22_8000h base + 67Ch offset = 22_867Ch



LAC_RXSCPR field descriptions

Field	Description
0 UNCORR	Specifies whether any of the counters had a parity (or uncorrectable ECC) error.
1 CORR	Specifies whether any of the counters had a correctable ECC error.

Table continues on the next page...

LAC_RXSCPR field descriptions (continued)

Field	Description
2–11 -	This field is reserved. Reserved
12–15 TYPE	The type of statistics counter being reported as described in the TXSCAR/RXSCAR register description. Only the per channel statistics counters are use this register, so the TYPE field will always be 0000
16–23 -	This field is reserved. Reserved
24–31 ADDR	The address of a statistics counter that is half full or has overflowed. When in Single Channel Stats mode the return value if the ADDR field will always be zero.

21.3.45 RX statistic counter write byte counter high register (LAC_RXSCWBCHR)

This register holds the write data that will be written into the byte counter when the access type given in the Statistics Counter Access register is write or read/write. Note, even if some of the bits of the associated statistic counter are unused (specified by the STATS_BYTE_CNT_WIDTH parameter) all the bits of this register still exist and have the indicated access type.

Address: 22_8000h base + 680h offset = 22_8680h

21.3.61 RX Interrupt Register n (LAC_RXINTR*n*)

This register holds the various interrupts available. Each bit in this register has an associated mask bit in the Interrupt Mask Register. The bits in this register will set regardless of the value of their associated mask. The Mask Register determines which bits of this register are OR'd together to create the interrupt outputs. Two separate interrupt outputs are provided, o_m_rx_int and o_m_rx_int_2nd. This may be used, for example, if firmware wants to differentiate between high priority and low priority interrupts. Each of the interrupt outputs has its own interrupt and interrupt mask registers. When the hardware sets an interrupt, it gets set in both of the interrupt registers. However, when firmare clears an interrupt it is only cleared in the register that is written.

Address: 22_8000h base + 780h offset + (8d × i), where i=0d to 1d

LAC_RXINTR*n* field descriptions

Field	Description
0 CTE	Control Word Bit Error. A control word looked like a valid synchronization or skip word, but bit [55:0] of the word did not match the expected value
1 -	This field is reserved. Reserved
2 MFE	For one or more of the enabled lanes, a valid synchronization word was not received at the metaframe period. RXMFER(0x5AC) must be cleared before MFE will clear
3 BCE	A control word was received that does not match one of the defined control word types. RXBCER(0x5B0) must be cleared before BADCTL_ERR bit[28] will clear.
4 SSE	For one or more enabled lanes, a scrambler state word did not match its expected value. RXSSER(0x5B4) must be cleared before SCRAM_ERR will clear.
5 C32E	For one or more enabled lanes, a CRC32 error was reported. RXC32ER must be cleared before C32E will clear.
6 CDE	For one or more enabled lanes, the i_rx_serdes_valid input is low. RXCDER must be cleared before CDE will clear.
7 WSC	For one or more enabled lanes, the 64b/67b synchronization has changed, either from out of sync to in sync or from in sync to out of sync. RXWSCR must be cleared before WSC bit will clear. A flow diagram for achieving and maintaining 64B/67B word boundary lock is shown in figure 5-10 on page 25 of the Interlaken Protocol Definition. Once we get sync (the middle64B/67B word lock state in the diagram) we need to get 16 out of 64 words with bad framing bits in order to go out of sync.
8 AC	The alignment state has changed, either from out of alignment to aligned or from aligned to out of alignment
9 AE	An alignment error occurred (synchronization word not seen on all lanes at the same time)
10 BE	A protocol error occurred in the datapath related to the burst delineation logic
11 BMINE	A BurstMin violation was detected

Table continues on the next page...

LAC_RXINTR*n* field descriptions (continued)

Field	Description
12 BMAXE	A BurstMax violation was detected
13 C24E	A burst CRC24 error was detected
14 -	This field is reserved. Reserved
15 SMC	When this interrupt is set, it indicates that the diagnostics word's status message has changed. The status message can be seen in register 0x5C8, RXSMR.
16 CUC	One of the statistics counters had an uncorrectable parity or ECC error
17 CC	One of the statistics counters had a correctable ECC error
18 BCCF	The RX_Bad_Control_Error counter is over half full.

21 C32CF	One or more of the per lane RX_Lane_CRC_Error counters is over half full
22 CDCF	One or more of the per lane RX_Lane_CDR_Error counters is over half full
23 WSCF	One or more of the per lane RX_Word_Sync_Error counters is over half full
24 AFCF	The RX_Alignment_Failure counter is over half full

Table continues on the next page...

LAC_RXINTFR field descriptions (continued)

Field	Description
25 ACF	The RX_Alignment_Error counter is over half fullll
26 BCF	The Burst error counter is over half full
27 BMINCF	The BurstMin error counter is over half full
28 BMAXCF	The RX_BurstMax_Error counter is over half full
29 C24CF	The RX_CRC_Error counter is over half full
30 -	This field is reserved. Reserved
31 CCF	One or more per channel statistics counters (TX_Bytes, TX_Packets, and/or TX_Bad_Packets) are half full or overflowed

21.3.64 RX MetaFrame Error register (LAC_RXMFER)

When a valid synchronization word was not received at the metaframe period, a status bit is set in this register for theaffected serdes lane. The bits of this register, not including disabled serdes lanes (as determined by the Lane Disable Register), are OR'd together to create the MFE interrupt in the RX interrupt registers.

Address: 22_8000h base + 7ACh offset = 22_87ACh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Reserved																								LANE							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

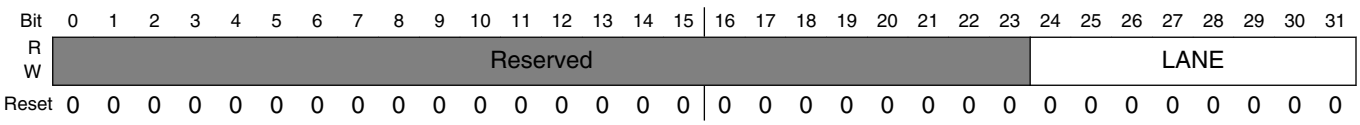
LAC_RXMFER field descriptions

Field	Description
0–23 -	This field is reserved. Reserved
24–31 LANE	The MetaFrame Period Error for the lanes. Bit [31] for lane 0, etc.

21.3.65 RX Bad Control Word Error register (LAC_RXBCER)

When a Control Word does not match one of the known control word types, a status bit is set in this register for the affected serdes lane. The bits of this register, not including disabled serdes lanes (as determined by the Lane Disable Register), are OR'd together to create the BCE bit in the RX interrupt registers.

Address: 22_8000h base + 7B0h offset = 22_87B0h



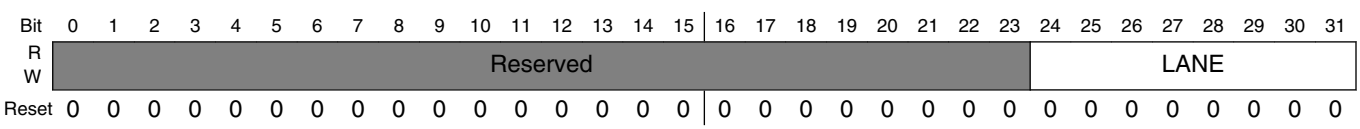
LAC_RXBCER field descriptions

Field	Description
0–23 -	This field is reserved. Reserved
24–31 LANE	The bad control word Error for the lanes. Bit [31] for lane 0, and so on.

21.3.66 RX Scambler State Error register (LAC_RXSSER)

When a received scrambler state word does not match its expected value, a status bit is set in this register for the affected serdes lane. The bits of this register, not including disabled serdes lanes (as determined by the Lane Disable Register), are OR'd together to create the SSE interrupt in the RX interrupt registers.

Address: 22_8000h base + 7B4h offset = 22_87B4h



LAC_RXSSER field descriptions

Field	Description
0–23 -	This field is reserved. Reserved
24–31 LANE	The scramble state Error for the lanes. Bit [0] for lane 0, etc.

21.3.67 RX CRC32 Error register (LAC_RXC32ER)

When a received diagnostic word has a mismatch in its CRC32 field, a status bit is set in this register for the affected serdes lane. The bits of this register, not including disabled serdes lanes (as determined by the Lane Disable Register), are OR'd together to create the C32E interrupt in the RX interrupt registers.

Address: 22_8000h base + 7B8h offset = 22_87B8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

LAC_RXC32ER field descriptions

Field	Description
0–23 -	This field is reserved. Reserved
24–31 LANE	The scramble state Error for the lanes. Bit [0] for lane 0, etc.

21.3.68 RX CDR Error register (LAC_RXCDER)

If the i_rx_serdes_valid inputs are used by the serdes, it is assumed that a low value on this input implies that clockdata-recovery has been lost. This sets a status bit in this register for the affected serdes lane. The bits of this register, not including disabled serdes lanes (as determined by the Lane Disable Register), are OR'd together to create the CDE interrupt in the RX interrupt registers.

Address: 22_8000h base + 7BCh offset = 22_87BCh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

LAC_RXCDER field descriptions

Field	Description
0–23 -	This field is reserved. Reserved
24–31 LANE	The scramble state Error for the lanes. Bit [0] for lane 0, etc.

21.3.69 RX Word Sync Changed register (LAC_RXWSCR)

The interrupt bits in this register set when the 64b/67b word boundary lock status changes for a lane. The bits of this register, not including disabled serdes lanes (as determined by the Lane Disable Register), are OR'd together to create the WSC interrupt in the RX interrupt registers.

Address: 22_8000h base + 7C0h offset = 22_87C0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Reserved																								LANE							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

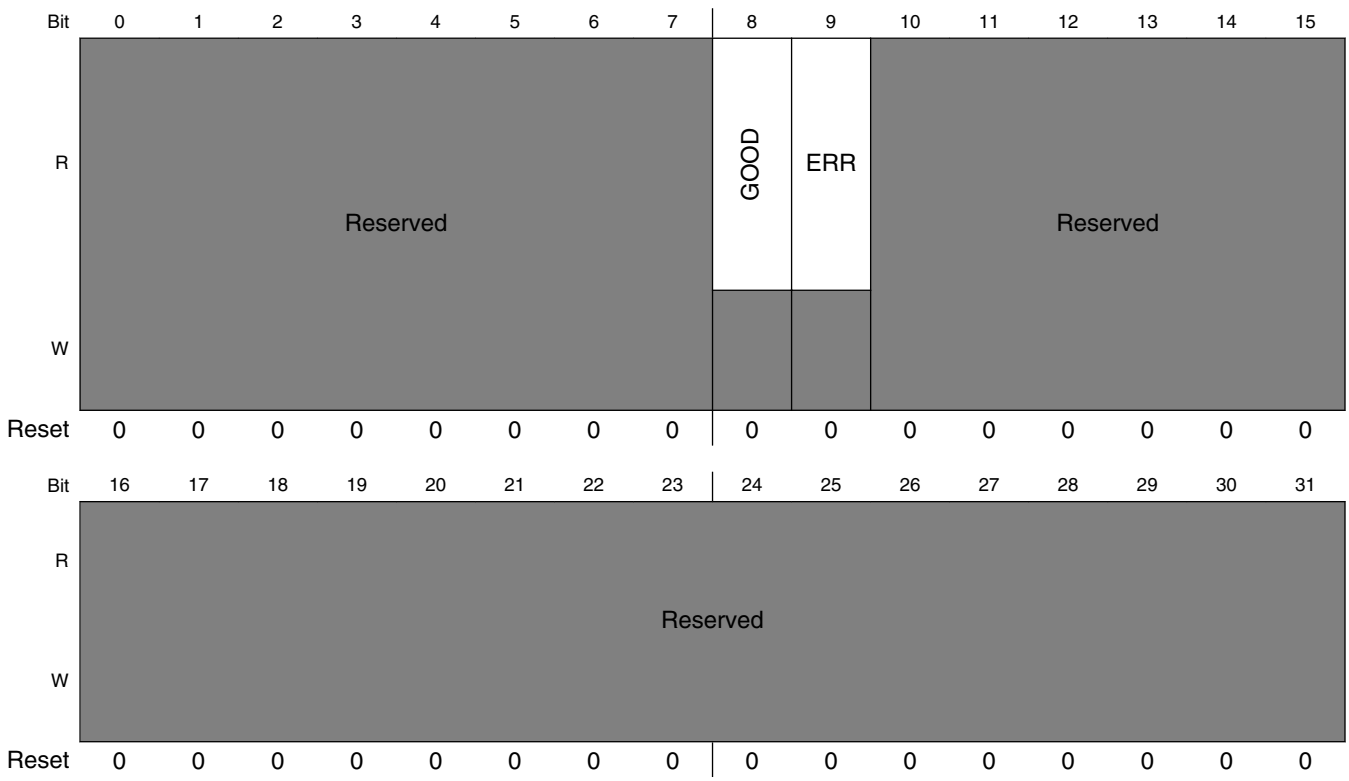
LAC_RXWSCR field descriptions

Field	Description
0–23 -	This field is reserved. Reserved
24–31 LANE	The scramble state Error for the lanes. Bit [0] for lane 0, etc.

21.3.70 RX aligned status register (LAC_RXASR)

This register shows the status of the alignment between the enabled lanes.

Address: 22_8000h base + 7C4h offset = 22_87C4h



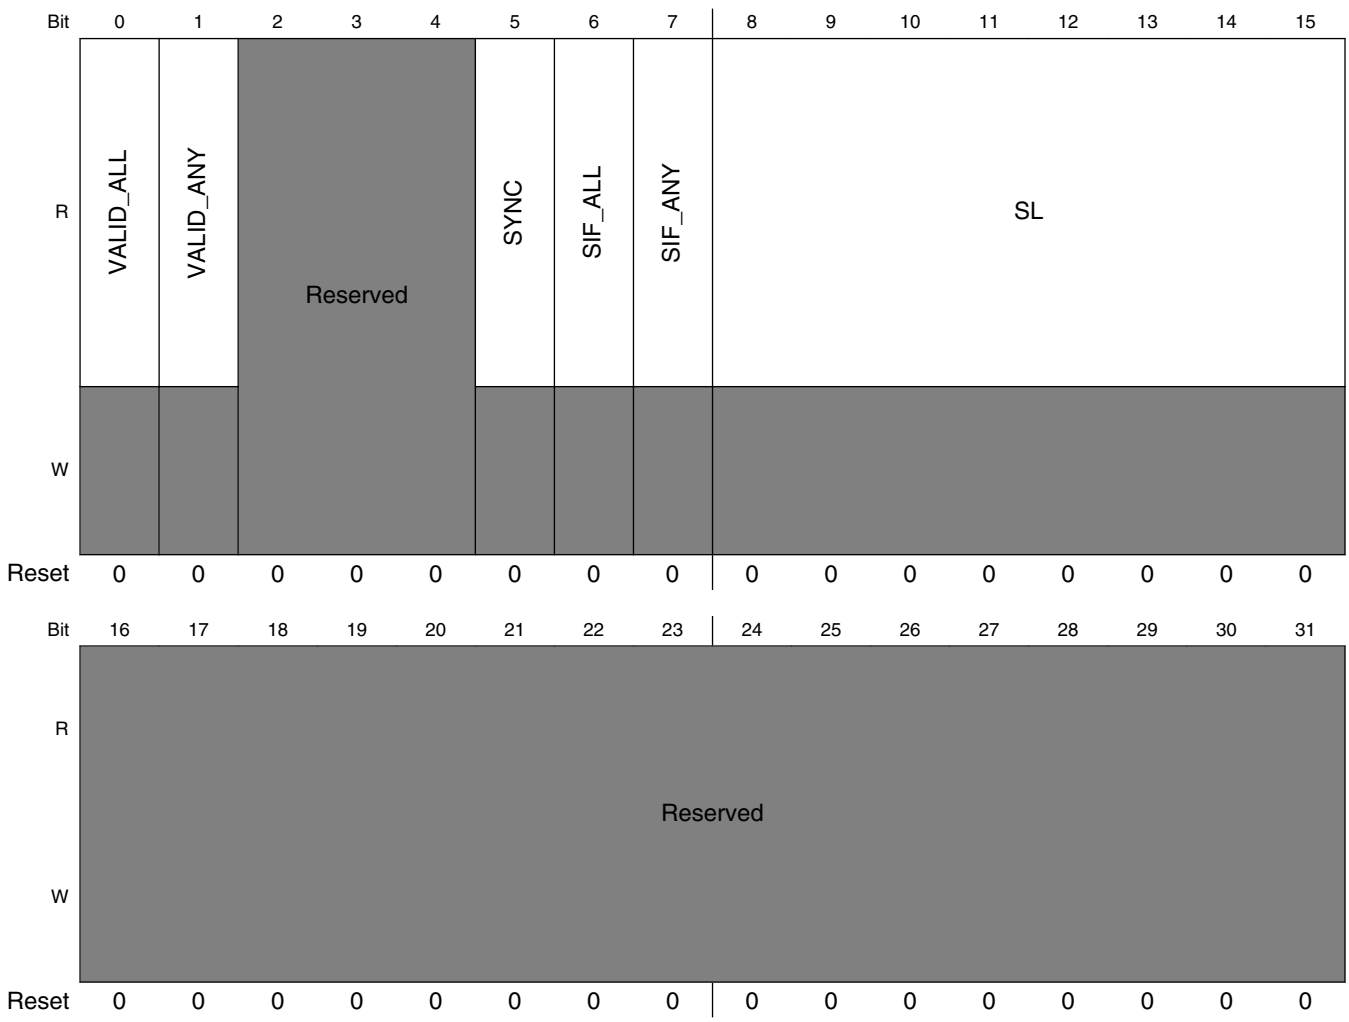
LAC_RXASR field descriptions

Field	Description
0–7 -	This field is reserved. Reserved
8 GOOD	Indicates that the interface is in alignment. When this bit changes, the AC bit gets set in the RX Interrupt Registers.
9 ERR	An invalid synchronization pattern has been found. The status bit is a one shot pulse so it will most likely not be seen on a register read.
10–31 -	This field is reserved. Reserved

21.3.71 RX Status Message register (LAC_RXSMR)

This register displays the optional status message (if received) from the meta-frame diagnostic word (RX). Whenever the bits of this register change, not including disabled lanes, the SMC interrupt is set in the RX interrupt registers.

Address: 22_8000h base + 7C8h offset = 22_87C8h



LAC_RXSMR field descriptions

Field	Description
0 VALID_ALL	RX (status message from diagnostic words) : The status message was extracted from diagnostic words on ALL enabled serdes lanes.
1 VALID_ANY	RX (status message from diagnostic words) : The status message was extracted from diagnostic words on ANY enabled serdes lanes.

Table continues on the next page...

LAC_RXSMR field descriptions (continued)

Field	Description
2–4 -	This field is reserved. Reserved
5 SYNC	Indicates if we are in sync, based on the SL and SIF bits for the enabled serdes lanes
6 SIF_ALL	RX (status message from diagnostic words) : Bit 0 of the status message was a '1' from ALL enabled lanes
7 SIF_ANY	RX (status message from diagnostic words) : Bit 0 of the status message was a '1' from ANY enabled lanes
8–15 SL	The status message received for the lanes. Bit [0] for lane 0, etc.
16–31 -	This field is reserved. Reserved

21.3.72 RX Word Sync register (LAC_RXWSR)

This register shows the 64b/67b word boundary lock status for each lane. Whenever the bits of this register change, the corresponding WSC bit is set in interrupt register.

Address: 22_8000h base + 7CCh offset = 22_87CCh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

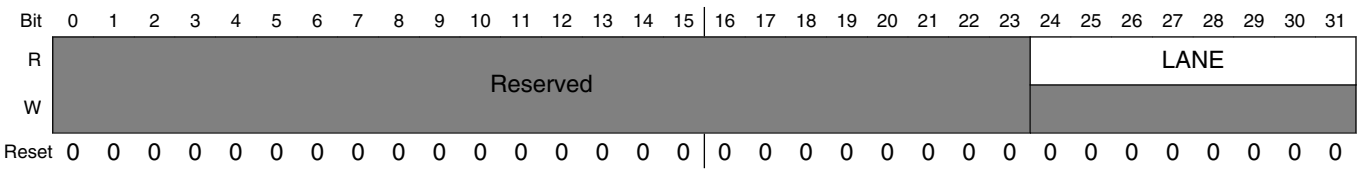
LAC_RXWSR field descriptions

Field	Description
0–23 -	This field is reserved. Reserved
24–31 LANE	The word sync lock status for the lanes. Bit [31] for lane 0, etc.

21.3.73 RX CRC32 Count Fill register (LAC_RXC32CFR)

This register shows the fill status for the RX_Lane_CRC_Error counters. These errors are counted separately for each lane. When one of the counters is over half full, the corresponding bit will be set in this register. Resetting the fill status is done via Statistics Counter Access register. The logical OR of the bits in this register set the C32CF interrupt in the interrupt registers.

Address: 22_8000h base + 7D8h offset = 22_87D8h



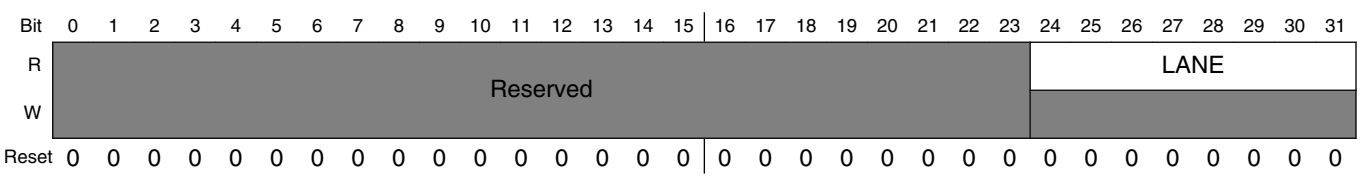
LAC_RXC32CFR field descriptions

Field	Description
0–23 -	This field is reserved. Reserved
24–31 LANE	The RX CRC32 half full status for the lanes. Bit [31] for lane 0, etc.

21.3.74 RX CDR lost Count Fill register (LAC_RXCDCFR)

This register shows the fill status for the RX_CDR_Error counters. These errors are counted separately for each lane. When one of the counters is over half full, the corresponding bit will be set in this register. Resetting the fill status is done via register 0x474 : Statistics Counter Access. The logical OR of the bits in this register set the CDCF interrupt in the interrupt registers.

Address: 22_8000h base + 7DCh offset = 22_87DCh



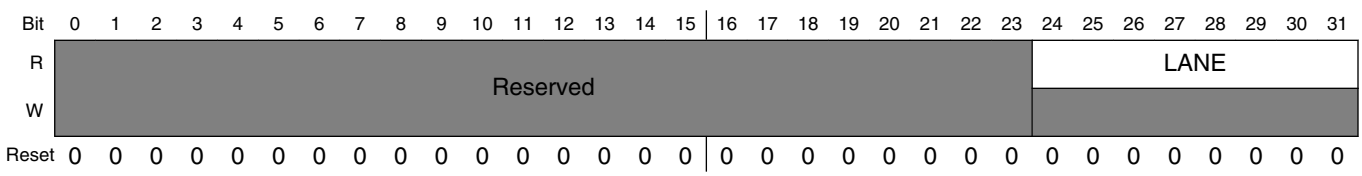
LAC_RXCDCFR field descriptions

Field	Description
0–23 -	This field is reserved. Reserved
24–31 LANE	The lost count half full status for the RX CDR error. Bit [31] for lane 0, etc.

21.3.75 RX word sync Count Fill register (LAC_RXWSCFR)

This register shows the fill status for the RX_Word_Sync_Error counters. These errors are counted separately for each lane. When one of the counters is over half full, the corresponding bit will be set in this register. Resetting the fill status is done via register 0x474 : Statistics Counter Access. The logical OR of the bits in this register set the WSCF interrupt in the interrupt registers.

Address: 22_8000h base + 7E0h offset = 22_87E0h



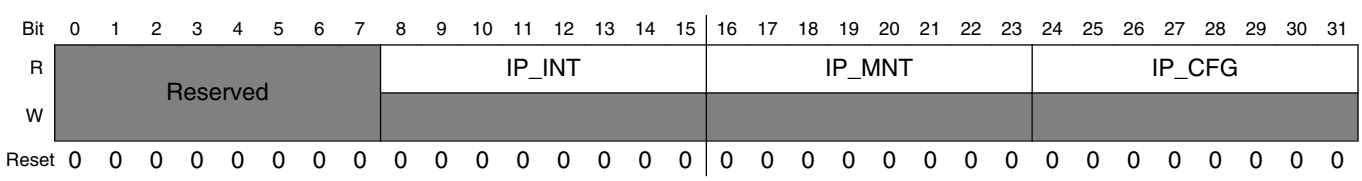
LAC_RXWSCFR field descriptions

Field	Description
0–23 -	This field is reserved. Reserved
24–31 LANE	The half full status for the RX word sync error. Bit [0] for lane 0, etc.

21.3.76 IP Block Revision register 1 (LAC_IPBRR1)

The IP block revision register 1 (IPBRR1), is used to identify LAC block configuration.

Address: 22_8000h base + BFCh offset = 22_8BFCh



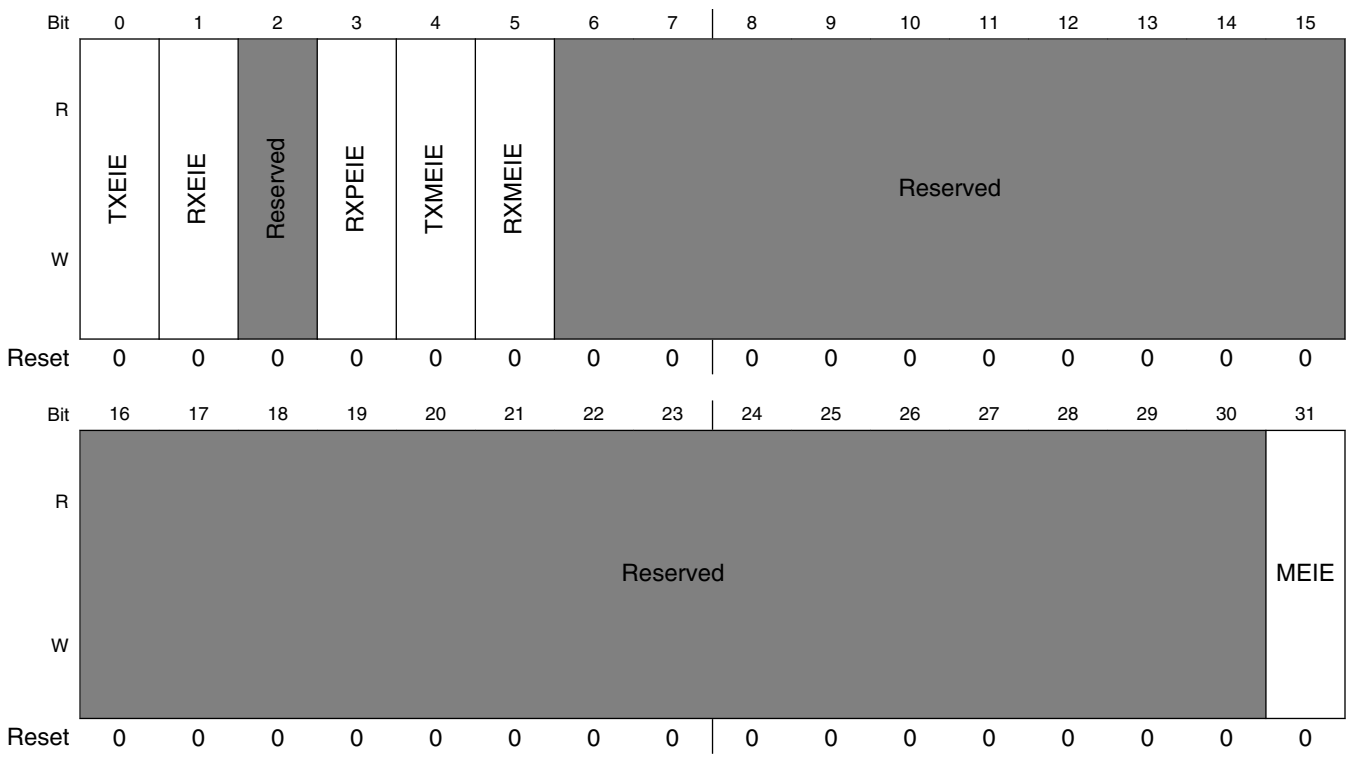
LAC_IPBRR1 field descriptions

Field	Description
0–7 -	This field is reserved. Reserved
8–15 IP_INT	IP block integration options
16–23 IP_MNT	IP block maintenance version
24–31 IP_CFG	IP block configuration options

21.3.77 LAC error interrupt enable register (LAC_LEIER)

The LAC error interrupt enable register determines if a detected error condition should cause a system error interrupt. A system error interrupt occurs if a bit in this register is set and the corresponding bit in the error interrupt register is also set. To clear the interrupt, write a 1 to the error interrupt register.

Address: 22_8000h base + E00h offset = 22_8E00h



LAC_LEIER field descriptions

Field	Description
0 TXEIE	TX error interrupt enable. 0 Disabled. 1 Interrupt enabled.
1 RXEIE	RX error interrupt enable. 0 Disabled. 1 Interrupt enabled.
2 -	This field is reserved. Reserved
3 RXPEIE	RX Packet error interrupt enable 0 Disabled. 1 Interrupt enabled.
4 TXMEIE	TX MAC error interrupt enable. 0 Disabled. 1 Interrupt enabled.
5 RXMEIE	RX MAC error interrupt enable. 0 Disabled. 1 Interrupt enabled.
6–30 -	This field is reserved. Reserved
31 MEIE	multiple error interrupt enable. 0 Disabled. 1 Interrupt enabled.

21.3.78 LAC error detect register (LAC_LEDR)

The LAC error detect register indicates if an error condition was detected that should generate a system error interrupt. The error capture registers may hold additional information regarding the error. Write 1 to clear the error condition and the interrupt, if enabled.

Address: 22_8000h base + E04h offset = 22_8E04h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LAC_LEDR field descriptions

Field	Description
0 TXE	Transmit block error. This includes: • SWPnTCR[GO]=1, but no SWPnTDRm has been written since last command with GO. • SWPnTCR[GO]=1, but there are gaps between SWPnTDR registers, e.g. SWPnTDR0 and SWPnTDR2 are written, but SWPnTDR1 was never written. • the incoming packet is dropped due to the amount of outstanding packet exceeding the allocated amount according to LMR[NUM_PORT]
1 RXE	Receive block error. This includes: • CRC24 error is detected on the incoming Interlaken packet • bad 64/67 word type is detected
2 -	This field is reserved. Reserved

Table continues on the next page...

LAC_LEDR field descriptions (continued)

Field	Description
3 RXPE	RX packet error, EOP with error is received on the control packet.
4 TXME	TX MAC error, MAC has sent tx interrupt to the LA controller
5 RXME	RX MAC error, MAC has sent rx interrupt to the LA controller
6–30 -	This field is reserved. Reserved
31 ME	Multiple of the same error is detected

21.3.79 LAC transmit error capture register0 (LAC_LTECR0)

This is the LAC transmit error capture register 0. Software must clear the error condition(s) to capture the next error information.

The following error conditions will capture :

- Transmit block error - TXE

Address: 22_8000h base + E08h offset = 22_8E08h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

LAC_LTECR0 field descriptions

Field	Description
0–31 SWPnTCR_ word_0	SWPnTCR word 0 associated with the error.

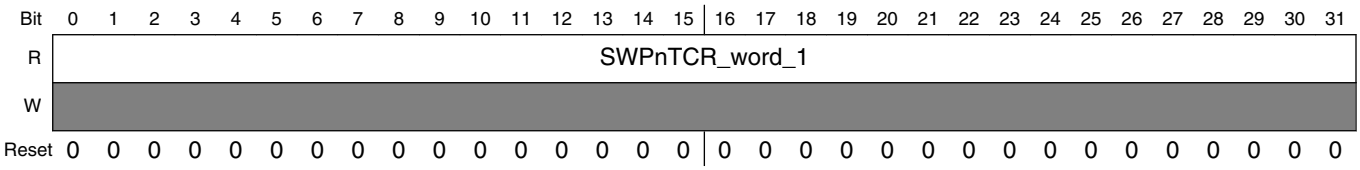
21.3.80 LAC transmit error capture register 1 (LAC_LTECR1)

This is the LAC transmit error capture register 1. Software must clear the error condition(s) to capture the next error information.

The following error conditions will capture :

- Transmit block error - TXE

Address: 22_8000h base + E0Ch offset = 22_8E0Ch



LAC_LTECR1 field descriptions

Field	Description
0–31 SWPnTCR_ word_1	SWPnTCR word 1 associated with the error.

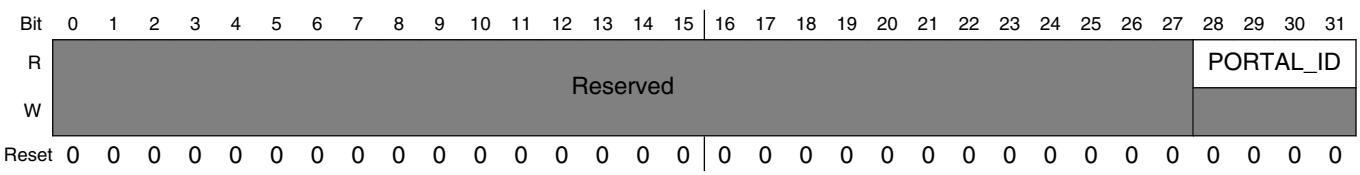
21.3.81 LAC transmit error capture register 2 (LAC_LTECR2)

This is the LAC transmit error capture register 2. Software must clear the error condition(s) to capture the next error information.

The following error conditions will capture :

- Transmit block error - TXE

Address: 22_8000h base + E10h offset = 22_8E10h



LAC_LTECR2 field descriptions

Field	Description
0–27 -	This field is reserved. Reserved
28–31 PORTAL_ID	Portal ID associated with the error.

21.3.82 LAC receive error capture register 0 (LAC_LRECR0)

This is the LAC receive error capture register 0. Software must clear the error condition(s) to capture the next error information.

The following error conditions will capture :

- Receive packet error - RXPE

Address: 22_8000h base + E14h offset = 22_8E14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

LAC_LRECR1 field descriptions

Field	Description
0–31 SWPnRSR_ word_1	SWPnRSR word 1 associated with the error.

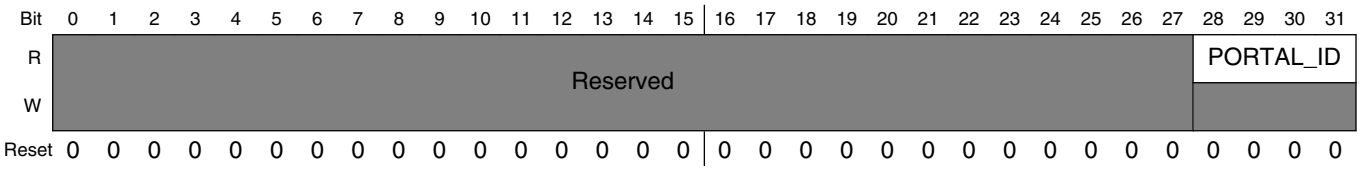
21.3.84 LAC receive error capture register 2 (LAC_LRECR2)

This is the LAC receive error capture register 2. Software must clear the error condition(s) to capture the next error information.

The following error conditions will capture :

- Receive packet error - RXPE

Address: 22_8000h base + E1Ch offset = 22_8E1Ch



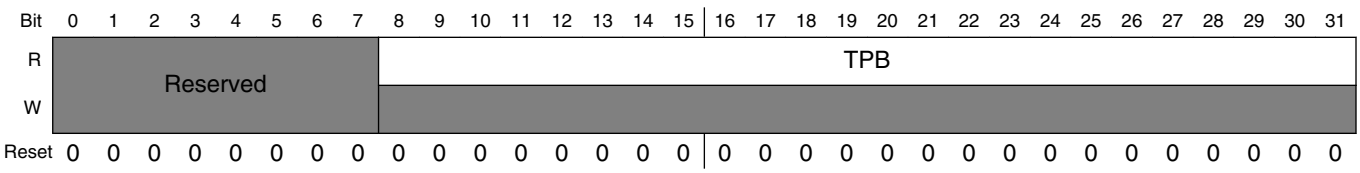
LAC_LRECR2 field descriptions

Field	Description
0–27 -	This field is reserved. Reserved
28–31 PORTAL_ID	Portal ID associated with the error.

21.3.85 LAC Transmit status register (LAC_LTSR)

The LAC transmit status register reports LAC transmit portal status.

Address: 22_8000h base + F00h offset = 22_8F00h



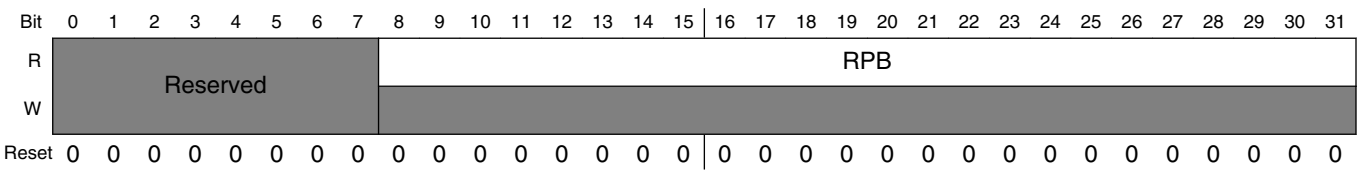
LAC_LTSR field descriptions

Field	Description
0–7 -	This field is reserved. Reserved
8–31 TPB	transmit portal busy, each bit corresponds to the status of a single portal, i.e. bit 8 indicating port 23 statsus, port 9 indicating port 22 status, and so on. 0 transmit portal is idle 1 transmit portal is processing a packet.

21.3.86 LAC receive status register (LAC_LRSR)

The LAC receive status register reports LAC receive portal status.

Address: 22_8000h base + F04h offset = 22_8F04h



LAC_LRSR field descriptions

Field	Description
0–7 -	This field is reserved. Reserved
8–31 RPB	receive portal busy, each bit corresponds to a single portal status, , i.e. bit 8 indicating port 23 statsus, port 9 indicating port 22 status, and so on. 0 receive portal is idle 1 receive portal is processing a packet.

21.4 LAC Software Portal Memory Map/Register Definitions

The entire software portal memory map occupies 128 KB memory space. Each software portal occupies 4 KB consecutive memory space accessible through system memory map. The upper address bits indicates software portal ID.

21.4.1 Software Portal transmit command register (LAC_SP_SWP*n*TCR)

This register provide transmit control packet content.

Register Offset	0x000
Reset	0x0000_0000_0000_0000
Access	RW

LAC_SP_SWP*n*TCR field descriptions

Field	Description
0 GO	Data is ready to be sent on transmit side 0 Data is not ready to be sent 1 The data written to transmit data registers is ready to be sent on transmit side
1 -	This field is reserved. Reserved
2–3 CHAN	The channel number to be sent alone with the Interlaken LA control word. Note bit 2 is reserved in 2 channel mode
4–9 -	This field is reserved. Reserved
10–15 EOP_format	This field refers to the highest order transmit data register that has been written prior to writing EOP to SWPnTCR. End of packet with bits [10:15] indicating the number valid bytes in the highest order transmit data register. Bits[10:15] are encoded such that '000000' means all 64 bytes are valid, 000001 means 1 byte valid, etc.
16–31 -	This field is reserved. Reserved
32–46 AppData0	Application specific data associated with newly started packet. This field corresponds to application specific 0 in Look-Aside control packet. Note that 6 bit of AppData0[0:14] are reserved for PORT ID. the location of the PORT ID is determined according to LMR[PID_LOC] encoding. AppData0[13:14] are ignored in 4-channel mode
47–52 AppData1	Application specific data associated with newly started packet. This field corresponds to application specific 1 in Look-Aside control packet. AppData1[5] is ignored in 4-channel mode
53–60 AppData2	Application specific data associated with newly started packet. This field corresponds to application specific 2 in Look-Aside control packet
61–63 -	This field is reserved. Reserved

21.4.2 Software Portal transmit error register (LAC_SP_SWP*n*TER)

This register contains error indication related to software portal n. ERR_EC reflects next error encoding when ERR is cleared by the software.

NOTE

Global soft reset cannot clear software portal TER errors. These need to be manually cleared if errors were detected prior to the assertion of global soft reset since it does not apply to them.

Register Offset	0x040
Reset	0x0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000
Access	RW

LAC_SP_SWP*n*TER field descriptions

Field	Description
0 ERR	Indicates a transmit packet has been dropped due to TXE error.
1–7 -	This field is reserved. Reserved
8–9 ERR_EC	Error encoding. 00 SWPnTCR[GO]=1, but no SWPnDRm has been written since last command with GO. 01 SWPnTCR[GO]=1, but there are gaps between SWPnTDR registers, e.g. SWPnTDR0 and SWPnTDR2 are written, but SWPnTDR1 was never written . 10 Packet is dropped due to the outstanding packet data exeeced the allocated amount 11 reserved
10–511 -	This field is reserved. Reserved

21.4.3 Software Portal transmit data register 0 (LAC_SP_SWP*n*TDR0)

This register contains data to be sent out on Interlaken links. Note that the highest order SWPnTDR register written may not have all the bytes valid if SWPnTCR has both GO and EOP_Format set as non 0.

Register Offset	0x100
Reset	0x0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000

Field	Description
0–511 Data	Data received through Interlaken links.

21.5 Functional Description

The following sections describe the functionality of the Interlaken LA controller in details.

21.5.1 Software portal operation

Software portals are used by software running on processor cores to communicate with the LAC.

There are 24 partitioned software portals in LAC. Each portal is mapped to 4K byte region that is intended to be private to initiator using it. Each software portal can independently send out LA packets according to transmit commands or receive LA packets and prepare receive status/data. The software portal space is intended to be cache-enabled. WIMG for each software space is required to be 0010 if stashing is enabled for the corresponding software portal, otherwise, WIMG can be 0000 or 0010. All IO initiators are required to have transaction size to be 64 byte, and stashing has to be disabled in this case.

LAC is guaranteed to accept up to 2 outstanding packets per portal when the number of enabled portal is 24 or 16. 4 outstanding packets per portal are accepted when the number of enabled portal is 12, 8, 4, 2 or 1. Each software portal needs to track its own number of outstanding packet , ensuring that it does not exceed the allocated amount, otherwise LAC could drop the packets from this software portal. In the event the LAC drops packet, it sets LEDR[TXE] in global register space and SWPnRSR[DRP] bit in software portal space.

21.5.1.1 Transmit software portal

From the LAC perspective, SWPnTCR and SWPnTDR[0-3] are read only. The LAC does not modify the data in these registers.

Since the software portal space is cache-able, to issue a Interlaken LA transmit packet, software must:

1. Do the following steps to write to SWPnTDR[0-m], where m = INT(data_size/64).
    a. Use dcbz to zero and allocate the entry in the processor's cache without reading it
    b. Write the data to SWPnTDRi address
    c. Use dcbf to flush the entry from cache and write into SWPnTDRi registers stored in the LAC
    d. If i<m, increment i, go back to step a).
    e. Note that SWPnTDR[0-m] are in order, i.e. SWPnTDR0 contains the first 64 byte data, SWPnTDR1, the second 64 byte data, and so on.
2. When all data has been written, prepare and write SWPnTCR
    a. Use dcbz to zero and allocate the entry in the processor's cache without reading it
    b. Prepare command, including GO/SOP/EOP_format, note that command is only valid when GO=1.
    c. Write 8 byte command to SWPnTCR address
    d. Use dcbf to flush the entry from cache and write into SWPnTCR registers stored in the LAC

SWPnTCR and SWPnTDR[0-3] are readable to accomodate a castout that may happen prior to dcbf while the data or command is being written. A read from SWPnTCR or SWPnTDR returns the cache granule data that has been last written. Once SWPnTCR[GO] is written to the LAC, SWPnTDR registers are ready to be written with new data, the previous data residing in SWPnTDR registers is not accessable anymore.

21.5.1.2 Receive software portal

In order to receive Interlaken LA packet data, software must:

1. Keep reading SWPnRSR until SWPnRSR[RDY] is set.
   - Note that when LSRER[SEn] is set LAC stashes SWPnRSR when it sets RDY bit.
   - When LSRER[SEn] is cleared, software must issue dcbf each time after SWPnRSR read returns and RDY bit is not set.
2. Read SWPnRDR[0-m], where m is indicated by encoding of SWPnRSR[Data mask]
   - Use dcbf to flush the entry
   - Use dcbt to load the cache line. Note SWPnRDRs are read-only registers
3. When software has processed all SWPnRDR data, it needs to clear SWPnRSR[RDY]:
   - Use dcbz to zero and allocate the entry in the processor's cache without reading it
   - Use dcbf to flush the entry from cache and write into SWPnRSR registers stored in the LAC
   - Go back to step 1 if there is more packet data to be received.

Note that software is not supposed to modify the data in SWPnRDR registers. All writes to SWPnRDR[0-3] are simply dropped. Once SWPnRSR[RDY] bit is cleared, SWPnRDR registers are loaded with the next receive Interlaken LA packet data, the previous data in SWPnRDR registers is not accessable anymore. Per software portal, the ordering in which packets are received from TCAM is maintained.

21.5.2 Error management and recovery

There are three types of errors, LAC transmit, LAC receive, and LA MAC error. The error checking level indicates the order in which errors are checked. Once an error is detected, no additional error checking beyond the current level is performed. The first error detected in the processing pipeline updates the error capture registers. Note that error is not captured for RXE error, since receive data is not reliable when RXE is detected.

21.5.2.1 LAC Transmit error

The table below lists transmit errors detected by the Interlaken LA controller. In summary, transmit errors are reported in two ways:

1. SWPnTER[ERR] is set with the corresponding ERR_EC
2. SWPnRSR[DRP] is set so that the corresponding software portal can be informed.
3. Global error reporting. Transmit errors are reported globally in the error detect register, LEDR[TXE] and error interrupt is generated if correcponding interrupt enable LEIER[TXEIE] is set. Transmit command and portal ID are captured in transmit error capture registers

Table 21-2. LAC transmit errors

Error	Interrupt Generated	Status Bit Set	Comments
SWPnTCR[GO]=1, but no SWPnTDRm has been written since last command with GO.	LAC error interrupt if LEIER[TXEIE] is set	Transmit error, LEDR[TXE]	Transmit command and portal ID are captured in transmit error capture registers, SWPnTER[ERR] is set with SWPnTER[ERR_EC]=00. The corresponding SWPnRSR has DRP bit set
SWPnTCR[GO]=1, but there are gaps between SWPnTDR registers.	LAC error interrupt if LEIER[TXEIE] is set	Transmit error, LEDR[TXE]	Transmit command and portal ID are captured in transmit error capture registers, SWPnTER[ERR] is set with SWPnTER[ERR_EC]=01. The corresponding SWPnRSR has DRP bit set
the incoming packet is dropped due to the amount of outstanding packet data exceeding the allocated amount according to LMR[NUM_PORT]	LAC error interrupt if LEIER[TXEIE] is set	Transmit error, LEDR[TXE]	Transmit command and portal ID are captured in transmit error capture registers, SWPnTER[ERR] is set with SWPnTER[ERR_EC]=10.The corresponding SWPnRSR has DRP bit set.

21.5.2.2 LAC Receive error

The table below lists the receive errors detected by the Interlaken LA controller. In summary, receive errors are reported in two ways:

1. SWPnRSR[ERR] is set when processor core read SWPnRSR.
2. Global error reporting. receive errors are reported globally in the error detect register, LEDR[RXE] or LEDR[OVE] or LEDR[RXPE] and error interrupt is generated if corresponding interrupt enable LEIER[RXEIE] or LEIER[OVEIE] or LEIER[RXPEIE] is set.

Table 21-3. LAC receive errors

Error	Interrupt Generated	Status Bit Set	Comments
CRC24 error or or other errors (bad 64/67 word type, a violation of the min/max burst size) is received on Interlaken links	LAC error interrupt if LEIER[RXEIE] is set	receive error, LEDR[RXE]	LAC drops received packets when the error is detected
The LAC receive storage is overflown	LAC error interrupt if LEIER[OVEIE] is set	overflow error, LEDR[OVE]	LAC drops received packets when the error is detected
The LAC received EOP with error packet indication	LAC error interrupt if LEIER[RXPEIE] is set	receive packet error, LEDR[RXPE]	LAC drops received packets when the error is detected

21.5.2.3 LAC MAC error

TXME and RXME are treated the same way as un-recoverable RXE or OVE

Table 21-4. LAC MAC errors

Error	Interrupt Generated	Status Bit Set	Comments
RXME is detected on the receive Interlaken LA packets	LAC error interrupt if LEIER[RXMEIE] is set	Receive MAC error, LEDR[RXME]	
TXME is detected on the receive Interlaken LA packets	LAC error interrupt if LEIER[TXMEIE] is set	Transmit MAC error, LEDR[TXME]	

21.5.3 Soft reset behavior

21.5.3.1 Global soft reset

Global soft reset is activated by setting LMR[GSR]. The following behavior is expected:

1. LAC starts to return 0 to software portal reads and drops software portal write except transactions accessing SWPnRSR.
2. LAC starts cleaning up internal buffers.
3. LAC stops sending transmit packets and drops receive packets.
4. LAC clears MACE, which reset Interlaken LA core.
5. LAC sets SWPnRSR[GSR] bit on all software portals.
6. Each software portal writes to SWPnRCR[GSRCLR] to clear GSR.

7. Each software portal enters polling mode when it reads back GSR to detect setting of GSR_DONE bit, i.e. read SWPnRSR, if GSR_DONE is not set, issues dcbf and read again.
8. Software issues command to reset the device connecting through the Interlaken links.
9. Software clears LMR[GSR] when the external device has been reset.
10. Upon detecting LMR[GSR] clearing by software, LAC sets GSR_DONE for all the software portals.
11. Each software portal writes to SWPnRCR[GSRDCLR] to clear GSR_DONE.
12. LAC starts accepting command through software portal.

21.5.3.2 Local soft reset

The register LSWPSRR is used by software to softreset each individual software portal.

1. SWPnRSR[SR] is set
2. LAC starts to return 0 to sowftware portal reads and drops software portal write execept transactions accessing SWPnRSR and SWPnRCR.
3. LAC controller stops setting RDY bit for all received packets to this portal, while the outstanding packet number is still being decremented for each dropped packet.
4. Software portal issues write to SWPnRCR[SRCLR] to clear SWPnRSR[SR], this is to flush out all outstanding requests issued by this software portal.
5. Software keeps polling SWPnRSR to get OPC, i.e. read SWPnRSR, if OPC is not 0, issues dcbf and read again.
6. LAC clears corresponding SRn bit in LSWPSRR when OPC becomes zero.
7. Software portal can start issuing new transmit packets when OPC becomes 0.

21.6 Initialization Information

The following steps are recommended for correct device initialization:

- Global register initialization
  a. Write to LBARE and LBAR to be the same as LAWs registers allocated to LAC memory space. Note that the memory map window has to be 128KB in size.
  b. Clear the error detect register by writing a 1 to the fields.
  c. Write to error interrupt enable register to enable corresponding error interrupt.
  d. Initialize the configuration registers:
     1. Lane Disable
     2. 0x410, 0x610 - Config Register
     3. Remap Lane Registers
     4. Burst Config Register

5. 0x434, 0x634 - MetaFrame Synchronization Register
6. Transmit Rate Limiter Register 0
7. Transmit Rate Limiter Register 1

e. write to LSRER to enable stashing if stashing is desired
f. write to LMR to setup NUM_PORT
g. the above steps can be done in any order. Write to LMR to enable MACE

- Software portal initialization
  a. Software portal issues write 0 to clear SWPnRSR[SR], this is flush out all outstanding requests issueed by this software portal.
  b. Software keeps polling SWPnRSR to get OPC.
  c. Software portal can start issuing new transmit packets when OPC becomes 0.
  d. Each software portal writes 0 to SWPnRSR.
  e. Each software portal writes 0 to SWPnTER to clear error bit.
  f. Each software portal writes to SWPnTDR and SWPnTCR to start sending out transmit packets.

Chapter 22
SATA Controller

22.1 SATA overview

The serial ATA controller is a high-performance SATA solution incorporating some of the latest SATA-IO extensions. The SATA may also be referred to as a host bus adapter (HBA). The SATA controller is designed to operate in a system that supports command queuing and, in particular, a switching scheme based on a frame information structure (FIS) using port multipliers.

FIS-based switching requires the SATA controllers to maintain in hardware a context for each command it has queued at the devices that are attached to it. FIS-based switching also requires the SATA controller to maintain a queue per attached device ensuring that the command issue order for each device is maintained. It can be used in SATA controllers, as well as storage area network (SAN), network attached storage (NAS), and RAID (redundant array of independent/inexpensive disks) devices.

22.2 SATA features

SATA controller includes the following features:

- Complies with *Serial ATA 2.6 Specification*
- Supports both speeds: 1.5 Gbps (first-generation SATA), and 3 Gbps (second-generation SATA)
- Supports FIS-based switching
- Supports advanced technology attachment packet interface (ATAPI) devices
- Contains high-speed descriptor-based DMA controller
- Supports native command queuing (NCQ) commands
- Supports port multiplier operation
- Supports hot plug including asynchronous signal recovery

This figure shows the SATA block diagram.

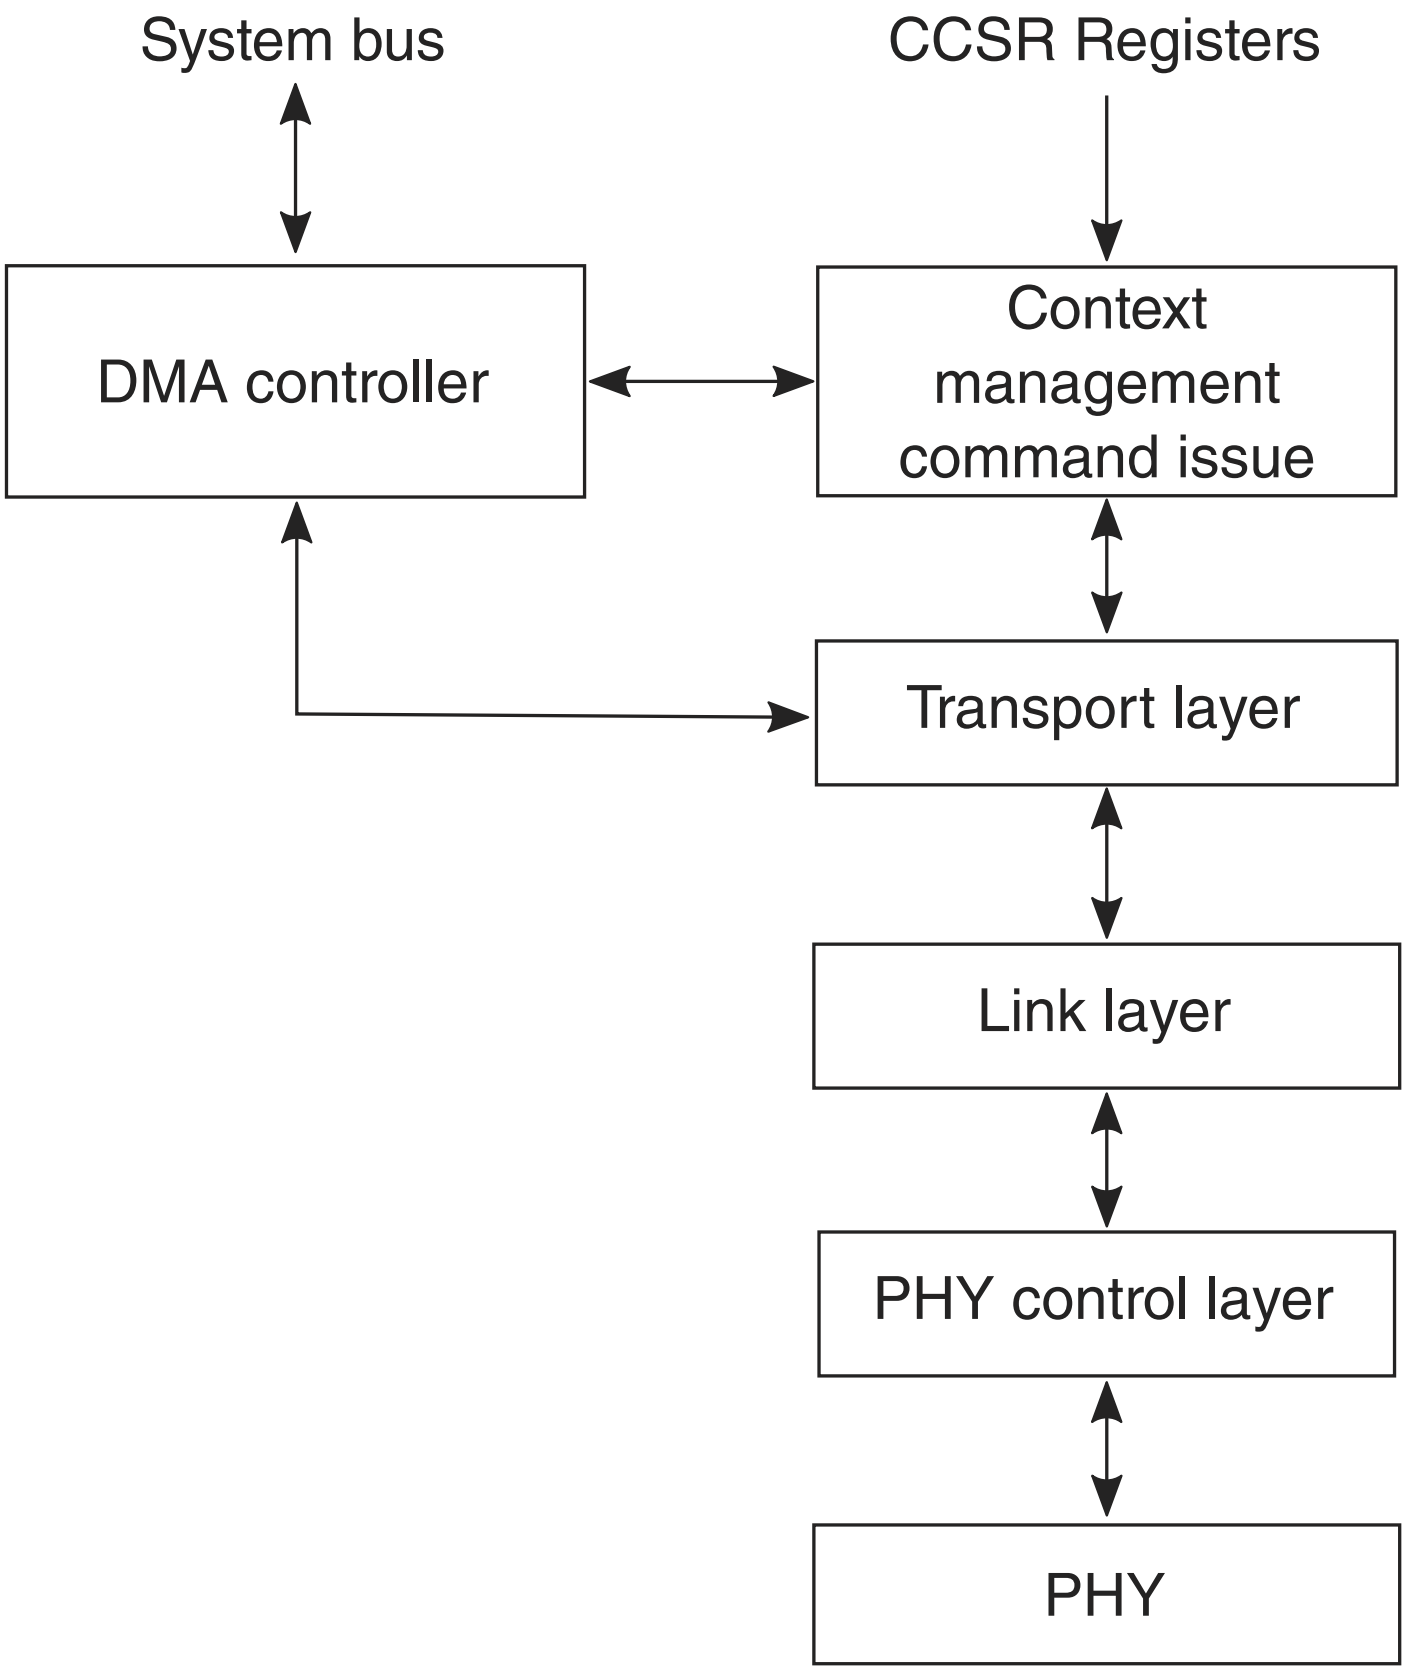

Figure 22-1. SATA block diagram

There are four layers in SATA architecture:

- Application layer: It is responsible for overall ATA command execution, including controlling command block register accesses
- Transport layer: It is responsible for placing control information and data to be transferred between the host and device in a packet/frame, known as a frame information structure (FIS)
- Link layer: It is responsible for taking data from the constructed frames, inserting control characters and moving data to the PHY layer
- PHY layer: It is responsible for 8B/10B encoding/decoding, then transmitting and receiving the encoded information as a serial data stream on the wire

22.3 SATA memory map/register definition

This table shows the memory map for the SATA registers. The offsets to the memory map table are defined for both SATA hosts. Undefined 4-byte address spaces within offset 0x000-0xFFF are reserved.

NOTE

All registers (except SYSPR) described in this section and descriptors described in Command header and Command descriptor use little-endian byte ordering. Software running on the local processor in big-endian mode must byte-swap the data.

SATA memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
22_0000	Command queue register (SATA1_CQR)	32	R/W	0000_0000h	22.3.1/2051
22_0008	Command active register (SATA1_CAR)	32	R	0000_0000h	22.3.2/2052
22_0010	Command completed register (SATA1_CCR)	32	w1c	0000_0000h	22.3.3/2052

22.3.1 Command queue register (SATAx_CQR)

Before queuing a command into the SATA controller, the CQR is first examined to detect a free command queue (CQ) slot. A free CQ slot is indicated by a 0 in a bit position. To queue a command, the bit corresponding to the CQ slot to use is set. At this point the SATA controller takes ownership of the command header space and command descriptor associated with the command slot. While the command is queued in the SATA controller or at the device, the command queue bit remains 1. When the command completes, this bit is cleared to 0 by the hardware. For a device error, the CQR holds the command queue bits at 1 for each command queued or issued to the device in error. When the host software clears the device error, the hardware in turn clears each of the commands queued.

Address: Base address + 0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SATAx_CQR field descriptions

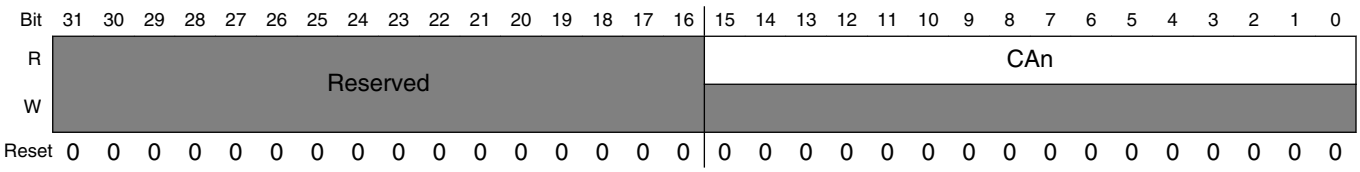
Field	Description
31–16 -	This field is reserved. Reserved
CQn	Command *n* queue bit

22.3.2 Command active register (SATAx_CAR)

When a command is issued from the SATA controller to the device, the command is marked as active by the hardware setting the appropriate command active bit of the CAR. Once a command completes, the hardware clears the appropriate bit of the CAR.

For a device error, the CAR holds the command active bits at 1 for each command issued to the device in error. When the host software clears the device error, the hardware in turn clears each of the commands queued.

Address: Base address + 8h offset



SATAx_CAR field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
CAn	Command n active bit

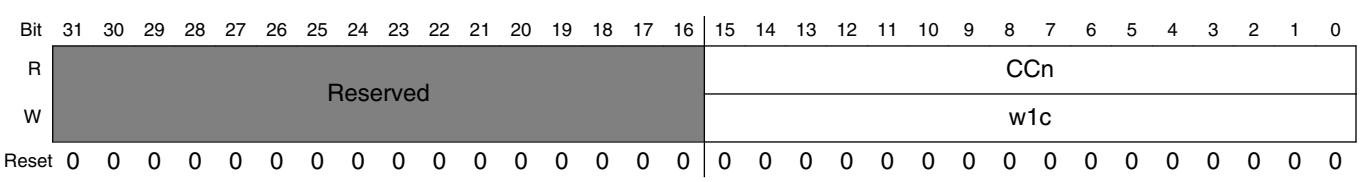
22.3.3 Command completed register (SATAx_CCR)

When a command completes, the hardware sets the command completed bit for that command in the CCR to a 1. The hardware also clears both the command queue and the command active bit for that command. When the software needs to acknowledge the reception of the completed command, it can do so in two ways:

- Writing a 1 to the command complete bit
- Issuing a command to the command slot

An interrupt coalescing scheme runs on the CCR. When the register contains a value other than 0x0000_0000, an interrupt coalescing timer runs. Each time a command completion is acknowledged, the timer is reset. When the timer times out, an interrupt is generated.

Address: Base address + 10h offset



SATAx_CCR field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
CCn	Command n completed bit

22.3.4 Command error register (SATAx_CER)

When a device errors a command by setting the error bit in the status register, this is detected by the SATA controller as a single device error. The associated command completing due to error is indicated by the hardware setting the command error bit for that command in the CER . For safe operation under both command queuing and non-queuing operation, all commands queued into the SATA controller and at the device are considered aborted. The queue for that device is stopped. The values of the registers CQR, CAR, and CCR will allow the host software to know which commands have completed without error and those that were queued at the SATA controller and at the device.

When the host software clears the device error (by setting DER), the software is also responsible to clear CER by writing a 1 to the command error bit for the command that was in error. After the error condition at the device has been cleared, the host application software can reissue the commands to the SATA controller, which were aborted on the reception of the single device error.

Address: Base address + 18h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SATAx_CER field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
CEn	Command n error bit

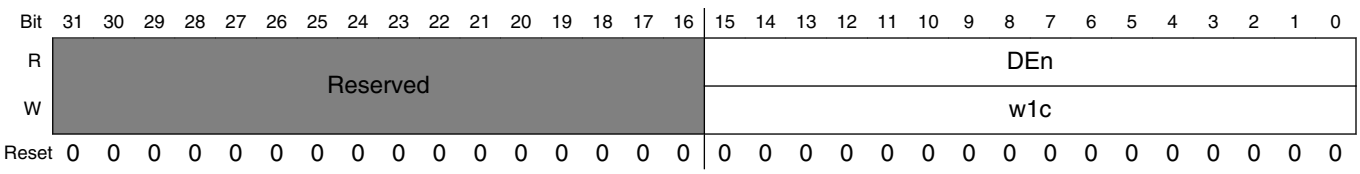
22.3.5 Device error register (SATAx_DER)

When a single device error is detected, the device that issued the error is indicated by the hardware setting the device error bit in the DER. The procedure as outlined in the command error register applies to the queues and to restarting the device.

The host application software acknowledges the device in error by clearing the device error bit. The device error is cleared by writing a 1 to the appropriate device error bit. When this action is performed, the queue to the device in error is cleared and is ready to have commands queue.

While a device is in error, no command can be queued for that device.

Address: Base address + 20h offset



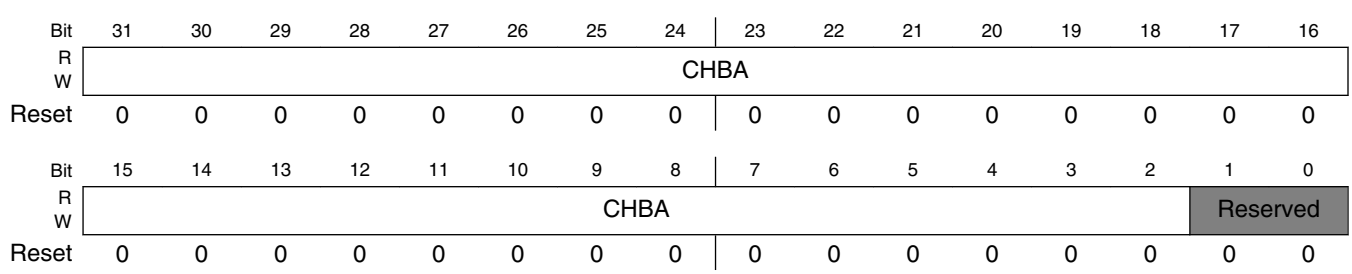
SATAx_DER field descriptions

Field	Description
31–16 -	This field is reserved. Reserved
DEn	Device n error bit

22.3.6 Command header base address (SATAx_CHBA)

The CHBA holds the address in memory of where the command header block is located. It must be written as part of the host software initialization process. After the SATA controller hardware is brought online, the SATA controller takes ownership of this register. The address in this register should not be changed while the SATA controller is online.

Address: Base address + 24h offset



SATAx_CHBA field descriptions

Field	Description
31–2 CHBA	Command header base address
-	This field is reserved. Reserved, should be 00.

22.3.7 Host status register (SATAx_HStatus)

HStatus, holds the status of the SATA controller as well as the interrupt sources. When an event occurs, the interrupt bit is set regardless of the status of the associated interrupt enable bit. The interrupt signal from the SATA controller is gated with the associated interrupt enable register. For all interrupt bits other than the interrupt on command complete bit, when software has processed the interrupt condition, it acknowledges the interrupt by writing a 1 to the interrupt source bit. This action will clear the interrupt signal if there are no other outstanding interrupts in HStatus.

The interrupt on command complete requires special processing. This bit is set as a result of the programmed interrupt coalescing algorithm running on the register CCR contents. For the interrupt on command complete bit, the command(s) that have completed to cause this interrupt need to be cleared by clearing the command N completed bit of the CCR. When the number or staleness of the CCR falls below the programmed interrupt coalescing algorithm, the interrupt on command complete bit clears.

Address: Base address + 28h offset

SATAx_HStatus field descriptions

Field	Description
31 HS_ON	Online/offline. This bit indicates if the SATA controller is online or offline. 0 Offline. The SATA controller is non-operational and the PHY is held in reset. 1 Online. The SATA controller is operational.
30 HS_OFF	Going offline. This bit indicates that the SATA controller is going offline it is waiting for the commands queued within the SATA controller or active at the device to complete. 0 Host is not in process going offline 1 Host is in process going offline
29 BE	BIST error. When the protocol is placed into BIST, this bit maps the BIST error. 0 Indicates that the link layer is passing BIST 1 Indicates that the link layer is not passing BIST When the protocol is not in BIST this bit asserts high and can be ignored.
28 OP_MODE	Operating mode. 0 The host controller is operating in legacy mode. 1 The host controller is operating in enterprise mode.
27–19 -	This field is reserved. Reserved
18 ME	SATA controller master error. Indicates if the host received an error on the interface during the access to memory. 0 No error response is received when a transfer was made into the memory 1 Error response is received during the transfer into the memory
17 PTx_ERR	SATA controller parity Tx error. 0 No parity errors were detected on Tx data path 1 One or more parity errors were detected on Tx data path
16 PRx_ERR	SATA controller parity Rx error. 0 No parity errors were detected on Rx data path 1 One or more parity errors were detected on Rx data path
15–13 -	This field is reserved. Reserved

Table continues on the next page...

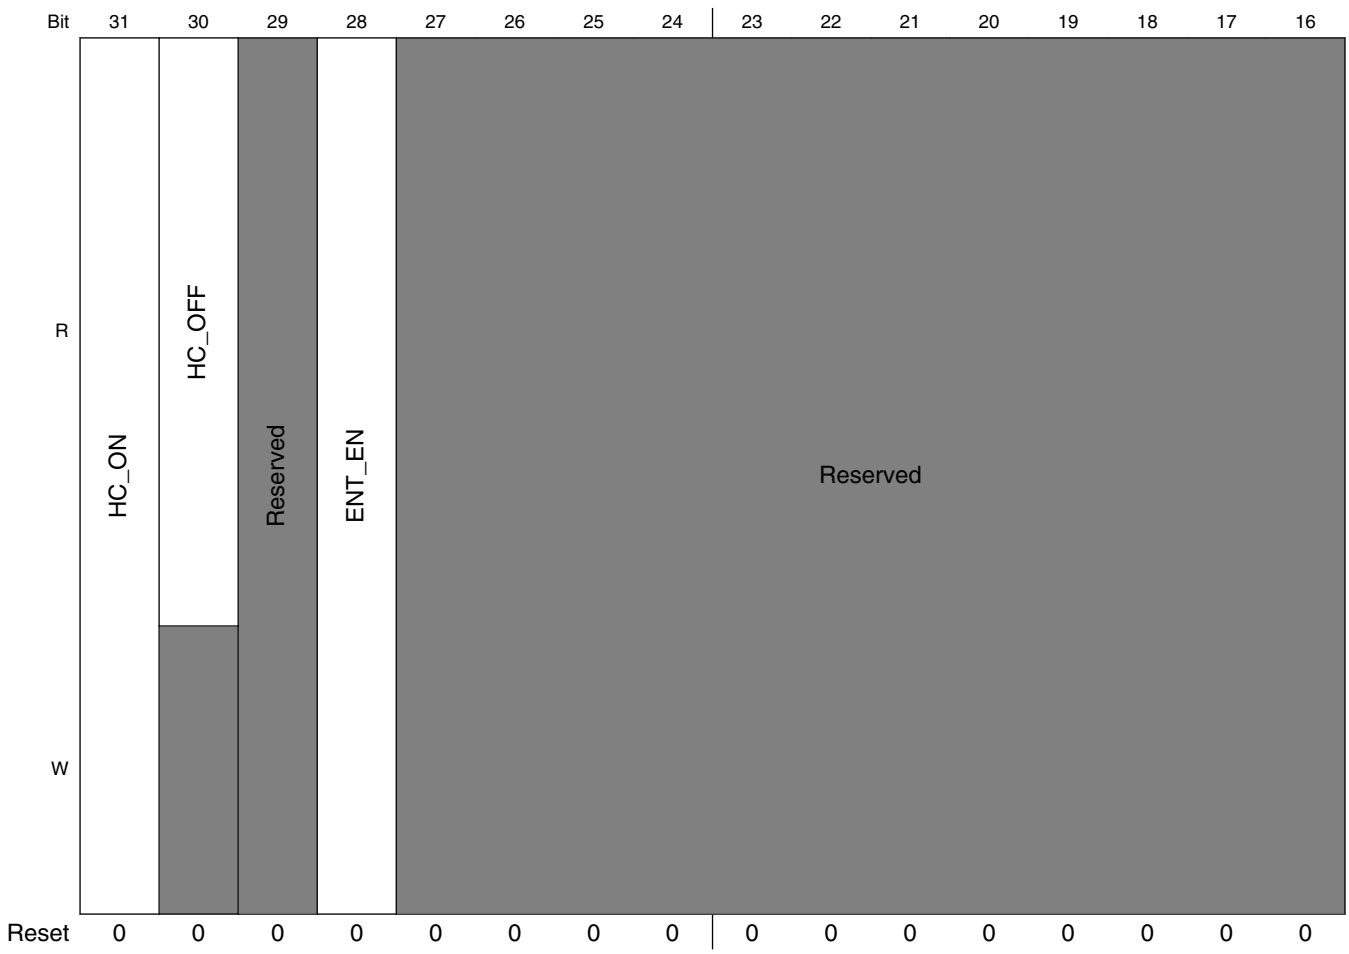
SATAx_HStatus field descriptions (continued)

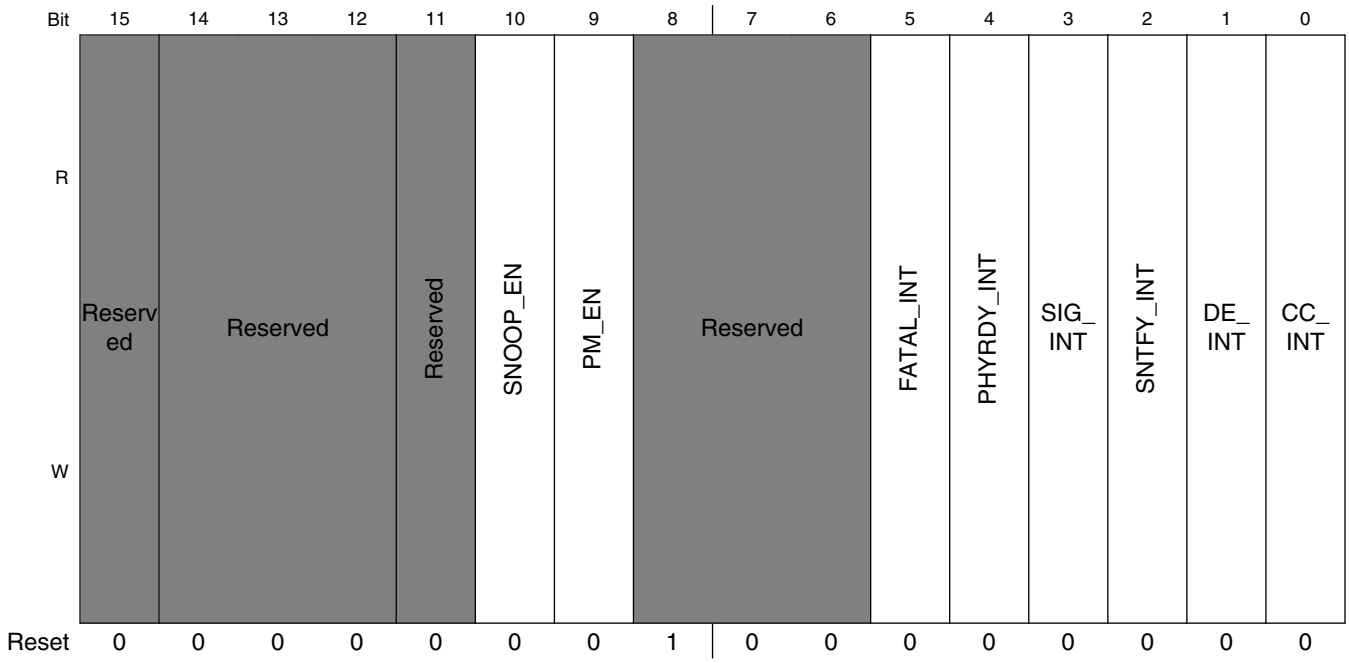
Field	Description
12 DLM	Data Length Mismatch
11 CET	CRC error Tx. When set, this bit indicates that one or more CRC errors occurred in Tx data path.
10 CER	CRC error Rx. When set, this bit indicates that one or more CRC errors occurred in Rx data path.
9 FOT	FIFO overflow Tx. When set, this bit indicates that Tx FIFO is in overflow condition while sending FIS.
8 FOR	FIFO overflow Rx. When set, this bit indicates that Rx FIFO is in overflow condition while receiving FIS.
7–6 -	This field is reserved. Reserved
5 FE	Fatal error. When set, this bit indicates that fatal error occurred in SATA controller. In this state, the interrupt will be generated if FATAL_INT is set in the host control register. Write '1' to clear the interrupt source.
4 PR	PHY ready. When set, this bit indicates that PHY READY signal was changed. In this state, the interrupt will be generated if PHYRDY_INT is set in the host control register. Write '1' to clear the interrupt source.
3 SIGU	Signature update. When set, this bit indicates that the signature is updated in the host signature register. In this state, the interrupt will be generated if SIG_INT is set in the host control register. Write '1' to clear the interrupt source.
2 SNTFU	SNotification update. When set, this bit indicates that the SNotification register has at least one bit set. In this state, the interrupt will be generated if SNTFY_INT is set in the host control register. Write '1' to clear the interrupt source.
1 DE	Device error. When set, this bit indicates that the DE register has at least one bit set. In this state, the interrupt will be generated if DE_INT is set in the host control register. Write '1' to clear the interrupt source.
0 CC	Command complete. When set, this bit indicates that the register CCR has at least one bit set. In this state, the interrupt will be generated if CC_INT is set in the host control register. Write '1' to clear the interrupt source.

22.3.8 Host control register (SATA*x*_HControl)

HControl is written to control the operation of the SATA controller. To enable an interrupt, the associated bit must be set; to disable the interrupt, the associated bit must be cleared.

Address: Base address + 2Ch offset





SATAx_HControl field descriptions

Field	Description
31 HC_ON	Online/offline control 0 Offline. Bring the SATA controller offline and place the PHY in reset 1 Online. Bring the SATA controller online
30 HC_OFF	Offline request status. This is a read only bit. 1 The SATA controller is currently completing an operation and will go offline when the operation completes. When this bit is set , the SATA controller can be forced to go offline by aborting its current operation by writing 0 to the HC_ON bit.
29 -	This field is reserved. Reserved
28 ENT_EN	Enterprise enable bit 0 Switch the host controller to enterprise mode. Can only be achieved when the host is offline 1 Switch the host controller to legacy mode. Can only be achieved when the host is offline
27–15 -	This field is reserved. Reserved
14–12 -	This field is reserved. Reserved. Reset value must be preserved when writing to the register.
11 -	This field is reserved. Reserved
10 SNOOP_EN	Snoop enable during header fetch. 0 Snoop not enabled during command header fetch. 1 Snoop enabled during command header fetch.
9 PM_EN	Port multiplier attached. This bit is used to indicate if the HBA is attached to a port multiplier. This bit is set or cleared by software.

Table continues on the next page...

SATAx_HControl field descriptions (continued)

Field	Description
	0 This SATA controller is directly attached to a SATA device. The SATA controller hardware does not auto-detect the presence of a port multiplier; this is to allow for future changes in signature type for the port multiplier. 1 A port multiplier is attached to the SATA controller.
8–6 -	This field is reserved. Reserved. Reset value must be preserved when writing to the register.
5 FATAL_INT	Enable interrupt on fatal error
4 PHYRDY_INT	Enable interrupt on PHY ready change
3 SIG_INT	Enable interrupt signature update
2 SNTFY_INT	Enable interrupt on SNotify register update
1 DE_INT	Enable interrupt on single device error
0 CC_INT	Enable interrupt on command complete

22.3.9 Port number queue register (SATAx_CQPMP)

When queuing a command into the SATA controller, the CQPMP is written with the value of the PMP field that addresses the device to which the command will be issued. If the device is directly attached (that is, there is no port multiplier in the system), then this register is not required and should be cleared.

Address: Base address + 30h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
31–24 LBA_HIGH	LBA high register
23–16 LBA_MID	LBA mid register
15–8 LBA_LOW	LBA low register
SEC_CNT	Sector count register

22.3.11 Interrupt coalescing control register (SATA*x*_ICC)

When a command completes, the SATA controller sets the corresponding bit in the command completed register. The interrupt coalescing scheme runs on the SIG register. The scheme runs in two ways:

- If the number of completed commands exceeds the threshold, then the interrupt will be signaled.
- If any command complete bit has been set in the register for a number of HCLK ticks equal to the programmed count, then the interrupt will be set. This timer will be reset each time a command completion is acknowledged by the application layer software.

Address: Base address + 38h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SATAx_ICC field descriptions

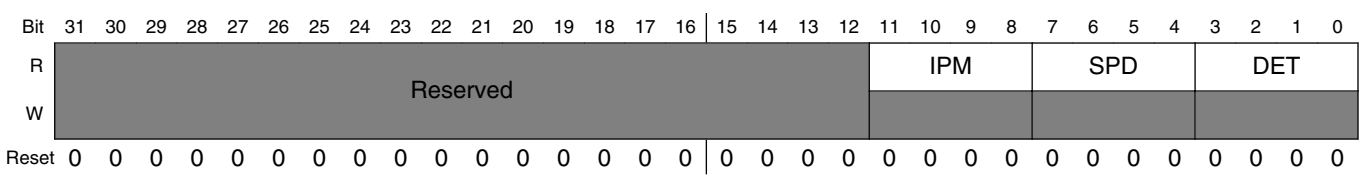
Field	Description
31–29 -	This field is reserved. Reserved
28–24 ITC	Interrupt threshold count. The number of command completions that will raise the interrupt. 00000 Implied no threshold and the interrupt will be signaled based on the threshold timer. 00001 The number of command complete bits which, if set, will cause the interrupt to be signaled. 01111 The number of command complete bits which, if set, will cause the interrupt to be signaled.
23–19 -	This field is reserved. Reserved
ITTCV	Interrupt threshold timer compare value. A value of 0 indicates that whenever a command complete bit is set the interrupt should be signaled.

22.3.12 SATA interface status register (SATAx_SStatus)

Serial ATA provides an additional block of registers to control the interface and to retrieve interface state information.

SStatus is a 32-bit read-only register that conveys the current state of the interface and host adapter. The register conveys the interface state at the time it is read and is updated continuously and asynchronously by the host adapter. Writes to this register have no effect.

Address: Base address + 100h offset



SATAx_SStatus field descriptions

Field	Description
31–12 -	This field is reserved. Reserved
11–8 IPM	Interface power management state. Indicates the current interface power management state. All other values reserved 0000 Device not present or communication not established 0001 Interface in active state 0010 Interface in partial power management state 0110 Interface in slumber power management state
7–4 SPD	Speed. Indicates the negotiated interface communication speed established. All other values reserved

Table continues on the next page...

SATAx_SStatus field descriptions (continued)

Field	Description
	0000 No negotiated speed (device not present or communication not established) 0001 First-generation communication rate negotiated 0010 Second-generation communication rate negotiated
DET	Detection. Indicates the interface device detection and PHY state. All other values reserved 0000 No device detected and PHY communication not established 0001 Device presence detected but PHY communication not established 0011 Device presence detected and PHY communication established 0100 PHY in offline mode as a result of the interface being disabled or running in a BIST loopback mode

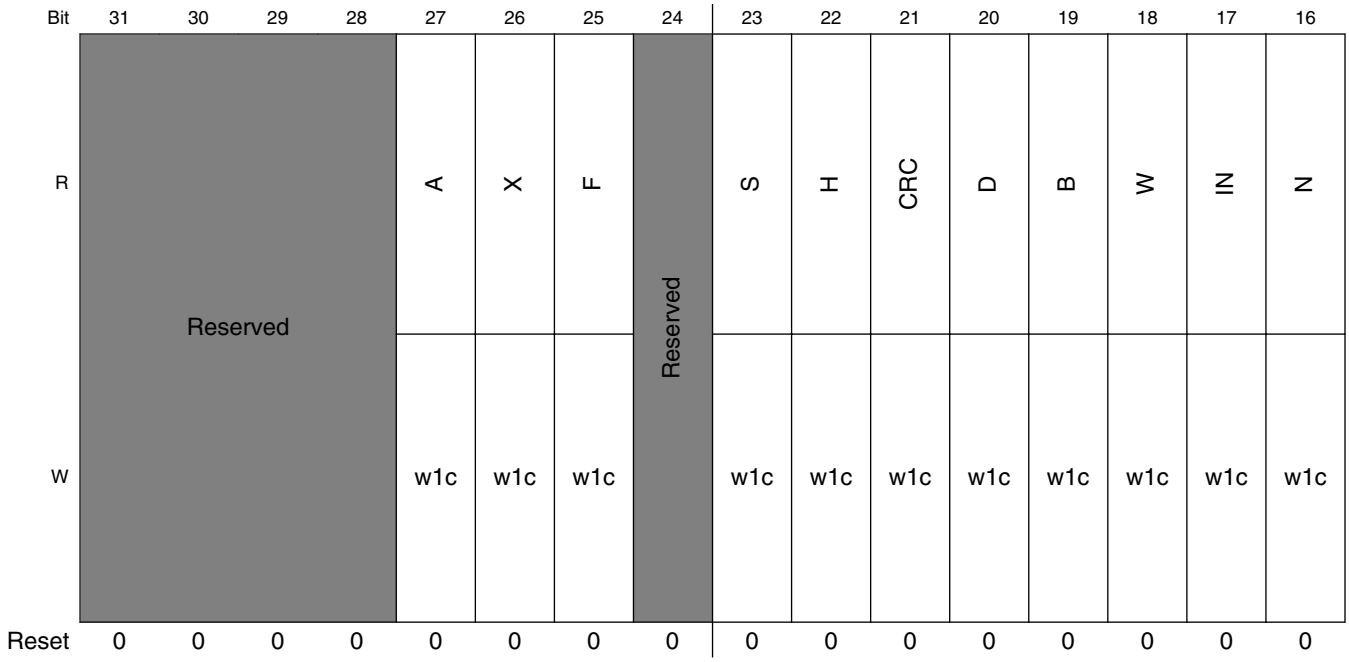
22.3.13 SATA interface error register (SATAx_SError)

SError is a 32-bit register that conveys supplemental interface error information to complement the error information available in the shadow register block error register. The register represents all the detected errors accumulated since the last time the SError register was cleared (whether recovered by the interface or not). Set bits in the error register are explicitly cleared by a write operation to the SError register or by a reset operation. The error bits that have been set in this register are cleared by writing a 1 to the corresponding field. Host software should clear the interface SError register at appropriate checkpoints in order to best isolate error conditions and the commands they impact.

Bits 31-16 of this register represent the DIAG decode bits, which contain diagnostic error information, for use by diagnostic software in validating correct operation or isolating failure modes. Bits 15-0 represent the ERR decode bits, which contain information for use by the host software in determining the appropriate response to the error condition.

SATA memory map/register definition

Address: Base address + 104h offset



SATAx_SError field descriptions

Field	Description
31–28 -	This field is reserved. Reserved bit for future use. Should be cleared.
27 A	Port selector presence detected. This bit is set when COMWAKE is received while the host is in state HP2: HR_AwaitCOMINIT. On power-up reset this bit is cleared. The bit is cleared when the host writes a 1 to this bit location.
26 X	Exchanged. When set to 1 this bit indicates that device presence has changed since the last time this bit was cleared. The means by which the implementation determines that the device presence has changed

Table continues on the next page...

SATAx_SError field descriptions (continued)

Field	Description
	is vendor specific. This bit may be set anytime a PHY reset initialization sequence occurs as determined by reception of the COMINIT signal, whether in response to a new device being inserted, to a COMRESET having been issued, or to power-up.
25 F	Unrecognized FIS type. When set to 1, this bit indicates that since the bit was last cleared, one or more FIS's were received by the transport layer with good CRC, but they had a type field that was not recognized.
24 -	This field is reserved. Reserved.
23 S	Link sequence error. When set to 1, this bit indicates that one or more link state machine error conditions were encountered since the last time this bit was cleared. The link layer state machine defines the conditions under which the link layer detects an erroneous transition.
22 H	Handshake error. When set to 1, this bit indicates that one or more R_ERRP handshake responses were received in response to frame transmission. Such errors may be the result of a CRC error detected by the recipient, of a disparity or 10b/8b decoding error, or of other error conditions leading to a negative handshake on a transmitted frame.
21 CRC	CRC error. When set to 1, this bit indicates that one or more CRC errors occurred with the link layer since the bit was last cleared.
20 D	Disparity error. When set to 1, this bit indicates that incorrect disparity was detected one or more times since the last time the bit was cleared.
19 B	10b to 8b decode error. When set to 1, this bit indicates that one or more 10-bit to 8-bit decoding errors occurred since the bit was last cleared.
18 W	COMWAKE detected. When set to 1, this bit indicates that a COMWAKE signal was detected by the PHY since the last time this bit was cleared.
17 IN	PHY internal error. When set to 1, this bit indicates that the PHY detected some internal error since the last time this bit was cleared.
16 N	PHYRDY change. When set to 1, this bit indicates that the PHYRDY signal changed state since the last time this bit was cleared.
15–12 -	This field is reserved. Reserved bit for future use; should be cleared.
11 E	E Internal error. The host bus adapter experienced an internal error that caused the operation to fail and may have put the host bus adapter into an error state. Host software should reset the interface before retrying the operation. If the condition persists, the host bus adapter may suffer from a design issue rendering it incompatible with the attached device.
10 -	This field is reserved. Reserved.
9 C	Non-recovered persistent communication or data integrity error. A communication error that was not recovered occurred that is expected to be persistent. Because the error condition is expected to be persistent, the operation need not be retried by the host software. Persistent communications errors may arise from faulty interconnect with the device, from a device that has been removed or has failed, or a number of other causes.
8 T	Non-recovered transient data integrity error: A data integrity error occurred that was not recovered by the interface. Because the error condition is not expected to be persistent, the operation should be retried by the host software.
7–2 -	This field is reserved. Reserved
1 M	Recovered communications error. Communications between the device and host were temporarily lost but were re-established. This can arise from a device temporarily being removed, from a temporary loss of PHY synchronization, or from other causes, and may be derived from the PHYRDY *n* signal between the

Table continues on the next page...

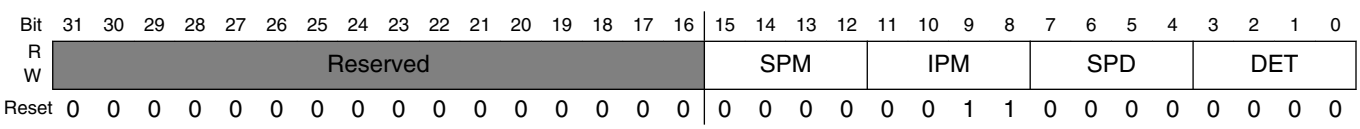
SATAx_SError field descriptions (continued)

Field	Description
	PHY and link layers. No action is required by the host software, because the operation ultimately succeeded. However, the host software may elect to track such recovered errors to gauge overall communications integrity and potentially step down the negotiated communication speed.
0 ITG	Recovered data integrity error. A data integrity error occurred that was recovered by the interface through a retry operation or other recovery action. This can arise from a noise burst in the transmission, a voltage supply variation, or other causes. No action is required by host software, because the operation ultimately succeeded. However, the host software may elect to track such recovered errors to gauge overall communications integrity and potentially step down the negotiated communication speed.

22.3.14 SATA interface control register (SATAx_SControl)

SControl is a 32-bit read-write register that provides the interface by which software controls SATA interface capabilities. Writes to the SControl register result in an action being taken by the host adapter or interface. Reads from the register return the last value written to it.

Address: Base address + 108h offset



SATAx_SControl field descriptions

Field	Description
31–16 -	This field is reserved. Reserved, should be cleared.
15–12 SPM	Select power management. Used to select a power management state. A non-zero value written to this field will cause the power management state specified to be initiated. A value written to this field is treated as a one-shot. All other values reserved 0000 No power management state transition requested 0001 Transition to the partial power management state initiated 0010 Transition to the slumber power management state initiated 0100 Transition to the active power management state initiated
11–8 IPM	Interface power management. The enabled interface power management states can be invoked via the SATA interface power management capabilities. All other values reserved 0000 No interface power management state restrictions 0001 Transitions to the partial power management state disabled 0010 Transitions to the slumber power management state disabled 0011 Transitions to both the partial and slumber power management states disabled

Table continues on the next page...

SATAx_SControl field descriptions (continued)

Field	Description
7–4 SPD	Speed. Highest allowed communication speed the interface is allowed to negotiate when interface communication speed is established. All other values reserved 0000 No speed negotiation restrictions 0001 Limit speed negotiation to a rate not greater than first-generation communication rate 0010 Limit speed negotiation to a rate not greater than second-generation communication rate
DET	Detection. Controls the host adapter device detection and interface initialization. All other values reserved 0000 No device detection or initialization action requested 0001 Perform interface communication initialization sequence to establish communication. This is functionally equivalent to a hard reset and results in the interface being reset and communications re-initialized. Upon a write to the SControl register that sets the DET field to 0001, the host interface should transition to the HP1: HR_Reset [Delete space after state and should remain in that state until the DET field is set to a value other than 0001 by a subsequent write to the SControl register. 0100 Disable the SATA interface and put PHY in offline mode

22.3.15 SATA interface notification register (SATAx_SNotification)

SNotification is a 32-bit, write-one-to-clear register that conveys the devices that have sent the host a set device bits FIS with the notification bit. When the host receives a set device bits FIS with the notification bit set to 1, the host should set the bit in SNotification corresponding to the value of the PM port field in the received FIS. For example, if the PM port field is set to 7 then the host should set bit 7 by writing a 1 to it. Next, the host should generate an interrupt if the I bit is set to one in the FIS and interrupts are enabled.

In this register, bits previously set are explicitly cleared by a write operation or by a power-on-reset operation. If the register is not cleared due to a COMRESET, the software is responsible for clearing the register as appropriate.The value written to clear set bits shall have ones encoded in the bit positions corresponding to the bits that are to be cleared.

Address: Base address + 10Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SATAx_SNotification field descriptions

Field	Description
31–16 -	This field is reserved. Reserved, should be cleared.
Notify_n	Represents whether a particular device with the corresponding PM port number *n* has sent a set device bits FIS to the host with the notification bit set.

22.3.16 Transport layer configuration (SATAx_TransCfg)

TransCfg controls the configuration of the transport layer.

Address: Base address + 140h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DFIS_SIZE																Reserved											RX_WATER_ MARK					
Reset	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1	1	0

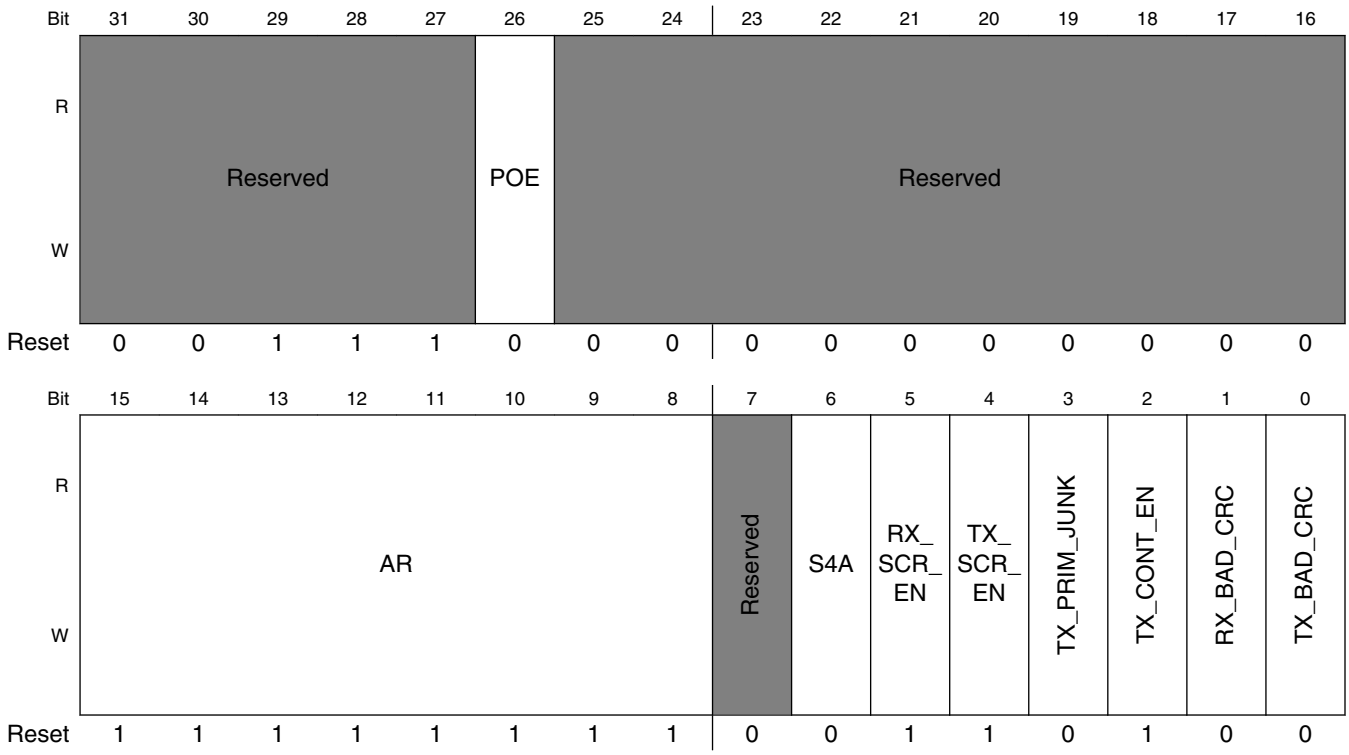
SATAx_TransCfg field descriptions

Field	Description
31–16 DFIS_SIZE	Data FIS framing length words. Determines the maximum length each data FIS should be. **NOTE:** Maximum data FIS size is 8K, it may vary depending on data size to be transfered.
15–5 -	This field is reserved. Reserved
RX_WATER_ MARK	This sets the number of locations in the 58-deep Rx FIFO that can be used before the transport layer instructs the link layer to transmit HOLDS to the transmitting end. Note that it can take some time for the HOLDs to get to the other end, and that in the interim there must be enough room in the FIFO to absorb all data that could arrive. An initial value of 15 is recommended.

22.3.17 Link layer configuration (SATAx_LinkCfg)

LinkCfg controls the configuration of the link layer.

Address: Base address + 148h offset



SATAx_LinkCfg field descriptions

Field	Description
31–27 -	This field is reserved. Reserved
26 POE	Primitive override enable. When set, this bit enables the replacement of a single primitive, as specified by CFG_PRIM/CFG_CD, when the link layer state machine is in the CFG_PRIM_OVR_STATE state. This bit has to be toggled from a 0 to a 1 to enable this feature.
25–16 -	This field is reserved. Reserved
15–8 AR	Align insertion rate. The SATA specification requires that the link layer send a pair of ALIGN primitives at least every 254 words of data. This is achieved by setting ALIGN_RATE to '11111111'. However, for test purposes it is possible to send ALIGNs at a higher rate. This can be achieved by setting ALIGN_RATE to a lower value (that is, ALIGN_RATE-1); words will be sent by the link layer between each set of ALIGN primitive pairs. **NOTE:** If SEND_4_ALIGNS is set, one should not set the ALIGN_RATE to be four or less. If SEND_4_ALIGNS is not set, one should not set the ALIGN_RATE to be two or less.
7 -	This field is reserved. Reserved

Table continues on the next page...

SATAx_LinkCfg field descriptions (continued)

Field	Description
6 S4A	Send four ALIGNs. When asserted, four ALIGN primitives are transmitted at the specified rate, instead of the normal two ALIGNS.
5 RX_SCR_EN	Rx scramble enable. If this bit is asserted, then descrambling of the receive data is enabled as per the SATA specification.
4 TX_SCR_EN	Tx scramble enable. If this bit is asserted, then scrambling of the transmit data is enabled as per the SATA specification.
3 TX_PRIM_JUNK	TX prim junk. If this bit is de-asserted, then scrambled junk data is sent after a CONT primitive, as per the SATA specification. If this bit is asserted, then the single character 0xDEADBEEF is sent continuously instead. This is to aid debug.
2 TX_CONT_EN	TX CONT. If this bit is asserted, then the transmission of CONT primitives is enabled. If de-asserted, then long sequences of repeated primitives can be sent by the link layer.
1 RX_BAD_CRC	RX bad CRC. When a rising edge is detected on this bit, it causes a bad CRC to be detected for the current frame. This bit has to be toggled from a 0 to a 1 to enable this feature.
0 TX_BAD_CRC	Tx bad CRC. A bad CRC (inverted value of the correct CRC) value will be transmitted for one FIS only by the link layer when a rising edge is detected on this signal. This bit has to be toggled from a 0 to a 1 to enable this feature.

22.3.18 Link layer configuration1 (SATAx_LinkCfg1)

LinkCfg1 controls the configuration of the link layer.

Address: Base address + 14Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved									CD	PRIM_OVR_STATE					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SATAx_LinkCfg1 field descriptions

Field	Description
31–7 -	This field is reserved. Reserved
6 CD	This bit specifies whether the data used during the primitive override should be a data character or a primitive. For example, if CD = 1, PRIM_OVR_STATE = L_SendEOF and PRIM = WTRM, then a WTRM primitive will be inserted into the datastream instead of an EOF (whenever a rising edge is seen on PRIM_OVR_EN). If CD = 0, then a normal data character (as specified by PRIM) is inserted into the datastream instead of the EOF.
PRIM_OVR_ STATE	Prim override state. These 6 bits are used in the primitive override debug functionality. When the link layer detects a positive edge on PRIM_OVR_EN, it overrides the next primitive that would be inserted during the PRIM_OVR_STATE, with the data specified by the PRIM and CD configuration bits.

22.3.19 Link layer configuration2 (SATAx_LinkCfg2)

LinkCfg2 controls the configuration of the link layer.

Address: Base address + 150h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SATAx_LinkCfg2 field descriptions

Field	Description
PRIM	This 32-bit bus specifies the data to be used in the overriding primitive debug logic, described in the definition of LinkCfg1 register.

22.3.20 PHY control configuration1 (SATAx_PhyCtrlCfg1)

PhyCtrlCfg1 controls the configuration of the link layer.

Address: Base address + 15Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved		Reserved	ENDEC_EN	Reserved			FPRFTI	Reserved				LPB_EN			Reserved
Reset	0	0	1	1	1	0	0	0	0	0	0	0	0	0	0	0

SATAx_PhyCtrlCfg1 field descriptions

Field	Description
31–14 -	This field is reserved. Reserved
13 -	This field is reserved. Reserved. Reset value must be preserved when writing to the register.
12 ENDEC_EN	Encode decode enable. Reset value must be preserved when writing to the register. 0 When negated low, the PCS is configured to operate in 10-bit mode; the 8B/10B encoder/decoders are bypassed and it is assumed this is done elsewhere. 1 When asserted high, it enables the PCS to operate in 8 bit mode, and to enable 8B/10B encoding and decoding.
11–9 -	This field is reserved. Reserved. Reset value must be preserved when writing to the register.
8–7 FPRFTI	Force PHY ready, force Tx idle. This pair of signals determines how phyRdy is driven, how the output buffer IDLE condition is controlled and how disparity errors in ALIGN primitives should be tolerated during OOB. The IDLE condition is defined in SATA as both traces of the transmit differential pair being driven to common mode. • frcPhyRdy = 0 • frcTxIdle = 0 In this mode phyRdy and Tx buffer IDLE control driven by OOB state machine. Disparity errors in ALIGN primitives are not tolerated during OOB. • frcPhyRdy = 0 • frcTxIdle = 1 In this mode phyRdy and Tx buffer IDLE control driven by OOB state machine. Disparity errors in ALIGN primitives are tolerated during OOB. • frcPhyRdy = 1 • frcTxIdle = 0 In this mode phyRdy is asserted high and Tx buffer IDLE control is forced off, causing the output buffer to be enabled. Tolerance of disparity errors in ALIGN primitives is of no consequence, because OOB is bypassed. • frcPhyRdy = 1 • frcTxIdle = 1 In this mode phyRdy is asserted high and Tx buffer IDLE control is forced on, causing the output buffer to the IDLE condition. Tolerance of disparity errors in ALIGN primitives is of no consequence as OOB is bypassed.
6–4 -	This field is reserved. Reserved
3–1 LPB_EN	Loopback enable. These bits control both loopback modes and power management modes. **NOTE:** This field is available only for SATA1. 000 No loopback and in normal power mode 001 Far end re-timed (parallel) loopback enabled 010 Near end analog (serial) loopback enabled 011 Invalid 100 Invalid 101 goPartial. This encoding results in the OOB state machine entering the partial state. Note that in the PCS, partial and slumber have the same effect.

Table continues on the next page...

17 -	This field is reserved. Reserved
18 PRI_DES	Descriptor fetch high priority enable. 0 Normal operation. SATA descriptor fetches have default (low) priority. 1 High priority enabled for SATA descriptor fetches.
19 -	This field is reserved. Reserved
20–28 -	This field is reserved. Reserved
29 RD_SAFE	Read safe. This bit should be set only if the target of the read DMA operation is a well behaved memory that is not affected by the read operation and which will return the same data if read again from the same location. This means that unaligned reading operation can be rounded up to enable more efficient read operations. 0 It is not safe to read more bytes that were intended. 1 It is safe to read more bytes that were intended.
30–31 -	This field is reserved. Reserved

22.4 Functional description

22.4.1 Error processing

On a single device error, perform the following tasks:

1. Examine the DER register to determine which device is in the error state. Note that there may be multiple devices in error.
2. Examine the CER register to determine which command was in error. Note that software knows which command belongs to which device.
3. Examine the status location of the descriptor of the command in error and determine the reason for the error.
4. If needed, software should send commands to the device to clear down the error condition on device or for further examination of the device's status.
5. Clear the DER*n* bit by writing 1 to bit *n*, where *n* indicates the device in error. This also clears out the outstanding commands for that device.
6. Clear the CER*n* bit by writing 1 to bit *n*, where *n* indicates the associated command in error. After that, the software can reissue command to the device if needed.

On fatal error, perform the following tasks:

1. Read the error register and other registers to determine how many commands are outstanding and how many have completed without error.
2. Bring the SATA controller offline. When this happens, all queues within the SATA controller are cleared.
3. Perform what corrective action the software determines is necessary.
4. Bring the SATA controller online. This will initiate Out-of-Band (OOB), resetting the BUS, host, and attached device.

22.4.2 Bringing the SATA controller online/offline

The HC_ON bit in HControl allows the host software to bring the SATA controller online or offline.

The SATA controller online status should only be changed when there are no commands queued in the SATA controller or at any attached device.

When the host application wishes to bring the SATA controller offline it clears the HC_ON control bit. This acts as a request to the SATA controller to go offline. The SATA controller will signal it has completed this operation by clearing the HS_ON bit in the HStatus register. If any commands are outstanding at SATA controller or device then the SATA controller will wait for the operation to complete before going offline.

If the host application wishes to bring the SATA controller offline regardless of the queue status, it clears the HC_ON bit a second time when the controller has set the HS_OFF bit of the HStatus register.

When the host application wishes to bring the SATA controller online, it sets the HC_ON control bit. This acts as a request to the SATA controller to go online. The SATA controller will signal it has completed this operation by setting the HS_ON status bit.

22.4.3 Command operation

The SATA controller maintains a queue consisting of up to 16 commands.

These commands can be distributed to a single attached device or, over each of the attached devices, if the system contains a port multiplier. It is possible to queue queued commands and non-queued commands into the SATA controller, provided the host software does not break protocol to any particular device (it is illegal to issue a non-queued command to a device that still has a queued command active as per ATAPI/ATA protocol).

22.4.3.1 Command issue

When the host software is preparing to issue a command, it first builds a command descriptor as shown in Figure 22-3. The format of the command FIS is defined in the Serial ATA 2.6 standard shown in Table 22-5. The software is also responsible for the creation of a scatter/gather list for data movement. This list should be defined to exactly match the transfer length as programmed into the command FIS. If the 16 entries are not sufficient, then an extended entry (ext) can be used to refer to an alternate table. When the descriptor is built, the host software locates a free command slot within the SATA controller by examining the command queue register. To issue the command, the host software programs the address of the command descriptor and the attributes into the appropriate command header locations and then issues the command by writing the PMP and setting the appropriate CQ bit in the command queue register.

22.4.3.2 Command service

After a command is issued, the SATA controller takes ownership of the command descriptor, transferring the command FIS to the targeted device when required, servicing the data transfer using the scatter/gather list provided and transferring the status back into the command descriptor (if programmed).

22.4.3.3 Command completion interrupt timing

When a command completes, it is possible to enable the SATA controller to generate an interrupt.

Associated with some commands there will be a command completion status FIS. The SATA controller will always transfer the status FIS to memory whether it indicates an error or good command completion.

22.4.3.4 DMA context (read data)

When receiving FIS's from attached devices, the SATA controller has to support interleaving from various devices.

Data FIS's from device 0 could be interleaved with data FIS's for device 1. In order to accomplish this, the SATA controller maintains in hardware a context for each command which is pushed onto and pulled from the DMA controller when needed to service the transfers.

22.4.3.5 DMA context (write data)

When the SATA controller receives an FIS indicating that the next operation to a particular device should be a data write transfer, the SATA controller will lock the interface by forcing the link layer to transition to X_RDY immediately and not go through idle SYNC.

This will mean that write transfers will not have to be interleaved, which simplifies the transmit data path and eliminates the need for a complex scheduler.

22.4.3.6 DMAT primitive processing

The SATA controller supports the reception of the DMAT primitive.

When the SATA controller receives a DMAT primitive from the device, it will perform the following actions.

The DMA controller will complete the current read burst and transfer the data to the transport layer FIFO. The DMA controller signals an EOF on the last data of the burst, which causes the link layer to insert the CRC and EOF. The context for this transfer is returned to the context store. Once this action is completed, the device can terminate the transfer or re-initiate the transfer as per Serial ATA Revision 2.6 .

22.4.4 Command header

Each entry in the command header table consists of the structure shown in this figure.

NOTE

In this chapter, "word" refers to 4 bytes or 32 bits.

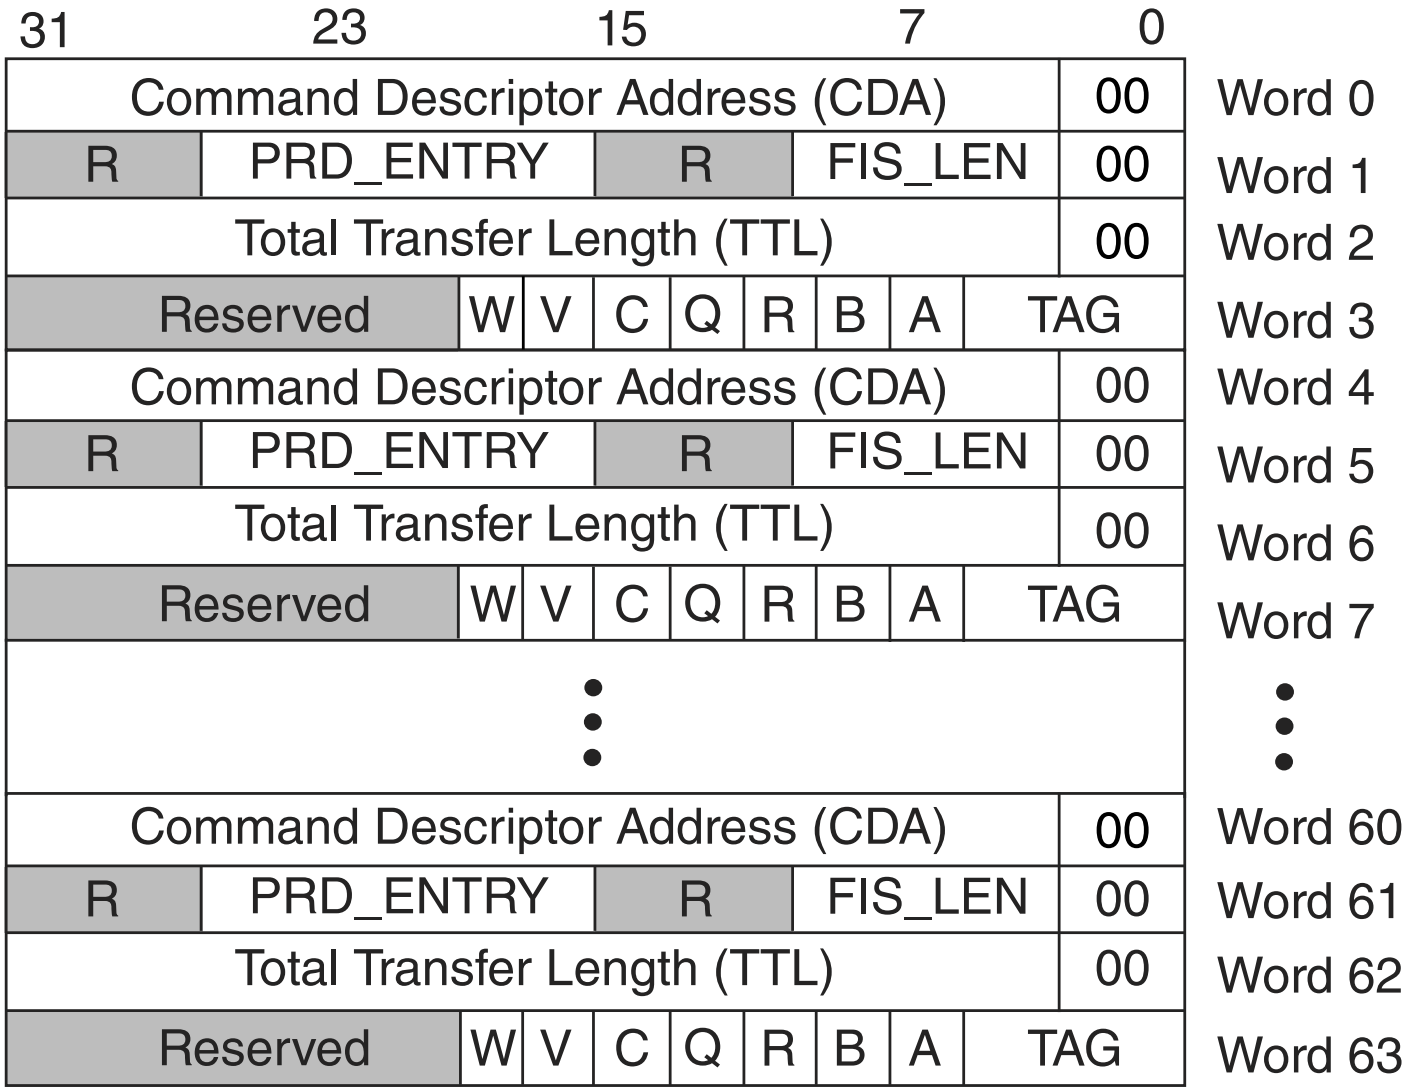

Figure 22-2. Command header

This table shows the command header word 0-data base address.

Table 22-1. Command header word 0-data base address

Bit	Name	Description
31-2	CDA	Command descriptor base address. Indicates the 32-bit physical address of the command descriptor block. The block must be word-aligned, indicated by bits 1-0 being reserved.
1-0	-	Reserved

This table shows the command header word 1-FIS_LEN.

Table 22-2. Command header word 1-FIS_LEN

Bit	Name	Description
31-22	-	Reserved

Table continues on the next page...

Table 22-2. Command header word 1-FIS_LEN (continued)

Bit	Name	Description
21-16	PRD_ENTRY	Number of PRD entries including indexed entries.
15-7	-	Reserved
6-2	FIS_LEN	FIS length. This is a 5-bit word count of the total length of the control or vendor-specific FIS to transfer.
1-0	-	Reserved

This table shows the command header word 2-data base address.

Table 22-3. Command header word 2-data base address

Bit	Name	Description
31-2	TTL	Total transfer length. This is a 30-bit word count of the total length of the data transfer. It is used to detect overruns/underruns between the transfer lengths programmed in the command and the PRDT.
1-0	-	Reserved

This table shows the command header word 3-description information.

Table 22-4. Command header word 3-description information

Bit	Name	Description
31-12	-	Reserved
11	W	Non-post last data write to memory. This bit gives the assurance that during disk read commands, last data was updated in memory before it receives an interrupt concerning the command completion. 0 Before generating the command completion interrupt SATA controller should not wait for acknowledgement from systemduring the last data write to memory of a read command. 1 Before generating the command completion interrupt SATA controller should wait for acknowledgement from system during the last data write to memory of a read command.
10	V	Vendor BIST. When this bit is set, it indicates that the command is a Vendor BIST, thus FIS will loop back at the PHY local test.
9	C	Snoop enable during all descriptor read/write operations associated with this command.
8	Q	Queued. Command is an FPDMA queued command.
7	R	Reset. The command is a SRST or device reset.
6	B	BIST. The command will require the host to enter BIST mode.
5	A	ATAPI command. The command is an ATAPI command and thus will require that the host uses the ATAPI portion of the command descriptor to issue the command. The CFIS also has to be written with the packet command.
4-0	TAG	The 5-bit TAG assigned by software for command tracking. It is the same as the value written to the command register host-to-device.

22.4.4.1 Command descriptor

Each entry in the command list points to a structure called the command descriptor.

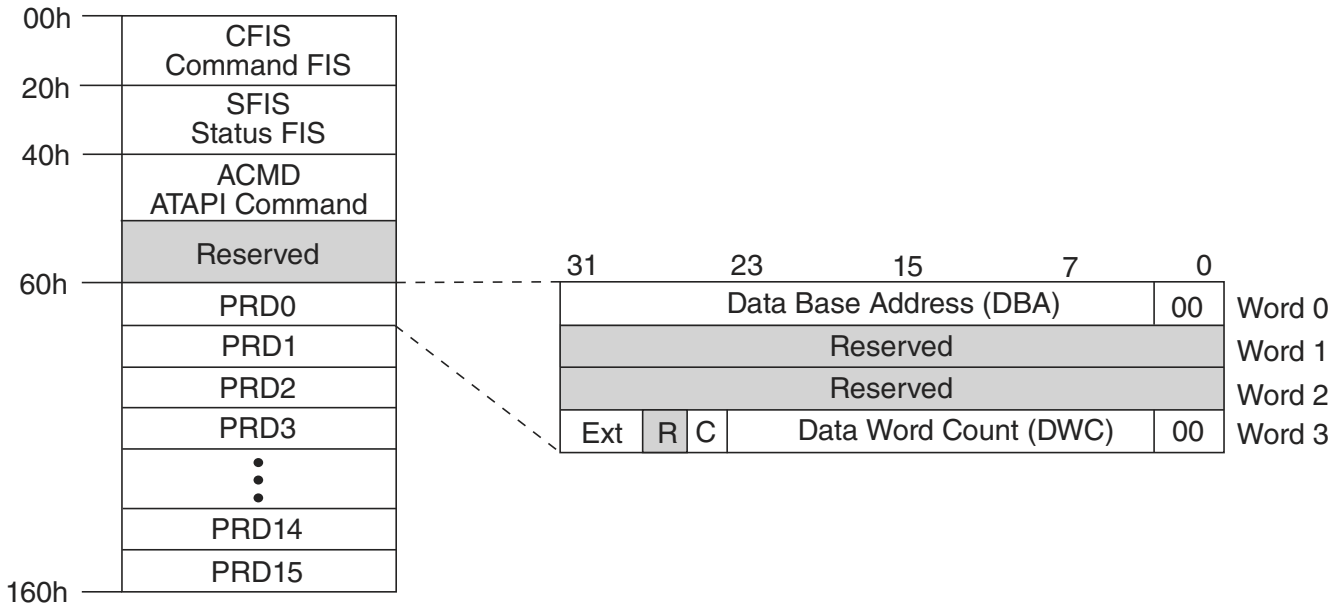

Figure 22-3. Command descriptor

22.4.4.1.1 Command FIS non-queued commands (CFIS)

Command FIS is a software constructed FIS. For data transfer operations, this is the H2D register FIS format as specified in the Serial ATA 2.6 standard.

The SATA controller fetches this from memory and sends the appropriate amount of data to the attached port. If a port multiplier is attached, this field must have the port multiplier port number in the FIS itself. CFIS lengths are two to eight words and must be in word granularity. A typical command FIS is shown in this figure.

Table 22-5. Register host-to-device

	Register FIS host-to-device																															
	31							24	23							16	15			12	11			8	7							0
0	Features								Command								C	R	R	R	PM port				FIS type (27h)							
1	Device								LBA high								LBA mid								LBA low							
2	Features (exp)								LBA high (exp)								LBA mid (exp)								LBA low (exp) (0)							
3	Control								Reserved (0)								Sector count (exp)								Sector count							
4	Reserved (0)								Reserved (0)								Reserved (0)								Reserved (0)							

22.4.4.1.2 Command FIS first party DMA commands NCQ

This figure shows register host-to-device first party DMA commands NCQ.

The shaded components show where this FIS differs for the non-NCQ register host-to-device FIS.

Table 22-6. Register host-to-device first party DMA commands NCQ

	Register FIS host to device-Read/write FPDMA queued			
	31 … 24	23 … 16	15 … 12	11 … 8 / 7 … 3 / 2 … 0
0	Features	Command	C R R R	PM port / FIS type (27h)
	Sector count 7:0			
1	Device	LBA high	LBA mid	LBA low
2	Features (exp)	LBA high (exp)	LBA mid (exp)	LBA low (exp) (0)
	Sector count 15:8			
3	Control	Reserved (0)	Sector count (exp)	Sector count
			Reserved (0)	TAG
4	Reserved (0)	Reserved (0)	Reserved (0)	Reserved (0)

22.4.4.1.3 Status FIS (SFIS)

This FIS is created in hardware. For normal operations, this is the D2H register FIS format as specified in the Serial ATA 2.6 standard.

SFIS lengths are two to eight words and must be of word granularity. A typical status FIS is shown in Table 22-7.

Table 22-7. Register device-to-host

	Register FIS device to host			
	31 … 24	23 … 16	15 … 12	11 … 8 / 7 … 0
0	Error	Status	R I R R	PM port / FIS type (34h)
1	Device	LBA high	LBA mid	LBA low
2	Reserved (0)	LBA high (exp)	LBA mid (exp)	LBA low (exp) (0)
3	Reserved (0)	Reserved (0)	Sector count (exp)	Sector count
4	Reserved (0)	Reserved (0)	Reserved (0)	Reserved (0)

22.4.4.1.4 ATAPI command (ACMD)

This is a software constructed region of three or four words in length that contains the ATAPI command to transmit if the 'A' bit is set in the command header.

The ATAPI command must be either 12 or 16 bytes in length. The length transmitted by the SATA IP is determined by the PIO setup FIS that is sent by the device requesting the ATAPI command.

22.4.4.1.5 Physical region descriptor table (PRDT)

This is a software constructed table of addresses to use to complete the data transfer. Up to 16 structures can be supported in the current command descriptor.

The format of the address entry is defined by the "Block vector structures for passing segmented data type of the IEEE Std. 1212.1-1993". The total definable length supported in the 16 entries is 64 Mbytes.

This table shows the PRDT word 0-data base address.

Table 22-8. PRDT word 0-data base address

Bit	Name	Description
31-2	DBA	Data base address. Indicates the 32-bit physical address of the data block. The block must be word aligned, indicated by bits 1-0 being "reserved, must be 00."
1-0	-	Reserved

This table shows the PRDT word 3-description information.

Table 22-9. PRDT Word 3-description information

Bit	Name	Description
31	EXT	If the extension flag is set to 1, then the DBA field contains the address of the extension segment, and the DWC field contains the size of this extension segment (this is called an "indirect descriptor").
30-29	-	Reserved
28	C	Data snoop enable bit. When this bit is set, all data read/write operations associated with the PRD entry for this command will be snoopable.
27-26	-	Reserved
25-2	DDC	Data DWord count. A 0-based value that Indicates the length, in DWords, of the data block. A maximum length of 32 Mbytes may exist for any entry. Bits 1-0 of this field must always be 0 to indicate that size is in 4-byte words. A value of 24'b0 indicates a full 32 Mbytes transfer.
1-0	-	Reserved

22.4.4.2 Vendor-specific BIST operation

As part of the host self-diagnostic operation, a vendor-specific BIST mode is supported.

This mode, in conjunction with a PHY that supports serial loopback, allows for the test of the SATA controller operation.

The mode exercises the following paths:

- DMA controller FIS transmission
- Command layer FIS transmission
- Transport layer Tx FIFO FIS transmission
- Link layer FIS transmission
- PHY modes
- Link layer FIS reception
- Transport layer Rx FIFO and FIS reception
- Command layer FIS reception
- Host DMA controller FIS reception

To run this self-test on SATA1 the software performs the following operations:

2. Builds the vendor-specific header and descriptor as detailed in the vendor-specific BIST header and descriptor.
3. Modifies the SerDes control register 2 to place the PHY into analog loopback mode.
4. Issues this command to the SATA controller.
5. When the SATA controller indicates the command has completed, the software examines the contexts of the command descriptor's stats field. If the pre-programmed values are present, the test has passed.
6. The contents of the vendor-specific FIS to be created in memory are as follows:
   - Build command header in the memory. See Table 22-10 :

Table 22-10. Vendor BIST test-command header

Word number	Hexadecimal value
Word 0	CDA
Word 1	0x0000_000C
Word 2	All zeros
Word 3	0x0000_0400

   - Build command descriptor in the memory. See Table 22-11.

Table 22-11. Vendor BIST test-command descriptor

Word number	Hexadecimal value	Comments
Word 0	0x0001_0058	-
Word 1	0xAAAA_A034	AAAA_A is the first test pattern (can be any value)

Table continues on the next page...

Table 22-11. Vendor BIST test-command descriptor (continued)

Word number	Hexadecimal value	Comments
Word 2	0xBBBB_B034	BBBB_B is the second test pattern (can be any value)
Word 3	Reserved	Reserved, must be all zeros
Word 4	Reserved	Reserved, must be all zeros
Word 5	Reserved	Reserved, must be all zeros
Word 6	Reserved	Reserved, must be all zeros
Word 7	Reserved	Reserved, must be all zeros

The values of A and B can be filled in by the user with the pattern to test as shown in the figure.

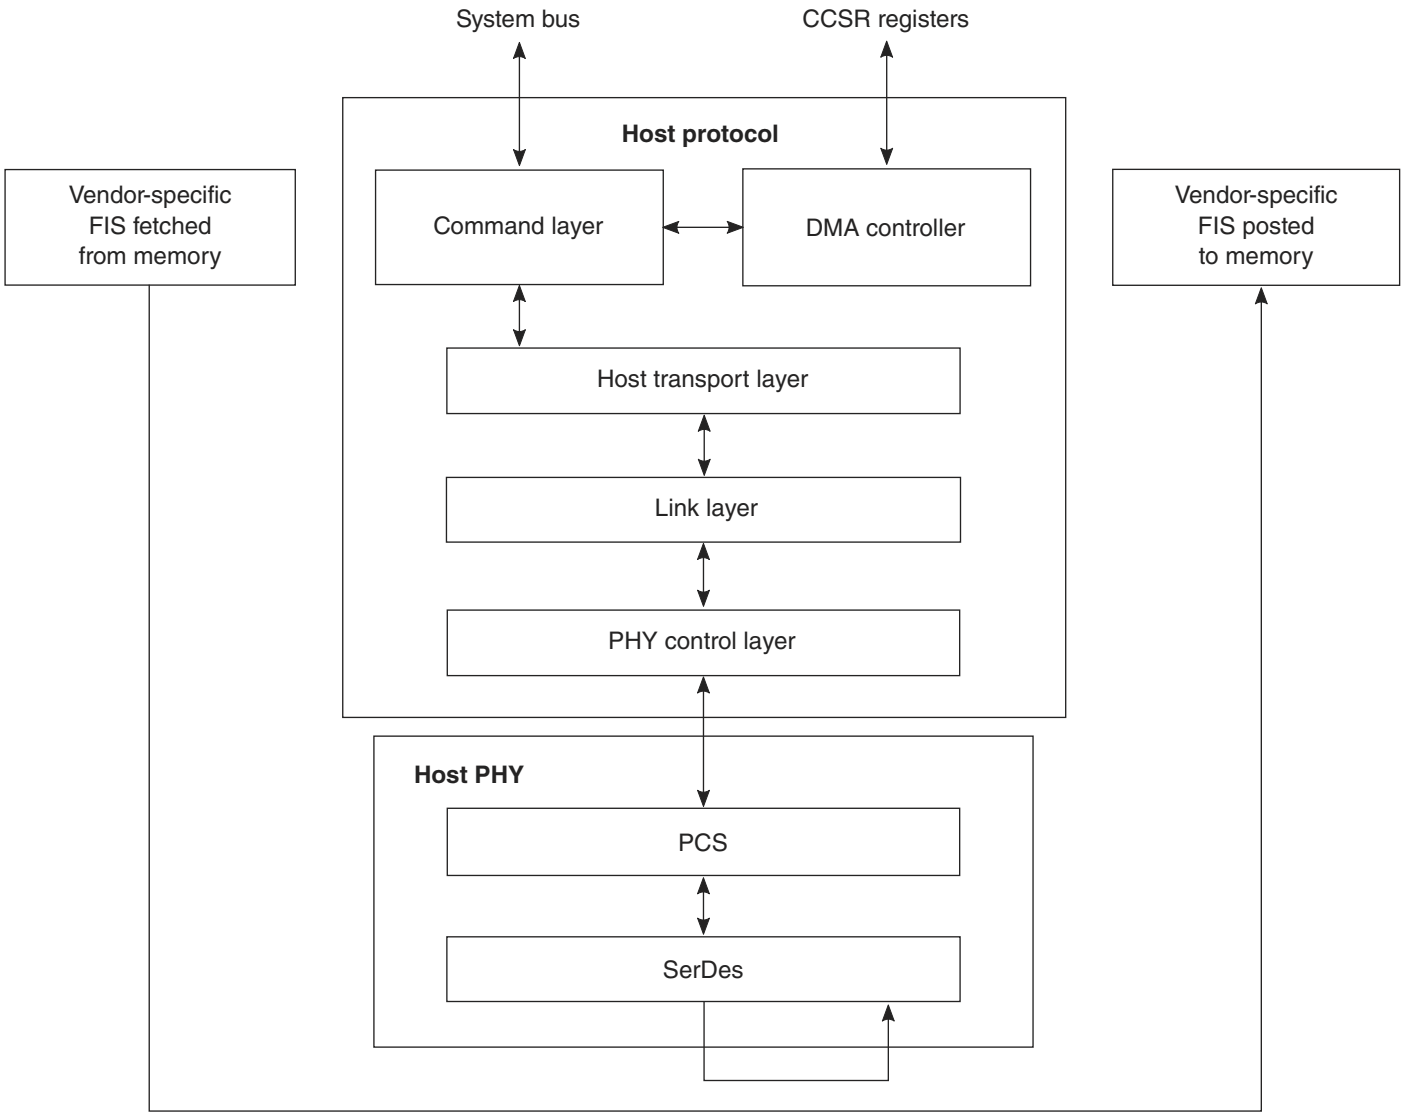

Figure 22-4. Vendor-specific BIST operation

22.4.5 Command layer overview

The function of the SATA command layer is to allow host software to queue commands.

It then manages the commands issued and services them using a hardware context to complete the queued commands.

22.4.6 Transport layer architectural overview

The function of the SATA transport layer is to interface between the command and link layers in the transmission and reception of FIS.

On the transmit path, the transport layer frames the FIS's placed into the Tx FIFO. The FIS's are framed based on a programmed length for non-data FIS and are a configurable length for data FIS. When the transport layer is instructed to send a non-data FIS, it employs a retry policy until the far end signals acceptance of the transmitted FIS.

On the reception path, the transport layer deframes the FIS's and places them into the Rx FIFO. When an FIS is received, the transport layer informs the command layer. For a non-data FIS, the FIS is considered received when the end-of-frame (EOF) is signaled by the link layer and the FIS has been received with a good CRC. For a short vendor-specific FIS, the FIS is considered as a non-data FIS. For a longer vendor-specific FIS, the FIS reception is signaled when the RX FIFO reaches its water mark. For a data FIS, the FIS is considered received when the first word (header) is written into the FIFO.

The receive FIFO is written with data contained in the FIS sent by the link layer. When the data is stable at the output of the receive FIFO, the command layer can take the data. If the command layer is not ready to accept the data, the data builds up in the receive FIFO. When the receive FIFO exceeds its threshold, the transport layer stalls the link layer, which will in turn send HOLD primitives to the far end. This threshold takes into consideration the latency involved in getting the far end to stop transmitting the data. This threshold is programmable to allow for the use of high-latency repeaters or retainers in between the host and device.

The transmit FIFO is written with data to be sent in the FIS transferred by the DMA controller. When the data is stable at the output of the transmit FIFO, the link layer can take the data. If the transmit FIFO cannot supply data to the link layer, the transport layer stalls the link layer, which will in turn send HOLD primitives to the far end.

22.4.7 Link layer overview

The function of the SATA link layer is to interface between the transport and physical layers in the transmission and reception of frames and primitives.

The link layer utilizes the two unidirectional links provided by the SATA interface to maintain coordinated communication between the host and the device. Payload data can only be transmitted in one direction at a time. The link layer can work at either SATA first-generation (1.5 Gbps) or second-generation 2 (3 Gbps) speeds.

On transmit, the link layer first communicates with the peer far end link layer to determine if it is ready to receive. Assuming the far end link layer can receive data, the local link layer can then begin to take data in the form of words from its transport layer. It inserts start-of-frame (SOF) before the start of the data portion of a frame, calculates and inserts the CRC after the data portion of a frame, and inserts the EOF primitive at the end. The link layer scrambles the contents of the frame, including the calculated CRC, but excluding the SOF and EOF diameters and any other embedded primitives. The 8B/10B encoding of the data is done in the PHY layer. At the end of the transmission, the link layer reports transmission status to the transport layer.

On receive, the link layer first acknowledges its readiness to receive with its peer link layer. Then it awaits reception of the SOF primitive that marks the start of the received data. Following detection of the SOF primitive, the link layer proceeds to accept the incoming data. The 8B/10B decoding of the data is done in the PHY layer. Next, the link layer removes all primitives including the SOF and EOF diameters. It then descrambles the contents of the frame. The link layer also calculates the CRC on the incoming frame between the SOF and EOF delimiters, and compares this calculated value to the received value. Any mismatch is reported to the transport layer. During frame reception, disparity or code errors are reported to the command layer, and appropriate action is taken in the link layer. The descrambled and decoded receive data stream is passed to the transport layer as the frame is being received. Finally, at the end of the frame, the link layer reports reception status to the transport layer.

The link layer also partakes in flow control between the local and remote ends. The layer supports flow control actions based on the local FIFO status (located in the transport layer), or in response to receiving flow control messages from the remote end.

The transmit side of the link layer is also responsible for inserting a pair of ALIGN primitives every 254 words, or more frequently if programmed by the user.

22.4.7.1 Link layer functionality

The link layer is composed of a number of functions:

- Link layer state machines
- Frame content scrambler and descrambler
- CRC generation and checking
- Bus interfaces to PHY and transport layer
- CONT primitive processing
- ALIGN insertion on transmit
- Debug functionality
- BIST support

The four link layer state machines are described in the following sections.

22.4.7.1.1 Link idle state machine

The link idle state machine is responsible for detecting a transmit request from the transport layer or a frame reception request from the far end.

The state machine arbitrates whether these two events coincide. The SATA specification defines that the host end always backs down in this case. Furthermore, this machine interprets power mode change requests from both the transport and PhyCtrl layers and initiates actions to enable the power mode change. Power mode change can only occur if the feature is enabled via the PhyCtrlCfg register LPB_EN bits. Finally, this state machine also detects the negation and assertion of PHY_READY from the PHY and notifies the transport layer of the change.

22.4.7.1.2 Transmit state machine

This state machine is responsible for frame transmission to the PHY.

The state machine places the SOF and EOF headers on each frame, calculates the CRC, and inserts it before the EOF delimiter. Between the SOF and CRC markers, the link layer accepts the current word from the transport layer and uses this as the next word of the frame. The link layer also inserts a pair of ALIGN primitives every 254 words of frame data. Finally, at the end of the frame transmission, the state machine waits for status from the far end link layer via received R_OK or R_ERR primitives. If the far end received the frame correctly, the local link layer signals TX_OK to the transport layer; otherwise, it signals TX_NOT_OK to the transport layer.

The transmit state machine also partakes in flow control actions, if necessary, during packet transmission. If the transport layer cannot supply a new word and the frame is not finished, the transmit state machine responds by sending HOLD primitives until the transport layer is ready with valid frame data. Also, during frame transmission, if the state machine detects a received HOLD primitive from the PHY layer, it interrupts the current frame transmission and sends HOLDA primitives to the PHY to be transmitted to the far end.

The current frame transmission can only be aborted by two events. The first is on reception of a DMAT primitive from the far end. In this case, the link layer state machine stops the current transfer and calculates and inserts the current CRC. This is a controlled termination. The second is when the transport layer wishes to send a control register frame signaled via TRANSMIT_CRF.

If at any point in the frame transmission process, the link layer detects error conditions, it signals these to the command layer. The errors can occur if the link layer detects the following conditions:

- PHY_READY negates
- SYNC primitive is received during frame transmission

22.4.7.1.3 Receive state machine

This state machine is responsible for frame reception from the PHY layer.

The state machine removes the SOF and EOF headers and other primitives from each frame, calculates the CRC, and compares it to the received CRC. Between the SOF and CRC markers, the link layer accepts the current word from the Phy layer and uses this as the next word of the frame, transferring it to the transport layer. At the end of the frame reception, if the calculated CRC is not the same as the received CRC, the link layer signals an error to the transport layer. This is done via RX_CRC_OK and RX_CRC_NOT_OK. During frame reception, if no errors are detected, the link layer transmits R_IP primitives to the far end peer link layer. Finally, at the end of the frame reception, the link layer sends the R_OK primitive if no error was detected during reception. If an error was detected, it sends a R_ERR primitive instead.

The receive state machine also partakes in flow control actions if necessary, during FIS reception. If the transport layer cannot accept a new word, (because its receive FIFO has reached its watermark level), and the FIS is not finished, the receive state machine responds by sending HOLD primitives on the back channel until such time as the transport layer is ready to accept FIS data again. Also, during FIS reception, if the state machine detects a received HOLD primitive from the far end, it responds by sending HOLDA primitives to the far end.

The current frame reception can be interrupted if the transport layer wishes to send a control register frame, signaled via TRANSMIT_CRF.

If at any point in the frame reception process, the link layer detects error conditions, it signals these to the command layer. The errors can occur if the link layer detects the following conditions:

- PHY_READY negates
- SYNC primitives is received during frame transmission
- WTRM primitive is received before EOF

22.4.7.1.4 Power mode change state machine

This state machine is responsible for handling change of power mode requests.

These requests can come from the command layer superset registers or the far end. This state machine responds by transmitting PMREQ_P/PMREQ_S primitives to the far end and waiting for PMACK primitives from it in response. Once PMACK is received, the state machine instructs the PHY layer to enter either a partial or slumber state.

A write to the SControl register SPM field or reception of a COMWAKE from the far end will initiate a resume to active power mode.

If the link layer receives a PMREQ_P/PMREQ_S primitive from a peer link layer and is enabled to perform power management modes (SControl IPM bits are cleared), it responds by sending at least four PMACK primitives. A write to the SControl register SPM field or reception of a COMWAKE from the far end will initiate a resume to active power mode.

If the link layer receives an XRDY primitive from the far end while it is in the partial or slumber state, it returns to idle and signals a link sequence error to the command layer, that is, SError[S] = 1.

22.4.7.1.5 Frame content scrambler and descrambler

There are two separate scramblers used in the SATA controller, one for the data payload and the other for repeated primitive suppression.

The contents of each word of data (excluding all primitives) between SOF and EOF must be scrambled before 8B/10B encoding. Scrambling is performed on word quantities according to the following polynomial:

$G(X) = X16 + X15 + X13 + X4 + 1$

The scrambler is initialized with a seed value of 0xFFFF at each SOF transmission and rolls over every 2048 words. Payload data is scrambled prior to transmission, by XORing the data to be transmitted with the output of this scrambler.

If a CONT primitive is transmitted, then the intervening data between the last CONT primitive and a subsequent primitive must be scrambled also. This scrambler uses the same polynomial as defined above for data payload scrambling and is reset to the initial value upon detection of a COMINIT or COMRESET event. If a CONT primitive is transmitted or received during a frame transfer, then the current data payload scrambler value at the last word is held.

When payload data is received by the link layer it is descrambled by XORing it with the output of its descrambler. The descrambler is re-seeded at the beginning of the received data payload, that is, at each SOF reception. The descrambler uses the same polynomial as the scrambler.

22.4.7.1.6 CRC generator and checker

A 32-bit CRC is calculated on the data contents of each frame and is inserted in the word before the EOF.

The CRC covers all data bytes in the frame excluding any primitives such as SOF, EOF, HOLD, HOLDA, DMAT, SYNC, X_RDY, R_RDY, or ALIGNs.

The CRC generator works on word quantities. Any padding to the boundary is done in the transport layer. The polynomial used for the CRC is as follows:

$G(X) = X32 + X26 + X23 + X22 + X16 + X12 + X11 + X10 + X8 + X7 + X5 + X4 + X2 + X + 1$

The CRC is initialized with a seed value of 0x52325032 at each SOF.

The CRC generation or checking does not apply to primitives (as stated above) or to CONT'ed primitives. If a CONT primitive is transmitted or received, then the intervening data between the last CONT primitive and a subsequent primitive is not included in the CRC calculation for a frame. If this happens during a frame transfer, then the current CRC scrambler value at the last word is held.

22.4.7.1.7 8B/10B encode and decode

All data and primitives must be encoded prior to transmission on the line.

The 8B/10B encode/decode occur in the PHY layer.

22.4.7.1.8 CONT primitive processing

Using the CONT primitive, the link layer is capable of replacing repetitive primitive streams with scrambled data.

This reduces EMI emissions because primitives are not scrambled.

The link layer can transmit a CONT primitive at a point where it knows it must transmit a number of repeating primitives. After a CONT primitive has been transmitted, the link layer then transmits scrambled junk data to the PHY layer. The content of this junk data is disregarded. At the far end link layer, the reception of a CONT primitive will cause the last received valid primitive to be implied to be repeated until it receives the next valid non-ALIGN primitive. Transmission of a new valid primitive halts the current CONT processing; reception of a new valid non-ALIGN primitive halts the current CONT processing.

This action can occur on transmit and receive. The link layer supports both the transmission and reception of CONT primitives.

22.4.7.1.9 ALIGN insertion

The link layer is responsible for ALIGN insertion and removal at a fixed frequency.

A pair of ALIGN primitives are inserted into the transmit data stream every 254 words. At the receive end, the ALIGN primitives are stripped from the incoming data stream in the link layer.

For diagnostic purposes, the rate of ALIGNs can be increased to as much as two ALIGNS per one word; for example, ALIGN, ALIGN, data, ALIGN, ALIGN. In addition, the SEND_4_ALIGNS bit can be set to instruct the link layer to send four ALIGNs at a time instead of two.

22.4.7.1.10 Debug functionality

There are a number of useful features designed into the link layer to aid debug, as follows:

- The align insertion rate can be increased using the ALIGN_RATE register field in the command layer.
- Four error counters can be monitored by issuing register reads to the command layer: the disparity error counter, the code error counter, the PHY internal error counter, and the control character error counter.
- A number of configuration bits in the command layer can be used to override normal primitive insertion. For example,
  - Set PRIM_OVR_STATE = (L_SendHold state (16))
  - Set PRIM = 0xb5b5957c, that is, a SYNC primitive
  - During the transfer, set PRIM_OVRD_EN = 1
- When the link layer detects a rising edge on PRIM_OVRD_EN, it will insert one SYNC primitive into the datastream in place of the HOLD, when the LINK_STATE reaches the L_SendHold state. Only one HOLD primitive will be overridden; the PRIM_OVRD_EN must be cleared and written to again to force another override to occur.

22.4.7.1.11 BIST support

The transmit and receive subblocks of the link layer contain logic to support BIST activate FIS functionality.

When a BIST activate FIS is either received or transmitted successfully by the transport layer, it issues a request to the link layer to enter BIST mode. This forces the link layer to enter a BIST state in its state machine as soon as it receives a SYNC primitive from the far end. In the BIST state, the link layer transmits a data sequence as specified by the two

BIST data patterns in the BIST activate FIS. The link layer also monitors the incoming data from the PHY to detect the BIST data pattern is as specified in the BIST activate FIS. When it detects the correct data sequence, the HStatus[BIST_Err] is deasserted. The BIST_Err bit will stay deasserted unless an error occurs in the datastream from the far end.

22.4.8 PHY control layer overview

The PHY control layer operates between the PHY and link layers.

On receive, the PHY control layer converts the 16-bit parallel data from the PHY to a 32-bit word, which it presents to the link layer. The PHY control layer aligns the control word of the SATA primitive to the lowest word position of the word. The PHY control layer takes in the per-byte error signals and the per-byte control/data bits output by the PHY and converts them into 4-bit buses, with each bit of the bus corresponding to a byte in the word.

On transmit, the PHY control layer takes in the 32-bit transmit data from the link layer and converts it to 16 bits of data which it presents to the PHY. The control/data bit from the link layer (which is always assumed to be associated with the lowest byte position of the transmit word) is also passed onto the PHY with the appropriate word.

22.5 SATA initialization/application information

22.5.1 SATA controller initialization steps

These steps bring the SATA controller online, synchronize the SATA controller with the attached device, and issue typical command for execution.

1. Write HControl[HC_ON] = 1 to bring the SATA controller online.
2. Poll the HStatus[HS_ON] till HS_ON = 1, indicating that the controller is online.
3. Poll the SStatus[DET] till DET = 3'b0011 meaning that the device presence is detected and PHY communication is established. In this state, SStatus[SPD] indicates the negotiated communication speed.
4. To read the device's signature, poll HStatus[SIG_UPD] till it goes up. Read the signature from the SIG register.
5. Initialize the CHBA register to point to the command header block.
6. Build a command header block in memory. Refer to Command header.
7. Build a command descriptor block in memory. Refer to Command descriptor.

8. Build a number of PRD tables in memory as defined by the PRD_NUM field in the command header. Refer to Physical region descriptor table (PRDT).
9. Initialize the CQPMP register with the device's PM number. If the port multiplier is not used, clear this field.
10. Poll the CQR[CQ*n*] to determine which command can be issued.
11. After CQ*n* is determined, write 1 to CQR[CQ*n*] to issue this command and start execution.
12. Poll the CCR[CC*n*] till CC*n* goes up, indicating that the command is completed.

The following example presents the structure of descriptors to issue the ReadDMA command:

- Build the command header in memory.

Table 22-12. Read DMA command-command header

Word number	Hexadecimal value	Description
Word 0	CDA	Pointer to memory where command descriptor begins
Word 1	0x0002_0014	Two PRD tables contain the data, FIS length = 20 bytes
Word 2	0x0000_0200	Length of data associated with this command = 0x200
Word 3	All zeros	Tag = 0

- Build command descriptor in memory.

Table 22-13. Read DMA command-command descriptor

Word number	Hexadecimal value	Description
Word 0	0x00C8_8027	Command = Read DMA
Word 1	0x0000_0010	LBA = 24'h10
Word 2	All zeros	LBA(exp) = 24'h0
Word 3	0x0000_0001	Sector count = 1
Word 4	All zeros	Reserved

- Build two PRD entries in memory.

Table 22-14. Read DMA command-PRD entries

Word number	Hexadecimal value	Description
Word 0	PRD1	Address of first portion of data.
Word 1	All zeros	Reserved
Word 2	All zeros	Reserved
Word 3	0x0000_0100	PRD1 contains 0x100 bytes of data
Word 4	PRD2	Address of second portion of data.
Word 5	All zeros	Reserved

Table continues on the next page...

Table 22-14. Read DMA command-PRD entries (continued)

Word number	Hexadecimal value	Description
Word 6	All zeros	Reserved
Word 7	0x0000_0100	PRD2 contains 0x100 bytes of data

- Fill the PRD1 and PRD2 with user-defined data.

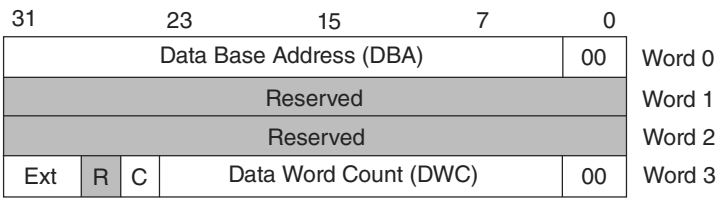

Figure 22-5. PRD entry

Chapter 23
DMA Controller

23.1 DMA overview

This chapter describes the DMA controller offered on this chip.

It describes a single DMA controller, which is instantiated three times on this chip. As such, all functionality is identical between the three controllers with the exception of the register offsets, as noted in the DMA register summary table , and the external signals, as noted in DMA signals table.

The DMA controller transfers blocks of data between the many interface and functional modules of this chip, independent of the cores or external hosts. It has eight high-speed DMA channels. Both the cores and external devices can initiate DMA transfers. The channels are capable of complex data movement and advanced transaction chaining. Operations such as descriptor fetches and block transfers are initiated by each channel. A channel is selected by the arbitration logic and information is passed to the source and destination control blocks for processing. The source and destination blocks generate read and write requests to the address tenure engine, which manages the DMA master port address interface. After a transaction is accepted by the master port, control is transferred to the data tenure engine that manages the read and write data transfers. A channel remains active in the shared resources for the duration of the data transfer unless the allotted bandwidth per channel is reached.

This figure shows the block diagram of the DMA controller.

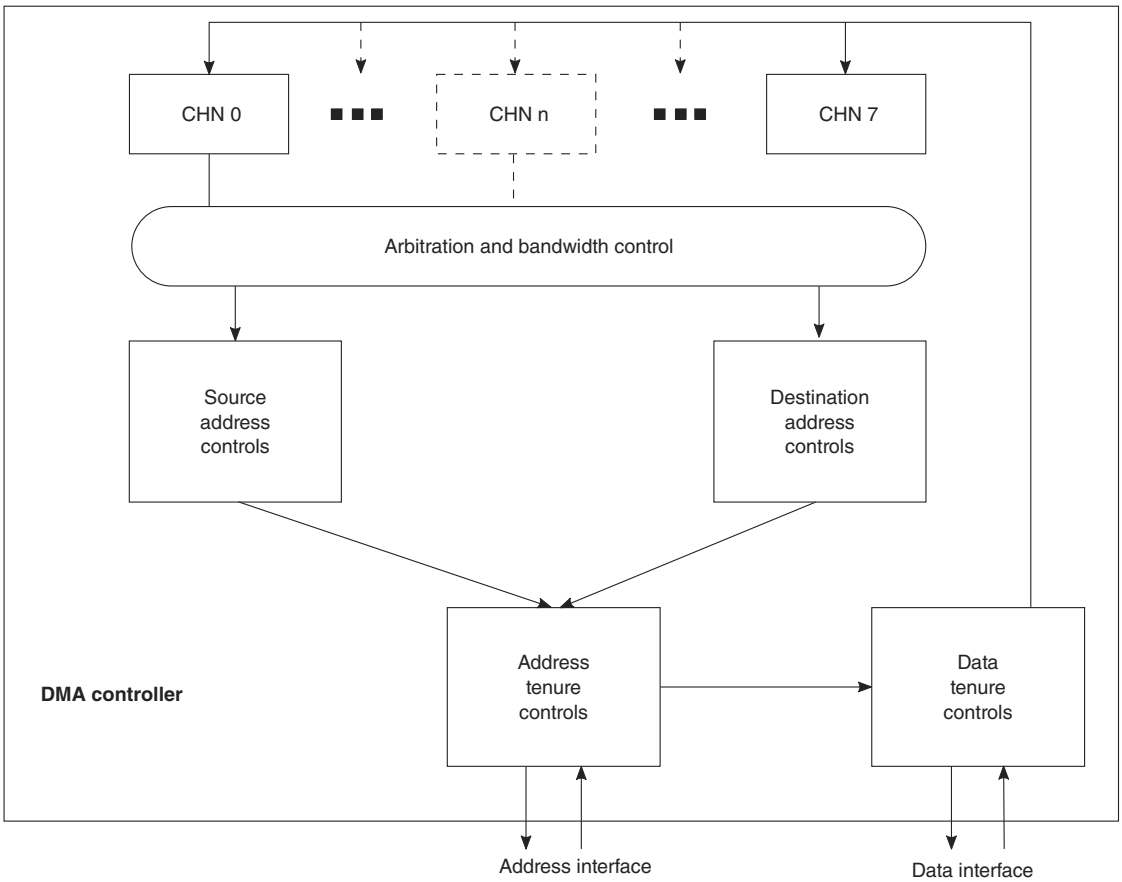

Figure 23-1. DMA block diagram

23.1.1 DMA features summary

The DMA controller offers the following features:

- Eight high-speed/high-bandwidth channels accessible by local and remote masters
- Basic DMA operation modes (direct, simple chaining)
- Extended DMA operation modes (advanced chaining and stride capability)
- Cascading descriptor chains
- Misaligned transfers
- Programmable bandwidth control between channels
- Up to 256 bytes for DMA sub-block transfers to maximize performance
- Interrupt on error and completed segment, list, or link
- Externally-controlled transfer using DMA_DREQ_B, DMA_DACK_B, and DMA_DDONE_B.

NOTE

These external control signals are available on DMA1 and DMA2. They are not supported by DMA3. For more details see Signals Overview

23.1.2 DMA modes of operation

The DMA module has two modes of operation: basic and extended.

Basic mode is the DMA legacy mode, which does not support advanced features. Extended mode supports advanced features such as striding and flexible descriptor structures.

These two modes allow users to initiate and end DMA transfers in various ways. Table 23-1 summarizes the relationship between the modes and the following features:

- Direct mode-No descriptors are involved. Software must initialize the required fields as described in Table 23-2 before starting a transfer.
- Chaining mode-Software must initialize descriptors in memory and the required fields as described in Table 23-2 before starting a transfer.
- Single-write start mode-The DMA process can be started using a single-write command to either the descriptor address register in one of the chaining modes or the source/destination address registers in one of the direct modes.
- External control capability-This allows an external agent to start, pause, and check the status of a DMA transfer that has already been initialized.
- Channel continue capability-The channel continue capability allows software the flexibility of having the DMA controller start with descriptors that have already been programmed while software continues to build more descriptors in memory.
- Channel abort capability-The software can abort a previously initiated transfer by setting the bit MR*n*[CA]. The DMA controller terminates all outstanding transfers initiated by the channel without generating any errors before entering an idle state.

Table 23-1. Relationship of modes and features

Mode	Mode with one additional feature	Mode with two additional features
B (Basic)	BD (basic direct)	BDS (BD single-write start)
		BDE (BD external control)
	BC (basic chaining)	BCE (BC external control)
		BCS (BC single-write start)
Ext (Extended)	ExtD (extended direct)	ExtDS (ExtD single-write start)
		ExtDE (ExtD external control)
	ExtC (extended chaining)	ExtCE (ExtC external control)

Table continues on the next page...

Table 23-1. Relationship of modes and features (continued)

Mode	Mode with one additional feature	Mode with two additional features
		ExtCS (ExtC single-write start)

The following table describes bit settings required for each DMA mode of operation.

Table 23-2. DMA mode bit settings

Modes with features	MRn[XFE]	MRn[CTM]	MRn[SRW]	MRn[CDSM_SWSM]	MRn[EMS_EN]
Basic direct modes					
Basic direct	0	1	0	0	0
Basic direct external control	0	1	0	0	1
Basic direct single-write start	0	1	1	1 or 0	0
Basic chaining modes					
Basic chaining	0	0	Reserved	0	0
Basic chaining external control	0	0	Reserved	0	1
Basic chaining single-write start	0	0	Reserved	1	0
Extended direct modes					
Extended direct	1	1	0	0	0
Extended direct external control	1	1	0	0	1
Extended direct single-write start	1	1	1	1 or 0	0
Extended chaining modes					
Extended chaining	1	0	Reserved	0	0
Extended chaining external control	1	0	Reserved	0	1
Extended chaining single-write start	1	0	Reserved	1	0

See DMA functional description for details on these modes.

This figure shows the general DMA operational flow chart.

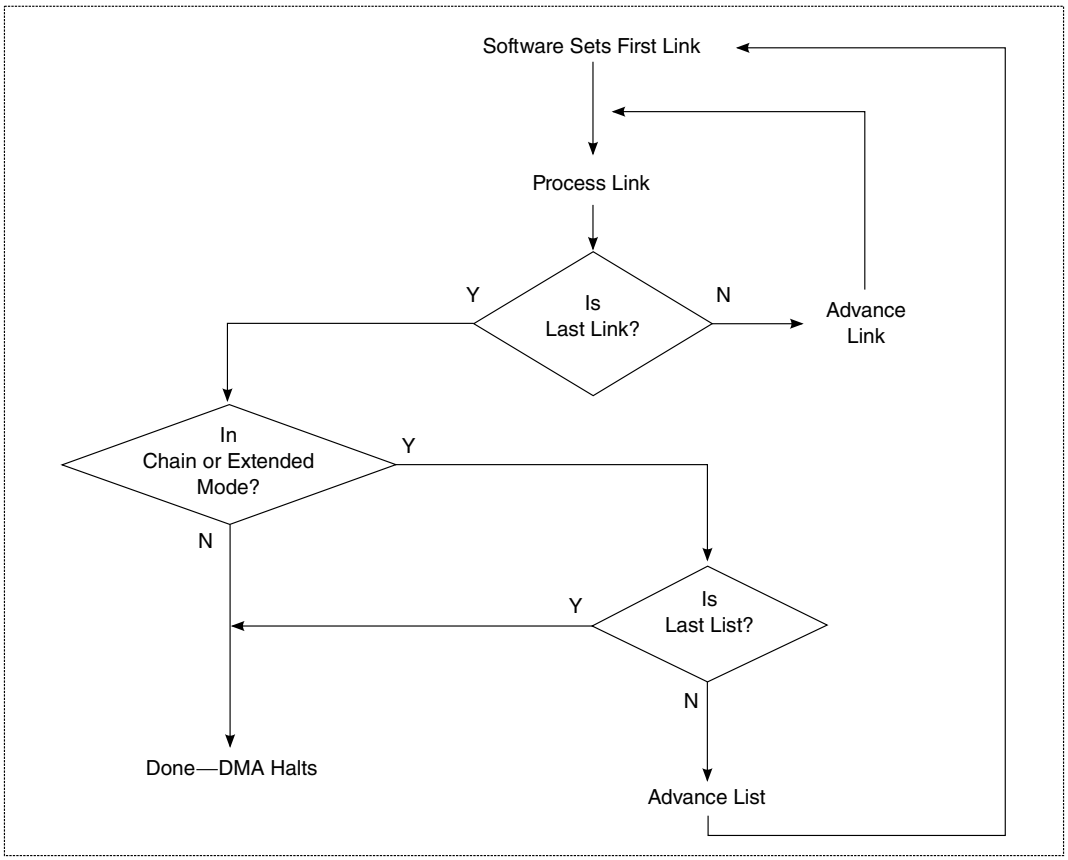

Figure 23-2. DMA operational flow chart

23.2 DMA external signal description

This section describes the external DMA signals.

23.2.1 Signal overview

This figure summarizes the DMA controller signals.

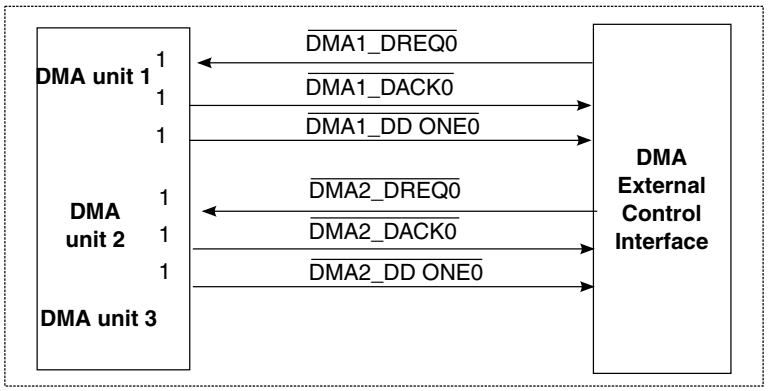

Figure 23-3. DMA signal summary

Note the DMA signals are multiplexed with a variety of other functionality.

NOTE

These signals are available on DMA1 and DMA2. They are not supported by DMA3.

23.2.2 DMA signal descriptions

This table describes the external DMA control signals. These signals are only utilized when operating in external master mode.

See External control mode transfer.

NOTE

External Control is supported on channel 0 only

Table 23-3. DMA signals-detailed signal descriptions

Signal	I/O	Description	
DMA_DREQ_B	I	DMA request. Indicates the start of a DMA transfer or a restart from a paused request. Assertion of DMA_DREQ_B causes MRn[CS] to be set, thereby activating the corresponding DMA channel.	
		State Meaning	Asserted-Assertion of DMA_DREQ_B while DMA_DACK_B is negated causes a new transfer to start OR resumes a paused transfer if the EMP_EN bit is set. Assertion while DMA_DACK_B is asserted results in an illegal condition. Negated-Negation while DMA_DACK_B is asserted has no effect. Negation before the assertion of DMA_DACK_B results in an illegal condition.
		Timing	Assertion-Can be asserted asynchronously Negation- Must remain asserted at least until the assertion of the corresponding DMA_DACK_B
DMA_DACK_B	O	DMA acknowledge. Indicates that a DMA transfer is currently in progress	
		State Meaning	Asserted-Indicates that a DMA transfer is currently in progress. Asserted after the assertion of DMA_DREQ_B to indicate the start of a transfer

Table continues on the next page...

Table 23-3. DMA signals-detailed signal descriptions (continued)

Signal	I/O	Description	
			Negated-Negated after finishing a complete transfer or after entering a paused state if MRn[EMP_EN] is set
		Timing	Assertion-Asynchronous assertion; asserted for more than three system clocks Negation-Asynchronous negation; negated for more than three system clocks
DMA_DDONE_B	O	DMA done. Indicates that a DMA transfer is complete	
		State Meaning	Asserted-Indicates transfer completion. SRn[CB] is clear. Note, however, that write data may still be queued at the target interface or in the process of transfer on an external interface. Negated-Indicates that the current transfer is in process
		Timing	Assertion-Always asserts asynchronously after the negation of the final DMA_DACK_B to indicate completion of a transfer. For a paused transfer, DMA_DDONE_B is asserted asynchronously after the negation of the final DMA_DACK_B. Negation-Negated asynchronously after the assertion of DMA_DREQ_B for the next transfer

NOTE

These signals are available on DMA1 and DMA2. They are not supported by DMA3. For more details see Signals Overview

23.3 DMA controller memory map

This section provides a detailed description of all accessible DMA memory and registers . The descriptions include individual, bit-level descriptions and reset states of each register. Undefined 4-byte address spaces within the map are reserved.

This table lists the DMA registers and their offsets. Note that the full register address is comprised of the programmable CCSRBAR together with the fixed DMA block base address and offset listed in table below.

DMA memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
10_0100	DMA mode register (DMA1_MR0)	32	R/W	0800_0000h	23.3.1/2121
10_0104	DMA status register (DMA1_SR0)	32	R/W	0000_0000h	23.3.2/2125
10_0108	DMA current link descriptor extended address register (DMA1_ECLNDAR0)	32	R/W	0000_0000h	23.3.3/2126

Table continues on the next page...

DMA memory map (continued)

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
10_010C	DMA current link descriptor address register (DMA1_CLNDAR0)	32	R/W	0000_0000h	23.3.4/2127
10_0110	DMA source attributes register (DMA1_SATR0)	32	R/W	0000_0000h	23.3.5/2129
10_0114	DMA source address register (DMA1_SAR0)	32	R/W	0000_0000h	23.3.6/2130

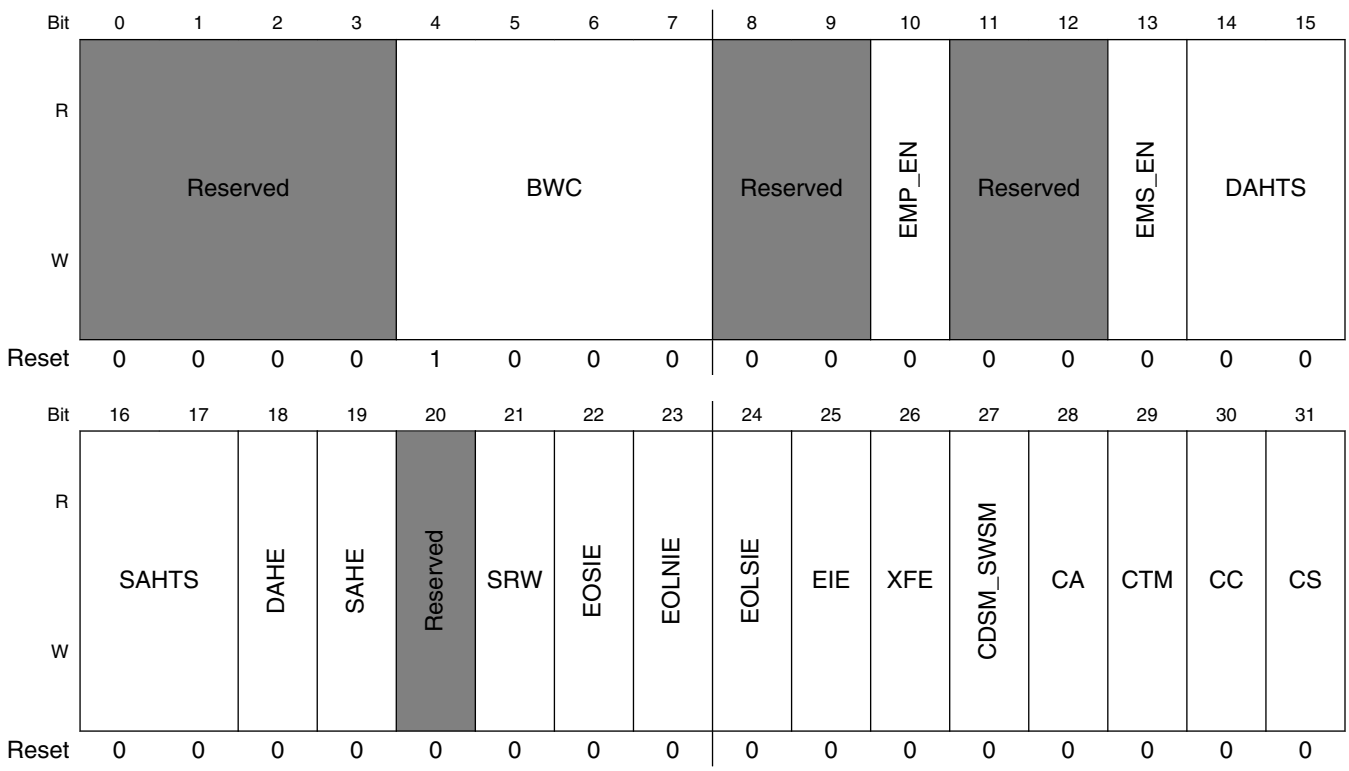
23.3.1 DMA mode register (DMA*x*_MR*n*)

The mode register allows software to start a DMA transfer and to control various DMA transfer characteristics.

Address: Base address + 100h offset + (128d × i), where i=0d to 3d



DMA*x*_MR*n* field descriptions

Field	Description
0–3 -	This field is reserved.
4–7 BWC	Bandwidth/pause control. Defined when single and multiple channels are executing or if MRn[EMP_EN] is set in external transfer mode.

Table continues on the next page...

DMAx_MRn field descriptions (continued)

Field	Description
	The value of MRn[BWC] determines how many bytes a given channel is allowed to transfer before the DMA engine pauses the current channel and re-arbitrates (switches to the next channel). In external pause mode, the value of MRn[BWC] dictates how many bytes are allowed to transfer before pausing the channel, after which a new assertion of DREQ_B resumes channel operation. 0000 1 byte 0001 2 bytes 0010 4 bytes 0011 8 bytes 0100 16 bytes 0101 32 bytes 0110 64 bytes 0111 128 bytes 1000 256 bytes 1001 512 bytes 1010 1024 bytes 1011-1110 Reserved 1111 Disable bandwidth sharing to allow uninterrupted transfers from each channel.
8–9 -	This field is reserved.
10 EMP_EN	External master pause enable. Valid only if MRn[EMS_EN] is set. 0 Disable the external master pause feature. 1 Enable the external master pause feature. Channel is paused as described by MRn[BWC].
11–12 -	This field is reserved.
13 EMS_EN	External master start enable. This bit does not apply to single-write start modes (direct or chaining). 0 Disable the channel from being started by an external DMA start pin. 1 Enable the channel to be started by an external DMA start pin, which sets MRn[CS].
14–15 DAHTS	Destination address hold transfer size. Indicates the transfer size used for each transaction while MRn[DAHE] is set. The byte count register must be in multiples of the size and the destination address register must be aligned based on the size. The transfer size assigned to MRn[DAHTS] must be equal to or smaller than that assigned to MRn[BWC] to avoid undefined behavior. 00 1 byte 01 2 bytes 10 4 bytes 11 8 bytes
16–17 SAHTS	Source address hold transfer size. Indicates the transfer size used for each transaction while MRn[SAHE] is set. The byte count register must be in multiples of the size and the source address register must be aligned based on the size. The transfer size assigned to MRn[SAHTS] must be equal to or smaller than that assigned to MRn[BWC] to avoid undefined behavior. 00 1 byte 01 2 bytes 10 4 bytes 11 8 bytes

Table continues on the next page...

DMA*x*_MR*n* field descriptions (continued)

Field	Description
18 DAHE	Destination address hold enable 0 Disable destination address hold 1 Enable the DMA controller to hold the destination address of a transfer to the size specified by MRn[DAHTS]. Hardware only supports aligned transfers for this feature.
19 SAHE	Source address hold enable 0 Disable source address hold 1 Enable the DMA controller to hold the source address of a transfer to the size specified by MRn[SAHTS]. Hardware only supports aligned transfers for this feature.
20 -	This field is reserved.
21 SRW	Single register write (Direct mode only; reserved for chaining mode.) 0 Normal operation 1 Enable a write to the source address register to simultaneously set MRn[CS], starting a DMA transfer, when MRn[CDSM_SWSM] is also set. Setting this bit and clearing CDSM_SWSM causes a write to the destination address register to simultaneously set MRn[CS], starting a DMA transfer.
22 EOSIE	End-of-segments interrupt enable 0 Do not generate an interrupt at the completion of a data transfer. CLNDARn[EOSIE] overrides this bit on a link descriptor basis. 1 Generate an interrupt at the completion of a data transfer (That is, SRn[EOSI] is set). This bit overrides the CLNDARn[EOSIE].
23 EOLNIE	End-of-links interrupt enable 0 Do not generate an interrupt at the completion of a list of DMA transfers. 1 Generate an interrupt at the completion of a list of DMA transfers (That is, NLNDARn[EOLND] is set).
24 EOLSIE	End-of-lists interrupt enable 0 Do not generate an interrupt at the completion of all DMA transfers. 1 Generate an interrupt at the completion of all DMA transfers (That is, NLNDARn[EOLND] and NLSDARn[EOLSD] are set).
25 EIE	Error interrupt enable 0 Do not generate an interrupt if a programming or transfer error is detected. 1 Generate an interrupt if a programming or transfer error is detected.
26 XFE	Extended features enable 0 Disable striding feature in direct mode or disable list chaining feature in chaining mode. 1 Enable striding feature in direct mode or enable list chaining feature in chaining mode.
27 CDSM_SWSM	In chaining mode, current descriptor start mode/single-write start mode is as follows: • In basic mode (MRn[XFE] is cleared), setting this bit causes a write to the current link descriptor address register to simultaneously set MRn[CS], starting a DMA transfer. • In extended chaining mode (MRn[XFE] is set), setting this bit causes a write to the current list descriptor address register to simultaneously set MRn[CS], starting a DMA transfer. In direct mode, setting this bit and MRn[SRW] causes a write to the source address register to simultaneously set MRn[CS], starting a DMA transfer. Clearing this bit and setting MRn[SRW] causes a write to the destination address register to simultaneously set MRn[CS], starting a DMA transfer. This bit must be cleared when MRn[SRW] is cleared.

Table continues on the next page...

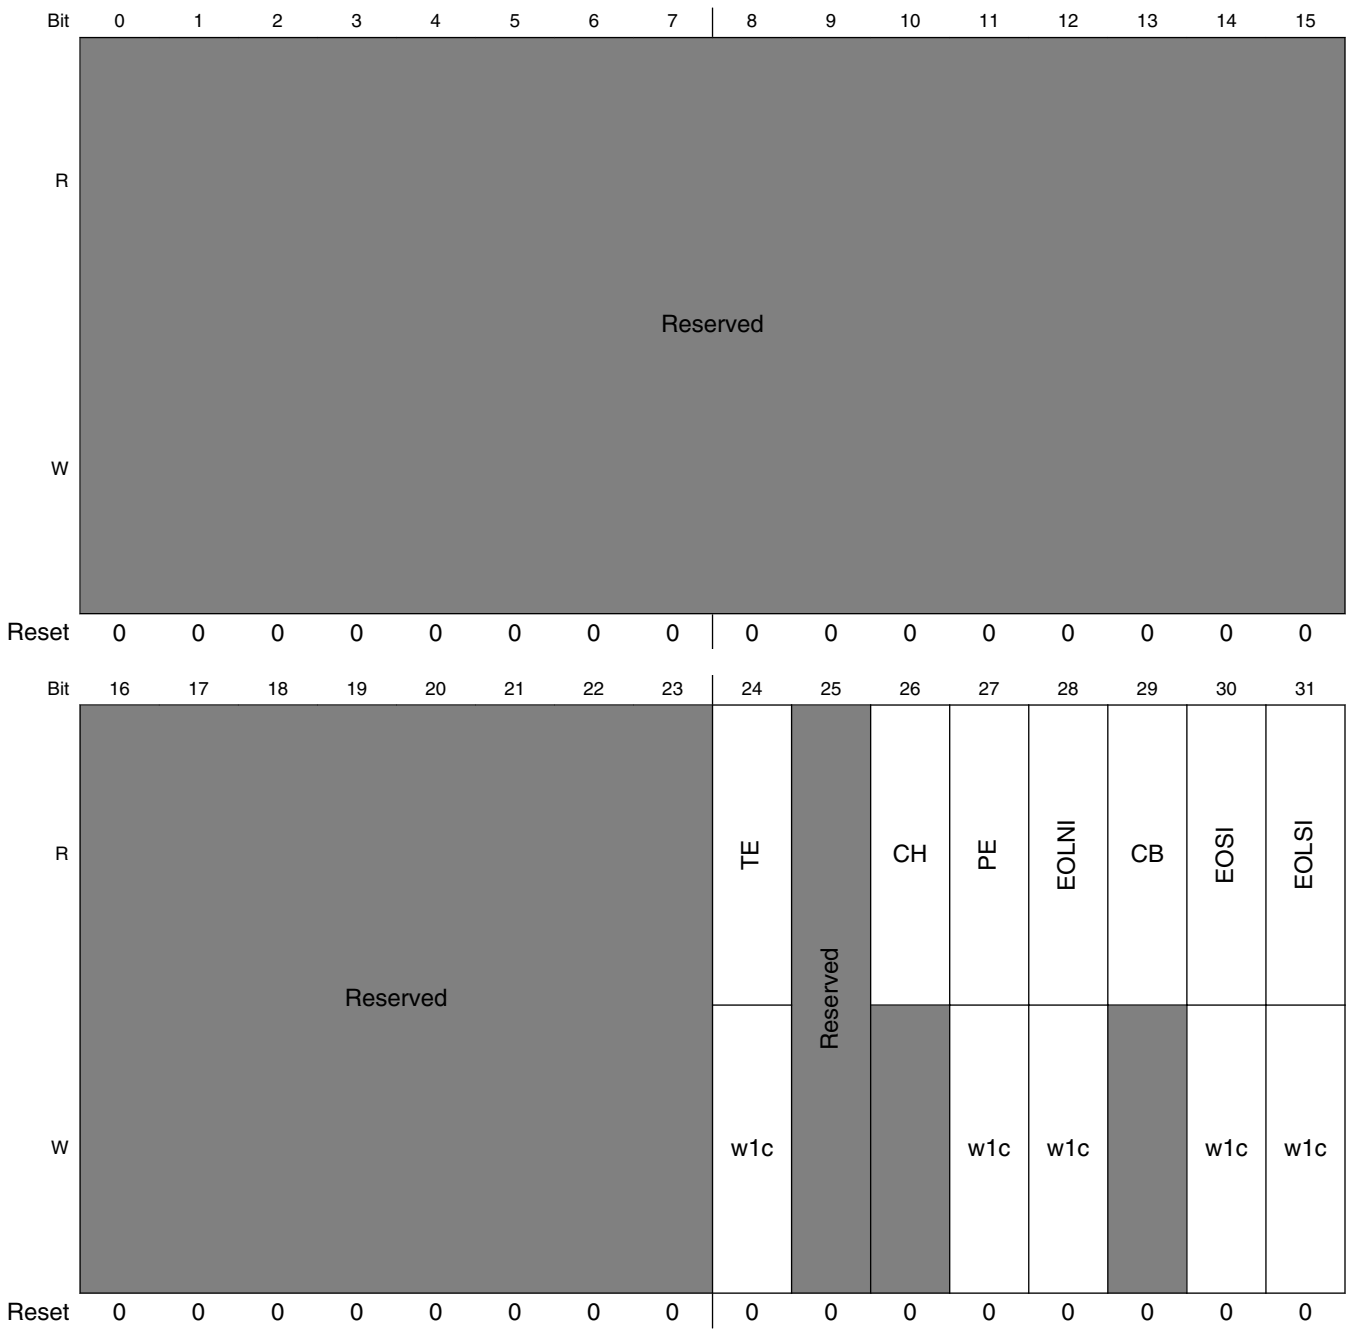
DMA*x*_MR*n* field descriptions (continued)

Field	Description
28 CA	Channel abort 0 No effect 1 Cause the current transfer to be aborted and SRn[CB] to be cleared if the channel is busy. The channel remains in the idle state until a new transfer is programmed.
29 CTM	Channel transfer mode 0 Configure the channel in chaining mode. 1 Configure the channel into direct mode. This means that software is responsible for placing all the required parameters into necessary registers to start the DMA process.
30 CC	Channel continue. This bit applies only to chaining mode and is cleared by hardware after the first descriptor read when continuing a transfer. This bit is reserved for external master mode. 0 No effect 1 The DMA transfer restarts the transferring process starting at the current descriptor address.
31 CS	Channel start. This bit is also automatically set by hardware during single-write start mode and external master start enable mode. Note that in external control mode, deasserting DMA_DREQ_B does NOT clear this bit. 0 Halt the DMA process if channel is busy (SRn[CB] is set). No effect if the channel is not busy. 1 Start the DMA process if channel is not busy (CB is cleared). If the channel was halted (CS = 0 and CB = 1), the transfer continues from the point at which it was halted.

23.3.2 DMA status register (DMA*x*_SR*n*)

The status registers report various DMA conditions during and after a DMA transfer.

Address: Base address + 104h offset + (128d × i), where i=0d to 3d



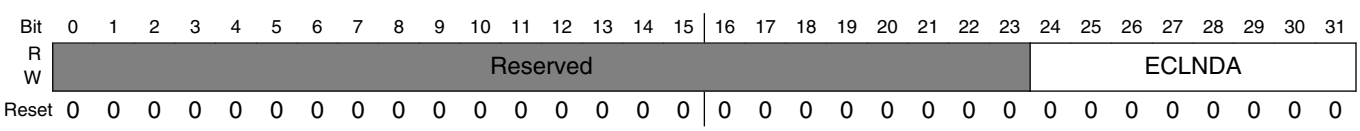
DMAx_SR*n* field descriptions

Field	Description
0–23 -	This field is reserved.
24 TE	Transfer error (Bit reset, write 1 to clear) 0 No error condition during the DMA transfer 1 Error condition during the DMA transfer. See DMA errors , for additional information.
25 -	This field is reserved.
26 CH	Channel halted. Cleared automatically by hardware if MR *n* [CS] is set again for resuming a halted transfer 0 Channel is not halted. If software attempts to halt an idle channel (SRn[CB] is cleared), this bit remains 0. 1 DMA transfer was successfully halted by software and can be resumed.
27 PE	Programming error (bit reset, write 1 to clear) 0 No programming error detected 1 A programming error is detected that prevents the DMA transfer from occurring.
28 EOLNI	End-of-links interrupt. After transferring the last block of data in the last link descriptor, if MRn[EOLNIE] is set, then this bit is set and an interrupt is generated. (Bit reset, write 1 to clear)
29 CB	Channel busy 0 DMA transfer is finished, an error occurred, or a channel abort occurred. 1 DMA transfer is currently in progress.
30 EOSI	End-of-segment interrupt. In chaining mode, after finishing a data transfer, if MRn[EOSIE] is set or if CLNDARn[EOSIE] is set, this bit gets set and an interrupt is generated. In direct mode, if MRn[EOSIE] is set, this bit gets set and an interrupt is generated. (Bit reset, write 1 to clear)
31 EOLSI	End-of-list interrupt. After transferring the last block of data in the last list descriptor, if MRn[EOLSIE] is set, then this bit is set and an interrupt is generated. (Bit reset, write 1 to clear)

23.3.3 DMA current link descriptor extended address register (DMAx_ECLNDAR*n*)

These registers contain the upper 8 bits of the address of the current link descriptor. See DMA current link descriptor address register (DMA_CLNDAR*n*) and DMA current link descriptor address register (DMA_CLNDAR*n*) for a description of basic chaining mode.

Address: Base address + 108h offset + (128d × i), where i=0d to 3d



DMAx_ECLNDAR*n* field descriptions

Field	Description
0–23 -	This field is reserved.
24–31 ECLNDA	Current link descriptor extended address (upper 8 bits of 40-bit address)

23.3.4 DMA current link descriptor address register (DMAx_CLNDAR*n*)

Current link descriptor address registers contain the address of the current link descriptor.

In basic chaining mode, shown in , software must initialize these registers to point to the first link descriptors in memory.

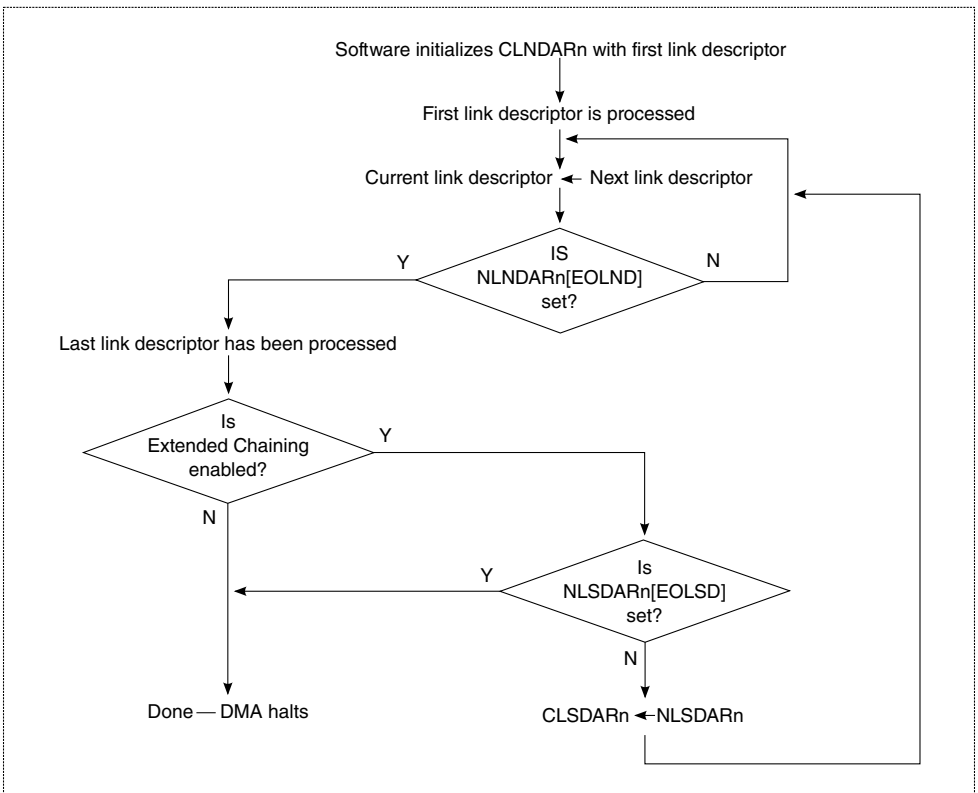


Figure 23-4. Basic Chaining Mode Flow Chart

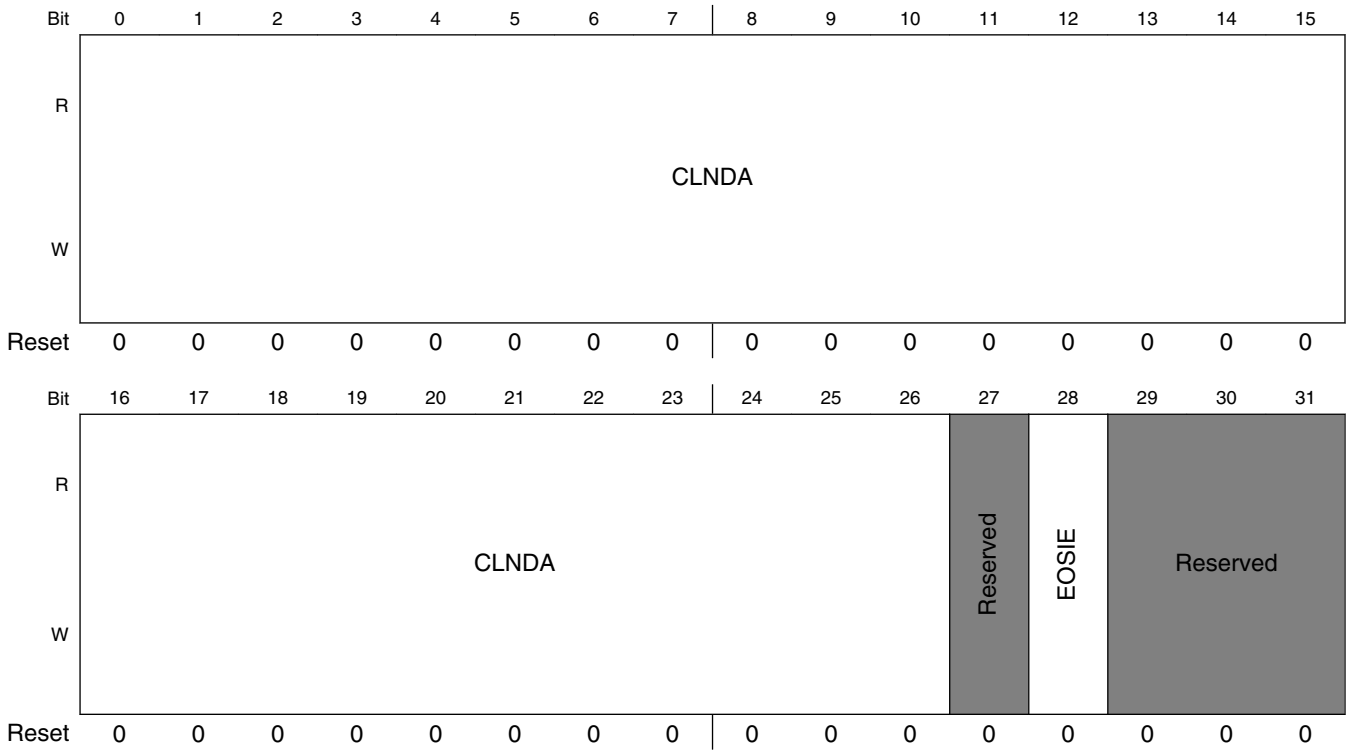
After the current descriptor is processed, the current link descriptor address register is loaded from the next link descriptor address register and NLNDAR *n* [EOLND] in the next link descriptor address register is examined. If EOLND is zero, the DMA controller reads in the new current link descriptor for processing. If EOLND is set, the last descriptor of the list was just completed. If extended chaining mode is not enabled, all DMA transfers are complete and the DMA controller halts.

If extended chaining mode is enabled, the DMA controller examines the state of NLSDAR *n* [EOLSD] in the next list descriptor address register. If EOLSD is clear, the controller loads the contents of the next list descriptor address register into the current list descriptor address register and reads the new list descriptor from memory. If EOLSD is set, all DMA transfers are complete and the DMA controller halts.

Address: Base address + 10Ch offset + (128d × i), where i=0d to 3d



DMA*x*_CLNDAR*n* field descriptions

Field	Description
0–26 CLNDA	Current link descriptor address. Contains the current descriptor address of the buffer descriptor in memory. The descriptor must be aligned to a 32-byte boundary. (This is the lower portion of the 40 -bit address formed by CLNDARn[CLNDA] and ECLNDARn[ECLNDA].)
27 -	This field is reserved.
28 EOSIE	End-of-segment interrupt enable 0 Do not generate an interrupt upon completion of the current DMA transfer for the current link descriptor. 1 Generate an interrupt upon completion of the current DMA transfer for the current link descriptor.
29–31 -	This field is reserved.

23.3.5 DMA source attributes register (DMA*x*_SATR*n*)

The source attributes registers contain the transaction attributes to be used for the DMA operation for channels 0-3. Stride mode is enabled by setting SATR*n*[SSME]. The target interface is derived from the local access window and outbound ATMU mappings and the transaction is obtained from the value specified in SATR*n*[SREADTTYPE].

Address: Base address + 110h offset + (128d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

DMA*x*_SATR*n* field descriptions

Field	Description
0–6 -	This field is reserved.
7 SSME	Source stride mode enable. Ignored in basic mode (MRn[XFE] is cleared). Striding on the source address can be accomplished by enabling SATRn[SSME] and setting the desired stride size and distance in the SSRn. 0 Stride mode disabled 1 Stride mode enabled
8–11 -	This field is reserved. Reserved
12–15 SREADTTYPE	DMA source transaction type. Reserved values result in a programming error being detected and logged in SR[PE]. Transaction type to run on local address space . 0000-0011 Reserved 0100 Read, do not snoop local processor 0101 Read, snoop local processor 0110-1011 Reserved 1100 Enhanced read, don't snoop local processor

Table continues on the next page...

DMAx_SATRn field descriptions (continued)

Field	Description
	1101 Enhanced read, snoop local processor 1110-1111 Reserved
16–23 -	This field is reserved.
24–31 ESAD	Extended source address. ESAD represents the eight high-order bits of the 40-bit source address.

23.3.6 DMA source address register (DMAx_SARn)

The source address registers contain the address from which the DMA controller (channels 0-3) reads data. In direct mode, if MR*n*[CDSM_SWSM] and MR*n*[SRW] are set, a write to this register simultaneously sets MR*n*[CS], starting a DMA transfer. Software must ensure that this is a valid address.

Address: Base address + 114h offset + (128d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	SAD																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

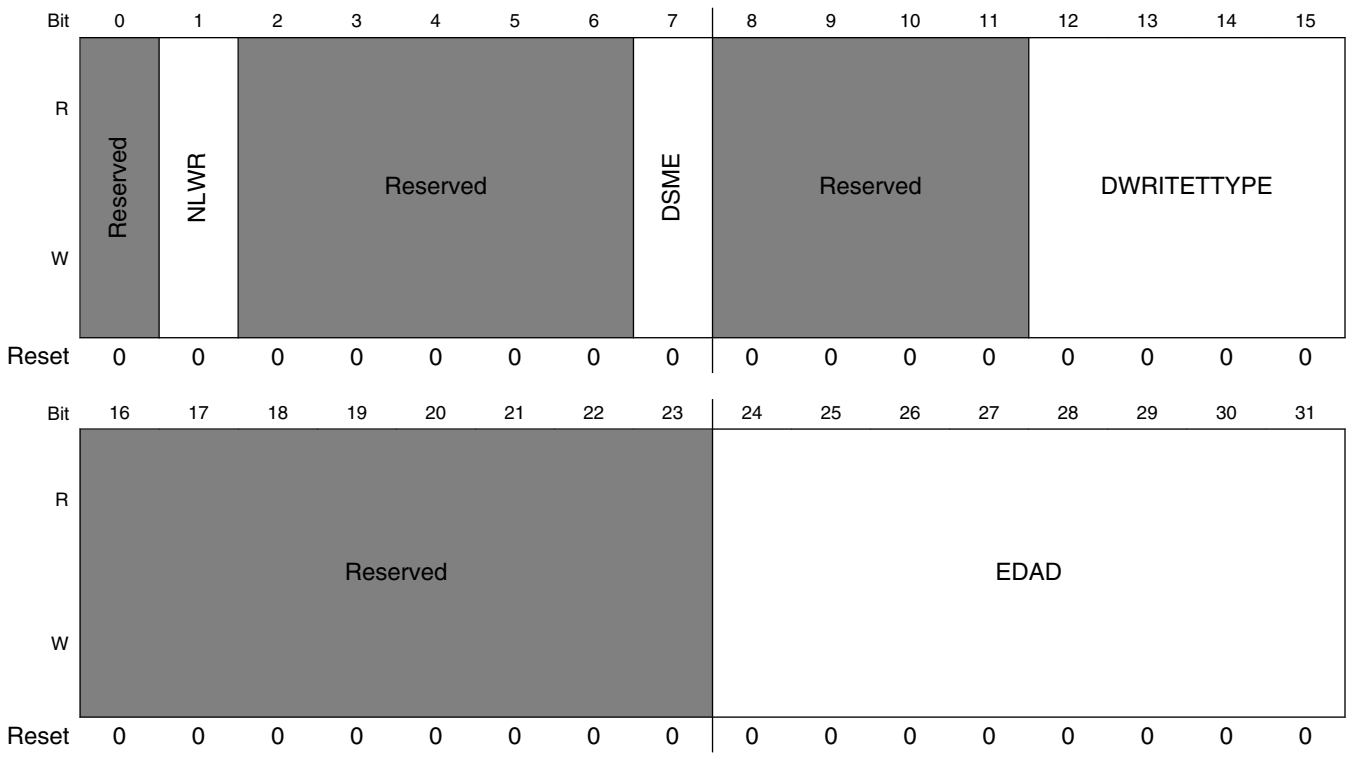
DMAx_SARn field descriptions

Field	Description
0–31 SAD	Source address. This register contains the low-order bits of the 40-bit source address of the DMA transfer for channels 0-3. The contents are updated after every DMA write operation unless the final stride of a striding operation is less than the stride size, in which case it remains equal to the address from which the last stride began.

23.3.7 DMA destination attributes register (DMA*x*_DATR*n*)

The destination attributes registers contain the transaction attributes for the DMA operation for DMA channels 0-3. Stride mode is enabled by setting DATR*n*[DSME]. The target interface is derived from the local access window and outbound ATMU mappings and the transaction is obtained from the value specified in DATR*n*[DWRITETTYPE].

Address: Base address + 118h offset + (128d × i), where i=0d to 3d



DMA*x*_DATR*n* field descriptions

Field	Description
0 -	This field is reserved.
1 NLWR	No last write with response. Performance impact: • When NLWR is cleared only one "write-with-response" transaction can be processed/in-flight at a time, which prevents pipelining of "write-with-response" transactions. • When NLWR is set "write-without-response" transactions can be issued in a pipelined manner not being stalled by a write response. Error impact:

Table continues on the next page...

DMAx_DATR*n* field descriptions (continued)

Field	Description
	• When NLWR is cleared the returned response includes error status which is used to update the SR[TE] field. • When NLWR is set, since no response is returned, the SR[TE] field is not updated with write transaction error status. 0 "Write-with-response" transactions are generated for the last transaction in a multi-transaction transfer. Single writes will be NWRITE_R. A response is returned from the module targeted by the write transfer (ex. DDR controller, IFC, PCI-Express,...) informing the DMA of write completion and error status. 1 "Write-without-response" transactions are generated for the last transaction in a multi-transaction transfer. The DMA considers a transfer to be complete when the last write transaction is issued (not necessarily when the transaction has reached the target).
2–6 -	This field is reserved.
7 DSME	Destination stride mode enable Ignored in basic mode (MRn[XFE] is cleared). Striding on the destination address can be accomplished by setting DSME and setting the desired stride size and distance in DSRn. 0 Stride mode disabled 1 Stride mode enabled
8–11 -	This field is reserved.
12–15 DWRITETTYPE	DMA destination transaction type. Reserved values result in a programming error being detected and logged in SR[PE]. Transaction type to run on local address space. 0000-0011 Reserved 0100 Write, do not snoop local processor 0101 Write, snoop local processor 0110-1011 Reserved 1100 Enhanced write, don't snoop local processor 1101 Enhanced write, snoop local processor 1110-1111 Reserved
16–23 -	This field is reserved.
24–31 EDAD	Extended destination address. EDAD represents the eight high-order bits of the 40-bit destination address.

23.3.8 DMA destination address register (DMA*x*_DAR*n*)

The destination address registers contain the addresses to which the DMA controller (channels 0-3) writes data.

In direct mode, if MR*n*[SRW] is set and MR*n*[CDSM_SWSM] is cleared, a write to this register simultaneously sets MR*n*[CS], starting a DMA transfer. Software must ensure that this is a valid address.

Address: Base address + 11Ch offset + (128d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Field	Description
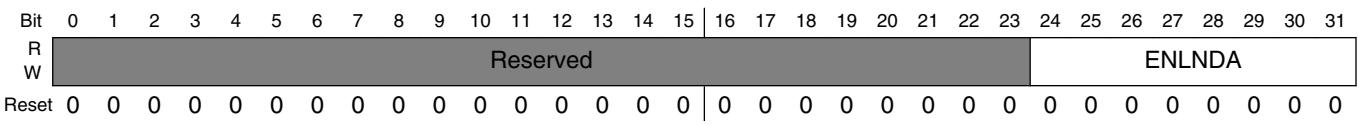
0–5 -	This field is reserved.
6–31 BC	Byte count. Contains the number of bytes to transfer. The value in this register is decremented after each DMA read operation. The maximum transfer size is (2^{26}) - 1 bytes.

23.3.10 DMA extended next link descriptor address register (DMAx_ENLNDAR*n*)

These registers contain the upper 8 bits of the address of the next link descriptor in memory. See DMA next link descriptor address register (DMA_NLNDAR*n*) and DMA next link descriptor address register (DMA_NLNDAR*n*).

Address: Base address + 124h offset + (128d × i), where i=0d to 3d



DMAx_ENLNDAR*n* field descriptions

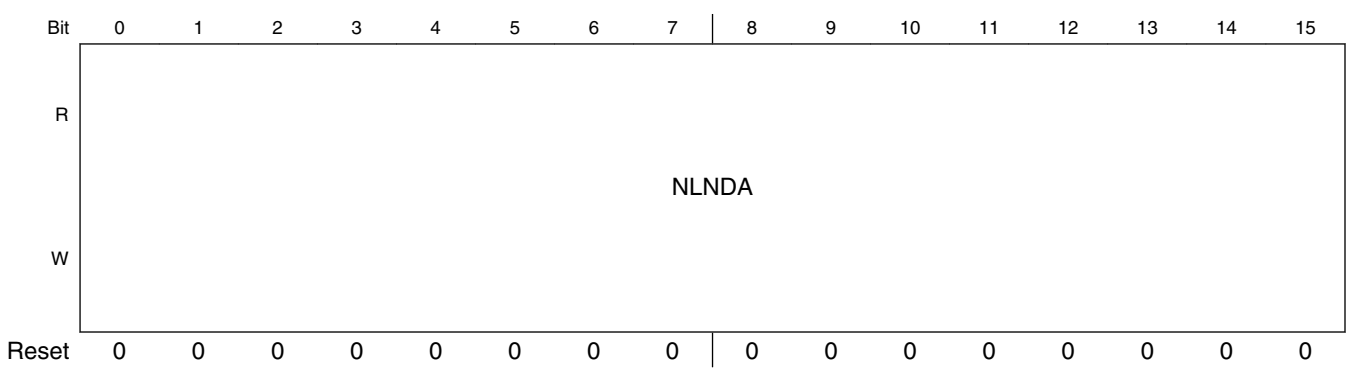
Field	Description
0–23 -	This field is reserved.
24–31 ENLNDA	Next link descriptor extended address bits (upper 8 bits of 40-bit address)

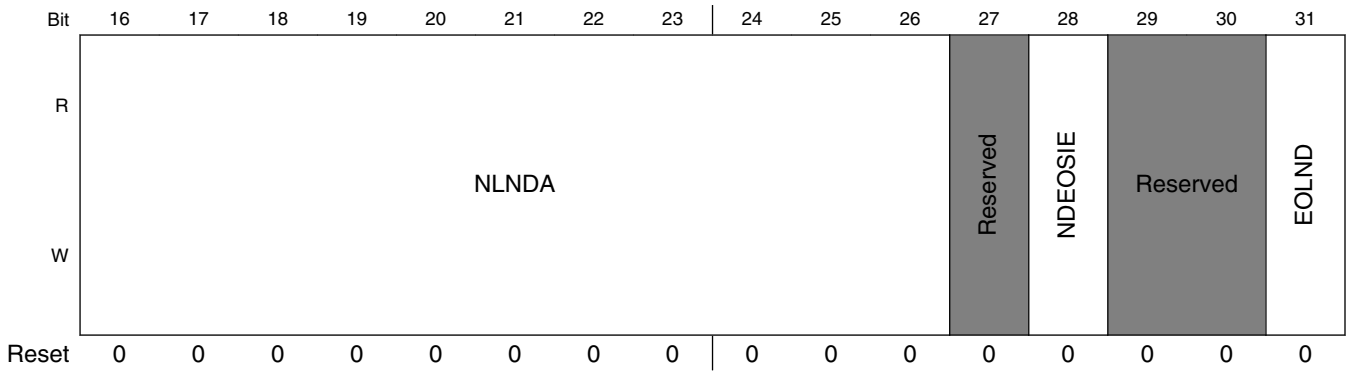
23.3.11 DMA next link descriptor address register (DMAx_NLNDAR*n*)

Current link descriptor address registers contain the address for the next link descriptor in memory.

Contents transferred to the current descriptor address registers become effective for the current transfer in basic and extended chaining modes.

Address: Base address + 128h offset + (128d × i), where i=0d to 3d





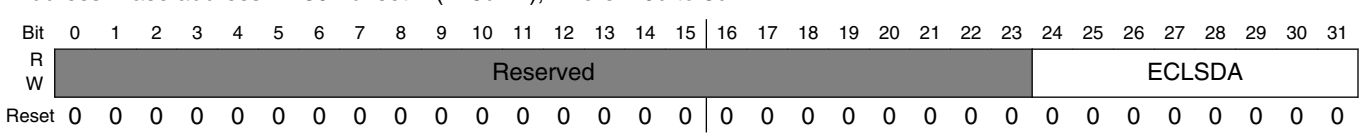
DMAx_NLNDAR*n* field descriptions

Field	Description
0–26 NLNDA	Next link descriptor address. Contains the bits 32-5 of the 40-bit next link descriptor address in memory. The descriptor must be aligned to a 32-byte boundary.
27 -	This field is reserved.
28 NDEOSIE	Next descriptor end-of-segment interrupt enable 0 Do not generate an interrupt if the current DMA transfer for the current descriptor is finished. 1 Generate an interrupt if the current DMA transfer for the current descriptor is finished.
29–30 -	This field is reserved.
31 EOLND	End-of-links descriptor. This bit is ignored in direct mode. 0 This descriptor is not the last link descriptor in memory for this list. 1 This descriptor is the last link descriptor in memory for this list. If this bit is set, the DMA controller advances to the next list descriptor in memory if NLSDARn[EOLSD] is also set in extended mode.

23.3.12 DMA extended current list descriptor address register (DMAx_ECLSDAR*n*)

These registers contain the upper 8 bits of the current address of the list descriptor in memory in extended chaining mode. See DMA current list descriptor address register (DMA_CLSDAR*n*) and DMA current list descriptor address register (DMA_CLSDAR*n*).

Address: Base address + 130h offset + (128d × i), where i=0d to 3d



DMA*x*_ECLSDAR*n* field descriptions

Field	Description
0–23 -	This field is reserved.
24–31 ECLSDA	Current list descriptor extended address bits (upper 8 bits of 40-bit address)

23.3.13 DMA current list descriptor address register (DMA*x*_CLSDAR*n*)

The current list descriptor address registers contain the current address of the list descriptor in memory in extended chaining mode.

In extended chaining mode, software must initialize CLSDAR*n* and ECLSDAR *n* to point to the first list descriptor in memory. After finishing the last link descriptor in the current list, the DMA controller loads the contents of the next list descriptor address register into the current list descriptor address register. If NLSDAR *n* [EOLSD] in the next list descriptor address register is clear, the DMA controller reads the new current list descriptor from memory to process that list. If EOLSD in the next list descriptor address register is set and the last link in the current list is finished, all DMA transfers are complete.

Address: Base address + 134h offset + (128d × i), where i=0d to 3d

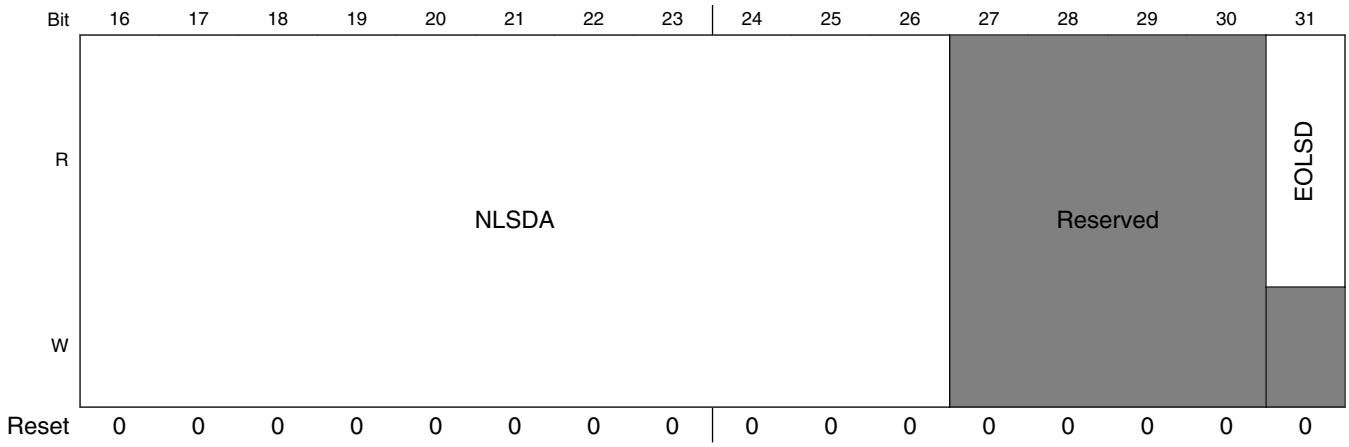
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



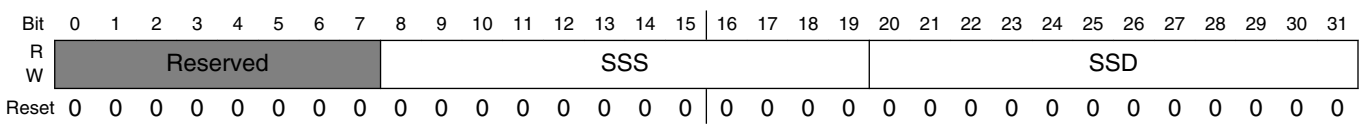
DMAx_NLSDAR*n* field descriptions

Field	Description
0–26 NLSDA	Next list descriptor address. Contains the bits 32-5 of the 40-bit next descriptor address of the buffer descriptor in memory. The descriptor must be aligned on a 32-byte boundary.
27–30 -	This field is reserved.
31 EOLSD	End-of-lists descriptor. This bit is ignored in direct mode. 0 This list descriptor is not the last list descriptor in memory. 1 This list descriptor is the last list descriptor in memory. If this bit is set, then the DMA controller halts after the last link descriptor transaction is finished.

23.3.16 DMA source stride register (DMAx_SSR*n*)

The source stride register contains the stride size and distance. Note that the source stride information is loaded when a new list descriptor is read from memory. Therefore, the source stride register is applicable for all link descriptors in the new list. Changing the source stride information for a link requires that a new list be generated.

Address: Base address + 140h offset + (128d × i), where i=0d to 3d



DMAx_SSR*n* field descriptions

Field	Description
0–7 -	This field is reserved.

Table continues on the next page...

DMA*x*_SSR*n* field descriptions (continued)

Field	Description
8–19 SSS	Source stride size. Number of bytes to transfer before jumping to the next address as specified in the source stride distance field.
20–31 SSD	Source stride distance. The source stride distance in bytes from start byte to start byte.

23.3.17 DMA destination stride register (DMA*x*_DSR*n*)

The destination stride register contains the stride size, and distance. Note that the destination stride information is loaded when a new list descriptor is read from memory. Therefore, the destination stride register is applicable for all link descriptors in the new list. Changing the destination stride information for a link requires that a new list be generated.

Address: Base address + 144h offset + (128d × i), where i=0d to 3d

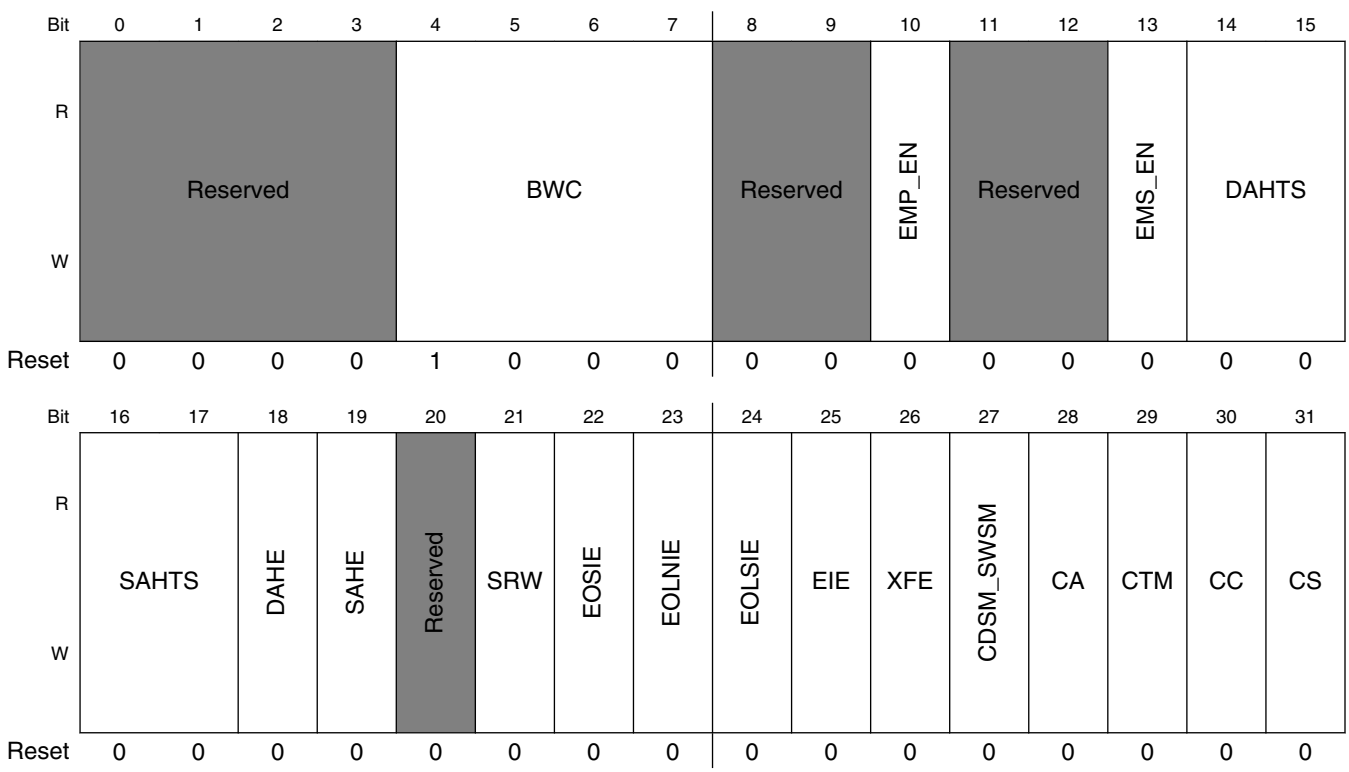
23.3.19 DMA mode register (DMAx_MR*n*)

The mode register allows software to start a DMA transfer and to control various DMA transfer characteristics.

Address: Base address + 400h offset + (128d × i), where i=0d to 3d



DMAx_MR*n* field descriptions

Field	Description
0–3 -	This field is reserved.

Table continues on the next page...

DMAx_MRn field descriptions (continued)

Field	Description
4–7 BWC	Bandwidth/pause control. Defined when single and multiple channels are executing or if MRn[EMP_EN] is set in external transfer mode. The value of MRn[BWC] determines how many bytes a given channel is allowed to transfer before the DMA engine pauses the current channel and re-arbitrates (switches to the next channel). In external pause mode, the value of MRn[BWC] dictates how many bytes are allowed to transfer before pausing the channel, after which a new assertion of DREQ_B resumes channel operation. 0000 1 byte 0001 2 bytes 0010 4 bytes 0011 8 bytes 0100 16 bytes 0101 32 bytes 0110 64 bytes 0111 128 bytes 1000 256 bytes 1001 512 bytes 1010 1024 bytes 1011-1110 Reserved 1111 Disable bandwidth sharing to allow uninterrupted transfers from each channel.
8–9 -	This field is reserved.
10 EMP_EN	External master pause enable. Valid only if MRn[EMS_EN] is set. 0 Disable the external master pause feature. 1 Enable the external master pause feature. Channel is paused as described by MRn[BWC].
11–12 -	This field is reserved.
13 EMS_EN	External master start enable. This bit does not apply to single-write start modes (direct or chaining). 0 Disable the channel from being started by an external DMA start pin. 1 Enable the channel to be started by an external DMA start pin, which sets MRn[CS].
14–15 DAHTS	Destination address hold transfer size. Indicates the transfer size used for each transaction while MRn[DAHE] is set. The byte count register must be in multiples of the size and the destination address register must be aligned based on the size. The transfer size assigned to MRn[DAHTS] must be equal to or smaller than that assigned to MRn[BWC] to avoid undefined behavior. 00 1 byte 01 2 bytes 10 4 bytes 11 8 bytes
16–17 SAHTS	Source address hold transfer size. Indicates the transfer size used for each transaction while MRn[SAHE] is set. The byte count register must be in multiples of the size and the source address register must be aligned based on the size. The transfer size assigned to MRn[SAHTS] must be equal to or smaller than that assigned to MRn[BWC] to avoid undefined behavior. 00 1 byte 01 2 bytes

Table continues on the next page...

DMA*x*_MR*n* field descriptions (continued)

Field	Description
	10 4 bytes 11 8 bytes
18 DAHE	Destination address hold enable 0 Disable destination address hold 1 Enable the DMA controller to hold the destination address of a transfer to the size specified by MRn[DAHTS]. Hardware only supports aligned transfers for this feature.
19 SAHE	Source address hold enable 0 Disable source address hold 1 Enable the DMA controller to hold the source address of a transfer to the size specified by MRn[SAHTS]. Hardware only supports aligned transfers for this feature.
20 -	This field is reserved.
21 SRW	Single register write (Direct mode only; reserved for chaining mode.) 0 Normal operation 1 Enable a write to the source address register to simultaneously set MRn[CS], starting a DMA transfer, when MRn[CDSM_SWSM] is also set. Setting this bit and clearing CDSM_SWSM causes a write to the destination address register to simultaneously set MRn[CS], starting a DMA transfer.
22 EOSIE	End-of-segments interrupt enable 0 Do not generate an interrupt at the completion of a data transfer. CLNDARn[EOSIE] overrides this bit on a link descriptor basis. 1 Generate an interrupt at the completion of a data transfer (That is, SRn[EOSI] is set). This bit overrides the CLNDARn[EOSIE].
23 EOLNIE	End-of-links interrupt enable 0 Do not generate an interrupt at the completion of a list of DMA transfers. 1 Generate an interrupt at the completion of a list of DMA transfers (That is, NLNDARn[EOLND] is set).
24 EOLSIE	End-of-lists interrupt enable 0 Do not generate an interrupt at the completion of all DMA transfers. 1 Generate an interrupt at the completion of all DMA transfers (That is, NLNDARn[EOLND] and NLSDARn[EOLSD] are set).
25 EIE	Error interrupt enable 0 Do not generate an interrupt if a programming or transfer error is detected. 1 Generate an interrupt if a programming or transfer error is detected.
26 XFE	Extended features enable 0 Disable striding feature in direct mode or disable list chaining feature in chaining mode. 1 Enable striding feature in direct mode or enable list chaining feature in chaining mode.
27 CDSM_SWSM	In chaining mode, current descriptor start mode/single-write start mode is as follows: • In basic mode (MRn[XFE] is cleared), setting this bit causes a write to the current link descriptor address register to simultaneously set MRn[CS], starting a DMA transfer. • In extended chaining mode (MRn[XFE] is set), setting this bit causes a write to the current list descriptor address register to simultaneously set MRn[CS], starting a DMA transfer.

Table continues on the next page...

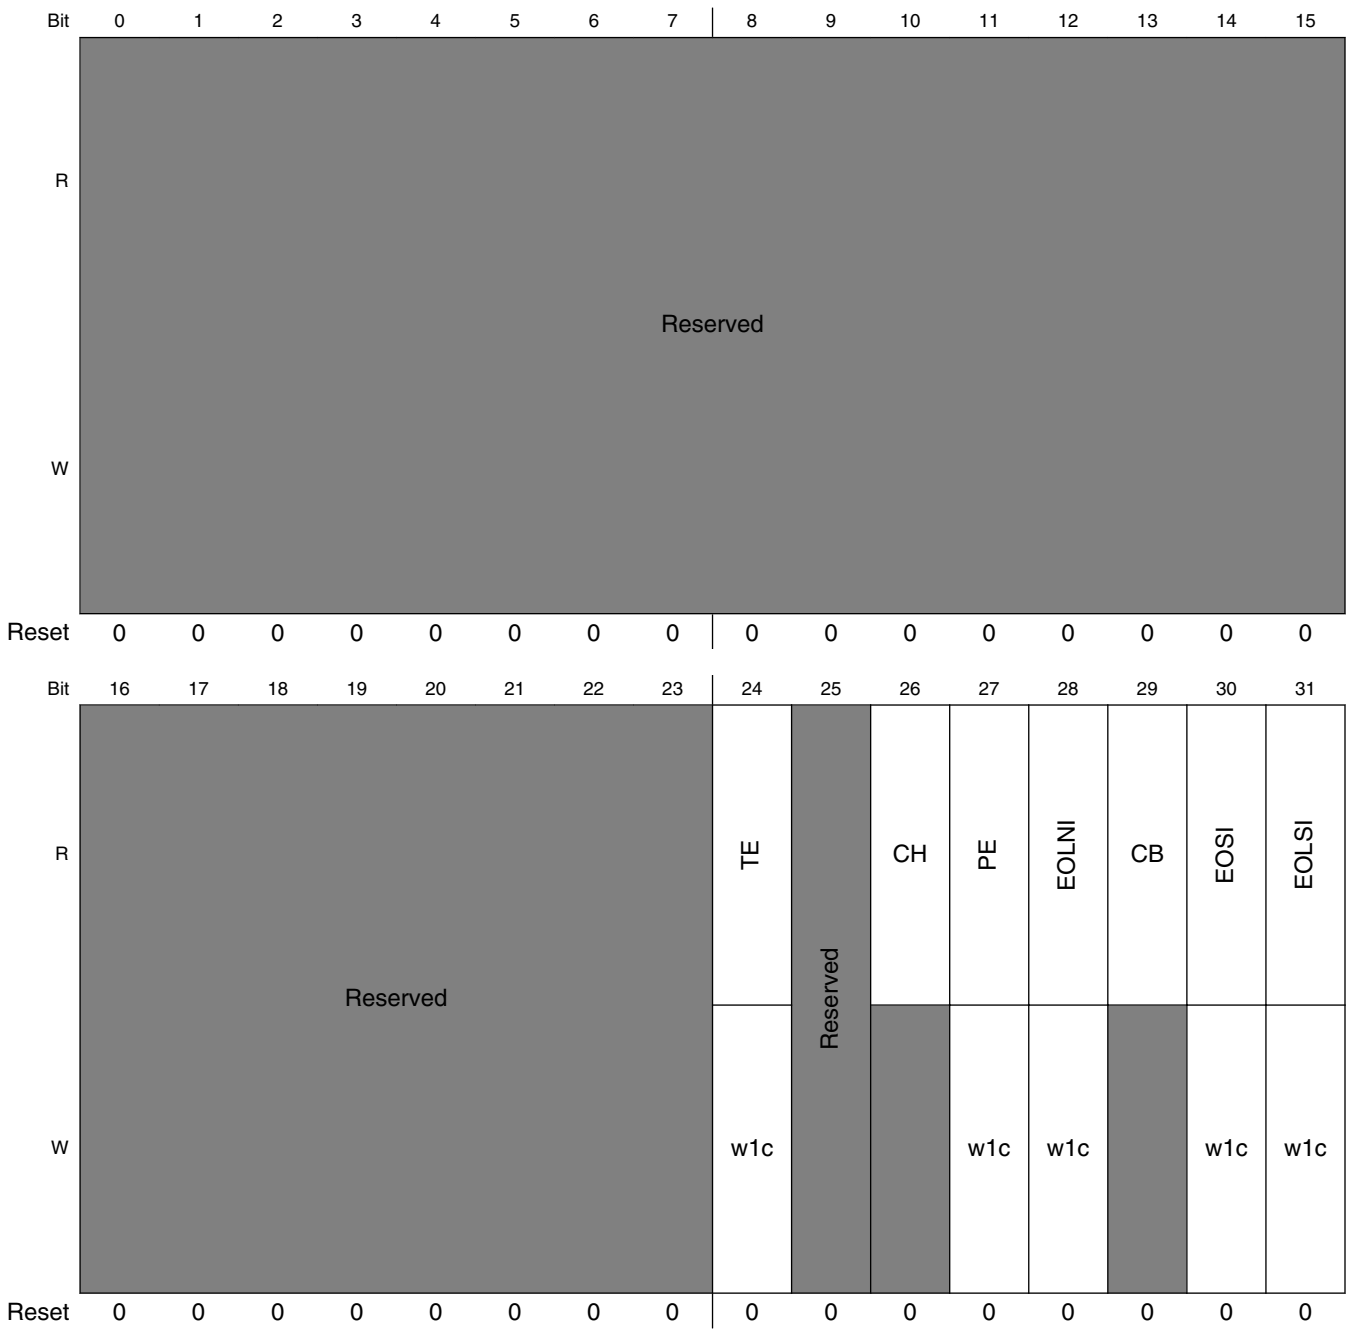
DMA*x*_MR*n* field descriptions (continued)

Field	Description
	In direct mode, setting this bit and MRn[SRW] causes a write to the source address register to simultaneously set MRn[CS], starting a DMA transfer. Clearing this bit and setting MRn[SRW] causes a write to the destination address register to simultaneously set MRn[CS], starting a DMA transfer. This bit must be cleared when MRn[SRW] is cleared.
28 CA	Channel abort 0 No effect 1 Cause the current transfer to be aborted and SRn[CB] to be cleared if the channel is busy. The channel remains in the idle state until a new transfer is programmed.
29 CTM	Channel transfer mode 0 Configure the channel in chaining mode. 1 Configure the channel into direct mode. This means that software is responsible for placing all the required parameters into necessary registers to start the DMA process.
30 CC	Channel continue. This bit applies only to chaining mode and is cleared by hardware after the first descriptor read when continuing a transfer. This bit is reserved for external master mode. 0 No effect 1 The DMA transfer restarts the transferring process starting at the current descriptor address.
31 CS	Channel start. This bit is also automatically set by hardware during single-write start mode and external master start enable mode. Note that in external control mode, deasserting DMA_DREQ_B does NOT clear this bit. 0 Halt the DMA process if channel is busy (SRn[CB] is set). No effect if the channel is not busy. 1 Start the DMA process if channel is not busy (CB is cleared). If the channel was halted (CS = 0 and CB = 1), the transfer continues from the point at which it was halted.

23.3.20 DMA status register (DMA*x*_SR*n*)

The status registers report various DMA conditions during and after a DMA transfer.

Address: Base address + 404h offset + (128d × i), where i=0d to 3d



DMAx_SRn field descriptions

Field	Description
0–23 -	This field is reserved.
24 TE	Transfer error (Bit reset, write 1 to clear) 0 No error condition during the DMA transfer 1 Error condition during the DMA transfer. See DMA errors , for additional information.
25 -	This field is reserved.
26 CH	Channel halted. Cleared automatically by hardware if MR *n* [CS] is set again for resuming a halted transfer 0 Channel is not halted. If software attempts to halt an idle channel (SRn[CB] is cleared), this bit remains 0. 1 DMA transfer was successfully halted by software and can be resumed.
27 PE	Programming error (bit reset, write 1 to clear) 0 No programming error detected 1 A programming error is detected that prevents the DMA transfer from occurring.
28 EOLNI	End-of-links interrupt. After transferring the last block of data in the last link descriptor, if MRn[EOLNIE] is set, then this bit is set and an interrupt is generated. (Bit reset, write 1 to clear)
29 CB	Channel busy 0 DMA transfer is finished, an error occurred, or a channel abort occurred. 1 DMA transfer is currently in progress.
30 EOSI	End-of-segment interrupt. In chaining mode, after finishing a data transfer, if MRn[EOSIE] is set or if CLNDARn[EOSIE] is set, this bit gets set and an interrupt is generated. In direct mode, if MRn[EOSIE] is set, this bit gets set and an interrupt is generated. (Bit reset, write 1 to clear)
31 EOLSI	End-of-list interrupt. After transferring the last block of data in the last list descriptor, if MRn[EOLSIE] is set, then this bit is set and an interrupt is generated. (Bit reset, write 1 to clear)

23.3.21 DMA extended current link descriptor address register (DMAx_ECLNDARn)

These registers contain the upper 8 bits of the address of the current link descriptor. See DMA current link descriptor address register (DMA_CLNDAR*n*)DMA current link descriptor address register (DMA_CLNDAR*n*) for a description of basic chaining mode.

Address: Base address + 408h offset + (128d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DMAx_ECLNDAR*n* field descriptions

Field	Description
0–23 -	This field is reserved.
24–31 ECLNDA	Current link descriptor extended address (upper 8 bits of 40-bit address)

23.3.22 DMA current link descriptor address register (DMAx_CLNDAR*n*)

Current link descriptor address registers contain the address of the current link descriptor.

In basic chaining mode, shown in , software must initialize these registers to point to the first link descriptors in memory.

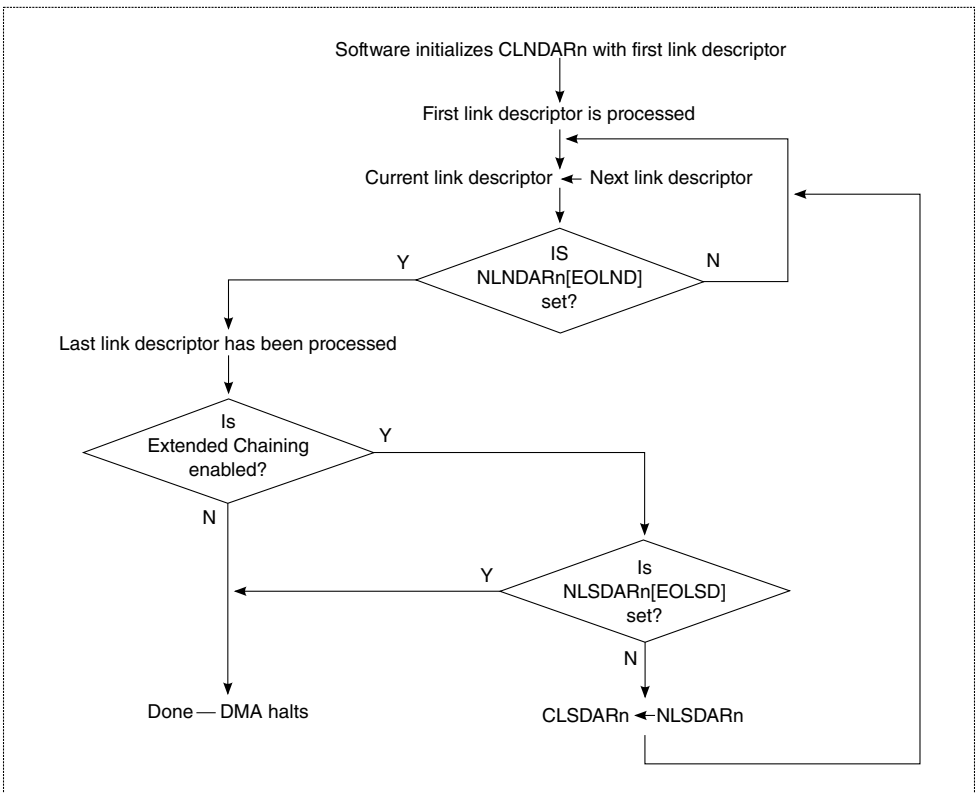

Figure 23-5. Basic Chaining Mode Flow Chart

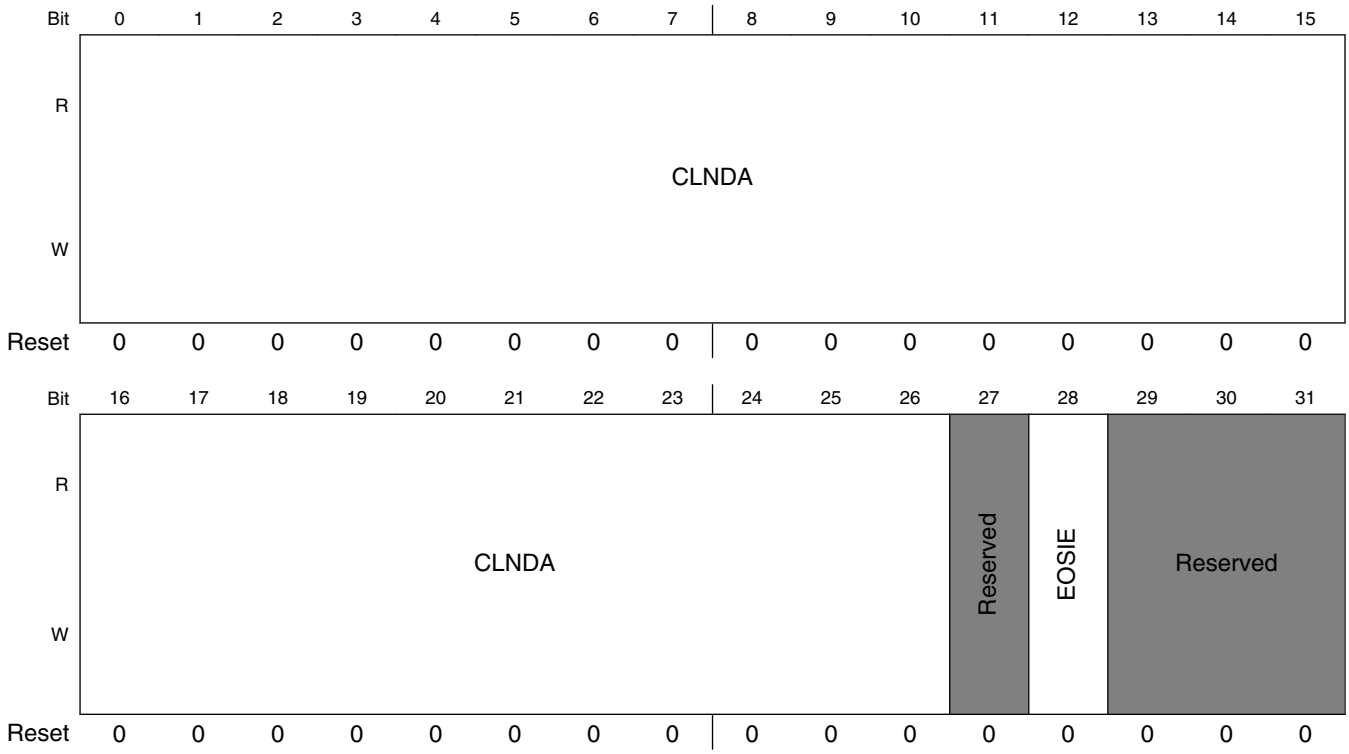
After the current descriptor is processed, the current link descriptor address register is loaded from the next link descriptor address register and NLNDAR *n* [EOLND] in the next link descriptor address register is examined. If EOLND is zero, the DMA controller reads in the new current link descriptor for processing. If EOLND is set, the last descriptor of the list was just completed. If extended chaining mode is not enabled, all DMA transfers are complete and the DMA controller halts.

If extended chaining mode is enabled, the DMA controller examines the state of NLSDAR *n* [EOLSD] in the next list descriptor address register. If EOLSD is clear, the controller loads the contents of the next list descriptor address register into the current list descriptor address register and reads the new list descriptor from memory. If EOLSD is set, all DMA transfers are complete and the DMA controller halts.

Address: Base address + 40Ch offset + (128d × i), where i=0d to 3d



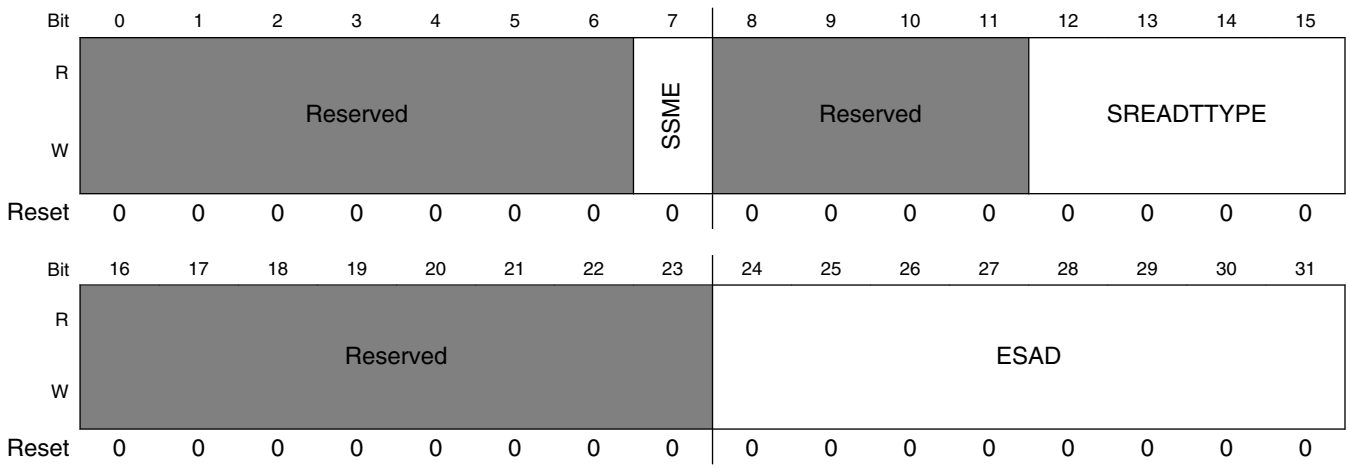
DMA*x*_CLNDAR*n* field descriptions

Field	Description
0–26 CLNDA	Current link descriptor address. Contains the current descriptor address of the buffer descriptor in memory. The descriptor must be aligned to a 32-byte boundary. (This is the lower portion of the 40 -bit address formed by CLNDARn[CLNDA] and ECLNDARn[ECLNDA].)
27 -	This field is reserved.
28 EOSIE	End-of-segment interrupt enable 0 Do not generate an interrupt upon completion of the current DMA transfer for the current link descriptor. 1 Generate an interrupt upon completion of the current DMA transfer for the current link descriptor.
29–31 -	This field is reserved.

23.3.23 DMA source attributes register (DMA*x*_SATR*n*)

The source attributes registers contain the transaction attributes to be used for the DMA operation for channels 4-7. Stride mode is enabled by setting SATR*n*[SSME]. The target interface is derived from the local access window and outbound ATMU mappings and the transaction is obtained from the value specified in SATR*n*[SREADTTYPE].

Address: Base address + 410h offset + (128d × i), where i=0d to 3d



DMA*x*_SATR*n* field descriptions

Field	Description
0–6 -	This field is reserved.
7 SSME	Source stride mode enable. Ignored in basic mode (MRn[XFE] is cleared). Striding on the source address can be accomplished by enabling SATRn[SSME] and setting the desired stride size and distance in the SSRn. 0 Stride mode disabled 1 Stride mode enabled
8–11 -	This field is reserved. Reserved
12–15 SREADTTYPE	DMA source transaction type. Reserved values result in a programming error being detected and logged in SR[PE]. Transaction type to run on local address space . 0000-0011 Reserved 0100 Read, do not snoop local processor 0101 Read, snoop local processor 0110-1011 Reserved 1100 Enhanced read, don't snoop local processor

Table continues on the next page...

DMAx_SATRn field descriptions (continued)

Field	Description
	1101 Enhanced read, snoop local processor 1110-1111 Reserved
16–23 -	This field is reserved.
24–31 ESAD	Extended source address. ESAD represents the eight high-order bits of the 40-bit source address.

23.3.24 DMA source address register (DMAx_SARn)

The source address registers contain the address from which the DMA controller (channels 4-7) reads data. In direct mode, if MR*n*[CDSM_SWSM] and MR*n* [SRW]are set, a write to this register simultaneously sets MR*n*[CS], starting a DMA transfer. Software must ensure that this is a valid address.

Address: Base address + 414h offset + (128d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	SAD																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

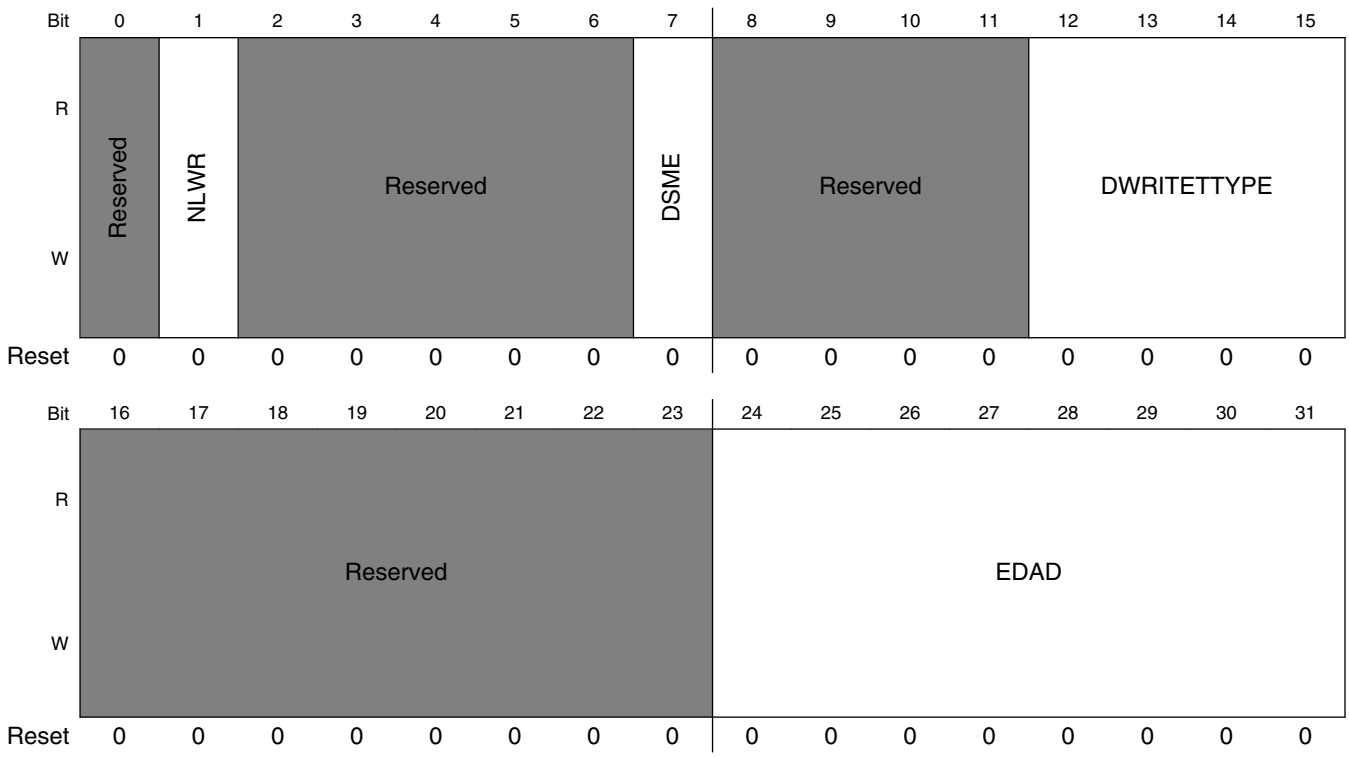
DMAx_SARn field descriptions

Field	Description
0–31 SAD	Source address. This register contains the low-order bits of the 40-bit source address of the DMA transfer for channels 4-7. The contents are updated after every DMA write operation unless the final stride of a striding operation is less than the stride size, in which case it remains equal to the address from which the last stride began.

23.3.25 DMA destination attributes register (DMA*x*_DATR*n*)

The destination attributes registers contain the transaction attributes for the DMA operation for DMA channels 4-7. Stride mode is enabled by setting DATR*n*[DSME]. The target interface is derived from the local access window and outbound ATMU mappings and the transaction is obtained from the value specified in DATR*n*[DWRITETTYPE].

Address: Base address + 418h offset + (128d × i), where i=0d to 3d



DMA*x*_DATR*n* field descriptions

Field	Description
0 -	This field is reserved.
1 NLWR	No last write with response. Performance impact: • When NLWR is cleared only one "write-with-response" transaction can be processed/in-flight at a time, which prevents pipelining of "write-with-response" transactions. • When NLWR is set "write-without-response" transactions can be issued in a pipelined manner not being stalled by a write response. Error impact:

Table continues on the next page...

DMAx_DATR*n* field descriptions (continued)

Field	Description
	• When NLWR is cleared the returned response includes error status which is used to update the SR[TE] field. • When NLWR is set, since no response is returned, the SR[TE] field is not updated with write transaction error status. 0 "Write-with-response" transactions are generated for the last transaction in a multi-transaction transfer. Single writes will be NWRITE_R. A response is returned from the module targeted by the write transfer (ex. DDR controller, IFC, PCI-Express,...) informing the DMA of write completion and error status. 1 "Write-without-response" transactions are generated for the last transaction in a multi-transaction transfer. The DMA considers a transfer to be complete when the last write transaction is issued (not necessarily when the transaction has reached the target).
2–6 -	This field is reserved.
7 DSME	Destination stride mode enable Ignored in basic mode (MRn[XFE] is cleared). Striding on the destination address can be accomplished by setting DSME and setting the desired stride size and distance in DSRn. 0 Stride mode disabled 1 Stride mode enabled
8–11 -	This field is reserved.
12–15 DWRITETTYPE	DMA destination transaction type. Reserved values result in a programming error being detected and logged in SR[PE]. Transaction type to run on local address space. 0000-0011 Reserved 0100 Write, do not snoop local processor 0101 Write, snoop local processor 0110-1011 Reserved 1100 Enhanced write, don't snoop local processor 1101 Enhanced write, snoop local processor 1110-1111 Reserved
16–23 -	This field is reserved.
24–31 EDAD	Extended destination address. EDAD represents the eight high-order bits of the 40-bit destination address.

23.3.26 DMA destination address register (DMAx_DAR*n*)

The destination address registers contain the addresses to which the DMA controller (channels 4-7) writes data.

In direct mode, if MR*n*[SRW] is set and MR*n*[CDSM_SWSM] is cleared, a write to this register simultaneously sets MR*n*[CS], starting a DMA transfer. Software must ensure that this is a valid address.

Address: Base address + 41Ch offset + (128d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DMA*x*_DAR*n* field descriptions

Field	Description
0–31 DAD	Destination address. This field contains the low-order bits of the40-bit destination address of the DMA transfer. The contents are updated after every DMA write operation unless the final stride of a striding operation is less than the stride size, in which case it remains equal to the address from which the last stride began.

23.3.27 DMA byte count register (DMA*x*_BCR*n*)

The byte count register contains the number of bytes to transfer.

Address: Base address + 420h offset + (128d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DMA*x*_BCR*n* field descriptions

Field	Description
0–5 -	This field is reserved.
6–31 BC	Byte count. Contains the number of bytes to transfer. The value in this register is decremented after each DMA read operation. The maximum transfer size is (2^{26}) - 1 bytes.

23.3.28 DMA next link descriptor extended address register (DMA*x*_ENLNDAR*n*)

These registers contain the upper 8 bits of the address of the next link descriptor in memory. See DMA next link descriptor address register (DMA_NLNDAR*n*)DMA next link descriptor address register (DMA_NLNDAR*n*).

Address: Base address + 424h offset + (128d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

24–31 ENLNDA	Next link descriptor extended address bits (upper 8 bits of 40-bit address)

23.3.29 DMA next link descriptor address register (DMA*x*_NLNDAR*n*)

Current link descriptor address registers contain the address for the next link descriptor in memory.

Contents transferred to the current descriptor address registers become effective for the current transfer in basic and extended chaining modes.

Address: Base address + 428h offset + (128d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

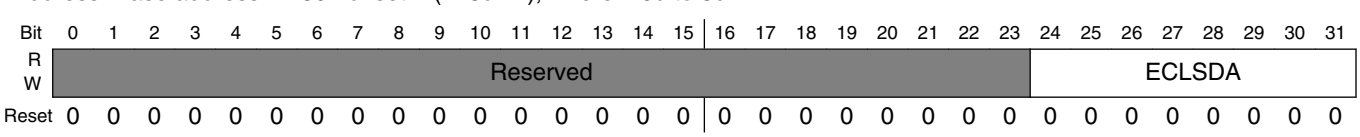
DMAx_NLNDAR*n* field descriptions

Field	Description
0–26 NLNDA	Next link descriptor address. Contains the bits 32-5 of the 40-bit next link descriptor address in memory. The descriptor must be aligned to a 32-byte boundary.
27 -	This field is reserved.
28 NDEOSIE	Next descriptor end-of-segment interrupt enable 0 Do not generate an interrupt if the current DMA transfer for the current descriptor is finished. 1 Generate an interrupt if the current DMA transfer for the current descriptor is finished.
29–30 -	This field is reserved.
31 EOLND	End-of-links descriptor. This bit is ignored in direct mode. 0 This descriptor is not the last link descriptor in memory for this list. 1 This descriptor is the last link descriptor in memory for this list. If this bit is set, the DMA controller advances to the next list descriptor in memory if NLSDARn[EOLSD] is also set in extended mode.

23.3.30 DMA extended current list descriptor address register (DMAx_ECLSDAR*n*)

These registers contain the upper 8 bits of the current address of the list descriptor in memory in extended chaining mode. See DMA current list descriptor address register (DMA_CLSDAR*n*)DMA current list descriptor address register (DMA_CLSDAR*n*).

Address: Base address + 430h offset + (128d × i), where i=0d to 3d



DMA*x*_ECLSDAR*n* field descriptions

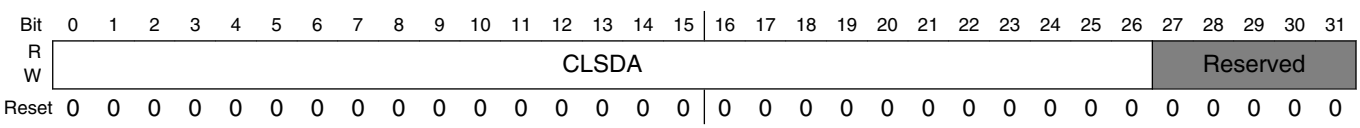
Field	Description
0–23 -	This field is reserved.
24–31 ECLSDA	Current list descriptor extended address bits (upper 8 bits of 40-bit address)

23.3.31 DMA current list descriptor address register (DMA*x*_CLSDAR*n*)

The current list descriptor address registers contain the current address of the list descriptor in memory in extended chaining mode.

In extended chaining mode, software must initialize CLSDAR*n* and ECLSDAR *n* to point to the first list descriptor in memory. After finishing the last link descriptor in the current list, the DMA controller loads the contents of the next list descriptor address register into the current list descriptor address register. If NLSDAR *n* [EOLSD] in the next list descriptor address register is clear, the DMA controller reads the new current list descriptor from memory to process that list. If EOLSD in the next list descriptor address register is set and the last link in the current list is finished, all DMA transfers are complete.

Address: Base address + 434h offset + (128d × i), where i=0d to 3d



DMA*x*_CLSDAR*n* field descriptions

Field	Description
0–26 CLSDA	Current list descriptor address. Contains the bits 32-5 of the 40-bit current list descriptor address of the buffer descriptor in memory in extended chaining mode. The descriptor must be aligned to a 32-byte boundary.
27–31 -	This field is reserved.

23.3.32 DMA extended next list descriptor address register (DMA*x*_ENLSDAR*n*)

These registers contain the upper 8 bits of the address of the next list descriptor in memory. See DMA next list descriptor address register (DMA_NLSDAR*n*)DMA next list descriptor address register (DMA_NLSDAR*n*).

Address: Base address + 438h offset + (128d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

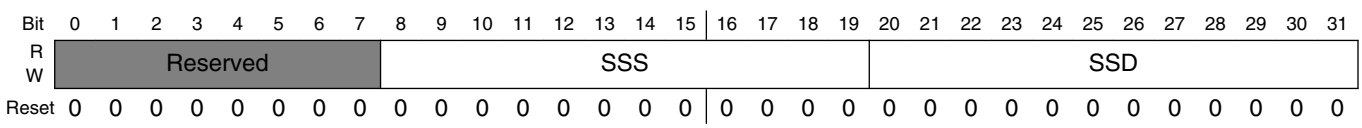
DMAx_NLSDAR*n* field descriptions

Field	Description
0–26 NLSDA	Next list descriptor address. Contains the bits 32-5 of the 40 -bit next descriptor address of the buffer descriptor in memory. The descriptor must be aligned on a 32-byte boundary.
27–30 -	This field is reserved.
31 EOLSD	End-of-lists descriptor. This bit is ignored in direct mode. 0 This list descriptor is not the last list descriptor in memory. 1 This list descriptor is the last list descriptor in memory. If this bit is set, then the DMA controller halts after the last link descriptor transaction is finished.

23.3.34 DMA source stride register (DMAx_SSR*n*)

The source stride register contains the stride size and distance. Note that the source stride information is loaded when a new list descriptor is read from memory. Therefore, the source stride register is applicable for all link descriptors in the new list. Changing the source stride information for a link requires that a new list be generated.

Address: Base address + 440h offset + (128d × i), where i=0d to 3d



DMAx_SSR*n* field descriptions

Field	Description
0–7 -	This field is reserved.

23.4 DMA functional description

This section describes the function of the DMA controller.

23.4.1 DMA channel operation

All DMA channels support two different modes of operation: a basic mode (MR*n*[XFE] is cleared) and an extended mode (MR*n*[XFE] is set). In both modes, a channel can be activated by clearing and setting MR*n*[CS], or through the single-write start mode using MR*n*[CDSM_SWSM] and MR*n*[SRW], or through an external control mode using MR*n*[EMS_EN] and the external DMA_DREQ signal.

In basic mode, the channel can be programmed in basic direct mode or basic chaining mode. In extended mode, the channel can be programmed in extended direct mode or extended chaining mode. Extended mode provides more capabilities, such as extended descriptor chaining, striding capabilities, and a more flexible descriptor structure.

The DMA controller supports misaligned transfers for both the source and destination addresses. In order to maximize performance, the source and destination engines issue one or more transactions to reach the desired alignment based on the rules described in Source/destination transaction size calculations. The DMA always reads/writes the maximum number of bytes for a given transfer as described by the capability inputs of the DMA controller except for globally coherent transactions that use the size of the cache coherence granule as described by the mode select input. Using 256 bytes over the RapidIO interface reduces packet overhead which translates to increased bandwidth utilization through the interface.

The DMA controller supports bandwidth control, which prevents a channel from consuming all the data bandwidth in the controller. Each channel is allowed to consume the bandwidth of the shared resources as specified by the bandwidth control value. After

the channel uses its allotted bandwidth, the arbiter grants the next channel access to the shared resources. The arbitration is round robin between the channels. This feature is also used to implement the external control pause feature. If the external control start and pause are enabled in the MR*n*, the channel enters a paused state after transferring the data described in the bandwidth control. External control can restart the channel from a paused state.

The DMA programming model permits software to program each DMA engine independently to interrupt on completed segment, chain, or error. It also provides the capability for software to resume the DMA engine from a hardware halted condition by setting the channel continue bit, MR*n*[CC]. See Table 23-4 for more complete descriptions of the channel states and state transitions.

23.4.1.1 Source/destination transaction size calculations

The DMA controller may issue smaller transactions from the source and destination address engines in an effort to reach alignment for improved performance.

The flow chart below shows the decision points made in determining the transaction size. The starting *Txfer_Size* is determined by min(BCR[BC],MR[BWC]), *Stride_En* is determined by SATR*n*[SSME] or DATR*n*[DSME], and *Stride_Size* is determined by SSR*n*[SSS] or DSR*n*[DSS].

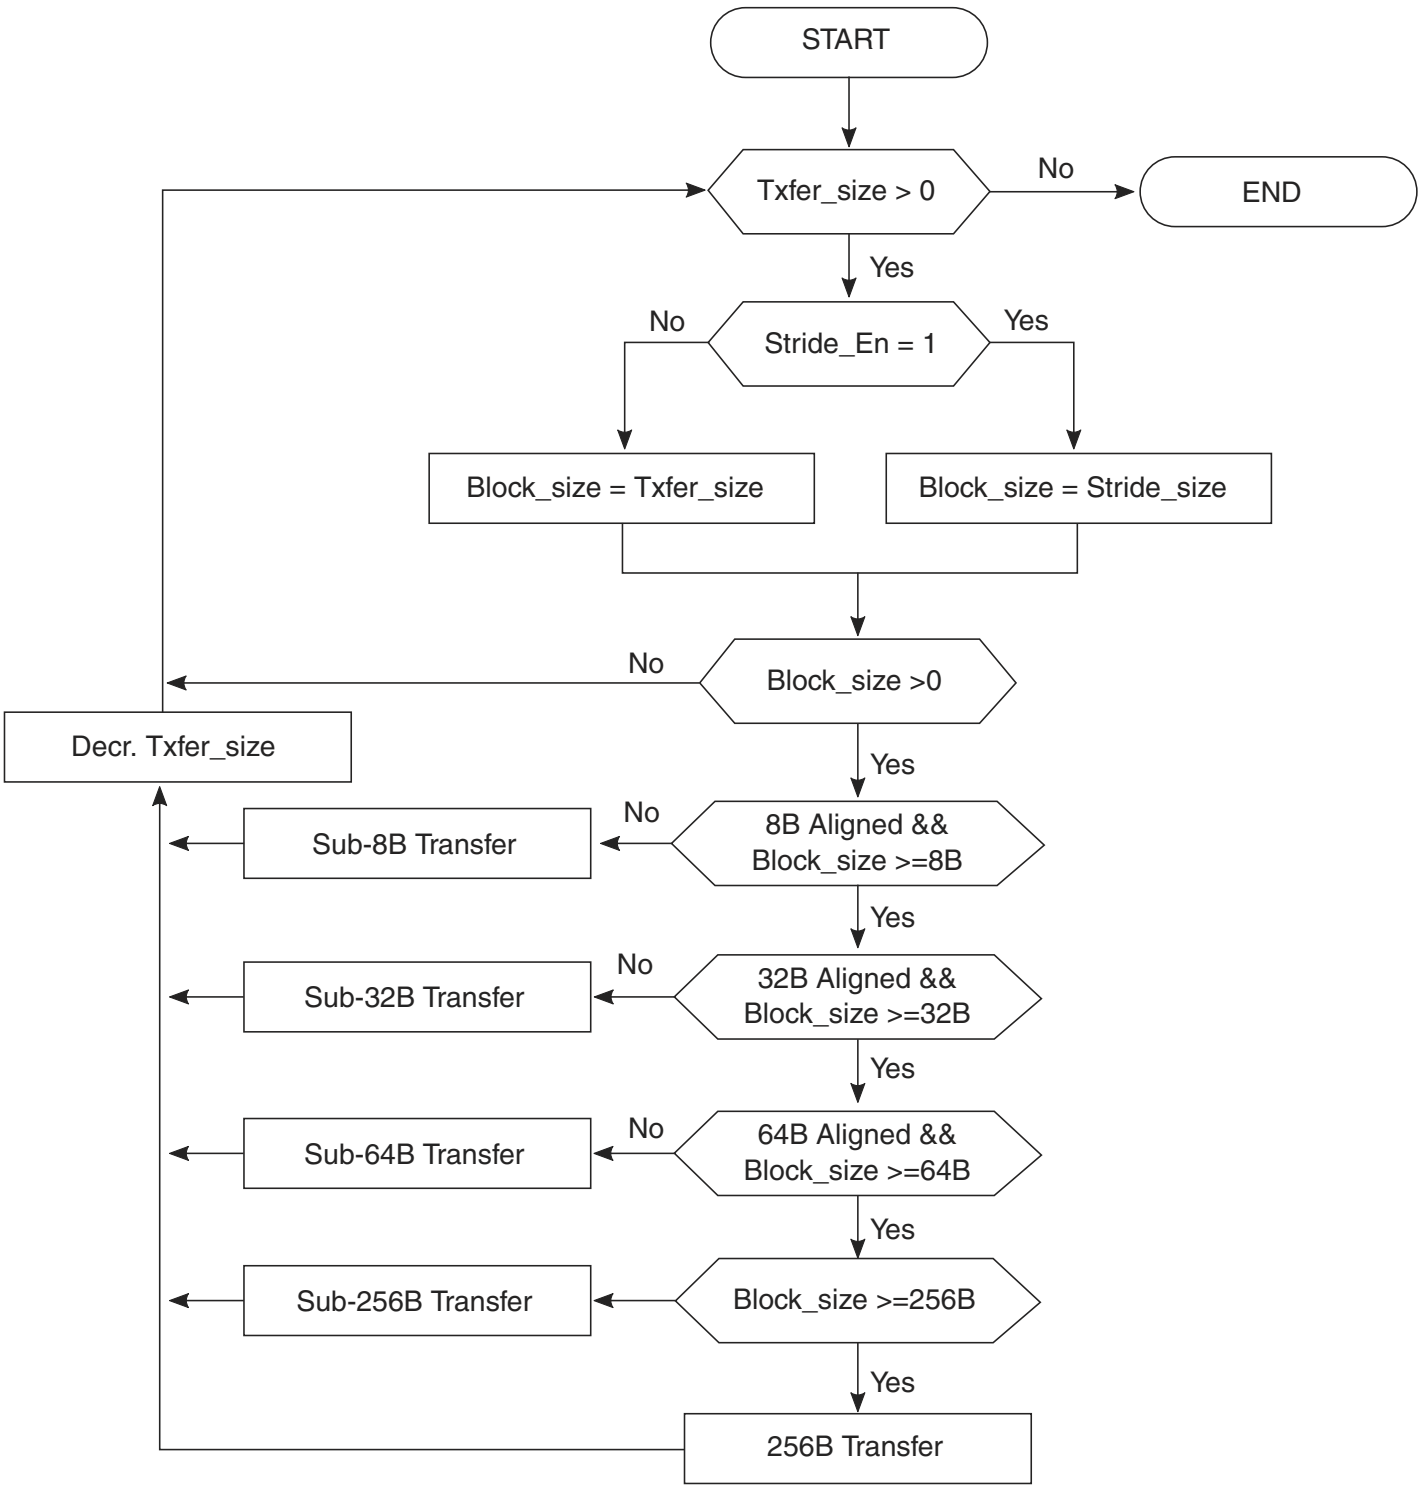

Figure 23-6. Source/destination engine transaction size flow chart

For example, if BCR[BC]=512 bytes and MR[BWC]=256 bytes, reading from starting address 0x5D0 will result in the following transaction sizes:

```
-- Channel arbitration --
0x5D0 - 16 bytes
0x5E0 - 32 bytes
```

```
0x600 - 128 bytes
0x680 - 64 bytes
0x6C0 - 16 bytes
-- Channel arbitration --
0x6D0 - 16 bytes
0x6E0 - 32 bytes
0x700 - 128 bytes
0x780 - 64 bytes
0x7C0 - 16 bytes
```

In the example above, the bandwidth control limits the channel from ever reaching the maximum transaction size of 256 bytes. Software should align addresses or increase the available bandwidth for best performance.

23.4.1.2 Basic DMA mode transfer

This mode is primarily included for backward compatibility with existing DMA controllers which use a simple programming model. This is the default mode out of reset.

The different modes of operation under the basic mode are explained in the following sections.

23.4.1.2.1 Basic direct mode

In basic direct mode, the DMA controller does not read descriptors from memory, but instead uses the current parameters programmed in the DMA registers to start the DMA transfer.

Software is responsible for initializing SAR*n*, SATR*n*, DAR*n*, DATR*n*, and BCR*n* registers. The DMA transfer is started when MR*n*[CS] is set. Software is expected to program all the appropriate registers before setting MR*n*[CS] to a 1. The transfer is finished after all the bytes specified in the byte count register have been transferred or if an error condition occurs. The sequence of events to start and complete a transfer in basic direct mode is as follows:

1. Poll the channel state (see Table 23-4) to confirm that the specific DMA channel is idle.
2. Initialize SAR*n*, SATR*n*, DAR*n*, DATR*n* and BCR*n*.
3. Set the mode register channel transfer mode bit, MR*n*[CTM], to indicate direct mode. Other control parameters may also be initialized in the mode register.
4. Clear, then set the mode register channel start bit, MR*n*[CS], to start the DMA transfer.
5. SR*n*[CB] is set by the DMA controller to indicate the DMA transfer is in progress.
6. SR*n*[CB] is automatically cleared by the DMA controller after the transfer is finished, or if the transfer is aborted (MR*n*[CA] transitions from a 0 to 1), or if a transfer error occurs.

7. End of segment interrupt is generated if MR*n*[EOSIE] is set.

23.4.1.2.2 Basic, direct, single-write start mode

In basic direct single-write start mode, the DMA controller does not read descriptors from memory, but instead uses the current parameters programmed in the DMA registers to start the DMA transfer.

Software is responsible for initializing the SATR*n*, DATR*n*, and BCR*n* registers. Setting MR*n*[SRW] configures the DMA controller to begin the DMA transfer either when SAR*n* is written or when DAR*n* is written, determined by the state of MR*n*[CDSM_SWSM]. Writing to SAR*n* initiates the DMA transfer if MR*n*[CDSM_SWSM] is set. Writing to DAR*n* initiates the DMA transfer if MR*n*[CDSM_SWSM] is cleared. The DMA controller automatically sets the channel start bit, MR*n*[CS]. Software is expected to program all the appropriate registers before writing the source or destination address registers. The transfer is finished after all the bytes specified in the byte count register have been transferred or if an error condition occurs. The sequence of events to start and complete a transfer in single-write start basic direct mode is as follows:

1. Poll the channel state (see Table 23-4) to confirm that the specific DMA channel is idle.
2. Initialize the source attributes (SATR*n*), DATR*n*, and BCR*n* registers.
3. Set the mode register channel transfer mode bit, MR*n*[CTM], and the single-write start direct mode bit, MR*n*[SRW]. Other control parameters may also be initialized in the mode register. Set MR*n*[CDSM_SWSM] for transfers started using SAR*n*. Clear MR*n*[CDSM_SWSM] for transfers started using the DAR*n*.
4. A write to the source or destination address register starts the DMA transfer and automatically sets MR*n*[CS].
5. SR*n*[CB] is set by the DMA controller to indicate the DMA transfer is in progress.
6. SR*n*[CB] is automatically cleared by the DMA controller after the transfer is finished, if the transfer is aborted (MR*n*[CA] transitions from a 0 to 1), or if a transfer error occurs.
7. End of segment interrupt is generated if MR*n*[EOSIE] is set.

23.4.1.2.3 Basic chaining mode

In basic chaining mode, software must first build link descriptor segments in memory.

Then the current link descriptor address register must be initialized to point to the first descriptor in memory. The DMA controller loads descriptors from memory prior to a DMA transfer. The DMA controller begins the transfer according to the link descriptor information loaded for the segment. After the current segment is finished, the DMA

controller reads the next link descriptor from memory and begins another DMA transfer. The transfer is finished if the current link descriptor is the last one in memory or if an error condition occurs. The sequence of events to start and complete a transfer in chaining mode is as follows:

1. Build link descriptor segments in memory.
2. Poll the channel state (see Table 23-4) to confirm that the specific DMA channel is idle.
3. Initialize CLNDAR*n* to point to the first link descriptor in memory.
4. Clear the mode register channel transfer mode bit, MR*n*[CTM], as well as MR*n*[XFE], to indicate basic chaining mode. Other control parameters may also be initialized in the mode register.
5. Clear and then set the mode register channel start bit, MR*n*[CS], to start the DMA transfer.
6. SR*n*[CB] is set by the DMA controller to indicate the DMA transfer is in progress.
7. SR*n*[CB] is automatically cleared by the DMA controller after finishing the transfer of the last descriptor segment, if the transfer is aborted (MR*n*[CA] transitions from a 0 to 1), or if an error occurs during any of the transfers.

23.4.1.2.4 Basic chaining, single-write start mode

Basic chaining, single-write start mode allows a chain to be started by writing the current link descriptor address register (CLNDAR*n*).

(Note that ECLNDAR*n* must be written *first* so that the full 40-bit descriptor address is present when the chain starts.) Setting MR*n*[CDSM_SWSM] in the mode register causes MR*n*[CS] to be automatically set when the current link descriptor address register is written. The sequence of events to start and complete a chain using single-write start mode is as follows:

1. Set the mode register current descriptor start mode bit, MR*n*[CDSM_SWSM], and clear the extended features enable bit MR*n*[XFE]. Also, clear the channel transfer mode bit, MR*n*[CTM]. This initialization indicates basic chaining and single-write start mode. Also other control parameters may be initialized in the mode register.
2. Build link descriptor segments in memory.
3. Poll the channel state (see Table 23-4) to confirm that the specific DMA channel is idle.
4. Initialize CLNDAR*n* to point to the first descriptor segment in memory. This write automatically causes the DMA controller to begin the link descriptor fetch and set MR*n*[CS].
5. SR*n*[CB] is set by the DMA controller to indicate the DMA transfer is in progress.

6. SR*n*[CB] is automatically cleared by the DMA controller after finishing the transfer of the last descriptor segment, if the transfer is aborted (MR*n*[CA] transitions from a 0 to 1), or if an error occurs during any of the transfers.

23.4.1.3 Extended DMA mode transfer

The extended DMA mode also operates in chaining and direct mode.

It offers additional capability over the basic mode by supporting striding and a more flexible descriptor structure. This additional functionality also requires a new and more complex programming model. The extended DMA mode is activated by setting MR*n*[XFE].

23.4.1.3.1 Extended direct mode

Extended direct mode has the same functionality as basic direct mode with the addition of stride capabilities.

The bit settings are the same as in direct mode with the exception of the MR*n*[XFE] being set. Striding on the source address can be accomplished by setting SATR*n*[SSME] and setting the desired stride size and distance in SSR*n*. Striding on the destination address can be accomplished by setting DATR*n*[DSME] and setting the desired stride size and distance in DSR*n*.

23.4.1.3.2 Extended direct, single-write start mode

Extended direct, single-write start mode has the same functionality as the basic direct single-write start mode with the addition of stride capabilities.

The bit settings are also the same with the exception of MR*n*[XFE] being set. Striding on the source address can be accomplished by setting SATR*n*[SSME] and setting the desired stride size and distance in SSR*n*. Striding on the destination address can be accomplished by setting DATR*n*[DSME] and setting the desired stride size and distance in DSR*n*.

23.4.1.3.3 Extended chaining mode

In extended chaining mode, the software must first build list and link descriptor segments in memory.

Then CLSDAR*n* must be initialized to point to the first list descriptor in memory. The DMA controller loads list descriptors and link descriptors from memory prior to a DMA transfer. The DMA controller begins the transfer according to the link descriptor information loaded. Once the current link descriptor is finished, the DMA controller

reads the next link descriptor from memory and begins another DMA transfer. If the current link descriptor is the last in the list, the DMA controller reads the next list descriptor in memory. The transfer is finished if the current link descriptor is the last one in the last list in memory or if an error condition occurs. The sequence of events to start and complete a transfer in extended chaining mode is as follows:

1. Build link and list descriptor segments in memory.
2. Poll the channel state (see Table 23-4) to confirm that the specific DMA channel is idle.
3. Initialize CLSDAR*n* to point to the first list descriptor in memory.
4. Clear the mode register channel transfer mode bit, MR*n*[CTM], to indicate chaining mode. MR*n*[XFE] must be set to indicate extended DMA mode. Other control parameters may also be initialized in the mode register.
5. Clear and then set the mode register channel start bit, MR*n*[CS], to start the DMA transfer.
6. SR*n*[CB] is set by the DMA controller to indicate the DMA transfer is in progress.
7. SR*n*[CB] is automatically cleared by the DMA controller after finishing the transfer of the last descriptor segment, if the transfer is aborted (MR*n*[CA] transitions from a 0 to 1), or if an error occurs during any of the transfers.

23.4.1.3.4 Extended chaining, single-write start mode

In the extended mode, the single-write start feature allows a chain to be started by writing the current list descriptor pointer.

Setting MR*n*[CDSM_SWSM] causes MR*n*[CS] to be set automatically when CLSDAR*n* is written. (Note that ECLSDAR*n* must be written *first* so that the full 40-bit descriptor address is present when the chain starts.) The sequence of events to start and complete an extended chain using single-write start mode is as follows:

1. Set MR*n*[CDSM_SWSM] and MR*n*[XFE] and clear MR*n*[CTM] to indicate extended chaining and single-write start mode. Also other control parameters may be initialized in the mode register.
2. Build list and link descriptor segments in local memory.
3. Poll the channel state (see Table 23-4) to confirm that the specific DMA channel is idle.
4. Initialize the current list descriptor address register to point to the first list descriptor segment in memory. This write automatically causes the DMA controller to begin the list descriptor fetch and set MR*n*[CS].
5. SR*n*[CB] is set by the DMA controller to indicate the DMA transfer is in progress.
6. SR*n*[CB] is automatically cleared by the DMA controller after finishing the transfer of the last descriptor segment, or if the transfer is aborted (MR*n*[CA] transitions from a 0 to 1), or if an error occurs during any of the transfers.

23.4.1.4 External control mode transfer

An external control can be used to control DMA1 and DMA2 channels that support external control signals by setting MR*n*[EMS_EN].

The external control can direct the DMA channel in the following transfer modes:

- Basic direct
- Basic chaining
- Extended direct
- Extended chaining

The external control and the DMA controller use a well defined protocol to communicate. The external control can start or restart a paused DMA transfer. The DMA controller acknowledges a DMA transfer in progress and also indicates a transfer completion. Note that external control cannot cause a channel to enter a paused state.

The pause feature can be enabled by setting MR*n*[EMP_EN]. MR*n*[BWC] specifies how much data to allow a specific channel to transfer before entering a paused state by clearing MR*n*[CS]. Note however, that write data for a paused transfer may not have reached the target interface when so indicated. The channel can be restarted from a paused state by the asserted edge of DREQ_B as driven by an external master. In chaining modes, the channel does not pause for descriptor fetch transfer; it only pauses during the actual data transfer.

Note that when operating the DMA in chaining mode the register byte count field, BCR[BC], must be initialized to zero before enabling the pause feature. In chaining modes, the channel does not pause for descriptor fetch transfer.

The following signals are defined for the external control interface:

- DMA_DREQ_B-Asserting edge triggers a DMA transfer start or restart from a pause request. Sets MR*n*[CS]. (Note that negating DMA_DREQ_B does NOT clear MR*n*[CS].)
- DMA_DACK_B-Indicates a DMA transfer currently in progress. SR*n*[CB] is set.
- DMA_DDONE_B-Indicates the completion of the DMA controller's involvement in the transfer and the readiness to accept a new DMA command. SR*n*[CB] is clear. Note however, that write data may still be queued at the target interface or in the process of transfer on an external interface.

Detailed descriptions of the external control interface are in Table 23-3. The timing diagram of the external control interface is shown in this figure.

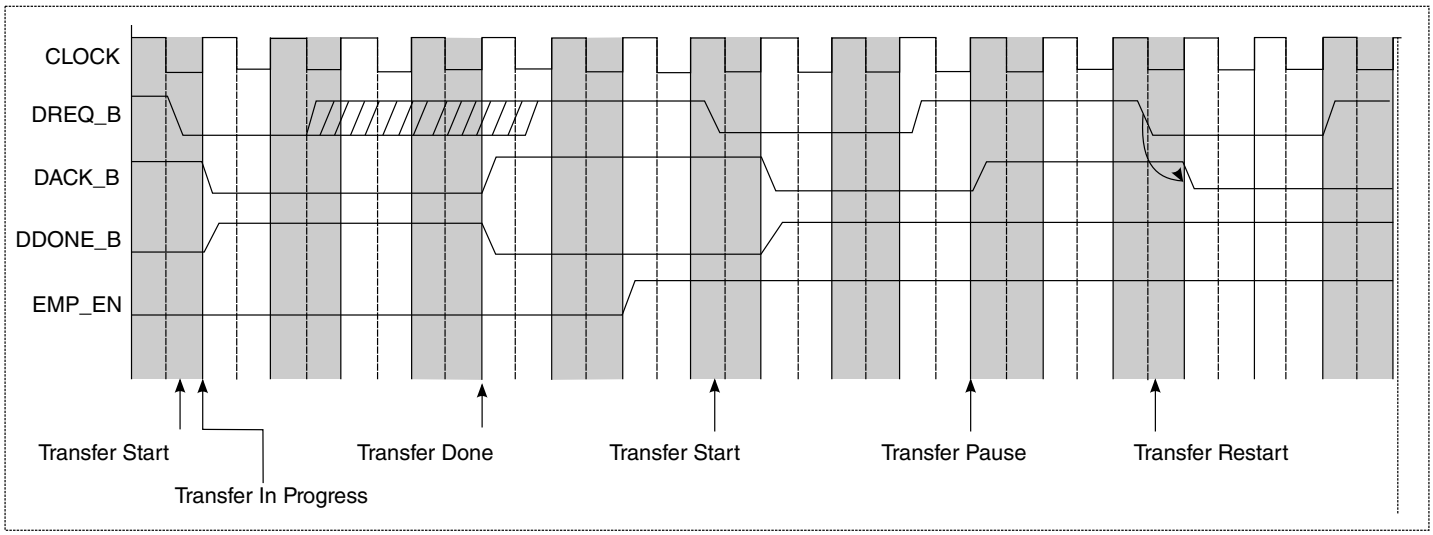

Figure 23-7. External control interface timing

23.4.1.5 Channel continue mode for cascading transfer chains

The channel continue mode (enabled when MR*n*[CC] is set) offers software the flexibility of having the DMA controller start on descriptors that have already been programmed while software continues to build more descriptors in memory.

Software can set the end-of-links descriptor (EOLND) in basic mode, or end-of-lists descriptor (EOLSD) in extended mode, to cause the channel to go into a halted state while software continues to build other descriptors in memory. Software can then set CC to force hardware to continue where it left off. Channel continue is only meaningful for chaining modes, not direct mode.

If CC is set by software while the channel is busy with a transfer, the DMA controller finishes all transfers until it reaches the EOLND in basic mode or EOLSD in extended mode. The DMA controller then refetches the last link descriptor in basic mode or the last list descriptor in extended mode and clears the channel continue bit. If EOLND or EOLSD is still set for their respective modes, the DMA controller remains in the idle state. If EOLND or EOLSD is not set, the DMA controller continues the transfer by refetching the new descriptor. The channel busy (SR*n*[CB]) bit is cleared when the DMA controller reaches EOLND/EOLSD and is set again when it initiates the refetch of the link or list descriptor.

If CC is set by software while the channel is not busy with a transfer, the DMA controller refetches the last link descriptor in basic mode, or the last list descriptor in extended mode and clears the channel continue bit. If EOLND or EOLSD is still set for their

respective modes, the DMA controller remains in the idle state. If the EOLND or EOLSD bits are not set, the DMA controller continues the transfer by refetching the new descriptor.

23.4.1.5.1 Basic mode

On a channel continue, the descriptor at the current link descriptor address register (CLNDAR*n*) is refetched to get the next link descriptor address field as updated by software.

The channel halts if NLNDAR*n*[EOLND] is still set. If EOLND is zero, the next link descriptor address is copied into CLNDAR*n* and the channel continues with another descriptor fetch of the current link descriptor address. As a result, two link descriptor fetches always exist after channel continue before starting the first transfer.

23.4.1.5.2 Extended mode

On a channel continue, the descriptor at the current list descriptor (CLSDAR*n*) address register is refetched to get the next list descriptor address field as updated by software.

The channel halts if NLSDAR*n*[EOLSD] is still set. If not, the next list descriptor address is copied into the CLSDAR*n* register and the channel continues with another descriptor fetch of the current list descriptor address. As a result, two list descriptor fetches always exist after channel continue before the first link descriptor fetch and the first transfer.

23.4.1.6 Channel abort

Software can abort a previously initiated transfer by setting MR*n*[CA].

Once the DMA channel controller detects a zero-to-one transition of MR*n*[CA], it finishes the current sub-block transfer and halts all further activity. The controller then waits for all previously initiated transfers from the specified channel to drain and clears SR*n*[CB]. Successful completion of a software initiated abort request can be recognized by MR*n*[CA] being set and SR*n*[CB] being cleared. Obviously, if the controller was already halted because of an error condition (SR*n*[TE] is set), or the channel has completed all transfers, then SR*n*[CB] being cleared may not signify that the controller entered a halt state due to the abort request.

23.4.1.7 Bandwidth control

MR*n*[BWC] specifies how much data to allow a specific channel to transfer before allowing the next channel to use the shared data transfer hardware.

This promotes equitable bandwidth allocation between channels. However, if only one channel is busy, hardware overrides the specified bandwidth control size value. The DMA controller allows a channel to transfer up to 1 Kbyte at a time when no other channel is active.

The maximum performance can be achieved on a single channel by disabling bandwidth control. This is recommended especially if only a single channel is utilized.

23.4.1.8 Channel state

This table defines the state of a channel based on the values of the channel start (MR*n*[CS]), channel busy (SR*n*[CB]), transfer error (SR*n*[TE]), and channel continue (MR*n*[CC]) bits.

Table 23-4. Channel state table

MRn[CS]	SRn[CB]	SRn[TE]	MRn[CC]	Channel state
0	0	0	0	Idle state. This is the state of the bits out of reset.
0	0	0	1	Channel continue unexpected. Channel remains idle
0	0	1	0	Error occurred after software halted the channel.
0	0	1	1	Channel continue unexpected. Channel remains in error halt state
0	1	0	0	Software halted channel. The channel was busy and software cleared MRn[CS].
0	1	0	1	Channel remains in halt state.
-	1	1	-	The channel has encountered an error condition and it is trying to halt.
1	0	0	0	Ready to start a transfer, or transfer completed
1	0	0	1	Continue transfer (only meaningful in chaining mode, not direct mode). In direct mode, the channel continue has no effect.
1	0	1	0	Error occurred during transfer
1	0	1	1	Channel remains in error halt state
1	1	0	0	Transfer in progress
1	1	0	1	Continue after reaching the end of list/link, or the first descriptor fetch after channel continue

23.4.1.9 Illustration of stride size and stride distance

If operating in stride mode, the stride size defines the amount of data to transfer before jumping to the next quantity of data as specified by the stride distance.

The stride distance is added to the current base address to point to the next quantity of data to be transferred. This figure illustrates the stride size and distance parameters.

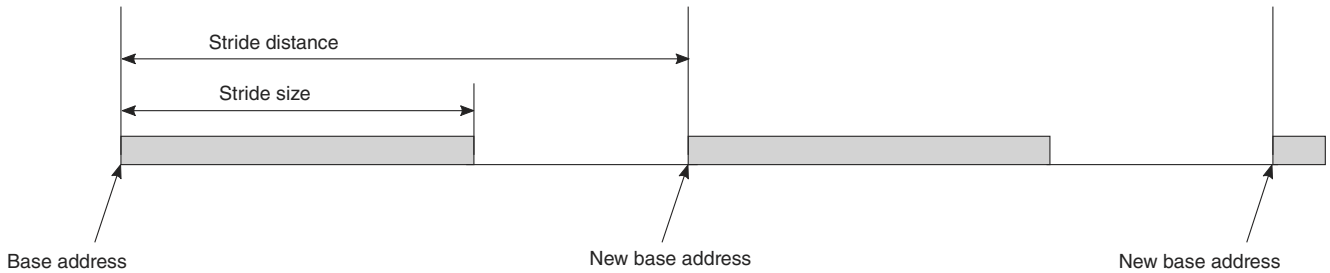

Figure 23-8. Stride size and stride distance

As shown, each time the stride distance is added to the base address, the resulting address becomes the new base address. This sequence repeats until the amount of data transferred equals the transfer size.

23.4.2 DMA transfer interfaces

The DMA can be used to achieve data transfers across the entire memory map.

23.4.3 DMA errors

On a transfer error (for example, non-correctable ECC errors on memory accesses, parity errors on flash controller, address mapping errors, and so on), the DMA halts by setting SR*n*[TE] and generates an interrupt if MR*n*[EIE] is set.

On a programming error, the DMA sets SR*n*[PE] and generates an interrupt if MR*n*[EIE] is set. The DMA controller detects the following programming errors:

- Transfer started with a byte count of zero
- Stride transfer started with a stride size of zero
- Illegal type, defined by SATR*n*[SREADTTYPE] and DATR*n*[DWRITETTYPE], used for the transfer.

23.4.4 DMA descriptors

The DMA engine recognizes the following types of descriptors:

- List descriptors connect lists of link descriptors.
- Link descriptors describe the DMA activity that is to take place.

DMA descriptors are built in either local or remote memory and are connected by the next descriptor fields. Only link descriptors contain information for the DMA controller to transfer data. Software must ensure that each descriptor is 32-byte aligned. The last link descriptor in the last list in memory sets the NLNDAR*n*[EOLND] bit in the next link descriptor and NLSDAR*n*[EOLSD] in the next list descriptor fields indicating that these are the last descriptors in memory. Software initializes the current list descriptor address register to point to the first list descriptor in memory. The DMA controller traverses through the descriptor lists until the last link descriptor is met. For each link descriptor in the chain, the DMA controller starts a new DMA transfer with the control parameters specified by that descriptor. Link and list descriptor fetches always snoop the local memory space.

NOTE

Software must ensure that each descriptor is aligned on a 32-byte boundary.

This table summarizes the DMA list descriptors.

Table 23-5. List DMA descriptor summary

Descriptor field	Description
Next list descriptor extended address	Points to the next list descriptor in memory. After the DMA controller reads the descriptor from memory, this field is loaded into the next list descriptor extended address registers.
Next list descriptor address	Points to the next list descriptor in memory. After the DMA controller reads the descriptor from memory, this field is loaded into the next list descriptor address registers.
First link descriptor extended address	Points to the first link descriptor in memory for this list. After the DMA controller reads the descriptor from memory, this field is loaded into the current link descriptor extended address registers.
First link descriptor address	Points to the first link descriptor in memory for this list. After the DMA controller reads the descriptor from memory, this field is loaded into the current link descriptor address registers.
Source stride	Contains the stride information used for the data source if striding is enabled for a link in the list
Destination stride	Contains the stride information used for the data destination if striding is enabled for a link in the list

This table summarizes the DMA link descriptors.

Table 23-6. Link DMA descriptor summary

Descriptor field	Description
Source attributes register	Contains source transaction attributes
Source address	Contains the source address of the DMA transfer. After the DMA controller reads the descriptor from memory, this field is loaded into the Source address register.
Destination attributes register	Contains destination transaction attributes
Destination address	Contains the destination address of the DMA transfer. After the DMA controller reads the descriptor from memory, this field is loaded into the destination address register.
Next link descriptor extended address	Points to the next link descriptor in memory. After the DMA controller reads the link descriptor from memory, this field is loaded into the extended next link descriptor address registers

Table continues on the next page...

Table 23-6. Link DMA descriptor summary (continued)

Descriptor field	Description
Next link descriptor address	Points to the next link descriptor in memory. After the DMA controller reads the link descriptor from memory, this field is loaded into the next link descriptor address registers.
Byte count	Contains the number of bytes to transfer. After the DMA controller reads the descriptor from memory, this field is loaded into the byte count register.

This figure describes the DMA transaction flow.

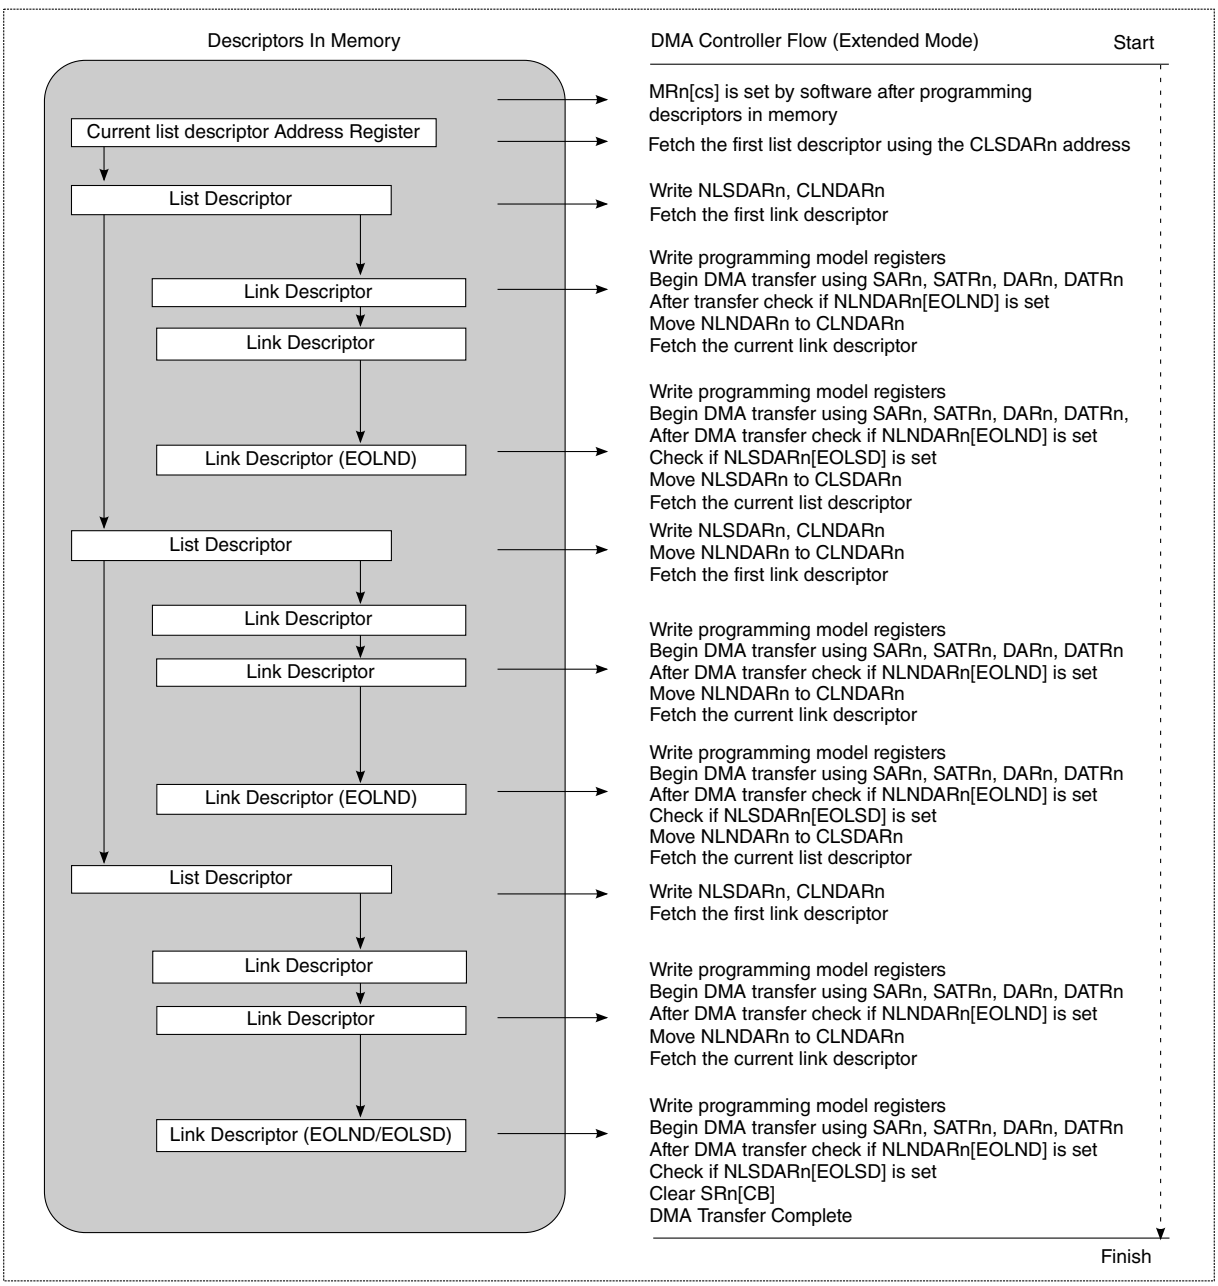

Figure 23-9. DMA transaction flow with DMA descriptors

This figure describes the format of the list descriptors.

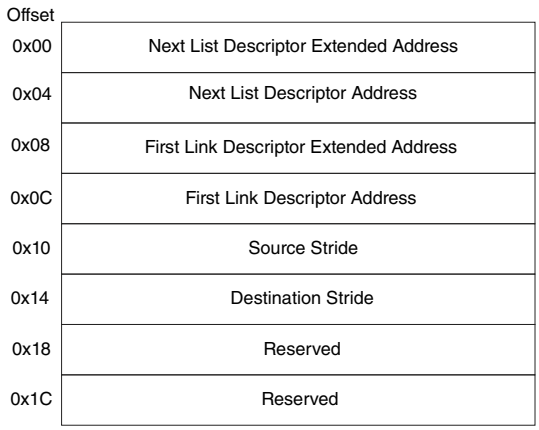

Figure 23-10. List descriptor format

This figure describes the format of the link descriptors.

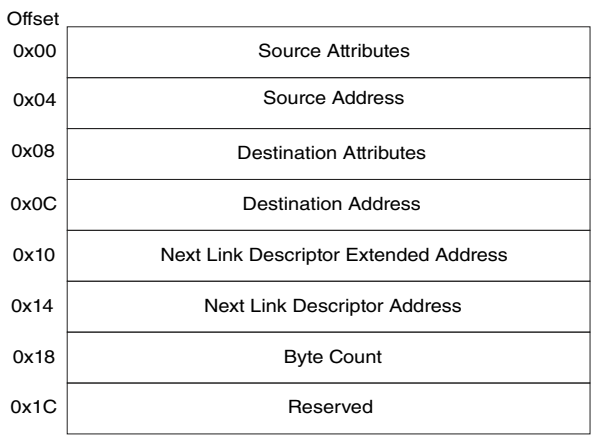

Figure 23-11. Link descriptor format

23.4.5 DMA controller limitations and restrictions

This section is intended to help software maximize the DMA performance and avoid DMA programming errors.

The limitations of the DMA controller are the following:

- Due to the limited number of buffers that the DMA controller can use, avoid stride sizes less than 64 bytes. Maximum utilization is obtained from strides greater than or equal to 256 bytes. However, small stride sizes can be used for scatter-gather functions.
- Coherent reads or writes are broken up into cache line accesses in the DMA.

The DMA controller restrictions are as follows:

- All interface capabilities from where descriptors are being fetched must support read sizes of 32 bytes or greater.
- If MR*n*[SAHE] is set, the source interface transfer size capability must be greater than or equal to MR*n*[SAHTS]. The source address must be aligned to a size specified by SAHTS.
- If MR*n*[DAHE] is set, the destination interface transfer size capability must be greater than or equal to MR*n*[DAHTS]. The destination address must be aligned to the size specified by DAHTS.
- Destination striding is not supported if MR*n*[DAHE] is set and source striding is not supported if MR*n*[SAHE] is set.

23.5 DMA system considerations

This section provides information about how to make most effective use of the DMA channels.

23.5.1 Unusual DMA scenarios

The following is a description of unusual DMA paths including explanations of why some functional modules cannot serve as DMA targets.

The following topics are addressed:

- DMA transaction initiators (masters)
- DMA targets, that is, data sources or destinations
- Transparency of the bus controllers to DMA transactions
- What is useful as opposed to what is possible. For example, any register can be addressed through an internal control bus, which means configuration and control registers can be DMA targets.

23.5.1.1 DMA to core

The L1 cache cannot be a direct DMA target because it cannot be directly addressed by software.

However, DMA access into the L1 cache occurs indirectly if a block of memory that is cached in the L1 is specified as the DMA target. This effect is deterministic if the target memory block was locked into the L1 with cache locking instructions.

23.5.1.2 DMA to configuration, control, and status registers (CCSR)

Because any internal register can be addressed with the four-channel DMA controller, configuration, control, and status registers throughout the device are valid DMA targets.

However, the primary purpose of DMA, to reduce processor load by moving large blocks of data, is not served by DMA transfers of configuration data. For example, while it is possible to DMA into the I^2C controller or programmable interrupt controller (PIC), doing so is extremely inefficient and is seldom beneficial in normal operation. The overhead of creating DMA descriptors far exceeds any savings in CPU cycles.

23.5.1.3 DMA to I^2C

The I^2C controller is not transparent to DMA transfers.

Observe the caveats listed in DMA to configuration, control, and status registers (CCSR) when accessing any I^2C register, including the data register (I2CDR).

23.5.1.4 DMA to DUART

The DUART provides complete and sophisticated DMA support, which is described in FIFO mode.

23.5.1.5 DMA in multi-partition systems

The DMA controller uses a privileged copy of the LAWs to resolve source and destination targets.

This means that when a logical address is passed to the DMA controller, it compares this logical address with true physical addresses in the LAWs. Because of this behavior, the DMA controller has the capability to resolve its target without the need for a PAMU, providing optimization when targeting outbound I/O transactions. Because the PAMU only authorizes inbound transactions, it does not authorize transactions that resolve to outbound I/O. Note that this behavior only applies to outbound I/O transactions from the DMA controller; only the DMA controller has access to the privileged copy of the LAWs.

In a multi-partitioned system (such as a system partitioned and controlled under a Hypervisor), where logical addresses are not mapped one-to-one to physical addresses, one of the following three techniques must be implemented to help ensure absolute partitioning:

1. The programming of the DMA controller from a guest OS must be virtualized in software so that the guest OS must make Hypervisor calls (hcalls) in order to program the DMA. The Hypervisor is aware of the global system memory map and can block any OS from trying to target an address it deems invalid for that OS.
2. The Hypervisor must enforce the following logical address restrictions on all partitions:
   a. All I/O logical addresses must be mapped one-to-one using their true physical addresses.
   b. All guest OSs must map their I/O logical address space in the same globally unique system-wide range, which does not overlap other non-I/O addresses. All OSs use this space only for I/O.

   For example, the following represents a valid setup:

   - OS-A is aware of logical addresses A-C, that are mapped one-to-one with physical addresses A-C.
   - OS-B is aware of logical addresses D-F, that are mapped one-to-one with physical addresses D-F.
   - A law entry for DDR maps the entire SDRAM space to physical addresses A-F.
   - The PCI express controller 1 outbound window is mapped to physical addresses 2-3.

   In this example all logical addresses are mapped one-to-one with true physical addresses, and the outbound PCI express space does not overlap either OS's view of logical space.

   As a counter-example, the following represents an invalid setup:

   - OS-A is aware of logical addresses 0-2, that are mapped to physical addresses A-C.
   - OS-B is aware of logical addresses D-F, that are mapped one-to-one with physical addresses D-F.
   - A LAW entry for DDR maps the entire SDRAM space to physical addresses A-F.
   - The PCI express controller 1 outbound window is mapped from 1-2.

In this example, the setup is invalid because the logical addresses of OS-A overlap the outbound PCI express physical I/O window. If the DMA targets logical address 1, it will use its privileged copy of the LAWs to resolve the target, and because address 1 overlaps with the outbound PCI express window, it will target PCI express instead of DDR, which may not be intended.

3. Do not grant direct DMA controller access to a guest OS which cannot meet one of the previous two constraints.

Chapter 24
Data Path Acceleration Architecture (DPAA) Overview and T4240 DPAA Implementation

24.1 DPAA Introduction and Terms

The data path processing subsystem is an implementation of the QorIQ Data Path Acceleration Architecture (DPAA).

The QorIQ T4240 Data Path Acceleration Architecture (DPAA) Reference Manual describes the superset of DPAA functionality. The chip implements a unique subset of this functionality, as described in the T4240-Specific DPAA Implementation Details.

As shown in the following figure, the DPAA consists of a parse, classify, and distribute module (PCD) and an accelerator module (FMan), along with these related network interfaces:

- Multirate Ethernet MAC (mEMAC)
- hardware offload accelerators:
  - SEC
  - PME
  - DCE
  - RMan
- the infrastructure blocks that support these accelerators (QMan and BMan)

Each of these accelerators provides its own unique set of functionality, and thus each has its own unique requirements for how software must program and interact with that accelerator.

The DPAA's common infrastructure modules and the desire to be able to pass data received from one accelerator to another led to some common requirements, restrictions, and conventions. This chapter outlines requirements and conventions that are common to multiple accelerators within the DPAA.

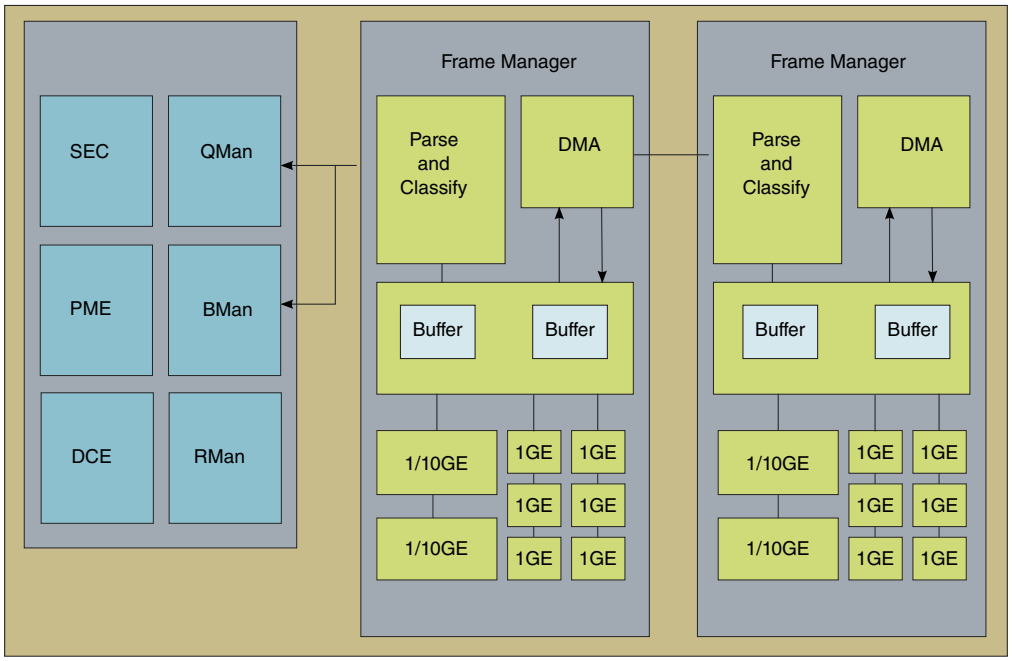

Figure 24-1. QorIQ Data Path Acceleration Architecture

The following list describes common DPAA terms and definitions.

Buffer

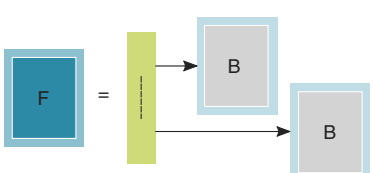
Region of contiguous memory, allocated by software, may be managed by the DPAA Buffer Manager (BMan).

Buffer pool

Set of buffers with common characteristics (mainly size, alignment, access control)

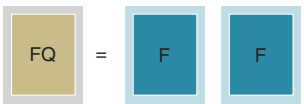
Frame

Contents of a single buffer or multiple buffers referenced by a table that hold data. For example, packet payload, header, and other control information.



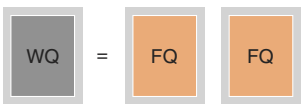
Frame queue (FQ)

FIFO of frames



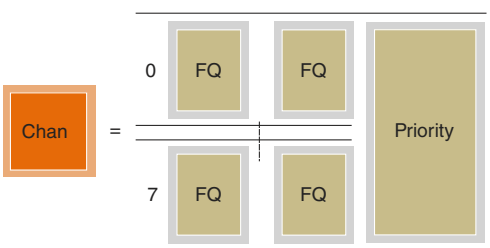
Work queue (WQ)

FIFO of frame queues (FQs)



Channel

Set of eight work queues (WQs), with hardware provided prioritized access



Dedicated channel

Channel statically assigned to a particular end point from which that end point can dequeue frames. End-point may be a CPU, FMan, PME, or SEC.

Pool channel

A channel statically assigned to a group of end points from which any of the end points may dequeue frames.

24.2 Data Formats Used in the DPAA

Data-to-be-processed is passed within the DPAA in distinct units known as “frames.”

The actual data is held in buffers in memory and a description of the frame is what is passed within the DPAA.

24.2.1 Frame Descriptor (FD)

A frame descriptor (FD) is the basic element queued by the QMan.

See the, "Frame Manager" chapter in the *QorIQ Data Path Acceleration Architecture (DPAA) Reference Manual* for a description of the QMan's usage of the FD. The use and interpretation of some fields is specific to the producer or consumer of the FD. Such usage is described in the chapter/section covering that module.

24.2.1.1 FD Format

The table below lists the Frame Descriptor:

Table 24-1. Frame Descriptor (FD)

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

STATUS/CMD																															

Table 24-2. FD Field Descriptions

FD Bits	FD Name	FD Field Description
0-1	DD	Dynamic Debug marking code point A frame with a non-zero debug code point can generate a trace event at various enqueue and/or dequeue points within the QMan. Individual QMan users have different mechanisms and criteria for setting non-zero DD values.
2-7	LIODN_ OFFSET	Frame LIODN Offset (6 lsbs of complete LIODN_OFFSET) The LIODN_OFFSET is set when the FD is enqueued. It is used by a hardware module that dequeues the FD as part of the memory access control mechanism supported by the PAMU (see Role of the PAMU in the DPAA) See Accessing Memory Using Logical IO Device Numbers (LIODNs) for more information on the use of this field.
8-15	BPID	Buffer Pool ID The Buffer Pool ID is the number of the BMan buffer pool to which the buffer at ADDR should be released, if it is to be released to BMan.
16-19	ELIODN_ OFFSET	Frame Extended LIODN offset (4 msbs of complete LIODN_OFFSET) The complete 10-bit LIODN_OFFSET value is a concatenation of {ELIODN_OFFSET, LIODN_OFFSET}. See Accessing Memory Using Logical IO Device Numbers (LIODNs) for more information on the use of this field.

Table continues on the next page...

Table 24-2. FD Field Descriptions (continued)

FD Bits		FD Name	FD Field Description
20-23		-	Reserved
24-63		ADDR	Address The memory address of the start of the buffer holding the frame data or the buffer containing the scatter/gather list describing the frame
64-66		FORMAT	A coded value that defines the format of the OFFSET and LENGTH fields, and of the frame referenced by this FD. See Frame Format Codes for a description of these codes.
Optional fields	67-75	OFFSET	This field is valid only when FORMAT bits 65-66 are 00; otherwise, a frame offset value of 0 is implied. Frame offset is the number of bytes from the frame address (ADDR) at which actual data begins. Note that this field is not present in all FDs
	76-95	LENGTH	Total number of valid bytes of data in the frame. Note that this field is not present in all FDs.
	67-95	CONGESTION WEIGHT	A value used by the QMan for certain congestion management/avoidance calculations. Note that this field is not present in all FDs.
96-127		STATUS/CMD	Status or Command This field allows the sender of a frame to communicate some out-of-band information to the receiver of the frame. For example, this field can be used to communicate a command describing what processing is to be performed to a hardware accelerator or the error/output status after a hardware accelerator has finished processing a frame.

24.2.1.2 FD Considerations

To support the diverse needs of the various accelerators in the DPAA, multiple frame formats are defined. FD[FORMAT] designates the frame format described by the FD.

Depending on the situation, one of the following must be stored:

- Data beginning at an offset from the actual start of the buffer, saving room at the beginning of the buffer (for adding new headers, for example)
- Large amount of data in contiguous memory

Because these cases tend to be mutually exclusive, formats are defined that trade off between the size of FD[LENGTH] and FD[OFFSET]. Depending on the FD[FORMAT], one of the following is present in the FD:

- FD[LENGTH] and FD[OFFSET]
- Just FD[LENGTH]
- Just FD[CONGESTION WEIGHT]

These fields occupy the same bits within the FD.

24.2.2 Multi-Buffer Frames

The actual data in a frame is held in one or more memory buffers.

If multiple buffers are required, a scatter/gather table (also known as a block vector or IO vector table) is used to describe the buffers in a multi-buffer frame. See Scatter/Gather Entry Format for a description of this data structure.

24.2.2.1 Scatter/Gather Entry Format

The table below lists the Scatter/Gather Table Entry Format:

Table 24-3. Scatter/Gather Table Entry Format

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
0	Reserved (must be 0)																								ADDR							
	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47	48	49	50	51	52	53	54	55	56	57	58	59	60	61	62	63
1	ADDR																															
	64	65	66	67	68	69	70	71	72	73	74	75	76	77	78	79	80	81	82	83	84	85	86	87	88	89	90	91	92	93	94	95
2	E	F	LENGTH																													
	96	97	98	99	100	101	102	103	104	105	106	107	108	109	110	111	112	113	114	115	116	117	118	119	120	121	122	123	124	125	126	127
3	Reserved (must be 0)								BPID								Reserved (Must be 0)			OFFSET												

Table 24-4. Scatter Gather Table Entry Field Description

Bits	Name	Description
0-23	-	Reserved (must be 0)
24-63	ADDR	Address of the buffer referenced by this table entry. This buffer may contain data or it may contain another scatter/gather table.
64	E	Extension bit. If set, this table entry points to a buffer that contains another scatter/gather table.
65	F	Final bit. If set, this is the last table entry for this frame. Note that the E (extension) bit takes precedence over the F (final) bit. If both are set, the F bit is ignored and processing continues with the entries in the scatter/gather table in referenced buffer.
66-95	LENGTH	Depending on the context, this field either specifies the number of valid bytes of data in the referenced buffer or the size of the referenced buffer (in the case that empty buffers are being provided to an accelerator). Note that if the E (extension) bit is set, LENGTH is ignored.
96-103	-	Reserved (must be 0)
104-111	BPID	Buffer Pool ID: The number of the BMan buffer pool to which this buffer should be released, if it is released to BMan.
112-114	-	Reserved (must be 0)
115-127	OFFSET	An offset in bytes from the ADDR at which valid data starts

Table 24-4. Scatter Gather Table Entry Field Description

Bits	Name	Description
		Note that if the E (extension) bit is set, "valid data" is a scatter/gather table.

24.2.2.2 Multi-Buffer Frame Considerations

Important multi-buffer frame considerations are as follows:

- The first scatter/gather table in a multi-buffer frame is held in the buffer referenced by the FD. In the case of a short, multi-buffer frame, the table starts at OFFSET bytes from the beginning of the buffer.
- “Trees” or hierarchy are not supported, because for simple, multi-buffer frames, processing never returns to the table in the original buffer.
- If the E bit is set, it indicates that the table entry points to another buffer containing more table entries. When a scatter/gather table entry with the E bit set is encountered, processing proceeds from the first entry in the new table found in the new buffer. This new table may begin at some offset from the start of the buffer as defined by the OFFSET field in the entry with the E bit set.
- In simple, multi-buffer frames, the LENGTH field in a table entry with its E bit set can be ignored.
- The E bit takes precedence over the F bit (that is, if both are set in an entry, the F bit is ignored).

This figure shows a simplified representation of a "long" simple frame using a scatter/gather table. Note that this diagram does not show the use of the Extension bit.

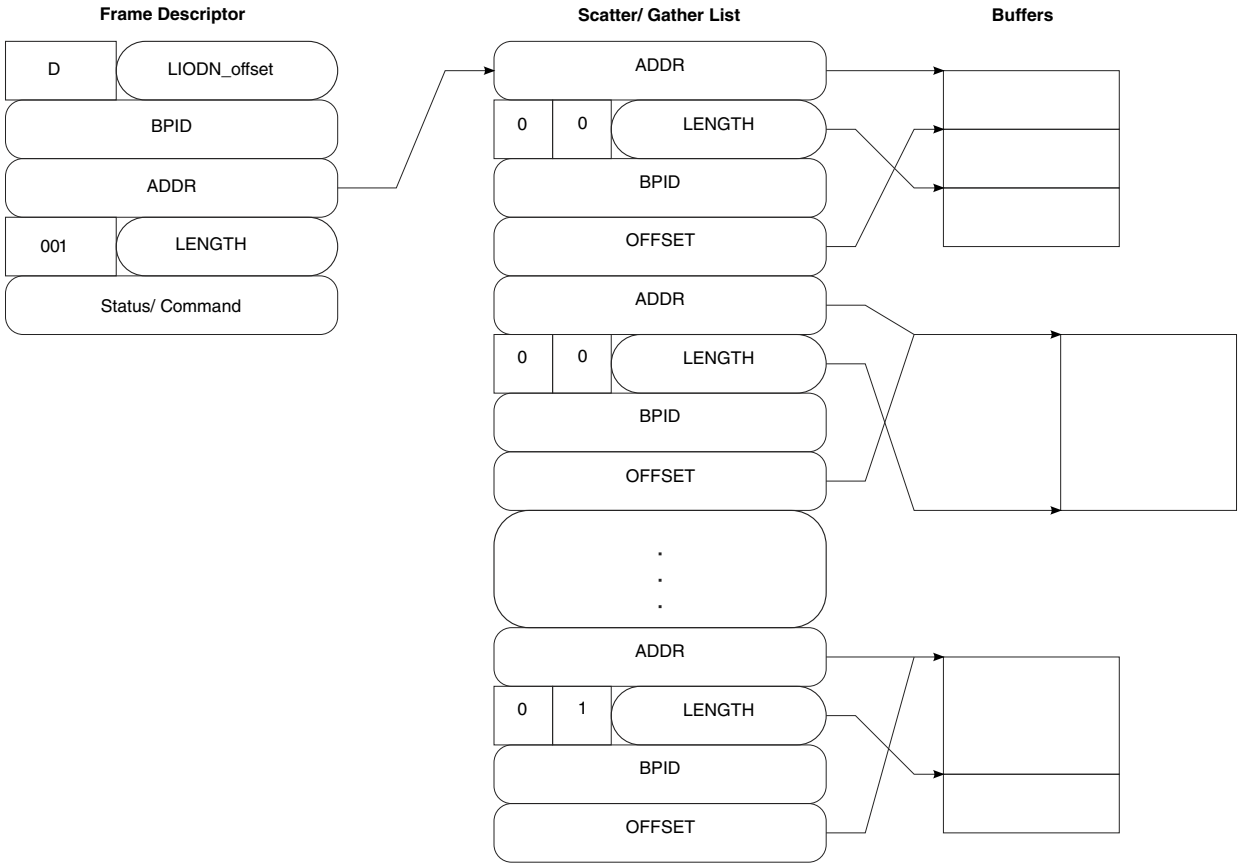

Figure 24-2. Simplified Representation of a Long, Multi-Buffer, Simple Frame

24.2.2.3 Situations Where Multi-Frame Buffering Stops

Multi-buffer frame processing stops in the following situations:

- When the data referenced by an entry with the F bit is processed regardless of the LENGTH indicated in the FD for the frame. In some cases, a mismatch (less data found in the frame compared to the FD length) may be an error condition for the accelerator module that is performing the processing, and it is reported as such.
- Processing also stops when the number of bytes specified by the overall length in the frame's FD have been processed. In this case, it is not necessary to have encountered an entry with the F bit set and it is not considered an error when this occurs.

24.2.3 Single-Buffer Frames

Most frame formats consist of a single delineated unit of data such as a single packet or Protocol Data Unit (PDU).

For a single buffer, the FD[LENGTH] field represents the total amount of valid data in the frame. The OFFSET represents the offset to the start of valid data.

For multiple buffers (used for scatter/gather), the FD[LENGTH] field still represents the total amount of valid data in the frame, but the OFFSET represents the offset to the start of the scatter/gather table in the first buffer.

24.2.4 Compound Frames

Frames may also consist of multiple, related, distinct units such as the encrypted form of a packet along with the decrypted form of the same packet. These are known as compound frames, which consist of two or more simple frames.

Each simple frame in a compound frame can in turn be stored in a single buffer or in multiple buffers. Compound frames exist so that all of the related data can be passed in a single unit within the DPAA. If an FD has a FORMAT code that identifies it as a compound frame then the FD[CONGESTION WEIGHT] is used to by the QMan for active queue management calculations such as WRED.

24.2.4.1 When to Use Compound Frames

Compound frames are used for the following purposes:

- To pass multiple, distinct pieces of data either to or from a hardware accelerator. For instance, it may be required to pass frames containing both encrypted and decrypted forms of a packet.
- To supply empty buffers to a hardware accelerator into which it may place its output. In this case, it is not desirable to use the BMan. Any LENGTH and OFFSET fields that refer to a specific buffer have special meaning; OFFSET specifies the byte offset from ADDR where the accelerator should start storing data and LENGTH gives the number of bytes of data which can be stored in the remainder of the buffer.

Consider the following when using compound frames:

- When multiple input or output frames are described by a compound frame, their order is consumer-dependent.
- If a compound frame is used to pass empty buffers to a consumer for its output, those buffers are in the first frame of the compound frame.
- If a module uses a compound frame to return the input frame as well as its output frame, the output frame is the first frame of the compound frame and the input frame is the second frame.

24.2.4.2 Compound Frame Considerations

Important compound frame considerations are as follows:

- Compound frames use the same scatter/gather table format as simple frames, but with slightly different semantics for the fields in the table entries.
- The buffer referenced by FD[ADDR] of a compound frame must contain a scatter/gather table (the compound scatter/gather table). A compound frame contains FD[CONGESTION WEIGHT] but does not contain FD[LENGTH] or FD[OFFSET]. The compound scatter/gather table must start at FD[ADDR].
- Each entry in the compound scatter/gather table references a simple frame. ADDR, LENGTH, BPID, and OFFSET fields in the compound scatter/gather table entry replace the corresponding fields in an FD. A compound frame contains FD[CONGESTION WEIGHT] but does not contain FD[LENGTH] or FD[OFFSET]. The compound scatter/gather table must start at FD[ADDR].
- The E bit is set if the simple frame occupies multiple buffers. The E bits in multiple entries in the compound scatter/gather table may be set, because each simple frame in the compound frame may occupy multiple buffers. In this case, the buffer at ADDR contains a scatter/gather table.
- The scatter/gather table(s) that make up a simple frame that is part of a compound frame follow the same semantics as described in Scatter/Gather Entry Format.
- There is no equivalent in the compound scatter/gather table for the FORMAT field in the FD. The entries in a compound scatter/gather table cannot themselves be compound frames; the E bit is used to indicate a multi-buffer frame, and the LENGTH and OFFSET fields supported in the scatter/gather entry are a superset of the fields in an FD.
- The F bit must be set in the last entry of a compound frame scatter/gather table.

This figure shows a representation of a compound frame.

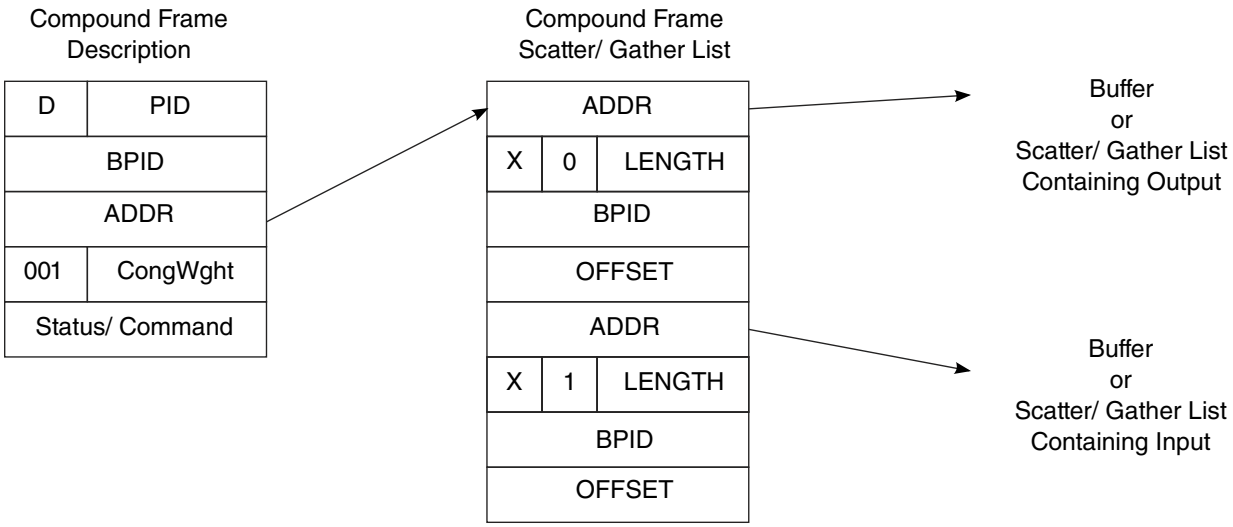

Figure 24-3. Simplified Representation of a Compound Frame

24.2.5 Simple Frames

Simple frames can be either short or long. Regardless of the length of the frame, data is stored in a single-buffer frame, whereas scatter/gather tables are stored in a multi-buffer frame.

A short frame can be no more than (1 Mbyte - 1 byte)-long but the data (in the case of a single buffer frame) or scatter/gather table (in the case of a multi-buffer frame) can be stored starting at an offset from the beginning of the buffer referenced by the FD. Long frames can be as much as (512 Mbytes - 1 byte)-long, but the data or scatter/gather table must be stored starting at the beginning of the buffer referenced by the FD.

Because network data (packets) are typically much less than 64 Kbytes in size, the short format is useful for most network processing needs.

24.2.6 Frame Format Codes

This table defines the frame format codes and provides a brief description of the frame format.

Table 24-5. Frame Format Codes

Value	Mnemonic	Definition	Size of LENGTH, OFFSET, and CONGESTION WEIGHT Fields
'000'	Short single buffer simple frame	Simple frame Single buffer, Offset and "small" length	9b OFFSET, 20b LENGTH
'010'	Long single buffer simple frame	Simple frame, single buffer, "big" length	29b LENGTH No OFFSET
'100'	Short multi-buffer simple frame	Simple frame, Scatter Gather table, Offset and "small" length	9b OFFSET, 20b LENGTH
'110'	Long multi-buffer simple frame	Simple frame, Scatter Gather table, "big" length	29b LENGTH No OFFSET
'001'	Compound frame	Compound Frame	29b <CONGESTION WEIGHT> No LENGTH or OFFSET
'011'	NA	Reserved	Not defined
'101'	NA	Reserved	Not defined
'111'	NA	Reserved	Not defined

24.2.7 Frame Formats Supported by Accelerators

Hardware accelerators (FMan, PME, and RMan) support a subset of the DPAA frame formats.

This table summarizes the frame formats supported by various accelerators.

Table 24-6. Frame Format Support Matrix

	Short, Single Buffer		Long, Single Buffer		Short Multi-Buffer		Long Multi-Buffer		Compound Frames	
	Input	Output	Input	Output	Input	Output	Input	Output	Input	Output
FMan	Yes	Yes	No	No	SG table [1] limited to 16 entries. E bit not supported	SG table limited to 16 entries E bit not supported	No	No	No	No
PME	Yes	Yes	Yes	Yes	Yes	Return input frame only	Yes	Return input frame only	Yes	Yes

Table continues on the next page...

Table 24-6. Frame Format Support Matrix (continued)

	Short, Single Buffer		Long, Single Buffer		Short Multi-Buffer		Long Multi-Buffer		Compound Frames	
	Input	Output	Input	Output	Input	Output	Input	Output	Input	Output
SEC	Yes	Yes	Yes	Yes	Yes	SG table limited to one one buffer E bit not supported	Yes	SG table limited to one one buffer E bit not supported	Yes	Yes
DCE	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
RMan	Yes	Yes	No	No	Yes	Yes	No	No	No	No

1. Scatter/Gather entry table

24.2.8 Special Values and Exceptions

The ADDR, BPID, and LENGTH fields can have special meanings under certain conditions, as follows:

- FDs
- Compound frame scatter/gather tables
- Multi-buffer scatter/gather tables

Exceptions and special behaviors are as follows:

- When the LENGTH field that describes a specific buffer is zero, this indicates that the buffer contains no data. If an accelerator finds a LENGTH of zero it should not access (read or write) the memory at ADDR.
- The LENGTH field in a scatter/gather table entry of a simple multi-buffer frame with its E (extension) bit set is an exception, because the value of this field is ignored.
- FDs, compound frame, or multi-buffer frame SG entries with ADDR/BPID/LENGTH=0 encoding indicate that the FD or SG entry does not convey buffer information, that is, the SG entry is unused and is therefore skipped during input and/or output processing.

24.2.9 Releasing Buffers to the BMan

Accelerators only release buffers to the BMan that they have processed or, in the case of a buffer with a zero LENGTH, that they have passed over during processing. Buffers with a zero ADDR, BPID, and LENGTH are not released.

REQUIREMENT: Because processing stops when the frame's total length of data is processed or after the data referenced by a scatter/gather entry with its F (final) bit set is processed, ensure that all buffers in a frame are released. For example, software must ensure that there are no entries in a scatter/gather table for a multi-buffer frame that are beyond the frame's total length or described in entries after the entry with the F bit set.

24.3 Accessing Memory Using Logical IO Device Numbers (LIODNs)

This topic describes use of LIODNs and peripheral access management units (PAMUs).

24.3.1 Role of the PAMU in the DPAA

QorIQ multicore SoCs include peripheral access management units (PAMUs), which provide a number of functions including memory access control.

When the PAMU is enabled, any hardware module in the SoC other than the cores access memory through PAMU. The PAMU can authorize the access, remap the memory address, and remap the transaction type (for example, a simple "write" to a "write with allocate to cache").

The PAMU determines what action to take and whether to authorize the action on the basis of the memory address, a logical IO device number (LIODN), and a configured table (logically) indexed by a LIODN and address. Hardware devices that need to access memory must provide a LIODN in addition to the memory address.

24.3.2 Using Multiple LIODNs

This topic describes the benefits and requirements of using multiple LIODNs.

24.3.2.1 Benefit of Using Multiple LIODNs

By using different LIODNs, a single hardware module can perform memory accesses on behalf of different requestors with the mapping and access controls appropriate to that requestor.

24.3.2.2 LIODN Requirements

Some important LIODN requirements are as follows:

- The requestor must communicate the LIODN to the hardware blockmodule. In the DPAA, this is done using the "<LIODN OFFSET>". <LIODN OFFSET> is formed by concatenating LIODN_OFFSET and ELIODN_OFFSET from the FD with the latter used as the 4 msbs.
- Hardware module determine the LIODN to use in accessing memory by adding <LIODN OFFSET> to a configured <LIODN BASE>. Because <LIODN OFFSET> is in the FD, the module can use a different LIODN for each frame.
- Some hardware module may make different types of memory accesses as a result of dequeuing a frame. For instance, they may access per queue context/state/descriptors as well as reading and writing frame data. These modules may have different <LIODN BASE> values for these different types of access. These modules compute different LIODNs using the <LIODN OFFSET> from the FD and the appropriate <LIODN BASE> configured for the type of access.
- The <LIODN OFFSET> must be set by the producer (enqueuer) of the FD. For software portals, this is done by the QMan from values configured for the portal to ensure that accesses by hardware module on behalf of software are controlled. In other words, software running on a core cannot get a hardware blockmodule to make accesses to memory, because it is not permitted to make these accesses by setting the <LIODN OFFSET> value in an FD.

24.4 Packet Walk-Through Example

The following example walks a packet through a DPAA-enabled, QorIQ device to illustrate how the DPAA offloads and accelerates packet forwarding while leaving key decisions under software control:

1. Datapath processing begins when Ethernet frames arrive at a network interface, assumed to be one of the Ethernet MACs within a Frame Manager (FMan). Alternatively, packets can arrive across a peripheral bus from an external network interface, in which case, the same packet walk-through stages can be applied with the help of a CPU acting as an I/O processor.
2. After FMan receives the Ethernet frame, it requests one or more buffers from the hardware Buffer Manager (BMan) to store the frame. BMan maintains pools of buffers, each with software-defined characteristics, and FMan is initialized to request a buffer from the most appropriate pool. If a sufficiently large buffer cannot be found for the incoming frame, FMan stores the frame across several smaller buffers and creates a scatter/gather list for these buffers.

3. FMan's configurable parsing and filing capabilities can perform initial classification, sufficient to steer a packet toward a control processor, or toward one of the datapath processors for flow-specific processing (or additional classification by means of software). The steering of a packet towards a processor or a group of processors could be also based on differentiating flows by means of the Quality of Service attributes of the flow (for example, DSCP, IP precedence, or by user-defined proprietary headers).
4. Steering is accomplished by FMan issuing an enqueue command to QMan with the designated Frame Queue ID, along with frame parameters such as Frame Queue ID and Color Marking. In this example FMan's initial classification causes it to select a Frame Queue ID which the Queue Manager uses to steer the Frame Queue to the dedicated channel of logical CPU#3, a CPU operating in a datapath role. Potentially, the Frame Queue could be selected based on the QoS requirements of the flow with a policing profile associated with the selection.
5. Continuing the example, QMan places the Frame Queue onto Work Queue#5 of CPU#3's dedicated channel. The Frame Queue was queued to CPU#3 due to user configuration decisions that all packets belonging to this specific flow should be processed by CPU#3, possibly to take advantage of special processing instructions locked in CPU#3's private cache, or due to user-defined load balancing. The Frame Queue was placed in Work Queue#5 for QoS reasons, as the amount of traffic processed from each Work Queue relative to other work queues is also user-configurable. All Frame Queues on a Work Queue have equal priority, but the amount of traffic that the CPU draws from each is user-configurable to allow fairness and appropriate bandwidth allocation.
6. Once configured, QMan can take care of the packet/frame level scheduling requirements of the CPU, that is, QMan would appropriately schedule the Work Queue and Frame Queue within the Work Queue. QMan can be configured to perform a stashing operation in response to a CPU (or co-processor) accessing a Frame Queue.
7. CPU#3 performs protocol processing on the packet, including modification of the packet data in the buffer. Any modifications which change the length of the packet would be noted by means of changes to the frame. The CPU determines that the packet requires IPsec ESP processing, and enqueues the frame back to the QMan using the FQ ID associated with the packet's specific ESP tunnel.
8. The QMan uses this Frame Queue ID to determine that the next consumer of the Frame Queue is the SEC, and places the Frame Queue onto Work Queue#5 of the SEC's dedicated channel. The SEC pulls Frame Queues from the Work Queues in its dedicated channel according to user-defined weights in a WFQ model.
9. The SEC dequeues and processes data from the Frame Queue, adding the tunnel IP header, ESP header, IV, trailer, and HMAC, and writing encrypted data to either the original buffers, or new buffers which the SEC requests from BMan. The SEC

updates the frame description (length change due to the addition of the headers, trailers, and HMAC) and enqueues the FQ back to QMan using a configured FQ ID. In this case, the FQ ID causes the QMan to enqueue the FQ to Work Queue #5 of logical CPU#4's dedicated channel. CPU#4 dequeues the FQ, determines the outbound interface for the newly encrypted packet, updates the tunnel IP header, and enqueues the frame back to QMan on a new FQ ID. This FQ ID causes the QMan to enqueue the FQ to a channel serviced by FMan #2, which dequeues the FQ, transmits one or more packets from that FQ out the appropriate mEMAC, and releases the buffers back to BMan.

The processing pipeline used in this example is not required by the QorIQ DPAA. The initial classification could have caused the packet to be steered toward a CPU dedicated to fine-grained classification, or to a pool channel of CPUs, any of which could have performed the operations described. CPU#3 could have added the ESP header and trailer to the packet and sent it to the SEC for crypto-only processing. Following SEC processing, the flow was steered to CPU#4, however it could have just as easily been steered back to CPU#3, or to a pool channel. At any FQ ID transition, the relative priority of the flow could have been elevated or reduced by enqueuing it to a different work queue.

24.5 T4240-Specific DPAA Implementation Details

The *QorIQ Data Path Acceleration Architecture (DPAA) Reference Manual* describes the superset of DPAA functionality. The T4240 implements a unique subset of this functionality, as described in the following sections.

24.5.1 T4240 Queue Manager (QMan) Implementation

The QMan of the T4240 is implemented as described in the *QorIQ Data Path Acceleration Architecture (DPAA) Reference Manual* with the following implementation parameters:

- QMan block base address: 31_8000h
- 2-Kbyte frame queue (FQ) cache
- 2-Kbyte SFDRs
- 256 congestion groups

24.5.2 T4240 Buffer Manager (BMan) Implementation

The BMan of the T4240 is implemented as described in the *QorIQ Data Path Acceleration Architecture (DPAA) Reference Manual* with the following implementation parameters:

- BMan block base address: 31_A000h
- 64 buffer pools

24.5.3 T4240 Frame Manager (FMan) Implementation

The FMan of the T4240 is implemented as described in the *QorIQ Data Path Acceleration Architecture (DPAA) Reference Manual* with the following implementation parameters:

- FMan1 block base address: 40_0000h
- FMan2 block base address: 50_0000h
- Six 1G/2.5G multirate Ethernet MACs (mEMACs) per Frame Manager
  - Up to ten SGMII interfaces and two parallel interfaces or two additional SGMII interfaces. See signals description and configuration chapter for valid interface combinations and corresponding signalling.
  - Block base addresses are as follows:
    - FM1 mEMAC1: 4E_0000h
    - FM1 mEMAC2: 4E_2000h
    - FM1 mEMAC3: 4E_4000h
    - FM1 mEMAC4: 4E_6000h
    - FM1 mEMAC5: 4E_8000h
    - FM1 mEMAC6: 4E_A000h
    - FM2 mEMAC1: 5E_0000h
    - FM2 mEMAC2: 5E_2000h
    - FM2 mEMAC3: 5E_4000h
    - FM2 mEMAC4: 5E_6000h
    - FM2 mEMAC5: 5E_8000h
    - FM2 mEMAC6: 5E_A000h
  - mEMAC PortIDs (RX/TX):
    - mEMAC1: 08h/28h
    - mEMAC2: 09h/29h
    - mEMAC3: 0Ah/2Ah
    - mEMAC4: 0Bh/2Bh
    - mEMAC5: 0Ch/2Ch
    - mEMAC6: 0Dh/2Dh
- Two 10G multirate Ethernet MACs (mEMACs) per Frame Manager

    - See signals description and configuration chapter for valid interface combinations and corresponding signalling.
    - Block base addresses are as follows:
        - FM1 mEMAC9: 4F_0000h
        - FM1 mEMAC10: 4F_2000h
        - FM2 mEMAC9: 5F_0000h
        - FM2 mEMAC10: 5F_2000h
    - 10G mEMAC PortIDs (RX/TX):
        - mEMAC9: 10h/30h (10G port)
        - mEMAC10: 11h/31h (10G port)
    - HiGig PortIDs (RX/TX):
        - HiGig1: 10h/30h
        - HiGig1 message interface: 0Ch/2Ch
        - HiGig2: 11h/31h
        - HiGig2 message interface: 0Dh/2Dh
- FM2 Dedicated MDIO1: 5F_C000h
- FM2 Dedicated MDIO2: 5F_D000h
- FM1 1588 Timer: 4F_E000h (slave)
- FM2 1588 Timer: 5F_E000h (master connected to external 1588 pins)
- Six Offline/Host Command ports (PortIDs: 02h...07h)
- Two FMan Controller complexes
- 384-Kbyte internal FMan memory
- 64-Kbyte FMan Controller configuration data
- Up to 32 Keygen schemes
- Up to 256 Policer profiles
- Up to 84 entries in FMan DMA command queue
- Up to 128 TNUMs
- Up to 3 FMan debug flows

24.5.4 T4240 Security and Encryption Engine (SEC) Implementation

The Security and Encryption Engine of the T4240 is implemented as described in the *T4240 SEC Reference Manual* with the following implementation parameters:

- SEC block base address: 30_0000h

Chapter 25
Multicore Programmable Interrupt Controller (MPIC)

25.1 Preface

This chapter describes how the multicore programmable interrupt controller (MPIC) manages the various types of interrupt sources managed by or originating from within the MPIC. It describes how to configure the MPIC to manage arbitration of those interrupt sources to ensure that the highest-priority interrupts are handled as quickly as possible.

25.2 MPIC as implemented on chip

NOTE

In this chapter, the mapping of the referenced MPIC core *n* to the T4240 e6500 core threads is as follows:

Table 25-1. T4240 MPIC Core *n* Mapping

MPIC Core *n*	T4240 Core/Thread	MPIC Core *n*	T4240 Core/Thread	MPIC Core *n*	T4240 Core/Thread
0	e6500 core 0, thread 0	8	e6500 core 4, thread 0	16	e6500 core 8, thread 0
1	e6500 core 0, thread 1	9	e6500 core 4, thread 1	17	e6500 core 8, thread 1
2	e6500 core 1, thread 0	10	e6500 core 5, thread 0	18	e6500 core 9, thread 0
3	e6500 core 1, thread 1	11	e6500 core 5, thread 1	19	e6500 core 9, thread 1
4	e6500 core 2, thread 0	12	e6500 core 6, thread 0	20	e6500 core 10, thread 0
5	e6500 core 2, thread 1	13	e6500 core 6, thread 1	21	e6500 core 10, thread 1
6	e6500 core 3, thread 0	14	e6500 core 7, thread 0	22	e6500 core 11, thread 0
7	e6500 core 3, thread 1	15	e6500 core 7, thread 1	23	e6500 core 11, thread 1

NOTE

References to other MPIC cores should be disregarded.

25.3 Introduction

The MPIC conforms to the OpenPIC architecture, but with many enhancements. The interrupt controller provides multiprocessor interrupt management, and is responsible for receiving hardware-generated interrupts from different sources (both internal and external), prioritizing them in the context of interrupts that are generated from within the MPIC (such as messaging, timer, and interprocessor interrupts), and delivering them to the appropriate destination for servicing.

25.3.1 Features

The MPIC supports the following interrupt sources:

- External-Off-chip signals, IRQ[0:11]
- Internal-Up to 256 internal interrupt sources. On-chip sources from peripheral logic within the integrated device, signalling error conditions that need to be addressed by software. It is implementation specific which of these sources are used and how they are assigned; refer to the Interrupt Assignments chapter for specific assignments for this chip.
- Shared message signaled registers-Defined within the MPIC, used for cross-program communication, triggered on a register write, and cleared on a register read.
    - Four interprocessor interrupt channels.
    - Two groups of eight 32-bit message interrupt channels.
    - Four blocks of eight or sixteen shared message signaled interrupt sources with up to 32 sharers per shared interrupt register with interrupt coalescing intended to support up to four PCI Express host ports on a device.
    - Two groups of four global 32-bit timers clocked with the MPIC input clock or the RTC input. Timers within each group can be concatenated to time longer durations.
- Interrupts generated from within the MPIC itself, which are as follows:
    - Global timers A and B internal to the MPIC
    - Interprocessor interrupts (IPI)-Intended for communication between different processor cores on the same device. (Can be used for self-interrupt.)
    - Message registers-From within the MPIC. Triggered on register write, cleared on read. Used for interprocessor communication.

The MPIC has the following features:

- Three different modes of operation:
    - Supports the external proxy facility of the e6500 core

    - Legacy intn interrupt delivery to the processor core(s)
    - Pass-through mode (MPIC disabled) in which the MPIC directs interrupts off-chip for external servicing.
- Selected processor core(s) can be programmed to run in Legacy mode when MPIC is programmed to run in External proxy facility mode.
- The following types of programmable interrupt outputs:
    - The *int* outputs (*intn*). Any of the MPIC interrupt sources can be programmed to direct interrupt requests to *intn*. Handling of such interrupt requests follows the OpenPIC specification, which guarantees that the highest priority interrupts can supersede lower priority ones. Interrupts Routed to *int* describes how the MPIC logic handles these interrupts.
    - The *cint* outputs (*cintn*). These are intended to be connected to the critical interrupt pin on the processor core(s).
    - The *mcp* outputs (*mcpn*). These are intended to be connected to the machine check pin on the processor core(s).
    - Interrupt output signal, IRQ_OUT_B. Interrupts Routed to cint, mcp, sie, or IRQ_OUT_B describes how the MPIC logic supports these interrupts.
    - SoC Interrupt Event outputs (*sien*). These are used to signal events to the SoC.
- Programming model compatible with the OpenPIC architecture.
    - Message, interprocessor and global timer interrupts. (Note that the interprocessor and global timer interrupts can only be routed to *intn*.)
    - The following OpenPIC-defined features support only interrupts routed to the *int* signals:
        - Fully-nested interrupt delivery, guaranteeing that the interrupt source with the highest priority is given precedence over lower priority interrupts, including any that are in service.
        - 16 programmable interrupt priority levels
        - Support for identifying and handling spurious interrupts
- Support for up to 24 processors.
    - Interrupts can be routed to any processor core, depending on the configuration
    - Multicast delivery mode for interprocessor, global timer, and edge-triggered interrupts allowing these interrupts to be routed any or all of the cores
- Processor core initialization control
- Processor core reset control
- Processor non-maskable interrupt control
- Programmable resetting of the MPIC unit through the global configuration register
- Support for connection of external interrupt controller device such as an 8259 programmable interrupt controller. In 8259 mode, an interrupt causes assertion of a local (that is, internal to the integrated device) interrupt output signal, IRQ_OUT_B.

25.3.2 Block Diagram

Below is a block diagram showing the relationship of the various functional blocks and how the signals external to the MPIC are connected to other blocks on the device, including the cores.

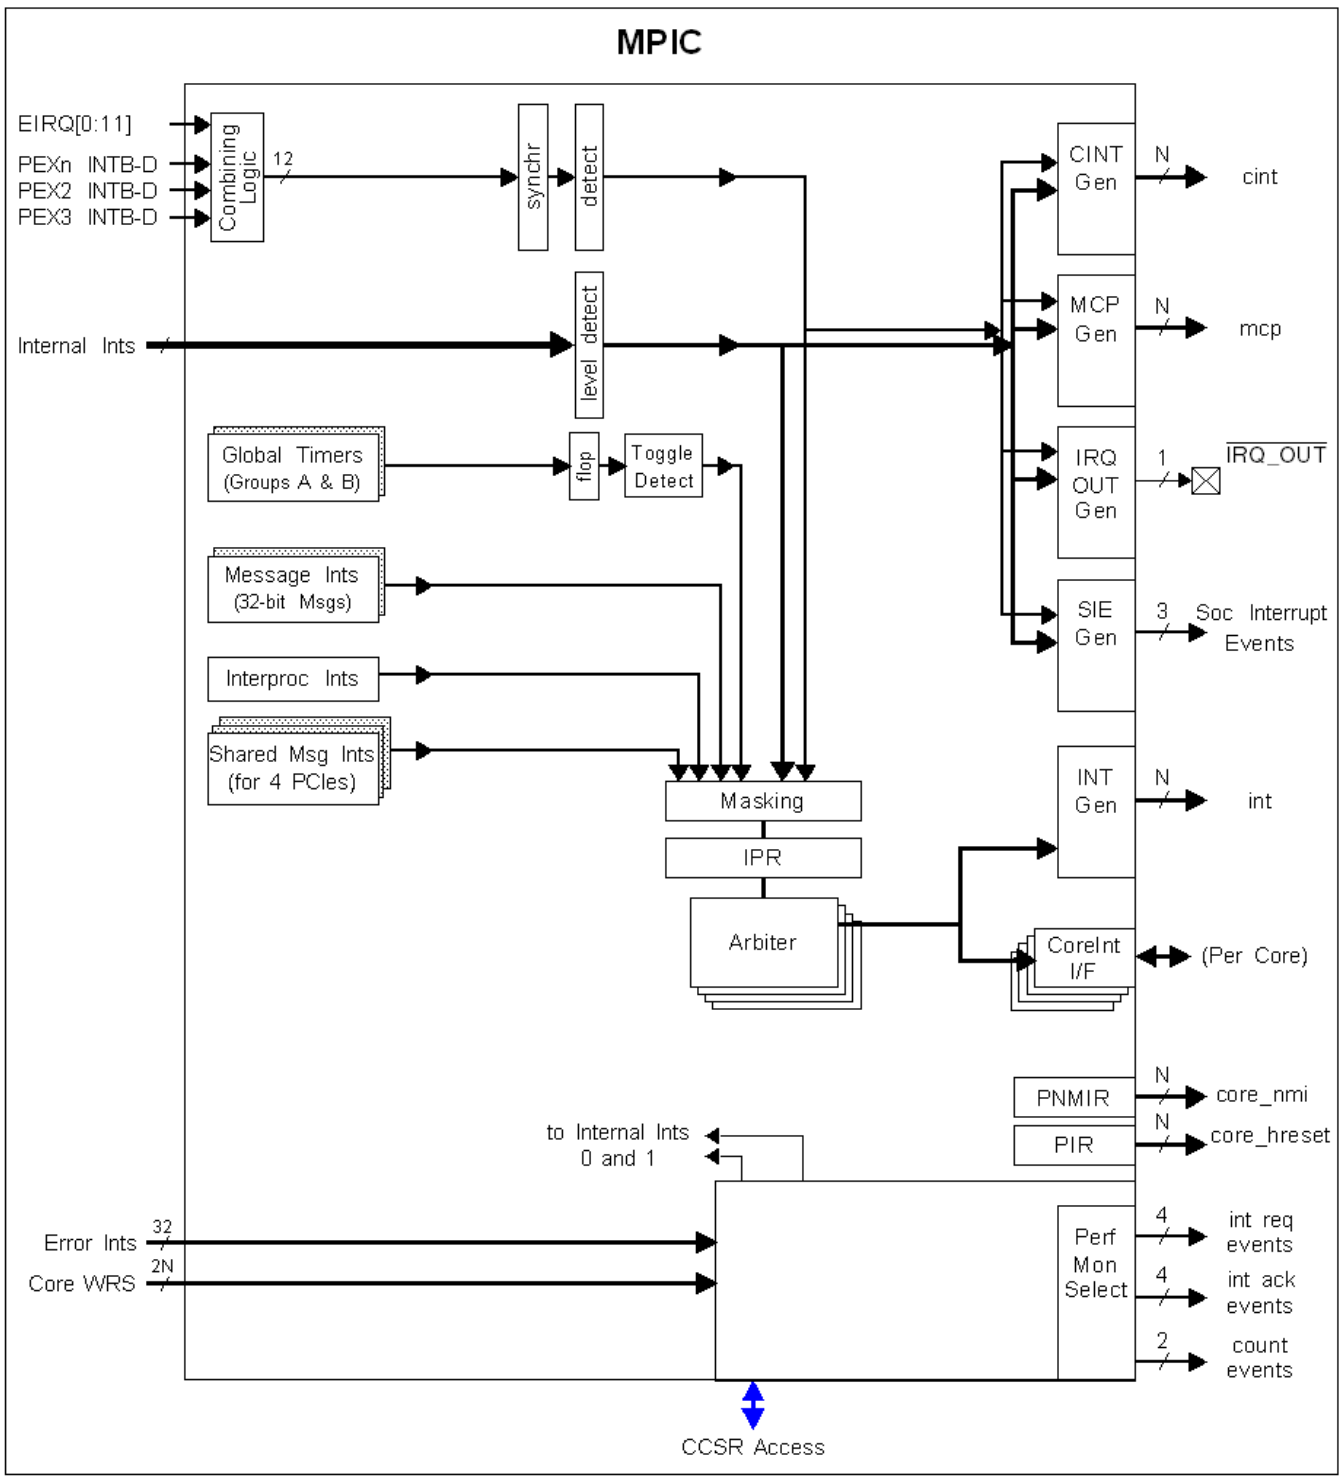

Figure 25-1. MPIC Block Diagram

25.3.3 The MPIC in Multiple- and Single-Core Implementations

In a multiprocessor system, it is possible for the MPIC to direct interrupts to the another processor. This functionality is supported by certain multiprocessor aspects to the programming model.

Note that while they are part of the programming model, such resources are reserved in a single-processor device.

25.3.4 Modes of Operation

The MPIC operates in one of the following modes:

- External Proxy Facility Mode
- Mixed Mode
- Pass-Through Mode

These are described below.

25.3.4.1 External Proxy Facility Mode (GCR[CI] = 1)

In external proxy facility mode, the vector is directly forwarded to the processor without the need for a software fetch. This feature is supported to all the interrupts. Detailed description of the external proxy facility is described in the *e6500 Core Reference Manual* .

NOTE

For processor core n to operate in external proxy facility mode, GCR1[PIn] must be 0.

For MPIC to operate in external proxy facility mode, GCR[M] must be 1. It is an invalid configuration to have MPIC in pass-through mode (GCR[M]=0) and in external proxy facility mode (GCR[CI]=1).

25.3.4.2 Mixed Mode (GCR[M] = 1)

In mixed mode, external and internal interrupts are delivered using the normal priority and delivery mechanisms detailed in Flow of Interrupt Control.

25.3.4.3 Pass-Through Mode (GCR[M] = 0)

The MPIC provides a mechanism to support alternate external interrupt controllers such as the PC/AT-compatible 8259 interrupt controller architecture. After a hard reset, the MPIC defaults to pass-through mode, in which active-high interrupts from external source IRQ0 are passed directly to core 0 as shown in Figure 25-2; all other external interrupt signals are ignored. Thus, the interrupt signal from an external interrupt controller can be connected to IRQ0 and cause direct interrupts to the processor core 0. The MPIC does not perform a vector fetch from an 8259 interrupt controller.

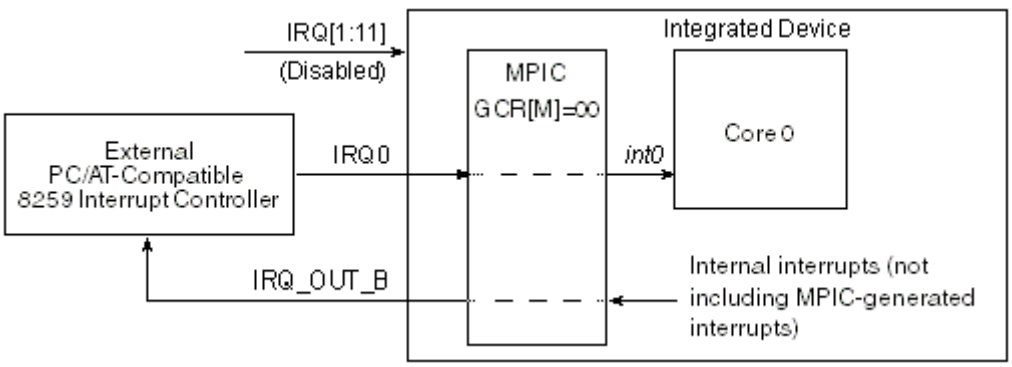

Figure 25-2. Pass-Through Mode Example

When pass-through mode is enabled, the internally-generated interrupts are not forwarded to core 0. Instead, the MPIC passes the raw interrupts from the internal sources to the interrupt output signal, IRQ_OUT_B.

NOTE

In pass-through mode, interrupts generated within the MPIC (global timers, interprocessor, and message register interrupts) are disabled. If internal or MPIC-generated interrupts must be reported internally to the processor, mixed mode must be used.

In pass-through mode, the target for each interrupt must be set to *int* (xILRn[INTTGT] = 0x00). This is the default setting of each register; therefore, no programming should be necessary to comply with this requirement.

25.3.5 Interrupts to the Processor Core

The *intn* signals, which signal an interrupt to the respective cores, are the main interrupt outputs from the MPIC unit to the processor cores. The global utilities block monitors the *intn* signals and wakes the corresponding core when one of these asserts and the core is in a low-power state (see Figure 25-1).

The interrupt sources can also specify the critical interrupt, mcp, or external interrupt outputs if the corresponding destination bits are set. For internal and external interrupts, the interrupt destination is decoded based on the Interrupt Level Registers (see External interrupt n (IRQn) level register (MPIC_EILR*n*) and Internal interrupt n level register (MPIC_IILR*n*)) and xIDRn[Pn]. These interrupt sources must be level sensitive.

The MPIC also defines the PIR, described in Processor initialization register (MPIC_PIR), which can be used to assert *hresetn* and trigger a hard reset. It also defines the PNMIR, described in Processor NMI register (MPIC_PNMIR), which can be used to assert *coren_nmi* and to trigger a non-maskable interrupt. Processor core interrupts generated by the MPIC are described in the following table.

Table 25-2. Processor Core Interrupts Generated by the MPIC-Types and Sources

Source	Internal, External, Message, Shared MSI, Global Timer, Interprocessor	Internal, External	Internal, External	Internal, External	PIR	PNMIR
MPIC output	*intn*	*cintn*	mcpn	IRQ_OUT_B, sien	*core0_hreset* through *core 23 _hreset*	*core0_nmi* through *core 23 _nmi*
Description	MPIC signals an interrupt in corresponding core.	Causes critical interrupt condition in correspondi ng core.	Causes machine check condition in correspondi ng core.	IRQ_OUT_B, sien assertion	One of the following: • External HRESETn assertion (and negation) • *hresetn* output from MPIC due to PIR update.	core0_nmi through core *23*_nmi outputs due to PNMIR update.

25.3.6 Interrupt Sources

The MPIC can receive separate interrupts from the following sources:

- External-Off-chip signals, IRQ[0:11]
- Internal-On-chip sources from peripheral logic within the integrated device. See the Interrupt Assignments chapter for a detailed list of all internal interrupt sources.

- Shared message signaled registers-Supports PCI Express Message Signalled Interrupts. Triggered on register write, cleared on read. Used for cross-program communication.
- Sources inside the MPIC:
  - Global timers A and B internal to the MPIC
  - Interprocessor interrupts (IPI)-Intended for communication between different processor cores on the same device. (Can be used for self-interrupt.)
  - Message registers-From within the MPIC. Triggered on register write, cleared on read. Used for interprocessor communication.
- Internal Error - internal errors from datapath etc. steered to processor interrupt, critical, or machine check of any core. It has a shared vector and destination (Internal Interrupt 0) supporting one bank for 32 error types.
- Watchdog timers-watchdog timer events that is steered to processor interrupt, critical, or machine check of any core. It has a shared vector and destination (Internal Interrupt 1).

25.3.6.1 Interrupt Destinations

When changed from Pass-Through mode to any of the other modes (external proxy or mixed mode), the MPIC directs all timer, shared message signaled, and interrupts from external and internal sources to the *int0* output (which is connected to the *int* signal of processor core 0). An interrupt can be routed to another core by explicitly setting the destination register for that source.

The interprocessor, global timers, and edge-triggered external interrupts can be programmed to be routed to one or more core's *int* signal. When more than one core is routed in destination, it is refered to as multi-casting. Level-sensitive external interrupts are not permitted for multi-casting.

Internal and external interrupts have more destination options, but only one destination can be chosen for a single non-multicasting interrupt. Instead of being routed to the *int* input of one of the processor cores, these interrupts can be alternatively routed to IRQ_OUT_B, *sie*, *mcp*, or *cint* with respect to the MPIC and routed to any core. These options are selected by writing to the *x*ILR*n*[INTTGT] field in the appropriate interrupt level register and xIDR*n*[Pn] in the appropriate destination register.

Message and Shared MSI interrupts can only be routed to one of *intn* by writing to xIDR*n*[Pn] fields in the appropriate destination register.

The table below summarizes the valid interrupt destinations for the various interrupt sources handled by the MPIC. It also indicates whether multicasting (MC) is supported or if only single destination (SD) is allowed for the interrupt. Single destination is used in the IRQ_OUT_B interrupt output column because there is only one IRQ_OUT_B signal-multicasting would not make sense for this selection.

Table 25-3. Destinations for MPIC Interrupt, NMI, and Reset Sources

Category	Interrupt Source	MPIC Interrupt Outputs[1] (Only one output type per source)					NMI & Core Reset		Debug[2]	Comments
		intn	*cintn*	*mcpn*	IRQ_OUT_B	*sien*	*coren_nmi*	*coren_hreset*	Perf - Mon	
Standard Interrupt Sources										
External Sources	EIRQ[0:m]		MC[1]	MC[3,]	SD[1]	SD[1]	-		SD	-
SoC Internal Sources[,4]	IRQ[0:n]	SD	MC	MC	SD	SD			SD	-
Shared Message Signalled Interrupts	Initiated by Inbound PCIe write transactions	SD	-	-	-	-			SD	This set has no level registers.
MPIC Sources	Global Timers	MC	-	-	-	-			SD	This set has no level registers.
	Interprocessor Interrupts (IPI)	MC	-	-	-	-			SD	This set has no level registers.
	Message Interrupts	SD	-	-	-	-			SD	This set has no level registers.
	Shared Message Signalled Interrupts	SD	-	-	-	-			SD	This set has no level registers.
Register-Driven NMI and Core Resets										
MPIC Register Driven	PNMIR	-					MC	-	-	-
	PIR						-	MC		-

1. Interrupt outputs are mutually exclusive and selected as follows:
   - *intn*: *x*ILR[INTTGT] = 0x00
   - *cintn*: *x*ILR[INTTGT] = 0x01
   - *mcpn*: *x*ILR[INTTGT] = 0x02
   - *sien*: *x*ILR[INTTGT] = 0xF0 through 0xF2
   - IRQ_OUT_B: *x*ILR[INTTGT] = 0xFF
2. Perfmon events can operate in parallel with selected MPIC interrupt outputs.
3. EIRQ source must be programmed as level-sensitive in EIVPRn[S] when used for this interrupt output. Note that all other sources are inherently level-sensitive.
4. Includes the following: ORed SoC error interrupt as IRQ[0] and ORed WDT interrupt as IRQ[1].

For each interrupt source, only one MPIC interrupt output type can be used as programmed in its corresponding *x*ILR*n*[INTTGT]. For example, it is not possible to generate both an *intn* and IRQ_OUT_B in response to EIRQ[3] but it is possible to

generate a *cint0* and *cint3* to cores 0 and 3 in response to EIRQ[3] since these share the same MPIC interrupt output type. Performance monitor events can be programmed to operate in parallel with a selected MPIC interrupt output.

25.3.6.2 Interrupt Routing-Mixed Mode

When an interrupt request is delivered to the MPIC, the corresponding interrupt destination register is checked to determine where the request should be routed, as follows:

- If Interrupt Level Register *x*ILRn[INTTGT] = 0xFF, the interrupt is routed off-chip to the interrupt output signal, IRQ_OUT_B.
- If Interrupt Level Register *x*ILRn[INTTGT] = 0xF0 to 0xF2, the interrupt is routed to the corresponding SoC interrupt event output signals, *sien*. See the Interrupt Assignments chapter for *sien* routing assignments.
- If Interrupt Level Register *x*ILRn[INTTGT] = 0x01, and one, but not multiple, *x*IDRn[Pn] is set, the interrupt is routed to the appropriate *cintn*.
- If Interrupt Level Register *x*ILRn[INTTGT] = 0x02, and one, but not multiple, *x*IDRn[Pn] is set, the interrupt is routed to the appropriate *mcpn*.
- If Interrupt Level Register *x*ILRn[INTTGT] = 0x00, and one, but not multiple, *x*IDRn[Pn] is set, the interrupt is routed to the appropriate *intnsignal*. In this case, the interrupt is latched by the interrupt pending register (IPR) and the interrupt flow is as described in Flow of Interrupt Control." Note that multicasting interrupts (global timer, interprocessor, and edge-triggered external interrupts) can set to any or all of P0 through P ; other interrupt sources cannot.

25.4 External Signal Descriptions

The following sections describe the MPIC signals.

25.4.1 Device External Pin Descriptions

The MPIC device external interface signals are described in the table below. There are 12 distinct external interrupt request input signals and 1 interrupt request output pin IRQ_OUT_B.

Implementation Note
The interrupt request signal is active low, open drain

This table provides detailed descriptions of the external MPIC signals.

Table 25-4. External Interrupt Signals-Detailed Signal Descriptions

Signal	I/O	Description	
IRQ[0:11]	I	External Interrupt request 0-11. The polarity and sense of each of these signals are programmable. All of these inputs can be driven asynchronously. **NOTE:** Refer to the Interrupt Assignments chapter for information on how external interrupt request signals and PCI virtual INTx signals are shared.	
		State Meaning	Asserted-When an external interrupt signal is asserted (according to the programmed polarity), the MPIC checks its priority and the interrupt is conditionally passed to the processor designated in the corresponding destination register. In pass-through mode, only interrupts detected on IRQ0 are passed directly to core 0. Negated-There is no incoming interrupt from that source.
		Timing	Assertion-All of these inputs can be asserted asynchronously. Negation-Interrupts programmed as level-sensitive must remain asserted until serviced. Timing requirements for edge-sensitive interrupts can be found in the datasheet.
IRQ_OUT	O	Interrupt request out. Active-high out of the IP block. When the MPIC is programmed in pass-through mode, this output reflects the raw interrupts generated by on-chip sources. See Modes of Operation.	
		State Meaning	Asserted-At least one interrupt is currently being signalled to the external system. Negated-Indicates no interrupt source currently routed to IRQ_OUT_B.
		Timing	Because external interrupts are asynchronous with respect to the system clock, both assertion and negation of IRQ_OUT_B occurs asynchronously with respect to the interrupt source. All timing given here is approximate. Assertion-Internal interrupt source: 2 clock cycles after interrupt occurs. External interrupt source: 4 cycles after interrupt occurs. Negation-Follows interrupt source negation with the following delay: Internal interrupt: 2 clock cycles External interrupt: 4 cycles.

25.5 MPIC Memory Map/Register Definition

The MPIC programmable register map occupies 256 Kbytes of memory-mapped space. Reading undefined portions of the memory map returns all zeros; writing has no effect. All MPIC registers are 32 bits wide and, although (mostly) located on 128-bit address boundaries, should be accessed only as 32-bit quantities.

The MPIC address offset map is divided into the following areas:

- 0xnn4_0020-0xnn4_0FFF-Global registers and Per-CPU private-access registers
- 0xnn5_0000-0xnn5_FFF0-Interrupt source configuration registers
- 0xnn6_0000-0xnn7_FFF0-Per-CPU global-access registers

The difference between Per-CPU private-access and global access registers is discussed in Global- and private-access per-CPU registers.

25.5.3 Interprocessor interrupt dispatch register n (MPIC_IPIDR*n*)

This section describes the four IPIDRs, one for each interprocessor interrupt channel. Writing to an IPIDR with a bit set causes a self interrupt for a single-core device. Because external bus masters can access the these registers by using the per-CPU global access offsets, this feature can serve as a doorbell-type interrupt.

Address: 4_0000h base + 40h offset + (16d × i), where i=0d to 3d

MPIC_IPIDR*n* field descriptions (continued)

Field	Description
	0 Processor core 1 does not receive the interrupt 1 Directs the interrupt to processor core 1
31 P0	Processor core 0. Determines if processor core 0 receives the interrupt. 0 Processor core 0 does not receive the interrupt. 1 Directs the interrupt to processor core 0.

25.5.4 Current task priority register (MPIC_CTPR)

There is one current task priority register per processor core on this chip. See Global- and private-access per-CPU registers, for more information.

NOTE

CTPR has meaning only for interrupts routed to *int*.

Software must write the priority of the current processor core task in the CTPR for each core. The MPIC uses this value for comparison with the priority of incoming interrupts. Given several concurrent incoming interrupts, the highest priority interrupt is asserted to that core if the following apply:

- The interrupt is not masked.
- The priority of the interrupt is higher than the values in the corresponding CTPR[TASKP] and ISR.

Address: 4_0000h base + 80h offset = 4_0080h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Reserved																												TASKP			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1

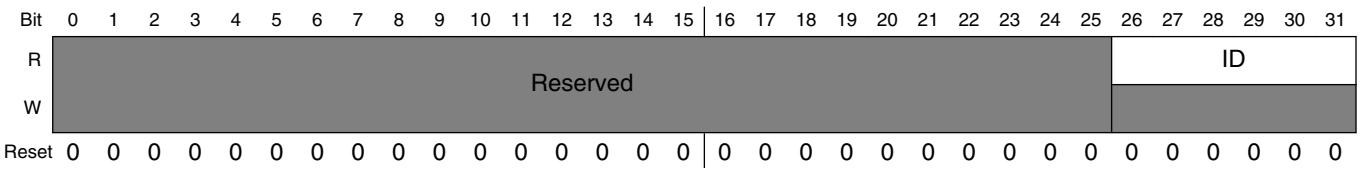
MPIC_CTPR field descriptions

Field	Description
0–27 -	This field is reserved. Reserved
28–31 TASKP	Task priority. Indicates the threshold that individual interrupt priorities must exceed for the interrupt request to be serviced. Task priority is meaningless (that is, a don't care) if the processor ID in WHOAMI[ID] is illegal. 0000-1111 xVPRn[PRIORITY] must exceed this value for the interrupt request to be serviced. Note the following special cases: 0000 Lowest priority. All interrupts except those whose priority are 0 can be serviced. 1111 Highest priority. No interrupts are signaled to that processor core. Hardware selects this value on a device hard reset or when the corresponding PIR[Pn] is set.

25.5.5 Who am I register (MPIC_WHOAMI)

The processor core WHOAMI*n* register can be read by a processor core to determine its physical connection to the MPIC. The value returned when reading this register may be used to determine the value for the destination masks used for dispatching interrupts.

Address: 4_0000h base + 90h offset = 4_0090h



MPIC_WHOAMI field descriptions

Field	Description
0–25 -	This field is reserved. Reserved
26–31 ID	Returns the ID of the processor core reading this register. **NOTE:** ID = 111111 indicates an illegal processor ID) 000000 Processor core 0 000001 Processor core 1 000010 Processor core 2 000011 Processor core 3 000100 Processor core 4 000101 Processor core 5 000110 Processor core 6 000111 Processor core 7 001000 Processor core 8 001001 Processor core 9 001010 Processor core 10 001011 Processor core 11 001100 Processor core 12 001101 Processor core 13 001110 Processor core 14 001111 Processor core 15 010000 Processor core 16 010001 Processor core 17 010010 Processor core 18 010011 Processor core 19 010100 Processor core 20 010101 Processor core 21 010110 Processor core 22 010111 Processor core 23

25.5.6 Interrupt acknowledge register (MPIC_IACK)

NOTE

IACK has meaning only for interrupts routed to *int* in mixed mode (GCR[M] = 01)and should not be accessed for interrupts routed to *cint*, *mcp*, *sie*, or IRQ_OUT_B.

NOTE

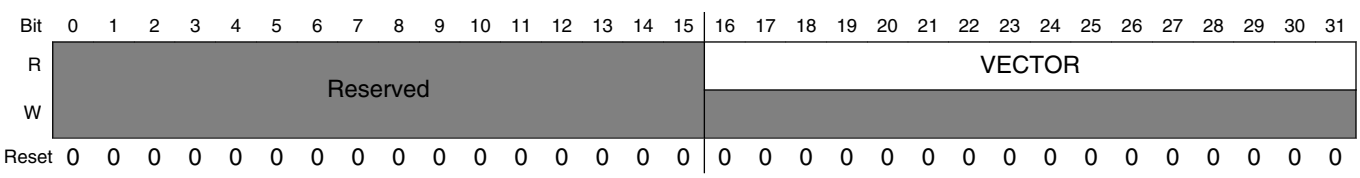
The external proxy facility mode (GCR[M] = 11), eliminates the need for the core to read the IACK register as the vector is automatically passed to the core's external proxy register (EPR) or guest external proxy register (GEPR).

In systems based on processors that implement the Power architecture, the interrupt acknowledge function occurs as an explicit read operation to a memory-mapped interrupt acknowledge register (IACK). Each processor core has an IACK register assigned to it. Reading IACK returns the interrupt vector corresponding to the highest priority pending interrupt. Reading IACK also has the following side effects:

- The associated field in the corresponding interrupt pending register (IPR) is cleared for edge-sensitive interrupts.
- The corresponding in-service register (ISR) is updated.
- The corresponding *int* output signal from the MPIC is negated.

Reading IACK when no interrupt is pending returns the spurious vector value, as described in Spurious vector register (MPIC_SVR)."

Address: 4_0000h base + A0h offset = 4_00A0h



MPIC_IACK field descriptions

Field	Description
0–15 -	This field is reserved. Reserved
16–31 VECTOR	Interrupt vector. Vector of the highest pending interrupt (read only). This field is meaningless (that is, a don't care) if the processor ID in WHOAMI[ID] is illegal.

25.5.7 End of interrupt register (MPIC_EOI)

NOTE

EOI has meaning only for interrupts routed to *int* and should not be accessed for interrupts routed to *cint*, *mcp*, *sie*, or IRQ_OUT_B.

Each core is assigned an EOI register. Writing to EOI signals the end of processing for the highest-priority interrupt (routed to *int*) currently in service. It also updates the corresponding ISR*n* by retiring the highest priority interrupt. Data values written to EOI are ignored, and zero is assumed.

Address: 4_0000h base + B0h offset = 4_00B0h

Bit	0–27	28–31
R	Reserved	
W		EOI_CODE
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0 0 0 0

MPIC_EOI field descriptions

Field	Description
0–27 -	This field is reserved. Reserved
28–31 EOI_CODE	EOI Code 0000 (write only)

25.5.8 Feature reporting register (MPIC_FRR)

FRR provides information about interrupt and processor core configurations. It also informs the programming environment of the controller version.

Address: 4_0000h base + 1000h offset = 4_1000h

Bit	0–4	5–15	16–18	19–23	24–31
R	Reserved	NIRQ	Reserved	NCPU	VID
W					
Reset	0 0 0 0 0	0 0 0 0 0 0 0 0 0 0 0	0 0 0	0 0 0 0 0	0 0 0 0 0 0 0 0

MPIC_FRR field descriptions

Field	Description
0–4 -	This field is reserved. Reserved

5–15
NIRQ
	Number of interrupts. Holds the binary value of the number of the highest interrupt source supported minus one.
	Equation: #internal + #external + MSGA + MSGB + MSIA + MSIB + MSIC + MSID + #(IPI * cores) + #timers
	256(internal) + 12(external) + 16(MSGA&B) + 64(MSIA&B&C&D) + 96(IPI4*24cores) + 8(timersA&B) = 0x1C3 (total-1)

16–18 -	This field is reserved. Reserved
19–23 NCPU	Number of CPUs. The number of virtual CPUs (or threads) supported minus one. **NOTE:** The OpenPIC standard specifies "physical" cores, but this chip uses "virtual CPUs" for NCPU. Example settings: 00000 Single core: core0 00001 Two cores: core0 and core1 00111 Eight cores: core0 - core7 10101 22 cores: core0 - core21
24–31 VID	Version ID. Reports the OpenPIC specification revision level supported by this interrupt controller implementation. The VID field's value of two (0x02) corresponds to revision 1.2 which is the revision level currently supported.

25.5.9 Global configuration register (MPIC_GCR)

GCR controls the MPIC's operating mode, and allows software to reset the MPIC.

Address: 4_0000h base + 1020h offset = 4_1020h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	RST	CI	M	Reserved												
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MPIC_GCR field descriptions

Field	Description
0 RST	Reset. Setting RST forces the MPIC to be reset. Cleared automatically when the reset sequence is complete. See Resetting the MPIC, for more information.

Table continues on the next page...

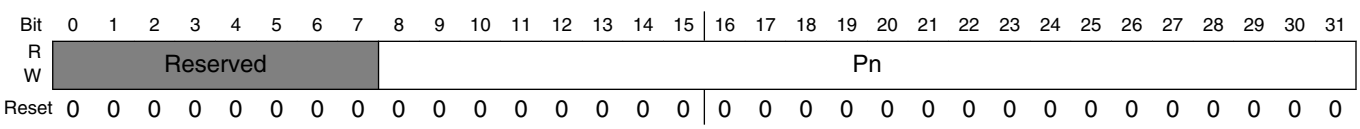
MPIC_GCR field descriptions (continued)

Field	Description
	NOTE: RST bit should not be used in CL=1 proxy mode.
1 CI	External proxy facility. Controls the method of core interrupt delivery 0 Legacy mode. Interrupts are delivered to the cores using the legacy OpenPIC model. 1 External proxy facilitymode. Interrupts are delivered to the cores using the external proxy facility model. Note: When Global configuration, GCR[M] = 0 (when the MPIC is in Pass-through mode), this field is a don't care.
2 M	Mode. MPIC operating mode. Modes of Operation, provides details about these modes. 0 Pass-through mode. On-chip MPIC is disabled and interrupts detected on IRQ0 are passed directly to core 0. 1 Mixed mode. Interrupts are handled by the normal priority and delivery mechanisms of the MPIC.
3–31 -	This field is reserved. Reserved

25.5.10 Global configuration register 1 (MPIC_GCR1)

GCR1 controls the MPIC's operating mode, and allows software to reset the MPIC.

Address: 4_0000h base + 1024h offset = 4_1024h



MPIC_GCR1 field descriptions

Field	Description
0–7 -	This field is reserved. Reserved
8–31 Pn	Selectable External Proxy facility vs legacy INT mode per n (CPU) 0 processor coren operates per GCR[CI] 1 processor coren operates in legacy INT mode

25.5.11 Vendor identification register (MPIC_VIR)

VIR is defined by the OpenPIC specifications and is provided for compliance. The zero value for VIR[VENDORID] indicates a generic OpenPIC-compliant device, which makes the other VIR fields meaningless.

Address: 4_0000h base + 1080h offset = 4_1080h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MPIC_VIR field descriptions

Field	Description
0–7 -	This field is reserved. Reserved
8–15 STEP	Stepping. Indicates the silicon revision for this device. Has no meaning if VENDOR ID value is zero.
16–23 DEVICE_ID	Device identification. Vendor-specified identifier for this device. Has no meaning if VENDOR ID is zero.
24–31 VENDOR_ID	Vendor identification. Specifies the manufacturer of this part. A value of zero implies a generic OpenPIC-compliant device.

25.5.12 Processor initialization register (MPIC_PIR)

PIR provides a way for software to initiate a reset to the processor cores. Setting Pn causes the respective signal to assert. These signals are routed to the appropriate *coren_hreset* signals and cause the corresponding core to redirect program flow to the reset interrupt vector.

For proper system operation, a core should be reset in this way only if the core is already in nap or sleep state. Because a core in either state cannot perform the necessary write to cause a hard reset, a core cannot put itself into hard reset.

Please refer MPIC as implemented on chip for details on core/thread mapping.

NOTE

The reset of a physical core with multiple threads will result in the reset of all threads on the physical core. There is no per thread reset.

Address: 4_0000h base + 1090h offset = 4_1090h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

30 P1	Processor core 1 reset. Setting this bit causes the MPIC to assert the pic_core_hard_reset signal to core 1.
31 P0	Processor core 0 reset. Setting this bit causes the MPIC to assert the pic_core_hard_reset signal to core 0.

25.5.13 Processor NMI register (MPIC_PNMIR)

The PNMIR provides a way for software on another device to signal a non-maskable interrupt event to the processor cores by writing to a MPIC register. A *coren_nmi* signal to the cores is asserted when a one is written to the corresponding PNMIR field; these signals are held active until a zero is written to those same bits. This deasserts the *core_nmi* input of the corresponding core.

The fields corresponding to processors on a device are shown in the figure.

Address: 4_0000h base + 1098h offset = 4_1098h

23 P8	Processor core 8 NMI. Setting P8 causes the MPIC to assert the *pic_core_nmi* signal to core 8.
24 P7	Processor core 7 NMI. Setting P7 causes the MPIC to assert the *pic_core_nmi* signal to core 7.
25 P6	Processor core 6 NMI. Setting P6 causes the MPIC to assert the *pic_core_nmi* signal to core 6.
26 P5	Processor core 5 NMI. Setting P5 causes the MPIC to assert the *pic_core_nmi* signal to core 5.
27 P4	Processor core 4 NMI. Setting P4 causes the MPIC to assert the *pic_core_nmi* signal to core 4.
28 P3	Processor core 3 NMI. Setting P3 causes the MPIC to assert the *pic_core_nmi* signal to core 3.
29 P2	Processor core 2 NMI. Setting P2 causes the MPIC to assert the *pic_core_nmi* signal to core 2.
30 P1	Processor core 1 NMI. Setting P1 causes the MPIC to assert the *pic_core_nmi* signal to core 1.
31 P0	Processor core 0 NMI. Setting P0 causes the MPIC to assert the *pic_core_nmi signal* to core 0.

25.5.14 IPI vector/priority register n (MPIC_IPIVPR*n*)

IPIVPRs contain the interrupt vector and priority fields for the four interprocessor interrupt channels. There is one vector/priority register per channel. The VECTOR and PRIORITY values should not be changed while IPIVPR*n*[A] is set.

Address: 4_0000h base + 10A0h offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

MPIC_IPIVPR*n* field descriptions

Field	Description
0 MSK	Mask. Mask interrupts from this source. MSK affects interrupts routed to int, *cint*, *mcp*, *sie*[0:2], and IRQ_OUT_B. 0 An interrupt request is generated if the corresponding IPR bit is set. 1 Further interrupts from this source are disabled.
1 A	Activity. Indicates an interrupt has been requested or is in service. The VECTOR and PRIORITY values should not be changed while this bit is set. Affects only interrupts routed to int. 0 No current interrupt activity associated with this source. 1 The interrupt field for this source is set in the IPR or ISR.
2–11 -	This field is reserved. Reserved
12–15 PRIORITY	Priority. Specifies the interrupt priority. The lowest priority is 0 and the highest priority is 15. A priority level of 0 inhibits signalling of this interrupt to the core. Affects only interrupts routed to int.
16–31 VECTOR	Vector (Affects only interrupts routed to int). Contains the value returned when IACK is read and this interrupt resides in the corresponding interrupt request register (IRR) for that core, as shown in Figure 25-3.

25.5.15 Spurious vector register (MPIC_SVR)

SVR contains the 16-bit vector returned to the processor core when the corresponding IACK register is read for a spurious interrupt.

Address: 4_0000h base + 10E0h offset = 4_10E0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

MPIC_TFRR*n* field descriptions

Field	Description
0–31 FREQ	Timer frequency (in ticks/second (Hz)). Used to communicate the frequency of the global timers' clock source,-either the MPIC input clock or the frequency of the RTC signal-to user software. TFRRx is set only by software for later use by other applications and its value in no way affects the operating frequency of the global timers. The timers operate at a ratio of this clock frequency, as set by TCRx[CLKR]. See Timer control register [Group n] (MPIC_TCR*n*)."

25.5.17 Global timer current count register [Group A] n (MPIC_GTCCRA*n*)

The GTCCRs contain the current count for each of the four MPIC timers in each of the two groups.

Address: 4_0000h base + 1100h offset + (64d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

R	COUNT															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MPIC_GTCCRA*n* field descriptions

Field	Description
0 TOG	Toggle. Toggles when the current count decrements to zero. Cleared when GTBCR*xn*[CI] goes from 1 to 0. **NOTE:** For cascade, there is only single CI bit as control, which is the most significant count CI bit.
1–31 COUNT	Current count. Decremented while GTBCR*xn*[CI] is zero. When the timer count reaches zero, an interrupt is generated (provided it is not masked), the toggle bit is inverted, and the count is reloaded. For non-cascaded timers, the reload value is the contents of the corresponding GTBCR*xn*. Cascaded timers are reloaded with either all ones, or the GTBCR*xn* contents, depending on the value of TCRn[ROVR]. See Timer control register [Group n] (MPIC_TCR*n*)," for more details.

25.5.18 Global timer base count register [Group A] n (MPIC_GTBCRA*n*)

The GTBCRs contain the base counts for each of the four MPIC timers in each of the two groups. This value is reloaded into the corresponding GTCCR*xn* when the current count reaches zero. Note that when zero is written to the base count field, (and GTCCR*xn*[CI] = 0), the timer generates an interrupt on every timer cycle.

Address: 4_0000h base + 1110h offset + (64d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	CI	BASE_CNT														
Reset	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	BASE_CNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MPIC_GTBCRA*n* field descriptions

Field	Description
0 CI	Count inhibit. Always set following reset. **NOTE:** For cascade, there is only single CI bit as control, which is the most significant count CI bit. 0 Counting enabled 1 Counting inhibited
1–31 BASE_CNT	Base count. When CI transitions from 1 to 0, this value is copied into the corresponding GTCCR*xn* and the toggle bit is cleared. If CI is already cleared (counting is in progress), the base count is copied to the GTCCR*xn* at the next zero crossing of the current count.

25.5.19 Global timer vector/priority register [Group A] n (MPIC_GTVPRA*n*)

The GTVPRs contain the interrupt vector and the interrupt priority values for the timers. They also contain the mask and activity fields for all the timers.

Address: 4_0000h base + 1120h offset + (64d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

25.5.21 Timer control register [Group n] (MPIC_TCR*n*)

The TCR registers provide various configuration options such as count frequency and roll-over behavior for the timers.

There are two choices for the clock source for the timers: a selectable frequency ratio from the MPIC input clock, or the RTC signal. TCRs can be cascaded to create timers larger than the default 31-bit global timers. Timer cascade fields allow configuration of up to two 63-bit timers, one 95-bit timer, or one 127-bit timer (within each group).

With one exception mentioned below, the value reloaded into a timer is determined by its roll-over control field, TCRx[ROVR]. Setting TCRx[ROVR] causes its GTCCR*xn* to roll over to all ones when the count reaches zero. This is equivalent to reloading the count register with 0xFFFF_FFFF instead of its base count value. Clearing a timer's associated ROVR bit ensures the timer always reloads with its base count value.

When timers are cascaded, the last (most significant) counter in the cascade also affects their roll-over behavior. Cascaded timers always reload their base count when the most significant counter has decremented to zero, regardless of the TCRx[ROVR] settings.

Address: 4_0000h base + 1300h offset + (4096d × i), where i=0d to 1d

MPIC_TCR*n* field descriptions

Field	Description
0–4 -	This field is reserved. Reserved
5–7 ROVR	Roll-over control for cascaded timers only. Specifies behavior when count reaches zero by identifying the source of the reload value. Cascaded timers are always reloaded with their base count value when the more significant timer in the cascade (the upstream timer) is zero. Bits 5-7 correspond to timers 2-0. Note that global timer 3 always reloads with its GTBCR*xn*. 0 The timer does not roll over. When the count reaches zero, GTCCR*xn* is reloaded with the GTBCR*xn* value. 1 Timer rolls over at zero to all ones. (When the count reaches zero, GTCCR*xn* is reloaded with 0xFFFF_FFFF.) 000 All timers reload with base count. 001 Timers 1 and 2 reload with base count, timer 0 rolls over (reloads with 0xFFFF_FFFF). 010 Timers 0 and 2 reload with base count, timer 1 rolls over (reloads with 0xFFFF_FFFF). 011 Timer 2 reloads with base count, timers 0 and 1 roll over (reload with 0xFFFF_FFFF). 100 Timers 0 and 1 reload with base count, timer 2 rolls over (reloads with 0xFFFF_FFFF). 101 Timer 1 reloads with base count, timers 0 and 2 roll over (reload with 0xFFFF_FFFF). 110 Timer 0 reloads with base count, timers 1 and 2 roll over (reload with 0xFFFF_FFFF). 111 Timers 0, 1, and 2 roll over (reload with 0xFFFF_FFFF).
8–14 -	This field is reserved. Reserved
15 RTM	Real time mode. Specifies the clock source for the MPIC timers. 0 Timer clock frequency is a ratio of the frequency of the MPIC input clock as determined by the CLKR field. This is the default value. 1 The RTC signal is used to clock the MPIC timers. If this bit is set, the CLKR field has no meaning.
16–21 -	This field is reserved. Reserved
22–23 CLKR	Clock ratio. Specifies the ratio of the timer frequency to the MPIC input clock. The following clock ratios are supported: 00 Default. Divide by 8 01 Divide by 16 10 Divide by 32 11 Divide by 64
24–28 -	This field is reserved. Reserved
29–31 CASC	Cascade timers. Specifies the output of particular global timers as input to others.

16–31 Sn	Status n. 0 MSIRn is not active. 1 MSIRn has an active interrupt.

25.5.27 Shared message signaled interrupt index register [Bank A] (MPIC_MSIIR*n*)

MSIIR provides the mechanism for setting an interrupt in the MSIRas. When MSIIRa is written, MSIIRa[SRS] selects the register in which an interrupt bit is to be set MSIIRa[IBS] selects the shared interrupt field in the selected MSIRa register. MSIIRa is primarily intended to support PCI Express MSIs.

NOTE

MSIIRA, MSIIRB, MSIIRC, and MSIIRD are aliased to offsets 0x4_4140, 0x4_5140, 0x4_6140, and 0x4_7140 respectively.

Address: 4_0000h base + 1740h offset + (512d × i), where i=0d to 3d

MPIC_GTCCRB*n* field descriptions

Field	Description
0 TOG	Toggle. Toggles when the current count decrements to zero. Cleared when GTBCR*xn*[CI] goes from 1 to 0.
1–31 COUNT	Current count. Decremented while GTBCR*xn*[CI] is zero. When the timer count reaches zero, an interrupt is generated (provided it is not masked), the toggle bit is inverted, and the count is reloaded. For non-cascaded timers, the reload value is the contents of the corresponding GTBCR*xn*. Cascaded timers are reloaded with either all ones, or the GTBCR*xn* contents, depending on the value of TCRn[ROVR]. See Timer control register [Group n] (MPIC_TCR*n*)," for more details.

25.5.32 Global timer base count register [Group B] n (MPIC_GTBCRB*n*)

The GTBCRs contain the base counts for each of the four MPIC timers in each of the two groups. This value is reloaded into the corresponding GTCCR*xn* when the current count reaches zero. Note that when zero is written to the base count field, (and GTCCR*xn*[CI] = 0), the timer generates an interrupt on every timer cycle.

Address: 4_0000h base + 2110h offset + (64d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

MPIC_GTVPRB*n* field descriptions

Field	Description
0 MSK	Mask. Mask interrupts from this source. MSK affects interrupts routed to int, *cint*, *mcp*, *sie*[0:2], and IRQ_OUT_B. 0 An interrupt request is generated if the corresponding IPR bit is set. 1 Further interrupts from this source are disabled.
1 A	Activity. Indicates an interrupt has been requested or is in service. The VECTOR and PRIORITY values should not be changed while this bit is set. Affects only interrupts routed to int. 0 No current interrupt activity associated with this source. 1 The interrupt field for this source is set in the IPR or ISR.
2–11 -	This field is reserved. Reserved
12–15 PRIORITY	Priority. Specifies the interrupt priority. The lowest priority is 0 and the highest priority is 15. A priority level of 0 inhibits signalling of this interrupt to the core. Affects only interrupts routed to int.
16–31 VECTOR	Vector (Affects only interrupts routed to int). Contains the value returned when IACK is read and this interrupt resides in the corresponding interrupt request register (IRR) for that core, as shown in Figure 25-3.

25.5.34 Global timer destination register [Group B] n (MPIC_GTDRB*n*)

The GTDR*xn* registers control the destination core to which each timer's interrupt is directed. Note that GTDR*xn* bits can be set independently of each other and any or all can be set for this type of interrupt.

Address: 4_0000h base + 2130h offset + (64d × i), where i=0d to 3d

MPIC_PM*n*MR11 field descriptions

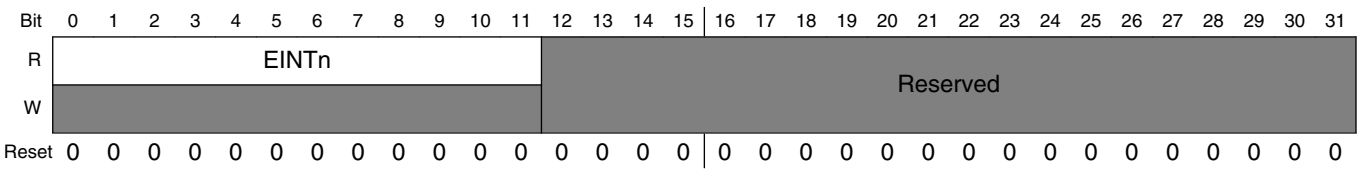
Field	Description
0–31 INT	Internal interrupts 224-255 0 The corresponding interrupt source generates a performance monitor event when the interrupt occurs. 1 The corresponding interrupt does not generate a performance monitor event.

25.5.48 External interrupt summary register (MPIC_ERQSR)

NOTE

The fields in ERQSR report only the current state of IRQ0-11. These fields were designed to work with level-sensitive interrupts; the values returned for edge-sensitive interrupts may be unreliable.

Address: 4_0000h base + 3800h offset = 4_3800h



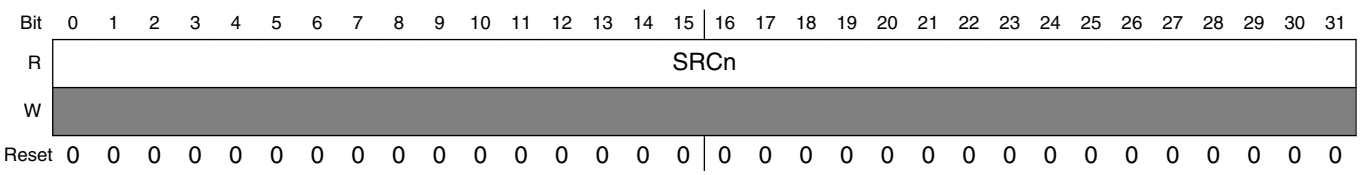
MPIC_ERQSR field descriptions

Field	Description
0–11 EINTn	External interrupts signal 0-11 status. Bit 0 represents external interrupt 0. 0 The corresponding external interrupt signal is not active. 1 The corresponding external interrupt signal is active.
12–31 -	This field is reserved. Reserved

25.5.49 Error interrupt summary register n (MPIC_EISR)

This section describes EISR0. The error interrupt is mapped to internal interrupt number 0.

Address: 4_0000h base + 3900h offset = 4_3900h



MPIC_EISR field descriptions

Field	Description
0–31 SRCn	Error interrupt source 0-31. Bit 0 represents SRC0.

MPIC_EISR field descriptions (continued)

Field	Description
	See "ORed Error Interrupt Sources," in the Interrupt Assignments chapter for the error interrupt sources reported in this register. 0 The corresponding error interrupt source is not active. 1 The corresponding error interrupt source is active.

25.5.50 Error interrupt mask register 0 (MPIC_EIMR0)

This section describes EIMR0. The error interrupt is mapped to internal interrupt number 0.

Address: 4_0000h base + 3910h offset = 4_3910h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

MPIC_EIMR0 field descriptions

Field	Description
0–31 SRCn_MSK	Error interrupt source mask 0-31. Bit 0 represents SRC0_MSK (for SRC0). See "ORed Error Interrupt Sources," in the Interrupt Assignments chapter for the error interrupt sources associated with this register. 0 The corresponding error interrupt source is not masked and will report an error in EISR0.. 1 The corresponding error interrupt source is masked and will not report an error in EISR0.

25.5.51 Watchdog status register summary register 0 (MPIC_WSRSR0)

If any of the WRSn bits in WSRSR0 or WSRSR1 are set, an internal interrupt is generated. The watchdog interrupt is mapped to internal interrupt number 1.

Address: 4_0000h base + 3A00h offset = 4_3A00h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

MPIC_WSRSR0 field descriptions

Field	Description
0–1 WRS15[0:1]	Processor 15 WRS signals. A non-zero value means that a core watchdog timer event has occurred. Write 1s to clear.
2–3 WRS14[0:1]	Processor 14 WRS signals. A non-zero value means that a core watchdog timer event has occurred. Write 1s to clear.
4–5 WRS13[0:1]	Processor 13 WRS signals. A non-zero value means that a core watchdog timer event has occurred. Write 1s to clear.
6–7 WRS12[0:1]	Processor 12 WRS signals. A non-zero value means that a core watchdog timer event has occurred. Write 1s to clear.
8–9 WRS11[0:1]	Processor 11 WRS signals. A non-zero value means that a core watchdog timer event has occurred. Write 1s to clear.
10–11 WRS10[0:1]	Processor 10 WRS signals. A non-zero value means that a core watchdog timer event has occurred. Write 1s to clear.
12–13 WRS9[0:1]	Processor 9 WRS signals. A non-zero value means that a core watchdog timer event has occurred. Write 1s to clear.
14–15 WRS8[0:1]	Processor 8 WRS signals. A non-zero value means that a core watchdog timer event has occurred. Write 1s to clear.
16–17 WRS7[0:1]	Processor 7 WRS signals. A non-zero value means that a core watchdog timer event has occurred. Write 1s to clear.
18–19 WRS6[0:1]	Processor 6 WRS signals. A non-zero value means that a core watchdog timer event has occurred. Write 1s to clear.
20–21 WRS5[0:1]	Processor 5 WRS signals. A non-zero value means that a core watchdog timer event has occurred. Write 1s to clear.
22–23 WRS4[0:1]	Processor 4 WRS signals. A non-zero value means that a core watchdog timer event has occurred. Write 1s to clear.

Table continues on the next page...

MPIC_WSRSR0 field descriptions (continued)

Field	Description
24–25 WRS3[0:1]	Processor 3 WRS signals. A non-zero value means that a core watchdog timer event has occurred. Write 1s to clear.
26–27 WRS2[0:1]	Processor 2 WRS signals. A non-zero value means that a core watchdog timer event has occurred. Write 1s to clear.
28–29 WRS1[0:1]	Processor 1 WRS signals. A non-zero value means that a core watchdog timer event has occurred. Write 1s to clear.
30–31 WRS0[0:1]	Processor 0 WRS signals. A non-zero value means that a core watchdog timer event has occurred. Write 1s to clear.

25.5.52 Watchdog status register summary register 1 (MPIC_WSRSR1)

If any of the WRSn bits in WSRSR1 or WSRSR0 are set, an internal interrupt is generated. The watchdog interrupt is mapped to internal interrupt number 1.

Address: 4_0000h base + 3A10h offset = 4_3A10h

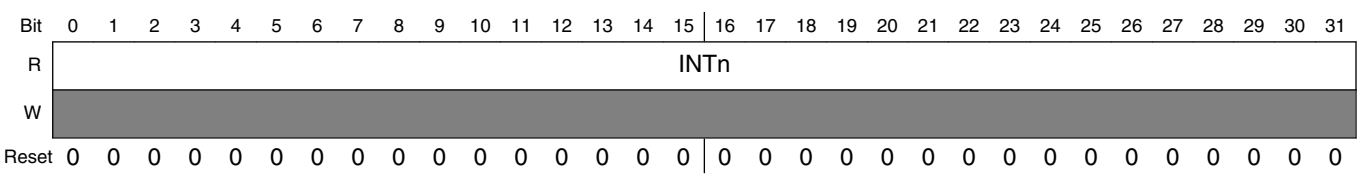
Address: 4_0000h base + 3DB0h offset = 4_3DB0h



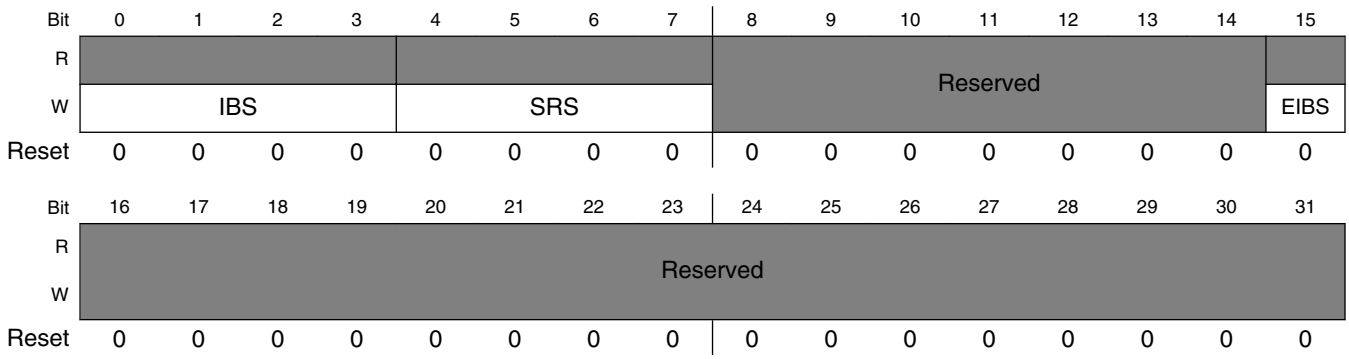
MPIC_IRQSIESR8 field descriptions

Field	Description
0–31 INTn	Internal interrupts status 224-255. Bit 0 represents INT224. 0 The corresponding interrupt is not active or not routed to sien or IRQ_OUT_B 1 The corresponding interrupt is active and is routed to sien or IRQ_OUT_B (if the corresponding *interrupt level register field* is set to sie[0:2] or IRQ_OUT_B).

25.5.80 Shared Message Signaled Interrupt Index Register n (MPIC_MSIIR1*n*)

MSIIR1a provides the mechanism for setting an interrupt in the MSIRas. When MSIIR1a is written, MSIIR1a[SRS] selects the register in which an interrupt bit is to be set MSIIR1a[IBS] selects the shared interrupt field in the selected MSIRa register. MSIIR1a is primarily intended to support PCI Express MSIs.

Address: 4_0000h base + 4148h offset + (4096d × i), where i=0d to 3d



MPIC_MSIIR1*n* field descriptions

Field	Description
0–3 IBS	Interrupt bit select. Selects the bit to set in the MSIR. This is a five bit field combined with MSIIR1[EIBS]. The x below represents the most significant bit MSIIR1[EIBS], for example: 00000 Set field SH0 (bit 31) 10001 Set field SH17 (bit 14) x0000 Set field SH0 or SH16 (bit 31 or bit 15) x0001 Set field SH1 or SH17 (bit 29 or bit 14) ... x1111 Set field SH15 or SH31 (bit 16 or bit 0)
4–7 SRS	Shared interrupt register select. Selects the MSIR to be written. 0000 MSIR 0 0001 MSIR 1 0010 MSIR 2 ... 1111 MSIR 15
8–14 -	This field is reserved. Reserved
15 EIBS	Interrupt bit select. Selects the bit to set in the MSIR. 0 Set field SH0-15 (lower 16 bits of MSIRn) 1 Set field SH16-31(upper 16 bits of MSIRn)

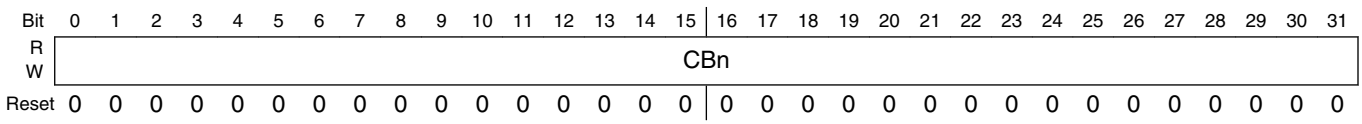
MPIC_MSICRC*n* field descriptions

Field	Description
0–31 CBn	Message signaled interrupt n has a coalescing set. 0 = event n is not included in coalescing 1 = event n is included in coalescing

25.5.84 Shared Message Signaled Coalescing Register n (MPIC_MSICRD*n*)

Each bank of sixteen MSICRs indicates which of the up to 32 interrupt sources sharing a message register have coalescing setup. A non-zero write to this register enables coalescing on the corresponding MSI. A write of zero to the same register disables MSI coalescing on the corresponding MSI.

Address: 4_0000h base + 7180h offset + (4d × i), where i=0d to 15d



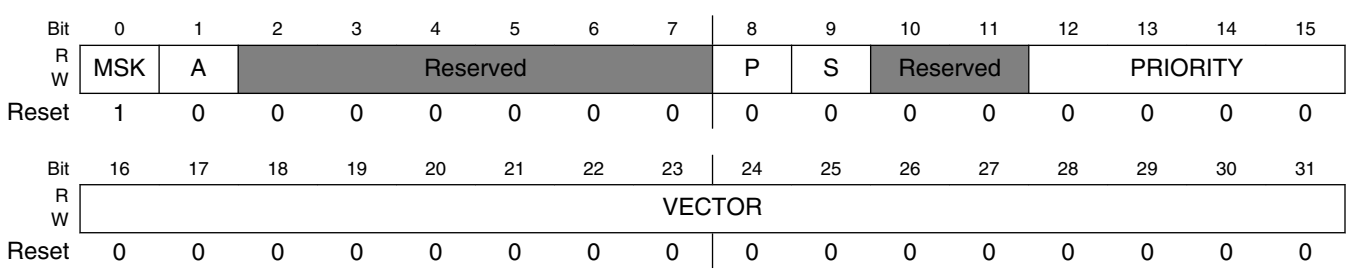
MPIC_MSICRD*n* field descriptions

Field	Description
0–31 CBn	Message signaled interrupt n has a coalescing set. 0 = event n is not included in coalescing 1 = event n is included in coalescing

25.5.85 External interrupt n (IRQn) vector/priority register (MPIC_EIVPR*n*)

The EIVPRs contain polarity and sense fields for the external interrupts, that is, those caused by the assertion of any of IRQ[0:11].

Address: 4_0000h base + 1_0000h offset + (32d × i), where i=0d to 11d



MPIC_EIVPR*n* field descriptions

Field	Description
0 MSK	Mask. Mask interrupts from this source. MSK affects interrupts routed to int, *cint*, *mcp*, *sie*[0:2], and IRQ_OUT_B. 0 An interrupt request is generated if the corresponding IPR bit is set. 1 Further interrupts from this source are disabled.
1 A	Activity. Indicates an interrupt has been requested or is in service. The VECTOR and PRIORITY values should not be changed while this bit is set. Affects only interrupts routed to int. 0 No current interrupt activity associated with this source. 1 The interrupt field for this source is set in the IPR or ISR.
2–7 -	This field is reserved. Reserved
8 P	Polarity. Specifies the polarity for the external interrupt. 0 Polarity is active-low or negative edge-triggered. 1 Polarity is active-high or positive edge-triggered.
9 S	Sense. Specifies the sense for external interrupts. Note: If an IRQ*n* signal is used to receive INT*x* signals from one of the PCI Express ports as a root complex, the sense (S) must be set to be level-sensitive. 0 The external interrupt is edge sensitive. 1 The external interrupt is level sensitive. This setting must be used to direct the interrupt to IRQ_OUT_B, sie, mcp or cint.
10–11 -	This field is reserved. Reserved
12–15 PRIORITY	Priority. Specifies the interrupt priority. The lowest priority is 0 and the highest priority is 15. A priority level of 0 inhibits signalling of this interrupt to the core. Affects only interrupts routed to int.
16–31 VECTOR	Vector (Affects only interrupts routed to int). Contains the value returned when IACK is read and this interrupt resides in the corresponding interrupt request register (IRR) for that core, as shown in Figure 25-3.

25.5.86 External interrupt n (IRQn) destination register (MPIC_EIDR*n*)

The EIDRs control the destination of external interrupts caused by the assertion of any of IRQ[0:11]. If the EILR is programmed to assert *int* pins and EIVPR is programmed to edge sensitive, the EIDRxn bits can be set independently of each other and any or all can be set for this type of interrupt. Otherwise, if the interrupt is programmed to assert *int* pins and EIVPR is programmed to level sensitive, only one destination bit may be set; otherwise, behavior is undefined. If the EILR is programmed to assert *cint* or *mcp* pins multiple destination pins may be set and system behavior must be managed by software.

Address: 4_0000h base + 1_0010h offset + (32d × i), where i=0d to 11d

0–23 -	This field is reserved. Reserved
24–31 INTTGT	Interrupt Target. Specifies which signal is asserted All values not listed are reserved. 0x00 int: The target processor core for *int*, *cint*, and *mcp* is specified in the associated EIDRn 0x01 cint: The target processor core for *int*, *cint*, and *mcp* is specified in the associated EIDRn 0x02 mcp: The target processor core for *int*, *cint*, and *mcp* is specified in the associated EIDRn 0xF0 sie*0*: *sie*[0:2] and IRQ_OUT_B override the processor specified in the associated EIDR. See the Interrupt Assignments chapter for *sie*[0:2] routing assignments. 0xF1 sie*1*: *sie*[0:2] and IRQ_OUT_B override the processor specified in the associated EIDR. See the Interrupt Assignments chapter for *sie*[0:2] routing assignments. 0xF2 sie*2*: *sie*[0:2] and IRQ_OUT_B override the processor specified in the associated EIDR. See the Interrupt Assignments chapter for *sie*[0:2] routing assignments. 0xFF IRQ_OUT_B external output signal: *sie*[0:2] and IRQ_OUT_B override the processor specified in the associated EIDR. See the Interrupt Assignments chapter for *sie*[0:2] routing assignments.

25.5.88 Internal interrupt n vector/priority register (MPIC_IIVPR*n*)

The IIVPRs have the same fields and format as the GTVPRs, except that they apply to the internal interrupt sources listed in Table 25-4. These interrupts are all level-sensitive.

Address: 4_0000h base + 1_0200h offset + (32d × i), where i=0d to 159d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

MPIC_IIVPR*n* field descriptions

Field	Description
0 MSK	Mask. Mask interrupts from this source. MSK affects interrupts routed to int, *cint*, *mcp*, *sie*[0:2], and IRQ_OUT_B. 0 An interrupt request is generated if the corresponding IPR bit is set. 1 Further interrupts from this source are disabled.
1 A	Activity. Indicates an interrupt has been requested or is in service. The VECTOR and PRIORITY values should not be changed while this bit is set. Affects only interrupts routed to int.

Table continues on the next page...

MPIC_IIVPR*n* field descriptions (continued)

Field	Description
	0 No current interrupt activity associated with this source. 1 The interrupt field for this source is set in the IPR or ISR.
2–7 -	This field is reserved. Reserved
8 P	Polarity. All internal interrupts are active-high. **NOTE:** This bit is read-only and always set specifying the polarity as active high.
9–11 -	This field is reserved. Reserved
12–15 PRIORITY	Priority. Specifies the interrupt priority. The lowest priority is 0 and the highest priority is 15. A priority level of 0 inhibits signalling of this interrupt to the core. Affects only interrupts routed to int.
16–31 VECTOR	Vector (Affects only interrupts routed to int). Contains the value returned when IACK is read and this interrupt resides in the corresponding interrupt request register (IRR) for that core, as shown in Figure 25-3.

25.5.89 Internal interrupt n destination register (MPIC_IIDR*n*)

The IIDRs have the same fields and format as EIVDRs, except that they apply to the internal interrupt sources listed in Table 25-4. If the IILR is programmed to assert *int* pins, only one destination bit may be set; otherwise, behavior is undefined. If the IILR is programmed to assert *cint* or *mcp* pins multiple destination pins may be set and system behavior must be managed by software.

Address: 4_0000h base + 1_0210h offset + (32d × i), where i=0d to 159d

MPIC_MIVPRA*n* field descriptions

Field	Description
0 MSK	Mask. Mask interrupts from this source. MSK affects interrupts routed to int, *cint*, *mcp*, *sie*[0:2], and IRQ_OUT_B. 0 An interrupt request is generated if the corresponding IPR bit is set. 1 Further interrupts from this source are disabled.
1 A	Activity. Indicates an interrupt has been requested or is in service. The VECTOR and PRIORITY values should not be changed while this bit is set. Affects only interrupts routed to int. 0 No current interrupt activity associated with this source. 1 The interrupt field for this source is set in the IPR or ISR.
2–11 -	This field is reserved. Reserved
12–15 PRIORITY	Priority. Specifies the interrupt priority. The lowest priority is 0 and the highest priority is 15. A priority level of 0 inhibits signalling of this interrupt to the core. Affects only interrupts routed to int.
16–31 VECTOR	Vector (Affects only interrupts routed to int). Contains value returned when IACK is read and this interrupt resides in the corresponding interrupt request register (IRR) for that core, as shown in Figure 25-3.

25.5.96 Messaging interrupt destination register [Group A] n (MPIC_MIDRA*n*)

The messaging interrupt destination registers (MIDRs) control the destination for the messaging interrupts. Only one destination bit may be set; otherwise, behavior is undefined.

Address: 4_0000h base + 1_1710h offset + (32d × i), where i=0d to 3d

R W	VECTOR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MPIC_MSIVPRC*n* field descriptions

Field	Description
0 MSK	Mask. Mask interrupts from this source. MSK affects interrupts routed to int, *cint*, *mcp*, *sie*[0:2], and IRQ_OUT_B. 0 An interrupt request is generated if the corresponding IPR bit is set. 1 Further interrupts from this source are disabled.
1 A	Activity. Indicates an interrupt has been requested or is in service. The VECTOR and PRIORITY values should not be changed while this bit is set. Affects only interrupts routed to int. 0 No current interrupt activity associated with this source. 1 The interrupt field for this source is set in the IPR or ISR.
2–11 -	This field is reserved. Reserved
12–15 PRIORITY	Priority. Specifies the interrupt priority. The lowest priority is 0 and the highest priority is 15. A priority level of 0 inhibits signalling of this interrupt to the core. Affects only interrupts routed to int.
16–31 VECTOR	Vector (Affects only interrupts routed to int). Contains the value returned when IACK is read and this interrupt resides in the corresponding interrupt request register (IRR) for that core, as shown in End of interrupt register (MPIC_EOI).

25.5.104 Shared message signaled interrupt destination register [Bank C] n (MPIC_MSIDRC*n*)

The MSIDRs contain the destination fields for shared message signaled interrupts. Only one destination bit may be set; otherwise, behavior is undefined.

Address: 4_0000h base + 1_1E10h offset + (32d × i), where i=0d to 7d

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	VECTOR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MPIC_IIVPR*n* field descriptions

Field	Description
0 MSK	Mask. Mask interrupts from this source. MSK affects interrupts routed to int, *cint*, *mcp*, *sie*[0:2], and IRQ_OUT_B. 0 An interrupt request is generated if the corresponding IPR bit is set. 1 Further interrupts from this source are disabled.
1 A	Activity. Indicates an interrupt has been requested or is in service. The VECTOR and PRIORITY values should not be changed while this bit is set. Affects only interrupts routed to int. 0 No current interrupt activity associated with this source. 1 The interrupt field for this source is set in the IPR or ISR.
2–7 -	This field is reserved. Reserved
8 P	Polarity. All internal interrupts are active-high. **NOTE:** This bit is read-only and always set specifying the polarity as active high.
9–11 -	This field is reserved. Reserved
12–15 PRIORITY	Priority. Specifies the interrupt priority. The lowest priority is 0 and the highest priority is 15. A priority level of 0 inhibits signalling of this interrupt to the core. Affects only interrupts routed to int.
16–31 VECTOR	Vector (Affects only interrupts routed to int). Contains the value returned when IACK is read and this interrupt resides in the corresponding interrupt request register (IRR) for that core, as shown in Figure 25-3.

25.5.116 Internal interrupt n destination register (MPIC_IIDR*n*)

The IIDRs have the same fields and format as EIVDRs, except that they apply to the internal interrupt sources listed in Table 25-4. If the IILR is programmed to assert *int* pins, only one destination bit may be set; otherwise, behavior is undefined. If the IILR is programmed to assert *cint* or *mcp* pins multiple destination pins may be set and system behavior must be managed by software.

Address: 4_0000h base + 1_3010h offset + (32d × i), where i=0d to 95d

MPIC_IIDR*n* field descriptions (continued)

Field	Description
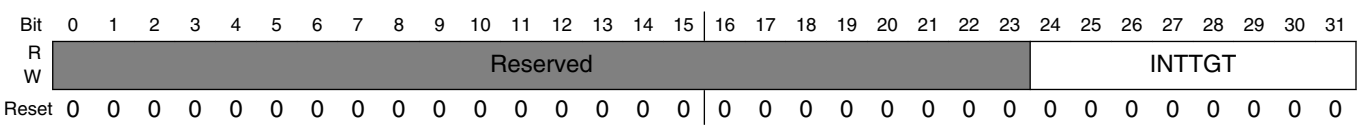
26 P5	Processor core 5. Indicates whether processor core 5 receives the interrupt. 0 Processor core 5 does not receive this interrupt. 1 Directs the interrupt to processor core 5.
27 P4	Processor core 4. Indicates whether processor core 4 receives the interrupt. 0 Processor core 4 does not receive this interrupt. 1 Directs the interrupt to processor core 4.
28 P3	Processor core 3. Indicates whether processor core 3 receives the interrupt. 0 Processor core 3 does not receive this interrupt. 1 Directs the interrupt to processor core 3.
29 P2	Processor core 2. Indicates whether processor core 2 receives the interrupt. 0 Processor core 2 does not receive this interrupt. 1 Directs the interrupt to processor core 2.
30 P1	Processor core 1. Indicates whether processor core 1 receives the interrupt. 0 Processor core 1 does not receive this interrupt. 1 Directs the interrupt to processor core 1.
31 P0	Processor core 0. Indicates whether processor core 0 receives the interrupt. The default destination is for processor core 0 to receive this interrupt after the MPIC is reset. 0 Processor core 0 does not receive this interrupt. 1 Directs the interrupt to processor core 0.

25.5.117 Internal interrupt n level register (MPIC_IILR*n*)

The IILRs specify the actual signal to assert to the destination processor.

Address: 4_0000h base + 1_3018h offset + (32d × i), where i=0d to 95d



MPIC_IILR*n* field descriptions

Field	Description
0–23 -	This field is reserved. Reserved
24–31 INTTGT	Interrupt Target. Specifies which signal is asserted. All values not listed are reserved.

See the Interrupt Assignments chapter for *sie*[0:2] routing assignments.

25.5.118 Interprocessor interrupt dispatch register n (MPIC_*n*IPIDR0)

This section describes IPIDR0, one for each interprocessor interrupt channel. Writing to an IPIDR with a bit set causes a self interrupt for a single-core device. Because external bus masters can access the these registers by using the per-CPU global access offsets, this feature can serve as a doorbell-type interrupt.

Address: 4_0000h base + 2_0040h offset + (4096d × i), where i=0d to 23d

Field	Description
28 P3	Processor core 3. Specifies if processor core 3 receives the interrupt. This interrupt is multicasting, so multiple bits can be set. 0 Processor core 3 does not receive the interrupt 1 Directs the interrupt to processor core 3
29 P2	Processor core 2. Specifies if processor core 2 receives the interrupt. This interrupt is multicasting, so multiple bits can be set. 0 Processor core 2 does not receive the interrupt 1 Directs the interrupt to processor core 2
30 P1	Processor core 1. Specifies if processor core 1 receives the interrupt. This interrupt is multicasting, so multiple bits can be set. 0 Processor core 1 does not receive the interrupt 1 Directs the interrupt to processor core 1
31 P0	Processor core 0. Determines if processor core 0 receives the interrupt. 0 Processor core 0 does not receive the interrupt. 1 Directs the interrupt to processor core 0.

25.5.122 Current task priority register (MPIC_*n*CTPR)

There is one current task priority register per processor core on this chip. See Global- and private-access per-CPU registers for more information.

NOTE

CTPR has meaning only for interrupts routed to *int*.

Software must write the priority of the current processor core task in the CTPR for each core. The MPIC uses this value for comparison with the priority of incoming interrupts. Given several concurrent incoming interrupts, the highest priority interrupt is asserted to that core if the following apply:

- The interrupt is not masked.
- The priority of the interrupt is higher than the values in the corresponding CTPR[TASKP] and ISR.

Address: 4_0000h base + 2_0080h offset + (4096d × i), where i=0d to 23d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Reserved																												TASKP			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1

MPIC_*n*CTPR field descriptions

Field	Description
0–27 -	This field is reserved. Reserved
28–31 TASKP	Task priority. Indicates the threshold that individual interrupt priorities must exceed for the interrupt request to be serviced. Task priority is meaningless (that is, a don't care) if the processor ID in WHOAMI[ID] is illegal. 0000-1111 xVPRn[PRIORITY] must exceed this value for the interrupt request to be serviced. Note the following special cases: 0000 Lowest priority. All interrupts except those whose priority are 0 can be serviced. 1111 Highest priority. No interrupts are signaled to that processor core. Hardware selects this value on a device hard reset or when the corresponding PIR[Pn] is set.

25.5.123 Who am I register (MPIC_*n*WHOAMI)

The processor core WHOAMI*n* register can be read by a processor core to determine its physical connection to the MPIC. The value returned when reading this register may be used to determine the value for the destination masks used for dispatching interrupts.

Address: 4_0000h base + 2_0090h offset + (4096d × i), where i=0d to 23d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

25.5.124 Interrupt acknowledge register (MPIC_*n*IACK)

NOTE

IACK has meaning only for interrupts routed to *int* in mixed mode (GCR[M] = 01)and should not be accessed for interrupts routed to *cint*, *mcp*, *sie*, or IRQ_OUT_B.

NOTE

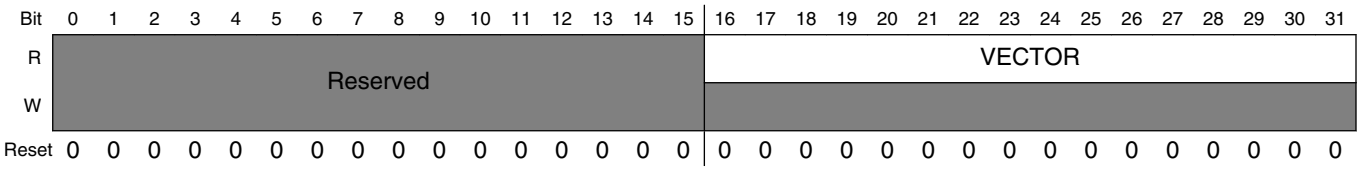
The external proxy facility mode (GCR[M] = 11), eliminates the need for the core to read the IACK register as the vector is automatically passed to the core's external proxy register (EPR) or guest external proxy register (GEPR).

In systems based on processors that implement the Power architecture, the interrupt acknowledge function occurs as an explicit read operation to a memory-mapped interrupt acknowledge register (IACK). Each processor core has an IACK register assigned to it. Reading IACK returns the interrupt vector corresponding to the highest priority pending interrupt. Reading IACK also has the following side effects:

- The associated field in the corresponding interrupt pending register (IPR) is cleared for edge-sensitive interrupts.
- The corresponding in-service register (ISR) is updated.
- The corresponding *int* output signal from the MPIC is negated.

Reading IACK when no interrupt is pending returns the spurious vector value, as described in Spurious vector register (MPIC_SVR)."

Address: 4_0000h base + 2_00A0h offset + (4096d × i), where i=0d to 23d



MPIC_*n*IACK field descriptions

Field	Description
0–15 -	This field is reserved. Reserved
16–31 VECTOR	Interrupt vector. Vector of the highest pending interrupt (read only). This field is meaningless (that is, a don't care) if the processor ID in WHOAMI[ID] is illegal.

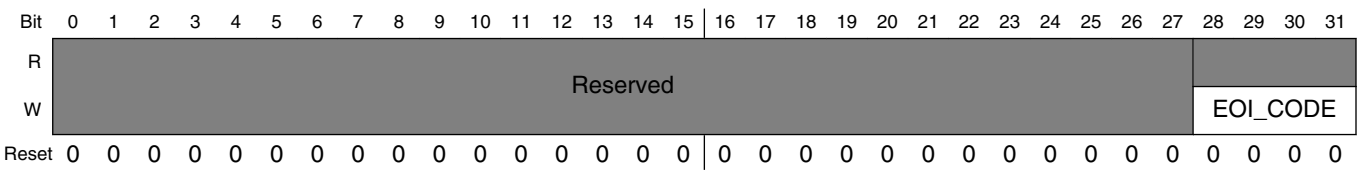
25.5.125 End of interrupt register (MPIC_*n*EOI)

NOTE

EOI has meaning only for interrupts routed to *int* and should not be accessed for interrupts routed to *cint*, *mcp*, *sie*, or IRQ_OUT_B.

Each core is assigned an EOI register. Writing to EOI signals the end of processing for the highest-priority interrupt (routed to *int*) currently in service. It also updates the corresponding ISR*n* by retiring the highest priority interrupt. Data values written to EOI are ignored, and zero is assumed.

Address: 4_0000h base + 2_00B0h offset + (4096d × i), where i=0d to 23d



MPIC_*n*EOI field descriptions

0–27 -	This field is reserved. Reserved
28–31 EOI_CODE	EOI Code 0000 (write only)

25.6 Register Sections Removed

25.6.1 Global Registers

Although most MPIC registers have one address, some are replicated for each processor core in a multiprocessor device. For such registers, each core accesses its separate registers using the same address, the address decoding being sensitive to the processor core. A copy of the per-CPU registers is available to each processor core at the same physical address, that is, in a private access address space that acts like an alias to a processor's own copy of the per-CPU registers. The ID of the core initiating the read/write transaction determines which processor's per-CPU registers to access. For more information, see Global- and private-access per-CPU registers.

NOTE

Register fields designated as write-1-to-clear are cleared only by writing ones to them. Writing zeros to them has no effect.

25.6.2 Global Timer Registers

The two independent groups of global timer registers, group A and group B, are identical in their functionality, except that they appear at different locations within the MPIC register map. Note that each of the four timers within an *x* group have four individual configuration registers (GTCCRxn, GTBCRxn, GTVPRxn, GTDRxn), but they are only shown once in this section. These two groups of timers cannot be cascaded together.

25.6.3 Global Performance Monitor Mask Registers (PMMRs)

The performance monitor mask registers consist of four sets of twelve 32-bit registers, PM*n*MR0, PM*n*MR1, through PM*n*MR11, one set per performance monitor signal. Each of the four sets can be configured to select one interrupt source (interprocessor, timer, message, shared message signaled, external, or internal) to generate a performance monitor event. The performance monitor can be configured to track this event in the performance monitor local control registers.

25.6.4 Global Interrupt Summary Registers

This section describes the various interrupt summary registers.

25.6.4.1 Critical Interrupt, Machine Check, and IRQ_OUT/SoC Interrupt Event Summary Registers

The summary registers indicate the specific interrupt sources routed to the *cintn*, *mcpn*, *sien*, or IRQ_OUT_B MPIC outputs. Summary register bits are cleared when the corresponding interrupt that caused a bit to be set is negated. Note that only level-sensitive interrupts can be routed to *cintn*, *mcpn*, *sien*, or IRQ_OUT_B. Also note that if an interrupt source is masked through *x*VPR*n* mask bit, and the destination is *cint*, *mcp*, IRQ_OUT_B, or *sie*, the corresponding summary register bit will not be set even if the source is active.

The critical interrupt summary registers, shown starting with Critical interrupt summary register 0 (MPIC_CISR0), contain one bit for each interrupt source that can be designated as a critical interrupt. The corresponding bit is set if the interrupt is active and is routed to the appropriate *cintn* outputs of the MPIC.

The machine check summary registers, shown starting with Machine check summary register 0 (MPIC_MCSR0), contain one bit for each interrupt source that can be designated as a machine check interrupt. The corresponding bit is set if the interrupt is active and is routed to the appropriate *mcpn* outputs of the MPIC.

The IRQ_OUT/SoC interrupt event summary registers, shown starting with IRQ_OUT_B/Soc Interrupt Event summary register 0 (MPIC_IRQSIESR0) contain one bit for each interrupt source that can be routed to *sien* or IRQ_OUT_B. The corresponding bit is set if the interrupt is active and is routed to *sien* or IRQ_OUT_B.

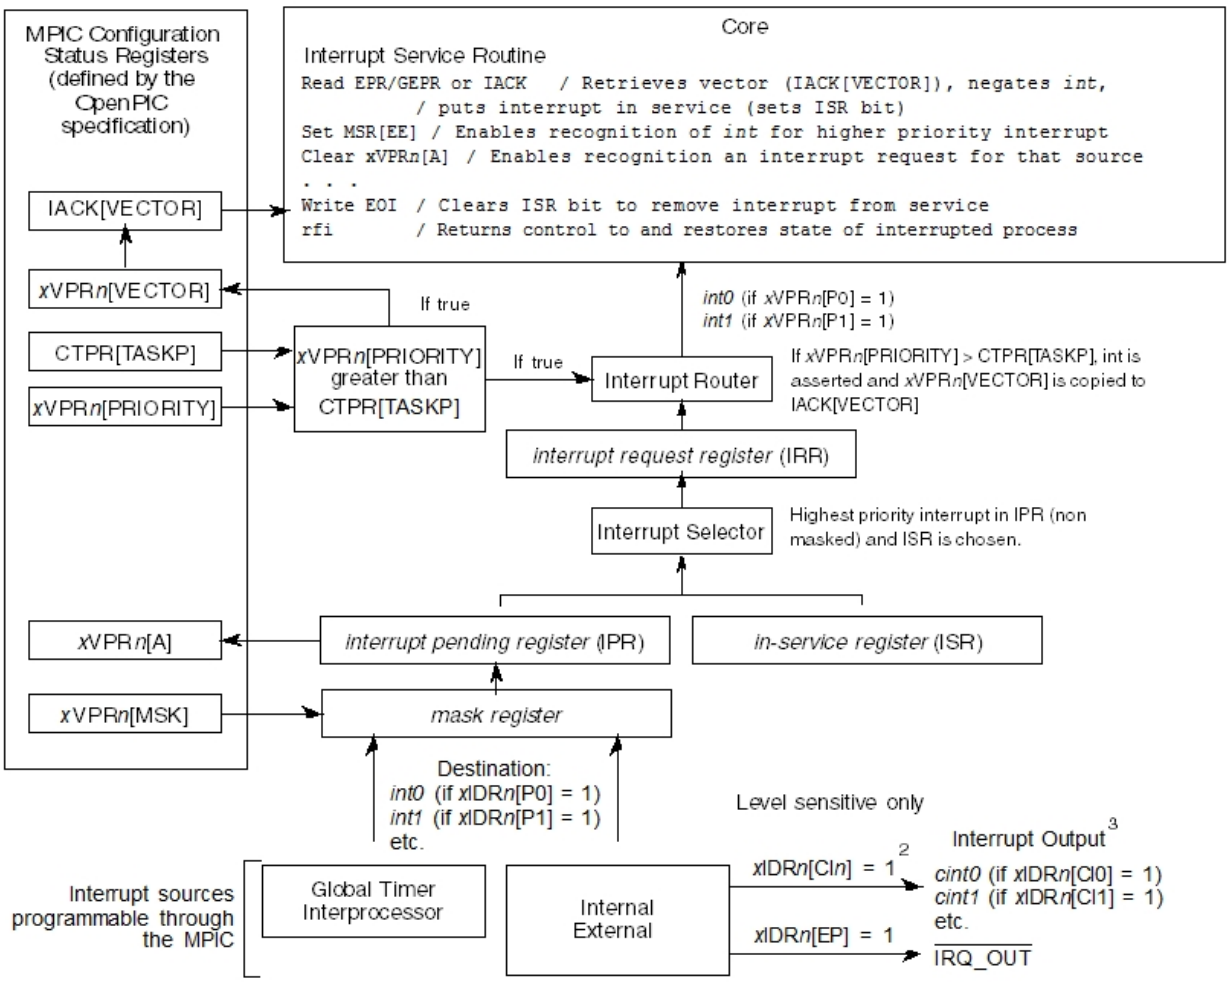
25.7 Functional Description

This section is a functional description of the MPIC.

25.7.1 Flow of Interrupt Control

Figure 25-3 shows the flow of interrupts directed by the MPIC to the *int*, *cint*, sie, or and IRQ_OUT_B outputs. Note that this diagram describes a conceptual model of an MPIC on a single processor. This logic is replicated for each implemented processor. This conceptual diagram does not fully represent all internal circuitry of the implementation

This figure focusses especially on the OpenPIC-defined logic and shows how the MPIC controls interrupt requests that target the *int* signal. The flow in Figure 25-3 is from the bottom to the top, and shows at the bottom how the destination register associated with each source determines the path.



1 If *cint*, *sie* or IRQ_OUT is the destination, EIVPR*n*[S] must be set to configure the source as level sensitive.

2 If multiple destination register bits are set, MPIC behavior is undefined.

3 Although setting CI*n* directs the interrupt request to the critical interrupt output (*cintn*), integrated logic may connect this signal to a different interrupt input to the core.

Figure 25-3. MPIC Interrupt Processing Flow Diagram for Each Core (*n*)

25.7.1.1 Interrupt Source Configuration

The interrupt source configuration registers include vectory/priority, destination, and level registers. These control the source and destinations of interrupts, specifying parameters such as the interrupting event, signal polarity, and relative priority.

The global timer, interprocessor, messaging, and shared message signaled destination register support only processor core options. That is, they cannot be routed to *cint*, *mcp*, *sie*[0:2] or to IRQ_OUT_B.

Only the global timer, interprocessor, and edge-triggered external interrupts are multicasting, so only these interrupts allow more than one destination bit to be specified in the destination register.

Table 25-5 shows a comparison of vector/priority registers.

Table 25-5. Vector/Priority Register Summary

Interrupt Source			0	1								10	11			14	15													31
Global timer, shared MSI, messaging	R W	MSK	A	-									PRIORITY				VECTOR													
Internal	R W	MSK	A	-						P	-		PRIORITY				VECTOR													
External	R W	MSK	A	-						P	S	-	PRIORITY				VECTOR													

Table 25-6 describes the vector priority fields. Note the following:

- The MSK, A, PRIORITY, and VECTOR fields are defined by the OpenPIC specification and have meaning only for interrupts routed to the *int* signal. However, for the internal and external interrupt sources, the MSK field is also repected for interrupts routed to the *int* , *cint*, *mcp*, *sie*[0:2], and IRQ_OUT_B signals.
- The polarity field, P, is provided to indicate whether the signals from the corresponding source are active high or low.

Table 25-6. Vector/Priority Register Fields

Bits	Name	Description
0	MSK	Mask. MSK affects interrupts routed to int, *cint*, *mcp*, *sie*[0:2], and IRQ_OUT_B. 0 An interrupt request (to int) is generated if the corresponding IPR bit is set. 1 Further interrupts routed to int from this source are disabled.
1	A	Activity. Indicates an interrupt has been requested or is in service. The VECTOR and PRIORITY values should not be changed while this bit is set. Affects only interrupts routed to int. 0 No current interrupt activity associated with this source. 1 The interrupt field for this source is set in the IPR or ISR.
2-7	-	Reserved
8	P	Polarity. (internal and external interrupts only) Specifies the polarity for the external and internal interrupt inputs. 0 Polarity is active-low or negative edge triggered. 1 Polarity is active-high or positive edge-triggered.
9	S	Sense. (external interrupts only) Specifies the sense for external interrupts. 0 The external interrupt is edge sensitive.

Table continues on the next page...

Table 25-6. Vector/Priority Register Fields (continued)

Bits	Name	Description
		1 The external interrupt is level sensitive. This setting must be used to direct the interrupt to IRQ_OUT_B, sie, cint, or mcp.
10-11	-	Reserved
12-15	PRIORITY	Priority. Specifies the interrupt priority. The lowest priority is 0 and the highest priority is 15. A priority level of 0 inhibits signalling of this interrupt to the core. Affects only interrupts routed to int.
16-31	VECTOR	Vector (Affects only interrupts routed to int). Contains the value returned when IACK is read and this interrupt resides in the corresponding interrupt request register (IRR) for that core, as shown in Figure 25-3.

25.7.1.2 Interrupts Routed to cint, mcp, sie, or IRQ_OUT_B

Interrupt requests routed to *cint*, *mcp*, *sie*, or IRQ_OUT_B bypass the logic that is dedicated to interrupt sources that compete for *int*.

NOTE

Because interrupt sources routed to *cint*, *sie*, IRQ_OUT_B and internal interrupt sources routed to *mcp* must be level sensitive, EIVPR[S] has no effect. External interrupt sources routed to *mcp* can be level-sensitive or edge-triggered since the core always uses edge detection logic. Consequently, EIVPR[S] has no effect in this case as well. See External interrupt n (IRQn) vector/priority register (MPIC_EIVPR*n*).

Because these interrupts bypass the OpenPIC logic, it is especially important that handlers do not read IACK. Doing so causes a spurious interrupt. Likewise, they should not write EOI.

25.7.1.3 Interrupts Routed to *int*

As shown in Figure 25-3, the MPIC receives interrupt requests from external and internal sources and from within the MPIC itself. As Figure 25-3 shows, all of these interrupt sources can be routed to *int*; the global timer and timer processor interrupts can be directed only to *int*.

The sources' mask bits (xVPRn[MSK]) are tracked in the internal mask register. If a source's MSK bit is set, the mask register prevents the MPIC from asserting *int* (or *cint*, *mcp*, *sie*[0:2], IRQ_OUT_B) on its behalf.

NOTE

An edge-sensitive interrupt event is lost if the corresponding interrupt's mask bit is set or if the interrupt event is level-sensitive and it deasserts before the interrupt is unmasked.

Unmasked interrupt requests are captured in the interrupt pending register (IPR), an internal interrupt summary register with a bit for each source. If an interrupt request is multicast, a bit is set in the IPR for each targeted processor. Although the IPR cannot be read by software, when an IPR bit is set, the corresponding source's activity bit (*x*VPRn[A]) is automatically set.

The interrupt selector monitors the IPR and the in-service register (ISR), which tracks previously taken interrupts that were superseded by a higher-priority interrupt before the interrupt handler finished. The interrupt selector recognizes the highest priority unmasked interrupt request and latches it into the interrupt request register (IRR). The source's vector (xVPRn[VECTOR]) is automatically passed to the core's external proxy register (EPR) or guest external proxy register (GEPR) in external proxy facility mode (GCR[M] = 11) or it is copied to IACK[VECTOR] in mixed mode (GCR[M] = 01).

If the priority (*x*VPR*n*[PRIORITY]) of an interrupt latched in the IRR is higher than the value in the target processor's CTPR[TASKP], the interrupt router asserts the external interrupt signal (*int*), causing that processor core to vector to its external interrupt handler.

In mixed mode (CGR[M] = 01), the interrupt handler must acknowledge the interrupt by explicitly reading the corresponding IACK register, described in Interrupt acknowledge register (MPIC_IACK). The MPIC interprets this read as an interrupt acknowledge (IACK) cycle. In external proxy facilty mode (GCR[M] = 11, the core automatically generates the IACK cycle (when MSR[EE] = 1) to the MPIC, although from system software perspective, the core does not acknowledge the interrupt until the external interrupt is taken.

NOTE

In external proxy facility mode, interrupt handlers should retrieve the vector from the core's EPR (or GEPR) and not read the IACK register. Reading the IACK registers in external proxy facility mode causes a spurious interrupt.

The IACK cycle not only returns the source's vector, it also negates the *int* signal to the processor (making it possible for a higher priority interrupt to assert *int*) and sets the source's bit in the ISR, indicating that this interrupt has been put in service. An interrupt remains in service from the time until the corresponding end-of-interrupt register (EOI) is written, generating what the MPIC considers an EOI signal.

Figure 25-3 shows required elements in the interrupt handler

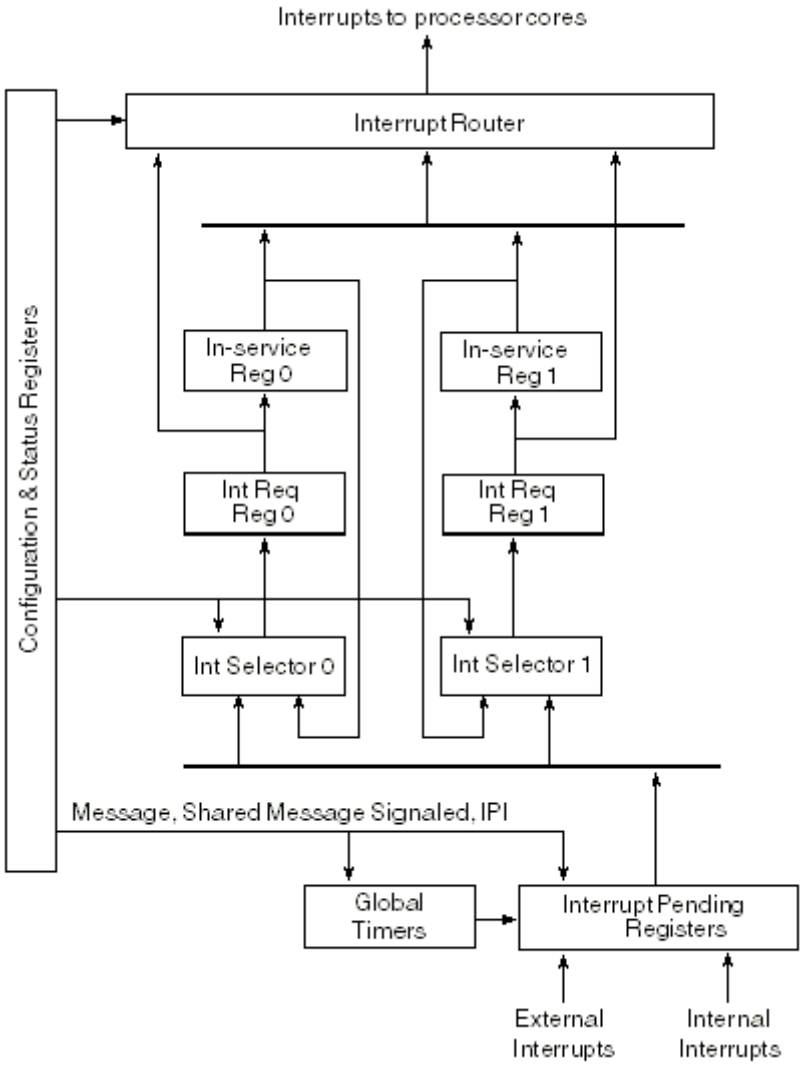


Figure 25-4. MPIC Block Diagram

25.7.1.3.1 Nesting of Interrupts

While an interrupt is being handled, if an interrupt request arrives with a higher *x*VPR*n*[PRIORITY] value, the interrupt being serviced is superseded. As described in Interrupts Routed to *int*, the MPIC asserts *int*, and the newer, higher priority interrupt is handled. This happens even if software, as part of its interrupt service routine, updates the corresponding CTPR with a lower value.

Thus, although several interrupts can be in service simultaneously (and tracked by the ISR), the highest priority interrupt by that processor is always the one actively handled. When the interrupt routine completes, it performs a write EOI cycle, a side effect of which is to take the current highest priority interrupt out of service (removes it from the

ISR). At this point, the interrupt selector chooses the new highest priority interrupt request, and, assuming CTPR[TASKP] has not been updated to a value higher than the new interrupt, the MPIC asserts *int* on its behalf.

The next write EOI cycle takes the current highest priority interrupt out of service. An interrupt with lower priority than those in service is not started until all higher priority interrupts complete even if its priority is greater than the CTPR value.

25.7.1.3.2 Interrupt Source Priority

Each interrupt source routed to *int* is assigned a value through its *x*VPR*n*[PRIORITY] field. Priority values range from 0 to 15, where 15 is the highest. Interrupts are delivered only when the priority of the source is greater than the destination processor's CTPR[TASKP]. Therefore, setting *x*VPR*n*[PRIORITY] to zero inhibits that interrupt. Likewise, setting TASKP to 15 prevents the MPIC from delivering interrupts to that core through the *int* signal. Note that this is the reset value, preventing the MPIC from asserting *int* before the MPIC is configured.

The MPIC services simultaneous interrupts occurring with the same priority according to the following order:

1. MSGA0-MSGA7
2. MSGB0-MSGB7
3. MSIA0-MSIA15
4. MSIB0-MSIB15
5. MSIC0-MSIC15
6. MSID0-MSID15
7. IPI0-IPI3
8. Group A timer0-timer3
9. Group B timer0-timer3
10. IRQ[0:11]
11. Internal0-internal255

For example, if MSGA0, MSGA2, and IPI0 are all assigned the same priority and receive simultaneous interrupts, they are serviced in the following order:

1. MSGA0
2. MSGA2
3. IPI0

25.7.1.3.3 Interrupt Acknowledge

In mixed mode, when the MPIC causes *int* to be asserted, the external interrupt service routine acknowledges the request by reading that core's IACK register, which at this point holds the 16-bit vector value for the interrupt source that generated the request. This is the value programmed in that source's *x*VPR*n*[VECTOR]. Reading IACK has the following effects:

- The *int* signal for that core is negated, making it possible for another interrupt source to signal an external interrupt to the core, and more particularly, allowing the MPIC to signal a higher-priority interrupt, as described in Nesting of Interrupts .
- The source that caused that resource is represented in the internal in-service register (ISR).

The interrupt is then considered to be in service. It remains so until the processor core performs a write to the corresponding EOI. Writing to EOI is referred to as an EOI cycle.

In external proxy facility mode, the interrupt is automatically acknowledged with the same effects as reading the IACK register. Detailed description of the external proxy facility is described in the *e6500 Core Reference Manual* .

25.7.1.3.4 Spurious Vector Generation

Under certain circumstances, the MPIC has no valid vector to return to a processor core during an interrupt acknowledge cycle. In these cases, the spurious vector from the spurious vector register is returned. The following cases cause a spurious vector fetch:

- *int* (ipi_int_proc) is asserted in response to an externally or internally-sourced interrupt which is activated with level-sensitive logic, and the asserted level is negated before the interrupt is acknowledged.
- *int* (ipi_int_proc) is asserted for an interrupt source that is later masked (using the mask bit in the vector/priority register corresponding to that source) before the interrupt is acknowledged.
- *int* (ipi_int_proc) is asserted for an interrupt source that is later masked by an increase in the task priority level before the interrupt is acknowledged.
- An interrupt acknowledge cycle is performed by the processor core in spite of the fact that the MPIC has not asserted int (ipi_int_proc).

In all cases, a spurious vector is returned only if no pending interrupt has sufficient priority to signal an interrupt, otherwise, the vector for that interrupt source is returned.

NOTE

EOI should not be written in response to a spurious vector. Otherwise, a previously accepted interrupt might be cleared unintentionally.

25.7.2 Global- and private-access per-CPU registers

Although most MPIC registers have one address, some are replicated for each processor core in a multiprocessor device. For such registers, each core accesses its separate registers using the same address, the address decoding being sensitive to the processor core; these registers are called the per-CPU global-access registers. A copy of the per-CPU registers is available to each processor core at the same physical address; these registers are called the per-CPU private-access registers. The private-access address acts like an alias to a core's per-CPU global-access register.

For example, CTPR is the per-CPU private-access current task priority register and CPUn_CTPR are the per-CPU global-access current task priority registers.

- When Core0 accesses CTPR at 04_0080h, the MPIC aliases CPU0_CTPR at 06_0080h.
- When Core1 accesses CTPR at 04_0080h, the MPIC aliases CPU1_CTPR at 06_1080h.

The registers in the following table are called per-CPU registers because they are duplicated for each core in a multicore device. The OpenPIC interface specifies that a copy of these registers be available to each core at the same physical address by using the ID of the processor core that initiates the transaction to determine the set of per-CPU registers to access.

Table 25-7. Per-CPU register mappings

Register name	Private-access		Global-access[1]	
	Register	Address	Register	Address
Interprocessor interrupt 0 dispatch register	IPIDR0	04_0040h	CPU*n*_IPIDR0	06_*n*040h
Interprocessor interrupt 1 dispatch register	IPIDR1	04_0050h	CPU*n*_IPIDR1	06_*n*050h
Interprocessor interrupt 2 dispatch register	IPIDR2	04_0060h	CPU*n*_IPIDR2	06_*n*060h
Interprocessor interrupt 3 dispatch register	IPIDR3	04_0070h	CPU*n*_IPIDR3	06_*n*070h
Current task priority register	CTPR	04_0080h	CPU*n*_CTPR	06_*n*080h
Who am I register	WHOAMI	04_0090h	CPU*n*_WHOAMI	06_*n*090h
Interrupt acknowledge register	IACK	04_00A0h	CPU*n*_IACK	06_*n*0A0h
End of interrupt register	EOI	04_00B0h	CPU*n*_EOI	06_*n*0B0h

1. *n* is the corresponding core number

The private-access addresses appear in the memory map at the same offset for every processor. This duplication allows user code to execute correctly in a multiprocessor environment without needing to know which core it is running on.

25.7.3 Interprocessor Interrupts

Processors can generate interprocessor interrupts that target any processor. A self interrupt occurs when a core dispatches an interprocessor interrupt event to itself. Interrupts are initiated by writing one or several of the P*n* bits in an interprocessor interrupt dispatch register (IPIDR0-IPIDR3) of one of the four IPI channels. Note that when initiating an interrupt event to more that one processor (by setting more than 1 P*n* bit in the IPIDR), each recipient processor must acknowledge, take delivery and EOI that interrupt. That is, the interrupt is delivered to each processor as a unique copy. Also note that if subsequent interprocessor interrupts from a given channel to a given target processor are initiated before the first is acknowledged, only one interrupt is generated.

25.7.4 Messaging Interrupts

25.7.4.1 Message Interrupts

The MPIC supports two banks (A and B) of eight 32-bit message registers. The MSGRs can be used to send 32-bit messages to one or more processors.

Writing a message register (MSGRx) causes a message interrupt, provided the interrupt is enabled in the Message Enable Register (MERx) and not masked by the MASK field in the corresponding Messaging Interrupt Vector/Priority Register (MIVPRx).

Reading a message register (MSGRx) or writing a 1 to the the corresponding field of the message status register (MSRx) clears the interrupt.

The following registers support message interrupts:

- Message register [Group A] n (MPIC_MSGRA*n*)
- Message enable register [Group n] (MPIC_MER*n*)
- Message status register [Group n] (MPIC_MSR*n*)
- Messaging interrupt vector/priority register [Group A] n (MPIC_MIVPRA*n*)
- Messaging interrupt destination register [Group A] n (MPIC_MIDRA*n*)

25.7.4.2 Shared Message Signaled Interrupts

The shared message signaled interrupt structures allows programs to interrupt each other by simply writing to these shared memory-mapped registers in the MPIC. These registers are primarily intended to support PCI Express MSIs and each of the PCI Express ports can only use one MSI target at a time, either MSIIR or MSIIR1.

The following registers support shared message signalled interrupts:

- Shared message signaled interrupt register [Bank A] n (MPIC_MSIRA*n*)
- Shared message signaled interrupt status register [Bank n] (MPIC_MSISR*n*)
- Shared message signaled interrupt index register [Bank A] (MPIC_MSIIR*n*)
- Shared Message Signaled Interrupt Index Register n (MPIC_MSIIR1*n*)
- Shared Message Signaled Coalescing Register n (MPIC_MSICRA*n*)
- Shared message signaled interrupt vector/priority register [Bank A] n (MPIC_MSIVPRA*n*)
- Shared message signaled interrupt destination register [Bank A] n (MPIC_MSIDRA*n*)

There are four sets of sixteen MSIRs (one set for each bank A, B, C, and D) that indicate which of the interrupt sources sharing the MSI register have pending interrupts. Each of the sixteen MSIRs for each bank can be thought of as collecting interrupts from 32 different memory-mapped writes that can cause shared message signaled interrupts. Up to 32 sources can share any individual MSI register.

There are two sources on each bank to set the message signaled interrupt registers. One (MSIIRa) can select up to eight registers of thirty-two sources each and the other (MSIIR1a) can select up to sixteen registers of thirty-two sources each.

A shared message signaled interrupt is generated by writing to the SRS and IBS fields in MSIIR or MSIIR1. The two fields, SRS and IBS, select one of the registers in which an interrupt bit is to be set and the bit in the selected register, respectively. The corresponding interrupt needs to be unmasked in MSIVPRx for the interrupt to happen. The result of the first eight MSIRs are OR of MSIIR and MSIIR1. This OR function is also valid for the Shared Message Signaled Status Register (MSISR). A read to MSI register will clear the interrupt.

Shared message signalled interrupt also supports a coalescing feature. Each MSIR register has a corresponding MSI Coalescing register (MSICRa0-MSICRa15). The coalescing feature is enabled when MSICR has a non-zero value. When this feature is enabled, a MSI interrupt enters pending state only if all the events matching the coalescing register are set in MSIR. If an event occurs which does not have a matching coalescing bit set the resulting interrupt is coalesced as if the bit is set.

25.7.5 PCI Express INTx

An INTx interrupt is signaled from the PCIe controller when it receives an in-band INTx message from a PCIe end point. These interrupts replace the out-of-band interrupts that historically were connected to the IRQ pins. Because the INTx interrupts and IRQ interrupts are generally mutually exclusive, the INTx signals are logically combined with the IRQ signals so that they share the same OpenPIC interrupt. See the Interrupt Assignments chapter for the association of INTx signals to IRQ signals.

25.7.6 Global Timers

There are appropriate clock prescalers and synchronizers to provide a time base for the internal MPIC timers. These 16 timers are organized as 2 groups of 8 timers each. The timers can be individually programmed to generate a processor core interrupt when they count down to zero and can be used to generate regular periodic interrupts. Each timer has the following four configuration and control registers:

- Global timer current count register (GTCCR*xn*)
- Global timer base count register (GTBCR*xn*)
- Global timer vector-priority register (GTVPR*xn*)
- Global timer destination register (GTDR*xn*)

The timer frequency should be written to the TFRRxn, described in Timer frequency reporting register [Group n] (MPIC_TFRR*n*).

Timer interrupts are all edge-triggered interrupts. If a timer period expires while a previous interrupt from the same source is pending or in service, the subsequent interrupt is lost.

The timer control register (TCR) provides users with the ability to create timers larger than the 31-bit global timers. The timer frequency can also be changed by setting the appropriate TCR fields, as described in Timer control register [Group n] (MPIC_TCR*n*).

Note that when global timer interrupts are set to multicast (interrupt more that one processor by setting more than 1 P*n* bit in the GTDR*xn*), each recipient processor must acknowledge, take delivery and EOI that interrupt. That is, the interrupt is delivered to each processor as a unique copy.

25.7.7 Resets

This section describes the behavior of the MPIC at reset and the MPIC's ability to initiate processor resets.

25.7.8 Resetting the MPIC

The MPIC is reset by a device power-on reset (POR) or by software that sets GCR[RST], either of which causes the following:

- All pending and in-service interrupts are cleared.
- All interrupt mask bits are set.
- Polarity, sense, external signal, critical interrupt, and activity fields are reset to default values.
- PIR, TFRR, TCR, MERx, MSR*x*, and MSGRx0-MSGRx7 are cleared.
- MSG and timer destination fields are set.
- The interprocessor dispatch registers are cleared.
- All timer base count values are reset to zero with count inhibited.
- CTPR[TASKP] is reset to 0x000F, disabling delivery of interrupts that target *int*.
- The spurious interrupt vector resets to 0xFFFF.
- The PMMRs are reset to 0xFFFF.
- The MPIC defaults to the pass-through mode (GCR[M] = 00).
- All other registers remain at their pre-reset programmed values.

GCR[RST] is automatically cleared when the reset sequence is complete.

25.7.8.1 Processor Core Initialization

A software reset can be routed to any of the cores by writing to the processor core initialization register (PIR). This causes the assertion of the *hresetn* output signals from the MPIC. When this occurs, the corresponding CTPR also gets written to 0x000F to prevent delivery of any interrupts to *intn*.

25.7.9 Processor Core Non-maskable Interrupt Register

The processor core non-maskable interrupt (PNMIR) provides a way for software on another device to signal a non-maskable interrupt event to the processor cores by writing to PNMIR register. A *coren_nmi* signal to the cores is asserted when a one is written to the corresponding PNMIR field; these signals are held active until a zero is written to those same bits. This asserts the *core_nmi* input of the corresponding core.

25.8 Initialization/Application Information

This section contains initialization and application information for the MPIC.

25.8.1 Programming Guidelines

The following subsections contain information about programming MPIC registers.

25.8.1.1 MPIC Registers

Most MPIC control and status registers are readable and return the last value written. The exceptions to this rule are as follows:

- Interprocessor dispatch and EOI registers, which return zeros on reads.
- Activity bits (A) of the vector/priority registers reflect the status of the corresponding interrupt source.
- IACK, which returns the vector of the highest priority pending interrupt or the spurious vector (SVR[VECTOR]) if none is pending.
- Reserved fields always return 0.

When the MPIC is in mixed mode (GCR[M] = 01), the following guidelines are recommended:

- All MPIC registers must be located in a cache-inhibited, guarded area (configured through the core's MMU).
- The MPIC portion of the address map must be set up appropriately.

In addition, the following initialization sequence is recommended:

1. Write the vector, priority, and polarity values in each interrupt's vector/priority register, leaving their MSK (mask) bit set. This is required only if interrupts are used.
2. Clear CTPR (CTPR = All zeros).
3. Program the MPIC to mixed mode by setting GCR[M] = 01.
4. Clear the MSK bit in the vector/priority registers to be used.
5. Perform a software loop to clear all pending interrupts:
    - Load counter with FRR[NIRQ].
    - While counter > 0, read IACK and write EOI to guarantee all the IPR and ISR bits are cleared.
6. Set the processor core CTPR values to the desired values.

Depending on the interrupt system configuration, the MPIC may generate spurious interrupts to clear interrupts latched during power-up. A spurious or non-spurious vector is returned for an interrupt acknowledge cycle in this case.

25.8.1.2 Changing Interrupt Source Configuration

To change the vector, priority, polarity, sense, or destination of an active (unmasked) interrupt source, the following steps should be taken:

1. Mask the source using the mask (MSK) bit in the vector/priority register.
2. Wait for the activity (A) bit for that source to be cleared.
3. Make the desired changes.
4. Unmask the source.

Note that changing the destination from *int* to *cint*, *mcp*, *sie*, or IRQ_OUT_B makes the A, and PRIORITY fields meaningless; however, the MSK field does affect *cint*, *mcp*, *sie*[0:2], and IRQ_OUT_B.

25.8.1.3 Requirement

1. After issuing a reset to the core, there needs to be 15 EOIs before any new interrupt is sent to the core to make sure no interrupt is stuck in an in-service state. Note that each core has its own EOI register and this procedure must be performed for each core that has been reset.

Chapter 26
Interrupt Assignments

26.1 Introduction

This chapter describes the programmable interrupt controller (PIC) internal interrupt assignments for the T4240. These are the on-chip interrupt sources from peripheral logic within the integrated device.

26.2 Internal Interrupt Sources

Table 26-1 shows the assignments of the internal interrupt sources and how they are mapped to the registers that control them. Only the internal interrupts used are listed; that is, the numbers are not consecutive.

Table 26-1. T4240 Internal Interrupt Assignments

Internal Interrupt Number	Interrupt Source

26.3 PCI Express INTx/External Interrupt IRQ*n* Sharing

The virtual INTA signals of the three PCI Express controllers are routed to dedicated internal interrupts (24, 25, 26, and 27) in the MPIC. The other INT*x* signals are logically combined with the IRQ*n* signals so that they share the external interrupt controlled by the associated EIVPR*n* and EIDR*n* registers. The table below details the association of PCI Express virtual INT*x* signals to MPIC external interrupt IRQ*n* signals.

Table 26-3. PCI Express INTx/External Interrupt IRQn Sharing

PCI Express Controller	INTx	IRQ*n*
PCI Express 1	INTA	-
	INTB	IRQ1
	INTC	IRQ2
	INTD	IRQ3
PCI Express 2	INTA	-
	INTB	IRQ5
	INTC	IRQ6

sie1	0xF1	PCI Express controllers (all). Triggers generation of outbound MSI transaction.	
sie2	0xF2	Reserved	-

Chapter 27
Device Configuration and Pin Control

27.1 Device Configuration and Pin Control Introduction

This chapter describes the device configuration and pin control facilities of the chip.

The device configuration unit provides general purpose configuration and status for the device and the pin control block implements general purpose configuration and status registers for the device, and the logic to configure the I/O pads to operate according to the requirements of the functional components. It also controls the data path between the SoC components and the I/O pads. The pin control block consists of the pins control module, the functional I/O multiplexing, and the JTAG boundary scan logic.

27.2 Features

The device configuration unit features the following:

- Pin sampling of device configuration pins at power-on reset and a corresponding POR status register for capturing the values of these configuration pins
- Reset Configuration Word (RCW) support via a set of RCW status registers written by the Preboot Loader (PBL) during power-on or hard reset in the PBL's RCW stage
- Boot release registers(s) used for releasing cores for booting
- Register file for the Reset module including:
  - Register for initiating a device RESET_REQ_B through software
  - Set of registers for control and status of sources on the device which can drive the device's RESET_REQ_B pin
- Core and device disable registers used for gating off clocks for any IP blocks or cores which are not used at all by an application
- Set of Local I/O Device Number (LIODN) registers for programming the LIODN of legacy peripherals which did not originally contain this register

27.3 Device Configuration/Pin Control Memory Map

The table below shows the memory-mapped CCSR registers of the Device Config module and lists the offset, name, and a cross-reference to the complete description of each register. These registers only support 32-bit accesses.

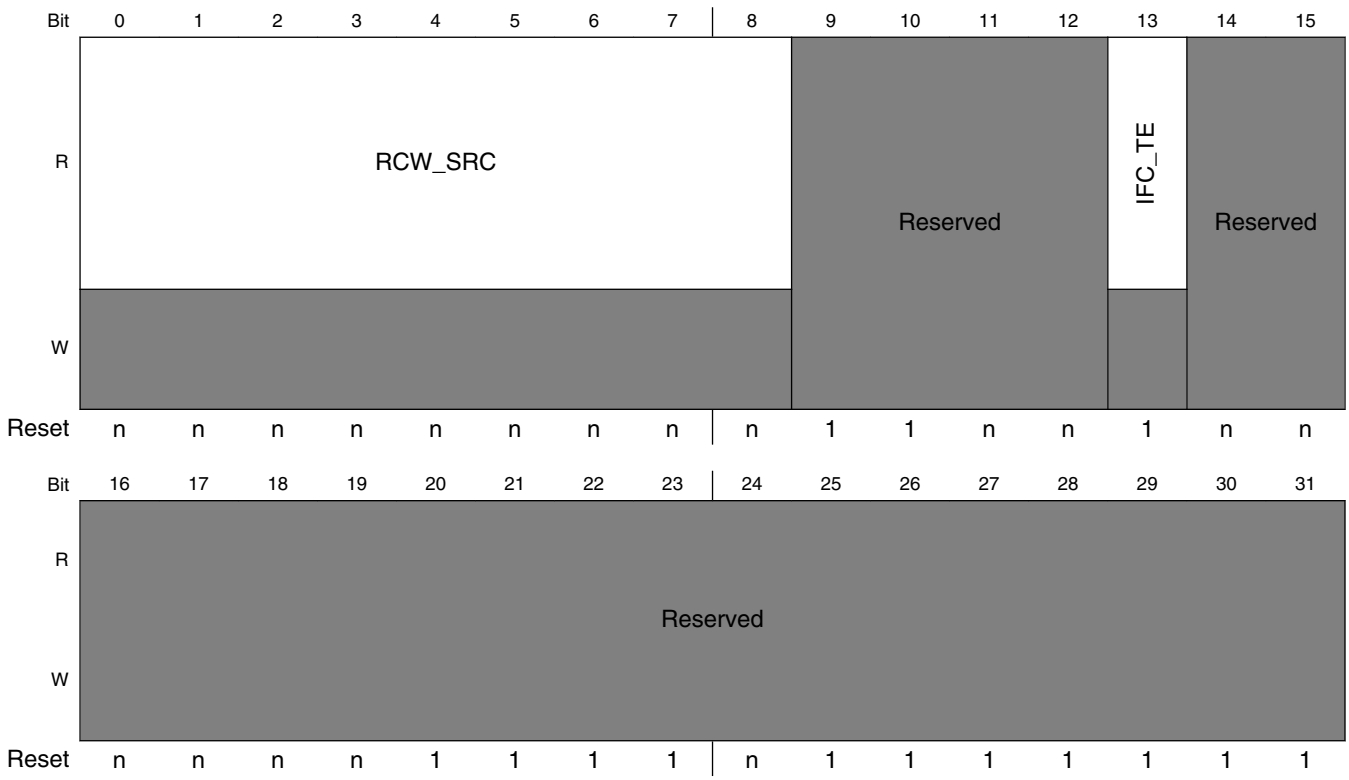
27.3.1 POR Status Register 1 (DCFG_CCSR_PORSR1)

PORSR1 captures the values of the device's POR configuration pins.

NOTE

The status of these bits depends on the sampling value driven on the pad.

Address: E_0000h base + 0h offset = E_0000h



DCFG_CCSR_PORSR1 field descriptions

Field	Description
0–8 RCW_SRC	Reset Configuration Word Source. Indicates which Flash memory contains the RCW information. Loaded with the value of cfg_rcw_src[0:8].
9–12 -	This field is reserved. Reserved
13 IFC_TE	IFC External Transceive Enable Polarity Selection. Loaded with the value of the cfg_ifc_te pin at power-on reset. 0 Transceiver Enable polarity is configured active high 1 Transceiver Enable polarity is configured active low
14–31 -	This field is reserved. Reserved

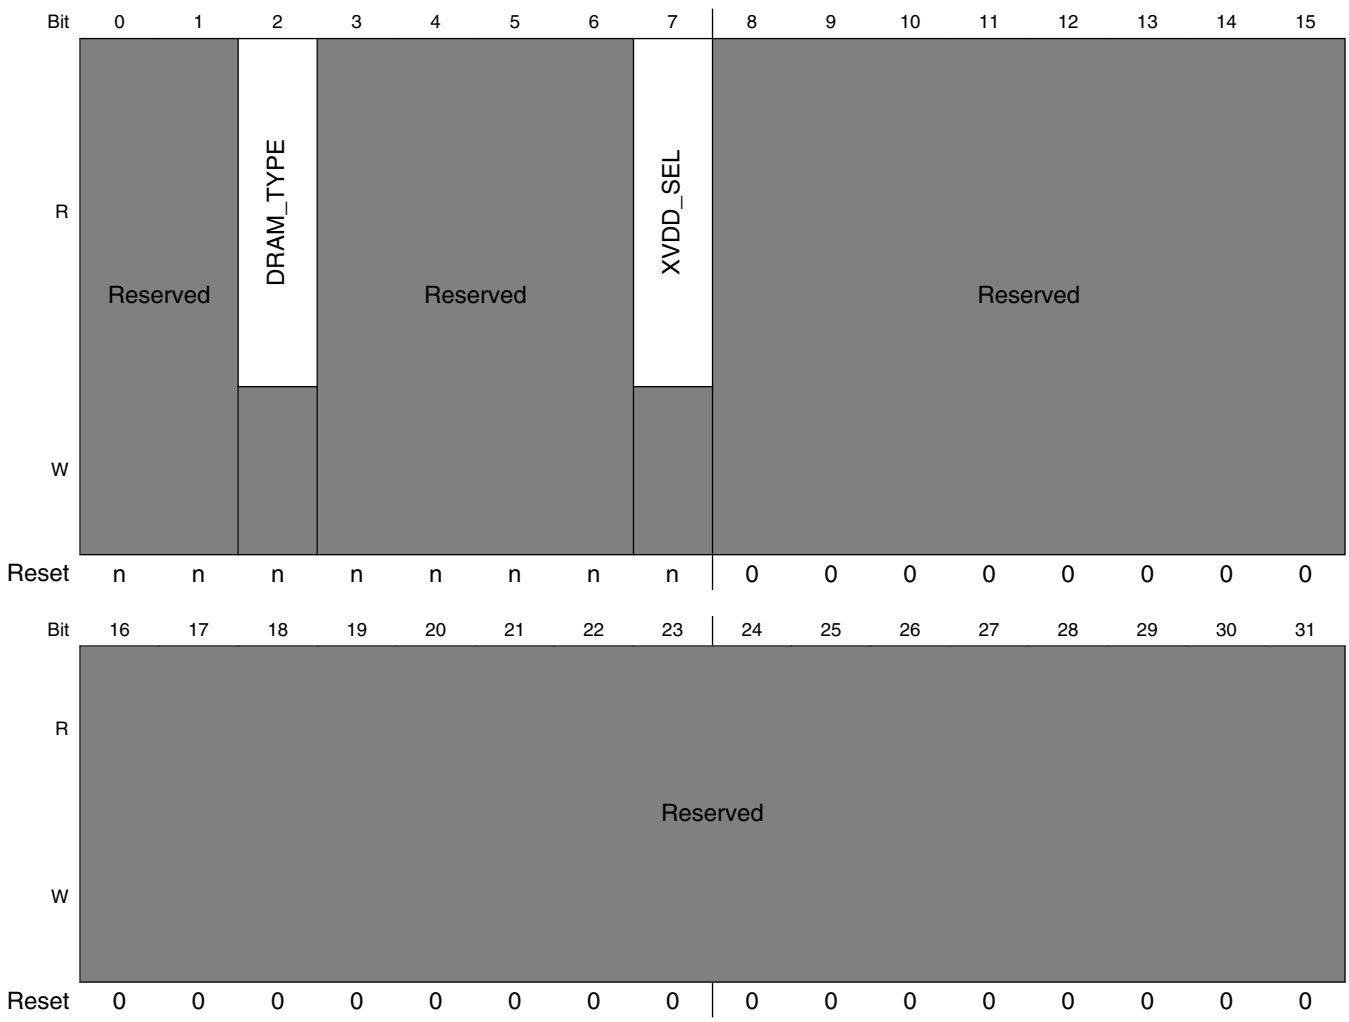
27.3.2 POR Status Register 2 (DCFG_CCSR_PORSR2)

PORSR2 captures the values of the device's POR configuration pins.

NOTE

The status of these bits depends on the sampling value driven on the pad.

Address: E_0000h base + 4h offset = E_0004h



DCFG_CCSR_PORSR2 field descriptions

Field	Description
0–1 -	This field is reserved. reserved
2 DRAM_TYPE	DRAM Type Selector.

Table continues on the next page...

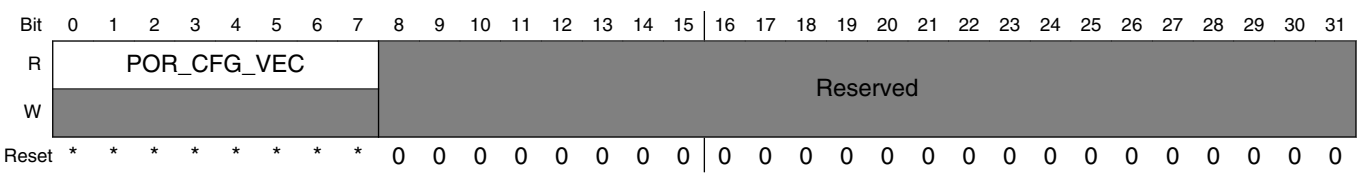
Field	Description
	0 DDR3 technology (1.5 V) 1 DDR3L technology (1.35 V)
3–6 -	This field is reserved. Reserved
7 XVDD_SEL	SerDes XVDD voltage select n 1.5 V 1 1.35 V
8–31 -	This field is reserved. Reserved

27.3.3 General-Purpose POR Configuration Register (DCFG_CCSR_GPPORCR1)

GPPORCR1 stores the value sampled from the integrated Flash controller address/data signals, IFC_AD[0:7], using sampling logic similar to that for the configuration pins It is provided for customer use and always samples 8-bits, independent of the width of the chip's flash controller's LAD bus. Software can use this value to inform the operating system about initial system configuration. Typical interpretations include circuit board type, board ID number, or a list of available peripherals.

Address: E_0000h base + 20h offset = E_0020h



* Notes:
- POR_CFG_VEC field: Reset value supplied by cfg_gpinput[0:7].

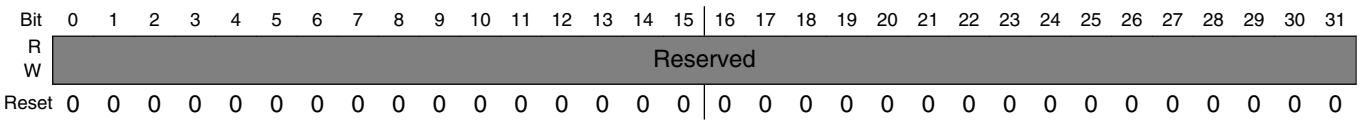
DCFG_CCSR_GPPORCR1 field descriptions

Field	Description
0–7 POR_CFG_VEC	General-purpose POR configuration vector sampled from integrated Flash controller address/data signals, IFC_AD[0:7] signals (uppermost 8-bits) at the negation of PORESET. **NOTE:** Reset value supplied by cfg_gpinput[0:7].
8–31 -	This field is reserved. Reserved

27.3.4 General-Purpose POR Configuration Register (DCFG_CCSR_GPPORCR2)

This register is reserved for factory use.

Address: E_0000h base + 24h offset = E_0024h



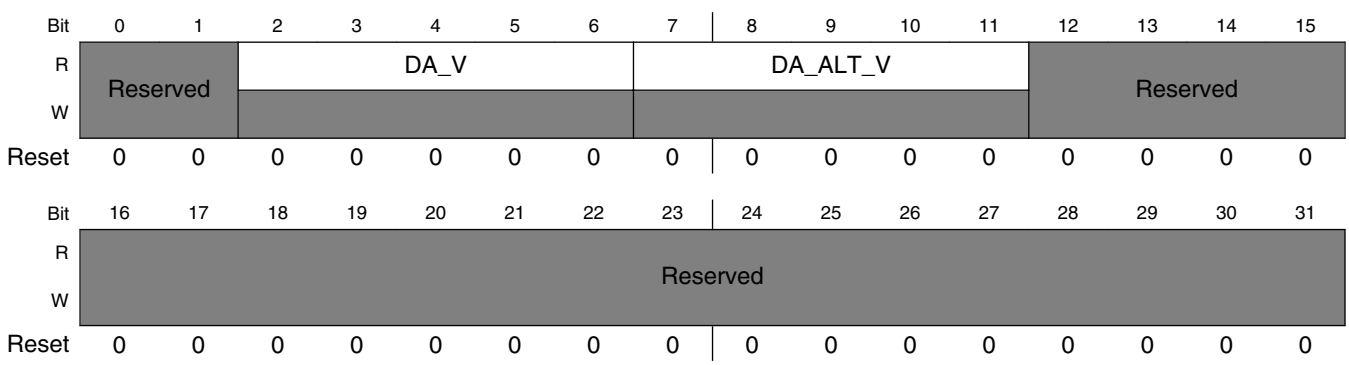
DCFG_CCSR_GPPORCR2 field descriptions

Field	Description
0–31 -	This field is reserved. Reserved

27.3.5 Fuse Status Register (DCFG_CCSR_FUSESR)

The fuse status register provides the values from on-chip voltage ID efuses programmed at the factory. These values define the voltage requirements for the chip. Boot software must read FUSESR and translate the values into the appropriate commands to set the voltage output value of an external voltage regulator.

Address: E_0000h base + 28h offset = E_0028h



DCFG_CCSR_FUSESR field descriptions

Field	Description
0–1 -	This field is reserved. Reserved

Table continues on the next page...

DCFG_CCSR_FUSESR field descriptions (continued)

Field	Description
2–6 DA_V	VDD voltage. This is the minimum voltage required to reach the frequency specified. Note that most of the possible voltages levels will never be specified by the factory. **NOTE:** This field is ignored if DA_ALT_V is not 5'b00000. Voltage ID settings changed to reserved will not be used. 00000 unused (default) 00001 0.9875 V 00010 0.9750 V 00011 0.9625 V 00100 0.9500 V 00101 0.9375 V (option available only on parts with max CPU speed of 1333MHz) 00110 0.9250 V (option available only on parts with max CPU speed of 1333MHz) 00111 0.9125 V (option available only on parts with max CPU speed of 1333MHz) 01000 0.9000 V (option available only on parts with max CPU speed of 1333MHz) 01001 Reserved 01010 Reserved 01011 Reserved 01100 Reserved 01101 Reserved 01110 Reserved 01111 Reserved 10000 1.0000 V 10001 1.0125 V 10010 1.0250 V 10011 1.0375 V 10100 1.0500 V 10101 Reserved 10110 Reserved 10111 Reserved 11000 Reserved 11001 Reserved 11010 Reserved 11011 Reserved 11100 Reserved 11101 Reserved 11110 Reserved 11111 Reserved
7–11 DA_ALT_V	VDD alternate voltage. This is a secondary voltage field for VDD. The field encodings are the same as DA_V . **NOTE:** If this field is not all zeros then the correct VID value should be read from here, other wise the correct VID value should be read from DA_V.
12–31 -	This field is reserved. Reserved

27.3.6 Device Disable Register 1 (DCFG_CCSR_DEVDISR1)

A given application may not use all the peripherals on the device. In this case, it may be desirable to disable unused peripherals. DEVDISR1 provides a mechanism for gating clocks to IP blocks that are not used when running an application.

NOTE

IP blocks disabled by setting the corresponding bit in the DEVDISR1 register must not be re-enabled.

Address: E_0000h base + 70h offset = E_0070h

27.3.8 Device Disable Register 3 (DCFG_CCSR_DEVDISR3)

A given application may not use all the peripherals on the device. In this case, it may be desirable to disable unused peripherals. DEVDISR3 provides a mechanism for gating clocks to IP blocks that are not used when running an application.

NOTE

IP Blocks disabled by setting the corresponding bit in the DEVDISR3 register must not be re-enabled.

Address: E_0000h base + 78h offset = E_0078h

27.3.11 Core Disable Register (DCFG_CCSR_COREDISR)

COREDISR provides a mechanism for gating clocks to any cores on the device that are not used when running an application.

COREDISR register should only be configured in the following conditions:

- Before system ready, COREDISR register can be programmed by the external debugger or Pre-Boot Initialization.
- After system ready, a COREDISR register bit can be programmed for the corresponding core by the external debugger or embedded software while the core is in boot-holdoff mode.

NOTE

Cores that have an interrupt pending will not be disabled by COREDISR until the interrupt is cleared.

NOTE

Cores disabled by setting the corresponding bit in the COREDISR register must not be re-enabled via software. The only supported mechanism for re-enabling a Core disabled in this manner is via power-on, hard reset, or core reset.

NOTE

The LSB, bit 31, is associated with Core 0.

Address: E_0000h base + 94h offset = E_0094h

27.3.12 Processor Version Register (DCFG_CCSR_PVR)

The PVR contains the processor version number. It is a memory-mapped copy of the PVR in core 0 (and is therefore accessible to external devices).

Address: E_0000h base + A0h offset = E_00A0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

28–29 -	This field is reserved. Reserved
30 RESET_REQ	Hardware reset request. External hardware may then decide to issue the desired reset signal (PORESET_B or HRESET_B) to the device. 0 No reset request initiated. 1 Hardware reset request initiated by software.
31 -	This field is reserved. Reserved

27.3.15 Reset Request Preboot Loader Status Register (DCFG_CCSR_RSTRQPBLSR)

The RSTRQPBLSR contains status bits to record the reasons for RESET_REQ_B assertion. It excludes core watchdog timer sources.

NOTE

This register's code is valid only when RSTRQSR[PBL_RR] is set.

NOTE

ECC errors detected during NAND flash loading during RCW and PBI phases are reported in RSTRQSR[IFC_RR]. See the description of this bit for more details.

Address: E_0000h base + B4h offset = E_00B4h

27.3.17 Reset Request Status Register (DCFG_CCSR_RSTRQSR1)

The RSTRQSR contains status bits to record the reasons for RESET_REQ_B assertion. The bits here are set independent of the RSTRQMR. This means if a reset reason occurs and is masked by RSTRQMR, it will still be recorded in RSTRQSR. It excludes core watchdog timer sources (see Reset Request WDT Status Register (DCFG_CCSR_RSTRQWDTSR)).

NOTE

For the different sources captured in this register, some of these can be serviced with either PORESET_B or HRESET_B and some of these must be serviced with PORESET_B only.

Address: E_0000h base + C8h offset = E_00C8h

27.3.20 Boot Release Register (DCFG_CCSR_BRR)

The BRR contains control bits for enabling boot for each core. On exiting HRESET or PORESET, the RCW BOOT_HO field optionally allows for logical core 0 to be released for booting or to remain in boot holdoff. All other cores remain in boot holdoff until their corresponding bit is set.

NOTE

The LSB, bit 31, is associated with Core 0.

NOTE

If a bit is changed from 1 to 0 outside of warm reset (at runtime), results are boundedly undefined for that core.

Address: E_0000h base + E4h offset = E_00E4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

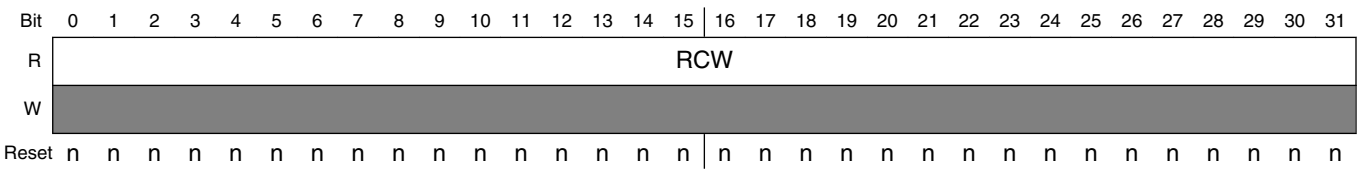
27.3.21 Reset Control Word Status Register n (DCFG_CCSR_RCWSR*n*)

RCWSR contains the Reset Configuration Word (RCW) information written with values read from flash memory by the device at power-on reset and read-only upon exiting reset.

NOTE

After a PORESET, RCWSRn registers can be read. If RSTRQSR[IFC_RR] is set after a PORESET and RCWSRn does not contain RCW values, then the failure occurred during RCW. If the bit is set and RCWSRn contains valid values, then the failure occurred during PBI.

Address: E_0000h base + 100h offset + (4d × i), where i=0d to 15d



DCFG_CCSR_RCWSR*n* field descriptions

Field	Description
0–31 RCW	Read-only value of RCW bits (n-1)*32 : (n*32)-1 loaded in power-on reset's Reset Configuration stage.

27.3.22 Core Reset Status Register n (DCFG_CCSR_CRSTSR*n*)

The CRSTSRn contains the reset status bits for each thread on the device.

In this register (one per physical core):

- Bits 0-23 reflect per-thread conditions for this specific core
- Bits 24-31 reflect device conditions which in turn affect this specific core

NOTE

The number of CRSTSRn registers is determined by the number of physical cores.

Reset of this Register

A power-on reset of the device causes the following to occur:

- RST_PORST is set
- All other bits are cleared

A hard reset of the device causes the following to occur:

- RST_PORST remains unchanged (PORST resources are not affected by Hard Reset)
- RST_HRST is set
- All other bits are cleared

If an application prefers that RST_PORST is not set after hard reset, then a write-1-clear must be done to CRSTSRn[RST_PORST] upon exiting power-on reset.

Ready Bit Functionality

This bit is cleared on a device power-on or hard reset. Upon completion of power-on or hard reset processing, this bit may be automatically set for a core if none of the conditions specified in the READY bit definition are true.

Address: E_0000h base + 400h offset + (4d × i), where i=0d to 11d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

27.3.30 QMBM Warm Reset Control Register (DCFG_CCSR_QMBM_WARMRST)

Software writes bit location to initiate warm reset to specific device.

Software polls bit location to know when warm reset has completed.

- Before initiating warm reset software must:
  - Shut down software portal interfaces (stop de-queueing new work from QMAN and stops enqueueing new work to QMAN).
  - Quiesce FMAN
- After setting the warm reset bits software must:
  - Poll QMBM_WARMRST to know when warm reset has completed.
  - Re-initialize QMAN/BMAN. This may include clearing out any history it has of QMAN portal ring state as well as forgetting about buffers it may not have previously released.
  - Restart FMAN.

See the QorIQ Data Path Acceleration Architecture (DPAA) Reference Manual for more details.

Address: E_0000h base + A00h offset = E_0A00h

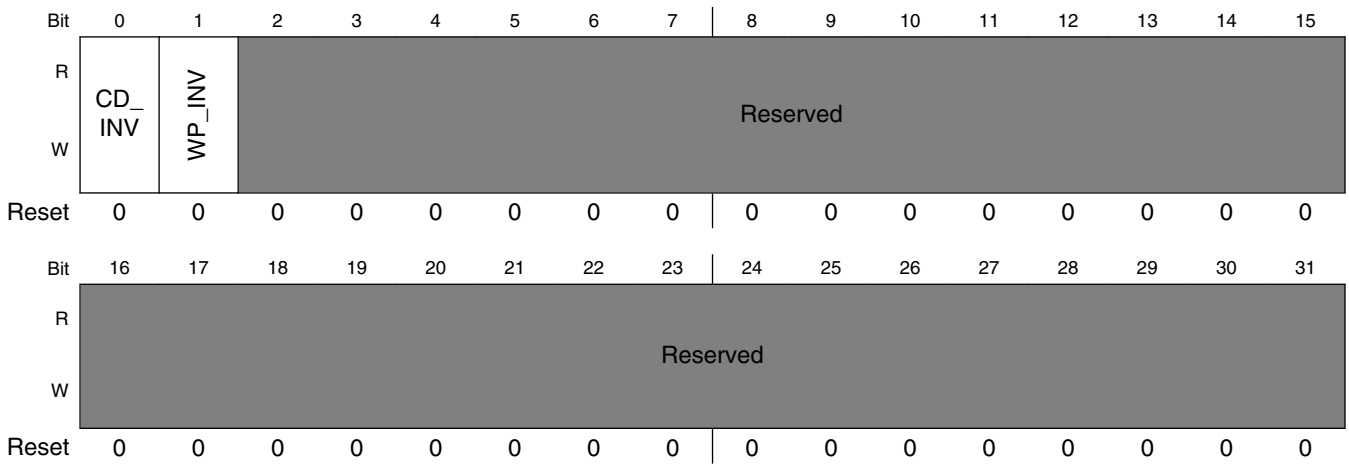
31 IFC_CLK2_DIS	IFC clock 2 disable. The output is not driven and in a high impedance state, when disabled. 0 IFC_CLK2 is enabled 1 IFC_CLK2 is disabled

27.3.33 eSDHC Polarity Configuration Register (DCFG_CCSR_SDHCPCR)

The SDHCPCR allows for specific polarity control of the eSDHC input signals.

Address: E_0000h base + E80h offset = E_0E80h



DCFG_CCSR_SDHCPCR field descriptions

Field	Description
0 CD_INV	eSDHC Card Detect Invert 0 SDHC_CD signal to the eSDHC module has the same polarity as the I/O Pin. 1 SDHC_CD signal to the eSDHC module has inverted polarity in relation to the I/O Pin.
1 WP_INV	eSDHC Write Protect Invert 0 SDHC_WP signal to the eSDHC module has the same polarity as the I/O Pin. 1 SDHC_WP signal to the eSDHC module has inverted polarity in relation to the I/O Pin.
2–31 -	This field is reserved. Reserved

Chapter 28
General Purpose I/O (GPIO)

28.1 GPIO overview

This chapter describes the general-purpose I/O (GPIO) module, including signal descriptions, register settings and interrupt capabilities.

This figure shows the block diagram for the GPIO module.

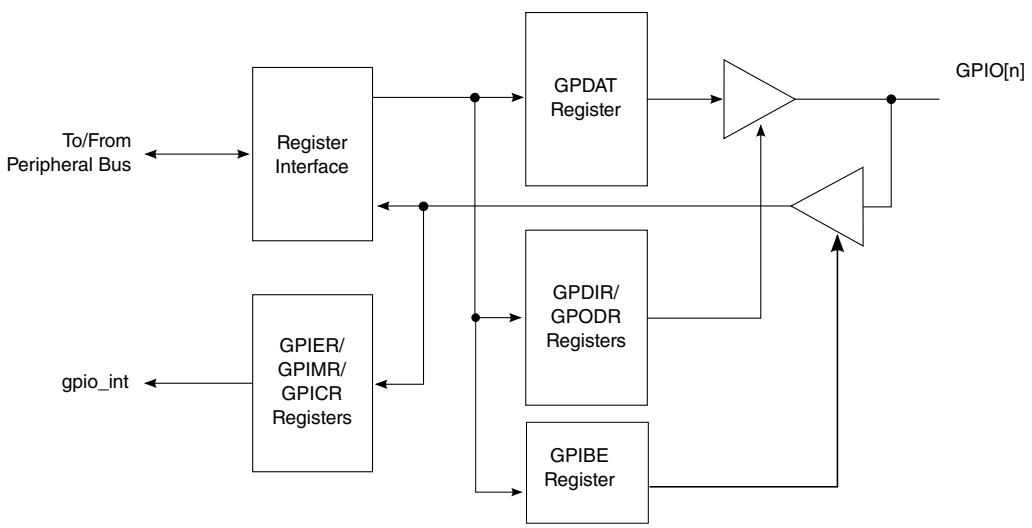


Figure 28-1. GPIO module block diagram

In general, the GPIO module supports up to 32 general-purpose I/O ports. Each port can be configured as an input or as an output. However, some implementations may restrict specific ports to input-only, output-only, or reserved (unimplemented). See The GPIO module as implemented on the chip for more information. If a port is configured as an input, it can optionally generate an interrupt upon detection of a change. If a port is configured as an output, it can be individually configured as an open-drain or a fully active output.

28.1.1 The GPIO module as implemented on the chip

This section provides details about how the GPIO module is integrated into this chip.

Table 28-1. GPIO module as implemented on chip

Module name	Module base address	Supported[1] ports	Number of ports
GPIO1	0x13_0000	9:31	23
GPIO2	0x13_1000	0:23, 25:31	31
GPIO3	0x13_2000	0:31	32
GPIO4	0x13_3000	0:9	10

1. GPIO signals are typically multiplexed with other signals. “Supported” in this context means that any signal multiplexing configuration has selected GPIO functionality. See the Signals chapter for signal multiplexing details.

28.2 GPIO features summary

The GPIO unit includes the following features:

- Supports 32 general-purpose input/output ports
- All signals are high-impedance during reset
- Open-drain capability on all ports
- All ports can optionally generate an interrupt upon changing their state
- Ports may be multiplexed with other functional signals

28.3 GPIO signal descriptions

This table provides detailed descriptions of the external GPIO signals. Note that depending on the signal multiplexing, some signals may not be available.

Table 28-2. GPIO external signals-detailed signal descriptions

Signal	I/O	Description	
GPIO*n*[0:31]	I/O	General Purpose I/O. Each signal can be individually set to act as input or output, according to application needs. Some implementations may restrict specific ports to input-only, output-only, or reserved (unimplemented). See The GPIO module as implemented on the chip for more information.	
		State Meaning	Asserted/Negated-Defined per application.
		Timing	Assertion/Negation-Inputs can be asserted completely asynchronously.

Table 28-2. GPIO external signals-detailed signal descriptions

Signal	I/O	Description	
			Outputs are asynchronous to any externally visible clock.

28.4 GPIO Memory Map/Register Definition

The programmable register map for the GPIO module occupies 28 bytes of memory-mapped space. The full register address is comprised of the base address (specified in CCSR address space) plus the module base address, plus the specific register's offset within the module. The table below shows the memory map for the GPIO module.

All GPIO registers are 32 bits wide located on 32-bit address boundaries. Note that reading undefined portions of the memory map returns all zeros and writing has no effect.

GPIO memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
13_0000	GPIO direction register (GPIO1_GPDIR)	32	R/W	0000_0000h	28.4.1/2496
13_0004	GPIO open drain register (GPIO1_GPODR)	32	R/W	0000_0000h	28.4.2/2496
13_0008	GPIO data register (GPIO1_GPDAT)	32	R/W	0000_0000h	28.4.3/2497
13_000C	GPIO interrupt event register (GPIO1_GPIER)	32	w1c	See section	28.4.4/2497
13_0010	GPIO interrupt mask register (GPIO1_GPIMR)	32	R/W	0000_0000h	28.4.5/2498
13_0014	GPIO interrupt control register (GPIO1_GPICR)	32	R/W	0000_0000h	28.4.6/2499
13_0018	GPIO Input Buffer Enable Register (GPIO1_GPIBE)	32	R/W	0000_0000h	28.4.7/2499
13_1000	GPIO direction register (GPIO2_GPDIR)	32	R/W	0000_0000h	28.4.1/2496
13_1004	GPIO open drain register (GPIO2_GPODR)	32	R/W	0000_0000h	28.4.2/2496
13_1008	GPIO data register (GPIO2_GPDAT)	32	R/W	0000_0000h	28.4.3/2497
13_100C	GPIO interrupt event register (GPIO2_GPIER)	32	w1c	See section	28.4.4/2497
13_1010	GPIO interrupt mask register (GPIO2_GPIMR)	32	R/W	0000_0000h	28.4.5/2498
13_1014	GPIO interrupt control register (GPIO2_GPICR)	32	R/W	0000_0000h	28.4.6/2499
13_1018	GPIO Input Buffer Enable Register (GPIO2_GPIBE)	32	R/W	0000_0000h	28.4.7/2499
13_2000	GPIO direction register (GPIO3_GPDIR)	32	R/W	0000_0000h	28.4.1/2496
13_2004	GPIO open drain register (GPIO3_GPODR)	32	R/W	0000_0000h	28.4.2/2496
13_2008	GPIO data register (GPIO3_GPDAT)	32	R/W	0000_0000h	28.4.3/2497
13_200C	GPIO interrupt event register (GPIO3_GPIER)	32	w1c	See section	28.4.4/2497
13_2010	GPIO interrupt mask register (GPIO3_GPIMR)	32	R/W	0000_0000h	28.4.5/2498
13_2014	GPIO interrupt control register (GPIO3_GPICR)	32	R/W	0000_0000h	28.4.6/2499
13_2018	GPIO Input Buffer Enable Register (GPIO3_GPIBE)	32	R/W	0000_0000h	28.4.7/2499

GPIO memory map (continued)

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
13_3000	GPIO direction register (GPIO4_GPDIR)	32	R/W	0000_0000h	28.4.1/2496
13_3004	GPIO open drain register (GPIO4_GPODR)	32	R/W	0000_0000h	28.4.2/2496
13_3008	GPIO data register (GPIO4_GPDAT)	32	R/W	0000_0000h	28.4.3/2497
13_300C	GPIO interrupt event register (GPIO4_GPIER)	32	w1c	See section	28.4.4/2497
13_3010	GPIO interrupt mask register (GPIO4_GPIMR)	32	R/W	0000_0000h	28.4.5/2498
13_3014	GPIO interrupt control register (GPIO4_GPICR)	32	R/W	0000_0000h	28.4.6/2499
13_3018	GPIO Input Buffer Enable Register (GPIO4_GPIBE)	32	R/W	0000_0000h	28.4.7/2499

28.4.1 GPIO direction register (GPIOx_GPDIR)

The GPIO direction register (GPDIR) defines the direction of the individual ports.

Address: Base address + 0h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	DRn																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPIOx_GPDIR field descriptions

Field	Description
0–31 DRn	Direction. Indicates whether a pin is used as an input or an output. 0 The corresponding pin is an input. 1 The corresponding pin is an output.

28.4.2 GPIO open drain register (GPIOx_GPODR)

The GPIO open drain register (GPODR) defines the way individual ports drive their output.

Address: Base address + 4h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	ODn																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPIOx_GPODR field descriptions

Field	Description
0–31 ODn	Open drain configuration. Indicates whether a signal is actively driven as an output or is an open-drain driver. This register has no effect on signals programmed as inputs in GPDIR. 0 The corresponding signal is actively driven as an output. 1 The corresponding signal is an open-drain driver. As an output, the signal is driven active-low, otherwise it is not driven (high impedance).

28.4.3 GPIO data register (GPIOx_GPDAT)

The GPIO data register (GPDAT) carries the data in/out for the individual ports.

Address: Base address + 8h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Dn																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPIOx_GPDAT field descriptions

Field	Description
0–31 Dn	Data. Writes to this register latches the data which is presented on the external pins provided the corresponding GPDIR bit is configured as an output. When GPDIR is in output mode, GPDAT read operation returns data at pin. When GPDIR is in input mode, GPDAT read operation returns state of the port.

28.4.4 GPIO interrupt event register (GPIOx_GPIER)

The GPIO interrupt event register (GPIER) carries information of the events that caused an interrupt. Each bit in GPIER, corresponds to an interrupt source. GPIER bits are cleared by writing ones. However, writing zero has no effect.

NOTE

Some implementations may ignore the interrupt mask as configured in GPIMR. In these implementations, a GPIER bit can be set even though the associated interrupt is masked. See The GPIO module as implemented on the chip for more information.

Address: Base address + Ch offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	EVn																															
W	w1c																															
Reset	n*	n*	n*	n*	n*	n*	n*	n*	n*	n*	n*	n*	n*	n*	n*	n*	n*	n*	n*	n*	n*	n*	n*	n*	n*	n*	n*	n*	n*	n*	n*	n*

* Notes:
- EVn field: Undefined. User should write 1s to clear before using.

GPIOx_GPIER field descriptions

Field	Description
0–31 EVn	Interrupt events. Indicates whether an interrupt event occurred on the corresponding GPIO signal. 0 No interrupt event occurred on the corresponding GPIO signal. 1 An interrupt event occurred on the corresponding GPIO signal.

28.4.5 GPIO interrupt mask register (GPIOx_GPIMR)

The GPIO interrupt mask register (GPIMR) defines the interrupt masking for the individual ports. When a masked interrupt request occurs, the corresponding GPIER bit is set, regardless of the GPIMR state. When one or more non-masked interrupt events occur, the GPIO module issues an interrupt to the interrupt controller.

Address: Base address + 10h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	IMn																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPIOx_GPIMR field descriptions

Field	Description
0–31 IMn	Interrupt mask. Indicates whether an interrupt event is masked or not masked for the corresponding GPIO signal. 0 The input interrupt signal is masked (disabled). 1 The input interrupt signal is not masked (enabled).

28.4.6 GPIO interrupt control register (GPIOx_GPICR)

The GPIO interrupt control register (GPICR) determines whether the corresponding port line asserts an interrupt request upon either a high-to-low change or any change on the state of the signal.

Address: Base address + 14h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	EDn																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPIOx_GPICR field descriptions

Field	Description
0–31 EDn	Edge detection mode. The corresponding port line asserts an interrupt request according to the following: 0 Any change on the state of the port generates an interrupt request. 1 High-to-low change on the port generates an interrupt request.

28.4.7 GPIO Input Buffer Enable Register (GPIOx_GPIBE)

The GPIO Input Buffer Enable register is used to control the input enable of each individual GPIO port. When an individual GPIO port's direction is set to input (GPIO_GPDIR[DRn=0]), the associated input enable must be set (GPIOxGPIE[IEn]=1) to propagate the port value to the GPIO Data Register. When a port's input enable is disabled, the port value does not propagate to the GPIO Data Register. Unused GPIO ports may be non-connected on the board if their "direction" and "input enable" are configured for "input" (GPIO_GPDIR[DRn=0]) and "disabled" (GPIBE[IEn=0]) respectively, which is the default configuration (based on GPIO input signal GPIBE_RESET_VAL[31:0] tied to 0x0000_0000 which sets the reset value of this register).

Address: Base address + 18h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	IBEn																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPIOx_GPIBE field descriptions

Field	Description
0–31 IBEn	Input Enable. Indicates whether a GPIO port's input is enabled. 0 The corresponding port input is disabled. 1 The corresponding port input is enabled.

Chapter 29
Run Control and Power Management (RCPM)

29.1 Introduction

This chapter provides the specification and programming model for the RCPM .

29.1.1 General Overview

The Run Control and Power Management (RCPM) module performs all device-level tasks associated with device run control and power management.

The RCPM module communicates with embedded cores and coherency modules extensively to achieve both device run control and power management function.

This document focuses solely on the mechanisms of the RCPM module that control the power managment aspects of the device and each of the processor clusters/cores/threads within the device.

Dynamic power management minimizes power consumption when a block is idle. Hypervisor software running on a master core can access RCPM memory-mapped registers (TPH10SETR, PCPH15SETR, PCPH20SETR, and PCPH30SETR, and POWMGTCSR) to put specific thread/core in PH10/PH15/PH20/PH30 state or put the device in LPM10/LPM20 state. The RCPM module supports several wake up sources through internal timers and internal and external interrupts.

29.1.2 The RCPM module as implemented on the chip

This section provides details about how the RCPM module is integrated into this chip.

NOTE

In this chapter, the mapping of the referenced RCPM core *n* to the T4240 e6500 core threads is as follows:

Table 29-1. T4240 RCPM Core *n* Mapping

RCPM Core n	T4240 Core/Thread	RCPM Core n	T4240 Core/Thread	RCPM Core n	T4240 Core/Thread
0	e6500 core 0, thread 0	8	e6500 core 4, thread 0	16	e6500 core 8, thread 0
1	e6500 core 0, thread 1	9	e6500 core 4, thread 1	17	e6500 core 8, thread 1
2	e6500 core 1, thread 0	10	e6500 core 5, thread 0	18	e6500 core 9, thread 0
3	e6500 core 1, thread 1	11	e6500 core 5, thread 1	19	e6500 core 9, thread 1
4	e6500 core 2, thread 0	12	e6500 core 6, thread 0	20	e6500 core 10, thread 0
5	e6500 core 2, thread 1	13	e6500 core 6, thread 1	21	e6500 core 10, thread 1
6	e6500 core 3, thread 0	14	e6500 core 7, thread 0	22	e6500 core 11, thread 0
7	e6500 core 3, thread 1	15	e6500 core 7, thread 1	23	e6500 core 11, thread 1

References to other RCPM threads and cores should be disregarded.

T4160 has 8 dual threaded e6500 cores; references to e6500 core 8 through 11 should be disregarded for T4160. T4080 has 4 dual threaded e6500 cores; references to e6500 core 4 through 11 should be disregarded for T4080.

29.1.3 Power Management Features

Lists features of power management:

- Software controlled power management, which minimizes power consumption of blocks when they are idle.
- Software-controlled power management states
  - Per thread-PH10
  - Per physical core-PH15 /PH20/PH30
  - Per cluster-PCL10
  - Per device-LPM10/LPM20
- Supports interrupt controller interrupt-based wake-up and the following wake-up sources:
  - Wake on internal timer event.
  - Wake on internal and external interrupt event.
- Enter software-controlled power state through core or external master (for example, PCI Express).
- Thread Power Management:
  - Independent power management control of each thread
  - PH10 state where:
    - Instruction fetching is suspended
    - All previously fetched instructions are completed
    - Thread is halted but clocks remain active

    - Entry into Thread Power Management states via:
        - RCPM TPH10SETR for request to enter the thread's PH10 State
        - Event Processing Unit (EPU) triggering to enter the thread's PH10 state
        - Device pin assertion to enter the thread's PH10 state
    - Independent wake up from per thread:
        - Set RCPM TPH10CLRR to clear the thread PH10 request.
        - Unmasked interrupt request
        - Unmasked critical interrupt
        - Unmasked external machine check
        - NMI
        - Core wake up event
        - Debug interrupt
        - Core hard reset
        - Core debug halt request
- Core Power Management:
    - Independent power management control of each core
    - PH15 state where:
        - Entry into PH15 core power management state via RCPM PCPH15SETR for request to enter the core's PH15 state. PH15 is also triggered when MPIC requests to place core in warm reset or core is disabled by COREDISR register.
        - Entered from both threads of the core in PH10 state.
        - PH15 state wake up source is captured in Table 29-4
        - Core caches (for the core has PH15 request pending) must be explicitly flushed before entering PH15 to maintain cache coherence.
        - Clocks are gated off
    - PH20 state where:
        - Entry into PH20 core power management state via RCPM PCPH20SETR for request to enter the core's PH20 state.
    - Independent wake up from per thread:
        - Unmasked interrupt request
        - Unmasked critical interrupt
        - Debug interrupt
    - PH30 state where:
        - Entry into PH30 core power management state via RCPM PCPH30SETR for request to enter the core's PH30 state.
        - Interrupt is ignored for core in PH30 state.
        - No state is retained.
        - The only wake up method is through core warm reset.
- Cluster Power Management:
    - PCL10 state where:

        - Clock distribution is inhibited to cluster functional unit.
        - T4240 Rev 2: Prior to entering PCL10 state, all cores in cluster should be placed in PH20 state.
        - The L2 cache no longer continues to participate in snooping activities, software should always flush, then invalidate the L2 cache prior to intiating PCL10 state to ensure that any modified data is written out to backing store.
    - The entry and exit mode of cluster power management is captured in Table 29-5
- Device Power Management:
    - LPM10 State where:
        - Not all cores are in Run (PH00) state.
    - LPM20 state where:
        - All cores are in PH20 state.
        - T4240 Rev 2: Cluster is in PCL10 state.
        - Platform clock is disabled.
        - Entry into LPM20 via setting POWMGTCSR[LPM20_REQ]
        - LPM20 state wake up source is captured in Table 29-6
    - Independent Device wake up from:
        - Unmasked interrupt
        - Unmasked critical interrupt
        - Unmasked machine check
        - Unmasked NMI. Note that for LPM20 mode, wake up through NMI is not supported.

29.1.4 Modes of Operation

The RCPM Module supports the following Power Management modes of operation:

- Reset modes
- Power management states
    - Core(s) Full On state
    - Thread(s) in PH10 state
    - Core(s) in PH15 state
    - Core(s) in PH20 state
    - Core(s) in PH30 (off) state
    - Cluster(s) in PCL10 state
    - Device Full On state
    - Device in LPM10 state
    - Device in LPM20 state

The different states available are summarized in Table 29-3 through Table 29-6.

29.1.4.1 Mode Summary - Core & Device Levels

Table 29-2 summarizes the core RCPM modes.

Table 29-2. Core RCPM Mode Summary for Power Management

Core Mode Name	Type	Resumable	Services Snoops	Device Clocks	Core Clocks	State Retained	Book E Core State Entry	Description
Power Management States								
PH10	PM	Y	Y	Y	Y	All	Seq: • Full On -> Core Halted	The *core* referred to is currently in the PH10 state.
PH15	PM	Y	N	Y	N	Latches, GPR, FPR, VPR, L1/L2 TLB, BTB, L1 Icache and Dcache tags and locks	Seq: • Full On -> Core Halted • Core Halted -> Core Stopped	The core referred to is currently in the PH15 state.
PH20	PM	Y	N	Y	N	Latches, GPR, FPR, VPR, L1/L2 TLB, BTB, L1 Icache and Dcache tags and locks	Seq: • Full On -> Core Halted • Core Halted -> Core Stopped	
PH30	PM	N	N	Y	N	None	Seq: • Full On -> Core Halted • Core Halted -> Core Stopped	PH 30 state can be exited by asserting HRESET_B. PH30 state can also be exited via core warm reset by writing to MPIC PIR.

Table 29-3 summarizes the device RCPM modes.

Table 29-3. Device RCPM Mode Summary for Power Management

Device Mode Name	Type	Resumable	Services Snoops	Device Clocks	Core Clocks	Book E Core State Entry	Description
Power Management States							
LPM10	PM	Y	N/A	Y	N/A	Seq: • Full On -> Core Halted • Core Halted -> Core Stopped	
LPM20	PM	Y	N	N	N	Seq: • Full On -> Core Halted • Core Halted -> Core Stopped	Platform clock to all IP are gated off. Core Timebase is turned-off.

29.1.5 Modes Entry & Exit for Power Management

Table 29-4 summarizes the entry and exit for the core power management modes.

Table 29-4. Core RCPM Mode: Entry and Exit for Power Management

Device Mode Name	Type	Entry via ...	Exit via ...	Book E Core State Entry
Power Management States				

PH10	PM	• Hypervisor set corresponding bit in RCPM/ TPH10SETR[T*] to 1	• Set RCPM/TPH10CLRR[T*]
			• Interrupt without RCPM/TPMIMR masking.
			• Critical interrupt without RCPM/TPMCIMR masking.
			• External machine check without RCPM/TPMMCMR masking.
			• NMI without RCPM/TPMNMIMR masking.
			• The following core wake up events will unconditionally wake up core from power management state via core_wakeup_req signal. :
			  • Decrementer exception (qualified by MSR[EE] | MSR[GS])
			  • FIT exception (qualified by MSR[EE] | MSR[GS])
			  • Watchdog exception (qualified by MSR[CE] | MSR[GS])
			  • Performance interrupt (qualified by MSR[EE] | MSR[GS])
			  • Machine check asynchronous exception (exclude external initiate machine check and NMI) (qualified by MSR[ME] | MSR[GS]). This includes core unrecoverable failure during snoop processing.
			  • Doorbell interrupt (qualified by MSR[EE] | MSR[GS]).
			  • Doorbell critical interrupt (qualified by MSR[CE] | MSR[GS]).
			  • Guest doorbell (qualified by MSR[EE] | MSR[GS]).
			  • Guest doorbell critical (qualified by MSR[CE] & MSR[GS]).
			  • Guest doorbell machine check event (qualified by MSR[ME] & MSR[GS]).
			• Decrementer exception (qualified by MSR[EE] | MSR[GS])
			• FIT exception (qualified by MSR[EE] | MSR[GS])
			• Watchdog exception (qualified by MSR[CE] | MSR[GS])
			• Performance interrupt (qualified by MSR[EE] | MSR[GS])
			• Machine check asynchronous exception (exclude external initiate machine check and NMI) (qualified by MSR[ME] | MSR[GS]). This includes core unrecoverable failure during snoop processing.

Table 29-4. Core RCPM Mode: Entry and Exit for Power Management (continued)

Device Mode Name	Type	Entry via ...	Exit via ...	Book E Core State Entry
			• Doorbell interrupt (qualified by MSR[EE] | MSR[GS]). • Doorbell critical interrupt (qualified by MSR[CE] | MSR[GS]). • Guest doorbell (qualified by MSR[EE] | MSR[GS]). • Guest doorbell critical (qualified by MSR[CE] & MSR[GS]). • Guest doorbell machine check event (qualified by MSR[ME] & MSR[GS]). • Core timebase interrupt if enable via PCTBENR. • Core Hard reset event (The power management entry need to be cleared during reset to avoid the power management event re-posted) • Core debug halt request [1] • Debug interrupt without masking • Wake on LAN - Magic packet, if programmed • Wake on USB - plug/unplug, if programmed • Wake on eSDHC - Card detect, if programmed • Wake on GPIO if programmed	

PH15	PM	• Hypervisor set corresponding bit in RCPM PCPH15SETR to 1.
		• MPIC core warm reset request assertion[2]
		• Core disable request by setting COREDISR[CORE] = 1
			• Hypervisor set corresponding bit in RCPM PCPH15CLRR to 1.
			• Interrupt without RCPM/TPMIMR masking.
			• Critical interrupt without RCPM/TPMCIMR masking.
			• External machine check without RCPM/TPMMCMR masking.
			• NMI without RCPM/TPMNMIMR masking.
			• The following core wake up events will unconditionally wake up core from power management state via core_wakeup_req signal. :
			  • Decrementer exception (qualified by MSR[EE] | MSR[GS])
			  • FIT exception (qualified by MSR[EE] | MSR[GS])
			  • Watchdog exception (qualified by MSR[CE] | MSR[GS])
			• Core timebase interrupt if enable via PCTBENR.
			• MPIC core warm reset request deassertion
			• Core debug halt request[1]
			• Debug interrupt without masking
			• Wake on LAN - Magic packet, if programmed
			• Wake on USB - plug/unplug, if programmed
			• Wake on eSDHC - Card detect, if programmed
			• Wake on GPIO if programmed
			• A core disabled by COREDISR can only exit by device hard reset or power on reset.
				Seq:
				• Full On -> Thread Halted
				• Thread Halted -> Core Stopped

PH20	PM	• Hypervisor set corresponding bit in RCPM PCPH20SETR to 1	• Hypervisor set corresponding bit in RCPM PCPH20CLRR to 1 • Interrupt without RCPM/TPMIMR masking. • Critical interrupt without RCPM/TPMCIMR masking. • External machine check without RCPM/TPMMCMR masking. • NMI without RCPM/TPMNMIMR masking.	Seq: • Full On -> Thread Halted • Thread Halted ->

Table continues on the next page...

Table 29-4. Core RCPM Mode: Entry and Exit for Power Management (continued)

Device Mode Name	Type	Entry via ...	Exit via ...	Book E Core State Entry

			• The following core wake up events will unconditionally wake up core from power management state via core_wakeup_req signal.:
			  • Decrementer exception (qualified by MSR[EE] | MSR[GS])
			  • FIT exception (qualified by MSR[EE] | MSR[GS])
			  • Watchdog exception (qualified by MSR[CE] | MSR[GS])
			• Core timebase interrupt if enable via PCTBENR.
			• MPIC core warm reset request deassertion
			• Core debug halt request[1]
			• Debug interrupt without masking
			• Wake on LAN - Magic packet, if programmed
			• Wake on USB - plug/unplug, if programmed
			• Wake on eSDHC - Card detect, if programmed
			• Wake on GPIO if programmed
				Core Stopped
				• Core Stopped -> Core PH20

PH30		• Hypervisor set corresponding bit in RCPM PCPH30SETR to 1	• Hypervisor set corresponding bit in RCPM PCPH30CLRR to 1 • Core hard reset. • Interrupt is ignored.	

1. For a core debug halt request to cause an exit from power management mode, the core must be operating at a frequency greater than the platform frequency.
2. A warm reset request is serviced by placing the core in the PH15 state prior to reset assertion in order for the CCF to be able to properly handle the core being reset.

The table below summarizes the entry and exit for the cluster power management mode.

Table 29-5. Cluster RCPM Mode: Entry and Exit for Power Management

Device Mode Name	Type	Entry via ...	Exit via ...	Book E Core State Entry
Power Management States				
PCL10	PM	• Hypervisor set corresponding bit in RCPM CLPCL10SETR register to 1.	• Hypervisor set corresponding bit in RCPM CLPCL10CLRR register to 1 to clear the power management request. (The exit from PCL10 is not recoverable in first implementation of e6500 cluster since it requires all cores being placed in PH30 prior to PCL10 state) • Any PH20 wakeup mechanism if some cores are in PH20. • Core hard reset. • Device hard reset	Seq: • Full On -> Thread Halted • Thread Halted -> Core Stopped • Core Stopped -> Core PH20 • Core PH20 -> Core

The table below summarizes the entry and exit for the device power management modes.

Table 29-6. Device RCPM Mode: Entry and Exit for Power Management

Device Mode Name	Type	Entry via ...	Exit via ...	Book E Core State Entry
Power Management States				

LPM20	PM	• Set RCPM POWMGTCSR[LPM20_REQ] to 1	• Clear RCPM POWMGTCSR[LPM20_REQ]
			• Core interrupt without RCPM/CPMIMR masking.
			• Core critical interrupt without RCPM/CPMCIMR masking.
			• Core external machine check without RCPM/CPMMCMR masking.
			• Core NMI without RCPM/CPMNMIMR masking.
			• The following core wake up events will unconditionally wake up core from power management state via core_wakeup_req signal. :
			  • Decrementer exception (qualified by MSR[EE] | MSR[GS])
			  • FIT exception (qualified by MSR[EE] | MSR[GS])
			  • Watchdog exception (qualified by MSR[CE] | MSR[GS])
			• Debug interrupt without masking
			• Wake on LAN - Magic packet, if programmed
			• Wake on USB - plug/unplug, if programmed
			• Wake on eSDHC - Card detect, if programmed
			• Wake on GPIO if programmed
				Seq:
				• Full On -> Core Halted
				• Core Halted -> Core Stopped

29.1.6 Reset Modes

29.1.6.1 Power-On Reset State

During Power-on Reset, the following hardware structures are reset:

- All CCSR registers
- SOC power management state machine
- Cluster power management state machine
- Core power management state machine
- Thread power management state machine

29.1.6.2 Hard Reset State

During Hard Reset, the following are affected:

- All CCSR registers
- SOC power management state machine
- Cluster power management state machine
- Core power management state machine
- Thread power management state machine

29.1.7 Power Management States

Hypervisor software can place the device in one of the following power states by writing to the indicated RCPM register, as shown in this table:

Table 29-7. Power state entry by register

State	Register
thread PH10	TPH10SETR
core PH15	PCPH15SETR
core PH20	PCPH20SETR
core PH30	PCPH30SETR
cluster PCL10	CLPCL10SETR

In addition, Hypervisor or external masters can write to memory-mapped POWMGTCSR in RCPM to cause the device to enter one of the following device power states:

- LPM20

29.1.7.1 PH10 State

In PH10 state, the thread suspends instruction execution, significantly reducing the power consumption of the core.

Snooping of the L1/L2 cache are still supported and thus the data in the data cache is kept coherent. Interrupts directed to the thread are monitored by the device and cause RCPM to use the defined handshake mechanism to exit the thread from PH10 state to allow the thread to recognize and process the interrupt.

The core's timer facilities are still enabled during thread PH10 state, and core timebase interrupts can be generated. All device logic external to the core remains fully operational in thread PH10 state.

29.1.7.2 PH15 State

In PH15 state, all clocks internal to the core are turned off except for its timer facilities clock (the core timebase).

The L1/L2 caches do not respond to snoops in PH15 state, so if coherency is required, the L1/L2 cache must be flushed before entering PH15 state.

All device logic external to core remains fully operational in PH15 state.

It is not possible for the device to place the core into PH15 state. This is because the device cannot initiate a cache flush of the core. Since this is not possible, if the device did place a core into PH15 state, then coherency would be lost because snooping does not occur in PH15 state.

29.1.7.3 PH20 State

Core PH20 state is core power gating with state retention.

29.1.7.4 PH30 State

Core PH30 state is core power gating without state retention. Interrupt is ignored for core being placed in PH30 state.

29.1.7.5 PCL10 State

PCL10 is a cluster power management state which cluster clock is gated off.

The first revision of the e6500 cluster implementation required the core to be placed in PH30 prior to putting the cluster into PCL10 state, Due to a limitation in the first revision of the e6500, the PCL10 state is not recoverable. In this case, a cluster that is placed in PCL10 and core PH30 is a requirement for the cores, an interrupt to any core in the cluster in PCL10 state should be ignored. Issuing a core warm reset to a core within a cluster when that cluster is in PCL10 is an illegal condition.

Later revisions of the e6500 cluster implementation require the core to be placed in PH20 prior to putting the cluster into PCL10 state, For a cluster which is placed in PCL10 (when core PH20 is the requirement for PCL10), an interrupt to any core within the cluster will wake up the cluster from the PCL10 state to the PCL00 state (cluster full on).

29.1.7.6 LPM10 State

LPM10 state is a device state which at least one core is not in PH00 (full on state).

29.1.7.7 LPM20 State

In LPM20 state, all clocks internal to the core are turned off as well as the clock in device logic so that only the modules which are required to wake up the device will still have a running clock. Core timebase is turned-off.

The modules which can be used as a wake up source are internal timers, internal and external interrupts.

After the core and I/O interfaces have shut down, ASLEEP pin is asserted.

29.2 External Signal Description

The table below lists the RCPM signal descriptions:

Table 29-8. RCPM Detailed Signal Descriptions

Signal	I/O	Description	
ASLEEP	O	Asleep. After negation of PORESET_B, ASLEEP is asserted until the device completes its power-on reset sequence and reaches its ready state.	
		State Meaning	Asserted- Indicates that the device is either still in its power-on reset sequence or it has reached a LPM20 state after a power-down command is issued by software. Negated- The device is not in LPM20 state. (It has either awake from a power-down state, or has completed the POR sequence.)
		Timing	Assertion- May occur at any time; may be asserted asynchronously to the input clocks. Negation- Negates synchronously with SYSCLK when leaving power-on sequence; otherwise negation is asynchronous.
RTC	I	Real Time Clock. Refer to the chip data sheet for timing specification. The signal can be optionally use to clock the global timers in the programmable interrupt controller.	
		Timing	Assertion/Negation - See the chip data sheet for specific timing information for this signal.

29.3 RCPM Memory Map/Register Definition

This section identifies Power Management resources that are not included as part of a processor core or platform IP.

RCPM_TPH10PSR0 field descriptions

Field	Description
0–31 T_P_PH10_n	Thread PH10 previous status. This bit is set when the corresponding TPH10SR bit transitions from 1 to 0 due to an interrupt. **NOTE:** Bit 31 corresponds to Thread 0, bit 30 corresponds to Thread 1, and so on. 0 Thread was not in the PH10 state before wake up by interrupt. 1 Thread was in the PH10 state before wake up by interrupt.

29.3.5 Thread Wait Status Register (RCPM_TWAITSR)

This register is used for reporting wait status per thread.

NOTE

The RCPM module as implemented on the chip describes the threads and cores implemented on this SoC. In the following register description, any bits associated with unimplemented threads or cores are reserved.

See The RCPM module as implemented on the chip for mapping of threads to cores.

Address: E_2000h base + 4Ch offset = E_204Ch

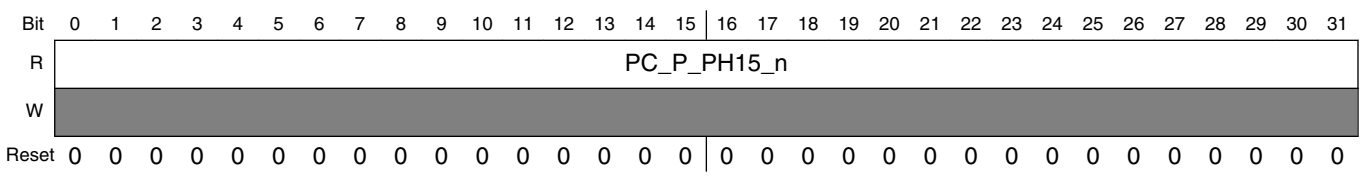
29.3.9 Physical Core PH15 Previous Status Register (RCPM_PCPH15PSR)

This register is used for reporting previous PH15 status per physical core. It is used by software to know which power saving state it was in before wake up by interrupt.

NOTE

In the following register description, any bits associated with unimplemented cores are reserved.

Address: E_2000h base + BCh offset = E_20BCh



RCPM_PCPH15PSR field descriptions

Field	Description
0–31 PC_P_PH15_n	Physical core PH15 previous status. The bit is set when the corresponding PCPH15SR bit transitions from 1 to 0 due to an interrupt. **NOTE:** Bit 31 corresponds to Core 0, bit 30 corresponds to Core 1, and so on. 0 Physical core was not in the PH15 state before wake up by interrupt. 1 Physical core was in the PH15 state before wake up by interrupt.

29.3.10 Physical Core PH20 Status Register (RCPM_PCPH20SR)

This register is used for reporting PH20 status per physical core.

NOTE

In the following register description, any bits associated with unimplemented cores are reserved.

Address: E_2000h base + D0h offset = E_20D0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

29.3.17 Physical Core PH30 Clear Control Register (RCPM_PCPH30CLRR)

This register is used for waking up the thread be placed in the PH30 state. The true value read from the register only means there is a pending physical core PH30 request.

NOTE

In the following register description, any bits associated with unimplemented cores are reserved.

Address: E_2000h base + F8h offset = E_20F8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

RCPM_PCPH30CLRR field descriptions

Field	Description
0–31 CP_PH30_REQ	Write one to cancel physical core PH30 request. The bit is set by write-one-event to PCPH30SETR register. This bit is also clear by interrupt event. The read true value of the register bit means there is pending Physical Core PH30 request for that core. xxxxxxxx_xxxxxxxx_xxxxxxxx_xxxxxxx1 core0 is receiving a PH30 request from PCPH30SETR xxxxxxxx_xxxxxxxx_xxxxxxxx_xxxxxx1x core1 is receiving a PH30 request from PCPH30SETR xxxxxxxx_xxxxxxxx_xxxxxxxx_xxxxx1xx core2 is receiving a PH30 request from PCPH30SETR xxxxxxxx_xxxxxxxx_xxxxxxxx_xxxx1xxx core3 is receiving a PH30 request from PCPH30SETR xxxxxxxx_xxxxxxxx_xxxxxxxx_xxx1xxxx core4 is receiving a PH30 request from PCPH30SETR xxxxxxxx_xxxxxxxx_xxxxxxxx_xx1xxxxx core5 is receiving a PH30 request from PCPH30SETR xxxxxxxx_xxxxxxxx_xxxxxxxx_x1xxxxxx core6 is receiving a PH30 request from PCPH30SETR xxxxxxxx_xxxxxxxx_xxxxxxxx_1xxxxxxx core7 is receiving a PH30 request from PCPH30SETR xxxxxxxx_xxxxxxxx_xxxxxxx1_xxxxxxxx core8 is receiving a PH30 request from PCPH30SETR xxxxxxxx_xxxxxxxx_xxxxxx1x_xxxxxxxx core9 is receiving a PH30 request from PCPH30SETR xxxxxxxx_xxxxxxxx_xxxxx1xx_xxxxxxxx core10 is receiving a PH30 request from PCPH30SETR xxxxxxxx_xxxxxxxx_xxxx1xxx_xxxxxxxx core11 is receiving a PH30 request from PCPH30SETR xxxxxxxx_xxxxxxxx_xxx1xxxx_xxxxxxxx core12 is receiving a PH30 request from PCPH30SETR xxxxxxxx_xxxxxxxx_xx1xxxxx_xxxxxxxx core13 is receiving a PH30 request from PCPH30SETR xxxxxxxx_xxxxxxxx_x1xxxxxx_xxxxxxxx core14 is receiving a PH30 request from PCPH30SETR xxxxxxxx_xxxxxxxx_1xxxxxxx_xxxxxxxx core15 is receiving a PH30 request from PCPH30SETR xxxxxxxx_xxxxxxx1_xxxxxxxx_xxxxxxxx core16 is receiving a PH30 request from PCPH30SETR xxxxxxxx_xxxxxx1x_xxxxxxxx_xxxxxxxx core17 is receiving a PH30 request from PCPH30SETR xxxxxxxx_xxxxx1xx_xxxxxxxx_xxxxxxxx core18 is receiving a PH30 request from PCPH30SETR xxxxxxxx_xxxx1xxx_xxxxxxxx_xxxxxxxx core19 is receiving a PH30 request from PCPH30SETR xxxxxxxx_xxx1xxxx_xxxxxxxx_xxxxxxxx core20 is receiving a PH30 request from PCPH30SETR xxxxxxxx_xx1xxxxx_xxxxxxxx_xxxxxxxx core21 is receiving a PH30 request from PCPH30SETR xxxxxxxx_x1xxxxxx_xxxxxxxx_xxxxxxxx core22 is receiving a PH30 request from PCPH30SETR xxxxxxxx_1xxxxxxx_xxxxxxxx_xxxxxxxx core23 is receiving a PH30 request from PCPH30SETR xxxxxxx1_xxxxxxxx_xxxxxxxx_xxxxxxxx core24 is receiving a PH30 request from PCPH30SETR xxxxxx1x_xxxxxxxx_xxxxxxxx_xxxxxxxx core25 is receiving a PH30 request from PCPH30SETR xxxxx1xx_xxxxxxxx_xxxxxxxx_xxxxxxxx core26 is receiving a PH30 request from PCPH30SETR xxxx1xxx_xxxxxxxx_xxxxxxxx_xxxxxxxx core27 is receiving a PH30 request from PCPH30SETR xxx1xxxx_xxxxxxxx_xxxxxxxx_xxxxxxxx core28 is receiving a PH30 request from PCPH30SETR xx1xxxxx_xxxxxxxx_xxxxxxxx_xxxxxxxx core29 is receiving a PH30 request from PCPH30SETR x1xxxxxx_xxxxxxxx_xxxxxxxx_xxxxxxxx core30 is receiving a PH30 request from PCPH30SETR 1xxxxxxx_xxxxxxxx_xxxxxxxx_xxxxxxxx core31 is receiving a PH30 request from PCPH30SETR

29.3.18 Physical Core PH30 Previous Status Register (RCPM_PCPH30PSR)

This register is used for reporting previous PH30 status per physical core. It is used by software to know which power saving state it was in before wake up by interrupt.

NOTE

In the following register description, any bits associated with unimplemented cores are reserved.

Address: E_2000h base + FCh offset = E_20FCh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

RCPM_PCPH30PSR field descriptions

Field	Description
0–31 PC_P_PH30_n	Physical core PH30 previous status. The bit is set when the corresponding PCPH30SR bit transitions from 1 to 0 due to an interrupt. **NOTE:** Bit 31 corresponds to Core 0, bit 30 corresponds to Core 1, and so on. 0 Physical core was not in the PH30 state before wake up by interrupt. 1 Physical core was in the PH30 state before wake up by interrupt.

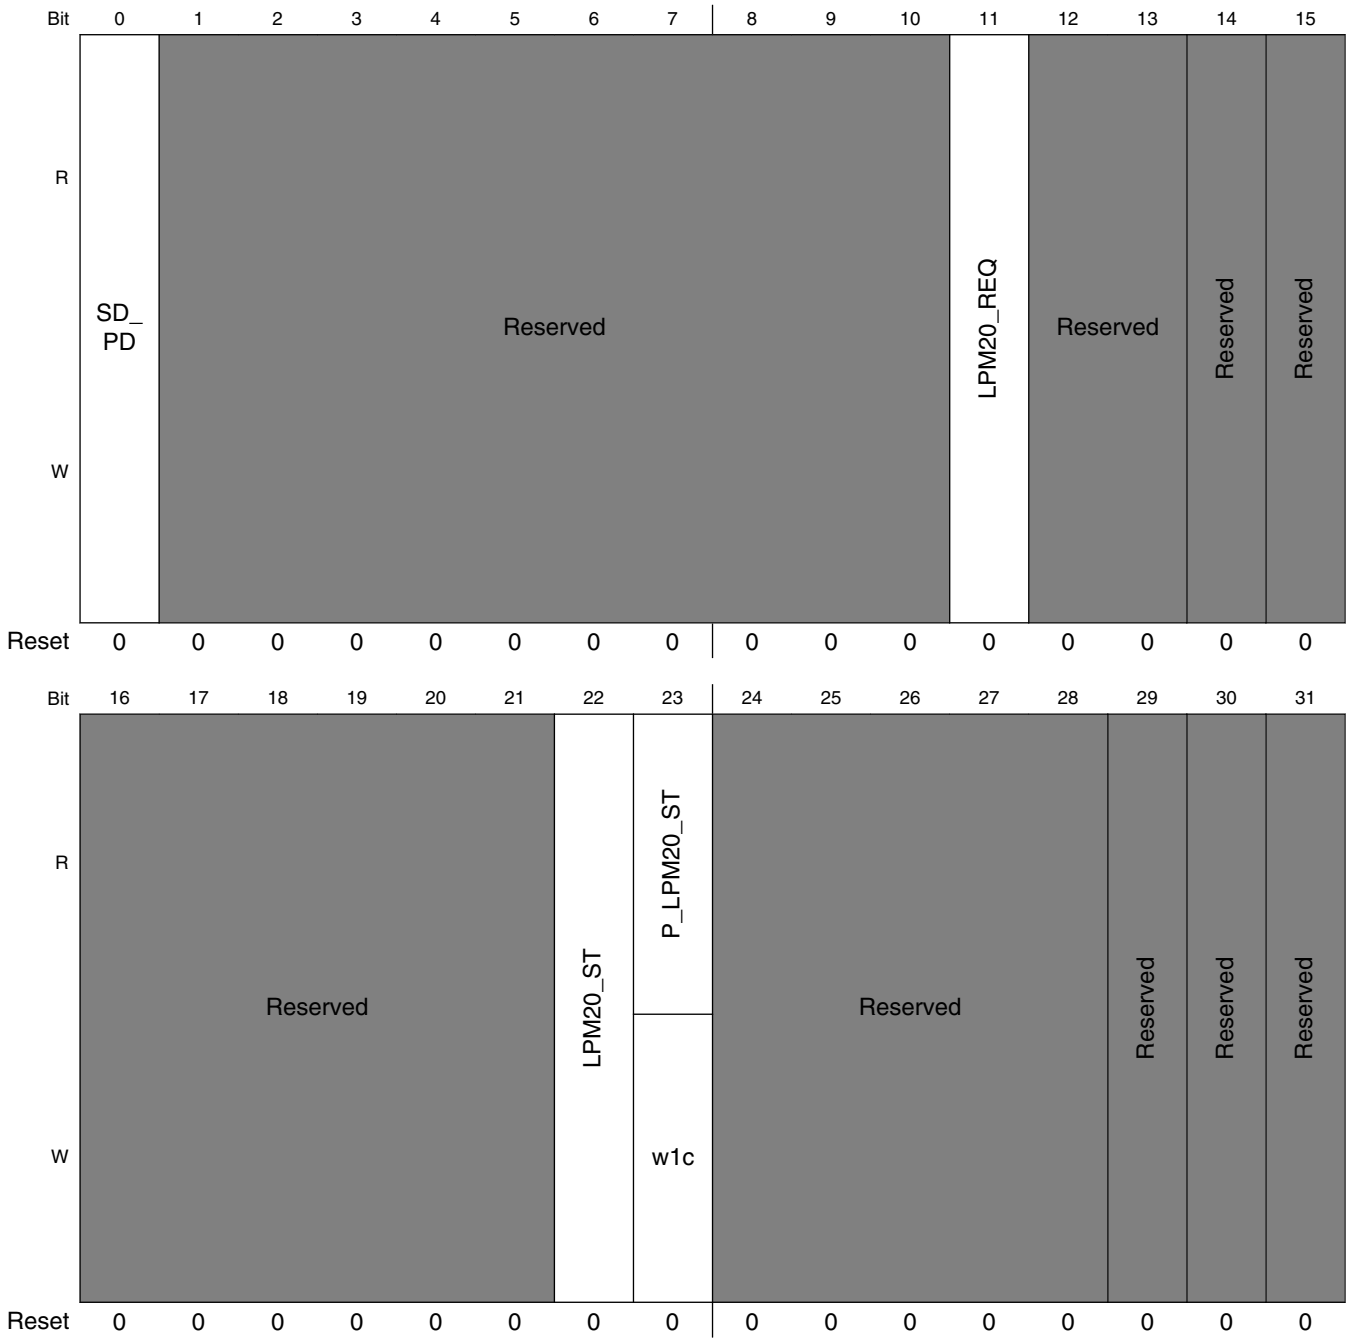
29.3.19 Power Management Control and Status Register (RCPM_POWMGTCSR)

This register is used for entering the device's LPM state. In addition, it provides status indicating successful entry into the correspinding power management state.

NOTE

If debugger wants to access memory content in LPM20 , it can put the device back to debug quiesced state. In quiesced state, the debugger can issue both coherent and non-coherent memory access and the content in the memory space should be the same as in LPM20 state.

Address: E_2000h base + 130h offset = E_2130h



RCPM_POWMGTCSR field descriptions

Field	Description
0 SD_PD	SerDes and Protocol Converter Powerdown Control 0 SerDes and Protocol Converter are not powerdown in LPM state. 1 SerDes and Protocol Converter are powerdown in LPM state for further power saving. If this bit is set, after system wake up from LPM state, SerDes has to go through the training sequence to return back to function.

Table continues on the next page...

RCPM_POWMGTCSR field descriptions (continued)

Field	Description
1–10 -	This field is reserved. Reserved
11 LPM20_REQ	LPM20 State Request. This bit is clear by interrupt event. 0 No request to put device in LPM20 state 1 Request to place device in LPM20 state.
12–13 -	This field is reserved. Reserved
14 -	This field is reserved. Reserved
15 -	This field is reserved. Reserved
16–21 -	This field is reserved. Reserved
22 LPM20_ST	LPM20 Status 0 Device is not attempting to reach LPM20 state 1 The device is attempting to enter LPM20 state because POWMGTCSR[LPM20_REQ] is set.
23 P_LPM20_ST	Previous LPM20 Status. It is used by software to know which state the device was in before being wake up. This bit must write one to clear before software set POWMGTCSR[LPM20_REQ]. The bit is set when LPM20_ST transitions from 1 to 0 due to an interrupt. 0 Device was not in LPM20 state before being wake up by interrupt. 1 Device was in LPM20 state before being wake up by interrupt.

30 -	This field is reserved. Reserved
31 -	This field is reserved. Reserved

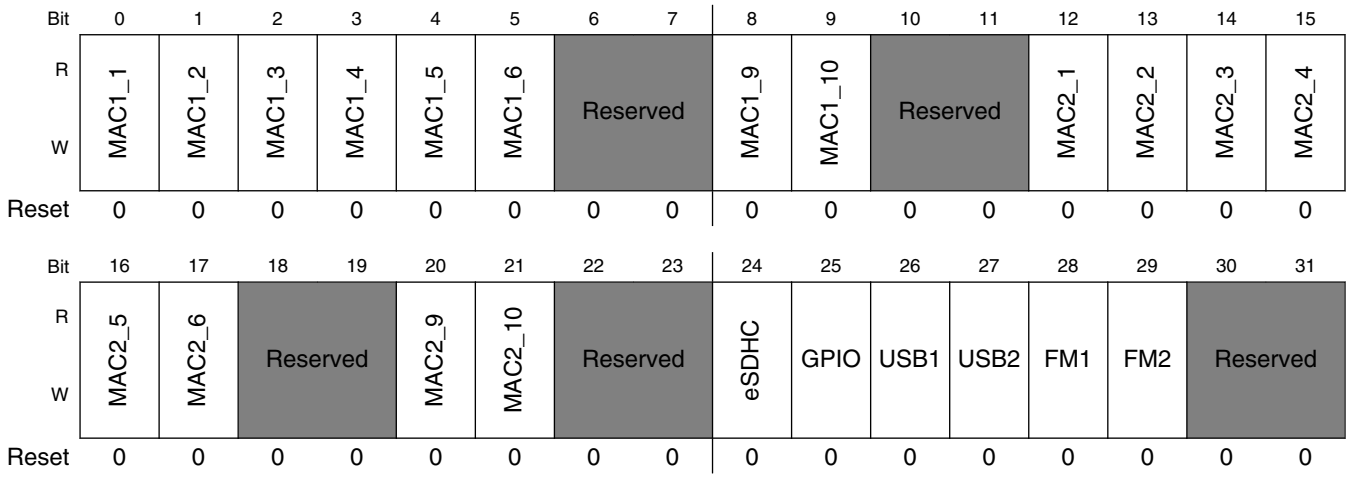
29.3.20 IP Powerdown Exception Control Register n (RCPM_IPPDEXPCRn)

IPPDEXPCR provides a mechanism for excluding certain IP blocks from device LPM20 mode to make these IP blocks available as sources for wake-up events. For example,

- Wake on LAN (magic packet) - Requires excluding the Ethernet controller from device LPM20 mode
- Wake on USB (unplug/plug event) - Requires excluding the USB controller from device LPM20 mode

- Wake on eSDHC (card detect event) - Requires excluding the eSDHC controller from device LPM20 mode
- Wake on GPIO - Requires excluding the GPIO controller from device LPM20 mode

Address: E_2000h base + 140h offset = E_2140h



RCPM_IPPDEXPCRn field descriptions

29.3.29 Thread Time Base Halt Control Register 0 (RCPM_TTBHLTCR0)

TTBHLTCR defines the time based behavior when thread is in halted state. The feature provides user more flexible timebase control in multi-thread programming debug.

NOTE

Proper use of TTBHLTCR requires that all threads within a physical core must be programmed with the same value.

The RCPM module as implemented on the chip describes the threads and cores implemented on this SoC. In the following register description, any bits associated with unimplemented threads or cores are reserved.

See The RCPM module as implemented on the chip for mapping of threads to cores.

Address: E_2000h base + 1BCh offset = E_21BCh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

RCPM_CLPCL10SR field descriptions

Field	Description
0–31 CLn	Cluster PCL10 status. **NOTE:** Bit 31 corresponds to Core Cluster 0, bit 30 corresponds to Core Cluster 1, and so on. 0 Cluster is not in the PCL10 state 1 Cluster is in the PCL10 state

29.3.31 Cluster PCL10 Set Control Register (RCPM_CLPCL10SETR)

This register is used for requesting that a cluster be placed in the PCL10 state. The true value read from the register means there is a pending cluster PCL10 request.

NOTE

The RCPM module as implemented on the chip describes the core clusters implemented on this SoC. In the following register

description, any bits associated with unimplemented core clusters are reserved.

Address: E_2000h base + 1C4h offset = E_21C4h

29.3.33 Cluster PCL10 Previous Status Register (RCPM_CLPCL10PSR)

This register is used for reporting previous PCL10 status per cluster. It is used by software to know which power saving state it was in before wake up by interrupt.

NOTE

The RCPM module as implemented on the chip describes the core clusters implemented on this SoC. In the following register description, any bits associated with unimplemented core clusters are reserved.

Address: E_2000h base + 1CCh offset = E_21CCh

RCPM_CLPCL10PSR field descriptions

Field	Description
0–31 CL_P_PCL10_n	Cluster PCL10 previous status. The bit is set when the corresponding CLPCL10SR bit transitions from 1 to 0 due to an interrupt. **NOTE:** Bit 31 corresponds to Core Cluster 0, bit 30 corresponds to Core Cluster 1, and so on. 0 Cluster was not in the PCL10 state before wake up by interrupt. 1 Cluster was in the PCL10 state before wake up by interrupt.

29.4 Functional Description

29.4.1 Thread/Core Power Management

29.4.1.1 Functional Overview

The RCPM supports minimizing the power consumption through software controlled power management states:

- PH10
- PH15
- PH20
- PH30

The RCPM handshakes with a thread to halt the instruction sequence and handshakes with CCF to gracefully stop the internal CoreNet network.

The RCPM allows several wake-up event sources to exit low power state (internal timer, internal and external interrupts). The wake-up events are mapped to interrupt controller interrupts to generate a wake-up interrupt to the RCPM.

29.4.1.2 Thread PH10 Operation

29.4.1.2.1 Thread PH10 Operation Entry

PH10 operation can be triggered by the following mechanisms:

- EPU event trigger via CGACRE.
- Device event trigger via CGACRD.
- Setting corresponding bit(s) in RCPM TPH10SETR via software.

29.4.1.2.2 Thread PH10 Operation Exit

Exit from PH10 state (wake up) is triggered by the following:

- Corresponding bit(s) in RCPM TPH10CLRR are set.
- Thread IRQ interrupt without RCPM TPMIMR masking.
- Thread critical interrupt without RCPM TPMCIMR masking.
- Thread debug interrupt
- Core time based interrupt
- Wake on LAN - magic packet. If IP is present and programmed

- Wake on USB - unplug/plug. If IP is present and programmed
- Wake on eSDHC - card detect. If IP is present and programmed
- Wake on GPIO. If IP is present and programmed
- Core unrecoverable failure
- Core Hard reset event

29.4.1.2.3 Thread PH10 Operation Sequence

The sequence of PH10 operation is described below:

- The RCPM core power management control logic takes PH10 request, and asks the core to halt thread (by asserting thrd_pm_halt signal). The power management halt request is recorded in core SBSR0[PM_HALT].
- When core receives power management halt request, it will stop decoding instruction, unless there is a **lmw** or **stmw** in progress, in which case it will stop after all of the micro-ops have been decoded. Next, the core will wait for the completion buffer to drain. In order to make sure that all load/store operation can been seen globally, the sequencer logic will jam an **msync** instruction and wait for it to deallocate.
- After that, core declares its halted state and asserts thrd_halted signal to RCPM. At this point, thread is in PH10 state.

A core in PH10 state can still handle snoop requests.

29.4.1.3 Core PH15 Operation

29.4.1.3.1 Core PH15 Operation Entry

PH15 operation can be triggered by the following mechanism:

- Setting corresponding bit(s) in RCPM PCPH15SETR via software.

Setting the following two programming registers will cause hardware trigger PH15 operation to bring the core in stopped state gracefully. In these two cases, PH15 state is used to gracefully stop core to prevent CoreNet hang.

- Setting corresponding bit(s) in DCFG COREDISR to disable core(s).
- Setting corresponding bit(s) in MPIC PIR to initiate core warm reset.

29.4.1.3.2 Core PH15 Operation Exit

Exit from PH15 state (wake up) is triggered by the following:

- Corresponding bit(s) in RCPM PCPH15CLRR are set.
- Thread IRQ interrupt without RCPM TPMIMR masking.
- Thread critical interrupt without RCPM TPMCIMR masking.
- Core time based interrupt
- Wake on LAN - magic packet. If IP is present and programmed
- Wake on USB - unplug/plug. If IP is present and programmed
- Wake on eSDHC - card detect. If IP is present and programmed
- Wake on GPIO. If IP is present and programmed
- Core unrecoverable failure
- Core Hard reset event
- A core disabled by COREDISR can only exit by device hard reset or power on reset.

29.4.1.3.3 Core PH15 Operation Sequence

The sequence of PH15 operation is described below:

- The RCPM core power management control logic takes PH15 request and starts the PH15 sequence. The first part of the PH15 sequence is the same as PH10 to bring the core to a halted state.
- After the core is halted, RCPM sends a core-specific stop request to CCF. It is to ask CCF start to drain the snoop transaction on the fly and to reach a transaction boundary which the user can stop.
- CCF puts the processor (port) into "No Snoop" mode and stops sending any new snoops to the processor. Note that there might be snoops (AIns) already enroute to the processor which are not stopped.
- After all the AIns have been delivered to the Async FIFO, CCF drives the stop signal with proper core IDs to the AIn FIFO.
- After all the AIns have been picked up by the core, the AIn FIFO delivers the stop signal to the processor (via core_stop signal).
- The processor completes all activities related to all transactions snooped by the core. After all such activity is complete, the core drives core_stopped signal out to AOut Async FIFO.
- At this time, the AOut FIFO should be empty. The Async FIFO forwards the stopped signal to CCF.
- The CCFensures that all activity from the core related to snoops delivered to the core has been received into CCF, CCF forwards the core_stopped signal to RCPM. This ensures that CCF has extracted all response transactions from the various FIFOs that may have been written to by the core. At this point, core is in PH15 state.

There is no need to handshake between core power management control logic and device power management control logic in PH15 operation since it is assumed that software flushes core L1/L2 cache data before triggering PH15 operation. For debug event, debugger need to do the necessary work to make sure the coherence state is still preserved. The power management stop request is recorded in core SBSR0[PM_STOP].

29.4.1.4 Core PH20 (PGSR) Operation

29.4.1.4.1 Core PH20 (PGSR) Operation Entry

Core PH20 (PGSR) operation can be triggered by the following mechanism:

- Setting corresponding bit(s) in RCPM PCPH20SETR via software.

The corresponding bit(s) in RCPM PCPH20SETR should be set when core is out of reset as indicated by CRSTSR status register in DCFG. If PCPH20SETR is set while the core(s) are still in reset then the corresponding core would enter PH20 after reaching PH15 in the core hreset sequence (see Core PH15 Operation Entry").

29.4.1.4.2 Core PH20 (PGSR) Operation Exit

Exit from core PH20 state (wake up) is triggered by the following:

- Corresponding bit(s) in RCPM PCPH20CLRR are set.
- Thread IRQ interrupt without RCPM TPMIMR masking.
- Thread critical interrupt without RCPM TPMCIMR masking.
- Core time based interrupt
- Wake on LAN - magic packet. If IP is present and programmed
- Wake on USB - unplug/plug. If IP is present and programmed
- Wake on eSDHC - card detect. If IP is present and programmed
- Wake on GPIO. If IP is present and programmed
- Core unrecoverable failure
- Core Hard reset event

29.4.1.4.3 Core PH20 (PGSR) Operation Sequence

The sequence of core PH20 (PGSR) operation is described below:

- The RCPM core power management control logic takes core PH20 (PGSR) request and start core PH20 (PGSR) sequence. In the first part of core PH20 (PGSR) sequence, RCPM requests thread to enter PH10 (doze) halted state.

- After core is halted and thread is in PH10, RCPM then requests core to enter PH15 (nap) stopped state.
- After core is stopped, RCPM asserts core_pg_sr and requests the core to initiate power gating with state retention sequence.
- Once core is power gated with state retention, core declares its PGSR state and asserts core_ph20 signal to RCPM.

29.4.1.5 Core PH30 (PG) Operation

29.4.1.5.1 Core PH30 (PG) Operation Entry

Core PH30 (PG) operation can be triggered by the following mechanism:

- Setting corresponding bit(s) in RCPM PCPH30SETR via software.

The corresponding bit(s) in RCPM PCPH30SETR should be set when core is out of reset as indicated by CRSTSR status register in DCFG. If PCPH30SETR is set while the core(s) are still in reset then the corresponding core would enter PH20 the PH30 after reaching PH15 in the core hreset sequence (see Core PH15 Operation Entry).

29.4.1.5.2 Core PH30 (PG) Operation Exit

Exit from core PH30 state (wake up) is triggered by the following:

- Corresponding bit(s) in RCPM PCPH30CLRR are set if the core has not yet reached the PH30 state.
- Core Hard reset event

29.4.1.5.3 Core PH30 (PG) Operation Sequence

The sequence of core PH30 (PG) operation is described below:

- The RCPM core power management control logic takes core PH30 (PG) request and start core PH30 (PG) sequence. In the first part of core PH30 (PG) sequence, RCPM requests thread to enter PH10 (doze) halted state.
- After core is halted and thread is in PH10, RCPM then requests core to enter PH15 (nap) stopped state.
- After core is stopped, RCPM asserts core_pg_sr and requests the core to initiate power gating with state retention sequence.
- Once core is power gated with state retention, core declares its PGSR state and asserts core_ph20 signal. RCPM then asserts core_off and requests the core to initiate full power gating sequence.

29.4.2 Device Power Management

29.4.2.1 Overview

RCPM supports minimizing the power consumption through software controlled device power management LPM20 state.

RCPM can handshake with various IP at the SoC level to gracefully stop the IP traffic and direct the memory controller to put DDR into self-refresh mode (if enabled).

RCPM allows several wake-up events source to exit low power state (core timebase, internal and external interrupts). The wake-up events are mapped to interrupt controller interrupts to generate a wake-up interrupt to the RCPM.

29.4.2.2 Device LPM20 Operation

LPM20 and device debug softstop are two different manners for gating off clocks to the entire chip. Both are recoverable but they are used for different purposes.

LPM20 is a device low power state. Device debug softstop is a debug state which can be utilized to do LSRL debug scan. Prior entering LPM20 , software is expected to quiesce all external devices/internal IPs through configuration. RCPM hardware is designed to implement sanity check for IPs idle status. Core timebase is turned off when the chip is in LPM20 state.

29.4.2.2.1 Device LPM20 Operation Entry

LPM20 operation can be triggered by the following mechanism:

- Setting RCPM POWMGTCSR[LPM20_REQ] to 1 via software.

29.4.2.2.2 Device LPM20 Operation Exit

Exit from LPM20 state (wake up) can be triggered by the following:

- Thread IRQ interrupt without RCPM TPMIMR masking.
- Thread critical interrupt without RCPM TPMCIMR masking.
- Core time based interrupt
- Wake on LAN - magic packet.
- Wake on USB - unplug/plug (through the interrupt controller).
- Wake on eSDHC - card detect (through the interrupt controller).

- Wake on GPIO.
- Core unrecoverable failure
- Core Hard reset event

29.4.2.2.3 Device LPM20 Operation Sequence

The sequence of device LPM20 operation is described below:

- The RCPM device power management control logic takes device LPM20 request and start device LPM20 sequence.
- RCPM watches the IP idle status and confirms that IPs reports idle.
- RCPM asserts stop request to all master IPs in device, and waits for the stop acknowledgement from all master IPs. After master IP receives stop request, it will stop mastering any new transaction. After its all transaction tenures are completed (request, response, data tenure), it will assert stop acknowledgement back to RCPM.
- RCPM asserts stop request to the IPs which can be served as both master and target device, and wait for the stop acknowledgement from all master/target IPs. During this process, the deadlock case could happen. If deadlock case has been detected by RCPM, RCPM will deassert the stop request to these IPs and let the transaction goes through to resolve the deadlock.
- RCPM asserts stop request to all target IPs in device, and wait for the stop acknowledgement from all target IPs.
- At this point, the chip is in the LPM20 state. RCPM asserts the power down bus to clock control unit to clock gate all IPs in device except for necessary IPs for wake up. For example, MPIC and USB (if programmed).

29.5 Initialization Information

This section describe RCPM initialization information. RCPM uses both Power-on reset and Hard reset for hardware initialization.

Interrupt sampling, RUNN counter, and core group logic are initialized only through power-on reset. SoC power management module and core power management module are initialized through Hard reset. RCPM CCSR are reset either by Power-on reset or Hard reset depending on their functionality. For details, refer to RCPM Memory Map/ Register Definition".

29.6 Application Information

29.6.1 Putting the Chip into LPM20 State

This section captures the software sequence to place the chip into LPM20 state.

- Frame manager needs to be initialized before software issues a LPM20 request. Refer to frame manager document for the initialization procedure.
- Write SECMON.LPPGDR (SM_LP Power Glitch Detector Register) with value 0x41736166.
- Write SECMON.LPSR (SM_LP Status Register) with value 0x00000008. It is to clear power supply glitch detection.

29.6.2 Magic Packet Wake Up

To enable magic packet wake up feature in LPM20 state, the frame manager module associated with the mEMAC receiving magic packets needs to be enabled.

Appendix A
T4160/T4161

A.1 Introduction

The T4160 is a lower power version of the T4240. The T4160 combines eight dual threaded Power Architecture e6500 cores and two memory complexes (CoreNet platform cache and DDR3 memory controller) with the same high-performance datapath acceleration, networking, and peripheral bus interfaces. The T4161 is functionally identical to the T4160 but has lower power. Statements about T4160 apply to T4161.

This figure shows the major functional units within the chip.

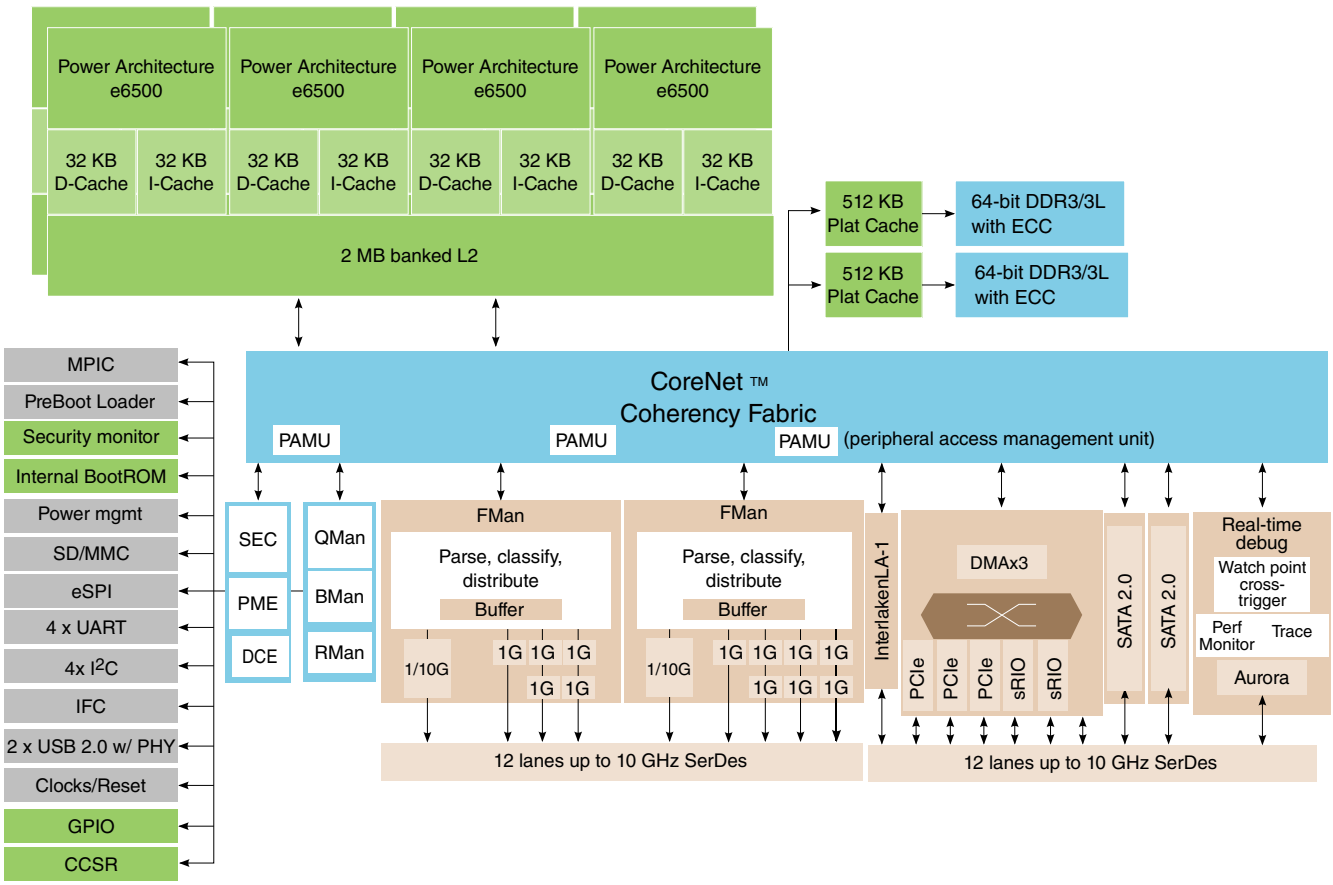

Figure A-1. T4160 block diagram

A.2 Overview of differences between T4240, T4241, T4160, T4161, T4080, and T4081

Table A-1. Differences between T4240, T4241, T4160, T4161, T4080, and T4081

Feature	T4240	T4241	T4160	T4161	T4080	T4081
Power	Standard	Low	Standard	Low	Standard	Low
Cores						
Number of physical cores	12		8		4	
Number of threads	24		16		8	
Number of clusters	3		2		1	
Memory subsystem						
Total CPC memory	3 x 512 KB		2 x 512 KB		2 x 512 KB	
Number of DDR controllers	3		2		2	
Peripherals						
Number of Frame Managers	2		2		2	

Table continues on the next page...

Table A-1. Differences between T4240, T4241, T4160, T4161, T4080, and T4081 (continued)

Feature	T4240	T4241	T4160	T4161	T4080	T4081
Total number of Anyspeed MACs	8 per Frame Manager		6 (FMan1) and 8 (FMan2)		6 (FMan1) and 8 (FMan2)	
Max number of Anyspeed MACs configured for 10 GE operation	2 per Frame Manager		1 per Frame Manager		1 per Frame Manager	
SerDes and pinout						
Total number of SerDes lanes	4 x 8		2 x 4 and 2 x 8		2 x 4 and 2 x 8	
High-speed IO						
PCIe	4		3 (PCIe 3 is disabled)		3 (PCIe 3 is disabled)	

A.3 Features of T4160

A.3.1 T4160 clocking and RCW differences

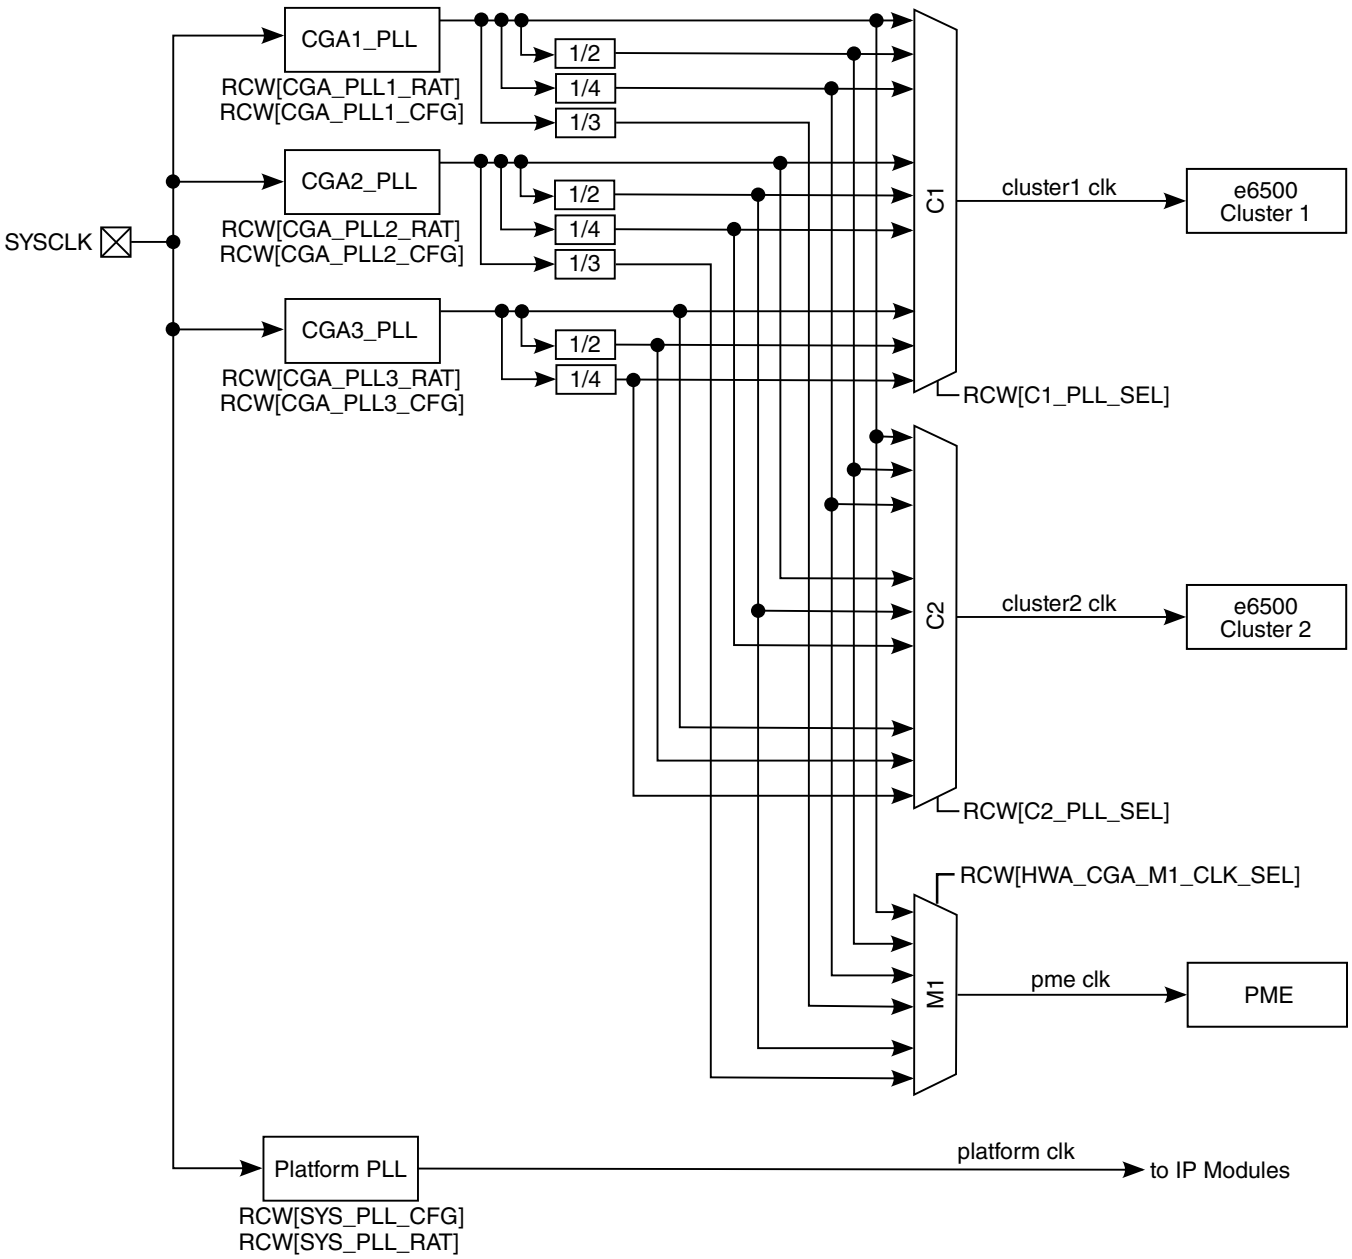

Figure A-2. T4160 Clocking diagram

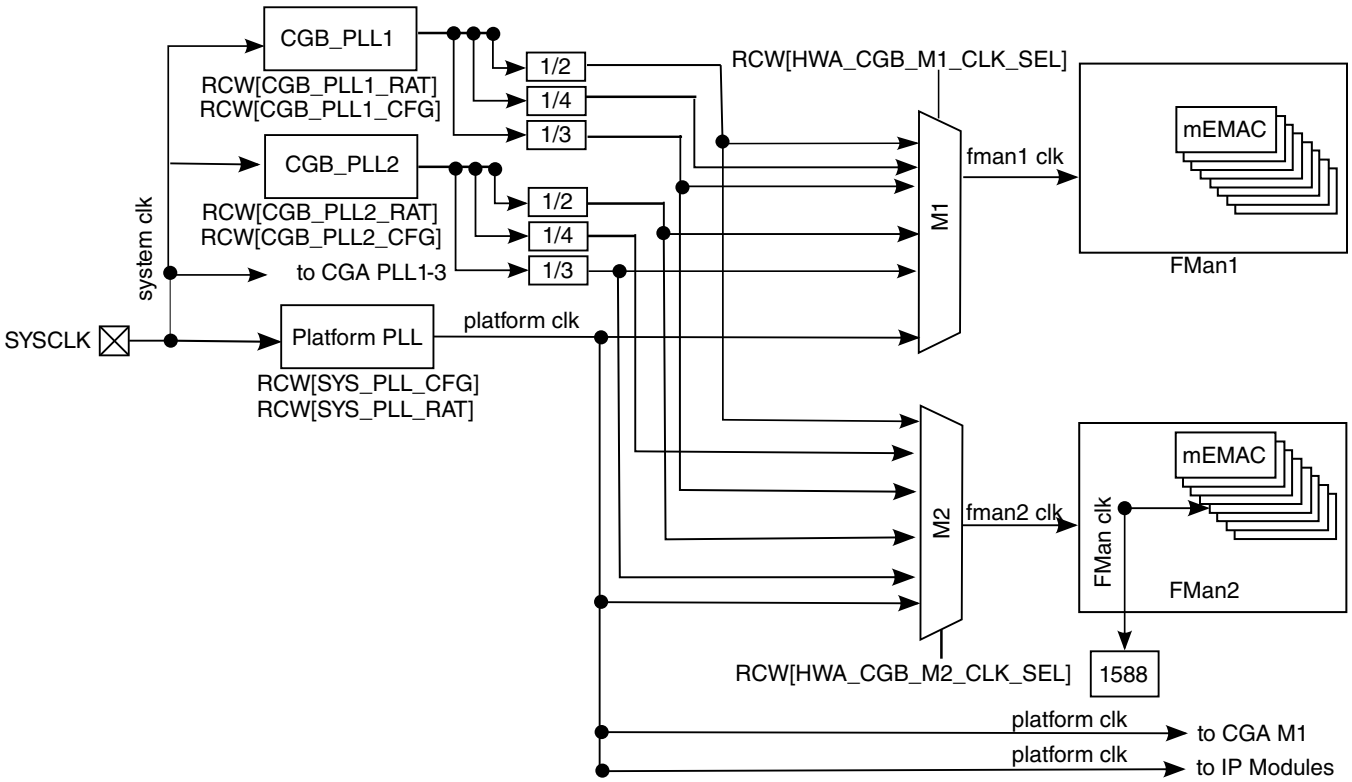

Figure A-3. T4160 Clocking diagram

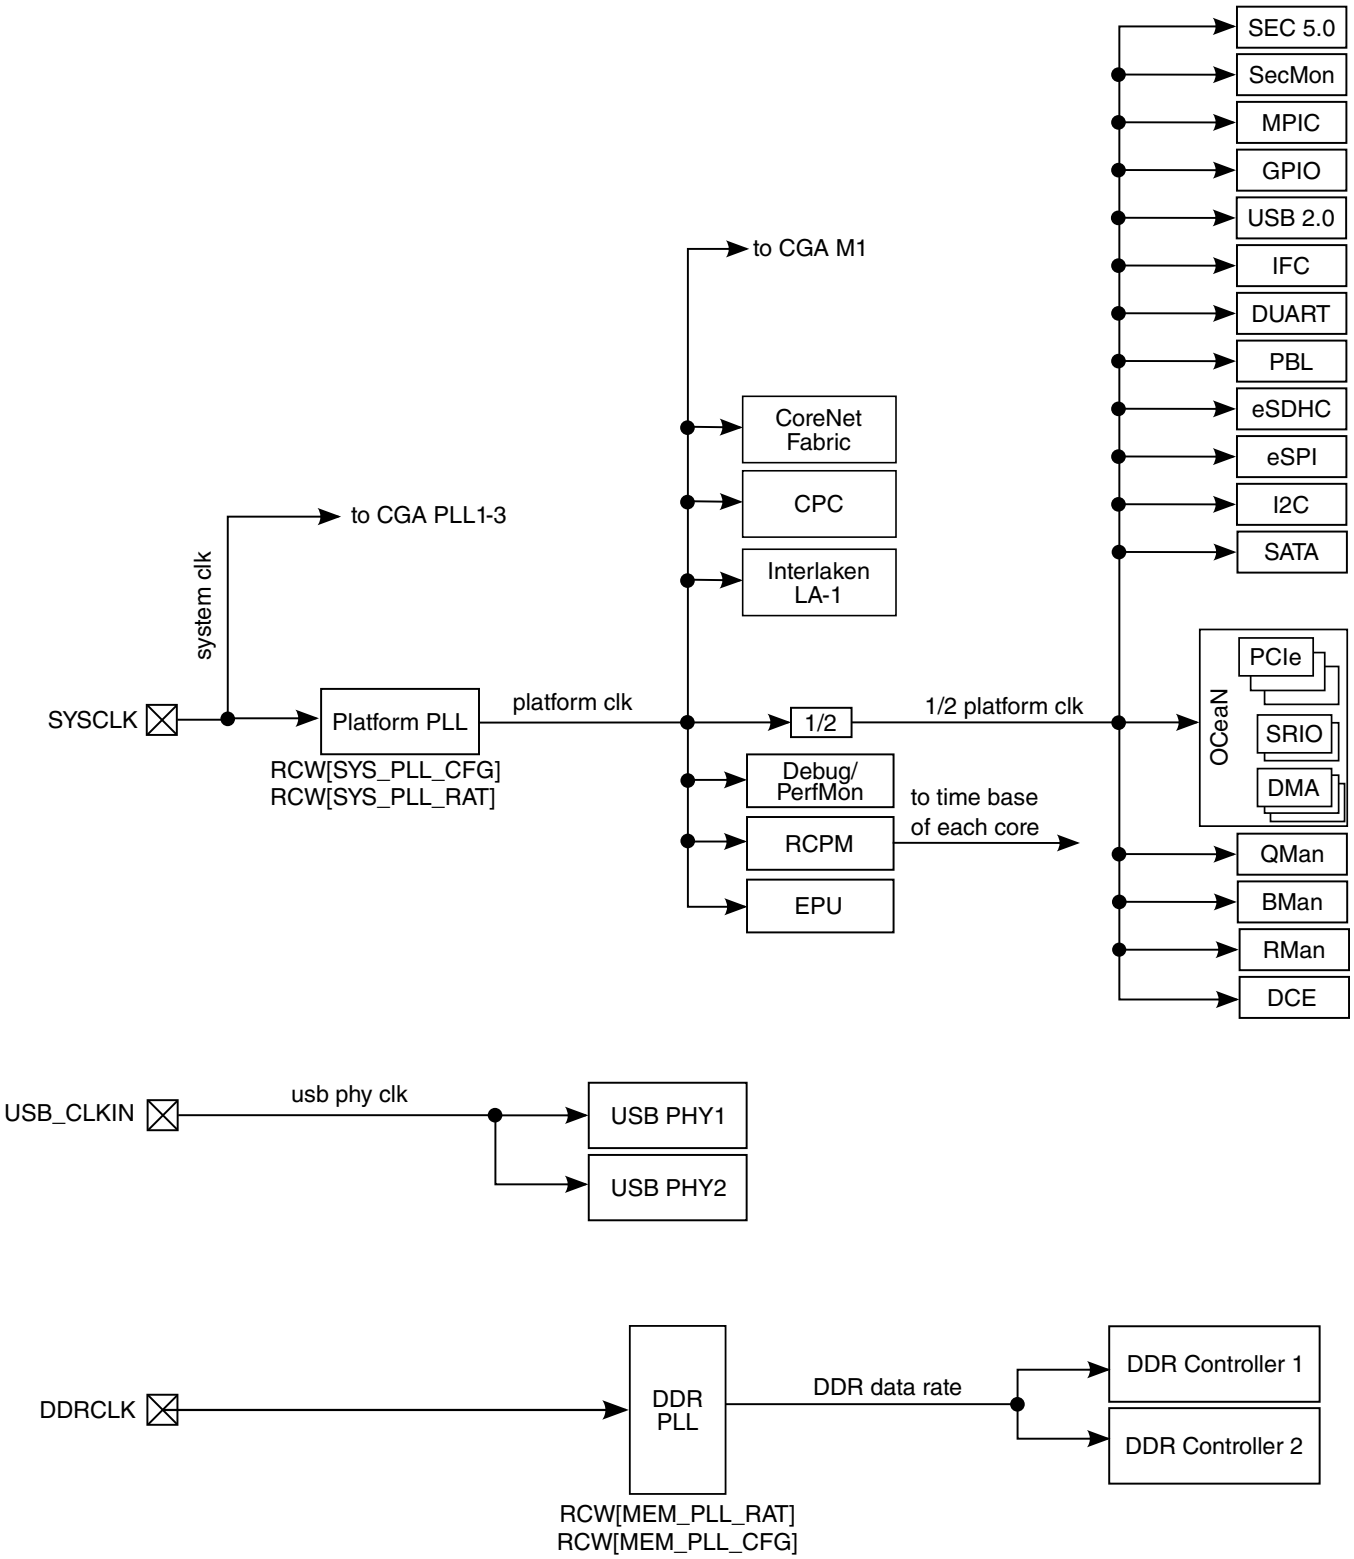

Figure A-4. T4160 Clocking diagram

RCW Field Differences from T4240:

RCW Field	Name	Description
104-107	C3_PLL_SEL	Set to 0
196-200	BOOT_LOC	0_0010(PCIe3) Reserved 1_0010 (memory complex 3) Reserved
264-268	HOST_AGT_PEX	011-Reserved 101-Reserved 111-Reserved

A.3.2 T4160 Register Differences from T4240

The modules unavailable on T4160 are not disabled by hardware. These are disabled in software such as through UBoot.

Table A-3. Unavailable Register Bits

Register Name	Bit Number	Description
Device Disable Register 3 (DCFG_DEVDISR3)	2 (PEX3)	Set to module is disabled
Device Disable Register 5 (DCFG_DEVDISR5)	2 (DDR3)	Set to module is disabled
Device Disable Register 2 (DCFG_DEVDISR2)	5 (FMAN1_MAC6)	Set to module is disabled
Device Disable Register 2 (DCFG_DEVDISR2)	8 (FMAN1_MAC9)	Set to module is disabled
Feature Reporting Register (MPIC_FRR)	5-15 (NIRQ)	Number of interrupts. Holds the binary value of the number of the highest interrupt source supported minus one = 1A3 (110100011)
Core Disable Register (DCFG_CCSR_COREDISR)	20-23	Selected Core is disabled

NOTE

DEVDISR[CPC3] must not be set for T4160. For correct operation, DEVDISR[CPC3] must remain on its default value of ‘Block is enabled’. This is also true for CPC1 and CPC2.

Table A-4. SVR and PVR

Device	SVR	PVR
T4160 (with security)	0x8249_0020	0x8040_0120
T4160 (without security)	0x8241_0020	0x8040_0120

6	e6500 core 3, thread 0
7	e6500 core 3, thread 1
8	e6500 core 4, thread 0
9	e6500 core 4, thread 1
10	e6500 core 5, thread 0
11	e6500 core 5, thread 1
12	e6500 core 6, thread 0
13	e6500 core 6, thread 1
14	e6500 core 7, thread 0
15	e6500 core 7, thread 1

NOTE

T4160 has eight dual threaded e6500 cores so register fields with other cores and threads should be considered reserved.

A.3.3 T4160 SerDes

The T4160 SerDes supports 4 SerDes modules:

- SerDes 1 and SerDes 4 modules support 4 lanes (remaining 4 lanes must be powered down by software)
- SerDes 2 and SerDes 3 modules support 8 lanes
- Each module has 2 PLLs, each with a dedicated Reference Clock pin
- Two modules support networking interfaces
- Two modules support all other interfaces

The following SerDes lanes are powered down

- SerDes 1: Lanes A, B, C, D
- SerDes 4: Lanes A, B, C, D

See the RCW bit definition for SRDS_PLL_PD_S1 for how lanes can be powered down based on the powering down of individual PLLs.

A.3.3.1 Networking SerDes options

Table A-7. SerDes1

SerDes1							
SRDS_PRTCL_S1		EC2 (RGMII)	E	F	G	H	Per Lane PLL mapping

15	F	Aurora (3.125)		SRIO2 (3.125)		2222

A.3.3.3 Requirements for Selecting Valid Networking SerDes Options

A valid configuration for SerDes 1 and 2 is subject to the following:

- Rules restricting protocol selections - the following SerDes 1 protocols (“S1”) are available only if one of the listed SerDes 2 protocols (“S2”) is selected:
  - S1 = 1 is available in Networking SerDes options where S2 = 6-53
- For T4160 refer Precedence Rules for details on rules restricting protocol selections due to max of 18 Gbps PCD
- Rules restricting PLL powerdown selection:
  - SerDes 1’s PLL2 must be powered down using SRDS_PLL_PD_S1 when SRDS_PRTCL_S1 is any of the following values: 1, 2, 4, 27, or 37
  - SerDes 2’s PLL2 must be powered down using SRDS_PLL_PD_S2 when SRDS_PRTCL_S2 is any of the following values: 27, 37, or 39

A.3.3.4 Rules for disabling PLLs when not all lanes are needed

- SerDes 1: Disabling Rightmost Lanes
  - Not applicable
- SerDes 2: Disabling Rightmost Lanes
  - If SRDS_PRTCL_S2 is 6, 15, 25, 26, 35, 47, or 49-57, it is permissible to power down SerDes 2's PLL2 only if software powers down SerDes 2's lanes E-H
  - If SRDS_PRTCL_S2 is 12 or 21, it is permissible to power down SerDes 2's PLL2 only if software powers down SerDes 2's lanes G-H
  - If SRDS_PRTCL_S2 is 45, it is permissible to power down SerDes 2's PLL2 only if software powers down SerDes 2's lanes C-D
- SerDes 2: Disabling Leftmost Lanes
  - If SRDS_PRTCL_S2 is 6, 15, 25, 26, 45, or 55-57, it is permissible to power down SerDes 2's PLL1 only if software powers down SerDes 2's lanes A-D
  - If SRDS_PRTCL_S2 is 12 or 21, it is permissible to power down SerDes 2's PLL1 only if software powers down SerDes 2's lanes A-F

A.3.3.5 Requirements for Selecting Valid Non Networking SerDes Options

A valid configuration for SerDes 3 and 4 is subject to the following:

- Rules restricting protocol selections:
  - PCIe4 configured as 4 lanes (SRDS_PRTCL_S4 = 3) is only available when SRDS_PRTCL_S3 is not equal to 5
- T4160 has no rules restricting protocol selections due to max of 18 Gbps PCD
- Rules restricting PLL powerdown selection:
  - SerDes 3's PLL2 must be powered down using SRDS_PLL_PD_S3 when SRDS_PRTCL_S3 is any of the following values:
    - 1, 5, 9, 10, 20
    - 3 and PCIe2 is limited to a maximum of 5 Gbps
  - SerDes 4's PLL2 must be powered down using SRDS_PLL_PD_S4 when SRDS_PRTCL_S4 is any of the following values:
    - 5, 13
    - 3 and PCIe4 is limited to a maximum of 5 Gbps

A.3.3.6 Precedence Rules

Precedence Rules If (55 <= S2 <= 57) (dual XFIs) and (27 <= S1 <= 48) (no 10G MACs), all XFI protocols are available on SerDes 2 and all SGMII and QSGMII are available on SerDes 1

Table A-11. Precedence Rule: S1=27-48 and S2=55-57

SerDes 1							SerDes 2									
SRDS_PRTCL_S 1	EC2(RGMII)	E	F	G	H	Per lane PLL mapping	SRDS_PRTCL_S 2	EC1(RGMII)	A	B	C	D	E	F	G	H	Per Lane PLL mapping
27	r1.5	sg1. 1	sg1. 2	sg1. 3	sg1. 4	11 11											
35	r1.5	*sg1. 1*	*sg1. 2*			22x x	55	r2.5		XFI1 . 10	XFI2. 10		sg2.1	sg2.2	sg2.3	sg2.4	x11x2 222
37	r1.5			qs1. a		xx2 x	57	r2.5		XFI1 . 10	XFI2. 10		*sg2.1*	*sg2.2*			x11x2 2xx

If (55 <= S2 <= 57) (dual XFIs) and (2 <= S1 < =5) (one 10G MAC), the HiGig[2]1.10 protocol is available on SerDes 1 and the XFI1.10 protocol is not available on SerDes 2

Table A-12. Precedence Rule: S1=2-5 and S2=55-57

SerDes1							SerDes2										
SRDS_PRTCL_S 1	EC2 (RGMII)	E	F	G	H	Per Lane PLL mapping	SRDS_PRTCL_S 2	EC1 (RGMII)	A	B	C	D	E	F	G	H	Per Lane PLL mapping
2	r1.5	HiGig[2]1.10 (3.125)				1111	55	r2.5			XFI2 .10		sg2.1	sg2.2	sg2.3	sg2.4	x11x 2222
4	r1.5	HiGig[2]1.10 (3.75)				1111	57	r2.5			XFI2 .10		*sg2.1*	*sg2.2*			x11x 22xx

Table A-13. Maximinum Ethernet Connectivity of T4160

Configuration	Configuration Number of 10G	Number of SGMII	Number of RGMII
Dual XAUI / HiGig	2	4	2
Dual XFI	2	8	2
Single XAUI / HiGig	1	8	2
Single XFI with / XAUI / HiGig	1+1	4	2
No XAUI / HiGig or XFI	0	12	1

Appendix B
T4080/T4081

B.1 Introduction

The T4080 is a smaller version of the T4160. The T4080 has four dual threaded Power Architecture e6500 cores with the same two memory complexes (CoreNet platform cache and DDR3 memory controller) with the same high-performance datapath acceleration, networking, and peripheral bus interfaces. The T4081 is functionally identical to the T4080 but has lower power. Statements about T4080 apply to T4081.

This figure shows the major functional units within the chip.

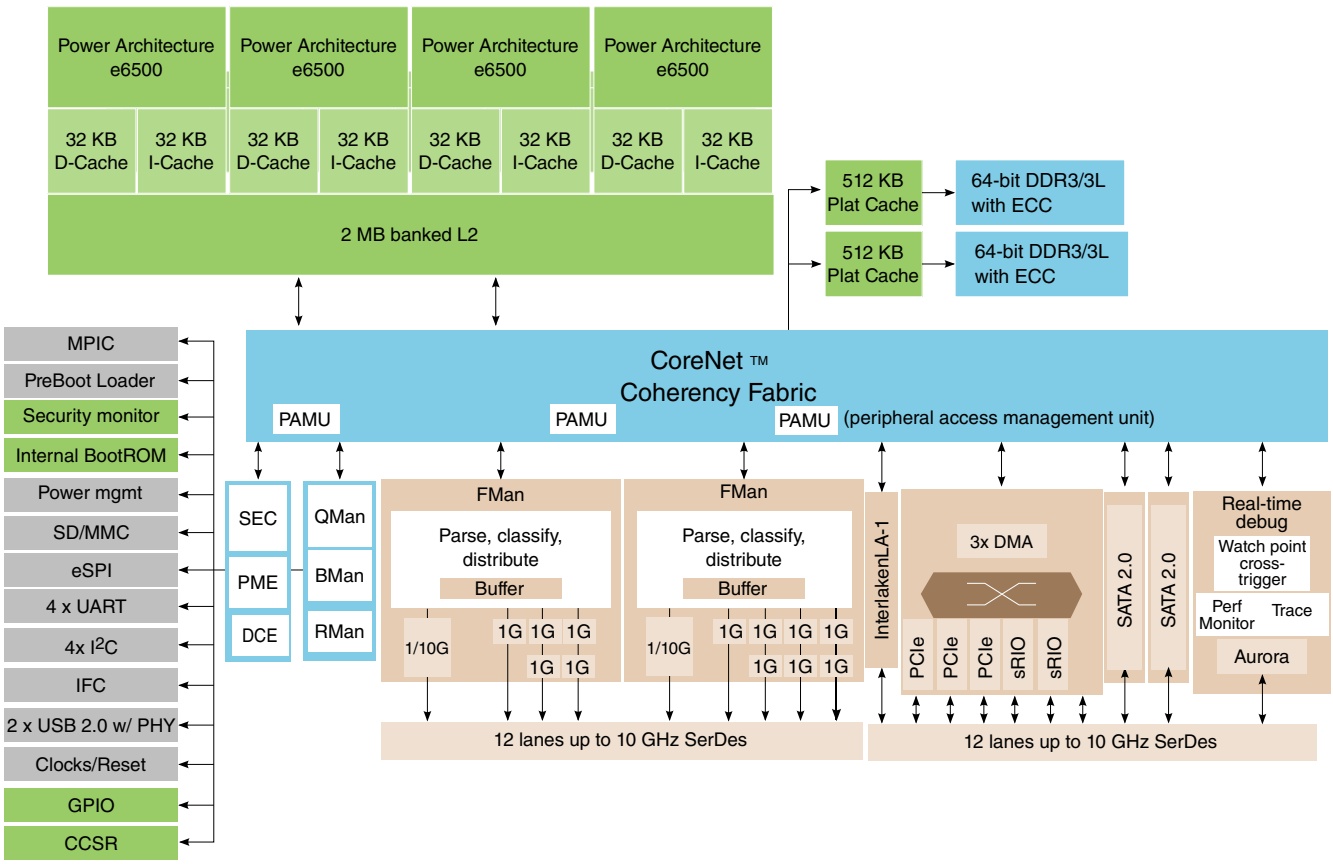

Figure B-1. T4080 block diagram

B.2 Overview of differences between T4160, T4161, T4080, and T4081

Table B-1. Differences between T4160, T4161, T4080, and T4081

Feature	T4160	T4161	T4080	T4161
Power	Standard	Low	Standard	Low
Cores				
Number of physical cores	8		4	
Number of threads	16		8	
Number of clusters	2		1	

B.3 T4080 clocking and RCW differences

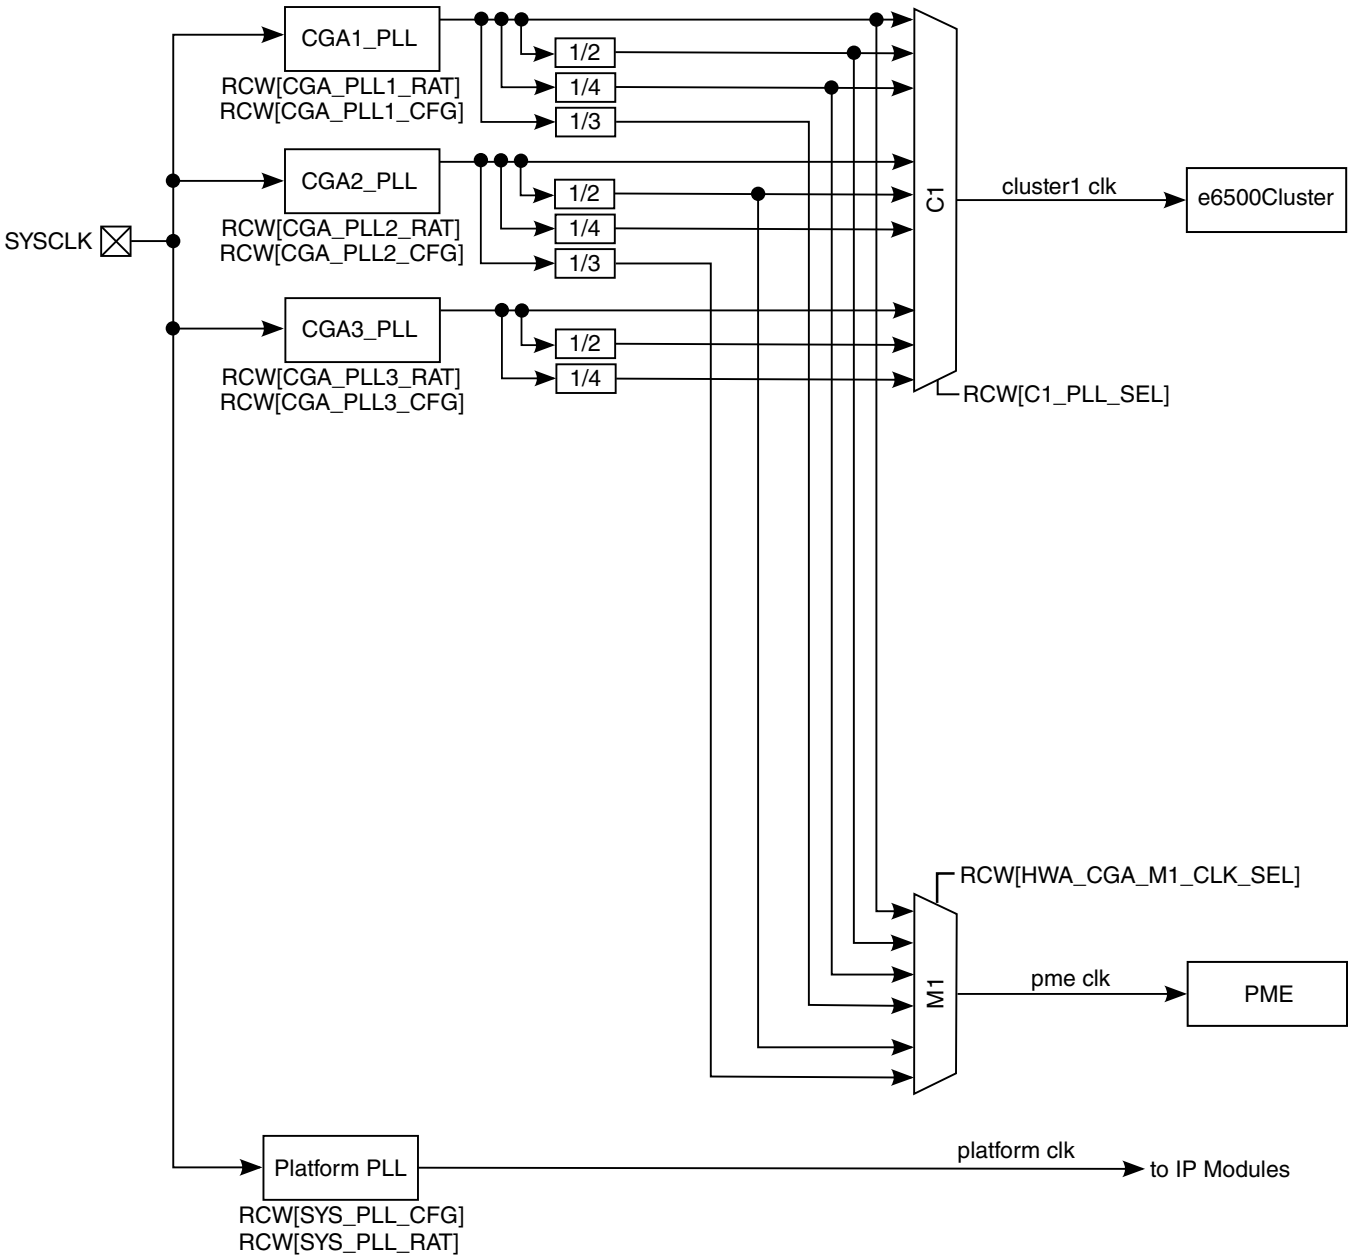

Figure B-2. T4080 Clocking diagram

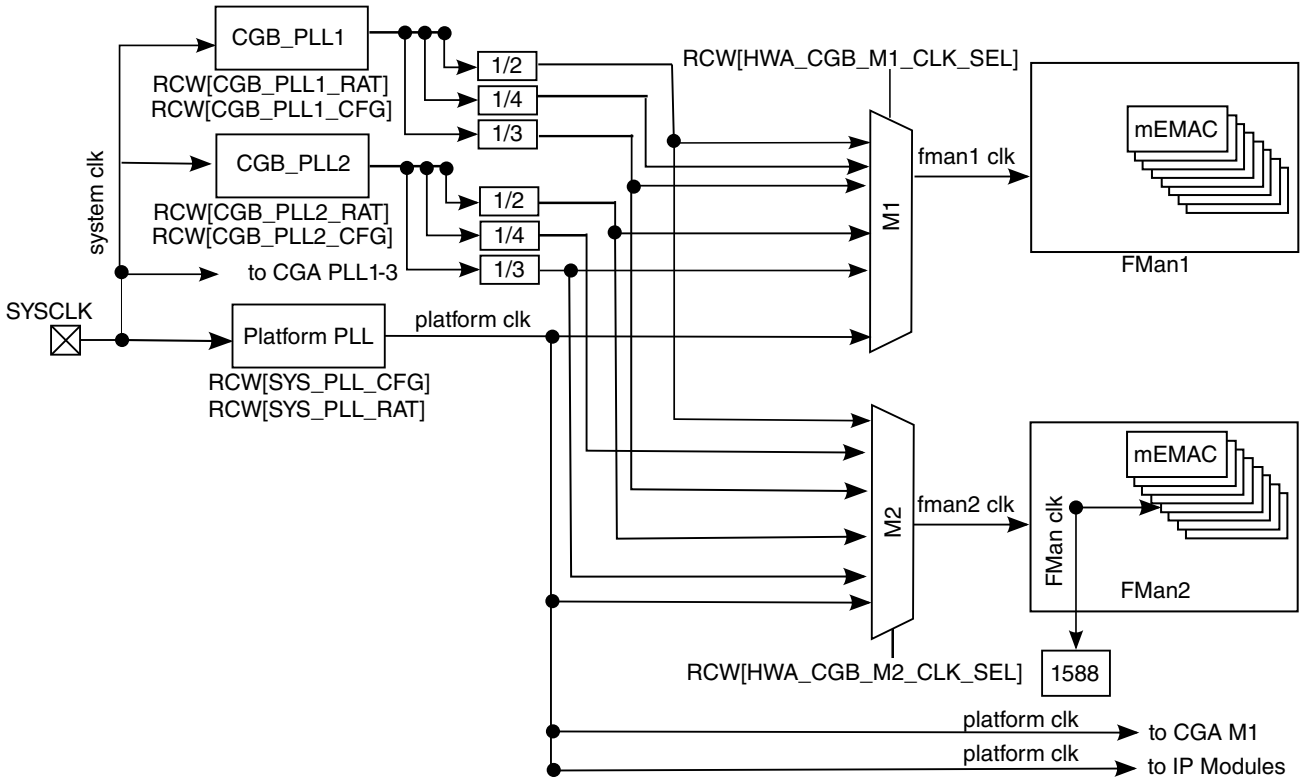

Figure B-3. T4080 Clocking diagram

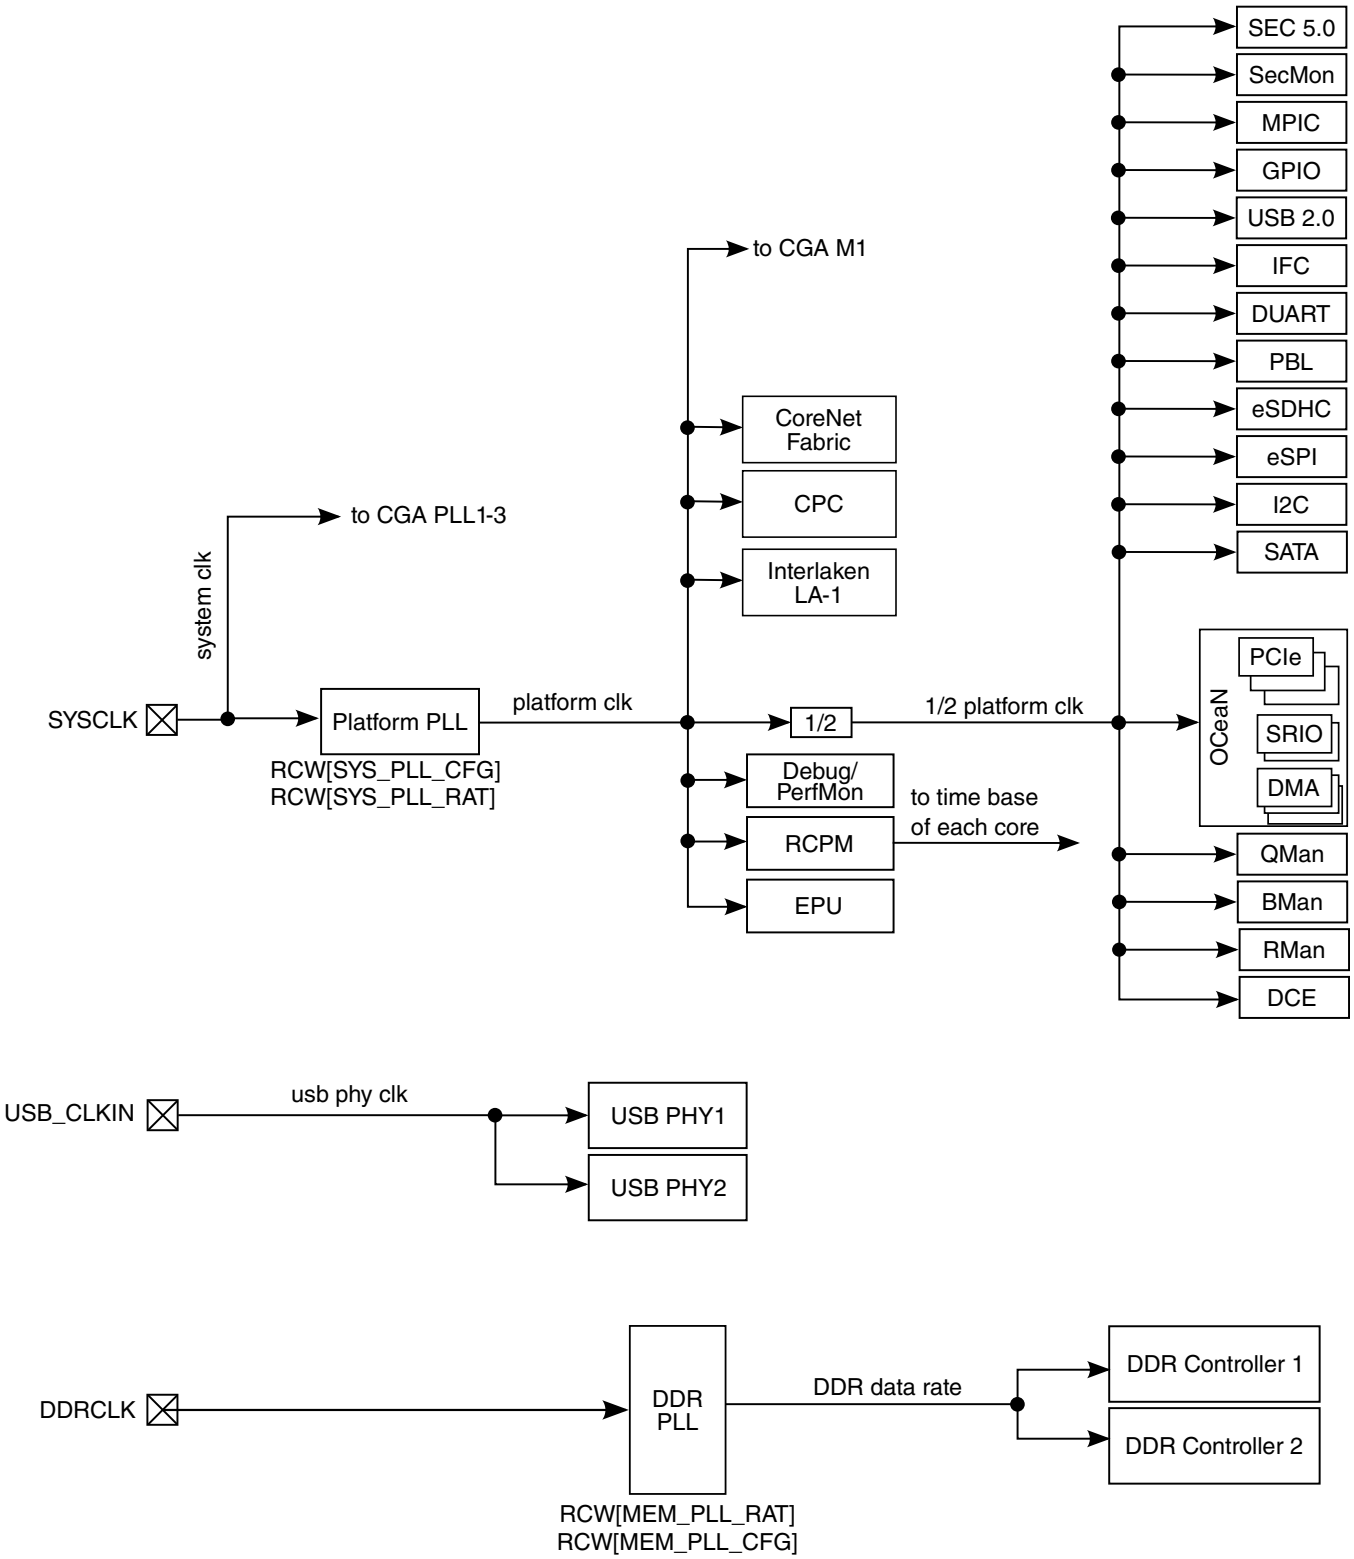

Figure B-4. T4080 Clocking diagram

Table B-2. RCW Differences from T4240

RCW Field	Name	Description
100-103	C2_PLL_SEL	Set to 0
104-107	C3_PLL_SEL	Set to 0
196-200	BOOT_LOC	0_0010(PCIe3) Reserved 1_0010 (memory complex 3) Reserved
264-268	HOST_AGT_PEX	011-Reserved 101-Reserved 111-Reserved

B.4 T4080 Register Differences from T4240

The modules unavailable on T4080 are not disabled by hardware. These are disabled in software such as through UBoot. Core Cluster 2 is not available for use on the T4080 but is not disabled by hardware; correct configuration requires that this cluster is disabled in software such as through UBoot.

Table B-3. Unavailable Register Bits

Register Name	Bit Number	Description
Device Disable Register 3 (DCFG_DEVDISR3)	2 (PEX3)	Set to module is disabled
Device Disable Register 5 (DCFG_DEVDISR5)	2 (DDR3)	Set to module is disabled
Device Disable Register 2 (DCFG_DEVDISR2)	5 (FMAN1_MAC6)	Set to module is disabled
Device Disable Register 2 (DCFG_DEVDISR2)	8 (FMAN1_MAC9)	Set to module is disabled
Feature Reporting Register (MPIC_FRR)	5-15 (NIRQ)	Number of interrupts. Holds the binary value of the number of the highest interrupt source supported minus one = 183 (110000011)
Core Disable Register	20-27	Selected Core is disabled

NOTE

DEVDISR[CPC3] must not be set for T4080. For correct operation, DEVDISR[CPC3] must remain on its default value of ‘Block is enabled’. This is also true for CPC1 and CPC2.

Table B-4. SVR and PVR

Device	SVR	PVR
T4080 (with security)	0x8249_0220	0x8040_0120
T4080 (without security)	0x8241_0220	0x8040_0120

Table B-5. PCI and RapidIO Device IDs

Device	PCI / RapidIO Device ID
T4080 (with security)	044B
T4080 (without security)	044A

Table B-6. MPIC and RCPM Core Mapping

Core n	T4080 thread
0	e6500 core 0, thread 0
1	e6500 core 0, thread 1
2	e6500 core 1, thread 0
3	e6500 core 1, thread 1
4	e6500 core 2, thread 0
5	e6500 core 2, thread 1
6	e6500 core 3, thread 0
7	e6500 core 3, thread 1

NOTE

References to other cores in MPIC and RCPM registers should be disregarded

B.5 T4080 SerDes

The following SerDes lanes are powered down

- SerDes 1: Lanes A, B, C, D
- SerDes 4: Lanes A, B, C, D

See the RCW bit definition for SRDS_PLL_PD_S1 for how lanes can be powered down based on the powering down of individual PLLs.

T4080 supports the same SerDes options as the T4160. Please refer Networking SerDes options and Non Networking SerDes Options for the SerDes options supported.

Appendix C
Revision history

C.1 Substantive changes from revision 3 to revision 4

Substantive changes from revision 3 to revision 4 are as follows:

C.1.1 Overview Revision History

Location cross-reference	Customer-facing description
Universal serial bus (USB) 2.0	Updated second paragraph
Universal serial bus (USB) 2.0	Updated to "The USB controller and integrated PHY can be configured to operate as a stand-alone host, stand-alone device, or with both host and device functions operating simultaneously".

C.1.2 Memory Map Revision History

No substantive changes

C.1.3 Signals Revision History

No substantive changes

C.1.4 Reset Revision History

Topic Name	Customer-facing Description
RCW Field Definitions	Added 12:1 option to MEM_PLL_RAT (bits 10-15)
Reset configuration word (RCW) source	Changed option 00 in 8-bit NOR Flash to Reserved.

Table continues on the next page...

Topic Name	Customer-facing Description
Table 4-1 and Table 4-2	Removed last columns of the tables.

C.1.5 Pre-Boot Loader Revision History

Location cross-reference	Customer-facing description
Features summary	Removed the voltage reference from SD and MMC feature list.

C.1.6 Secure Boot and Trust Architecture Revision History

No substantive changes

C.1.7 e6500 Core Integration Revision History

No substantive changes

C.1.8 CoreNet Platform Cache (CPC) Revision History

No substantive changes

C.1.9 CoreNet Coherency Fabric (CCF) Revision History

No substantive changes

C.1.10 Peripheral Access Management Unit (PAMU) Revision History

No substantive changes

C.1.11 DDR Revision History

Topic Name	Customer-facing Description
DDR SDRAM timing configuration 2 (DDR_TIMING_CFG_2)	Added note to description of FOUR_ACT. Made all FOUR_ACT settings between 0x21 and 0x3F (inclusive) reserved.
Supported DDR Interleaving Configurations	Added footnote to two way interleaving options saying "When more than one chip select is present in each of the two memory controllers only chip select 0 (CS0) or the chip selects that are bank interleaved with CS0 will be available after memory controller interleaving. For example, MC1 and MC2 each has CS0 and CS1 and. CS0 and CS1 of each memory controller are not interleaved. After memory controller interleaving between MC1 and MC2, only the combined memory space of CS0 or two controllers would be interleaved and available for access. The CS1 or each of the controllers that do not participate in the memory controller interleaving are not available or accessible".

C.1.12 Integrated Flash Controller (IFC) Revision History

Topic Name	Customer-facing Description
Transceiver enable during boot	Updated the second bullet.
Normal GPCM external termination-based program operation	Updated the third paragraph.
External signal descriptions	In Row IFC_WE0_B, added entry for NDWE_B signal.
Chip-Select Option register - NOR Flash Mode (IFC_CSOR*n*_NOR)	Changed if cfg_rcw_src[6:7]=00 to Reserved. Added if cfg_rcw_src[6:7]=11 (00 32b addressability) then ADM_SHFT = 0.

C.1.13 I2C Revision History

No substantive changes

C.1.14 Enhanced Serial Peripheral Interface Revision History

No substantive changes

C.1.15 eSDHC Revision History

Topic Name	Customer-facing Description
Protocol control register (eSDHC_PROCTL)	Updated PROCTL[LCTL] as reserved.
Suspend	Reordered Suspend sequence steps to move step 5 (Save the context registers.....) next to step 1.

C.1.16 Universal Serial Bus 2.0 Interface Revision History

Location cross-reference	Customer-facing Description
PHY clocks	Updated the first sentence: "The USBn_CLK input is the clock from the external ULPI PHY to the controller." Updated the note: "A write to registers in the USB controller memory map may cause the system to hang if PORTSC[PHCD]=0 and there is no clock from the ULPI PHY."

C.1.17 DUART Revision History

No substantive changes

C.1.18 SerDes Module Revision History

Location cross-reference	Customer-facing description
XAUI lane alignment recovery	Added section.
SerDes Protocol Configuration Register 0 (SerDes_PCCR0)	Removed "Default value set by RCW configuration" in description of SRIOA_LRV.
SerDes 3 Options	Updated footnote to say "This SerDes combination supports PCIe 8 GT/s which starts out with only PLL1 enabled. Since PLL2 is automatically enabled during speed switch, the system must supply a reference clock to PLL2.and SRDS_PLL_PD_S3 must be set to 2'b01. Write SRDS_PLL_REF_CLK_SEL_S3[PLL2]=100 MHz or 125MHz and supply the reference clock to PLL2 accordingly. "
SerDes 4 options	Updated footnote to say "This SerDes combination supports PCIe 8 GT/s which starts out with only PLL1 enabled. Since PLL2 is automatically enabled during speed switch, the system must supply a reference clock to PLL2 and SRDS_PLL_PD_S4 must be set to 2'b01 ."
Rules restricting non-networking SerDes PLL powerdown	Updated to "SerDes 3 PLL2 must be powered down using SRDS_PLL_PD_S3 when SRDS_PRTCL_S3 is any of the following values: 1, 3, 5, 10, 20 SerDes 4 PLL2 must be powered down using SRDS_PLL_PD_S4 when SRDS_PRTCL_S4 is any of the following values: 1, 3, 5, 13".

C.1.19 PCI Express Interface Controller Revision History

Location cross-reference	Customer-facing description
PCI Express Device ID Register (Device ID Register) and PCI Express Device ID Register (Device ID Register) PCI Express Device ID Register (Device ID Register)	Updated Device ID for T4160 and added values for T4080.

C.1.20 Serial RapidIO Interface Revision History

Location cross-reference	Customer-facing description
Device identity capability register (SRIO_DIDCAR)	Updated Device ID for T4160 and T4080.

C.1.21 LAC Revision History

No substantive changes

C.1.22 SATA Controller Revision History

No substantive changes

C.1.23 DMA Controller Revision History

No substantive changes

C.1.24 DPAA Overview Revision History

No substantive changes

C.1.25 Multicore Programmable Interrupt Controller (MPIC) Revision History

Location cross-reference	Customer-facing description
Global configuration register (MPIC_GCR)	Added note "RST bit should not be used in CL=1 proxy mode" to RST description

C.1.26 Interrupt Assignments Revision History

No substantive changes

C.1.27 Device Configuration and Pin Control Revision History

Topic Name	Customer-facing Description
Fuse Status Register (DCFG_CCSR_FUSESR)	Updated settings of DA_V to show support for VDD voltages of 0.9375, 0.9250, 0.9125, and 0.9000
POR Status Register 1 (DCFG_CCSR_PORSR1) and POR Status Register 2 (DCFG_CCSR_PORSR2)	Moved bit 24 XVDD_SEL in PORSR1 to bit 7 in PORSR2.
POR Status Register 1 (DCFG_CCSR_PORSR1)	Removed internal information in bits ENG0, ENG1, and ENG2.
Reset Request Status Register (DCFG_CCSR_RSTRQSR1)	Replaced the word error with "detected security violation/ tampering event".

C.1.28 General Purpose I/O (GPIO) Revision History

No substantive changes

C.1.29 Run Control and Power Management (RCPM) Revision History

Topic Name	Customer-facing Description
Power Management State Summary	Updated the Resumable under "Full On" power state for both the tables.
Physical Core PH15 Status Register (RCPM_PCPH15SR)	Removed the sentence “The RCPM module as implemented on the chip describes the cores implemented on this SoC” from the note in all the Physical Core .... registers.

C.1.30 T4160 Appendix

No substantive changes

C.1.31 T4080 Appendix

No substantive changes

C.2 Substantive changes from revision 2 to revision 3

Substantive changes from revision 2 to revision 3 are as follows:

C.2.1 Overview Revision History

Location	Description
Throughout	Added support for devices: T4241, T4161, T4081.
PCI Express	Updated description of PCIe controllers

C.2.2 Memory Map Revision History

No substantive changes

C.2.3 Signals Revision History

No substantive changes

C.2.4 Reset Revision History

Location	Description
Hard Coded RCW Options	Corrected 0_1000_1010 to 0_1001_1010.
RCW Field Definitions	Added 12:1 option to MEM_PLL_RAT (bits 10-15)

C.2.5 Pre-Boot Loader Revision History

No substantive changes

C.2.6 Secure Boot and Trust Architecture Revision History

Location	Description
Secure Boot and Trust Architecture	Replaced the chapter with an overview of Trust Architecture and a list of resources for more detailed technical information.

C.2.7 e6500 Core Integration Revision History

No substantive changes

C.2.8 CoreNet Platform Cache (CPC) Revision History

Location	Description
Cache Operation Instructions and Transactions	Updated the section.

C.2.9 CoreNet Coherency Fabric (CCF) Revision History

No substantive changes

C.2.10 Peripheral Access Management Unit (PAMU) Revision History

Location	Description
PAMU Features Summary	Updated bullet "Support for up to 4-Kbyte..." to "Support for up to 4-K".

C.2.11 DDR Revision History

Location	Description
DDR SDRAM timing configuration 1 (DDR_TIMING_CFG_1)	Updated setting 0000 of WRREC from 'Reserved' to 'Reserved when DDR_TIMING_CFG_3[EXT_WRREC] = 0; otherwise 0 clocks'
DDR Functional Description	Changed last sentence of paragraph 3 to show maximum single bank size of 16 GB and maximum total memory size of 64 GB.
DDR SDRAM timing configuration 3 (DDR_TIMING_CFG_3)	Updated all non-reserved settings of CNTL_ADJ except 000 to use DDR clock cycles
DDR SDRAM timing configuration 2 (DDR_TIMING_CFG_2)	Added note to description of FOUR_ACT. Made all FOUR_ACT settings between 0x21 and 0x3F (inclusive) reserved.

C.2.12 Integrated Flash Controller (IFC) Revision History

Location	Description
Throughout chapter	Updated all references of different clock names as ip_clk.
, , , GPCM Event and Error Enable register (IFC_GPCM_EVTER_EN), GPCM Event and Error Status register (IFC_GPCM_EVTER_STAT), GPCM Event and Error Interrupt enable register (IFC_GPCM_EVTER_INTR_EN), GPCM Transfer Error Attributes register 0 (IFC_GPCM_ERATTR0), GPCM Status register (IFC_GPCM_STAT), GPCM Transfer Error Attributes register 1 (IFC_GPCM_ERATTR1), and GPCM Transfer Error Attributes register 2 (IFC_GPCM_ERATTR2)	Changed offsets of registers.
Table 12-2	In description of CLK[0:n], removed "This clock is active only when there is any access on GPCM or synchronous NOR."
NOR flash features	Added bullet "Burst size in NOR is governed by system bus size and length" .
Normal GPCM external termination-based program operation	Added sentence saying "IFC is not available for further transactions until IFC_TA is deasserted".
Figure 12-45	Updated second last signal from "read_data_mem" to 'AD'.
Normal GPCM external termination-based read operation	Removed "Normal GPCM access termination with IFCTA (write access)" figure.
Figure 12-37	Updated AVD_B as active low.
External signal descriptions	Provided clarity to AD[0:n] by adding explanation towards end of description.
NAND asynchronous mode program data timing	Updated the figure to reflect CLE and ALE high time as TWP+TWCHT.
Internal connectivity of RB signal	In second para added "Note that ,If IFC_CS_B[5] is used, then IFC_RB_B[3] cannot be used and vice-versa."
IFC memory map/register definition	Removed registers: IFC_RB_MAP (offset 404) and IFC_WP_MAP (offset 408)
Internal connectivity of RB signalInternal connectivity of WP signal	Rewrote sections

C.2.13 I2C Revision History

No substantive changes

C.2.14 Enhanced Serial Peripheral Interface Revision History

No substantive changes

C.2.15 eSDHC Revision History

No substantive changes

C.2.16 Universal Serial Bus 2.0 Interface Revision History

Location	Description
Config1, Config2, and Status1	Reversed endianness of registers.
Config5	Added registers.

C.2.17 DUART Revision History

No substantive changes

C.2.18 SerDes Module Revision History

Location	Description
SerDes Memory Map/Register Definition	Revised the paragraph before the memory map table for clarity.
Transmit Equalization Control Register 0 - Lane n (SerDes_LN*n*TECR0)	Added recommended setting for "Others."
SerDes Memory Map/Register Definition	Removed register LNnPSSR0
XFIx Protocol Control Register 1 (SerDes_XFI*n*CR1)	In XFInCR1, MDEV_PORT bitfield corrected MDIO_COMMAND[Device Address] to MDIO_CTL[DEV_ADDR].
QSGMIIx Protocol Control Register 1 (SerDes_QSGMII*n*CR1)	In QSGMIInCR1, MDEV_PORT bitfield corrected MDIO_COMMAND[PHY Address] to MDIO_CTL[PHY_ADDR].

C.2.19 PCI Express Interface Controller Revision History

Location	Description
PCI Express capability structure	Reinstated Slot Capabilities and Slot Control Registers. Added notes to fields that are intended to support hot-plug that this chip does not support hot-plug.
	Changed field at bits 24-20 to "Reserved."
	Changed field at bit 19 to "Reserved."
iATU Overview	Removed specific references to AHB/AXI internal platform. Removed Limitations section. (Does not apply to end user systems.)
CFG Handling	Changed AHB/AXI references to "internal platform."
Memory map/register overview	Added BAR Mask registers
Configuring the chip for inbound CCSR accesses	Added new section.
Internal Address Translation Unit	Throughout this section (including subordinate sections) and also in the iATU registers, removed references to the "Invert Feature." Throughout this section (including subordinate sections), changed references to "TRGT0," to "internal platform," and "TRGT1," to "configuration registers."
Lane Reversal	Added table describing supported lane reversal scenarios.
Overview (Address Match Mode)	Clarified that there are six address regions and revised paragraph concerning CX_ATU_MIN_REGION_SIZE.
RID BDF Number Replacement	Clarified multifunction operation and removed reference to Function Number Translation Bypass.
No Address Match Result	Clarified paragraph concerning TLP header information.
I/O and MEM Match Modes	Clarified that there are six address regions
CFG Handling (Upstream Port)	Removed note referring to non-existent sections.
Overview (Address Match Mode)	Removed note concerning DBI transactions
PCI Express Link Control Register (Link Control Register)	Link Control Register (offset 80h) - Changed reset value of RCB field from 0 to 1
PCI Express Root Capabilities Register (Root Capabilities Register)	Root Capabilities Register (offset 1Eh) - Added register.
PCI Express Expansion ROM Base Address Register (Expansion ROM BAR) and PCI Express Expansion ROM Base Address Register (Expansion ROM BAR)	Expansion ROM BAR (Type 0) (offset 30h) and Expansion ROM BAR (Type 1) (offset 38h): Changed from 16-bit to 32-bit register and fields revised according to the PCI Express Base Specification, Revision 3.0
PCI Express	Updated description of PCIe controllers
PEX Register Descriptions	Register updates: PEXMSIIWAR (offset D10): updated reset value, TRGT bitfield values PEXIWAR (offset D90): updated TRGT bitfield values general: Updated VF window registers to show 64 virtual functions

C.2.20 Serial RapidIO Interface Revision History

Location	Description
SRIO Memory Map/Register Definition	Define SRIO as one controller with two ports.

C.2.21 LAC Revision History

No substantive changes

C.2.22 SATA Controller Revision History

No substantive changes

C.2.23 DMA Controller Revision History

No substantive changes

C.2.24 DPAA Overview Revision History

No substantive changes

C.2.25 Multicore Programmable Interrupt Controller (MPIC) Revision History

Location	Description
MPIC Memory Map/Register Definition	Changed the offsets for the MPIC_MSICRB[0-15] registers. The previous values were incorrect.

C.2.26 Interrupt Assignments Revision History

No substantive changes

C.2.27 Device Configuration and Pin Control Revision History

Location	Description
System Version Register (DCFG_CCSR_SVR)	Updated DCFG_CCSR_SVR[VAR_PER]. Removed DCFG_CCSR_SVR[SEC].
Fuse Status Register (DCFG_CCSR_FUSESR)	Updated settings of DA_V to show support for VDD voltages of 0.9375, 0.9250, 0.9125, and 0.9000
POR Status Register 1 (DCFG_CCSR_PORSR1) and POR Status Register 2 (DCFG_CCSR_PORSR2)	Moved bit 24 XVDD_SEL in PORSR1 to bit 7 in PORSR2.

C.2.28 General Purpose I/O (GPIO) Revision History

No substantive changes

C.2.29 Run Control and Power Management (RCPM) Revision History

Location	Description
	Updated the register description.
PW15 State Operation Exit	Added FlexTimer, IIC, UART, IRQ0 and IRQ2 interrupts to trigger exit.
Device LPM20 operation sequence	Added two new steps in the LPM20 sequence. Updated PCL10 state to stop mode In the last step, removed GIC from the example IPs.
Power Management State Summary	Made state retained for PH20 as "Y".

C.2.30 T4160 Appendix

Location	Description
Throughout	Added support for T4241, T4161, T4081

C.2.31 T4080 Appendix

Location	Description
Throughout	Added support for T4161, T4081

C.3 Substantive changes from revision 1 to revision 2

Substantive changes from revision 1 to revision 2 are as follows:

C.3.1 Overview Revision History

Reference	Description
Features summary and Interlaken Look-Aside Controller (LAC) and interface	Removed 10.3125 GHz Interlaken support.

C.3.2 Memory Map Revision History

No substantive changes

C.3.3 Signals Revision History

No substantive changes

C.3.4 Reset Revision History

Reference	Description
Platform clock domain control/status register (Clocking_CLKPCSR)	Updated CLKOSEL setting 11001 to platform/3
Power-on reset sequence	Replace SRDSBnRSTCTL with SerDesx_PLLnRSTCTL
External Clock Signals	Added IEEE 1588 Timer Module to "This signal can also be used (optionally) to clock the global timers in the programmable interrupt controller (PIC)."

C.3.5 Pre-Boot Loader Revision History

Reference	Description
Required format of data structure used by PBL	In the SYS_ADDR field description, removed reference to alternate configuration BAR.

C.3.6 Secure Boot and Trust Architecture Revision History

Reference	Description
HPVIDR1	Updated reset value of HPVIDR1 to 003C_0102.
FSWPR	Removed note stating that "secure boot can still be used in chips without the SEC...."
DCVR, DRVR	Updated the bit description as DCVR0 is upper part and DCVR1 is lower part.
HPCOMR	Removed "including zeroization of the ZMK, the GPRs, and the monotonic counter with " and added "The monotonic counter, and time alarm registers are not reset" to LP_SWR bit.
State definitions	Replaced "to stop using the OTPMK, ZMK, and KEKs, and zeroize any ephemeral secrets within the SEC" by "switch to the test master key and to zeroize the KEKs and all key registers" in soft fail. Added "The master key input (OTPMK, ZMK, or the XOR of the two) to SEC is forced to be all zeros, but the KEK is not. The KEK is a random value that can be read or overwritten. Replaced "Ephemeral secrets" by "black keys".
Internal boot ROM and ISBC	Removed sentence saying "The ISBC is also involved in unlocking the SFP to allow key revocation fuses to be set."
Key revocation	Replaced paragraph concerning write protection of the key revocation fuses.

C.3.7 e6500 Core Integration Revision History

No substantive changes

C.3.8 CoreNet Platform Cache (CPC) Revision History

Reference	Description
CPC hardware debug control register 0 (CPC_CPCHDBCR0)	Added note: Any write to this register must maintain the default reset values for the reserved bits.

C.3.9 CoreNet Coherency Fabric (CCF) Revision History

No substantive changes

C.3.10 Peripheral Access Management Unit (PAMU) Revision History

Reference	Description
Setting Up PAMU	Removed "The PAMU fetch attributes register is programmed with the necessary information" .

C.3.11 DDR Revision History

No substantive changes

C.3.12 Integrated Flash Controller (IFC) Revision History

Reference	Description
NAND flash asynchronous mode	Updated the second paragraph for the commands and address bytes.

C.3.13 I2C Revision History

No substantive changes

C.3.14 Enhanced Serial Peripheral Interface Revision History

Reference	Description
24-bit address example, 16-bit address example	In the first step, updated the output signal from CS1 to CS0.
eSPI CS0 mode register (ESPI_SPMODE0)	Updated HO_ADJ default setting to 011.

C.3.15 eSDHC Revision History

Reference	Description
Protocol control register (eSDHC_PROCTL)	Added 8-bit mode to DTW bit.

C.3.16 Universal Serial Bus 2.0 Interface Revision History

Reference	Description
Port Status/Control (USB_PORTSC)	Added the following note in the OCA bit description: Whenever over-current condition occurs, the correct operation of controller is not guaranteed even if over-current condition goes away. Software should reset the controller by writing in USBCMD[RST] bit and repeat the host controller initialization steps again before expecting the controller to behave properly.

C.3.17 DUART Revision History

No substantive changes

C.3.18 SerDes Module Revision History

Reference	Description
Throughout	Removed 10.3125 Gbps Interlaken support.
PLL Reset and Reconfiguration	Added "and wait no longer than 0.5 µsecs before going to step 7".
SerDes 1 options, SerDes 2 options, SerDes 3 Options and SerDes 4 options	Added hex values of protocols.
Precedence Rules	Removed note "S1=1 (dual XAUI) with S2=55,57 (dual XFI) protocol combination is not supported" as the restriction no longer applies.

C.3.19 PCI Express Interface Controller Revision History

Reference	Description
Power Management	Removed statement, "L2 is supported since main power will remain on during L2/L3 Ready to L2 transition."
PCI Express Link Capabilities Register (Link Capabilities Register)	Updated MAX_LINK_SP bit description.

C.3.20 Serial RapidIO Interface Revision History

Reference	Description
Port 1 RapidIO inbound window attributes register 0 (SRIO_P1RIWAR0) Port 2 RapidIO inbound window attributes register 0 (SRIO_P2RIWAR0) Port 1 RapidIO inbound window attributes register n (SRIO_P1RIWAR*n*) Port 2 RapidIO inbound window attributes register n (SRIO_P2RIWAR*n*)	Updated TGINT settings.

C.3.21 LAC Revision History

No substantive changes

C.3.22 SATA Controller Revision History

No substantive changes

C.3.23 DMA Controller Revision History

No substantive changes

C.3.24 DPAA Overview Revision History

No substantive changes

C.3.25 Multicore Programmable Interrupt Controller (MPIC) Revision History

No substantive changes

C.3.26 Interrupt Assignments Revision History

No substantive changes

C.3.27 Device Configuration and Pin Control Revision History

Reference	Description
Fuse Status Register (DCFG_CCSR_FUSESR)	In bitfield DA_V, changed settings 00101(0.9375V) to 01111 (0.8125V) and 10101 (1.0625V) to 11000 (1.100V) to reserved. Changed 11111 to reserved. In DA_ALT_V removed "except 11111 is reserved". Added note "Voltage ID settings changed to reserved will not be used. ". Removed "all ones" in the description of DA_ALT_V description.
Reset Request Mask Register (DCFG_CCSR_RSTRQMR1)	Updated security controller to security monitor in the bit description.

C.3.28 General Purpose I/O (GPIO) Revision History

Reference	Description
GPIO Memory Map/Register Definition	In the memory map description, updated memory map space to 28 bytes.

C.3.29 Run Control and Power Management (RCPM) Revision History

Reference	Description
	Updated the register description.
PW15 State Operation Exit	Added FlexTimer, IIC, UART, IRQ0 and IRQ2 interrupts to trigger exit.
Device LPM20 operation sequence	Added two new steps in the LPM20 sequence. Updated PCL10 state to stop mode In the last step, removed GIC from the example IPs.

C.3.30 T4160 Appendix

Reference	Description
T4160 Networking SerDes and T4160 Non Networking SerDes	Added hex values of protocols.
T4160 Non Networking SerDes	De-featured 10.3125 Gbps Interlaken.

C.3.31 T4080 Appendix

No substantive changes

C.4 Substantive changes from revision 0 to revision 1

Substantive changes from revision 0 to revision 1 are as follows:

C.4.1 Overview Revision History

Reference	Description
Features summary	Half duplex is not supported on RGMII interface

C.4.2 Memory Map Revision History

Reference	Description
Global Source and Target IDs	Updated the transaction source to 0xC0 FMAN 1 XAUI 1 0xC1 FMAN 1 XAUI 2 0xCE Reserved 0xCF Reserved 0xD0 FMAN 2 XAUI 1 0xD1 FMAN 2 XAUI 2
Global Source and Target IDs	Added 0x49 SAP.

C.4.3 Signals Revision History

Reference	Description
MPIC and GPIO1 signal multiplexing	Added note "When GPIO functionality is selected, the corresponding MPIC external interrupt vector priority registers (MPIC_EIVPRn) must have their polarity set to active high".

C.4.4 Reset Revision History

Reference	Description
Hard Coded RCW Options and RCW Settings for Hard-Coded Options	Added sections.
Dynamic frequency switching (DFS) control	Added "The wait time should be larger than 12 SYSCLK Window in which DFS occurs."

C.4.5 Pre-Boot Loader Revision History

Reference	Description
Modes of operation	Removed "Load Pre-Boot initialization words only if default RCW is to be used."
Overview, Features summary, Device initialization by PBL	Updated IFC GPCM mode to IFC FCM (NOR Flash) for loading the PBI commands.

C.4.6 Secure Boot and Trust Architecture Revision History

Reference	Description
HPVIDR1	Updated the IP_ID bit description to remove the actual ID value.
Security fuse processor, Fuse programming	Removed reference to "Manufacturing to Trust" whitepaper.
ISBC phase	Updated the last two steps for primary image validation and secondary image validation.
FUIDR	Revised the register description to state the provisioned value is pseudo-random and is highly unique.
HPSR	Added bit 27 LP_DIS.
HPSR	Changed bits 7-15 to reserved.
HPSR	Added bit 30 PI and bit 31 HPTA.

Table continues on the next page...

Substantive changes from revision 0 to revision 1

Reference	Description
HPCOMR	Added bit 0 NPSWA_EN.
LPLR	Added bit 22 MKS_HL.
LPTDCR	Added bit 20 ET1P.
HPTAMR HPTALR	Added registers.
HPSR	Changed bit 31 HPTA to RW.
LPGPR0_ALIAS	Added register.

C.4.7 e6500 Core Integration Revision History

No substantive changes

C.4.8 CoreNet Platform Cache (CPC) Revision History

No substantive changes

C.4.9 CoreNet Coherency Fabric (CCF) Revision History

Reference	Description
CCF Error Detect Register (CCF_ERRDET)	Added register description "The Error Detect Register holds error detection status for each of the supported error types. One bit is implemented for each error type. An error bit gets set when an error occurs unless error detection for that error type is disabled. An error bit gets cleared when software writes a 1 to that bit." To CTYPE bit description added " 0x0000_0001<;CTYPE decodes to the corresponding detect bit position. For example, Bit 0 set = local access error Bit 1 set = illegal coherency response error Others reserved

C.4.10 Peripheral Access Management Unit (PAMU) Revision History

No substantive changes

C.4.11 DDR Revision History

Reference	Description
DDR SDRAM control configuration (DDR_DDR_SDRAM_CFG)	Updated the bit description for HSE.
DDR SDRAM timing configuration 0 (DDR_TIMING_CFG_0)	Updated reset value of DDR_TIMING_CFG_0 from 0x0011_0105 to 0x0011_0005
	Removed DDR_EOR register
Programming Summary	updated summary for 8_BE in table "Programming Summary"
DDR Debug Status Register 1 (DDR_DDRDSR_1) DDR Debug Status Register 2 (DDR_DDRDSR_2)	Updated register reset values: DDR_DDRDSR_1 is now 0000_8080; DDR_DDRDSR_2 is now 8000_0000
DDR SDRAM Initialization Sequence	Added note "It is recommended to check DDR_ERR_DETECT after initialization has completed, assuming it has been cleared before. If any error is reported in DDR_ERR_DETECT due to the initialization procedure, the initialization has failed and the memory interface cannot be considered stable for use".
DDR SDRAM control configuration 2 (DDR_DDR_SDRAM_CFG_2)	Changed DDR_SDRAM_CFG_2[ODT_CFG] setting 11 to Reserved
DDR Memory Test Control Register (DDR_DDR_MTCR)	Added note to DDR_MTCR[MT_ADDR_EN], DDR_DDR_MT_ST_EXT_ADDR[MT_ST_EXT_ADDR], DDR_DDR_MT_ST_ADDR[MT_ST_ADDR], DDR_DDR_MT_END_EXT_ADDR[MT_END_EXT_ADDR], DDR_DDR_MT_END_ADDR[MT_END_ADDR]: Please note the following restriction when using DDR_MTCR[MT_ADDR_EN] to limit the address range to be tested: For any individual test, neither the starting address (DDR_MT_ST_EXT_ADDR || DDR_MT_ST_ADDR) nor the ending address (DDR_MT_END_EXT_ADDR || DDR_MT_END_ADDR) can be less than that used during the previous test.

C.4.12 Integrated Flash Controller (IFC) Revision History

Reference	Description
Chip-Select Option register - NAND Flash Mode (IFC_CSOR*n*_NAND)	Added 'NAND_MODE' bit.
GPCM Transfer Error Attributes register 0 (IFC_GPCM_ERATTR0)	Updated the ERCS bit access from R/W to RO.

Table continues on the next page...

Substantive changes from revision 0 to revision 1

Reference	Description
Normal GPCM internal counter-based read operation	Updated last sentence of last paragraph.
Flash Timing register 2 for Chip Select n - NAND Flash Mode (IFC_FTIM2_CS*n*_NAND) Flash Timing register 2 for Chip Select n - NAND Flash Mode (IFC_FTIM2_CS*n*_NAND)	Updated bit description of [TWW].
External signal descriptions	Added row for the IFC_OE_B signal.
Clock Control register (IFC_CCR)	Updated the CLKDIV bit description.
Chip-Select Option register - NAND Flash Mode (IFC_CSOR*n*_NAND)	Updated the NAND_MODE bit setting.
Throughout	Updated BRn register to CSPRn.
Chip-Select Option register - NAND Flash Mode (IFC_CSOR*n*_NAND), Chip-Select Option register - NOR Flash Mode (IFC_CSOR*n*_NOR), Chip-Select Option register - GPCM (IFC_CSOR*n*_GPCM)	Updated the CSORn[TRHZ] reset value to 011.
External signal descriptions	In the "Signal properties" table, updated IO type for IFC_A address signal from 'IO' to 'O'.
Internal connectivity of WP/RB signal	Added the following note: The internal connectivity of WP/RB signal depends on the IFC mode selected by RCW[IFC_MODE].

C.4.13 I2C Revision History

No substantive changes

C.4.14 Enhanced Serial Peripheral Interface Revision History

No substantive changes

C.4.15 eSDHC Revision History

Reference	Description
throughout	Updated the reset value for PRSSTAT for some products.

C.4.16 Universal Serial Bus Interface Revision History

Reference	Description
PHY PLL Initialization	Updated USBx_PLLPRG2 value for 24 MHz clock. Updated the fourth step for both 24 MHz and 100 MHz clocks as follows: Set USB_PHY_PnCTRL[USBPEN]. Added the following steps at the end: Wait for USB_PHY_PnSTS[CLK_VALID] bit to go high, which ensures that USBPHY PLL is up and clock is running.
Control (USB_CONTROL)	Updated IPS transactions to configuration space transactions in the PHY_CLK_VALID bit description.
Transmit FIFO Tuning Controls (USB_TXFILLTUNING)	Updated note.
USB_PHY Memory Map/Register Definition	Updated endianness of USB PHY registers.

C.4.17 DUART Revision History

Reference	Description
DMA mode select	Added the following note: The chip does not support the DMA operation where software or an external DMA fills the inbuilt FIFO. When FIFO is full, DUART initiates the transmission.

C.4.18 SerDes Module Revision History

Reference	Description
SerDes PCIe Equalization Configuration Register (SerDes_PEXEQCR)	Changed reset value to 0x3000_0C10
SerDes PEXx Protocol Control Register 7 (SerDes_PEX*n*CR7)	Changed name and description of bit 0 from Rx EQ disable (EQ_DIS) to Rx EQ enable (EQ_EN)
General Control Register 0 - Lane n (SerDes_LN*n*GCR0)	Added "or unused lane" to FIRST_LANE = 0 value description
General Control Register 1 - Lane n (SerDes_LN*n*GCR1)	Changed reset value for REIDL_EX_SEL, REIDL_ET_SEL, REIDL_EX_MSB, and REIDL_ET_MSB to n. (The reset value depends on the protocol selected at reset for the lane.)
General Control Register 1 - Lane n (SerDes_LN*n*GCR1)	In field REIDL_ET_SEL (bits 14-15), changed recommended setting for SGMII-1G protocol to 100 (1.25 Gbaud)
Speed Switch Control Register 0 - Lane n (SerDes_LN*n*SSCR0)	In field BASE_WAND_0 (bits 14-15), revised description for BASE_WAND_0 = 11
Receive Equalization Control Register 0 - Lane n (SerDes_LN*n*RECR0)	In field OSETOVD_EN (bit 18), revised description of field values

Table continues on the next page...

Substantive changes from revision 0 to revision 1

Reference	Description
Receive Equalization Control Register 0 - Lane n (SerDes_LN*n*RECR0)	In field BASE_WAND (bits 20-21), revised description for BASE_WAND = 11 In field OSETOVD, revised note regarding BASE_WAND and Rx EQ offset
Speed Switch Control Register 1- Lane n (SerDes_LN*n*SSCR1)	In field BASE_WAND_1 (bits 14-15), revised description for BASE_WAND_1 = 11
TTL Control Register 0 - Lane n (SerDes_LN*n*TTLCR0)	In field PM_DIS (bit 17), added default setting for SRIO
QSGMIIx Protocol Control Register 1 (SerDes_QSGMII*n*CR1)	Changed bit 8 to reserved.
Receive Equalization Control Register 0 - Lane n (SerDes_LN*n*RECR0)	Removed the word "START" from the field description for LNmRECR0[RXEQ_BST]
Receive Equalization Control Register 0 - Lane n (SerDes_LN*n*RECR0)	Removed note regarding setting taken from LNmSSCR0 from the field descriptions of GK2OVD, GK3OVD, GK2OVD_EN, and GK3OVD_EN
Speed Switch Control Register 0 - Lane n (SerDes_LN*n*SSCR0)	Added ISLEW_RCTL_0 and OSLEW_RCTL_0 fields In field description for OSETOVD6_0, changed "LNmSSCR1[OSETOVD6_0]" to "LNmSSCR1[OSETOVD6_1] " In field description for RATIO_PST1Q_0, changed "LNmTECR0[AMP_RED]" to "LNmTECR0[RATIO_PST1Q]" In field description for RATIO_PST1Q_0, changed "LNmSSCR1[AMP_RED_1]" to "LNmSSCR1[RATIO_PST1Q_1]" In field description for AMP_RED_0, changed "LNmSSCR1[AMP_RED_0]" to "LNmSSCR1[AMP_RED_1]"
Speed Switch Control Register 1- Lane n (SerDes_LN*n*SSCR1)	Added ISLEW_RCTL_1 and OSLEW_RCTL_1 fields In field description for RATIO_PST1Q_1, changed "LNmTECR0[AMP_RED]" to "LNmTECR0[RATIO_PST1Q]" In field description for RATIO_PST1Q_1, changed "LNmSSCR0[AMP_RED_0]" to "LNmSSCR0[RATIO_PST1Q_0]"
XAUIx Protocol Control Register 1 (SerDes_XAUI*n*CR1)	Removed sentences refering to internal signals Removed PAT field
XFIx Protocol Control Register 1 (SerDes_XFI*n*CR1)	In MDEV_PORT field description changed "SGMIIn PCS," to "XFIn PCS."
XFI PCS Control 1 (MDIO_XFI_PCS_CR1)	Changed bit 13 to SPEED_SEL0 and bit 6 to SPEED_SEL1 Changed SPEED_SEL0, SPEED_SEL1, and SPEED_SEL to read-only
SGMII Control (MDIO_SGMII_CR)	Changed SPEED_SEL0, FD, COL_TEST, and SPEED_SEL1 to read-only
QSGMII Control (MDIO_QSGMII_CR)	Changed SPEED_SEL0, FD, COL_TEST, and SPEED_SEL1 to read-only
Features	Updated frequency units for various protocols.
Receive Equalization Control Register 0 - Lane n (SerDes_LN*n*RECR0)	Added bit LNmRECR0[RXEQ_BST]
SerDes Lane Assignments and Multiplexing	Throughout the section updated frequency units of protocols to be in sync with industry standards.
Rules restricting networking SerDes PLL powerdown	Added note "HiGig and HiGig2 use XAUI configuration."
Rules restricting protocol selections due to max of 25 Gbps PCD	Added note " The rate is directly proportional to the Frame manager clocking frequency which determines the availability of protocols the frame manager runs.

Table continues on the next page...

Reference	Description
	The rate calculated from the equation below should be less or equal 25 Gbps to avoid protocols from being unavailable: Rate = (Frame Manager clocking frequency in MHz / 800 MHz) * 25 Gbps For FMan clocking frequency of 733 MHz: • If pause is acceptable, then 25 Gbps connectivity is okay with a max processing rate of 23 Gbps ≈ 733/(800)* 25 Gbps • If pause is not acceptable, then max allowed connectivity is 23 Gbps For FMan clocking frequency of 667 MHz: • If pause is acceptable, then 25 Gbps connectivity is okay with a max processing rate of 21 Gbps ≈ 667/800 * 25 Gbps • If pause is not acceptable, then max allowed connectivity is 21 Gbps
Ethernet management interface (EMI)	Added section
SerDes 3 Options	Added footnote to SRDS_PRTCL_S4 option 3 saying "This SerDes combination supports PCIe 8 Gbps which starts out with only PLL1 enabled. Since PLL2 is automatically enabled during speed switch, the system must supply a reference clock to PLL2. Write SRDS_PLL_REF_CLK_SEL_S4[PLL2]=100 MHz or 125MHz to apply the reference clock to PLL2."

C.4.19 PCI Express Interface Controller Revision History

Reference	Description
Gen3 Control Register (PEX_module_internal_GEN3_RELATED_OFF)	Added RXEQ_PH01_EN (bit 12) and EQ_EIEOS_CNT (bit 10) to the GEN3_RELATED_OFF register
Lane Reversal	Removed statement about manual lane reversal. Added table showing supported lane reversal.
PCI Express configuration register (CONFIG)	Changed RF and TF (bits 8 and 9) to Reserved.
PCI Express Expansion ROM inbound window attribute register (PFa_PEXEPROMIWAR), PCI Express MSI inbound window attributes register (PEXMSIIWAR), PCI Express inbound window attributes (PFa_PEXIWARb), and PCI Express VF inbound window attributes register n (PEX_PFaVFIWARb)	Removed notes regarding OCN targets and all OCN targets from the supported TRGT values. Bridging is not supported on this SoC.
PCI Express Inbound ATMU Registers	Added note that the inbound ATMU windows must be programmed and enabled before any inbound memory transaction can be handled.
Memory Space Addressing	Revised last sentence to reflect that internal platform addresses are 40-bits (not 36-bits).
PCI Express outbound window base address register (PFa_PEXOWBARb)	Changed WBEA field to an 8-bit field to support a 40-bit internal platform address. In the field descriptions for WBEA and WBA, adjusted the internal platform address bit numbers.
PCI Express Expansion ROM inbound translation address register (PFa_PEXEPROMITAR), PCI Express MSI inbound translation address register	Changed TEA field to an 8-bit field to support a 40-bit internal platform address.

Table continues on the next page...

Substantive changes from revision 0 to revision 1

Reference	Description
(PEXMSIITAR), and PCI Express inbound translation address (PFa_PEXITARb)	In the field descriptions for TEA and TA, adjusted the internal platform address bit numbers.
PCI Express Expansion ROM inbound translation address register (PFa_PEXEPROMITAR)	Revised the Function description (regarding the base address of the window).

C.4.20 Serial RapidIO Interface Revision History

Reference	Description
SRIO Features Summary	Updated feature list with pass through mode of operation for RapidIO packets.
Port 1 Pass through/Accept-all configuration register (SRIO_P1AACR)Port 2 Pass through/ Accept-all configuration register (SRIO_P2AACR)	Updated registers P1AACR and P2AACR title and bitfields to with updated descriptions.

C.4.21 LAC Revision History

Reference	Description
RX block config register (LAC_RXCFGR) and TX block config register (LAC_TXCFGR)	Added registers
TX Burst control register (LAC_TXBCR) and RX Burst control register (LAC_RXBCR)	Updated reset value to 0x0300_0200.
TX interrupt register n (LAC_TXINTR*n*)	Updated reset value to 0xF003_C003.
RX Interrupt Register n (LAC_RXINTR*n*)	Updated reset value to 0xBFFF_E7FF.
LAC mode register (LAC_LMR)	Added note "Global soft reset will not affect the SWPnTER register. After a GSR, the SWPnTER register needs to be manually cleared if errors were detected prior to the assertion of GSR."
TX block config register (LAC_TXCFGR)	Changed NLAC to bit 13.
TX block config register (LAC_TXCFGR)	Changed NLAC to bit 13.

C.4.22 SATA Controller Revision History

No substantive changes

C.4.23 DMA Controller Revision History

Reference	Description
DMA signal descriptions	Added note "These signals are available on DMA1 and DMA2. They are not supported by DMA3. "

C.4.24 DPAA Overview Revision History

Reference	Description
Special Values and Exceptions	Updated last bullet under exceptions and special behaviors.
Releasing Buffers to the BMan	Updated first paragraph.
DPAA Introduction and Terms	Resized images in the common DPAA terms and definitions section.

C.4.25 Multicore Programmable Interrupt Controller (MPIC) Revision History

Reference	Description
Global timer base count register [Group A] n (MPIC_GTBCRA*n*), Global timer current count register [Group A] n (MPIC_GTCCRA*n*)	Added note "For cascade, there is only single CI bit as control, which is the most significant count CI bit."

C.4.26 Interrupt Assignments Revision History

No substantive changes

C.4.27 Device Configuration and Pin Control Revision History

Reference	Description
POR Status Register 1 (DCFG_CCSR_PORSR1)	Updated reset value of bit [9:12] to '11nn' and added the following note: "The status of these bits depends on the sampling value driven on the pad".
POR Status Register 2 (DCFG_CCSR_PORSR2)	Updated reset value and added the following note: "The status of these bits depends on the sampling value driven on the pad".
USB n Logical I/O Device Number register (DCFG_CCSR_USB*n*LIODNR)SD/MMC Logical I/O Device	Updated bitwidth of LDEVNUM bits to 12 from 16

Table continues on the next page...

Reference	Description
Number register (DCFG_CCSR_SDMMCLIODNR)SATA n Logical I/O Device Number register (DCFG_CCSR_SATA*n*LIODNR)DMA n Logical I/O Device Number register (DCFG_CCSR_DMA*n*LIODNR)	
Fuse Status Register (DCFG_CCSR_FUSESR)	Changed DA_ALT_V 11111 to reserved. Added note if this field is not (all ones or all zeros) then the correct VID value should be read from here, other wise the correct VID value should be read from DA_V. Added note to DA_V field to say "Note: This field is ignored if DA_ALT_V is not 00000. "

C.4.28 General Purpose I/O (GPIO) Revision History

No substantive changes

C.4.29 Run Control and Power Management (RCPM) Revision History

No substantive changes

C.4.30 T4160 Appendix

No substantive changes

C.4.31 T4080 Appendix

No substantive changes

Appendix D
Terminology, Conventions, and Resources

D.1 About this content

The primary objective of this document is to define the functionality of the T4240 QorIQ Advanced Multiprocessing Processor. The T4240 provides integration of processing power for networking and communications peripherals, resulting in higher device performance. The T4240 contains four dual-threaded processor cores built on Power Architecture® technology. The e6500 processor core is a low-power implementation of the family of reduced instruction set computing (RISC) embedded processors that implement the embedded category features of the Power Architecture technology. This document is intended as a companion to the following:

- The *EREF 2.0: A Programmer's Reference Manual for Freescale Power Architecture® Processors* describes the instruction, register, and interrupt models, as well as other functionality at the architecture level.
- The *e6500 Reference Manual* describes functionality that is specific to the e6500 and that is not defined by the architecture, such as instructions, registers, and register fields. It also provides e6500-specific details about how the e6500 implements functionality that is defined by the architecture.
- The *AltiVec Technology Programming Environments Manual for Power ISA™ Processors* describes how AltiVec technology is defined for NXP processors that implement Power ISA.

NOTE

The diagrams in this content are provided to aid in understanding the overall functionality and features of this product. They do not depict the implementation details of the product, which are subject to change.

D.2 Acronyms and abbreviations

This table describes commonly-used acronyms and abbreviations used in this document.

Table D-1. Acronyms and abbreviations

Acronym/ Abbreviation	Meaning
8b/10b	8-bit/10-bit encoding
AMC	Advanced mezzanine card
ATMU	Address translation and mapping unit
BD	Buffer descriptor
BTB	Branch target buffer
BUID	Bus unit ID
CAM	Content-addressable memory
CCF	CoreNet coherence fabric
CCSR	Configuration control and status register
CLASS	Chip-level arbitration and switching system
CRC	Cyclic redundancy check
DCSR	Debug configuration and status register
DDR	Double data-rate
DIP	Dual inline package
DPLL	Digital phase-locked loop
DTLB	Data translation lookaside buffer
dTSEC	Data path three-speed Ethernet controller
DUART	Dual universal asynchronous receiver/transmitter
ECC	Error checking and correction
EEST	Enhanced Ethernet serial transceiver
EHCI	Enhanced host controller interface
EEPROM	Electrically-erasable programmable read-only memory
EPROM	Erasable programmable read-only memory
FCS	Frame-check sequence
FIFO	First in, first out
GCI	General circuit interface
GMII	Gigabit media-independent interface
GPCM	General-purpose chip-select machine
GPIO	General-purpose I/O
GPR	General-purpose register
HSSI	High-speed serial interface
I2C	Inter-integrated circuit
IFC	Integrated Flash controller

Table continues on the next page...

Table D-1. Acronyms and abbreviations (continued)

Acronym/ Abbreviation	Meaning
IPG	Interpacket gap
IrDA	Infrared Data Association
ISDN	Integrated services digital network
ITLB	Instruction translation lookaside buffer
IU	Integer unit
LAE	Local access error
LAW	Local access window
LIFO	Last-in-first-out
LRU	Least recently used
LSB	Least significant byte
lsb	Least significant bit
LSU	Load/store unit
MAC	Media access control
MDI	Medium-dependent interface
MII	Media independent interface
MMU	Memory management unit
MPIC	Multicore programmable interrupt controller
MSB	Most significant byte
msb	Most significant bit
NMI	Non-maskable interrupt
NMSI	Nonmultiplexed serial interface
No-op	No operation
OCeaN	On-chip network
OCN	
OSI	Open systems interconnection
PAMU	Peripheral Access Management Unit
PBL	Pre-Boot Loader
PCS	Physical coding sublayer
PLL	Phase-locked loop
PMA	Physical medium attachment
PMD	Physical medium dependent
POR	Power-on reset
PRI	Primary rate interface
PWM	Pulse-width modulation
RCPM	Run Control and Power Management
RCW	Reset Configuration Word
RGMII	Reduced gigabit media-independent interface
RMW	Read-modify-write
RTOS	Real-time operating system

Table continues on the next page...

Table D-1. Acronyms and abbreviations (continued)

Acronym/ Abbreviation	Meaning
RWITM	Read with intent to modify
Rx	Receiver
RxBD	Receive buffer descriptor
SATA	Serial advanced technology attachment
SCP	Serial control port
SDLC	Synchronous data link control
SD/MMC	Secure digital/multimedia card
SDOS	SmartDSP operating system
SEC	Security Engine
SerDes	Serializer/Deserializer
SFD	Start frame delimiter
SGMII	Serial gigabit media-independent interface
SIU	System interface unit
SMC	Serial management controller
SPI	Serial peripheral interface
SPR	Special-purpose register
SRAM	Static random access memory
SRIO	Serial RapidIO
TAP	Test access port
TBI	Ten-bit interface
TLB	Translation lookaside buffer
TSA	Time-slot assigner
Tx	Transmitter
TxBD	Transmit buffer descriptor
UART	Universal asynchronous receiver/transmitter
UPM	User-programmable machine
uTCA	Micro telecommunications computing platform
UTP	Unshielded twisted pair
VA	Virtual address
ZBT	Zero bus turnaround

D.3 Audience

It is assumed that the reader understands operating systems, microprocessor system design, and the basic principles of RISC processing.

D.4 Notational conventions

This table shows notational conventions used in this content.

Table D-2. Notational conventions

Convention	Definition
General	
Cleared	When a bit takes the value zero, it is said to be cleared.
Set	When a bit takes the value one, it is said to be set.
mnemonics	Instruction mnemonics are shown in lowercase bold.
italics	Italics can indicate the following: • Variable command parameters, for example, **bcctr***x* • Titles of publications • Internal signals, for example, *core_int*
0x	Prefix to denote hexadecimal number
h	Suffix to denote hexadecimal number
0b	Prefix to denote binary number
b	Suffix to denote binary number
rA, **r**B	Instruction syntax used to identify a source GPR
rD	Instruction syntax used to identify a destination GPR
REGISTER[FIELD]	Abbreviations for registers are shown in uppercase text. Specific bits, fields, or ranges appear in brackets. For example, MSR[LE] refers to the little-endian mode enable bit in the machine state register.
x	In some contexts, such as signal encodings, an unitalicized x indicates a don't care.
x	An italicized *x* indicates an alphanumeric variable
n	An italicized *n* indicates either: • An integer variable • A general-purpose bitfield unknown
Â¬	NOT logical operator
&	AND logical operator
|	OR logical operator
||	Concatenation, for example, TCR[WPEXT] || TCR[WP]
Signals	
SIGNAL_B or $\overline{\text{OVERBAR}}$	A trailing _B or an overbar indicates that a signal is active-low.
lowercase_italics	Lowercase italics is used to indicate internal signals
lowercase_plaintext	Lowercase plain text is used to indicate signals that are used for configuration.
Register access	
Reserved	Ignored for the purposes of determining access type
R/W	Indicates that all non-reserved fields in a register are read/write
R	Indicates that all non-reserved fields in a register are read only
W	Indicates that all non-reserved fields in a register are write only
w1c	Indicates that all non-reserved fields in a register are cleared by writing ones to them

D.5 Related resources

This table shows related resources that may be helpful. Additional literature is published as new processors become available. For current literature, visit www.nxp.com or contact your local FAE.

Table D-3. Related resources

Resource	Purpose
Reference manual	Provides details about individual implementations
Datasheet	Provides specific data regarding bus timing, signal behavior, and AC, DC, and thermal characteristics, as well as other design considerations
Chip errata	Provides additional or corrective information for a particular device mask set. Individual errata items are published cumulatively.
Application note	Addresses specific design issues useful to programmers and engineers working with Freescale processors
