QorIQ T4240 Reference Manual

Also supports T4241, T4160, T4161, T4080, and T4081

Document Number: T4240RM
Rev. 4, 11/2017

Contents

Section number **Title** **Page**

Chapter 1
T4240 Overview

1.1 Introduction....91

1.2 Summary of benefits....92

1.3 Chip features....92

1.3.1 Block diagram....92

1.3.2 Features summary....93

1.3.3 Core and CPU clusters....95

1.3.4 Inverted cache hierarchy....97

1.3.5 CoreNet fabric and address map....98

1.3.6 Memory complex....98

1.3.6.1 DDR memory controllers....98

1.3.6.1.1 DDR bandwidth optimizations....99

1.3.6.2 PreBoot Loader and nonvolatile memory interfaces....99

1.3.6.2.1 Integrated Flash Controller (IFC)....100

1.3.6.2.1.1 NAND Flash features....100

1.3.6.2.1.2 NOR Flash features....100

1.3.6.2.1.3 General-purpose chip-select machine (GPCM)....100

1.3.6.2.2 Serial memory controllers....101

1.3.7 Universal serial bus (USB) 2.0....102

1.3.8 High-speed peripheral interface complex (HSSI)....102

1.3.8.1 PCI Express....103

1.3.8.2 Serial RapidIO....103

1.3.8.3 SATA....105

1.3.8.4 Interlaken Look-Aside Controller (LAC) and interface....105

1.3.9 Data Path Acceleration Architecture (DPAA)....106

1.3.9.1 Packet distribution and queue/congestion management....106

1.3.9.2 Accelerating content processing ... 107
1.3.9.3 Enhancements of T4240 compared to first generation DPAA ... 107
1.3.9.4 DPAA terms and definitions ... 108
1.3.9.5 Major DPAA components ... 110
1.3.9.5.1 Frame Manager and network interfaces ... 111
1.3.9.5.1.1 Receiver functionality: parsing, classification, and distribution 112
1.3.9.5.1.2 FMan distribution and policing ... 113
1.3.9.5.2 Queue Manager ... 114
1.3.9.5.3 Buffer Manager ... 115
1.3.9.5.4 SEC 5.0 ... 115
1.3.9.5.5 Pattern Matching Engine (PME 2.1) ... 117
1.3.9.5.6 Decompression and Compression Engine (DCE 1.0) ... 119
1.3.9.6 DPAA capabilities ... 120
1.3.9.6.1 Ingress policing and congestion management ... 120
1.3.9.6.2 Customer-edge egress-traffic management (CEETM) ... 121
1.3.9.6.2.1 CEETM features ... 121
1.3.9.6.2.2 CEETM configuration ... 122
1.3.9.6.3 Data Center Bridging (DCB) ... 125
1.3.10 Resource partitioning and QorIQ Trust Architecture ... 125
1.3.10.1 Core MMU, UX/SX bits, and embedded hypervisor ... 126
1.3.10.2 Peripheral access management unit (PAMU) ... 127
1.3.10.3 IO partitioning ... 127
1.3.10.4 Secure boot and sensitive data protection ... 128
1.3.11 Advanced power management ... 128
1.3.11.1 Transparent power management ... 129
1.3.11.2 Non-transparent power management ... 130
1.3.11.3 Cascade power management ... 131
1.3.12 Debug support ... 131
1.3.13 JTAG ... 132

Chapter 2
Memory Map

2.1 Memory Map Overview....133

2.2 Global Source and Target IDs....134

2.3 Local Access Windows (LAWs)....138

2.3.1 Precedence of Local Access Windows....138

2.3.2 Configuring Local Access Windows....139

2.3.3 Distinguishing Local Access Windows from Other Mapping Functions....139

2.3.4 SRAM Windows....140

2.3.5 Local Address Map Example....140

2.4 Local Access Window (LAW) Memory Map....142

2.4.1 LAWn base address register high (LAW_LAWBARH*n*)....145

2.4.2 LAWn base address register low (LAW_LAWBARL*n*)....145

2.4.3 LAWn attribute register (LAW_LAWAR*n*)....146

2.5 Address Translation and Mapping Units....147

2.5.1 Address Translation....147

2.5.2 Outbound ATMUs....148

2.5.3 Inbound ATMUs....148

2.5.3.1 Illegal Interaction Between Inbound ATMUs and LAWs....149

2.6 Configuration, Control, and Status Register (CCSR) Space....149

2.6.1 Accessing CCSR Memory from the Local Processor....149

2.6.2 Accessing CCSR Memory from External Masters....150

2.6.3 Accessing Reserved Registers and Bits....150

2.6.4 Organization of CCSR Memory....151

2.6.5 CCSR Address Map....151

Chapter 3
Signal Descriptions

3.1 Signals Introduction....157

3.2 Signals Overview....157

3.3 Configuration signals sampled at reset 167
3.4 Signal multiplexing details..... 168
3.4.1 UART and GPIO1 signal multiplexing..... 168
3.4.2 ASLEEP and GPIO1 signal multiplexing..... 169
3.4.3 RTC and GPIO1 signal multiplexing..... 169
3.4.4 eSDHC and GPIO2 signal multiplexing..... 170
3.4.5 MPIC and debug signal multiplexing..... 170
3.4.6 MPIC and GPIO1 signal multiplexing..... 171
3.4.7 eSPI, eSDHC, and GPIO2 signal multiplexing..... 171
3.4.8 IFC, GPIO1, and GPIO2 signal multiplexing..... 171
3.4.9 IEEE 1588 and GPIO3 signal multiplexing..... 172
3.4.10 Ethernet controller 1 and GPIO3 signal multiplexing..... 173
3.4.11 Ethernet controller 2 and GPIO3 signal multiplexing..... 173
3.4.12 I2C3 and GPIO4 signal multiplexing..... 174
3.4.13 I2C4, GPIO4, and Debug Signal Multiplexing..... 175
3.4.14 DMA1 and GPIO4 signal multiplexing..... 175
3.4.15 DMA2, debug, and GPIO4 signal multiplexing..... 175
3.5 Output Signal States During Reset..... 176

Chapter 4
Reset, Clocking, and Initialization

4.1 Reset, clocking, and initialization overview..... 177
4.2 External signal descriptions..... 177
4.2.1 System control signals..... 178
4.2.2 External Clock Signals..... 179
4.3 Local Configuration Control Registers..... 180
4.3.1 Accessing Configuration, Control, and Status Registers..... 180
4.3.1.1 Updating CCSRBARs..... 180
4.3.2 Accessing Alternate Configuration Space..... 181
4.3.3 Boot Space Translation..... 182

4.4 Local Configuration Control Memory Map....183
4.4.1 Configuration, control, and status registers base address register high (LCC_CCSRBARH)....184
4.4.2 Configuration, control, and status registers base address register low (LCC_CCSRBARL)....184
4.4.3 Configuration, control, and status registers attribute register (LCC_CCSRAR)....185
4.4.4 Alternate configuration base address register high (LCC_ALTCBARH)....185
4.4.5 Alternate configuration base address register low (LCC_ALTCBARL)....186
4.4.6 Alternate configuration attribute register (LCC_ALTCAR)....186
4.4.7 Boot space translation register high (LCC_BSTRH)....187
4.4.8 Boot space translation register low (LCC_BSTRL)....187
4.4.9 Boot space translation attribute register (LCC_BSTAR)....187
4.5 Clocking Memory Map....188
4.5.1 Core cluster n clock control/status register (Clocking_CLKC*n*CSR)....189
4.5.2 Clock generator n hardware accelerator control/status register (Clocking_CLKCG*n*HWACSR)....190
4.5.3 PLL cluster n general status register (Clocking_PLLC*n*GSR)....192
4.5.4 Platform clock domain control/status register (Clocking_CLKPCSR)....194
4.5.5 Platform PLL general status register (Clocking_PLLPGSR)....196
4.5.6 DDR PLL general status register (Clocking_PLLDGSR)....198
4.6 Functional description....199
4.6.1 Power-on reset sequence....199
4.6.2 Hard reset sequence....202
4.6.3 Power-on reset configuration....203
4.6.3.1 Reset configuration word (RCW) source....203
4.6.3.2 General-purpose input....206
4.6.3.3 DRAM type select....206
4.6.3.4 SerDes XVDD voltage select....207
4.6.3.5 IFC external transceiver enable polarity select....207
4.6.4 Reset configuration word (RCW)....208
4.6.4.1 RCW Field Definitions....208
4.6.4.1.1 Hard Coded RCW Options....223

4.6.4.1.2 RCW Settings for Hard-Coded Options ... 224
4.6.5 Clocking ... 227
4.6.5.1 IP logic clock distribution and configuration ... 227
4.6.5.2 Dynamic frequency switching (DFS) control ... 232
4.6.6 Voltage ID ... 232

Chapter 5
Pre-Boot Loader (PBL)

5.1 Overview ... 235
5.2 Features summary ... 236
5.3 Modes of operation ... 236
5.4 Functional description ... 237
5.4.1 Device configuration using reset configuration word (RCW) ... 237
5.4.2 Device initialization by PBL ... 237
5.4.2.1 CCSR registers blocked from PBL during secure boot ... 238
5.4.3 Required format of data structure used by PBL ... 238
5.4.4 RCW loading by PBL ... 240
5.4.5 Pre-boot initialization command loading by PBL ... 241
5.4.6 Reserved address space used as internal PBL commands ... 241
5.4.7 Error codes ... 243
5.4.8 Registers written by PBL during RCW and PBI phases ... 252
5.4.8.1 I2C registers ... 252
5.4.8.2 eSPI registers ... 252
5.4.8.3 IFC registers ... 252
5.4.8.4 eSDHC registers ... 253
5.4.9 Addressing multiple I2C EEPROMs ... 253
5.4.10 eSPI mode assumptions ... 254
5.5 Initialization/Application information ... 254
5.5.1 Starting addresses ... 254
5.5.2 Software restrictions ... 255

5.5.3 Software recommendations....255

Chapter 6
Secure Boot and Trust Architecture

6.1 Trust architecture objectives....257
6.2 Characteristics and claims....257
6.3 Non-claims....259
6.4 Related resources....260

Chapter 7
e6500 Core Integration

7.1 Introduction....263
7.2 Overview....264
7.3 Core and CPU clusters....266
7.4 Chip-Specific Core Implementation Details....269
7.4.1 Benefits and Flexibility of Twelve Dual-Threaded Cores....269
7.4.2 CoreNet Coherency Fabric (CCF)....269
7.4.3 Reset and Clocking....269
7.4.4 Register Model Implementation Details....270
7.4.4.1 Processor Version Register (PVR)....270
7.4.4.2 System Version Register (SVR)....270
7.4.4.3 (Guest) Processor ID Register (PIR/GPIR)....271
7.4.4.4 Timer Control Register (TCR)....272
7.4.5 Cache Model Implementation Details....272
7.4.6 Interrupt Model Implementation Details....273
7.4.6.1 Watchdog Timer Expiration Out to Platform....274
7.4.7 Performance Monitor Details....274
7.4.8 Decorated Load and Store Operations....275
7.4.9 Debug Features....275
7.4.10 Power Management....275
7.4.11 Dealing with Guest OS WIMGE Aliasing in a Boundedly Undefined Manner....276

Chapter 8
CoreNet Platform Cache (CPC)

8.1 Introduction....279

8.1.1 CPC Overview....279

8.1.2 Features....279

8.2 CoreNet Platform Cache (CPC) Memory Map....280

8.2.1 CPC configuration and status register 0 (CPC*x*_CPCCSR0)....287

8.2.2 CPC configuration register 0 (CPC*x*_CPCCFG0)....290

8.2.3 CPC external write control register n (CPC*x*_CPCEWCR*n*)....292

8.2.4 CPC external write base address register n (CPC*x*_CPCEWBAR*n*)....293

8.2.5 CPC SRAM control register 1 (CPC*x*_CPCSRCR1)....294

8.2.6 CPC SRAM control register 0 (CPC*x*_CPCSRCR0)....294

8.2.7 CPC partition ID register 0 (CPC*x*_CPCPIR0)....295

8.2.8 CPC partition allocation register 0 (CPC*x*_CPCPAR0)....296

8.2.9 CPC partition way register 0 (CPC*x*_CPCPWR0)....297

8.2.10 CPC partition ID register n (CPC*x*_CPCPIR*n*)....298

8.2.11 CPC partition allocation register n (CPC*x*_CPCPAR*n*)....298

8.2.12 CPC partition way register 0 (CPC*x*_CPCPWR*n*)....300

8.2.13 CPC error injection high register (CPC*x*_CPCERRINJHI)....300

8.2.14 CPC error injection low register (CPC*x*_CPCERRINJLO)....300

8.2.15 CPC error injection control register (CPC*x*_CPCERRINJCTL)....301

8.2.16 CPC capture data high register (CPC*x*_CPCCAPTDATAHI)....302

8.2.17 CPC capture data low register (CPC*x*_CPCCAPTDATALO)....302

8.2.18 CPC capture ECC register (CPC*x*_CPCCAPTECC)....302

8.2.19 CPC error detect register (CPC*x*_CPCERRDET)....304

8.2.20 CPC error disable register (CPC*x*_CPCERRDIS)....305

8.2.21 CPC error interrupt enable register (CPC*x*_CPCERRINTEN)....306

8.2.22 CPC error extended address register (CPC*x*_CPCERREADDR)....307

8.2.23 CPC error address register (CPC*x*_CPCERRADDR)....307

8.2.24 CPC error control register (CPC*x*_CPCERRCTL)..... 308
8.2.25 CPC hardware debug control register 0 (CPC*x*_CPCHDBCR0)..... 309
8.3 CPC Functional Description..... 309
8.3.1 Register Sections..... 309
8.3.1.1 SRAM Mode Registers..... 309
8.3.1.2 Partitioning Control Registers..... 310
8.3.1.3 Error Registers..... 311
8.3.1.3.1 Error Detection and Reporting..... 311
8.3.1.3.2 Error Capture..... 311
8.3.1.3.3 Error Injection..... 312
8.3.2 Line Locking..... 312
8.3.3 Cache Operation Instructions and Transactions..... 313
8.3.4 Decorated Storage..... 313
8.3.4.1 Decorated Load Operations..... 313
8.3.4.2 Decorated Store Operations..... 314
8.3.4.3 Notify Operations..... 317
8.3.5 Cache/SRAM Data Clear..... 317
8.4 Initialization/Application Information..... 317
8.4.1 Supported SRAM Mode Configurations..... 317
8.4.2 Programming Examples..... 319
8.4.2.1 Modifying CPC Control and Status Registers..... 319
8.4.2.2 Enabling the CPC after Power-On Reset..... 319
8.4.2.3 Changing the Configuration of an Enabled CPC..... 320
8.4.2.4 Disabling the CPC..... 320

Chapter 9
CoreNet Coherency Fabric (CCF)

9.1 CCF Introduction..... 321
9.1.1 CCF Features Summary..... 322
9.2 CoreNet Coherency Fabric (CCF) Memory Map..... 324

9.2.1 Memory Controller 3-way Interleave Register (CCF_MCINTLV3R)..... 326
9.2.2 Snoop ID 0 Port Mapping Register (CCF_SIDMR0)..... 327
9.2.3 Snoop ID n Port Mapping Register (CCF_SIDMR*n*)..... 328
9.2.4 CSD ID 0 Port Mapping Register (CCF_CIDMR0)..... 329
9.2.5 CSDID n Port Mapping Register (CCF_CIDMR*n*)..... 330
9.2.6 CCF Error Detect Register (CCF_ERRDET)..... 331
9.2.7 CCF Error Disable Register (CCF_ERRDIS)..... 333
9.2.8 CCF Error Interrupt Enable Register (CCF_ERRINTEN)..... 334
9.2.9 CCF Error Capture Attribute Register (CCF_CECAR)..... 334
9.2.10 CCF Error Capture Address Register High (CCF_CECADDRH)..... 335
9.2.11 CCF Error Capture Address Register Low (CCF_CECADDRL)..... 335
9.2.12 CCF Error Capture Attribute Register 2 (CCF_CECAR2)..... 336

Chapter 10
Peripheral Access Management Unit (PAMU)

10.1 PAMU Introduction..... 337
10.1.1 PAMU Overview..... 337
10.1.2 PAMU Features Summary..... 338
10.2 Data Structures Used by PAMU..... 339
10.2.1 Overview of Data Structures..... 339
10.2.1.1 Peripheral Access Authorization and Control Tables (PAACTs)..... 340
10.2.1.2 Operation Mapping Table..... 341
10.2.1.3 Access Capabilities Across LIODs..... 341
10.2.2 Structure and Contents of PAACTs..... 341
10.2.3 Peripheral Access Authorization and Control Entry (PAACE)..... 343
10.2.3.1 PAACE Offset 0x00..... 344
10.2.3.2 PAACE Offset 0x08..... 346
10.2.3.2.1 PAACE Domain Attributes..... 347
10.2.3.3 PAACE Offset 0x10..... 348
10.2.3.4 PAACE Offset 0x18..... 349

10.3 PAMU Memory Map/Register Definitions 350
10.4 PAMU Memory Map 350
10.4.1 Primary PAACT Base Address High register (PAMU*x*_PPBAH) 371
10.4.2 Primary PAACT Base Address Low register (PAMU*x*_PPBAL) 371
10.4.3 Primary PAACT Limit Address High register (PAMU*x*_PPLAH) 372
10.4.4 Primary PAACT Limit Address Low register (PAMU*x*_PPLAL) 372
10.4.5 Secondary PAACT Base Address High register (PAMU*x*_SPBAH) 372
10.4.6 Secondary PAACT Base Address Low register (PAMU*x*_SPBAL) 373
10.4.7 Secondary PAACT Limit Address High register (PAMU*x*_SPLAH) 373
10.4.8 Secondary PAACT Limit Address Low register (PAMU*x*_SPLAL) 374
10.4.9 OMT Base Address High register (PAMU*x*_OBAH) 374
10.4.10 OMT Base Address Low register (PAMU*x*_OBAL) 375
10.4.11 OMT Limit Address High register (PAMU*x*_OLAH) 375
10.4.12 OMT Limit Address Low register (PAMU*x*_OLAL) 375
10.4.13 PAMU Address Capabilities Register 1 (PAMU*x*_PAC1) 376
10.4.14 PAMU Address Capabilities Register 2 (PAMU*x*_PAC2) 377
10.4.15 PAMU Operation Error Status register 1 (PAMU*x*_POES1) 378
10.4.16 PAMU Operation Error Status register 2 (PAMU*x*_POES2) 379
10.4.17 PAMU Operation Error Address High register (PAMU*x*_POEAH) 379
10.4.18 PAMU Operation Error Address Low register (PAMU*x*_POEAL) 379
10.4.19 Access Violation Status register 1 (PAMU*x*_AVS1) 380
10.4.20 Access Violation Status register 2 (PAMU*x*_AVS2) 382
10.4.21 Access Violation Address High register (PAMU*x*_AVAH) 383
10.4.22 Access Violation Address Low register (PAMU*x*_AVAL) 383
10.4.23 ECC Error Control Register (PAMU*x*_EECTL) 383
10.4.24 ECC Error Interrupt Enable Register (PAMU*x*_EEINTEN) 384
10.4.25 ECC Error Detect Register (PAMU*x*_EEDET) 385
10.4.26 ECC Error Attributes Register (PAMU*x*_EEATTR) 386
10.4.27 ECC Error Address High (PAMU*x*_EEAHI) 387

10.4.28 ECC Error Address Low (PAMU*x*_EEALO)..... 387
10.4.29 ECC Error Data High (PAMU*x*_EEDHI)..... 388
10.4.30 ECC Error Data Low (PAMU*x*_EEDLO)..... 388
10.4.31 Unauthorized device access detection register (PAMU*x*_UDAD)..... 389
10.4.32 PAMU Revision register 1 (PAMU*x*_PR1)..... 389
10.4.33 PAMU Revision register 2 (PAMU*x*_PR2)..... 390
10.4.34 PAMU Capabilities register 1 (PAMU*x*_PC1)..... 390
10.4.35 PAMU Capabilities register 2 (PAMU*x*_PC2)..... 391
10.4.36 PAMU Capabilities register 3 (PAMU*x*_PC3)..... 392
10.4.37 PAMU Capabilities register 4 (PAMU*x*_PC4)..... 394
10.4.38 PAMU Control register (PAMU*x*_PC)..... 395
10.4.39 PAMU Interrupt Control and Status register (PAMU*x*_PICS)..... 396
10.5 PAMU Functional Description..... 397
10.5.1 System Set-Up for PAMU Operation..... 397
10.5.2 Steps in Processing of DSA Operations by PAMU..... 398
10.5.3 Detailed Description of PAMU Actions..... 400
10.5.3.1 PAMU Gate Closed and PAMU Enable Check..... 400
10.5.3.2 PPAACT Request Range Check..... 401
10.5.3.3 PPAACT Cache Lookup..... 402
10.5.3.4 PAMU Fetch Request..... 402
10.5.3.5 Primary PAACE Processing..... 402
10.5.3.6 SPAACE Access and Processing..... 404
10.5.3.6.1 SPAACT Request Range Check..... 404
10.5.3.6.2 SPAACT Cache Lookup Request..... 405
10.5.3.6.3 Secondary PAACE Processing..... 405
10.5.3.7 Address Translation Service..... 406
10.5.3.7.1 No Address Translation Mode..... 406
10.5.3.7.2 Window Address Translation Mode..... 407
10.5.3.8 OMT Access and Service..... 409

10.5.3.8.1 No Operation Translation ... 409
10.5.3.8.2 Operation Type Translation ... 410
10.5.3.8.3 OMT Cache Access ... 412
10.5.3.9 Access Violation ... 413
10.6 PAMU Initialization/Application Information ... 413
10.6.1 System Set-Up ... 413
10.6.1.1 Setting Up PAMU ... 413
10.6.1.2 Power-On Reset ... 414
10.6.2 System with Multiple PAMUs ... 414
10.6.2.1 PAACT Locations ... 414
10.6.2.2 OMT Locations ... 415
10.6.2.3 Location of PAACT and OMT Data Structures ... 415
10.6.3 Peer-to-Peer I/O Operations ... 415
10.6.4 PAMU Cache Coherency ... 416
10.6.5 Quiescing I/O Devices ... 416
10.6.5.1 Quiescing I/O Devices for Table/Entry Updates ... 417
10.6.5.2 Quiescing I/O Devices for Enabling PAMU and its Caches ... 417
10.6.6 Locality of References ... 417
10.6.6.1 Spatial Locality ... 417
10.6.6.2 Temporal Locality ... 418
10.6.7 Recovering Address Space ... 418
10.6.7.1 Primary PAACT Address Window ... 418
10.6.7.2 Secondary PAACT Address Window ... 418
10.6.7.3 Secondary Sub-Windows and PAACEs ... 419
10.6.8 Data Structure Size and Alignment ... 419
10.7 PAMU Setup ... 419
10.7.1 PAMU Operation Encoding ... 419
10.7.1.1 Ingress Operation Encoding (IOE) ... 420
10.7.1.2 Egress Operation Encodings ... 421

10.7.1.3 IOE to EOE Translations ... 422
10.7.1.3.1 PAMU Bypass Mode or No Operation Translation Mode ... 422
10.7.1.3.2 Immediate and Indexed Operation Translation Modes ... 423
10.7.2 Domain Attributes ... 424
10.7.2.1 Constrained Domain Attribute ... 424
10.7.3 Implementation Attributes ... 424
10.7.4 Operation Mapping Table (OMT) ... 425

Chapter 11
DDR Memory Controller

11.1 DDR Introduction ... 427
11.2 DDR Features ... 428
11.2.1 DDR Modes of Operation ... 429
11.3 DDR External Signal Descriptions ... 429
11.3.1 DDR Signals Overview ... 430
11.3.2 DDR Detailed Signal Descriptions ... 431
11.3.2.1 Memory Interface Signals ... 431
11.3.2.2 Clock Interface Signals ... 435
11.4 DDR Memory Map/Register Definition ... 435
11.4.1 Chip select n memory bounds (DDR*x*_CS*n*_BNDS) ... 444
11.4.2 Chip select n configuration (DDR*x*_CS*n*_CONFIG) ... 445
11.4.3 Chip select n configuration 2 (DDR*x*_CS*n*_CONFIG_2) ... 447
11.4.4 DDR SDRAM timing configuration 3 (DDR*x*_TIMING_CFG_3) ... 449
11.4.5 DDR SDRAM timing configuration 0 (DDR*x*_TIMING_CFG_0) ... 452
11.4.6 DDR SDRAM timing configuration 1 (DDR*x*_TIMING_CFG_1) ... 455
11.4.7 DDR SDRAM timing configuration 2 (DDR*x*_TIMING_CFG_2) ... 459
11.4.8 DDR SDRAM control configuration (DDR*x*_DDR_SDRAM_CFG) ... 462
11.4.9 DDR SDRAM control configuration 2 (DDR*x*_DDR_SDRAM_CFG_2) ... 465
11.4.10 DDR SDRAM mode configuration (DDR*x*_DDR_SDRAM_MODE) ... 468
11.4.11 DDR SDRAM mode configuration 2 (DDR*x*_DDR_SDRAM_MODE_2) ... 469

11.4.12 DDR SDRAM mode control (DDR*x*_DDR_SDRAM_MD_CNTL)..... 469
11.4.13 DDR SDRAM interval configuration (DDR*x*_DDR_SDRAM_INTERVAL).....473
11.4.14 DDR SDRAM data initialization (DDR*x*_DDR_DATA_INIT).....473
11.4.15 DDR SDRAM clock control (DDR*x*_DDR_SDRAM_CLK_CNTL).....474
11.4.16 DDR training initialization address (DDR*x*_DDR_INIT_ADDR).....475
11.4.17 DDR training initialization extended address (DDR*x*_DDR_INIT_EXT_ADDRESS).....476
11.4.18 DDR SDRAM timing configuration 4 (DDR*x*_TIMING_CFG_4).....477
11.4.19 DDR SDRAM timing configuration 5 (DDR*x*_TIMING_CFG_5).....481
11.4.20 DDR SDRAM timing configuration 6 (DDR*x*_TIMING_CFG_6).....483
11.4.21 DDR ZQ calibration control (DDR*x*_DDR_ZQ_CNTL)..... 485
11.4.22 DDR write leveling control (DDR*x*_DDR_WRLVL_CNTL).....488
11.4.23 DDR Self Refresh Counter (DDR*x*_DDR_SR_CNTR).....490
11.4.24 DDR Register Control Words 1 (DDR*x*_DDR_SDRAM_RCW_1)..... 491
11.4.25 DDR Register Control Words 2 (DDR*x*_DDR_SDRAM_RCW_2)..... 492
11.4.26 DDR write leveling control 2 (DDR*x*_DDR_WRLVL_CNTL_2).....493
11.4.27 DDR write leveling control 3 (DDR*x*_DDR_WRLVL_CNTL_3).....494
11.4.28 DDR SDRAM mode configuration 3 (DDR*x*_DDR_SDRAM_MODE_3)..... 496
11.4.29 DDR SDRAM mode configuration 4 (DDR*x*_DDR_SDRAM_MODE_4)..... 497
11.4.30 DDR SDRAM mode configuration 5 (DDR*x*_DDR_SDRAM_MODE_5)..... 497
11.4.31 DDR SDRAM mode configuration 6 (DDR*x*_DDR_SDRAM_MODE_6)..... 498
11.4.32 DDR SDRAM mode configuration 7 (DDR*x*_DDR_SDRAM_MODE_7)..... 499
11.4.33 DDR SDRAM mode configuration 8 (DDR*x*_DDR_SDRAM_MODE_8)..... 500
11.4.34 DDR Debug Status Register 1 (DDR*x*_DDRDSR_1)..... 501
11.4.35 DDR Debug Status Register 2 (DDR*x*_DDRDSR_2)..... 502
11.4.36 DDR Control Driver Register 1 (DDR*x*_DDRCDR_1).....503
11.4.37 DDR Control Driver Register 2 (DDR*x*_DDRCDR_2).....505
11.4.38 DDR IP block revision 1 (DDR*x*_DDR_IP_REV1)..... 506
11.4.39 DDR IP block revision 2 (DDR*x*_DDR_IP_REV2)..... 506
11.4.40 DDR Memory Test Control Register (DDR*x*_DDR_MTCR)..... 507

11.4.41 DDR Memory Test Pattern n Register (DDR*x*_DDR_MTP*n*)..... 509
11.4.42 DDR Memory Test Start Extended Address (DDR*x*_DDR_MT_ST_EXT_ADDR).....509
11.4.43 DDR Memory Test Start Address (DDR*x*_DDR_MT_ST_ADDR).....510
11.4.44 DDR Memory Test End Extended Address (DDR*x*_DDR_MT_END_EXT_ADDR)..... 510
11.4.45 DDR Memory Test End Address (DDR*x*_DDR_MT_END_ADDR)..... 511
11.4.46 Memory data path error injection mask high (DDR*x*_DATA_ERR_INJECT_HI).....511
11.4.47 Memory data path error injection mask low (DDR*x*_DATA_ERR_INJECT_LO).....512
11.4.48 Memory data path error injection mask ECC (DDR*x*_ECC_ERR_INJECT).....512
11.4.49 Memory data path read capture high (DDR*x*_CAPTURE_DATA_HI)..... 513
11.4.50 Memory data path read capture low (DDR*x*_CAPTURE_DATA_LO)..... 514
11.4.51 Memory data path read capture ECC (DDR*x*_CAPTURE_ECC)..... 514
11.4.52 Memory error detect (DDR*x*_ERR_DETECT).....515
11.4.53 Memory error disable (DDR*x*_ERR_DISABLE)..... 517
11.4.54 Memory error interrupt enable (DDR*x*_ERR_INT_EN)..... 519
11.4.55 Memory error attributes capture (DDR*x*_CAPTURE_ATTRIBUTES).....521
11.4.56 Memory error address capture (DDR*x*_CAPTURE_ADDRESS)..... 522
11.4.57 Memory error extended address capture (DDR*x*_CAPTURE_EXT_ADDRESS).....523
11.4.58 Single-Bit ECC memory error management (DDR*x*_ERR_SBE).....523
11.5 DDR Functional Description..... 524
11.5.1 DDR SDRAM interface operation.....529
11.5.1.1 Supported DDR SDRAM Organizations..... 530
11.5.2 DDR SDRAM Address Multiplexing..... 531
11.5.3 JEDEC Standard DDR SDRAM Interface Commands..... 539
11.5.4 DDR SDRAM Interface Timing..... 541
11.5.4.1 Clock Distribution.....544
11.5.5 DDR SDRAM Mode-Set Command Timing.....545
11.5.6 DDR SDRAM Registered DIMM Mode..... 546
11.5.7 DDR SDRAM Write Timing Adjustments..... 546
11.5.8 DDR SDRAM Refresh.....547

11.5.8.1 DDR SDRAM Refresh Timing....548
11.5.8.2 DDR SDRAM Refresh and Power-Saving Modes....549
11.5.8.2.1 Self-Refresh in Sleep Mode....550
11.5.9 DDR Data Beat Ordering....551
11.5.10 Page Mode and Logical Bank Retention....552
11.5.11 Error Checking and Correcting (ECC)....553
11.5.12 Error Management....554
11.5.13 DDR Rapid Clear of Memory....555
11.6 Initialization/Application Information....556
11.6.1 Programming Summary....560
11.6.2 Supported DDR Interleaving Configurations....562
11.6.3 DDR SDRAM Initialization Sequence....566
11.6.4 Using Forced Self-Refresh Mode to Implement a Battery-Backed RAM System....567
11.6.4.1 Hardware Based Self-Refresh Scheme....567
11.6.4.2 Software Based Self-Refresh Scheme....567
11.6.4.3 Bypassing Re-initialization During Battery-Backed Operation....568

Chapter 12
Integrated Flash Controller (IFC)

12.1 IFC overview....569
12.1.1 IFC features summary....570
12.1.1.1 NAND flash features....571
12.1.1.2 NOR flash features....572
12.1.1.3 GPCM and GASIC features....572
12.1.2 IFC modes of operation....573
12.2 External signal descriptions....573
12.2.1 Internal connectivity of WP/RB signal....577
12.2.1.1 Internal connectivity of WP signal....578
12.2.1.2 Internal connectivity of RB signal....579
12.3 IFC memory map/register definition....580

12.3.1 IFC Revision Control register (IFC_REV)..... 591
12.3.2 Extended Chip Select Property registers (IFC_CSPR*n*_EXT)..... 592
12.3.3 Chip-select Property register n (IFC_CSPR*n*)..... 592
12.3.4 Address Mask register (IFC_AMASK*n*)..... 594
12.3.5 Chip-Select Option register - NAND Flash Mode (IFC_CSOR*n*_NAND)..... 595
12.3.6 Chip-Select Option register - NOR Flash Mode (IFC_CSOR*n*_NOR)..... 598
12.3.7 Chip-Select Option register - GPCM (IFC_CSOR*n*_GPCM)..... 600
12.3.8 Extended Chip-Select Option register - NAND Flash Mode (IFC_CSOR*n*_EXT)..... 604
12.3.9 Flash Timing register 0 for Chip Select *n* - NAND flash async mode (IFC_FTIM0_CS*n*_NAND)..... 605
12.3.10 Flash Timing register 0 for Chip Select *n* - NAND flash Asynchronous Mode (IFC_FTIM0_CS*n*_NAND_ASYNC_MODE)..... 608
12.3.11 Flash Timing register 0 for CS*n* - NOR Flash Mode (IFC_FTIM0_CS*n*_NOR)..... 610
12.3.12 Flash Timing register 0 for CS*n* - Normal GPCM Mode (IFC_FTIM0_CS*n*_GPCM)..... 611
12.3.13 Flash Timing register 1 for Chip-Select n - NAND Flash Mode (IFC_FTIM1_CS*n*_NAND)..... 612
12.3.14 Flash Timing register 1 for Chip Select n - Asynchronous Mode (IFC_FTIM1_CS*n*_NAND_ASYNC_MODE)..... 613
12.3.15 Flash Timing register 1 for CS*n* - NOR Flash Mode (IFC_FTIM1_CS*n*_NOR)..... 614
12.3.16 Flash Timing register 1 for CS*n* - Normal GPCM Mode (IFC_FTIM1_CS*n*_GPCM)..... 615
12.3.17 Flash Timing register 2 for Chip Select n - NAND Flash Mode (IFC_FTIM2_CS*n*_NAND)..... 616
12.3.18 Flash Timing register 2 for Chip Select n - NAND Flash Asynchronous Mode (IFC_FTIM2_CS*n*_NAND_ASYNC_MODE)..... 617
12.3.19 Flash Timing register 2 for CS*n* - NOR Flash Mode (IFC_FTIM2_CS*n*_NOR)..... 618
12.3.20 Flash Timing register 2 for CS*n* - Normal GPCM Mode (IFC_FTIM2_CS*n*_GPCM)..... 620
12.3.21 Flash Timing register 3 for Chip Select n - NAND Flash Mode (IFC_FTIM3_CS*n*_NAND)..... 621
12.3.22 Flash Timing register 3 for Chip Select n - NAND Flash Asynchronous Mode (IFC_IFC_FTIM*n*3_CS_NAND_ASYNC_MODE)..... 621
12.3.23 Flash Timing register 3 for CS*n* - NOR Flash Mode (IFC_FTIM3_CS_NOR)..... 622
12.3.24 Flash Timing register 3 for CS*n* - Normal GPCM Mode (IFC_FTIM3_CS*n*_GPCM)..... 622
12.3.25 Ready Busy Status for each Chip Select (IFC_RB_STAT)..... 623
12.3.26 General Control register (IFC_GCR)..... 625

Section number	Title	Page
12.3.27	Common Event and Error Status register (IFC_CM_EVTER_STAT)	626
12.3.28	Common Event and Error Enable register (IFC_CM_EVTER_EN)	627
12.3.29	Common Event and Error Interrupt Enable register (IFC_CM_EVTER_INTR_EN)	628
12.3.30	Common Transfer Error Attributes register 0 (IFC_CM_ERATTR0)	628
12.3.31	Common Transfer Error Attributes register 1 (IFC_CM_ERATTR1)	629
12.3.32	Clock Control register (IFC_CCR)	630
12.3.33	Clock Status register (IFC_CSR)	632
12.3.34	NAND Configuration register (IFC_NCFGR)	633
12.3.35	NAND Flash Command register 0 (IFC_NAND_FCR0)	635
12.3.36	NAND Flash Command register 1 (IFC_NAND_FCR1)	635
12.3.37	Flash Row Address register n (IFC_ROW*n*)	636
12.3.38	Flash COL Address register n (IFC_COL*n*)	636
12.3.39	Flash COL Address register for 2 KB Large-Page Device (IFC_COL*n*_2KB)	638
12.3.40	Flash COL Address register for 4 KB Large-Page Device (IFC_COL*n*_4KB)	639
12.3.41	Flash COL Address register for 8 KB Large-Page Device (IFC_COL*n*_8KB)	640
12.3.42	Flash Byte Count register for NAND Flash (IFC_NAND_BC)	641
12.3.43	NAND Flash Instruction register 0 (IFC_NAND_FIR0)	641
12.3.44	NAND Flash Instruction register 1 (IFC_NAND_FIR1)	644
12.3.45	NAND Flash Instruction register 2 (IFC_NAND_FIR2)	644
12.3.46	NAND Chip-Select register (IFC_NAND_CSEL)	645
12.3.47	NAND Operation Sequence Start (IFC_NANDSEQ_STRT)	646
12.3.48	NAND Event and Error Status register (IFC_NAND_EVTER_STAT)	647
12.3.49	NAND Page Read Completion Event Status register (IFC_PGRDCMPL_EVT_STAT)	649
12.3.50	NAND Event and Error Enable register (IFC_NAND_EVTER_EN)	651
12.3.51	NAND Event and Error Interrupt Enable register (IFC_NAND_EVTER_INTR_EN)	653
12.3.52	NAND Transfer Error Attributes register 0 (IFC_NAND_ERATTR0)	654
12.3.53	NAND Transfer Error Attributes register 1 (IFC_NAND_ERATTR1)	655
12.3.54	NAND Flash Status register (IFC_NAND_FSR)	656
12.3.55	ECC Status and Result of Flash Operation register 0 (IFC_ECCSTAT0)	656

12.3.56 ECC Status and Result of Flash Operation register 1 (IFC_ECCSTAT1)..... 658
12.3.57 ECC Status and Result of Flash Operation register 2 (IFC_ECCSTAT2)..... 659
12.3.58 ECC Status and Result of Flash Operation register 3 (IFC_ECCSTAT3)..... 660
12.3.59 NAND Control register (IFC_NANDCR)..... 661
12.3.60 NAND Autoboot Trigger register (IFC_NAND_AUTOBOOT_TRGR)..... 661
12.3.61 NAND Flash Memory Data register (IFC_NAND_MDR)..... 663
12.3.62 NOR Event and Error Status register (IFC_NOR_EVTER_STAT)..... 664
12.3.63 NOR Event and Error Enable register (IFC_NOR_EVTER_EN)..... 666
12.3.64 NOR Event and Error Interrupt enable register (IFC_NOR_EVTER_INTR_EN)..... 667
12.3.65 NOR Transfer Error Attributes register 0 (IFC_NOR_ERATTR0)..... 668
12.3.66 NOR Transfer Error Attribute register 1 (IFC_NOR_ERATTR1)..... 670
12.3.67 NOR Transfer Error Attribute register 2 (IFC_NOR_ERATTR2)..... 670
12.3.68 NOR Control register (IFC_NORCR)..... 671
12.3.69 GPCM Event and Error Status register (IFC_GPCM_EVTER_STAT)..... 672
12.3.70 GPCM Event and Error Enable register (IFC_GPCM_EVTER_EN)..... 675
12.3.71 GPCM Event and Error Interrupt enable register (IFC_GPCM_EVTER_INTR_EN)..... 676
12.3.72 GPCM Transfer Error Attributes register 0 (IFC_GPCM_ERATTR0)..... 678
12.3.73 GPCM Transfer Error Attributes register 1 (IFC_GPCM_ERATTR1)..... 679
12.3.74 GPCM Transfer Error Attributes register 2 (IFC_GPCM_ERATTR2)..... 680
12.3.75 GPCM Status register (IFC_GPCM_STAT)..... 682
12.4 IFC functional description..... 683
12.4.1 General architecture..... 685
12.4.1.1 Bank selection through address decoding..... 685
12.4.1.2 Address/Data pin muxing for external address latch..... 685
12.4.1.2.1 Mode 0 pin muxing (CSORn[ADM_SHFT_MODE] = 0)..... 686
12.4.1.2.2 Mode 1 pin muxing (CSORn[ADM_SHFT_MODE] = 1)..... 688
12.4.2 Programming model for flash interface timing..... 693
12.4.3 Booting methods..... 693
12.4.4 Software reset handling..... 693

12.4.4.1 System bus handling ... 694
12.4.4.2 Flash interface handling ... 694
12.4.5 Data buffer control (BCTL) ... 694
12.4.6 External transceiver enable (TE) ... 696
12.4.6.1 Transceiver enable during boot ... 696
12.4.6.2 Transceiver enable post-boot ... 697
12.4.6.3 Transceiver enable example ... 698
12.5 NAND flash control machine ... 698
12.5.1 NAND flash asynchronous mode ... 698
12.5.2 Write protect ... 699
12.5.3 SRAM buffer ... 699
12.5.3.1 Guidelines for SRAM buffer for NAND access ... 700
12.5.3.2 Buffer layout and page mapping for 512-byte page NAND flash ... 701
12.5.3.3 Buffer layout and page mapping for 2-KB page NAND flash ... 702
12.5.3.4 Buffer layout and page mapping for 4 KB page NAND flash ... 703
12.5.3.5 Buffer layout and page mapping for 8 KB page NAND flash ... 704
12.5.3.6 SRAM buffer initialization requirement ... 705
12.5.4 Use of ECC algorithms ... 705
12.5.4.1 Generating Galois field elements ... 705
12.5.4.2 BCH encoding ... 706
12.5.5 Programming the NAND FCM ... 713
12.5.5.1 FCM command instructions ... 714
12.5.5.2 FCM address instructions ... 715
12.5.5.3 FCM data read instructions ... 715
12.5.5.4 FCM data write instructions ... 716
12.5.6 Looping FIR sequences ... 716
12.5.7 NAND asynchronous mode timings ... 717
12.5.7.1 NAND asynchronous mode program data timing ... 717
12.5.7.2 NAND asynchronous mode read data timing ... 717

12.5.7.3 NAND asynchronous mode calculating read data window width..... 718
12.5.7.4 NAND asynchronous mode read data sampling approach..... 719
12.5.7.5 NAND asynchronous mode read status timing..... 719
12.5.8 NAND asynchronous mode boot mechanism..... 720
12.5.8.1 NAND asynchronous mode boot process..... 722
12.6 NOR flash control machine..... 724
12.6.1 NOR boot..... 724
12.6.2 Unmuxed (parallel) asynchronous NOR read timings..... 724
12.6.3 Simple asynchronous NOR write timings..... 725
12.6.4 Muxed (ADM) asynchronous NOR read timings..... 726
12.6.5 Muxed (ADM) asynchronous NOR write timings..... 727
12.7 General purpose chip-select machine (GPCM)..... 728
12.7.1 Normal GPCM mode of operation..... 728
12.7.1.1 Normal GPCM program operation..... 728
12.7.1.1.1 Normal GPCM internal counter-based program operation..... 728
12.7.1.1.2 Normal GPCM external termination-based program operation..... 732
12.7.1.2 Normal GPCM read operation..... 733
12.7.1.2.1 Normal GPCM internal counter-based read operation..... 734
12.7.1.2.2 Normal GPCM external termination-based read operation..... 738
12.7.2 Generic ASIC mode of operation..... 740
12.7.2.1 General ASIC program operation..... 741
12.7.2.2 Generic ASIC read data sampling..... 742
12.8 Clock generation module..... 744
12.9 Initialization/Application information..... 744
12.9.1 IFC flash connections..... 744
12.9.1.1 NAND flash connections..... 744
12.9.1.2 NOR flash connections..... 746
12.9.2 Bus turnaround..... 747
12.9.2.1 Address phase after previous read..... 748

12.9.2.2 Read-data phase after address phase....748
12.9.2.3 Read-modify-write cycle for parity protected memory banks....748
12.9.3 Interfacing to different port sizes....749
12.9.4 Command sequence examples for NAND flash EEPROM....749
12.9.4.1 NAND flash soft reset command sequence example....750
12.9.4.2 NAND flash read status command sequence example....750
12.9.4.3 NAND flash read identification command sequence example....751
12.9.4.4 NAND flash page read command sequence example....752
12.9.4.5 NAND flash program command sequence example....752
12.9.4.6 Read status command during busy period of program/erase operation....753
12.9.4.7 Valid opcode transitions in the IFC....754

Chapter 13
I2C Modules

13.1 I2C Overview....757
13.2 Introduction to I2C....757
13.2.1 Definition: I2C Module....757
13.2.2 Advantages of the I2C Bus....758
13.2.3 I2C Module Block Diagram....758
13.2.4 I2C Features Summary....758
13.2.5 I2C Modes of Operation....759
13.2.6 Definition: I2C Conditions....759
13.3 I2C Signal Descriptions....760
13.3.1 Signal Overview....760
13.3.2 I2C Detailed Signal Descriptions....760
13.4 I2C Controller Memory Map....761
13.4.1 I2C address register (I2C*x*_I2CADR)....763
13.4.2 I2C frequency divider register (I2C*x*_I2CFDR)....763
13.4.3 I2C control register (I2C*x*_I2CCR)....765
13.4.4 I2C status register (I2C*x*_I2CSR)....767

13.4.5 I2C data register (I2C*x*_I2CDR)....769
13.4.6 I2C digital filter sampling rate register (I2C*x*_I2CDFSRR)....769
13.5 I2C Functional Description....770
13.5.1 Notes About Module Operation....770
13.5.2 Transactions....770
13.5.2.1 Protocol Overview....771
13.5.2.2 Definitions....771
13.5.2.3 I2C Calling Address Requirements....772
13.5.2.4 High-Level Protocol Steps....772
13.5.2.5 START Condition....772
13.5.2.6 Slave Address Transmission....773
13.5.2.7 General Call (Broadcast) Addressing....773
13.5.2.8 Data Transmission....774
13.5.2.9 STOP Condition....774
13.5.2.10 Repeated START Condition....774
13.5.3 Protocol Implementation Details....775
13.5.3.1 Transaction Monitoring....775
13.5.3.2 Control Transfer....775
13.5.4 Bus Arbitration....776
13.5.4.1 Bus Arbitration Overview....776
13.5.4.2 Loss of Arbitration....776
13.5.4.3 Module Startup During a Data Transfer....777
13.5.5 Clock Behavior....777
13.5.5.1 SCL Synchronization....777
13.5.5.2 Clock Stretching....778
13.5.5.3 Handshaking....778
13.5.6 Filtering of SCL and SDA Lines....778
13.5.6.1 Filtering of SCL and SDA Lines-Overview....778
13.5.6.2 Sample Rate Control....778

13.6 I2C Initialization/Application Information....779
13.6.1 Recommended Interrupt Service Flow....779
13.6.2 General Programming Guidelines (for Both Master and Slave Mode)....781
13.6.2.1 Initializing the Module....781
13.6.2.2 Software Response After a Transfer....781
13.6.2.3 Generating SCL when SDA is Low....782
13.6.3 Programming Guidelines Specific to Master Mode....783
13.6.3.1 Generating START....783
13.6.3.2 Generating STOP....783
13.6.3.3 Generating Repeated START....784
13.6.3.4 Loss of Arbitration and Forcing Slave Mode....784
13.6.4 Programming Guidelines Specific to Slave Mode....784
13.6.4.1 Slave Mode Interrupt Service Routine....785
13.6.4.2 Acknowledge Receipt During Transmission....785

Chapter 14
Enhanced Serial Peripheral Interface

14.1 Introduction....787
14.1.1 Features....788
14.1.2 eSPI transmission and reception process....789
14.1.3 Modes of operation....789
14.2 External signal descriptions....790
14.2.1 eSPI detailed signal descriptions....791
14.3 Enhanced serial peripheral interface (eSPI) memory map....792
14.3.1 eSPI mode register (ESPI_SPMODE)....793
14.3.2 eSPI event register (ESPI_SPIE)....795
14.3.3 eSPI mask register (ESPI_SPIM)....797
14.3.4 eSPI command register (ESPI_SPCOM)....799
14.3.5 eSPI transmit FIFO access register (ESPI_SPITF)....801
14.3.6 eSPI receive FIFO access register (ESPI_SPIRF)....803

14.3.7 eSPI CS0 mode register (ESPI_SPMODE0)..... 804
14.3.8 eSPI CS1 mode register (ESPI_SPMODE1)..... 806
14.3.9 eSPI CS2 mode register (ESPI_SPMODE2)..... 808
14.3.10 eSPI CS3 mode register (ESPI_SPMODE3)..... 810
14.4 eSPI transfer formats.....811
14.5 CI and CP values for various eSPI devices.....812
14.6 eSPI programming examples..... 813
14.6.1 24-bit address example.....813
14.6.2 16-bit address example.....813

Chapter 15
Enhanced Secured Digital Host Controller (eSDHC)

15.1 Overview.....815
15.1.1 eSDHC features summary.....817
15.1.2 Modes and operations..... 818
15.1.2.1 Data transfer modes..... 818
15.2 External signals.....819
15.2.1 External signals overview..... 819
15.2.2 eSDHC signal descriptions..... 819
15.3 eSDHC memory map/register definition..... 820
15.3.1 SDMA system address register (eSDHC_DSADDR)..... 821
15.3.2 Block attributes register (eSDHC_BLKATTR).....822
15.3.3 Command argument register (eSDHC_CMDARG)..... 823
15.3.4 Transfer type register (eSDHC_XFERTYP)..... 824
15.3.5 Command response 0 register (eSDHC_CMDRSP0).....828
15.3.6 Command response 1 register (eSDHC_CMDRSP1).....828
15.3.7 Command response 2 register (eSDHC_CMDRSP2).....829
15.3.8 Command Response 3 register (eSDHC_CMDRSP3)..... 829
15.3.9 Buffer data port register (eSDHC_DATPORT).....831
15.3.10 Present state register (eSDHC_PRSSTAT)..... 832

15.3.11 Protocol control register (eSDHC_PROCTL)..... 837
15.3.12 System control register (eSDHC_SYSCTL).....840
15.3.13 Interrupt status register (eSDHC_IRQSTAT).....843
15.3.14 Interrupt status enable register (eSDHC_IRQSTATEN).....848
15.3.15 Interrupt signal enable register (eSDHC_IRQSIGEN).....852
15.3.16 Auto CMD error status register (eSDHC_AUTOCERR).....854
15.3.17 Host controller capabilities register (eSDHC_HOSTCAPBLT)..... 858
15.3.18 Watermark level register (eSDHC_WML)..... 861
15.3.19 Force event register (eSDHC_FEVT).....863
15.3.20 ADMA error status register (eSDHC_ADMAES).....865
15.3.21 ADMA system address register (eSDHC_ADSADDR).....867
15.3.22 Host controller version register (eSDHC_HOSTVER)..... 868
15.3.23 DMA error address register (eSDHC_DMAERRADDR)..... 869
15.3.24 DMA error attribute register (eSDHC_DMAERRATTR).....869
15.3.25 eSDHC control register (eSDHC_ESDHCCTL)..... 870
15.4 Functional description.....871
15.4.1 System interface and control unit (SysICU)..... 872
15.4.1.1 Data buffer..... 872
15.4.1.1.1 Write operation sequence.....874
15.4.1.1.2 Read operation sequence.....874
15.4.1.1.3 Data buffer and block size..... 875
15.4.1.1.4 Dividing large data transfer..... 878
15.4.1.1.5 Byte order (endianness) of buffer data port register..... 879
15.4.1.2 DMA system interface..... 880
15.4.1.2.1 DMA burst length..... 881
15.4.1.2.2 System master interface..... 881
15.4.1.3 Single DMA (SDMA).....882
15.4.1.3.1 SDMA error..... 882
15.4.1.4 Advanced DMA (ADMA)..... 882

15.4.1.4.1 ADMA concept and descriptor format 882
15.4.1.4.2 ADMA interrupt 887
15.4.1.4.3 ADMA error 887
15.4.2 SD interface and control unit (SDICU) 887
15.4.2.1 Command CRC 888
15.4.2.2 Data CRC 888
15.4.3 Register bank 888
15.4.4 Clock and reset module 889
15.4.4.1 Clock generator 890
15.4.5 SD monitor 891
15.4.5.1 SDIO card interrupt 891
15.4.5.1.1 Interrupts in 1-bit mode 892
15.4.5.1.2 Interrupt in 4-bit mode 892
15.4.5.1.3 Card interrupt handling 892
15.4.5.2 Card insertion and removal detection 894
15.4.5.3 Power management and wake up events 894
15.4.5.3.1 Setting wake up events 895
15.5 Initialization/application of eSDHC 895
15.5.1 Command send and response receive basic operation 895
15.5.2 Card identification mode 896
15.5.2.1 Card detect 896
15.5.2.2 Reset 897
15.5.2.3 Voltage validation 898
15.5.2.4 Card registry 900
15.5.3 Card access 901
15.5.3.1 Block write 901
15.5.3.1.1 Normal write 901
15.5.3.1.2 Write with pause 903
15.5.3.2 Block read 904

15.5.3.2.1 Normal read ... 904
15.5.3.2.2 Read with pause ... 906
15.5.3.3 Suspend resume ... 907
15.5.3.3.1 Suspend ... 907
15.5.3.3.2 Resume ... 908
15.5.3.4 ADMA usage ... 908
15.5.3.5 Transfer error ... 908
15.5.3.5.1 CRC transfer error ... 908
15.5.3.5.2 DMA transfer error ... 909
15.5.3.5.3 ADMA transfer error ... 909
15.5.3.5.4 Auto CMD12 error ... 910
15.5.3.6 Card interrupt ... 910
15.5.4 Switch function ... 911
15.5.4.1 Query, enable and disable SDIO high speed mode ... 911
15.5.4.2 Query, enable and disable SD high speed mode ... 912
15.5.4.3 Query, enable and disable MMC high speed mode ... 912
15.5.4.4 Set MMC bus width ... 913
15.5.5 ADMA operation ... 913
15.5.5.1 ADMA1 operation ... 913
15.5.5.2 ADMA2 operation ... 913
15.6 Commands for MMC/SD/SDIO ... 914
15.7 Software restrictions ... 920
15.7.1 Software polling procedure ... 920
15.7.2 Suspend operation ... 921
15.7.3 Data port access ... 921
15.7.4 Multi-block read ... 921
15.7.5 ADMA address ... 921
15.7.6 Allowed operations after stop at block gap ... 921
15.7.7 SDIO card interrupt during soft reset ... 922

15.7.8 Soft reset for data not allowed when SD clock is disabled....922
15.7.9 Data transfer with Auto CMD12 Enable....922
15.7.10 Buffer Data port register should not be read when in DMA mode or buffer is empty....922

Chapter 16
Universal Serial Bus Interface

16.1 Overview....923
16.1.1 USB features summary....924
16.1.2 Modes of operation....925
16.2 USB External Signals....925
16.2.1 UTMI....925
16.2.2 PHY clocks....926
16.3 USB memory map/register definition....926
16.3.1 Identification register (USB*x*_USB_ID)....930
16.3.2 General purpose timer load n (USB*x*_GPTIMER*n*LD)....931
16.3.3 General purpose timer control n (USB*x*_GPTIMER*n*CTRL)....932
16.3.4 Capability Register Length (USB*x*_CAPLENGTH)....933
16.3.5 Host Controller Interface Version Number (USB*x*_HCIVERSION)....934
16.3.6 Host Controller Structural Parameters (USB*x*_HCSPARAMS)....934
16.3.7 Host Controller Capability Parameters (USB*x*_HCCPARAMS)....936
16.3.8 Device Controller Interface Version Number (USB*x*_DCIVERSION)....938
16.3.9 Device Controller Capability Parameters (USB*x*_DCCPARAMS)....939
16.3.10 USB Command (USB*x*_USBCMD)....939
16.3.11 USB Status (USB*x*_USBSTS)....944
16.3.12 USB Interrupt Enable (USB*x*_USBINTR)....948
16.3.13 USB Frame Index (USB*x*_FRINDEX)....950
16.3.14 Periodic Frame List Base Address [host mode] (USB*x*_PERIODICLISTBASE)....951
16.3.15 USB Device Address [device mode] (USB*x*_DEVICEADDR)....952
16.3.16 Next Asynchronous List Addr [host mode] (USB*x*_ASYNCLISTADDR)....952
16.3.17 Address at Endpoint List [device mode] (USB*x*_ENDPOINTLISTADDR)....953

16.3.18 Master Interface Data Burst Size (USB*x*_BURSTSIZE)....954
16.3.19 Transmit FIFO Tuning Controls (USB*x*_TXFILLTUNING)....954
16.3.20 Endpoint NAK Indicaton Register (USB*x*_ENDPTNAK)....956
16.3.21 Endpoint NAK Indication Enable Register (USB*x*_ENDPTNAKEN)....957
16.3.22 Configured Flag Register (USB*x*_CONFIGFLAG)....958
16.3.23 Port Status/Control (USB*x*_PORTSC)....958
16.3.24 USB Device Mode (USB*x*_USBMODE)....965
16.3.25 Endpoint Setup Status (USB*x*_ENDPTSETUPSTAT)....967
16.3.26 Endpoint Initialization (USB*x*_ENDPOINTPRIME)....968
16.3.27 Endpoint Flush (USB*x*_ENDPTFLUSH)....968
16.3.28 Endpoint Status (USB*x*_ENDPTSTATUS)....969
16.3.29 Endpoint Complete (USB*x*_ENDPTCOMPLETE)....970
16.3.30 Endpoint Control 0 (USB*x*_ENDPTCTRL0)....971
16.3.31 Endpoint Control n (USB*x*_ENDPTCTRL*n*)....973
16.3.32 Snoop n (USB*x*_SNOOP*n*)....975
16.3.33 Age Count Threshold (USB*x*_AGE_CNT_THRESH)....976
16.3.34 Priority Control (USB*x*_PRI_CTRL)....977
16.3.35 System Interface Control (USB*x*_SI_CTRL)....978
16.3.36 Control (USB*x*_CONTROL)....980
16.4 USB_PHY Memory Map/Register Definition....982
16.4.1 PHY identification register (USB_PHY_ID)....983
16.4.2 PHY control register (USB_PHY_CTRL_PHY*n*)....984
16.4.3 PHY DRVVBUS configuration register (USB_PHY_DRVVBUSCFG_PHY*n*)....985
16.4.4 PHY PWRFLT configuration register (USB_PHY_PWRFLTCFG_PHY*n*)....987
16.4.5 PHY status register (USB_PHY_STS_PHY*n*)....988
16.4.6 PHY transceiver program register (USB_PHY_XCVRPRG_PHY*n*)....989
16.4.7 PHY trim value register (USB_PHY_TVR)....992
16.4.8 PHY PLL program register 1 (USB_PHY_PLLPRG1)....993
16.4.9 PHY PLL program register 2 (USB_PHY_PLLPRG2)....994

16.5 Functional description....995
16.5.1 System interface....995
16.5.2 DMA engine....995
16.5.3 FIFO RAM controller....996
16.5.4 PHY interface....996
16.6 Host data structures....997
16.6.1 Periodic frame list....997
16.6.2 Asynchronous list queue head pointer....999
16.6.3 Isochronous (high-speed) transfer descriptor (iTD)....1000
16.6.3.1 Next link pointer-iTD....1000
16.6.3.2 iTD transaction status and control list....1001
16.6.3.3 iTD buffer page pointer list (plus)....1002
16.6.4 Split transaction isochronous transfer descriptor (siTD)....1004
16.6.4.1 Next link pointer-siTD....1004
16.6.4.2 siTD Endpoint capabilities/characteristics....1005
16.6.4.3 siTD transfer state....1006
16.6.4.4 siTD buffer pointer list (plus)....1007
16.6.4.5 siTD back link pointer....1008
16.6.5 Queue element transfer descriptor (qTD)....1008
16.6.5.1 Next qTD pointer....1009
16.6.5.2 Alternate next qTD pointer....1009
16.6.5.3 qTD token....1010
16.6.5.4 qTD buffer page pointer list....1012
16.6.6 Queue head....1013
16.6.6.1 Queue head horizontal link pointer....1014
16.6.6.2 Endpoint capabilities/characteristics....1014
16.6.6.3 Transfer overlay....1016
16.6.7 Periodic frame span traversal node (FSTN)....1018
16.6.7.1 FSTN normal path pointer....1018

16.6.7.2 FSTN back path link pointer....1019
16.7 Host operations....1020
16.7.1 Host controller initialization....1020
16.7.2 Power port....1021
16.7.3 Reporting over-current....1021
16.7.4 Suspend/resume....1022
16.7.4.1 Port suspend/resume....1023
16.7.5 Schedule traversal rules....1024
16.7.6 Periodic schedule frame boundaries vs. bus frame boundaries....1026
16.7.7 Periodic schedule....1029
16.7.8 Managing isochronous transfers using iTDs....1030
16.7.8.1 Host controller operational model for iTDs....1031
16.7.8.2 Software operational model for iTDs....1033
16.7.8.2.1 Periodic scheduling threshold....1035
16.7.9 Asynchronous schedule....1036
16.7.9.1 Adding queue heads to asynchronous schedule....1038
16.7.9.2 Removing queue heads from asynchronous schedule....1038
16.7.9.3 Empty asynchronous schedule detection....1041
16.7.9.4 Asynchronous schedule traversal: Start event....1042
16.7.9.5 Reclamation status bit (USBSTS Register)....1042
16.7.10 Managing control/bulk/interrupt transfers via queue heads....1043
16.7.10.1 Buffer pointer list use for data streaming with qTDs....1044
16.7.10.2 Adding interrupt queue heads to the periodic schedule....1046
16.7.10.3 Managing transfer complete interrupts from queue heads....1046
16.7.11 Ping control....1047
16.7.12 Split transactions....1048
16.7.12.1 Split transactions for asynchronous transfers....1049
16.7.12.1.1 Asynchronous-do-start-split....1049
16.7.12.1.2 Asynchronous-do-complete-split....1050

16.7.12.2 Split transaction interrupt 1051
16.7.12.2.1 Split transaction scheduling mechanisms for interrupt 1052
16.7.12.2.2 Host controller operational model for FSTNs 1055
16.7.12.2.3 Software operational model for FSTNs..... 1058
16.7.12.2.4 Tracking split transaction progress for interrupt transfers 1059
16.7.12.2.5 Split transaction execution state machine for interrupt 1060
16.7.12.2.6 Periodic interrupt-do-start-split 1061
16.7.12.2.7 Periodic interrupt-do-complete-split 1062
16.7.12.2.8 Managing the QH[FrameTag] field 1066
16.7.12.2.9 Rebalancing the periodic schedule 1067
16.7.12.3 Split transaction isochronous 1067
16.7.12.3.1 Split transaction scheduling mechanisms for isochronous 1068
16.7.12.3.2 Tracking split transaction progress for isochronous transfers 1073
16.7.12.3.3 Split transaction execution state machine for isochronous 1075
16.7.12.3.4 Periodic isochronous-do-start-split 1076
16.7.12.3.5 Periodic isochronous-do complete split..... 1078
16.7.12.3.6 Complete-split for scheduling boundary cases 2a, 2b..... 1081
16.7.12.3.7 Split transaction for isochronous-processing example..... 1083
16.7.13 Port test modes..... 1085
16.7.14 Interrupts..... 1085
16.7.14.1 Transfer/transaction based interrupts..... 1086
16.7.14.1.1 Transaction error..... 1087
16.7.14.1.2 Serial bus babble..... 1087
16.7.14.1.3 Data buffer error 1088
16.7.14.1.4 USB interrupt (interrupt on completion (IOC))..... 1089
16.7.14.1.5 Short packet..... 1089
16.7.14.2 Host controller event interrupts..... 1090
16.7.14.2.1 Port change events..... 1090
16.7.14.2.2 Frame list rollover..... 1090

16.7.14.2.3 Interrupt on async advance ... 1090
16.7.14.2.4 Host system error ... 1091
16.8 Device data structures ... 1091
16.8.1 Endpoint queue head ... 1092
16.8.1.1 Endpoint capabilities/characteristics ... 1093
16.8.1.2 Transfer overlay ... 1094
16.8.1.3 Current dTD pointer ... 1094
16.8.1.4 Setup buffer ... 1095
16.8.2 Endpoint transfer descriptor (dTD) ... 1095
16.9 Device operational model ... 1098
16.9.1 Device controller initialization ... 1098
16.9.2 Port state and control ... 1099
16.9.2.1 Bus reset ... 1101
16.9.2.2 Suspend/resume ... 1102
16.9.2.2.1 Suspend description ... 1102
16.9.2.2.2 Suspend operational model ... 1103
16.9.2.2.3 Resume ... 1103
16.9.3 Managing endpoints ... 1103
16.9.3.1 Endpoint initialization ... 1104
16.9.3.1.1 Stalling ... 1105
16.9.3.2 Data toggle ... 1105
16.9.3.2.1 Data toggle reset ... 1106
16.9.3.2.2 Data toggle inhibit ... 1106
16.9.3.3 Device operational model for packet transfers ... 1106
16.9.3.3.1 Priming transmit endpoints ... 1107
16.9.3.3.2 Priming receive endpoints ... 1107
16.9.3.4 Interrupt/bulk endpoint operational model ... 1107
16.9.3.4.1 Interrupt/bulk endpoint bus response matrix ... 1109
16.9.3.5 Control endpoint operation model ... 1110

16.9.3.5.1 Setup phase ... 1110
16.9.3.5.2 Data phase ... 1111
16.9.3.5.3 Status phase ... 1111
16.9.3.5.4 Control endpoint bus response matrix ... 1112
16.9.3.6 Isochronous endpoint operational model ... 1112
16.9.3.6.1 Isochronous pipe synchronization ... 1114
16.9.3.6.2 Isochronous endpoint bus response matrix ... 1114
16.9.4 Managing queue heads ... 1115
16.9.4.1 Queue head initialization ... 1115
16.9.4.2 Operational model for setup transfers ... 1116
16.9.5 Managing transfers with transfer descriptors ... 1117
16.9.5.1 Software link pointers ... 1117
16.9.5.2 Building a transfer descriptor ... 1118
16.9.5.3 Executing a transfer descriptor ... 1118
16.9.5.4 Transfer completion ... 1119
16.9.5.5 Flushing/depriming an endpoint ... 1120
16.9.5.6 Device error matrix ... 1120
16.9.6 Servicing interrupts ... 1121
16.9.6.1 High-frequency interrupts ... 1121
16.9.6.2 Low-frequency interrupts ... 1121
16.9.6.3 Error interrupts ... 1122
16.10 PHY PLL Initialization ... 1122
16.11 Deviations from the EHCI specifications ... 1124
16.11.1 Embedded transaction translator function ... 1124
16.11.1.1 Capability registers ... 1125
16.11.1.2 Operational registers ... 1125
16.11.1.3 Discovery differences ... 1125
16.11.1.4 Data structures ... 1126
16.11.1.5 Operational model ... 1127

16.11.1.5.1 Microframe pipeline....1127
16.11.1.5.2 Split state machines....1128
16.11.1.5.3 Asynchronous transaction scheduling and buffer management....1128
16.11.1.5.4 Periodic transaction scheduling and buffer management....1128
16.11.1.5.5 Multiple transaction translators....1129
16.11.2 Device operation....1129
16.11.3 Non-zero fields the register file....1129
16.11.4 SOF interrupt....1130
16.11.5 Embedded design....1130
16.11.5.1 Frame adjust register....1130
16.11.6 Miscellaneous variations from EHCI....1130
16.11.6.1 Discovery....1130
16.11.6.1.1 Port reset....1130
16.11.6.1.2 Port speed detection....1131

Chapter 17
DUART

17.1 Overview....1133
17.1.1 The DUART module as implemented on the chip....1134
17.1.2 Features....1134
17.1.3 Modes of operation....1135
17.2 DUART external signal descriptions....1135
17.3 DUART memory map/register definition....1137
17.3.1 UART receiver buffer register (DUART*x*_URBR*n*)....1139
17.3.2 UART transmitter holding register (DUART*x*_UTHR*n*)....1140
17.3.3 UART divisor least significant byte register (DUART*x*_UDLB*n*)....1140
17.3.4 UART divisor most significant byte register (DUART*x*_UDMB*n*)....1142
17.3.5 UART interrupt enable register (DUART*x*_UIER*n*)....1143
17.3.6 UART interrupt ID register (DUART*x*_UIIR*n*)....1143
17.3.7 UART FIFO control register (DUART*x*_UFCR*n*)....1145

17.3.8 UART alternate function register (DUART*x*_UAFR*n*)....1146
17.3.9 UART line control register (DUART*x*_ULCR*n*)....1147
17.3.10 UART modem control register (DUART*x*_UMCR*n*)....1148
17.3.11 UART line status register (DUART*x*_ULSR*n*)....1149
17.3.12 UART modem status register (DUART*x*_UMSR*n*)....1151
17.3.13 UART scratch register (DUART*x*_USCR*n*)....1151
17.3.14 UART DMA status register (DUART*x*_UDSR*n*)....1152
17.4 Functional description....1153
17.4.1 Serial interface....1153
17.4.1.1 START bit....1154
17.4.1.2 Data transfer....1154
17.4.1.3 Parity bit....1155
17.4.1.4 STOP bit....1155
17.4.2 Baud-rate generator logic....1155
17.4.3 Local loopback mode....1156
17.4.4 Errors....1156
17.4.4.1 Framing error....1156
17.4.4.2 Parity error....1157
17.4.4.3 Overrun error....1157
17.4.5 FIFO mode....1157
17.4.5.1 FIFO interrupts....1157
17.4.5.2 DMA mode select....1158
17.4.5.3 Interrupt control logic....1158
17.5 Initialization/Application information....1159

Chapter 18
SerDes Module

18.1 Overview....1161
18.1.1 The SerDes module as implemented on the chip....1161
18.1.1.1 T4240 SerDes Integration....1161

18.1.1.2 SerDes Lane Assignments and Multiplexing....1161
18.1.1.2.1 Configuration of Networking SerDes....1161
18.1.1.2.2 Networking Protocols (SerDes 1 and SerDes 2)....1162
18.1.1.2.2.1 SerDes 1 options....1163
18.1.1.2.2.2 SerDes 2 options....1164
18.1.1.2.2.3 Precedence Rules....1164
18.1.1.2.2.4 Networking SerDes Option Restrictions....1166
18.1.1.2.2.5 Rules for disabling networking SerDes PLLs when not all lanes are needed....1168
18.1.1.2.3 Non-Networking Protocols (SerDes 3 and SerDes 4)....1168
18.1.1.2.3.1 SerDes 3 Options....1169
18.1.1.2.3.2 SerDes 4 options....1170
18.1.1.2.3.3 SerDes 3 Lane Assignments....1170
18.1.1.2.3.4 SerDes 4 Lane Assignments....1171
18.1.1.2.3.5 Non-Networking SerDes Option Restrictions....1172
18.1.1.3 Disabling Unused SerDes Modules....1172
18.1.1.3.1 Powering Down Unused SerDes Lanes....1173
18.1.1.4 Reference Clocks for SerDes Protocols....1173
18.1.1.4.1 SerDes Clocking Restrictions....1175
18.1.1.5 Ethernet management interface (EMI)....1175
18.1.1.6 MDIO port mapping....1175
18.1.2 Features....1176
18.2 Modes of Operation....1177
18.3 External Signals Description....1177
18.4 SerDes Memory Map/Register Definition....1177
18.4.1 SerDes PLLn Reset Control Register (SerDes*x*_PLL*n*RSTCTL)....1202
18.4.2 SerDes PLLn Control Register 0 (SerDes*x*_PLL*n*CR0)....1203
18.4.3 SerDes PLLn Control Register 1 (SerDes*x*_PLL*n*CR1)....1206
18.4.4 SerDes Transmit Calibration Control Register (SerDes*x*_TCALCR)....1207

18.4.5 SerDes Receive Calibration Control Register (SerDes*x*_RCALCR)....1208
18.4.6 SerDes General Control Register 0 (SerDes*x*_GR0)....1209
18.4.7 SerDes Protocol Configuration Register 0 (SerDes*x*_PCCR0)....1209
18.4.8 SerDes Protocol Configuration Register 1 (SerDes*x*_PCCR1)....1211
18.4.9 SerDes Protocol Configuration Register 2 (SerDes*x*_PCCR2)....1213
18.4.10 SerDes Protocol Configuration Register 4 (SerDes*x*_PCCR4)....1215
18.4.11 SerDes PCIe Equalization Configuration Register (SerDes*x*_PEXEQCR)....1217
18.4.12 SerDes PCIe Equalization Preset n Register (SerDes*x*_PEXEQP*n*CR)....1218
18.4.13 SerDes PEXx Protocol Control Register 0 (SerDes*x*_PEX*n*CR0)....1219
18.4.14 SerDes PEXx Protocol Control Register 7 (SerDes*x*_PEX*n*CR7)....1220
18.4.15 SGMIIx Protocol Control Register 1 (SerDes*x*_SGMII*n*CR1)....1221
18.4.16 QSGMIIx Protocol Control Register 1 (SerDes*x*_QSGMII*n*CR1)....1222
18.4.17 XAUIx Protocol Control Register 1 (SerDes*x*_XAUI*n*CR1)....1223
18.4.18 XFIx Protocol Control Register 1 (SerDes*x*_XFI*n*CR1)....1224
18.4.19 General Control Register 0 - Lane n (SerDes*x*_LN*n*GCR0)....1224
18.4.20 General Control Register 1 - Lane n (SerDes*x*_LN*n*GCR1)....1229
18.4.21 Speed Switch Control Register 0 - Lane n (SerDes*x*_LN*n*SSCR0)....1233
18.4.22 Receive Equalization Control Register 0 - Lane n (SerDes*x*_LN*n*RECR0)....1237
18.4.23 Receive Equalization Control Register 1- Lane n (SerDes*x*_LN*n*RECR1)....1241
18.4.24 Transmit Equalization Control Register 0 - Lane n (SerDes*x*_LN*n*TECR0)....1242
18.4.25 Speed Switch Control Register 1- Lane n (SerDes*x*_LN*n*SSCR1)....1245
18.4.26 TTL Control Register 0 - Lane n (SerDes*x*_LN*n*TTLCR0)....1250
18.4.27 TTL Control Register 1 - Lane n (SerDes*x*_LN*n*TTLCR1)....1250
18.4.28 Test Control/Status Register 1 - Lane n (SerDes*x*_LN*n*TCSR1)....1251
18.4.29 Test Control/Status Register 3 - Lane n (SerDes*x*_LN*n*TCSR3)....1252
18.5 MDIO register spaces....1253
18.5.1 XFI PMA/PMD MDIO Memory Map/Register Definition....1254
18.5.1.1 XFI PMD Control 1 (MDIO_XFI_PMD_CR1)....1255
18.5.1.2 XFI 10GBASE-KR PMD Control Register (MDIO_XFI_10GKR_PMD_CR)....1256

18.5.1.3 XFI 10GBASE-KR PMD Status Register (MDIO_XFI_10GKR_PMD_SR)....1257
18.5.1.4 XFI 10GBASE-KR LP Coefficient Update Register (MDIO_XFI_10GKR_LP_COEF_UPDATE)....1258
18.5.1.5 XFI 10GBASE-KR LP Status Report Register (MDIO_XFI_10GKR_LP_SRR)....1259
18.5.1.6 XFI 10GBASE-KR LD Coefficient Update Register (MDIO_XFI_10GKR_LD_COEF_UPDATE)....1260
18.5.1.7 XFI 10GBASE-KR LD Status Report Register (MDIO_XFI_10GKR_LD_SRR)....1261
18.5.1.8 XFI 10GBASE-R FEC Ability (MDIO_XFI_10GR_FEC_ABIL)....1262
18.5.1.9 XFI Number of PRBS Sequence Errors Lower (MDIO_XFI_10GKR_NPRBS_ERR_CNT_LO)....1263
18.5.1.10 XFI Number of PRBS Sequence Errors Upper (MDIO_XFI_10GKR_NPRBS_ERR_CNT_HI)....1263
18.5.2 XFI PCS MDIO Memory Map/Register Definition....1264
18.5.2.1 XFI PCS Control 1 (MDIO_XFI_PCS_CR1)....1265
18.5.2.2 XFI PCS Status 1 (MDIO_XFI_PCS_SR1)....1266
18.5.2.3 XFI PCS Device Identifier Upper (MDIO_XFI_PCS_DEV_ID_H)....1268
18.5.2.4 XFI PCS Device Identifier Lower (MDIO_XFI_PCS_DEV_ID_L)....1268
18.5.2.5 XFI PCS Speed Ability (MDIO_XFI_PCS_SPEED_ABIL)....1269
18.5.2.6 XFI PCS Devices In Package 0 (MDIO_XFI_PCS_DEV_PRES0)....1270
18.5.2.7 XFI PCS Devices in Package 1 (MDIO_XFI_PCS_DEV_PRES1)....1271
18.5.2.8 XFI 10G PCS Control 2 (MDIO_XFI_PCS_CR2)....1272
18.5.2.9 XFI 10G PCS Status 2 (MDIO_XFI_PCS_SR2)....1272
18.5.2.10 XFI PCS Package Identifier Upper (MDIO_XFI_PCS_PKG_ID_H)....1273
18.5.2.11 XFI PCS Package Identifier Lower (MDIO_XFI_PCS_PKG_ID_L)....1274
18.5.2.12 XFI 10GBASE-R PCS Status 1 (MDIO_XFI_PCS_10GR_SR1)....1275
18.5.2.13 XFI 10GBASE-R PCS Status 2 (MDIO_XFI_PCS_10GR_SR2)....1276
18.5.2.14 XFI 10GBASE-R PCS Test Pattern Seed A 0 (MDIO_XFI_PCS_TP_SEED_A0)....1277
18.5.2.15 XFI 10GBASE-R PCS Test Pattern Seed A 1 (MDIO_XFI_PCS_TP_SEED_A1)....1277
18.5.2.16 XFI 10GBASE-R PCS Test Pattern Seed A 2 (MDIO_XFI_PCS_TP_SEED_A2)....1278
18.5.2.17 XFI 10GBASE-R PCS Test Pattern Seed A 3 (MDIO_XFI_PCS_TP_SEED_A3)....1278

18.5.2.18 XFI 10GBASE-R PCS Test Pattern Seed B 0 (MDIO_XFI_PCS_TP_SEED_B0)..... 1279
18.5.2.19 XFI 10GBASE-R PCS Test Pattern Seed B 1 (MDIO_XFI_PCS_TP_SEED_B1)..... 1279
18.5.2.20 XFI 10GBASE-R PCS Test Pattern Seed B 2 (MDIO_XFI_PCS_TP_SEED_B2)..... 1280
18.5.2.21 XFI 10GBASE-R PCS Test Pattern Seed B 3 (MDIO_XFI_PCS_TP_SEED_B3)..... 1280
18.5.2.22 XFI 10GBASE-R PCS Test Pattern Control (MDIO_XFI_PCS_TP_CR).....1281
18.5.2.23 XFI 10GBASE-R PCS Test Pattern Error Counter (MDIO_XFI_PCS_TP_ERR_CNT)..... 1282
18.5.2.24 Vendor Specific PCS Status (MDIO_XFI_PCS_VENDOR_SR)..... 1283
18.5.3 XFI Auto-Negotiation MDIO Memory Map/Register Definition..... 1283
18.5.3.1 XFI AN Control (MDIO_XF_AN_CR).....1285
18.5.3.2 XFI AN Status (MDIO_XF_AN_SR).....1286
18.5.3.3 XFI AN Device Identifier Upper (MDIO_XFI_AN_DEV_ID_H)..... 1287
18.5.3.4 XFI AN Device Identifier Lower (MDIO_XFI_DEV_ID_L)..... 1288
18.5.3.5 XFI AN Devices In Package 0 (MDIO_XFI_AN_DEV_PRES0).....1288
18.5.3.6 XFI AN Devices In Package 1 (MDIO_XFI_AN_DEV_PRES1).....1290
18.5.3.7 XFI AN Package Identifier Upper (MDIO_XF_AN_PKG_ID_H).....1291
18.5.3.8 XFI AN Package Identifier Lower (MDIO_XFI_AN_PKG_ID_L).....1291
18.5.3.9 XFI AN Advertisement 0 (MDIO_XFI_AN_ADVERT0)..... 1292
18.5.3.10 XFI AN Advertisement 1 (MDIO_XFI_AN_ADVERT1)..... 1293
18.5.3.11 XFI AN Advertisement 2 (MDIO_XFI_AN_ADVERT2)..... 1293
18.5.3.12 XFI AN LP Base Page Ability 0 (MDIO_XFI_AN_LP_BASE_PG_ABIL0)..... 1294
18.5.3.13 XFI AN LP Base Page Ability 1 (MDIO_XFI_AN_LP_BASE_PG_ABIL1)..... 1295
18.5.3.14 XFI AN LP Base Page Ability 2 (MDIO_XFI_AN_LP_BASE_PG_ABIL2)..... 1296
18.5.3.15 XFI AN Extended Next Page Transmit 0 (MDIO_XFI_AN_XNP_TX0)..... 1296
18.5.3.16 XFI AN Extended Next Page Transmit 1 (MDIO_XFI_AN_XNP_TX1)..... 1297
18.5.3.17 XFI AN Extended Next Page Transmit 2 (MDIO_XFI_AN_XNP_TX2)..... 1298
18.5.3.18 XFI AN LP Extended Next Page Ability 0 (MDIO_XFI_AN_LP_XNP_ABIL0)..... 1298
18.5.3.19 XFI AN LP Extended Next Page Ability 1 (MDIO_XFI_AN_LP_XNP_ABIL1)..... 1299
18.5.3.20 XFI AN LP Extended Next Page Ability 2 (MDIO_XFI_AN_LP_XNP_ABIL2)..... 1300
18.5.3.21 XFI Backplane Ethernet Status (MDIO_XFI_BP_STAT)..... 1301

18.5.4 XFI Vendor-Specific 1 MDIO Memory Map/Register Definition ... 1302
18.5.4.1 XFI Revision (MDIO_XFI_VND_REV) ... 1303
18.5.4.2 XFI Scratch (MDIO_XFI_VND_SCRATCH) ... 1304
18.5.4.3 XFI PCS Interrupt Event (MDIO_XFI_VND_PCS_INT) ... 1304
18.5.4.4 XFI PCS Interrupt Mask (MDIO_XFI_VND_PCS_INT_MSK) ... 1306
18.5.4.5 XFI Auto-Negotiation Interrupt Event (MDIO_XFI_VND_AN_INT) ... 1308
18.5.4.6 XFI Auto-Negotiation Interrupt Mask (MDIO_XFI_VND_AN_INT_MSK) ... 1309
18.5.4.7 XFI Link Training Interrupt Event (MDIO_XFI_VND_LT_INT) ... 1310
18.5.4.8 XFI Link Training Interrupt Mask (MDIO_XFI_VND_LT_INT_MSK) ... 1311
18.5.5 SGMII MDIO Memory Map/Register Definition ... 1312
18.5.5.1 SGMII Control (MDIO_SGMII_CR) ... 1313
18.5.5.2 SGMII Status (MDIO_SGMII_SR) ... 1315
18.5.5.3 SGMII PHY Identifier Upper (MDIO_SGMII_PHY_ID_H) ... 1316
18.5.5.4 SGMII PHY Identifier Lower (MDIO_SGMII_PHY_ID_L) ... 1317
18.5.5.5 SGMII Device Ability for SGMII (MDIO_SGMII_DEV_ABIL_SGMII) ... 1317
18.5.5.6 SGMII Partner Ability for SGMII (MDIO_SGMII_LP_DEV_ABIL_SGMII) ... 1318
18.5.5.7 SGMII AN Expansion (MDIO_SGMII_AN_EXP) ... 1319
18.5.5.8 SGMII Next Page Transmit (MDIO_SGMII_NP_TX) ... 1320
18.5.5.9 SGMII LP Next Page Receive (MDIO_SGMII_NP_RX) ... 1321
18.5.5.10 SGMII Extended Status (MDIO_SGMII_XTND_STAT) ... 1322
18.5.5.11 SGMII Scratch (MDIO_SGMII_SCRATCH) ... 1322
18.5.5.12 SGMII Design Revision (MDIO_SGMII_REV) ... 1323
18.5.5.13 SGMII Link Timer Lower (MDIO_SGMII_LINK_TMR_L) ... 1323
18.5.5.14 SGMII Link Timer Upper (MDIO_SGMII_LINK_TMR_H) ... 1324
18.5.5.15 SGMII IF Mode (MDIO_SGMII_IF_MODE) ... 1324
18.5.6 QSGMII MDIO Memory Map/Register Definition ... 1325
18.5.6.1 QSGMII Control (MDIO_QSGMII_CR) ... 1326
18.5.6.2 QSGMII Status (MDIO_QSGMII_SR) ... 1328
18.5.6.3 QSGMII PHY Identifier Upper (MDIO_QSGMII_PHY_ID_H) ... 1329

18.5.6.4 QSGMII PHY Identifier Lower (MDIO_QSGMII_PHY_ID_L)..... 1330
18.5.6.5 QSGMII Device Ability for SGMII (MDIO_QSGMII_DEV_ABIL_SGMII)..... 1330
18.5.6.6 QSGMII Partner Ability for SGMII (MDIO_QSGMII_LP_DEV_ABIL_SGMII)..... 1331
18.5.6.7 QSGMII AN Expansion (MDIO_QSGMII_AN_EXP)..... 1332
18.5.6.8 QSGMII Next Page Transmit (MDIO_QSGMII_NP_TX)..... 1333
18.5.6.9 QSGMII LP Next Page Receive (MDIO_QSGMII_NP_RX)..... 1334
18.5.6.10 QSGMII Extended Status (MDIO_QSGMII_XTND_STAT)..... 1335
18.5.6.11 QSGMII Scratch (MDIO_QSGMII_SCRATCH)..... 1335
18.5.6.12 QSGMII Design Revision (MDIO_QSGMII_REV)..... 1336
18.5.6.13 QSGMII Link Timer Lower (MDIO_QSGMII_LINK_TMR_L)..... 1336
18.5.6.14 QSGMII Link Timer Upper (MDIO_QSGMII_LINK_TMR_H)..... 1337
18.5.6.15 QSGMII IF Mode (MDIO_QSGMII_IF_MODE)..... 1337
18.6 Initialization/Application Information..... 1338
18.6.1 Initialization..... 1338
18.6.1.1 SGMII..... 1338
18.6.1.2 QSGMII..... 1339
18.6.1.3 XFI/10GBase-KR..... 1339
18.6.1.4 SRIO Long Reach..... 1340
18.6.1.5 Interlaken Long Reach..... 1340
18.6.2 Unused Lanes..... 1340
18.6.3 Frequency Negotiation..... 1340
18.6.4 Soft Reset and Reconfiguring Procedures..... 1341
18.6.4.1 Lane Reset and Reconfiguration..... 1341
18.6.4.2 Lane Enable After Powerdown..... 1342
18.6.4.3 XAUI lane alignment recovery..... 1342
18.6.4.4 PLL Reset and Reconfiguration..... 1342
18.6.5 Quiesce Sequences for System Sleep..... 1343

19.1 Introduction..... 1345
19.1.1 Overview..... 1345
19.1.1.1 PCI Express 1347
19.1.1.2 The PCI Express controller as implemented on the chip..... 1347
19.1.1.3 Outbound Transactions..... 1348
19.1.1.4 Inbound Transactions..... 1348
19.1.2 Features..... 1349
19.1.3 Modes of Operation..... 1350
19.1.3.1 Root Complex/Endpoint Modes..... 1350
19.1.3.2 Link Width..... 1350
19.1.3.3 Link Speed..... 1350
19.1.3.4 LIODN..... 1351
19.1.3.5 EP SR-IOV..... 1351
19.1.3.6 MSI-X (SR-IOV-only)..... 1351
19.2 External Signal Descriptions..... 1351
19.3 Memory map/register overview..... 1352
19.4 PEX Register Descriptions..... 1353
19.4.1 PEX Memory Map..... 1353
19.4.2 PCI Express configuration address register (CONFIG_ADDR)..... 1403
19.4.2.1 Offset..... 1403

19.4.2.2 Function ... 1403
19.4.2.3 Diagram ... 1403
19.4.2.4 Fields ... 1404
19.4.3 PCI Express configuration address register [SR-IOV] (CONFIG_ADDR_S) ... 1404
19.4.3.1 Offset ... 1405
19.4.3.2 Function ... 1405
19.4.3.3 Diagram ... 1405
19.4.3.4 Fields ... 1405
19.4.4 PCI Express configuration data register (CONFIG_DATA) ... 1406
19.4.4.1 Offset ... 1406
19.4.4.2 Function ... 1406
19.4.4.3 Diagram ... 1407
19.4.4.4 Fields ... 1407
19.4.5 PCI Express outbound completion timeout register (OTB_CPL_TOR) ... 1407
19.4.5.1 Offset ... 1407
19.4.5.2 Function ... 1407
19.4.5.3 Diagram ... 1408
19.4.5.4 Fields ... 1408
19.4.6 PCI Express configuration retry timeout register (CONF_RTY_TOR) ... 1409
19.4.6.1 Offset ... 1409
19.4.6.2 Function ... 1409
19.4.6.3 Diagram ... 1409
19.4.6.4 Fields ... 1410
19.4.7 PCI Express configuration register (CONFIG) ... 1410
19.4.7.1 Offset ... 1410
19.4.7.2 Function ... 1411
19.4.7.3 Diagram ... 1411
19.4.7.4 Fields ... 1411
19.4.8 PCI Express interrupt status register (INT_STAT) ... 1412

19.4.8.1 Offset....1412
19.4.8.2 Function....1412
19.4.8.3 Diagram....1412
19.4.8.4 Fields....1413
19.4.9 PCI Express PME message detect (PFa_PME_MES_DR)....1414
19.4.9.1 Offset....1414
19.4.9.2 Function....1414
19.4.9.3 Diagram....1414
19.4.9.4 Fields....1415
19.4.10 PCI Express PME & message disable register (PFa_PME_MES_DISR)....1416
19.4.10.1 Offset....1416

Chapter 20
Serial RapidIO Interface

20.1 SRIO Overview ... 1641
20.2 SRIO Features Summary ... 1641
20.3 SRIO RapidIO Port Modes of Operation ... 1643
20.4 LP-Serial Signal Descriptions ... 1643
20.4.1 Serial Rapid I/O Interface Overview ... 1643
20.4.2 Serial Rapid I/O Interface Detailed Signal Descriptions ... 1643
20.4.2.1 SDn_TX[n]/SDn_TX[n]_B-Outputs ... 1643
20.4.2.2 SDn_RX[n]/SDn_RX[n]_B-Inputs ... 1644

20.5 SRIO Memory Map/Register Definition..... 1644
20.5.1 Device identity capability register (SRIO_DIDCAR)..... 1655
20.5.2 Device information capability register (SRIO_DICAR)..... 1656
20.5.3 Assembly identity capability register (SRIO_AIDCAR)..... 1656
20.5.4 Assembly information capability register (SRIO_AICAR)..... 1657
20.5.5 Processing element features capability register (SRIO_PEFCAR)..... 1657
20.5.6 Source operations capability register (SRIO_SOCAR)..... 1660
20.5.7 Destination operations capability register (SRIO_DOCAR)..... 1663
20.5.8 Data streaming information capability register (SRIO_DSICAR)..... 1666
20.5.9 Data streaming logic layer command and status register (SRIO_DSLLCSR)..... 1666
20.5.10 Processing element logical layer control command and status register (SRIO_PELLCCSR)..... 1667
20.5.11 Local configuration space base address 1 command and status register (SRIO_LCSBA1CSR)..... 1668
20.5.12 Base device ID command and status register (SRIO_BDIDCSR)..... 1669
20.5.13 Host base device ID lock command and status register (SRIO_HBDIDLCSR)..... 1670
20.5.14 Component tag command and status register (SRIO_CTCSR)..... 1670
20.5.15 Port maintenance block header 0 (SRIO_PMBH0)..... 1671
20.5.16 Port link time-out control command and status register (SRIO_PLTOCCSR)..... 1671
20.5.17 Port response time-out control command and status register (SRIO_PRTOCCSR)..... 1672
20.5.18 Port General control command and status register (SRIO_GCCSR)..... 1673
20.5.19 Port 1 Link maintenance request command and status register (SRIO_P1LMREQCSR)..... 1674
20.5.20 Port 1 Link maintenance response command and status register (SRIO_P1LMRESPCSR)..... 1675
20.5.21 Port 1 Local ackID status command and status register (SRIO_P1LASCSR)..... 1676
20.5.22 Port 1 Error and status command and status register (SRIO_P1ESCSR)..... 1677
20.5.23 Port 1 Control command and status register (SRIO_P1CCSR)..... 1679
20.5.24 Port 2 Link maintenance request command and status register (SRIO_P2LMREQCSR)..... 1681
20.5.25 Port 2 Link maintenance response command and status register (SRIO_P2LMRESPCSR)..... 1682
20.5.26 Port 2 Local ackID status command and status register (SRIO_P2LASCSR)..... 1683
20.5.27 Port 2 Error and status command and status register (SRIO_P2ESCSR)..... 1684
20.5.28 Port 2 Control command and status register (SRIO_P2CCSR)..... 1686

20.5.29 Error reporting block header (SRIO_ERBH)....1688
20.5.30 Logical/Transport layer error detect command and status register (SRIO_LTLEDCSR)....1689
20.5.31 Logical/Transport layer error enable command and status register (SRIO_LTLEECSR)....1692
20.5.32 Logical/Transport layer address capture command and status register (SRIO_LTLACCSR)....1693
20.5.33 Logical/Transport layer device ID capture command and status register (SRIO_LTLDIDCCSR)....1694
20.5.34 Logical/Transport layer control capture command and status register (SRIO_LTLCCCSR)....1695
20.5.35 Port 1 Error detect command and status register (SRIO_P1EDCSR)....1696
20.5.36 Port 1 Error rate enable command and status register (SRIO_P1ERECSR)....1698
20.5.37 Port 1 Error capture attributes command and status register (SRIO_P1ECACSR)....1700
20.5.38 Port 1 Packet/control symbol error capture command and status register 0 (SRIO_P1PCSECCSR0)....1702
20.5.39 Port 1 Packet error capture command and status register 1 (SRIO_P1PECCSR1)....1702
20.5.40 Port 1 Packet error capture command and status register 2 (SRIO_P1PECCSR2)....1703
20.5.41 Port 1 Packet error capture command and status register 3 (SRIO_P1PECCSR3)....1703
20.5.42 Port 1 Error rate command and status register (SRIO_P1ERCSR)....1704
20.5.43 Port 1 Error rate threshold command and status register (SRIO_P1ERTCSR)....1705
20.5.44 Port 2 Error detect command and status register (SRIO_P2EDCSR)....1706
20.5.45 Port 2 Error rate enable command and status register (SRIO_P2ERECSR)....1708
20.5.46 Port 2 Error capture attributes command and status register (SRIO_P2ECACSR)....1710
20.5.47 Port 2 Packet/control symbol error capture command and status register 0 (SRIO_P2PCSECCSR0)....1712
20.5.48 Port 2 Packet error capture command and status register 1 (SRIO_P2PECCSR1)....1712
20.5.49 Port 2 Packet error capture command and status register 2 (SRIO_P2PECCSR2)....1713
20.5.50 Port 2 Packet error capture command and status register 3 (SRIO_P2PECCSR3)....1713
20.5.51 Port 2 Error rate command and status register (SRIO_P2ERCSR)....1714
20.5.52 Port 2 Error rate threshold command and status register (SRIO_P2ERTCSR)....1715
20.5.53 Logical layer configuration register (SRIO_LLCR)....1716
20.5.54 Error / port-write interrupt status register (SRIO_EPWISR)....1717
20.5.55 Logical retry error threshold configuration register (SRIO_LRETCR)....1718
20.5.56 Physical retry error threshold configuration register (SRIO_PRETCR)....1719
20.5.57 Port 1 Alternate device ID command and status register (SRIO_P1ADIDCSR)....1719

20.5.58 Port 1 Pass through/Accept-all configuration register (SRIO_P1AACR)..... 1720
20.5.59 Port 1 Logical Outbound Packet time-to-live configuration register (SRIO_P1LOPTTLCR)..... 1721
20.5.60 Port 1 Implementation error command and status register (SRIO_P1IECSR)..... 1722
20.5.61 Port 1 Physical configuration register (SRIO_P1PCR)..... 1723
20.5.62 Port 1 Serial link command and status register (SRIO_P1SLCSR)..... 1724
20.5.63 Port 1 Serial link error injection configuration register (SRIO_P1SLEICR)..... 1725
20.5.64 Port 1 Arbitration 0 Tx Configuration Register (SRIO_P1A0TxCR)..... 1726
20.5.65 Port 1 Arbitration 1 Tx Configuration Register (SRIO_P1A1TxCR)..... 1727
20.5.66 Port 1 Arbitration 2 Tx Configuration Register (SRIO_P1A2TxCR)..... 1728
20.5.67 Port 1 Message Request Tx Buffer Allocation Configuration Register 0 (SRIO_P1MReqTxBACR0)..... 1729
20.5.68 Port 1 Message Request Tx Buffer Allocation Configuration Register 2 (SRIO_P1MReqTxBACR2)..... 1731
20.5.69 Port 1 Message Response / Flow Control Tx Buffer Allocation Configuration Register (SRIO_P1MRspFcTxBACR)..... 1732
20.5.70 Port 2 Alternate device ID command and status register (SRIO_P2ADIDCSR)..... 1733
20.5.71 Port 2 Pass through/Accept-all configuration register (SRIO_P2AACR)..... 1734
20.5.72 Port 2 Logical Outbound Packet time-to-live configuration register (SRIO_P2LOPTTLCR)..... 1735
20.5.73 Port 2 Implementation error command and status register (SRIO_P2IECSR)..... 1736
20.5.74 Port 2 Physical configuration register (SRIO_P2PCR)..... 1737
20.5.75 Port 2 Serial link command and status register (SRIO_P2SLCSR)..... 1738
20.5.76 Port 2 Serial link error injection configuration register (SRIO_P2SLEICR)..... 1739
20.5.77 Port 2 Arbitration 0 Tx Configuration Register (SRIO_P2A0TxCR)..... 1740
20.5.78 Port 2 Arbitration 1 Tx Configuration Register (SRIO_P2A1TxCR)..... 1741
20.5.79 Port 2 Arbitration 2 Tx Configuration Register (SRIO_P2A2TxCR)..... 1742
20.5.80 Port 2 Message Request Tx Buffer Allocation Configuration Register 0 (SRIO_P2MReqTxBACR0)..... 1743
20.5.81 Port 2 Message Request Tx Buffer Allocation Configuration Register 2 (SRIO_P2MReqTxBACR2)..... 1745
20.5.82 Port 2 Message Response / Flow Control Tx Buffer Allocation Configuration Register (SRIO_P2MRspFcTxBACR)..... 1746
20.5.83 IP Block Revision Register 1 (SRIO_IPBRR1)..... 1747
20.5.84 IP Block Revision Register 2 (SRIO_IPBRR2)..... 1748

20.5.85 Port 1 RapidIO outbound window translation address register n (SRIO_P1ROWTAR0)..... 1748
20.5.86 Port 1 RapidIO outbound window translation extended address register 0 (SRIO_P1ROWTEAR0)..... 1749
20.5.87 Port 1 RapidIO outbound window attributes register 0 (SRIO_P1ROWAR0)..... 1749
20.5.88 Port 1 RapidIO outbound window translation address register n (SRIO_P1ROWTAR*n*)..... 1752
20.5.89 Port 1 RapidIO outbound window translation extended address register n (SRIO_P1ROWTEAR*n*)..... 1753
20.5.90 Port 1 RapidIO outbound window base address register n (SRIO_P1ROWBAR*n*)..... 1753
20.5.91 Port 1 RapidIO outbound window attributes register n (SRIO_P1ROWAR*n*)..... 1754
20.5.92 Port 1 RapidIO outbound window segment 1 register n (SRIO_P1ROWS1R*n*)..... 1757
20.5.93 Port 1 RapidIO outbound window segment 2 register n (SRIO_P1ROWS2R*n*)..... 1759
20.5.94 Port 1 RapidIO outbound window segment 3 register n (SRIO_P1ROWS3R*n*)..... 1761
20.5.95 Port 1 RapidIO Inbound window translation address register n (SRIO_P1RIWTAR*n*)..... 1763
20.5.96 Port 1 RapidIO Inbound window base address register n (SRIO_P1RIWBAR*n*)..... 1764
20.5.97 Port 1 RapidIO inbound window attributes register n (SRIO_P1RIWAR*n*)..... 1765
20.5.98 Port 1 RapidIO inbound window translation address register 0 (SRIO_P1RIWTAR0)..... 1767
20.5.99 Port 1 RapidIO inbound window attributes register 0 (SRIO_P1RIWAR0)..... 1768
20.5.100 Port 2 RapidIO outbound window translation address register n (SRIO_P2ROWTAR0)..... 1770
20.5.101 Port 2 RapidIO outbound window translation extended address register 0 (SRIO_P2ROWTEAR0)..... 1771
20.5.102 Port 2 RapidIO outbound window attributes register 0 (SRIO_P2ROWAR0)..... 1771
20.5.103 Port 2 RapidIO outbound window translation address register n (SRIO_P2ROWTAR*n*)..... 1774
20.5.104 Port 2 RapidIO outbound window translation extended address register n (SRIO_P2ROWTEAR*n*)..... 1775
20.5.105 Port 2 RapidIO outbound window base address register n (SRIO_P2ROWBAR*n*)..... 1775
20.5.106 Port 2 RapidIO outbound window attributes register n (SRIO_P2ROWAR*n*)..... 1776
20.5.107 Port 2 RapidIO outbound window segment 1 register n (SRIO_P2ROWS1R*n*)..... 1779
20.5.108 Port 2 RapidIO outbound window segment 2 register n (SRIO_P2ROWS2R*n*)..... 1781
20.5.109 Port 2 RapidIO outbound window segment 3 register n (SRIO_P2ROWS3R*n*)..... 1783
20.5.110 Port 2 RapidIO Inbound window translation address register n (SRIO_P2RIWTAR*n*)..... 1785
20.5.111 Port 2 RapidIO Inbound window base address register n (SRIO_P2RIWBAR*n*)..... 1786
20.5.112 Port 2 RapidIO inbound window attributes register n (SRIO_P2RIWAR*n*)..... 1787
20.5.113 Port 2 RapidIO inbound window translation address register 0 (SRIO_P2RIWTAR0)..... 1789

20.5.114 Port 2 RapidIO inbound window attributes register 0 (SRIO_P2RIWAR0)..... 1790
20.5.115 Port 1 LIODN Base Register (SRIO_P1LBR)..... 1792
20.5.116 Port 1 LIODN Address Offset Register (SRIO_P1LAOR)..... 1793
20.5.117 Port 1 LIODN upper data Register (SRIO_P1LUDR)..... 1793
20.5.118 Port 1 LIODN lower data register (SRIO_P1LLDR)..... 1794
20.5.119 Port 2 LIODN Base Register (SRIO_P2LBR)..... 1795
20.5.120 Port 2 LIODN Address Offset Register (SRIO_P2LAOR)..... 1795
20.5.121 Port 2 LIODN upper data Register (SRIO_P2LUDR)..... 1796
20.5.122 Port 2 LIODN lower data Register (SRIO_P2LLDR)..... 1797
20.6 RapidIO Functional Description..... 1797
20.6.1 RapidIO Implementation Space-ATMU Registers..... 1797
20.6.1.1 Segmented Outbound Window Description..... 1798
20.6.2 RapidIO Transaction Summary..... 1800
20.6.3 RapidIO Packet Format Summary..... 1802
20.6.4 RapidIO Control Symbol Summary..... 1804
20.6.5 Accessing Configuration Registers Using RapidIO Packets..... 1806
20.6.5.1 Inbound Maintenance Accesses..... 1806
20.6.5.2 Outbound Maintenance Accesses..... 1807
20.6.6 Interaction with the Message Unit..... 1807
20.6.6.1 Inbound (Rx)..... 1807
20.6.6.2 Outbound (Tx)..... 1808
20.6.6.2.1 Buffer Allocation..... 1808
20.6.6.2.1.1 Tx Message Unit Request Packets..... 1809
20.6.6.2.1.2 Tx Message Unit Response/Flow Control Packets..... 1810
20.6.6.2.2 Arbitration..... 1810
20.6.6.2.2.1 Arbitration Point 0..... 1811
20.6.6.2.2.2 Arbitration Point 1..... 1812
20.6.6.2.2.3 Arbitration Point 2..... 1812
20.6.7 RapidIO Outbound ATMU..... 1812

20.6.7.1 Valid Hits to Multiple ATMU Windows ... 1813
20.6.7.2 Window Boundary Crossing Errors-Outbound ... 1814
20.6.8 RapidIO Inbound ATMU ... 1815
20.6.8.1 Hits to Multiple ATMU Windows ... 1815
20.6.8.2 Window Boundary Crossing Errors-Inbound ... 1815
20.6.9 Inbound LIODN Translation ... 1816
20.6.9.1 LIODN Lookup table ... 1816
20.6.9.1.1 Accessing the LIODN Lookup table ... 1817
20.6.9.1.2 Translation ... 1818
20.6.10 Generating Link-Request/Reset-Device ... 1818
20.6.10.1 LP-Serial Mode ... 1818
20.6.11 Outbound Drain Mode ... 1818
20.6.12 Input Port Disable Mode ... 1819
20.6.13 Software Assisted Error Recovery Register Support ... 1819
20.6.14 Hot-Swap Support ... 1821
20.6.14.1 Method 1 ... 1821
20.6.14.1.1 Extraction Sequence (Method 1) ... 1821
20.6.14.1.2 Insertion Sequence (Method 1) ... 1822
20.6.14.2 Method 2 with RapidIO Port Hot-Swapped ... 1822
20.6.14.2.1 Extraction Sequence (Method 2) ... 1823
20.6.14.2.2 Insertion Sequence (Method 2) ... 1823
20.6.15 Software Re-Training ... 1824
20.6.16 Errors and Error Handling ... 1825
20.6.16.1 RapidIO Error Description ... 1825
20.6.16.2 Physical Layer RapidIO Errors Detected ... 1826
20.6.16.3 Logical Layer Errors and Error Handling ... 1829
20.6.16.3.1 Logical Layer RapidIO Errors Detected ... 1829

Chapter 21
Interlaken LA Controller (LAC)

21.1 LAC Introduction 1861
21.1.1 LAC Overview 1861
21.1.2 Features 1862
21.1.3 Mode of Operation 1863
21.1.3.1 Stashing mode 1863
21.2 External Signal Descriptions 1863
21.3 LAC Memory Map/Register Definition 1864
21.3.1 LAC mode register (LAC_LMR) 1870
21.3.2 LAC software portal soft reset register (LAC_LSWPSRR) 1871
21.3.3 LAC stashing request enable register (LAC_LSRER) 1873
21.3.4 LAC extended base address register (LAC_LBARE) 1874
21.3.5 LAC base address register (LAC_LBAR) 1875
21.3.6 LAC logical IO device number register n (LAC_LLIODNR*n*) 1876
21.3.7 TX lane disable register (LAC_TXLDR) 1876
21.3.8 TX block config register (LAC_TXCFGR) 1877
21.3.9 TX SERDES FIFO watermark register (LAC_TXSFWMR) 1878
21.3.10 TX Burst control register (LAC_TXBCR) 1879
21.3.11 TX MetaFrame synchronization register (LAC_TXMSR) 1881
21.3.12 TX transmit rate limiter register 0 (LAC_TXTRLR0) 1882
21.3.13 TX transmit rate limiter register 1 (LAC_TXTRLR1) 1883
21.3.14 TX transmit error injection register n (LAC_TXERRINJ*n*) 1884
21.3.15 TX statistic counter access register (LAC_TXSCAR) 1885
21.3.16 TX statistic counter fill register (LAC_TXSCFR) 1887
21.3.17 TX statistic counter parity register (LAC_TXSCPR) 1888
21.3.18 TX statistic counter write byte counter high register (LAC_TXSCWBCHR) 1889
21.3.19 TX statistic counter write byte counter low register (LAC_TXSCWBCLR) 1890
21.3.20 TX statistic counter write packet counter high register (LAC_TXSCWPCHR) 1891
21.3.21 TX statistic counter write packet counter low register (LAC_TXSCWPCLR) 1891
21.3.22 TX statistic counter write error counter high register (LAC_TXSCWECHR) 1892

21.3.23 TX statistic counter write error counter low register (LAC_TXSCWECLR)..... 1893
21.3.24 TX statistic counter write parity register (LAC_TXSCWPR)..... 1893
21.3.25 TX statistic counter read byte counter high register (LAC_TXSCRBCHR)..... 1894
21.3.26 TX statistic counter read byte counter low register (LAC_TXSCRBCLR)..... 1895
21.3.27 TX statistic counter read packet counter high register (LAC_TXSCRPCHR)..... 1896
21.3.28 TX statistic counter read packet counter low register (LAC_TXSCRPCLR)..... 1897
21.3.29 TX statistic counter read error counter high register (LAC_TXSCRECHR)..... 1898
21.3.30 TX statistic counter read error counter low register (LAC_TXSCRECLR)..... 1899
21.3.31 TX statistic counter read parity register (LAC_TXSCRPR)..... 1900
21.3.32 TX lane re-mapping register 0 (LAC_TXLRR0)..... 1900
21.3.33 TX lane re-mapping register 1 (LAC_TXLRR1)..... 1901
21.3.34 TX interrupt register n (LAC_TXINTR*n*)..... 1902
21.3.35 TX interrupt mask register n (LAC_TXINTMRn*n*)..... 1903
21.3.36 TX interrupt force register (LAC_TXINTFR)..... 1904
21.3.37 RX lane disable register (LAC_RXLDR)..... 1905
21.3.38 RX block config register (LAC_RXCFGR)..... 1906
21.3.39 RX SERDES FIFO watermark register (LAC_RXSFWMR)..... 1907
21.3.40 RX Burst control register (LAC_RXBCR)..... 1908
21.3.41 RX MetaFrame synchronization register (LAC_RXMSR)..... 1909
21.3.42 RX statistic counter access register (LAC_RXSCAR)..... 1910
21.3.43 RX statistic counter fill register (LAC_RXSCFR)..... 1912
21.3.44 RX statistic counter parity register (LAC_RXSCPR)..... 1913
21.3.45 RX statistic counter write byte counter high register (LAC_RXSCWBCHR)..... 1914
21.3.46 RX statistic counter write byte counter low register (LAC_RXSCWBCLR)..... 1915
21.3.47 RX statistic counter write packet counter high register (LAC_RXSCWPCHR)..... 1915
21.3.48 RX statistic counter write packet counter low register (LAC_RXSCWPCLR)..... 1916
21.3.49 RX statistic counter write error counter high register (LAC_RXSCWECHR)..... 1917
21.3.50 RX statistic counter write error counter low register (LAC_RXSCWECLR)..... 1917
21.3.51 RX statistic counter write parity register (LAC_RXSCWPR)..... 1918

21.3.52 RX statistic counter read byte counter high register (LAC_RXSCRBCHR)..... 1919
21.3.53 RX statistic counter read byte counter low register (LAC_RXSCRBCLR)..... 1920
21.3.54 RX statistic counter read packet counter high register (LAC_RXSCRPCHR)..... 1921
21.3.55 RX statistic counter read packet counter low register (LAC_RXSCRPCLR)..... 1922
21.3.56 RX statistic counter read error counter high register (LAC_RXSCRECHR)..... 1923
21.3.57 RX statistic counter read error counter low register (LAC_RXSCRECLR)..... 1924
21.3.58 RX statistic counter read parity register (LAC_RXSCRPR)..... 1925
21.3.59 RX lane re-mapping register 0 (LAC_RXLRR0)..... 1925
21.3.60 RX lane re-mapping register 1 (LAC_RXLRR1)..... 1926
21.3.61 RX Interrupt Register n (LAC_RXINTR*n*)..... 1927
21.3.62 RX Interrupt mask Register n (LAC_RXINTMR*n*)..... 1930
21.3.63 RX Interrupt force Register (LAC_RXINTFR)..... 1932
21.3.64 RX MetaFrame Error register (LAC_RXMFER)..... 1934
21.3.65 RX Bad Control Word Error register (LAC_RXBCER)..... 1935
21.3.66 RX Scambler State Error register (LAC_RXSSER)..... 1935
21.3.67 RX CRC32 Error register (LAC_RXC32ER)..... 1936
21.3.68 RX CDR Error register (LAC_RXCDER)..... 1936
21.3.69 RX Word Sync Changed register (LAC_RXWSCR)..... 1937
21.3.70 RX aligned status register (LAC_RXASR)..... 1938
21.3.71 RX Status Message register (LAC_RXSMR)..... 1939
21.3.72 RX Word Sync register (LAC_RXWSR)..... 1940
21.3.73 RX CRC32 Count Fill register (LAC_RXC32CFR)..... 1941
21.3.74 RX CDR lost Count Fill register (LAC_RXCDCFR)..... 1941
21.3.75 RX word sync Count Fill register (LAC_RXWSCFR)..... 1942
21.3.76 IP Block Revision register 1 (LAC_IPBRR1)..... 1942
21.3.77 LAC error interrupt enable register (LAC_LEIER)..... 1943
21.3.78 LAC error detect register (LAC_LEDR)..... 1945
21.3.79 LAC transmit error capture register0 (LAC_LTECR0)..... 1946
21.3.80 LAC transmit error capture register 1 (LAC_LTECR1)..... 1946

21.3.81 LAC transmit error capture register 2 (LAC_LTECR2)....1947
21.3.82 LAC receive error capture register 0 (LAC_LRECR0)....1947
21.3.83 LAC receive error capture register 1 (LAC_LRECR1)....1948
21.3.84 LAC receive error capture register 2 (LAC_LRECR2)....1948
21.3.85 LAC Transmit status register (LAC_LTSR)....1949
21.3.86 LAC receive status register (LAC_LRSR)....1950
21.4 LAC Software Portal Memory Map/Register Definitions....1950
21.4.1 Software Portal transmit command register (LAC_SP_SWP*n*TCR)....2033
21.4.2 Software Portal transmit error register (LAC_SP_SWP*n*TER)....2034
21.4.3 Software Portal transmit data register 0 (LAC_SP_SWP*n*TDR0)....2034
21.4.4 Software Portal transmit data register 1 (LAC_SP_SWP*n*TDR1)....2035
21.4.5 Software Portal transmit data register 2 (LAC_SP_SWP*n*TDR2)....2035
21.4.6 Software Portal transmit data register 3 (LAC_SP_SWP*n*TDR3)....2036
21.4.7 Software Portal receive status register (LAC_SP_SWP*n*RSR)....2036
21.4.8 Software Portal receive configuration register (LAC_SP_SWP*n*RCR)....2038
21.4.9 Software Portal receive data register 0 (LAC_SP_SWP*n*RDR0)....2038
21.4.10 Software Portal receive data register 1 (LAC_SP_SWP*n*RDR1)....2039
21.4.11 Software Portal receive data register 2 (LAC_SP_SWP*n*RDR2)....2039
21.4.12 Software Portal receive data register 3 (LAC_SP_SWP*n*RDR3)....2040
21.5 Functional Description....2040
21.5.1 Software portal operation....2040
21.5.1.1 Transmit software portal....2041
21.5.1.2 Receive software portal....2042
21.5.2 Error management and recovery....2042
21.5.2.1 LAC Transmit error....2043
21.5.2.2 LAC Receive error....2043
21.5.2.3 LAC MAC error....2044
21.5.3 Soft reset behavior....2044
21.5.3.1 Global soft reset....2044

21.5.3.2 Local soft reset ... 2045
21.6 Initialization Information ... 2045

Chapter 22
SATA Controller

22.1 SATA overview ... 2047
22.2 SATA features ... 2047
22.3 SATA memory map/register definition ... 2049
22.3.1 Command queue register (SATA*x*_CQR) ... 2051
22.3.2 Command active register (SATA*x*_CAR) ... 2052
22.3.3 Command completed register (SATA*x*_CCR) ... 2052
22.3.4 Command error register (SATA*x*_CER) ... 2053
22.3.5 Device error register (SATA*x*_DER) ... 2054
22.3.6 Command header base address (SATA*x*_CHBA) ... 2054
22.3.7 Host status register (SATA*x*_HStatus) ... 2055
22.3.8 Host control register (SATA*x*_HControl) ... 2058
22.3.9 Port number queue register (SATA*x*_CQPMP) ... 2060
22.3.10 Signature register (SATA*x*_SIG) ... 2061
22.3.11 Interrupt coalescing control register (SATA*x*_ICC) ... 2061
22.3.12 SATA interface status register (SATA*x*_SStatus) ... 2062
22.3.13 SATA interface error register (SATA*x*_SError) ... 2063
22.3.14 SATA interface control register (SATA*x*_SControl) ... 2066
22.3.15 SATA interface notification register (SATA*x*_SNotification) ... 2067
22.3.16 Transport layer configuration (SATA*x*_TransCfg) ... 2068
22.3.17 Link layer configuration (SATA*x*_LinkCfg) ... 2069
22.3.18 Link layer configuration1 (SATA*x*_LinkCfg1) ... 2070
22.3.19 Link layer configuration2 (SATA*x*_LinkCfg2) ... 2071
22.3.20 PHY control configuration1 (SATA*x*_PhyCtrlCfg1) ... 2071
22.3.21 System priority register (SATA*x*_SYSPR) ... 2073
22.4 Functional description ... 2074

22.4.1 Error processing ... 2074
22.4.2 Bringing the SATA controller online/offline ... 2075
22.4.3 Command operation ... 2075
22.4.3.1 Command issue ... 2076
22.4.3.2 Command service ... 2076
22.4.3.3 Command completion interrupt timing ... 2076
22.4.3.4 DMA context (read data) ... 2076
22.4.3.5 DMA context (write data) ... 2077
22.4.3.6 DMAT primitive processing ... 2077
22.4.4 Command header ... 2077
22.4.4.1 Command descriptor ... 2079
22.4.4.1.1 Command FIS non-queued commands (CFIS) ... 2080
22.4.4.1.2 Command FIS first party DMA commands NCQ ... 2080
22.4.4.1.3 Status FIS (SFIS) ... 2081
22.4.4.1.4 ATAPI command (ACMD) ... 2081
22.4.4.1.5 Physical region descriptor table (PRDT) ... 2082
22.4.4.2 Vendor-specific BIST operation ... 2082
22.4.5 Command layer overview ... 2085
22.4.6 Transport layer architectural overview ... 2085
22.4.7 Link layer overview ... 2086
22.4.7.1 Link layer functionality ... 2087
22.4.7.1.1 Link idle state machine ... 2088
22.4.7.1.2 Transmit state machine ... 2088
22.4.7.1.3 Receive state machine ... 2089
22.4.7.1.4 Power mode change state machine ... 2089
22.4.7.1.5 Frame content scrambler and descrambler ... 2090
22.4.7.1.6 CRC generator and checker ... 2090
22.4.7.1.7 8B/10B encode and decode ... 2091
22.4.7.1.8 CONT primitive processing ... 2091

22.4.7.1.9 ALIGN insertion ... 2092
22.4.7.1.10 Debug functionality ... 2092
22.4.7.1.11 BIST support ... 2092
22.4.8 PHY control layer overview ... 2093
22.5 SATA initialization/application information ... 2093
22.5.1 SATA controller initialization steps ... 2093

Chapter 23
DMA Controller

23.1 DMA overview ... 2097
23.1.1 DMA features summary ... 2098
23.1.2 DMA modes of operation ... 2099
23.2 DMA external signal description ... 2101
23.2.1 Signal overview ... 2101
23.2.2 DMA signal descriptions ... 2102
23.3 DMA controller memory map ... 2103
23.3.1 DMA mode register (DMA*x*_MR*n*) ... 2121
23.3.2 DMA status register (DMA*x*_SR*n*) ... 2125
23.3.3 DMA current link descriptor extended address register (DMA*x*_ECLNDAR*n*) ... 2126
23.3.4 DMA current link descriptor address register (DMA*x*_CLNDAR*n*) ... 2127
23.3.5 DMA source attributes register (DMA*x*_SATR*n*) ... 2129
23.3.6 DMA source address register (DMA*x*_SAR*n*) ... 2130
23.3.7 DMA destination attributes register (DMA*x*_DATR*n*) ... 2131
23.3.8 DMA destination address register (DMA*x*_DAR*n*) ... 2132
23.3.9 DMA byte count register (DMA*x*_BCR*n*) ... 2133
23.3.10 DMA extended next link descriptor address register (DMA*x*_ENLNDAR*n*) ... 2134
23.3.11 DMA next link descriptor address register (DMA*x*_NLNDAR*n*) ... 2134
23.3.12 DMA extended current list descriptor address register (DMA*x*_ECLSDAR*n*) ... 2135
23.3.13 DMA current list descriptor address register (DMA*x*_CLSDAR*n*) ... 2136
23.3.14 DMA extended next list descriptor address register (DMA*x*_ENLSDAR*n*) ... 2137

23.3.15 DMA next list descriptor address register (DMA*x*_NLSDAR*n*)....2137
23.3.16 DMA source stride register (DMA*x*_SSR*n*)....2138
23.3.17 DMA destination stride register (DMA*x*_DSR*n*)....2139
23.3.18 DMA general status register 0 (DMA*x*_DGSR0)....2140
23.3.19 DMA mode register (DMA*x*_MR*n*)....2143
23.3.20 DMA status register (DMA*x*_SR*n*)....2147
23.3.21 DMA extended current link descriptor address register (DMA*x*_ECLNDAR*n*)....2148
23.3.22 DMA current link descriptor address register (DMA*x*_CLNDAR*n*)....2149
23.3.23 DMA source attributes register (DMA*x*_SATR*n*)....2151
23.3.24 DMA source address register (DMA*x*_SAR*n*)....2152
23.3.25 DMA destination attributes register (DMA*x*_DATR*n*)....2153
23.3.26 DMA destination address register (DMA*x*_DAR*n*)....2154
23.3.27 DMA byte count register (DMA*x*_BCR*n*)....2155
23.3.28 DMA next link descriptor extended address register (DMA*x*_ENLNDAR*n*)....2156
23.3.29 DMA next link descriptor address register (DMA*x*_NLNDAR*n*)....2156
23.3.30 DMA extended current list descriptor address register (DMA*x*_ECLSDAR*n*)....2157
23.3.31 DMA current list descriptor address register (DMA*x*_CLSDAR*n*)....2158
23.3.32 DMA extended next list descriptor address register (DMA*x*_ENLSDAR*n*)....2159
23.3.33 DMA next list descriptor address register (DMA*x*_NLSDAR*n*)....2159
23.3.34 DMA source stride register (DMA*x*_SSR*n*)....2160
23.3.35 DMA destination stride register (DMA*x*_DSR*n*)....2161
23.3.36 DMA general status register 1 (DMA*x*_DGSR1)....2162
23.4 DMA functional description....2165
23.4.1 DMA channel operation....2165
23.4.1.1 Source/destination transaction size calculations....2166
23.4.1.2 Basic DMA mode transfer....2168
23.4.1.2.1 Basic direct mode....2168
23.4.1.2.2 Basic, direct, single-write start mode....2169
23.4.1.2.3 Basic chaining mode....2169

23.4.1.2.4 Basic chaining, single-write start mode....2170
23.4.1.3 Extended DMA mode transfer....2171
23.4.1.3.1 Extended direct mode....2171
23.4.1.3.2 Extended direct, single-write start mode....2171
23.4.1.3.3 Extended chaining mode....2171
23.4.1.3.4 Extended chaining, single-write start mode....2172
23.4.1.4 External control mode transfer....2173
23.4.1.5 Channel continue mode for cascading transfer chains....2174
23.4.1.5.1 Basic mode....2175
23.4.1.5.2 Extended mode....2175
23.4.1.6 Channel abort....2175
23.4.1.7 Bandwidth control....2175
23.4.1.8 Channel state....2176
23.4.1.9 Illustration of stride size and stride distance....2176
23.4.2 DMA transfer interfaces....2177
23.4.3 DMA errors....2177
23.4.4 DMA descriptors....2177
23.4.5 DMA controller limitations and restrictions....2180
23.5 DMA system considerations....2181
23.5.1 Unusual DMA scenarios....2181
23.5.1.1 DMA to core....2181
23.5.1.2 DMA to configuration, control, and status registers (CCSR)....2182
23.5.1.3 DMA to I2C....2182
23.5.1.4 DMA to DUART....2182
23.5.1.5 DMA in multi-partition systems....2182

Chapter 24
Data Path Acceleration Architecture (DPAA) Overview and T4240 DPAA Implementation

24.1 DPAA Introduction and Terms....2185
24.2 Data Formats Used in the DPAA....2187

24.2.1 Frame Descriptor (FD)....2187
24.2.1.1 FD Format....2188
24.2.1.2 FD Considerations....2189
24.2.2 Multi-Buffer Frames....2189
24.2.2.1 Scatter/Gather Entry Format....2190
24.2.2.2 Multi-Buffer Frame Considerations....2191
24.2.2.3 Situations Where Multi-Frame Buffering Stops....2192
24.2.3 Single-Buffer Frames....2192
24.2.4 Compound Frames....2193
24.2.4.1 When to Use Compound Frames....2193
24.2.4.2 Compound Frame Considerations....2194
24.2.5 Simple Frames....2195
24.2.6 Frame Format Codes....2195
24.2.7 Frame Formats Supported by Accelerators....2196
24.2.8 Special Values and Exceptions....2197
24.2.9 Releasing Buffers to the BMan....2197
24.3 Accessing Memory Using Logical IO Device Numbers (LIODNs)....2198
24.3.1 Role of the PAMU in the DPAA....2198
24.3.2 Using Multiple LIODNs....2198
24.3.2.1 Benefit of Using Multiple LIODNs....2198
24.3.2.2 LIODN Requirements....2198
24.4 Packet Walk-Through Example....2199
24.5 T4240-Specific DPAA Implementation Details....2201
24.5.1 T4240 Queue Manager (QMan) Implementation....2201
24.5.2 T4240 Buffer Manager (BMan) Implementation....2201
24.5.3 T4240 Frame Manager (FMan) Implementation....2202
24.5.4 T4240 Security and Encryption Engine (SEC) Implementation....2203

Chapter 25
Multicore Programmable Interrupt Controller (MPIC)

Section number	Title	Page
25.1	Preface	2205
25.2	MPIC as implemented on chip	2205
25.3	Introduction	2206
25.3.1	Features	2206
25.3.2	Block Diagram	2207
25.3.3	The MPIC in Multiple- and Single-Core Implementations	2209
25.3.4	Modes of Operation	2209
25.3.4.1	External Proxy Facility Mode (GCR[CI] = 1)	2209
25.3.4.2	Mixed Mode (GCR[M] = 1)	2209
25.3.4.3	Pass-Through Mode (GCR[M] = 0)	2210
25.3.5	Interrupts to the Processor Core	2210
25.3.6	Interrupt Sources	2211
25.3.6.1	Interrupt Destinations	2212
25.3.6.2	Interrupt Routing-Mixed Mode	2214
25.4	External Signal Descriptions	2214
25.4.1	Device External Pin Descriptions	2214
25.5	MPIC Memory Map/Register Definition	2215
25.5.1	Block revision register 1 (MPIC_BRR1)	2282
25.5.2	Block revision register 2 (MPIC_BRR2)	2282
25.5.3	Interprocessor interrupt dispatch register n (MPIC_IPIDR*n*)	2283
25.5.4	Current task priority register (MPIC_CTPR)	2286
25.5.5	Who am I register (MPIC_WHOAMI)	2287
25.5.6	Interrupt acknowledge register (MPIC_IACK)	2288
25.5.7	End of interrupt register (MPIC_EOI)	2289
25.5.8	Feature reporting register (MPIC_FRR)	2289
25.5.9	Global configuration register (MPIC_GCR)	2290
25.5.10	Global configuration register 1 (MPIC_GCR1)	2291
25.5.11	Vendor identification register (MPIC_VIR)	2292
25.5.12	Processor initialization register (MPIC_PIR)	2292

Section number	Title	Page
25.5.13	Processor NMI register (MPIC_PNMIR)	2294
25.5.14	IPI vector/priority register n (MPIC_IPIVPR*n*)	2296
25.5.15	Spurious vector register (MPIC_SVR)	2297
25.5.16	Timer frequency reporting register [Group n] (MPIC_TFRR*n*)	2297
25.5.17	Global timer current count register [Group A] n (MPIC_GTCCRA*n*)	2298
25.5.18	Global timer base count register [Group A] n (MPIC_GTBCRA*n*)	2299
25.5.19	Global timer vector/priority register [Group A] n (MPIC_GTVPRA*n*)	2300
25.5.20	Global timer destination register [Group A] n (MPIC_GTDRA*n*)	2301
25.5.21	Timer control register [Group n] (MPIC_TCR*n*)	2303
25.5.22	Message register [Group A] n (MPIC_MSGRA*n*)	2305
25.5.23	Message enable register [Group n] (MPIC_MER*n*)	2305
25.5.24	Message status register [Group n] (MPIC_MSR*n*)	2306
25.5.25	Shared message signaled interrupt register [Bank A] n (MPIC_MSIRA*n*)	2307
25.5.26	Shared message signaled interrupt status register [Bank n] (MPIC_MSISR*n*)	2307
25.5.27	Shared message signaled interrupt index register [Bank A] (MPIC_MSIIR*n*)	2308
25.5.28	Shared message signaled interrupt register [Bank B] n (MPIC_MSIRB*n*)	2309
25.5.29	Shared message signaled interrupt register [Bank C] n (MPIC_MSIRC*n*)	2309
25.5.30	Shared message signaled interrupt register [Bank D] n (MPIC_MSIRD*n*)	2310
25.5.31	Global timer current count register [Group B] n (MPIC_GTCCRB*n*)	2310
25.5.32	Global timer base count register [Group B] n (MPIC_GTBCRB*n*)	2311
25.5.33	Global timer vector/priority register [Group B] n (MPIC_GTVPRB*n*)	2312
25.5.34	Global timer destination register [Group B] n (MPIC_GTDRB*n*)	2313
25.5.35	Message register [Group B] n (MPIC_MSGRB*n*)	2315
25.5.36	Performance monitor n mask register 0 (MPIC_PM*n*MR0)	2316
25.5.37	Performance monitor n mask register 1 (MPIC_PM*n*MR1)	2317
25.5.38	Performance monitor n mask register 2 (MPIC_PM*n*MR2)	2317
25.5.39	Performance monitor n mask register 3 (MPIC_PM*n*MR3)	2318
25.5.40	Performance monitor n mask register 4 (MPIC_PM*n*MR4)	2318
25.5.41	Performance monitor n mask register 5 (MPIC_PM*n*MR5)	2319

25.5.42 Performance monitor n mask register 6 (MPIC_PM*n*MR6)....2319
25.5.43 Performance monitor n mask register 7 (MPIC_PM*n*MR7)....2320
25.5.44 Performance monitor n mask register 8 (MPIC_PM*n*MR8)....2320
25.5.45 Performance monitor n mask register 9 (MPIC_PM*n*MR9)....2320
25.5.46 Performance monitor n mask register 10 (MPIC_PM*n*MR10)....2321
25.5.47 Performance monitor n mask register 11 (MPIC_PM*n*MR11)....2321
25.5.48 External interrupt summary register (MPIC_ERQSR)....2322
25.5.49 Error interrupt summary register n (MPIC_EISR)....2322
25.5.50 Error interrupt mask register 0 (MPIC_EIMR0)....2323
25.5.51 Watchdog status register summary register 0 (MPIC_WSRSR0)....2324
25.5.52 Watchdog status register summary register 1 (MPIC_WSRSR1)....2325
25.5.53 Critical interrupt summary register 0 (MPIC_CISR0)....2326
25.5.54 Critical interrupt summary register 1 (MPIC_CISR1)....2326
25.5.55 Critical interrupt summary register 2 (MPIC_CISR2)....2327
25.5.56 Critical interrupt summary register 3 (MPIC_CISR3)....2327
25.5.57 Critical interrupt summary register 4 (MPIC_CISR4)....2327
25.5.58 Critical interrupt summary register 5 (MPIC_CISR5)....2328
25.5.59 Critical interrupt summary register 6 (MPIC_CISR6)....2328
25.5.60 Critical interrupt summary register 7 (MPIC_CISR7)....2329
25.5.61 Critical interrupt summary register 8 (MPIC_CISR8)....2329
25.5.62 Machine check summary register 0 (MPIC_MCSR0)....2329
25.5.63 Machine check summary register 1 (MPIC_MCSR1)....2330
25.5.64 Machine check summary register 2 (MPIC_MCSR2)....2330
25.5.65 Machine check summary register 3 (MPIC_MCSR3)....2331
25.5.66 Machine check summary register 4 (MPIC_MCSR4)....2331
25.5.67 Machine check summary register 5 (MPIC_MCSR5)....2331
25.5.68 Machine check summary register 6 (MPIC_MCSR6)....2332
25.5.69 Machine check summary register 7 (MPIC_MCSR7)....2332
25.5.70 Machine check summary register 8 (MPIC_MCSR8)....2333

25.5.71 IRQ_OUT_B/Soc Interrupt Event summary register 0 (MPIC_IRQSIESR0)..... 2333
25.5.72 IRQ_OUT_B/Soc Interrupt Event summary register 1 (MPIC_IRQSIESR1)..... 2334
25.5.73 IRQ_OUT_B/Soc Interrupt Event summary register 2 (MPIC_IRQSIESR2)..... 2334
25.5.74 IRQ_OUT_B/Soc Interrupt Event summary register 3 (MPIC_IRQSIESR3)..... 2335
25.5.75 IRQ_OUT_B/Soc Interrupt Event summary register 4 (MPIC_IRQSIESR4)..... 2335
25.5.76 IRQ_OUT_B/Soc Interrupt Event summary register 5 (MPIC_IRQSIESR5)..... 2336
25.5.77 IRQ_OUT_B/Soc Interrupt Event summary register 6 (MPIC_IRQSIESR6)..... 2336
25.5.78 IRQ_OUT_B/Soc Interrupt Event summary register 7 (MPIC_IRQSIESR7)..... 2337
25.5.79 IRQ_OUT_B/Soc Interrupt Event summary register 8 (MPIC_IRQSIESR8)..... 2337
25.5.80 Shared Message Signaled Interrupt Index Register n (MPIC_MSIIR1*n*).....2338
25.5.81 Shared Message Signaled Coalescing Register n (MPIC_MSICRA*n*).....2339
25.5.82 Shared Message Signaled Coalescing Register n (MPIC_MSICRB*n*).....2339
25.5.83 Shared Message Signaled Coalescing Register n (MPIC_MSICRC*n*).....2340
25.5.84 Shared Message Signaled Coalescing Register n (MPIC_MSICRD*n*).....2341
25.5.85 External interrupt n (IRQn) vector/priority register (MPIC_EIVPR*n*).....2341
25.5.86 External interrupt n (IRQn) destination register (MPIC_EIDR*n*)..... 2343
25.5.87 External interrupt n (IRQn) level register (MPIC_EILR*n*).....2346
25.5.88 Internal interrupt n vector/priority register (MPIC_IIVPR*n*)..... 2347
25.5.89 Internal interrupt n destination register (MPIC_IIDR*n*)..... 2348
25.5.90 Internal interrupt n level register (MPIC_IILR*n*)..... 2351
25.5.91 Messaging interrupt vector/priority register [Group A] n (MPIC_MIVPRA*n*).....2352
25.5.92 Messaging interrupt destination register [Group A] n (MPIC_MIDRA*n*)..... 2353
25.5.93 Messaging interrupt vector/priority register [Group B] n (MPIC_MIVPRB*n*)..... 2355
25.5.94 Messaging interrupt destination register [Group B] n (MPIC_MIDRB*n*).....2356

Chapter 1
T4240 Overview

1.1 Introduction

The QorIQ T4 family of processors combine NXP advanced, dual-threaded e6500 Power Architecture® processor cores with AltiVec, high-performance data path acceleration architecture (DPAA), and network and peripheral interfaces to address a wide variety of applications in networking, telecom/datacom, data center, wireless infrastructure, industrial and mil/aerospace applications.

The T4 family consists of devices with eight, sixteen, or twenty-four threads, with each size available in standard power or a lower power variant. The low power variant is functionally identical to the standard power variant.

Table 1-1. T4240 Family Devices

	Standard Power	Low Power	Comments
12-dual threaded e6500 cores with a total of 24 threads	T4240	T4241	
8-dual threaded e6500 cores with a total of 16 threads	T4160	T4161	For more details, see Appendix T4160/T4161
4-dual threaded e6500 cores with a total of 16 threads	T4081	T4081	For more details, see Appendix T4080/T4081

NOTE

Throughout this document, references to T4240 also apply to T4241, references to T4160 also apply to T4161, and references to T4080 also apply to T4081.

1.2 Summary of benefits

The T4 family of processors are ideal for combined control and data plane processing. A wide variety of applications can benefit from the processing, I/O integration, and power management capabilities. Similar to other QorIQ devices, the T4 family of processors' high level of integration offers significant space, weight, and power benefits compared to multiple discrete devices. Examples include:

- Service provider networking: RNC, metro networking, gateway, core/edge router, EPC, CRAN, ATCA, and AMC solutions.
- Enterprise equipment: router, switch services, and UTM appliances.
- Data centers: NFV, SDN, ADC, WOC, UTM, proxy, server appliance, and PCI Express (PCIe) offload.
- Storage controllers: FCoE bridging, iSCSI controller, and SAN controller.
- Aerospace, defense, and government: radar imaging, ruggedized network appliance, and cockpit display.
- Industrial computing: single-board computers and test equipment.

1.3 Chip features

This section describes the key features and functionalities of the T4240 chip.

See the T4160/T4161 and T4080/T4081 appendices for those devices' specific block diagrams.

1.3.1 Block diagram

This figure shows the major functional units within the chip.

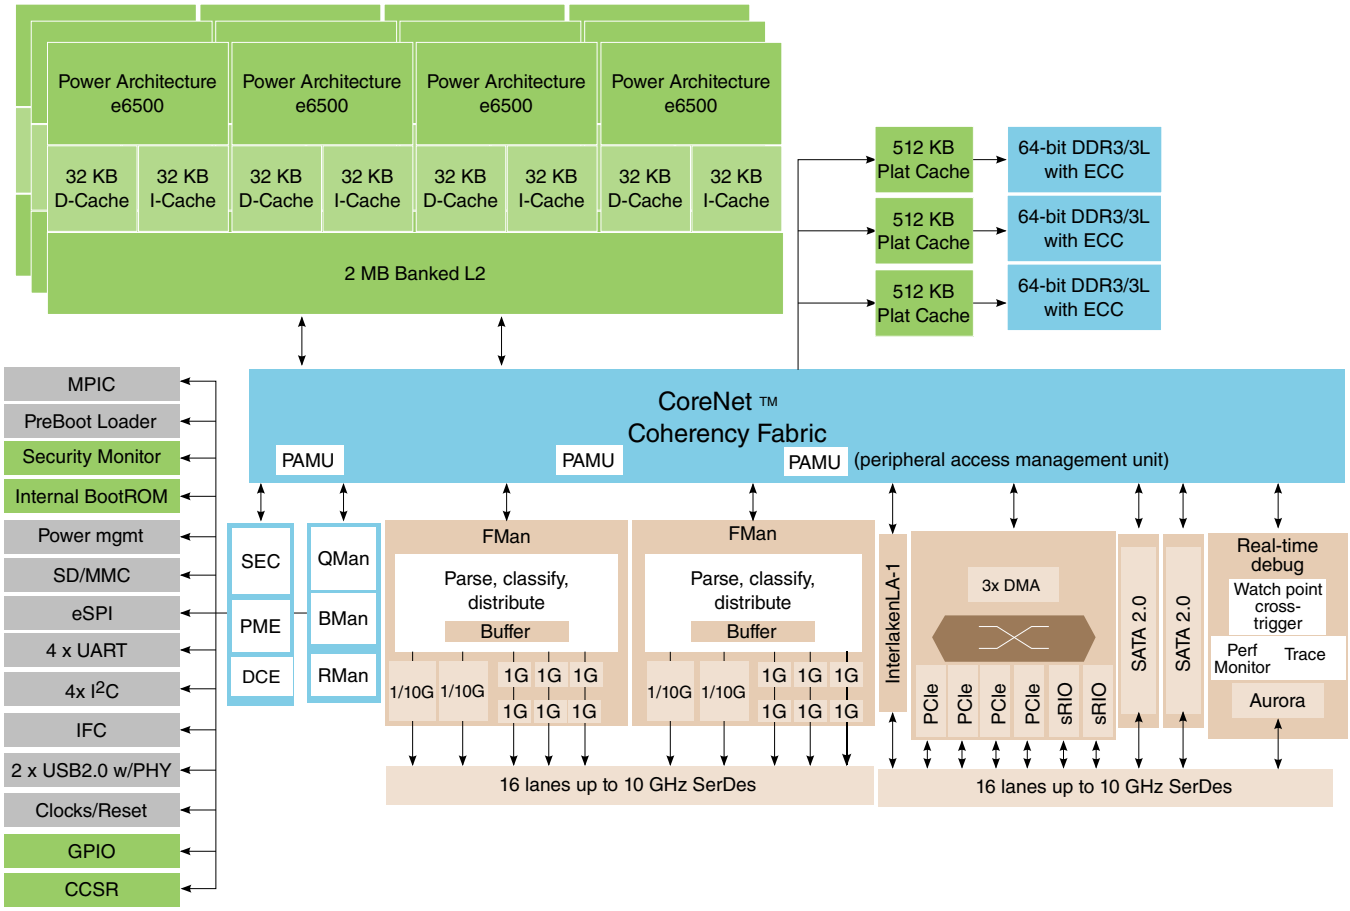

Figure 1-1. T4240 block diagram

1.3.2 Features summary

This chip includes the following functions and features:

- 12, dual-threaded e6500 cores for a total of 24/16/8 threads (T4240 and T4241 / T4160 and T4161 / T4080 and T4081) built on Power Architecture® technology
  - Arranged as three clusters of four cores sharing a 2 MB L2 cache, 6 MB L2 cache total.
  - Up to 1.8 GHz with 64-bit ISA support (Power Architecture v2.06-compliant)
  - Three privilege levels of instruction: user, supervisor, and hypervisor
- Up to 1.5 MB CoreNet Platform Cache (CPC)
- Hierarchical interconnect fabric
  - CoreNet fabric supporting coherent and non-coherent transactions with prioritization and bandwidth allocation amongst CoreNet end-points
  - 1.46 Tbps coherent read bandwidth
- Up to three 64-bit DDR3/3L SDRAM memory controllers with ECC and interleaving support

    - Up to 1.867 GT/s data transfer rate
    - 64 GB per DDR controller
- Data Path Acceleration Architecture (DPAA) incorporating acceleration for the following functions:
    - Packet parsing, classification, and distribution (Frame Manager 1.1) up to 50 Gbps
    - Queue management for scheduling, packet sequencing, and congestion management (Queue Manager 1.1)
    - Queue Manager (QMan) fabric supporting packet-level queue management and quality of service scheduling
    - Hardware buffer management for buffer allocation and de-allocation (BMan 1.1)
    - Cryptography acceleration (SEC 5.0) at up to 40 Gbps
    - RegEx Pattern Matching Acceleration (PME 2.1) at up to 10 Gbps
    - Decompression/Compression Acceleration (DCE 1.0) at up to 20 Gbps
    - DPAA chip-to-chip interconnect via RapidIO Message Manager (RMAN 1.0)
- Up to 32 SerDes lanes at up to 10.3125 GHz
- Ethernet interfaces
    - Up to four 10 Gbps Ethernet XAUI or 10GBase-KR XFI MACs
    - Up to sixteen 1 Gbps Ethernet MACs
    - Up to two 1 Gbps Ethernet RGMII MACs.

NOTE

Half duplex is not supported on RGMII inteface.

    - Maximum configuration of 4 x 10 GE (XFI) + 10 x 1 GE (SGMII) + 2 x 1 GE (RGMII)
- High-speed peripheral interfaces
    - Up to four PCI Express 2.0 controllers, two supporting 3.0
    - Two Serial RapidIO 2.0 controllers/ports running at up to 5 GHz with Type 11 messaging and Type 9 data streaming support
    - Interlaken look-aside interface for serial TCAM connection at 6.25 Gbps per-lane rates.
- Additional peripheral interfaces
    - Two serial ATA (SATA 2.0) controllers
    - Two high-speed USB 2.0 controllers with integrated PHY
    - Enhanced secure digital host controller (SD/MMC/eMMC)
    - Enhanced serial peripheral interface (eSPI)
    - Four I2C controllers
    - Four 2-pin or two 4-pin UARTs
    - Integrated Flash controller supporting NAND and NOR flash
- Three eight-channel DMA engines.

- Support for hardware virtualization and partitioning enforcement
- QorIQ Platform's Trust Architecture 2.0

1.3.3 Core and CPU clusters

This chip offers 12, high-performance, 64-bit Power Architecture, Book E-compliant cores. Each CPU core supports two hardware threads, which software views as a virtual CPU. The core CPUs are arranged in clusters of four with a shared 2 MB L2 cache.

The core subsystem includes the following features:

- Up to 1.8 GHz
- Dual-thread with simultaneous multi-threading (SMT)
    - Threading can be disabled on a per CPU basis
- 40-bit physical addressing
- L2 MMU
    - Supporting 4 KB pages
    - TLB0; 8-way set-associative, 1024-entries (4 KB pages)
    - TLB1; fully associative, 64-entry, supporting variable size pages and indirect page table entries
- Hardware page table walk
- 64-byte cache line size
- L1 caches, running at core frequency
    - 32 KB instruction, 8-way set-associative
    - 32 KB data, 8-way set-associative
    - Each with data and tag parity protection
- Hardware support for memory coherency
- Five integer units: 4 simple (2 per thread), 1 complex (integer multiply and divide)
- Two load-store units: one per thread
- Classic double-precision floating-point unit
    - Uses 32 64-bit floating-point registers (FPRs) for scalar single- and double-precision floating-point arithmetic
    - Designed to comply with IEEE Std. 754™-1985 FPU for both single and double-precision operations
- AltiVec unit
    - 128-bit Vector SIMD engine
    - 32 128-bit VR registers
    - Operates on a vector of
        - Four 32-bit integers
        - Four 32-bit single precision floating-point units

        - Eight 16-bit integers
        - Sixteen 8-bit integers
    - Powerful permute unit
    - Enhancements include: Move from GPRs to VR, sum of absolute differences operation, extended support for misaligned vectors, handling head and tails of vectors
- Supports Data Path Acceleration Architecture (DPAA) data and context "stashing" into L1 and L2 caches
- User, supervisor, and hypervisor instruction level privileges
- Addition of Elemental Barriers and "wait on reservation" instructions
- New power-saving modes including "drowsy core" with state retention and nap
    - State retention power-saving mode allows core to quickly wake up and respond to service requests
- Processor facilities
    - Hypervisor APU
    - "Decorated Storage" APU for improved statistics support
        - Provides additional atomic operations, including a "fire-and-forget" atomic update of up to two 64-bit quantities by a single access
    - Addition of Logical to Real Address translation mechanism (LRAT) to accelerate hypervisor performance
    - Expanded interrupt model
        - Improved Programmable Interrupt Controller (PIC) automatically ACKs interrupts
        - Implements message send and receive functions for interprocessor communication, including receive filtering
    - External PID load and store facility
        - Provides system software with an efficient means to move data and perform cache operations between two disjoint address spaces
        - Eliminates the need to copy data from a source context into a kernel context, change to destination address space, then copy the data to the destination address space or alternatively to map the user space into the kernel address space

The arrangement of cores into clusters with shared L2 caches is part of a major re-architecture of the QorIQ cache hierarchy. Details of the banked L2 are provided below.

- 2 MB cache with ECC protection (data, tag, & status)
    - Pipelined data array access with 2 cycle repeat rate
- 4 banks, supporting up to four concurrent accesses.
- 64-byte cache line size
- 16 way, set associative

    - Ways in each bank can be configured in one of several modes
    - Flexible way partitioning per vCPU
        - I-only, D-only, or unified
- Supports direct stashing of datapath architecture data into L2

The chip also contains up to 1.5 MB of shared L3 CoreNet Platform Cache (CPC), with the following features:

- Total 1.5 MB, implemented as three 512 KB arrays, one per DDR controller
    - ECC protection for Data, Tag and Status
    - 16-way set associative with configurable replacement algorithms
    - Allocation control for data read, data store, castout, decorated read, decorated store, instruction read and stash
    - Configurable SRAM partitioning

1.3.4 Inverted cache hierarchy

From the perspective of software running on an core vCPU, the SoC incorporates a 2.5-level cache hierarchy. These levels are as follows:

- Level 1: Individual core 32 KB Instruction and Data caches
- Level 2: Locally banked 2 MB cache (configurably shared by other vCPUs in the cluster)
- Level 2.5: Remote banked 2 MB caches (total 4 MB)

When vCPUs in different physical clusters are part of the same coherency domain, the CoreNet Coherency Fabric causes any cache miss in the vCPU's local L2 to be snooped by the remote L2s belonging to the other clusters. On a hit in a remote L2, the associated data is returned directly to the requesting vCPU, eliminating the need for a higher latency flush and retry protocol. This direct cache transfer is called cache intervention.

Previous generation QorIQ products also support cache intervention from their private backside L2 caches; however, the SoC's allocation policies make greater use of intervention. The sum of the SoC's L2 caches are 3x larger than the CPC. Ttherefore, the CPC is not intended to act as backing store for the L2s, as it typically is in the previous generation. This allows the CPCs to be dedicated to the non-CPU masters in the SoC, storing DPAA data structures and IO data that the CPUs and accelerators will most likely need.

Although the SoC supports allocation policies that would result in CPU instructions and in data being held in the CPC (CPC acting as vCPU L3), this is not the default. Because the CPC serves fewer masters, it serves those masters better, by reducing the DDR bandwidth consumed by the DPAA and improving the average latency.

1.3.5 CoreNet fabric and address map

The CoreNet fabric provides the following:

- A highly concurrent, fully cache coherent, multi-ported fabric
- Point-to-point connectivity with flexible protocol architecture allows for pipelined interconnection between CPUs, platform caches, memory controllers, and I/O and accelerators at up to 733 MHz
- The CoreNet fabric has been designed to overcome bottlenecks associated with shared bus architectures, particularly address issue and data bandwidth limitations. The chip's multiple, parallel address paths allow for high address bandwidth, which is a key performance indicator for large coherent multicore processors.
- Eliminates address retries, triggered by CPUs being unable to snoop within the narrow snooping window of a shared bus. This results in the chip having lower average memory latency.

This chip's 40-bit, physical address map consists of local space and external address space. For the local address map, 32 local access windows (LAWs) define mapping within the local 40-bit (1 TB) address space. Inbound and outbound translation windows can map the chip into a larger system address space such as the RapidIO or PCIe 64-bit address environment. This functionality is included in the address translation and mapping units (ATMUs).

1.3.6 Memory complex

The SoC's memory complex consists of up to three DDR controllers for main memory, and the memory controllers associated with the Integrated Flash Controller (IFC).

1.3.6.1 DDR memory controllers

The chip offers up to three 64-bit DDR controllers supporting ECC protected memories. These DDR controllers operate at up to 1.867 GT/s for DDR3, and, in more power sensitive applications, up to 1.6 GHz for DDR3L. Some key DDR controller features are as follows:

- Interleaving options
  - None, three fully independent controllers
  - Two interleaved, one independent
  - Three interleaved
  - Interleaving can be configured on 1 KB, 4 KB, and 8 KB granules
- Support x4, x8, and x16 memory widths
  - Programmable support for single, dual, and quad ranked devices and modules
  - Support for both unbuffered and registered DIMMs
  - 4 chip-selects per controller
  - 64 GB per controller, 192 GB per chip
- The SoC can be configured to retain the currently active SDRAM page for pipelined burst accesses. Page mode support of up to 64 simultaneously open pages can dramatically reduce access latencies for page hits. Depending on the memory system design and timing parameters, page mode can save up to ten memory clock cycles for subsequent burst accesses that hit in an active page.
- Using ECC, the SoC detects and corrects all single-bit errors and detects all double-bit errors and all errors within a nibble.
- Upon detection of a loss of power signal from external logic, the DDR controllers can put compliant DDR SDRAM DIMMs into self-refresh mode, allowing systems to implement battery-backed main memory protection.
- In addition, the DDR controllers offer an initialization bypass feature for use by system designers to prevent re-initialization of main memory during system power-on after an abnormal shutdown.
- Support active zeroization of system memory upon detection of a user-defined security violation.

1.3.6.1.1 DDR bandwidth optimizations

Multicore SoCs are able to increase CPU and network interface bandwidths faster than commodity DRAM technologies are improving. As a result, it becomes increasingly important to maximize utilization of main memory interfaces to avoid a memory bottleneck. The T4 family's DDR controllers are NXP-developed IP, optimized for the QorIQ SoC architecture, with the goal of improving DDR bandwidth utilization by fifty percent when compared to first generation QorIQ SoCs.

The WRITE and READ bandwidth improvement is achieved through target queue enhancements; specifically, changes to the scheduling algorithm, improvements in the bank hashing scheme, support for more transaction re-ordering, and additional proprietary techniques.

1.3.6.2 PreBoot Loader and nonvolatile memory interfaces

The PreBoot Loader (PBL) operates similarly to an I^2C boot sequencer but on behalf of a large number of interfaces.

It supports IFC, I^2C, eSPI, eSDHC.

The PBL's functions include the following:

- Simplifies boot operations, replacing pin strapping resistors with configuration data loaded from nonvolatile memory
- Uses the configuration data to initialize other system logic and to copy data from low speed memory interfaces (I^2C, IFC, eSPI, and SD/MMC) into fully initialized DDR or the 2 MB front-side cache

1.3.6.2.1 Integrated Flash Controller (IFC)

The SoC incorporates an Integrated Flash Controller similar to the one used in some previous generation QorIQ SoCs. The IFC supports both NAND and NOR flash, as well as a general purpose memory mapped interface for connecting low speed ASICs and FPGAs.

1.3.6.2.1.1 NAND Flash features

- x8/x16 NAND Flash interface
- Optional ECC generation/checking
- Flexible timing control to allow interfacing with proprietary NAND devices
- SLC and MLC Flash devices support with configurable page sizes of up to 4 KB
- Support advance NAND commands like cache, copy-back, and multiplane programming
- Boot chip-select (CS0) available after system reset, with boot block size of 8 KB, for execute-in-place boot loading from NAND Flash
- Up to terabyte Flash devices supported

1.3.6.2.1.2 NOR Flash features

- Data bus width of 8/16/32
- Compatible with asynchronous NOR Flash
- Directly memory mapped
- Supports address data multiplexed (ADM) NOR device
- Flexible timing control allows interfacing with proprietary NOR devices
- Boot chip-select (CS0) available at system reset

1.3.6.2.1.3 General-purpose chip-select machine (GPCM)

The IFC's GPCM supports the following features:

- Normal GPCM
  - Support for x8/16/32-bit device
  - Compatible with general purpose addressable device, for example, SRAM and ROM
  - External clock is supported with programmable division ratio (2, 3, 4, and so on, up to 16)
- Generic ASIC Interface
  - Support for x8/16/32-bit device
  - Address and Data are shared on I/O bus
  - Following address and data sequences are supported on I/O bus:
    - 32-bit I/O: AD
    - 16-bit I/O: AADD
    - 8-bit I/O: AAAADDDD

1.3.6.2.2 Serial memory controllers

In addition to the parallel NAND and NOR flash supported by the IFC, the SoC supports serial flash using eSPI, I^2C and SD/MMC/eMMC card and device interfaces. The SD/MMC/eMMC controller includes a DMA engine, allowing it to move data from serial flash to external or internal memory following straightforward initiation by software.

Detailed features of the eSDHC include the following:

- Conforms to the SD Host Controller Standard Specification version 2.0, including Test event register support
- Compatible with the MMC System Specification version 4.2
- Compatible with the SD Memory Card Specification version 2.0, and supports the high capacity SD memory card
- Designed to work with SD memory, SD combo, MMC, and their variants like mini and micro.
- Card bus clock frequency up to 52 MHz
- Supports 1-/4-bit SD, 1-/4-/8-bit MMC modes
- Supports single-block and multi-block read, and write data transfer
- Supports block sizes of 1-2048 bytes
- Supports the mechanical write protect detection. In the case where write protect is enabled, the host will not initiate any write data command to the card
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports Auto CMD12 for multi-block transfer

- Host can initiate command that do not use data lines, while data transfer is in progress
- Embodies a configurable 128x32-bit FIFO for read/write data
- Supports SDMA, ADMA1, and ADMA2 capabilities
- Supports external SD bus voltage selection by register configuration
- Host will send 80 idle SD clock cycles to card, which are needed during card power-up, if bit INITA in the system control register (SYSCTL) is set

1.3.7 Universal serial bus (USB) 2.0

The two USB 2.0 controllers with integrated PHY provide point-to-point connectivity that complies with the USB specification, Rev. 2.0.

Each of the USB controllers with integrated PHY can be configured to operate as a stand-alone host, a stand-alone device, or with both host and device functions operating simultaneously.

Key features of the USB 2.0 controller include the following:

- Complies with USB specification, Rev. 2.0
- Supports high-speed (480 Mbps), full-speed (12 Mbps), and low-speed (1.5 Mbps) operations
- Both controllers support operation as a stand-alone USB host controller
  - Support USB root hub with one downstream-facing port
  - Enhanced host controller interface (EHCI)-compatible
- Both controllers support operation as a stand-alone USB device
  - Support one upstream-facing port
  - Support six programmable USB endpoints

The host and device functions are both configured to support all four USB transfer types:

- Bulk
- Control
- Interrupt
- Isochronous

1.3.8 High-speed peripheral interface complex (HSSI)

This chip offers a variety of high-speed serial interfaces, sharing a set of 16 SerDes lanes. Each interface is backed by a high speed serial interface controller. This chip has the following types and quantities of controllers:

- Four PCI Express controllers
- Two Serial RapidIO 2.0
- Two SATA 2.0
- One Interlaken look-aside
- Aurora
- Up to sixteen Ethernet controllers with various protocols

1.3.8.1 PCI Express

Each of the chip's PCI Express controllers is compatible with the PCI Express Base Specification Revision 3.0. Key features of each PCI Express controller include the following:

- Power-on reset configuration options allow root complex or endpoint functionality.
- The physical layer operates at up to 8 GT/s data rate per lane
  - x4, x2, and x1 link widths supported on all controllers at 2.5, 5, or 8 GT/s
  - x8 link width supported on two controllers at 2.5 or 5 GT/s
- Both 32- and 64-bit addressing
- 256-byte maximum payload size
- Full 64-bit decode with 40-bit wide windows
- Inbound INTx transactions
- Message signaled interrupt (MSI) transactions
- One PCI Express controller supports end-point SR-IOV
  - Two physical functions, each with 64 virtual functions
  - Eight MSI-X per virtual function

1.3.8.2 Serial RapidIO

The Serial RapidIO interface is based on the *RapidIO Interconnect Specification, Revision 2.1* . RapidIO is a high-performance, point-to-point, low-pin-count, packet-switched system-level interconnect that can be used in a variety of applications as an open standard. The rich feature set includes high data bandwidth, low-latency capability, and support for high-performance I/O devices as well as message-passing and software-managed programming models. Receive and transmit ports operate independently, and with 2 x 4 Serial RapidIO controllers, the aggregate theoretical bandwidth is 32 Gbps.

The chip offers two Serial RapidIO controllers, muxed onto the SerDes blocks. The Serial RapidIO interface is based on the *RapidIO Interconnect Specification, Revision 2.1* . Receive and transmit ports operate independently and with 2 x 4 Serial RapidIO

controllers; the aggregate theoretical bandwidth is 32 Gbps. The Serial RapidIO controllers can be used in conjunction with "Rapid IO Message Manager (RMAN), as described in RapidIO Message Manager (RMan)."

Key features of the Serial RapidIO interface unit include the following:

- Support for *RapidIO Interconnect Specification, Revision 2.1* (All transaction flows and priorities.)
- 2x, and 4x LP-serial link interfaces, with transmission rates of 2.5, 3.125, or 5.0 Gbaud (data rates of 1.0, 2.0, 2.5, or 4.0 Gbps) per lane
- Auto-detection of 1x, 2x, or 4x mode operation during port initialization
- 34-bit addressing and up to 256-byte data payload
- Support for SWRITE, NWRITE, NWRITE_R and Atomic transactions
- Receiver-controlled flow control
- RapidIO error injection
- Internal LP-serial and application interface-level loopback modes

The Serial RapidIO controller also supports the following capabilities, many of which are leveraged by the RMan to efficient chip-to-chip communication through the DPAA:

- Support for RapidIO Interconnect Specification 2.1, "Part 2: Message Passing Logical Specification"
- Supports RapidIO Interconnect Specification 2.1, "Part 10: Data Streaming Logical Specification"
- Supports RapidIO Interconnect Specification 2.1, "Annex 2: Session Management Protocol"
    - Supports basic stream management flow control (XON/XOFF) using extended header message format
- Up to 16 concurrent inbound reassembly operations
    - One additional reassembly context is reservable to a specific transaction type
- Support for outbound Type 11 messaging
- Support for outbound Type 5 NWRITE and Type 6 SWRITE transactions
- Support for inbound Type 11 messaging
- Support for inbound Type 9 data streaming transactions
- Support for outbound Type 9 data streaming transactions
    - Up to 64 KB total payload
- Support for inbound Type 10 doorbell transactions
    - Transaction steering through doorbell header classification
- Support for outbound Type 10 doorbell transactions
    - Ordering can be maintained with respect to other types of traffic.
- Support for inbound and outbound port-write transactions
    - Data payloads of 4 to 64 bytes

1.3.8.3 SATA

Each of the SoC's two SATA controllers is compliant with the *Serial ATA 2.6 Specification*. Each of the SATA controllers has the following features:

- Supports speeds: 1.5 Gbps (first-generation SATA), and 3Gbps (second-generation SATA)
- Supports advanced technology attachment packet interface (ATAPI) devices
- Contains high-speed descriptor-based DMA controller
- Supports native command queuing (NCQ) commands
- Supports port multiplier operation
- Supports hot plug including asynchronous signal recovery

1.3.8.4 Interlaken Look-Aside Controller (LAC) and interface

Interlaken Look-Aside is a high speed serial channelized chip-to-chip interface. To facilitate interoperablility between a GPU or NPU and a look-aside co-processor, the Interlaken Look-Aside protocol is defined for short transaction with small data & command transfers. Although based on the Interlaken protocol, Interlaken Look-Aside is not directly compatible with the Interlaken streaming specification, and can be considered a different operational mode. The SoC's Interlaken LAC is Look-Aside only.

The Interlaken LAC features:

- Supports Interlaken Look-Aside Protocol definition, Rev. 1.1
- Supports up to 32 software portals, with stashing option
- Supports inband per-channel flow control options, with a simple xon/xoff semantics
- Supports SerDes frequency 6.25 GHz and widths (x4, x8)
- 64B/67B data encoding and scrambling
- Programmable BURSTMAX (256 to 512-byte) and BURSTSHORT (8 to 16 bytes)
- Error detection: illegal burst sizes, bad 64/67 word type, CRC-24 error, receiver data overflow
- Built in statistics and error counters
- Dynamic power-down of each software portal

Although not part of the DPAA, the LAC leverages DPAA concepts, including software portals and stashing. Each vCPU has a private software portal into the LAC, through which it issues commands and receives its results. Software commands to the LAC commands are translated into the Interlaken control words and data words, which are transmitted across the SerDes lanes to the co-processor, generally expected to be a TCAM.

TCAM responses received by the LAC (control words and data words) are then written to memory mapped space defined for the software portal of the vCPU that initiated the request. These writes can be configured to stash data directly into the vCPU's cache to reduce latency.

Each vCPU can generally have four outstanding transactions with the LAC; however, if not all vCPUs are configured to use the LAC, those that are configured can have more outstanding transactions. Order is maintained for all transactions issued by a single portal.

1.3.9 Data Path Acceleration Architecture (DPAA)

This chip includes an enhanced implementation of the QorIQ Datapath Acceleration Architecture (DPAA). This architecture provides the infrastructure to support simplified sharing of networking interfaces and accelerators by multiple CPUs. These resources are abstracted as enqueue/dequeue operations by CPU 'portals' into the datapath. Beyond enabling multicore sharing of resources, the DPAA significantly reduces software overheads associated with high-touch packet-processing operations.

Examples of the types of packet-processing services that this architecture is optimized to support are as follows:

- Traditional routing and bridging
- Firewall
- Security protocol encapsulation and encryption

The functions off-loaded by the DPAA fall into two broad categories:

- Packet distribution and queue-congestion management
- Accelerating content processing

1.3.9.1 Packet distribution and queue/congestion management

This table lists some packet distribution and queue/congestion management offload functions.

Table 1-2. Offload functions

Function type	Definition
Data buffer management	Supports allocation and deallocation of buffers belonging to pools originally created by software with configurable depletion thresholds. Implemented in a module called the Buffer Manager (BMan).

Table continues on the next page...

Table 1-2. Offload functions (continued)

Function type	Definition
Queue management	Supports queuing and quality-of-service scheduling of frames to CPUs, network interfaces and DPAA logic blocks, maintains packet ordering within flows. Implemented in a module called the Queue Manager (QMan). The QMan, besides providing flow-level queuing, is also responsible for congestion management functions such as RED/WRED, congestion notifications and tail discards.
Packet distribution	Supports in-line packet parsing and general classification to enable policing and QoS-based packet distribution to the CPUs for further processing of the packets. This function is implemented in the block called the Frame Manager (FMan).
Policing	Supports in-line rate-limiting by means of two-rate, three-color marking (RFC 2698). Up to 256 policing profiles are supported. This function is also implemented in the FMan.
Egress Scheduling	Supports hierarchical scheduling and shaping, with committed and excess rates. This function is supported in the QMan, although the FMan performs the actual transmissions.

1.3.9.2 Accelerating content processing

Properly implemented acceleration logic can provide significant performance advantages over most optimized software with acceleration factors on the order of 10-100x. Accelerators in this category typically touch most of the bytes of a packet (not just headers). To avoid consuming CPU cycles in order to move data to the accelerators, these engines include well-pipelined DMAs. This table lists some specific content-processing accelerators on the chip.

Table 1-3. Content-processing accelerators

Interface	Definition
SEC	Acceleration for protocols such as IPsec, TLS, and LTE PDCP, and for cryptographic algorithms such as AES, DES, SHA-1, SHA-2 family, SNOW3G, and ZUC.
PME	Regex style pattern matching for unanchored searches, including cross-packet stateful patterns
DCE	Compression/Decompression acceleration for ZLib and deflate

1.3.9.3 Enhancements of T4240 compared to first generation DPAA

A short summary of T4240 enhancements over the first generation DPAA (as implemented in the P4080) is provided below:

- Frame Manager
  - 2x performance increase (up to 25 Gbps per FMan)
  - Storage profiles.
  - HiGig (3.125 GHz) and HiGig2 (3.125 GHz and 3.75 GHz)
  - Energy Efficient Ethernet
- SEC 5.0

    - 2x performance increase for symmetric encryption and protocol processing
        - Up to 20 Gbps for IPsec @ Imix
    - 10x performance increase for public key algorithms
    - Support for 3GPP Confidentiality and Integrity Algorithms 128-EEA3 & 128-EIA3 (ZUC)
- DCE 1.0, new accelerator for compression/decompression
- RMan (Serial RapidIO Manager)
- DPAA overall capabilities
    - Data Center Bridging
    - Egress Traffic Shaping

1.3.9.4 DPAA terms and definitions

The QorIQ Platform's Data Path Acceleration Architecture (henceforth DPAA) assumes the existence of network flows, where a flow is defined as a series of network datagrams, which have the same processing and ordering requirements. The DPAA prescribes data structures to be initialized for each flow. These data structures define how the datagrams associated with that flow move through the DPAA. Software is provided a consistent interface (the software portal) for interacting with hardware accelerators and network interfaces.

All DPAA entities produce data onto frame queues (a process called enqueuing) and consume data from frame queues (dequeuing). Software enqueues and dequeues through a software portal (each vCPU has two software portals), and the FMan, RMan, and DPAA accelerators enqueue/dequeue through hardware portals. This figure illustrates this key DPAA concept.

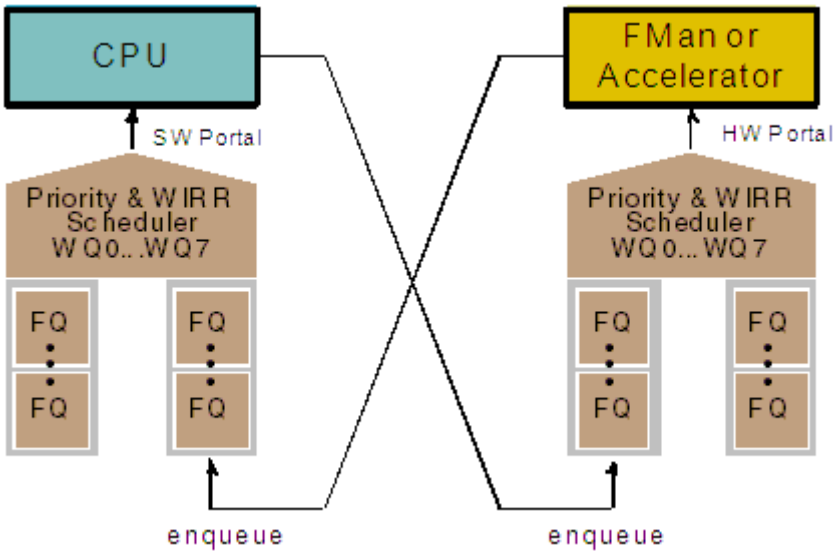

Figure 1-2. DPAA enqueuing and dequeuing

This table lists common DPAA terms and their definitions.

Table 1-4. DPAA terms and definitions

Term	Definition	Graphic representation
Buffer	Region of contiguous memory, allocated by software, managed by the DPAA BMan	
Buffer pool	Set of buffers with common characteristics (mainly size, alignment, access control)	Frame	Single buffer or list of buffers that hold data, for example, packet payload, header, and other control information	Frame queue (FQ)	FIFO of frames	Work queue (WQ)	FIFO of FQs	
Table continues on the next page...

Table 1-4. DPAA terms and definitions (continued)

Term	Definition	Graphic representation
Channel	Set of eight WQs with hardware provided prioritized access	Dedicated channel	Channel statically assigned to a particular end point, from which that end point can dequeue frames. End point may be a CPU, FMan, PME,DCE,RMan or SEC.	-
Pool channel	A channel statically assigned to a group of end points, from which any of the end points may dequeue frames.	

1.3.9.5 Major DPAA components

The SoC's Datapath Acceleration Architecture, shown in the figure below, includes the following major components:

- Frame Manager (FMan)
- Queue Manager (QMan)
- Buffer Manager (BMan)
- RapidIO Message Manager (RMan 1.0)
- Security Engine (SEC 5.0)
- Pattern Matching Engine (PME 2.1)
- Decompression and Compression Engine (DCE 1.0)

The QMan and BMan are infrastructure components, which are used by both software and hardware for queuing and memory allocation/deallocation. The Frame Managers and RMan are interfaces between the external world and the DPAA. These components receive datagrams via Ethernet or Serial RapidIO and queue them to other DPAA entities, as well as dequeue datagrams from other DPAA entities for transmission. The SEC, PME, and DCE are content accelerators that dequeue processing requests (typically from software) and enqueue results to the configured next consumer. Each component is described in more detail in the following sections.

This figure is a logical view of the DPAA.

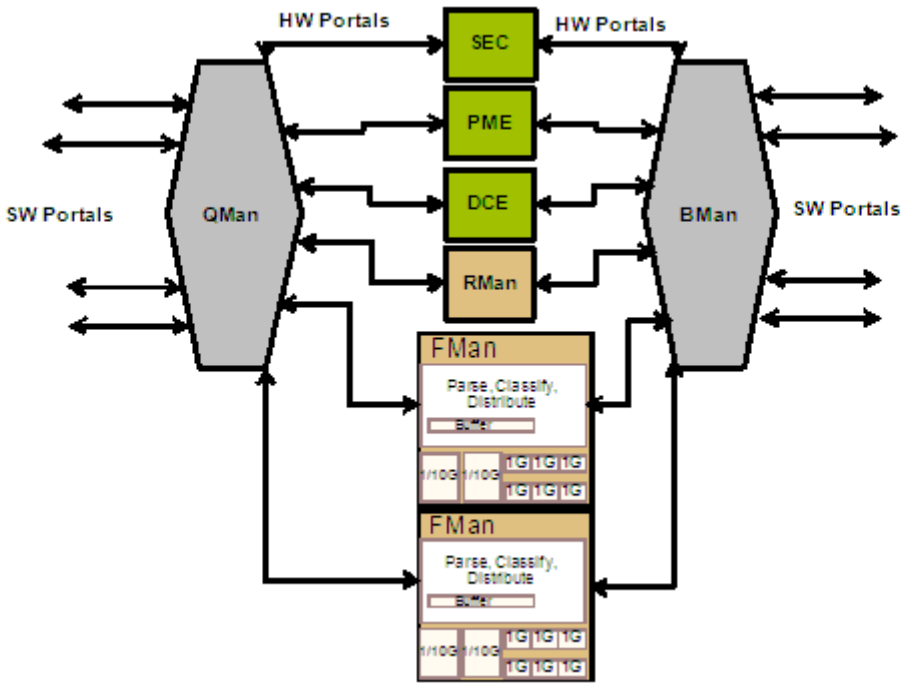

Figure 1-3. Logical representation of DPAA

1.3.9.5.1 Frame Manager and network interfaces

The chip incorporates two enhanced Frame Managers. The Frame Manager improves on the bandwidth and functionality offered in the P4080.

Each Frame Manager, or FMan, combines Ethernet MACs with packet parsing and classification logic to provide intelligent distribution and queuing decisions for incoming traffic. Each FMan supports PCD at 37.2 Mpps, supporting line rate 2x10G + 2x2.5G at minimum frame size.

These Ethernet combinations are supported:

- 10 Gbps Ethernet MACs are supported with XAUI (four lanes at 3.125 GHz) or XFI (one lane at 10.3125 GHz SerDes).
- 1 Gbps Ethernet MACs are supported with SGMII (one lane at 1.25 GHz with 3.125 GHz option for 2.5 Gbps Ethernet).
  - SGMIIs can be run at 3.125 GHz so long as the total Ethernet bandwidth does not exceed 25 Gbps on the associated FMan.
  - If not already assigned to SGMII, two MACs can be used with RGMII.
- Four x1Gbps Ethernet MACs can be supported using a single lane at 5 GHz (QSGMII).
- HiGig is supported using four lanes at 3.125 GHz or 3.75 GHz (HiGig2).

The Frame Manager's Ethernet functionality also supports the following:

- 1588v2 hardware timestamping mechanism in conjunction with IEEE Std. 802.3bf (Ethernet support for time synchronization protocol)
- Energy Efficient Ethernet (IEEE Std. 802.3az)
- IEEE Std. 802.3bd (MAC control frame support for priority based flow control)
- IEEE Std. 802.1Qbb (Priority-based flow control) for up to eight queues/priorities
- IEEE Std. 802.1Qaz (Enhanced transmission selection) for three or more traffic classes

1.3.9.5.1.1 Receiver functionality: parsing, classification, and distribution

Each Frame Manager matches its 25 Gbps Ethernet connectivity with 25 Gbps (37.2 Mpps) of Parsing, Classification, and Distribution (PCD) performance. PCD is the process by which the Frame Manager identifies the frame queue on which received packets should be enqueued. The consumer of the data on the frame queues is determined by Queue Manager configuration; however, these activities are closely linked and managed by the FMan Driver and FMan Configuration Tool, as in previous QorIQ SoCs.

This figure provides a logical view of the FMan's processing flow, illustrating the PCD features.

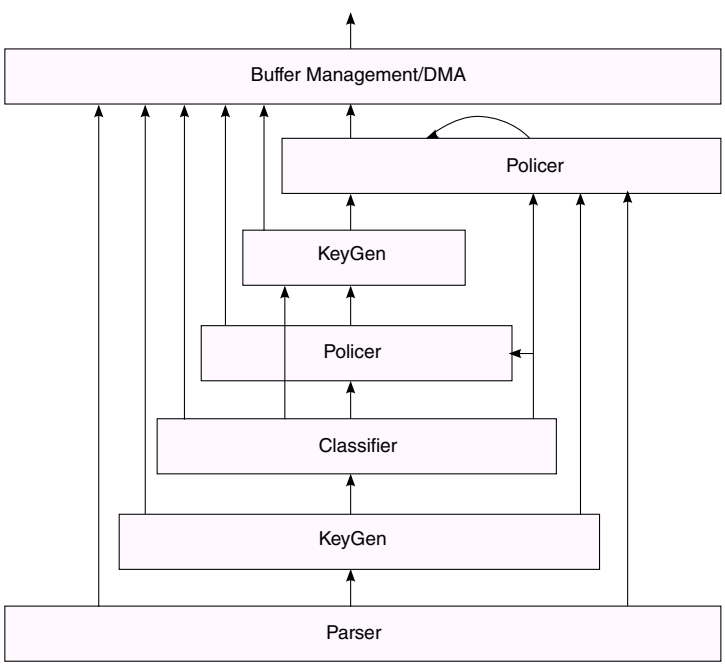

Figure 1-4. Logical view of FMan processing

Each frame received by the FMan is buffered internally while the Parser, KeyGen, and Classification functions operate.

The parse function can parse many standard protocols, including options and tunnels, and it supports a generic configurable capability to allow proprietary or future protocols to be parsed. Hard parsing of the standard protocol headers can be augmented with user-defined soft parsing rules to handle proprietary header fields. Hard and soft parsing occurs at wire speed.

This table defines several types of parser headers.

Table 1-5. Parser header types

Header type	Definition
Self-describing	Announced by proprietary values of Ethertype, protocol identifier, next header, and other standard fields. They are self-describing in that the frame contains information that describes the presence of the proprietary header.
Non-self-describing	Does not contain any information that indicates the presence of the header. For example, a frame that always contains a proprietary header before the Ethernet header would be non-self-describing. Both self-describing and non-self-describing headers are supported by means of parsing rules in the FMan.
Proprietary	Can be defined as being self-describing or non-self-describing

The underlying notion is that different frames may require different treatment, and only through detailed parsing of the frame can proper treatment be determined.

Parse results can (optionally) be passed to software.

1.3.9.5.1.2 FMan distribution and policing

After parsing is complete, there are two options for treatment, as shown in this table.

Table 1-6. Post-parsing treatment options

Treatment	Function	Benefits
Hash	• Hashes select fields in the frame as part of a spreading mechanism. • The result is a specific frame queue identifier. • To support added control, this FQID can be indexed by values found in the frame, such as TOS or p-bits, or any other desired field(s).	Useful when spreading traffic while obeying QoS constraints is required
Classification look-up	• Looks up certain fields in the frame to determine subsequent action to take, including policing. • The FMan contains internal memory that holds small tables for this purpose. • The user configures the sets of lookups to perform, and the parse results dictate which one of those sets to use. • Lookups can be chained together such that a successful look-up can provide key information for a subsequent look-up. After all the look-ups are complete, the final classification result provides either a hash key to use for spreading, or a FQ ID directly.	• Useful when hash distribution is insufficient and a more detailed examination of the frame is required • Can determine whether policing is required and the policing context to use

Key benefits of the FMan policing function are as follows:

- Because the FMan has up to 256 policing profiles, any frame queue or group of frame queues can be policed to either drop or mark packets if the flow exceeds a preconfigured rate.
- Policing and classification can be used in conjunction to mitigate Distributed Denial of Service Attack (DDOS).
- The policing is based on the two-rate-three-color marking algorithm (RFC2698). The sustained and peak rates, as well as the burst sizes, are user-configurable. Therefore, the policing function can rate-limit traffic to conform to the rate that the flow is mapped to at flow set-up time. By prioritizing and policing traffic prior to software processing, CPU cycles can focus on important and urgent traffic ahead of other traffic.

Each FMan also supports PCD on traffic arriving from within the chip. This is referred to as off-line parsing, and it is useful for reclassification following decapsulation of encrypted or compressed packets.

FMan PCD supports virtualization and strong partitioning by delaying buffer pool selection until after classification. In addition to determining the FQ ID for the classified packet, the FMan also determines the 'storage profile.' Configuration of storage profiles (up to 32 per physical port) allows the FMan to store received packets using buffer pools owned by a single software partition, and enqueue the associated Frame Descriptor to a frame queue serviced by only that software partition. This capability includes copying from one buffer pool to another if the traffic is received via the FMan's off-line parsing port. Packets can be copied to multiple buffer pools and enqueued to multiple frame queues to support broadcast and multicast requirements.

1.3.9.5.2 Queue Manager

The Queue Manager (QMan) is the primary infrastructure component in the DPAA, allowing for simplified sharing of network interfaces and hardware accelerators by multiple CPU cores. It also provides a simple and consistent message and data passing mechanism for dividing processing tasks amongst multiple vCPUs.

The Queue Manager offers the following features:

- Common interface between software and all hardware
  - Controls the prioritized queuing of data between multiple processor cores, network interfaces, and hardware accelerators.
  - Supports both dedicated and pool channels, allowing both push and pull models of multicore load spreading.
- Atomic access to common queues without software locking overhead

- Mechanisms to guarantee order preservation with atomicity and order restoration following parallel processing on multiple CPUs
- Egress queuing for Ethernet interfaces
  - Hierarchical (2-level) scheduling and dual-rate shaping
  - Dual-rate shaping to meet service-level agreements (SLAs) parameters (1 Kbps... 10 Gbps range, 1 Kbps granularity across the entire range)
  - Configurable combinations of strict priority and fair scheduling (weighted queuing) between the queues
  - Algorithms for shaping and fair scheduling are based on bytes
- Queuing to cores and accelerators
  - Two level queuing hierarchy with one or more Channels per Endpoint, eight work queues per Channel, and numerous frame queues per work queue
  - Priority and work conserving fair scheduling between the work queues and the frame queues
- Loss-less flow control for ingress network interfaces
- Congestion avoidance (RED/WRED) and congestion management with tail discard

1.3.9.5.3 Buffer Manager

The Buffer Manager (BMan) manages pools of buffers on behalf of software for both hardware (accelerators and network interfaces) and software use.

The Buffer Manager offers the following features:

- Common interface for software and hardware
- Guarantees atomic access to shared buffer pools
- Supports 64 buffer pools
  - Software, hardware buffer consumers can request different size buffers and buffers in different memory partitions
- Supports depletion thresholds with congestion notifications
- On-chip per pool buffer stockpile to minimize access to memory for buffer pool management
- LIFO (last in first out) buffer allocation policy
  - Optimizes cache usage and allocation
  - A released buffer is immediately used for receiving new data

1.3.9.5.4 SEC 5.0

The SEC 5.0 is NXP's fifth generation crypto-acceleration engine. The SEC 5.0 is backward-compatible with the SEC 4.x, as implemented in the first generation of high-end QorIQ products, which includes the P4080. As in the SEC 4.x, the SEC 5.0 offers

high performance symmetric and asymmetric encryption, keyed and unkeyed hashing algorithms, NIST-compliant random number generation, and security protocol header and trailer processing.

The SEC 5.0 can perform full protocol processing for the following security protocols:

- IPsec
- SSL/TLS
- 3GPP RLC encryption/decryption
- LTE PDCP
- SRTP
- IEEE 802.1AE MACSec
- IEEE 802.16e WiMax MAC layer

The SEC 5.0 supports the following algorithms, modes, and key lengths as raw modes, or in combination with the security protocol processing described above.

- Public Key Hardware Accelerator (PKHA)
  - RSA and Diffie-Hellman (to 4096b)
  - Elliptic curve cryptography (1023b)
- Data Encryption Standard Accelerators (DESA)
  - DES, 3DES (2-key, 3-key)
  - ECB, CBC, OFB, and CFB modes
- Advanced Encryption Standard Accelerators (AESA)
  - Key lengths of 128-bit, 192-bit, and 256-bit
  - ECB, CBC, CTR, CCM, GCM, CMAC, OFB, CFB, xcbc-mac, and XTS
- ARC Four Hardware Accelerator (AFHA)
  - Compatible with RC4 algorithm
- Message Digest Hardware Accelerators (MDHA)
  - SHA-1, SHA-256, 384, 512-bit digests
  - MD5 128-bit digest
  - HMAC with all algorithms
- Kasumi/F8 Hardware Accelerators (KFHA)
  - F8, F9 as required for 3GPP
  - A5/3 for GSM and EDGE, GEA-3 for GPRS
- Snow 3G Hardware Accelerator (SNOWf8 and SNOWf9)
  - Implements Snow 3.0, F8 and F9 modes
- ZUC hardware Accelerators (ZUCE and ZUCA)
  - Implements 128-EEA3 & 128-EIA3
- CRC hardware accelerator
  - Standard and user-defined polynomials
- Random Number Generator

- Incorporates TRNG entropy generator for seeding and deterministic engine (SHA-256)
- Supports random IV generation

The SEC 5.0 is designed to support bulk encryption at up to 40 Gbps, large packet/record IPsec/SSL at up to 30 Gbps, and 20 Gbps for IPsec ESP at Imix packet sizes. 3G and LTE algorithms are supported at 10 Gbps or more.

The SEC dequeues data from its QMan hardware portal and, based on FQ configuration, also dequeues associated instructions and operands in the Shared Descriptor. The SEC processes the data then enqueues it to the configured output FQ. The SEC uses the Status/CMD word in the output Frame Descriptor to inform the next consumer of any errors encountered during processing (for example, received packet outside the anti-replay window.)

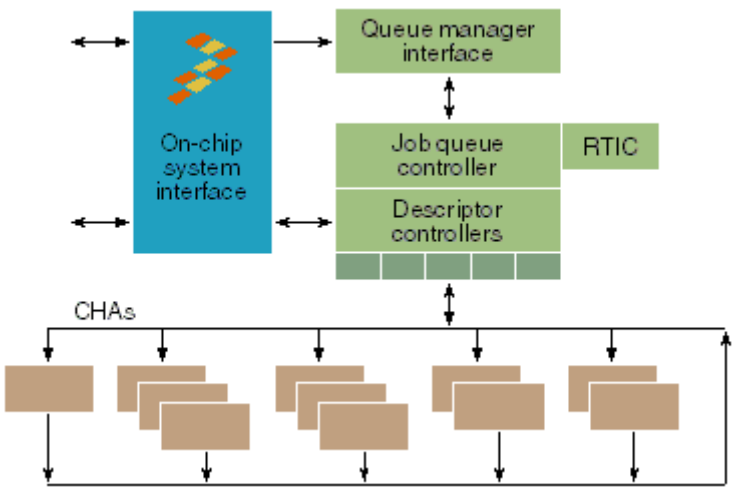

Figure 1-5. SEC 5.0 block diagram

The SEC 5.0 is also part of the QorIQ Platform's Trust Architecture, which gives the SoC the ability to perform secure boot, runtime code integrity protection, and session key protection. The Trust Architecture is described in Resource partitioning and QorIQ Trust Architecture.

1.3.9.5.5 Pattern Matching Engine (PME 2.1)

The PME 2.1 is NXP's second generation of extended NFA style pattern matching engine. Unchanged from the first generation QorIQ products, it supports ~10 Gbps data scanning.

Key benefits of a NFA pattern matching engine:

- No pattern "explosion" to support "wildcarding" or case-insensitivity

    - Comparative compilations have shown 300,000 DFA pattern equivalents can be achieved with ~8000 extended NFA patterns
- Pattern density much higher than DFA engines.
    - Patterns can be stored in on-chip tables and main DDR memory
    - Most work performed solely with on-chip tables (external memory access required only to confirm a match)
    - No need for specialty memories; for example, QDR SRAM, RLDRAM, and so on.
- Fast compilation of pattern database, with fast incremental additions
    - Pattern database can be updated without halting processing
    - Only affected pattern records are downloaded
    - DFA style engines can require minutes to hours to recompile and compress database

NXP's basic NFA capabilities for byte pattern scanning are as follows:

- The PME's regex compiler accepts search patterns using syntax similar to that in software-based regex engines, such as Perl-Compatible Regular Expression (PCRE).
    - Supports Perl meta-characters including wildcards, repeats, ranges, anchors, and so on.
    - Byte patterns are simple matches, such as gabcd123h, existing in both the data being scanned and in the pattern specification database.
- Up to 32 KB patterns of length 1-128 bytes

NXP's extensions to NFA style pattern matching are principally related to event pattern scanning. Event patterns are sequences of byte patterns linked by 'stateful rules.' NXP uses event pattern scanning and stateful rule processing synonymously. Stateful rules are hardware instructions by which users define reactions to pattern match events, such as state changes, assignments, bitwise operations, addition, subtraction, and comparisons.

Some key characteristics and benefits of the Stateful Rule extensions include:

- Ability to match patterns across data "work units" or packet boundaries
    - Can be used to correlate patterns, qualify matches (for example, contextual match), or to track protocol state change
- Easily support "greedy" wildcards
    - For example, ABC.*DEF == two patterns tied together by a stateful rule
- Delays the need for software post-processing. Software is alerted after all byte patterns are detected in the proper sequence, rather than any time a byte pattern is detected.
- Implements a significant subset of the regex pattern definition syntax as well as many constructs which cannot be expressed in standard PCRE
- PME 2.1 supports up to 32K stateful rules, linking multiple byte patterns

The PME 2.1 dequeues data from its QMan hardware portal and, based on FQ configuration, scans the data against one of 256 pattern sets, 16 subsets per pattern set.

When the PME finds a byte pattern match, or a final pattern in a stateful rule, it generates a report.

1.3.9.5.6 Decompression and Compression Engine (DCE 1.0)

The Decompression and Compression Engine (DCE 1.0) is an accelerator compatible with Datapath Architecture providing lossless data decompression and compression for the QorIQ family of SoCs. The DCE supports the raw DEFLATE algorithm (RFC1951), GZIP format (RFC1952) and ZLIB format (RFC1950). The DCE also supports Base 64 encoding and decoding (RFC4648).

The DEFLATE algorithm is a basic building block for data compression in most modern communication systems. It is used by HTTP to compress web pages, by SSL to compress records, by gzip to compress files and email attachments, and by many other applications.

Deflate involves searching for repeated patterns previously seen in a Frame, computing the length and the distance of the pattern with respect to the current location in the Frame, and encoding the resulting information into a bitstream.

The decompression algorithm involves decoding the bitstream and replaying past data. The Decompression and Compression Engine is architected to minimize the system memory bandwidth required to do decompression and compression of Frames while providing multi-gigabits per second of performance.

Detailed features include the following:

- Deflate; as specified as in RFC1951
- GZIP; as specified in RFC1952
- Zlib; as specified in RFC1950
    - Interoperable with the zlib 1.2.5 compression library
- Compression
    - ZLIB, GZIP and DEFLATE header insertion
    - ZLIB and GZIP CRC computation and insertion
    - Zlib sync flush and partial flush for chunked compression (for example, for HTTP1.1)
    - Four modes of compression
        - No compression (just add DEFLATE header)
        - Encode only using static/dynamic Huffman codes
        - Compress and encode using static Huffman codes
        - Compress and encode using dynamic Huffman codes
    - Uses a 4KB sliding history window

    - Supports Base 64 encoding (RFC4648) after compression
    - Provides at least 2.5:1 compression ratio on the Calgary Corpus
- Decompression supports:
    - ZLIB, GZIP and DEFLATE header removal
    - ZLIB and GZIP CRC validation
    - 32KB history
    - Zlib flush for chunked decompression (for HTTP1.1 for example)
        - All standard modes of decompression
        - No compression
        - Static Huffman codes
        - Dynamic Huffman codes
    - Provides option to return original compressed Frame along with the uncompressed Frame or release the buffers to BMan
    - Does not support use of ZLIB preset dictionaries (FDICT flag = 1 is treated as an error).
    - Base 64 decoding (RFC4648) prior to decompression

The DCE 1.0 is designed to support up to 8.8 Gbps for either compression or decompression, or 17.5 Gbps aggregate at ~4 KB data sizes.

1.3.9.6 DPAA capabilities

Some DPAA features and capabilities have been described in the sections covering individual DPAA components. This section describes some capabilities enabled by DPAA components working together.

1.3.9.6.1 Ingress policing and congestion management

In addition to selecting FQ ID and storage profile, classification can determine whether policing is required for a received packet, along with the specific policing context to be used.

FMan policing capabilities include the following:

- RFC2698: two-rate, three-color marking algorithm
- RFC4115: Differentiated service two-rate, three-color marker with efficient handling of in-profile traffic
- Up to 256 internal profiles

The sustained and peak rates, and burst size for each policing profile are user-configurable.

1.3.9.6.2 Customer-edge egress-traffic management (CEETM)

Customer-edge egress-traffic management (CEETM) is a DPAA enhancement first appearing in the T4240. T4240 continues to support the work queue and frame queue scheduling functionality available in the P4080 and other first generation QorIQ chips, but introduces alternative functionary, CEETM, that can be mode selected on a network interface basis to support the shaping and scheduling requirements of carrier Ethernet connected systems.

1.3.9.6.2.1 CEETM features

Each instance of CEETM (one per FMan) provides the following features:

- Supports hierarchical multi-level scheduling and shaping, which:
  - is performed in an atomic manner; all context at all levels is examined and updated synchronously.
  - employs no intermediate buffering between class queues and the direct connect portal to the FMan.
- Supports dual-rate shaping (paired committed rate (CR) shaper and excess rate (ER) shaper) at all shaping points.
  - Shapers are token bucket based with configurable rate and burst limit.
  - Paired CR/ER shapers may be configured as independent or coupled on a per pair basis; coupled means that credits to the CR shaper in excess of its token bucket limit is credited to the ER bucket
- Supports eight logical network interfaces (LNI)
  - Each LNI:
    - aggregates frames from one or more channels.
    - priority schedules unshaped frames (aggregated from unshaped channels), CR frames, and ER frames (aggregated from shaped channels)
    - applies a dual-rate shaper to the aggregate of CR/ER frames from shaped channels
    - can be configured (or reconfigured for lossless interface failover) to deliver frames to any network interface.
- Supports 32 channels available for allocation across the eight LNIs
- Each channel:
  - can be configured to deliver frames to any LNI.
  - can be configure to be unshaped or shaped; when shaped, a dual rate shaper applies to the aggregate of CR/ER frames from the channel.
  - has eight independent classes and eight grouped classes; grouped classes can be configured as one class group of eight or as two class groups of four.
  - supports weighted bandwidth fairness within grouped class groups with weights configured on a channel and class basis.

    - strict priority scheduling of the eight independent classes and the aggregate(s) of the grouped classe(s); the priority of each of the two class groups can be independently configured to be immediately below any of the independent classes.
    - is configurable such that each of the eight independent classes and two class groups can supply CR frames, ER frames or both when channel is configured to be shaped.
    - is configured independently.
- Each class:
    - has a dedicated class queue (CQ) with equivalent congestion management functionality available to FQs.
    - can have a dedicated or shared Congestion Management Record supports sufficient number of CMRs for all CQs to have a dedicated CMR, if desired.
    - can be flow-controlled by traffic-class flow control messages via portal; achieves backward compatibility with by allowing each of these 16 classes to be configured (per LNI) to respect one or none of the 8 on/off control bits within existing message format (as was defined for 8-class non-CEETM channels).
    - is identified via a "logical frame queue identifier" to maintain semantic compatibility with enqueue commands to frame queues (non-CEETM queues).
    - supports the identification of intra-class flows (logically equivalent to FQs but not queued separately) in order to apply static context (Context_A and Context_B) to frames as they are dequeued from CQs; this provides functionality equivalent to that available when a frame is dequeue from a frame queue (non-CEETM queues).

1.3.9.6.2.2 CEETM configuration

The CEETM configuration, shown in Figure 1-6, is very asymmetrical and is intended to demonstrate the degrees of configurability rather than an envisioned use case.

NOTE

The color green denotes logic units and signal paths that relate to the request and fulfillment of committed rate (CR) packet transmission opportunities. The color yellow denotes the same for excess rate (ER). The color black denotes logic units and signal paths that are used for unshaped opportunities or that operate consistently whether used for CR or ER opportunities.

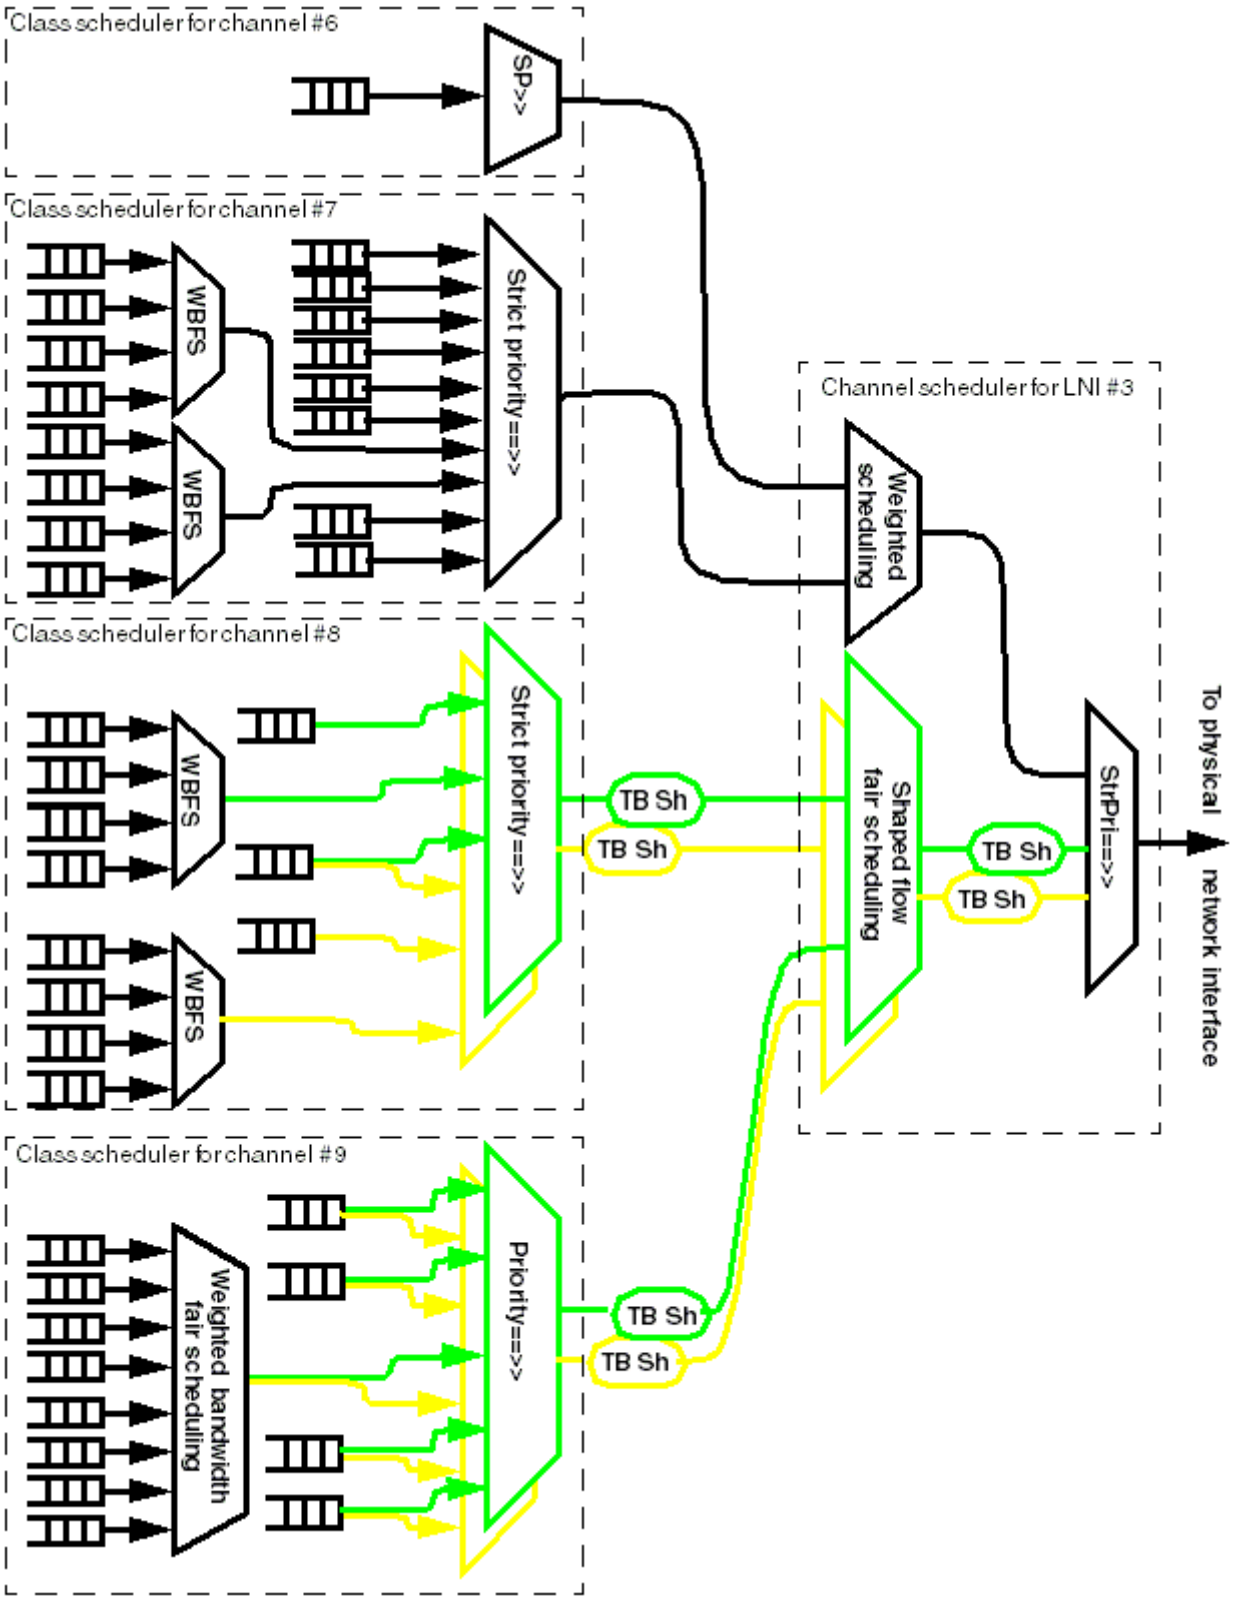

Figure 1-6. CEETM scheduler: illustrative configuration scenario

Figure 1-6 illustrates the following scenario:

- Channels #6, #7, #8 and #9 have been configured to be scheduled by the channel scheduler for LNI#3 (for example, all the packets from these channels are directed to the physical network interface configurably coupled to LNI#3).
- Channels #6 and #7 have been configured to be "unshaped." Packets from these channels will not be subjected to shaping at the channel level and will feed the top priority level within the LNI, which is also not subjected to shaping. Their class schedulers will not distinguish between CR and ER opportunities.
- Channels #8 and #9 have been configured to be "shaped." Their class schedulers will distinguish between CR and ER opportunities. The CR/ER packets to be sent from each channel shall be subjected to a pair of CR/ER token bucket shapers specific to that channel. The aggregate of CR/ER packets from these channels are subject to a pair of CR/ER token bucket shapers specific to LNI#3.
- Channel #6 has only one class in use. That class queue behaves as if it were a channel queue and as a peer to Channel #7. Unused classes do not have to be configured as such; they are simply not used.
- Channel #7 has all 16 classes in use.
  - The group classes have been configured as two groups (A and B) of four classes.
  - The priority of the groups A and B have both been set to be immediately below independent class 5. In a case of similar configuration group A has higher priority than group B.
- Channel #8 has three independent classes and two groups of four grouped classes in use.
  - The priorities of the class groups A and B have been set to be immediately below independent class 0 and class 2 respectively.
  - Independent class 0 and class group A have been configured to request and fulfill only CR packet opportunities.
  - Independent class 1 has been configured to request and fulfill both CR and ER packet opportunities.
  - Independent class 2 and class group B have been configured to request and fulfill only ER packet opportunities.
- Channels #9 has four independent classes and one group of eight grouped classes in use.
  - The group classes have been configured as one group (A) of eight classes.
  - All independent classes and the class group (A) have been configured to request and fulfill both CR and ER packet opportunities.

Benefits of the CEETM include the following:

- Provides "virtual" ports for multiple applications or users with different QoS/CoS requirements which are sharing an egress interface
- Supports DSCP capable scheduling for the following virtual link with configurable combinations of strict priority and weighted scheduling

    - Weighted scheduling closely approximating WFQ
- Supports traffic shaping
    - dual rate shaping of the virtual links
- Supports aggregating traffic from multiple virtual links and shaping this aggregate
- Hierarchical scheduling and shaping
- Class-based scheduling and dual rate shaping
- Supports a subset of the IEEE Data Center Bridging (DCB) standards

1.3.9.6.3 Data Center Bridging (DCB)

Data Center Bridging (DCB) refers to a series of inter-related IEEE specifications collectively designed to enhance Ethernet LAN traffic prioritization and congestion management. Although the primary objective is the data center environment (consisting of servers and storage arrays), some aspects of DCB are applicable to more general uses of Ethernet, within and between network nodes.

The SoC DPAA is compliant with the following DCB specifications :

- IEEE Std. 802.1Qbb: Priority-based flow control (PFC)
    - PAUSE frame per Ethernet priority code point (8)
    - Prevents single traffic class from throttling entire port
- IEEE Std. 802.1Qaz: Enhanced transmission selection (ETS)
    - Up to three Traffic Class Groups (TCG), where a TCG is composed of one or more priority code points
    - Bandwidth allocation and transmit scheduling (1% granularity) by traffic class group
    - If one of the TCGs does not consume its allocated bandwidth, unused bandwidth is available to other TCGs

1.3.10 Resource partitioning and QorIQ Trust Architecture

Consolidation of discrete CPUs into a single, multicore chip introduces many opportunities for unintended resource contentions to arise, particularly when multiple, independent software entities reside on a single chip. A system may exhibit erratic behavior if multiple software partitions cannot effectively partition resources. Device consolidation, combined with a trend toward embedded systems becoming more open (or more likely to run third-party or open-source software on at least one of the cores), creates opportunities for malicious code to enter a system.

This chip offers a new level of hardware partitioning support, allowing system developers to ensure software running on any CPU only accesses the resources (memory, peripherals, and so on) that it is explicitly authorized to access. This section provides an

overview of the features implemented in the chip that help ensure that only trusted software executes on the CPUs, and that the trusted software remains in control of the system with intended isolation.

1.3.10.1 Core MMU, UX/SX bits, and embedded hypervisor

The chip's first line of defense against unintended interactions amongst the multiple CPUs/OSes is each core vCPU's MMU. A vCPU's MMU is configured to determine which addresses in the global address map the CPU is able to read or write. If a particular resource (memory region, peripheral device, and so on) is dedicated to a single vCPU, that vCPU's MMU is configured to allow access to those addresses (on 4 KB granularity); other vCPU MMUs are not configured for access to those addresses, which makes them private. When two vCPUs need to share resources, their MMUs are both configured so that they have access to the shared address range.

This level of hardware support for partitioning is common today; however, it is not sufficient for many core systems running diverse software. When the functions of multiple discrete CPUs are consolidated onto a single multicore chip, achieving strong partitioning should not require the developer to map functions onto vCPUs that are the exclusive owners of specific platform resources. The alternative, a fully open system with no private resources, is also unacceptable. For this reason, the core's MMU also includes three levels of access permissions: user, supervisor (OS), and hypervisor. An embedded hypervisor (for example, KVM, XEN, QorIQ ecosystem partner hypervisor) runs unobtrusively beneath the various OSes running on the vCPUs, consuming CPU cycles only when an access attempt is made to an embedded hypervisor-managed shared resource.

The embedded hypervisor determines whether the access should be allowed and, if so, proxies the access on behalf of the original requestor. If malicious or poorly tested software on any vCPU attempts to overwrite important device configuration registers (including vCPU's MMU), the embedded hypervisor blocks the write. High and low-speed peripheral interfaces (PCI Express, UART), when not dedicated to a single vCPU/ partition, are other examples of embedded hypervisor managed resources. The degree of security policy enforcement by the embedded hypervisor is implementation-dependent.

In addition to defining regions of memory as being controlled by the user, supervisor, or hypervisor, the core MMU can also configure memory regions as being non-executable. Preventing CPUs from executing instructions from regions of memory used as data buffers is a powerful defense against buffer overflows and other runtime attacks. In previous generations of Power Architecture, this feature was controlled by the NX (no execute) attribute. In new Power Architecture cores such as the e6500 core, there are separate bits controlling execution for user (UX) and supervisor (SX).

1.3.10.2 Peripheral access management unit (PAMU)

MMU-based access control works for software running on CPUs; however, these are not the only bus masters in the SoC. Internal components with bus mastering capability (FMan, RMan, PCI Express controller, PME, SEC, and so on) also need to be prevented from reading and writing to certain memory regions. These components do not spontaneously generate access attempts; however, if programmed to do so by buggy or malicious software, any of them could read or write sensitive data registers and crash the system. For this reason, the SoC also includes a distributed function referred to as the peripheral access management unit (PAMU).

PAMUs provide address translation and access control for all non-CPU initiators in the system. PAMU access control is based on the logical I/O device number (LIODN) advertised by a bus master for a given transaction. LIODNs can be static (for example, PCI Express controller #1 always uses LIODN 123) or they can be dynamic, based on the ID of the CPU that programmed the initiator (for example, the SEC uses LIODN 456 because it was given a descriptor by vCPU #2). In the dynamic example, the SoC architecture provides positive identification of the vCPU programming the SEC, preventing LIODN spoofing.

1.3.10.3 IO partitioning

The simplest IO configuration in chips running multiple independent software partitions is to dedicate specific IO controllers (PCI Express, SATA, Serial RapidIO controllers) to specific vCPUs. The core MMUs and PAMUs can enforce these access permissions to insure that only the software partition owning the IO is able to use it. The obvious problem with this approach is that there are likely to be more software partitions wanting IO access than there are IO controllers to dedicate to each.

Safe IO sharing can be accomplished through the use of a hypervisor; however, there is a performance penalty associated with virtual IO, as the hypervisor must consume CPU cycles to schedule the IO requests and get the results back to the right software partition.

The DPAA (described in Data Path Acceleration Architecture (DPAA)") was designed to allow multiple partitions to efficiently share accelerators and IOs, with its major capabilities centered around sharing Ethernet ports. These capabilities were enhanced in the chip with the addition of FMan storage profiles. The chip's FMans perform classification prior to buffer pool selection, allowing Ethernet frames arriving on a single port to be written to the dedicated memory of a single software partition. This capability is fully described in Receiver functionality: parsing, classification, and distribution."

The addition of the RMan extends the chip's IO virtualization by allowing many types of traffic arriving on Serial RapidIO to enter the DPAA and take advantage of its inherent virtualization and partitioning capabilities.

The PCI Express protocol lacks the PDU semantics found in Serial RapidIO, making it difficult to interwork between PCI Express controllers and the DPAA; however, PCI Express has made progress in other areas of partition. The Single Root IO Virtualization specification, which the chip supports as an endpoint, allows external hosts to view the chip as multiple four physical functions (PFs), where each PF supports up to 64 virtual functions (VFs). Having multiple VFs on a PCI Express port effectively channelizes it, so that each transaction through the port is identified as belonging to a specific PF/VF combination (with associated and potentially dedicated memory regions). Message signalled interrupts (MSIs) allow the external Host to generate interrupts associated with a specific VF.

1.3.10.4 Secure boot and sensitive data protection

The core MMUs and PAMU allow the SoC to enforce a consistent set of memory access permissions on a per-partition basis. When combined with an embedded hypervisor for safe sharing of resources, the SoC becomes highly resilient to poorly tested or malicious code. For system developers building high reliability/high security platforms, rigorous testing of code of known origin is the norm.

For this reason, the SoC offers a secure boot option, in which the system developer digitally signs the code to be executed by the CPUs, and the SoC insures that only an unaltered version of that code runs on the platform. The SoC offers both boot time and run time code authenticity checking, with configurable consequences when the authenticity check fails. The SoC also supports protected internal and external storage of developer-provisioned sensitive instructions and data. For example, a system developer may provision each system with a number of RSA private keys to be used in mutual authentication and key exchange. These values would initially be stored as encrypted blobs in external non-volatile memory; but, following secure boot, these values can be decrypted into on-chip protected memory (portion of platform cache dedicated as SRAM). Session keys, which may number in the thousands to tens of thousands, are not good candidates for on-chip storage, so the SoC offers session key encryption. Session keys are stored in main memory, and are decrypted (transparently to software and without impacting SEC throughput) as they are brought into the SEC 5.0 for encryption or decryption of session traffic.

1.3.11 Advanced power management

Power dissipation is always a major design consideration in embedded applications; system designers need to balance the desire for maximum compute and IO density against single-chip and board-level thermal limits.

Advances in chip and board level cooling have allowed many OEMs to exceed the traditional 30 W limit for a single chip, and NXP's flagship T4240 multicore chip, has consequently retargeted its maximum power dissipation. A top-speed bin T4240 dissipates approximately 2x the power dissipation of the P4080; however, the T4240 increases computing performance by ~4x, yielding a 2x improvement in DMIPs per watt.

To achieve the previously-stated 2x increase in performance per watt, the chip implements a number of software transparent and performance transparent power management features. Non-transparent power management features are also available, allowing for significant reductions in power consumption when the chip is under lighter loads; however, non-transparent power savings are not assumed in chip power specifications.

1.3.11.1 Transparent power management

This chip's commitment to low power begins with the decision to fabricate the chip in 28 nm bulk CMOS. This process technology offers low leakage, reducing both static and dynamic power. While 28 nm offers inherent power savings, transistor leakage varies from lot to lot and device to device. Leakier parts are capable of faster transistor switching, but they also consume more power. By running devices from the leakier end of the process spectrum at less than nominal voltage and devices from the slower end of the process spectrum at higher nominal voltage, T4240-based systems can achieve the required operating frequency within the specified max power. During manufacturing, NXP will determine the voltage required to achieve the target frequency bin and program this Voltage ID into each device, so that initialization software can program the system's voltage regulator to the appropriate value.

Dynamic power is further reduced through fine-grained clock control. Many components and subcomponents in the chip automatically sleep (turn off their clocks) when they are not actively processing data. Such blocks can return to full operating frequency on the clock cycle after work is dispatched to them. A portion of these dynamic power savings are built into the chip max power specification on the basis of impossibility of all processing elements and interfaces in the chip switching concurrently. The percent switching factors are considered quite conservative, and measured typical power consumption on QorIQ chips is well below the maximum in the data sheet.

As noted in Frame Manager and network interfaces, the chip supports Energy-Efficient Ethernet. During periods of extended inactivity on the transmit side, the chip transparently sends a low power idle (LPI) signal to the external PHY, effectively telling it to sleep.

Additional power savings can be achieved by users statically disabling unused components. Developers can turn off the clocks to individual logic blocks (including CPUs) within the chip that the system is not using. Based on a finite number of SerDes, it is expected that any given application will have some inactive Ethernet MACs, PCI Express, or serial RapidIO controllers. Re-enabling clocks to a logic block generally requires an chip reset, which makes this type of power management infrequent (effectively static) and transparent to runtime software.

1.3.11.2 Non-transparent power management

Many load-based power savings are use-case specific static configurations (thereby software transparent), and were described in the previous section. This section focuses on SoC power management mechanisms, which software can dynamically leverage to reduce power when the system is lightly loaded. The most important of these mechanisms involves the cores.

At a high level, the most important of these states can be viewed as "PH10" and "PH20," described as follows. Note that these are relative terms, which do not perfectly correlate to previous uses of these terms in Power Architecture and other ISAs:

- In PH10 state CPU stops instruction fetches but still performs L1 snoops. The CPU retains all state, and instruction fetching can be restarted instantly.
- In PH20 state CPU stops instruction fetches and L1 snooping, and turns off all clocks. Supply voltage is reduced, using a technique NXP calls State Retention Power Gating (SRPG). In the "napping" state, a CPU uses ~75% less power than a fully operational CPU, but can still return to full operation quickly (~100 platform clocks).

The core offers two ways to enter these (and other) low power states: registers and instructions.

As the name implies, register-based power management means that software writes to registers to select the CPU and its low power state. Any CPU with write access to power management registers can put itself, or another CPU, into a low power state; however, a CPU put into a low power state by way of register write cannot wake itself up.

Instruction-based power management means that software executes special WAIT instruction to enter a low power state. CPUs exit the low power state in response to external triggers, interrupts, doorbells, stashes into L1-D cache, or clear reservation on snoop. Each vCPU can independently execute WAIT instructions; however, the physical CPU enters PH20 state after the second vCPU executes its wait. The instruction-based "enters PH20 state" state is particularly well-suited for use in conjunction with NXP's patented Cascade Power Management, which is described in the next section.

While significant power savings can be achieved through individual CPU low power states, the SoC also supports a register-based cluster level low power state. After software puts all CPUs in a cluster in a PH10 state, it can additionally flush the L2 cache and have the entire cluster enter PH20 state . Because the L2 arrays have relatively low static power dissipation, this state provides incremental additional savings over having four napping CPUs with the L2 on.

1.3.11.3 Cascade power management

Cascade power management refers to the concept of allowing SoC load, as defined by the depth of queues managed by the Queue Manager, to determine how many vCPUs need to be awake to handle the load. Recall from Queue Manager that the QMan supports both dedicated and pool channels. Pool channels are channels of frame queues consumed by parallel workers (vCPUs), where any worker can process any packet dequeued from the channel.

Cascade Power Management exploits the QMan's awareness of vCPU membership in a pool channel and overall pool channel queue depth. The QMan uses this information to tell vCPUs in a pool channel (starting with the highest numbered vCPU) that they can execute instructions to "take a nap." When pool channel queue depth exceeds configurable thresholds, the QMan wakes up the lowest numbered vCPU.

The SoC's dynamic power management capabilities, whether using the Cascade scheme or a master control CPU and load to power matching software, enable up to a 75% reduction to each corein power consumption versus data sheet max power.

1.3.12 Debug support

Processing on a multicore chip with shared caches and peripherals also leads to greater concurrency and an increased potential for unintended interactions between device components. To ensure that software developers have the same or better visibility into the device as they would with multiple discrete communications processors, NXP developed an Advanced Multicore Debug Architecture.

The debugging and performance monitoring capability enabled by the device hardware coexists within a debug ecosystem that offers a rich variety of tools at different levels of the hardware/software stack. Software development and debug tools from NXP (CodeWarrior), as well as third-party vendors, provide a rich set of options for configuring, controlling, and analyzing debug and performance related events.

1.3.13 JTAG

The JTAG Test Access Port (TAP) and Boundary Scan Architecture is designed to comply with IEEE Std. 1149.1™ and 1149.6™. The JTAG IDCODE is 0x0022_001D

Table 1-7. JTAG IDCODE

Field	Assignment (hex)	Comments
0:3	0000	Fixed
4:9	0000_00	Freescale Design Center
10:17	10_0010_00	Device number
18	0	Package Size
19	0	Number of Cores
20:31	0000_0001_1101	Manufacturer ID (FSL)

Chapter 2
Memory Map

2.1 Memory Map Overview

This chapter describes the mechanisms that define the device memory map: the local access windows (LAWs), the address translation and mapping units (ATMUs), and the configuration, control, and status registers (CCSRs).

There are several address domains within the device, including the following:

- Logical, virtual, and physical (real) address spaces within the Power Architecture core(s)
- Internal local address space
  - Internal configuration, control, and status register (CCSR) address space, which is a special-purpose subset of the internal local address space
  - Internal debug control and status register (DCSR) address space, which is another special-purpose set of registers mapped in the internal local address space
- External memory, I/O, and configuration address spaces of the serial RapidIO link
- External memory, I/O, and configuration address spaces of the PCI Express links

The MMU in the core handles translation of logical (effective) addresses, into virtual addresses, and ultimately to the physical addresses for the local address space. The MMU is described in the *e6500 Core Reference Manual*.

The local address map refers to the physical address space seen by the core as it accesses memory and I/O space. The DMA engines also see this same local address map. All memory controlled by the DDR and other modules exists in this address map, as do all memory-mapped configuration, control, and status registers (CCSRs). The local address map is defined by a set of 32 local access windows (LAWs). Each of these windows maps a region of the local address space to a specified target interface, such as the DDR controller, PCI Express controller, or other targets. The internal configuration, control,

and status registers (CCSRs) for all the functional blocks are located in the local memory space at a specific CCSR window. There is also a fixed (8 MB of local memory space) default boot window from 00_FF80_0000h to 00_FFFF_FFFFh.

The internal debug control and status registers (DCSRs) control the hardware debug and performance monitoring capabilities of many functional blocks. The DCSRs are mapped into the local memory space by specifying the DCSR space as a LAW target.

If the target mapping performed by the local access windows directs the transaction to one of the external peripheral interfaces (as an outbound read or write), the transaction is then mapped into that interface's external address space by the address translation and mapping unit (ATMU) windows associated with the external interface. Outbound ATMUs perform the mapping from the local address space to the address space of the external peripheral interface; inbound ATMU windows perform the address translation from the external address space to the local address space.

2.2 Global Source and Target IDs

In many instances throughout the system, certain register or packet fields need to indicate or specify a transaction source or target. Table 2-1 provides the encodings used for these fields.

Table 2-1. T4240 Global Source/Target ID Assignments

Source/Target ID Value	Transaction source	Transaction target	Notes

2.3 Local Access Windows (LAWs)

The local address map is defined by a set of 32 local access windows (LAWs).

Each of these windows maps a programmable region of the local address space to a specified target interface, such as the DDR controller, 512 KB platform SRAM, or other targets. This allows the internal interconnections of the device to route a transaction from its source to the proper target.

Each LAW is defined by a pair of base address registers that specify the starting address for the window, and an attribute register that specifies whether the mapping is enabled, the size of the window, a coherency subdomain, and the target interface for that window. Note that the LAWs do not perform any address translation, and therefore there are no corresponding translation address registers. The local access window registers exist as part of the local access control block in the CCSR space.

With the exception of configuration space (mapped by CCSRBAR) and the boot window, all addresses used by the system must be mapped by a LAW. This includes addresses that are mapped by inbound ATMU windows. Thus, target mappings of the LAWs and the inbound ATMU windows must be consistent.

2.3.1 Precedence of Local Access Windows

If two or more LAWs overlap, the lower-numbered window takes precedence.

For example, consider two LAWs, set up as shown in Table 2-2.

Table 2-2. Overlapping Local Access Windows

LAW	Base Address	Size	Target Interface
1	00_7FF0_0000h	1 MB	Integrated flash controller (IFC)
2	00_0000_0000h	2 GB	Memory complex (DDR controller)

In this case, LAW 1 governs the mapping of the 1 MB region from 00_7FF0_0000h to 00_7FFF_FFFFh, even though the window described in LAW 2 also encompasses that memory region.

NOTE

The CCSR mapping, defined by the CCSRBARs, supersedes all local access window mappings.

NOTE

The boot window is another special area. In unsecured boot, the boot window has lower priority than the LAWs. However, secure boot, will preempt accesses to the boot window and send them to the internal secure boot code (ISBC). In this case, the secure boot effectively makes the boot window higher priority than the LAWs.

2.3.2 Configuring Local Access Windows

Once a local access window is enabled, it should not be modified while any device in the system may be using the window.

Neither should a new window be used until the effect of the write to the window is visible to all blocks that use the window. This can be guaranteed by completing a read of the last LAW configuration register before enabling any other devices to use the window. For example, if LAWs 0-3 are being configured in order during the initialization process, the last write (to LAWAR3) should be followed by a read of LAWAR3 before any devices try to use any of these windows. If the configuration is being performed by the core, the read of LAWAR3 should be followed by an **isync** instruction.

2.3.3 Distinguishing Local Access Windows from Other Mapping Functions

It is important to distinguish between the mapping function performed by the LAWs and the additional mapping functions that occur at the target interfaces.

The LAWs define how a transaction is routed through the device's internal interconnects from the transaction's source to its target. After the transaction has arrived at its target interface, that interface controller may perform additional mapping. For instance, the DDR controller has chip select registers that map a memory request to a particular external device. Similarly, the integrated flash controller has base registers that perform a similar function. The external peripheral interface controllers (for example, serial RapidIO and PCI Express) have outbound address translation and mapping units (ATMUs) that map the local address into an external address space.

These other mapping functions are configured by programming the CCSRs of the individual interfaces. Note that there is no need to have a one-to-one correspondence between LAWs and chip select regions or outbound ATMU windows. A single LAW can be further decoded to any number of chip selects or to any number of outbound ATMU windows at the target interface.

2.3.4 SRAM Windows

The CoreNet platform cache (CPC) can be configured as a memory-mapped SRAM.

The CPC SRAM control registers (CPCSRCRs) in the CPC cache controller set the base addresses and sizes for these windows. See SRAM Mode Registers for information about configuring SRAM windows.

In addition to defining the SRAM regions in the CPCSRCRs, the CPC SRAM regions need to be covered by LAWs using their associated memory complex as the target ID (TRGT_ID).

2.3.5 Local Address Map Example

Figure 2-1 shows what a typical local address map might look like.

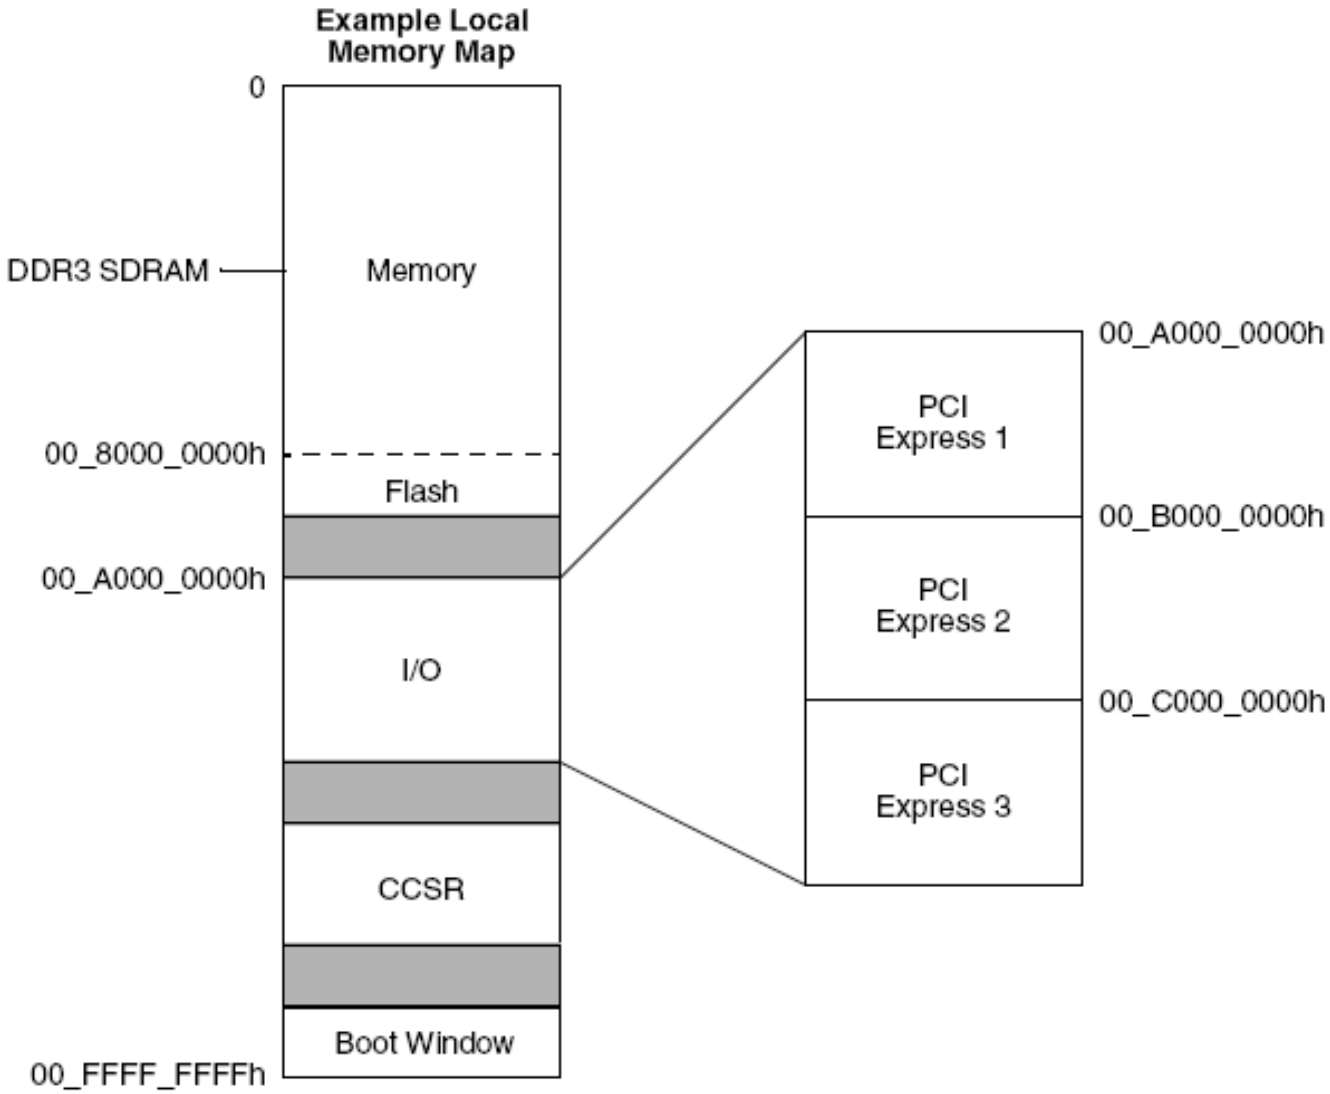

Figure 2-1. Local Address Map Example

Table 2-3 shows the corresponding set of LAW settings for the example shown in Figure 2-1.

Table 2-3. Local Access Window Settings Example

Window	Base Address	SIZE	Target Interface
0	00_0000_0000h	2 Gbytes	DDR
1	00_8000_0000h	1 Mbyte	Integrated Flash controller (IFC) - Flash
2	00_A000_0000h	256 Mbytes	PCI Express 1
3	00_B000_0000h	256 Mbytes	PCI Express 2
4	00_C000_0000h	256 Mbytes	PCI Express 3
5-9	Unused		

In this example, note that it is not required to define a LAW to describe the range of memory used for memory-mapped configuration, control, and status registers because these occupy a fixed 16-Mbyte space pointed to by the CCSRBARs. See Accessing Configuration, Control, and Status Registers. Also note that the boot window is always enabled and covers local addresses from 00_FF80_0000h to 00_FFFF_FFFFh.

2.4 Local Access Window (LAW) Memory Map

The table below shows the memory map for the LAW registers. The local access window registers are accessed by reading and writing to an address comprised of the base address (specified in the CCSRBAR), plus the block base address, plus the offset of the specific register to be accessed. For the LAWs, the block base address is local access control block at 0x00_0000.

Note that all LAW registers should only be accessed a word (4 bytes) at a time.

LAW memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
C00	LAWn base address register high (LAW_LAWBARH0)	32	R/W	0000_0000h	2.4.1/145

LAW memory map (continued)

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
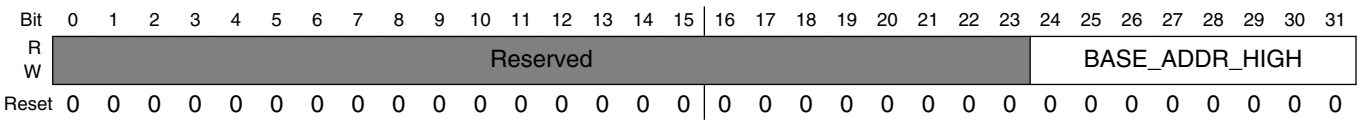
DF8	LAWn attribute register (LAW_LAWAR31)	32	R/W	0000_0000h	2.4.3/146

2.4.1 LAWn base address register high (LAW_LAWBARH*n*)

Address: 0h base + C00h offset + (16d × i), where i=0d to 31d

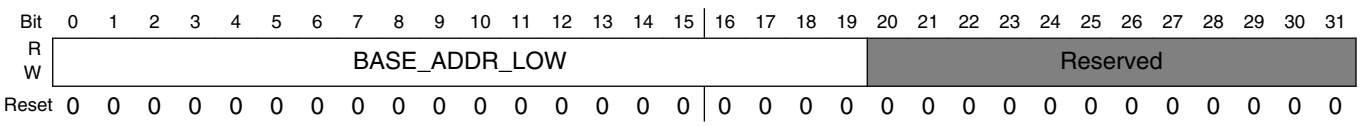


LAW_LAWBARH*n* field descriptions

Field	Description
0–23 -	This field is reserved. Reserved
24–31 BASE_ADDR_ HIGH	Identifies bits 0-7 of the 40-bit base address of local access window*n*. The specified base address should be aligned to the window size, as defined by LAWAR*n*[SIZE].

2.4.2 LAWn base address register low (LAW_LAWBARL*n*)

Address: 0h base + C04h offset + (16d × i), where i=0d to 31d

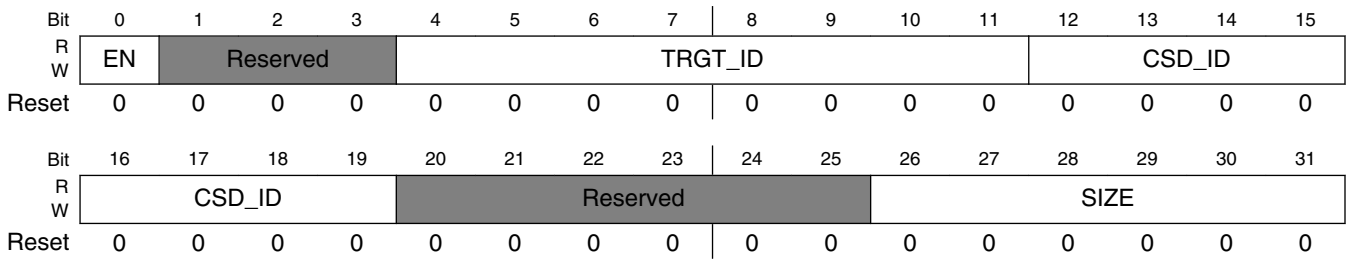


LAW_LAWBARL*n* field descriptions

Field	Description
0–19 BASE_ADDR_ LOW	Identifies bits 8-27 of the 40-bit base address of local access window *n* . The specified base address should be aligned to the window size, as defined by LAWAR *n* [SIZE].
20–31 -	This field is reserved. Write reserved, read = 0. Because the minimum window size is 4 KB, the 12 least significant bits are treated as zeros.

2.4.3 LAWn attribute register (LAW_LAWAR*n*)

Address: 0h base + C08h offset + (16d × i), where i=0d to 31d



LAW_LAWAR*n* field descriptions

Field	Description
0 EN	Enable 0 The local access window *n* (and all other LAWAR *n* and LAWBAR *n* fields) are disabled. 1 The local access window *n* is enabled and other LAWAR *n* and LAWBAR *n* fields combine to identify an address range for this window.
1–3 -	This field is reserved. Write reserved, read = 0
4–11 TRGT_ID	Target identifier. Identifies the target interface when a transaction hits in the address range defined by this window. See Global Source and Target IDs for the defined encodings. **NOTE:** • CPC SRAM regions are generally mapped by LAWs using their associated memory complex target ID. However, these regions also need to be defined by the CPC SRAM control registers (CPCSRCRs) in the CPC block. • Configuration registers are mapped by the windows defined by the CCSRBARs. These mappings supersede local access window mappings, so configuration registers do not appear as a target for local access windows. • Whenever a Local Access Window targets DCSR space, the size of this space must always be set to 4 MB. • TRGT_ID = 0x0F (local space) is an illegal encoding in the LAWARn registers and causes a local access error (CEDR[LAE]) if detected.
12–19 CSD_ID	Coherency subdomain identifier. Identifies a group of one or more partitions that have access to the address space defined by this access window. Each such group may contain one or more processors and/or other caching devices representing a coherency subdomain within the system. For a coherent access via this window, coherency is enforced over this subdomain.
20–25 -	This field is reserved. Write reserved, read = 0
26–31 SIZE	Identifies the size of the window from the starting address. Window size is 2 $^{(SIZE+1)}$ bytes. Example values are as follows: **NOTE:** When using DMA with OCN peripherals (PEX or SRIO), the local access window size for the OCN peripherals must be less than or equal to 64 GBytes. 000000-001010 Reserved 001011 4 KB 001100 8 KB 100010 32 GB 100011 64 GB

2.5 Address Translation and Mapping Units

To facilitate flexibility in defining the address maps for the external interfaces (serial RapidIO and PCI Express), the device provides address translation and mapping units (ATMUs).

The following types of translation and mapping operations are performed by the ATMUs:

- Translating the local address to an external address space
- Translating external addresses to the local address space
- Assigning attributes to transactions
- Mapping a local address to a target interface

Outbound address translation and mapping refers to the translation of addresses from the local address space to the external address space and attributes of a particular I/O interface.

Inbound address translation and mapping refers to the translation of an address from the external address space of an I/O interface to the local address space understood by the internal interfaces of this device. It also refers to the mapping of transactions to a particular target interface and the assignment of transaction attributes. Note that in mapping the transaction to the target interface, an inbound ATMU window performs a function similar to that of the local access windows. The target mappings created by an inbound ATMU must be consistent with those of the LAWs. That is, if an inbound ATMU maps a transaction to a given local address and a given target, a LAW must also map that same local address to the same target.

2.5.1 Address Translation

All of the configuration registers that define an ATMU window's translation and mapping functions follow the same general register format.

The register format is summarized in Table 2-4.

Table 2-4. Format of ATMU Window Definitions

Register	Function
Translation address (TAR/TEAR)	High-order address bits defining location of the window in the target address space
Base address (BAR/BEAR)	High-order address bits defining location of the window in the initiator address space
Window attributes (WAR)	Window enable, window size, target interface, and transaction attributes

The size of the windows must be a power-of-two. To perform a translation or mapping function, the address of the transaction is compared with the base address register of each window. The number of bits used in the comparison is dictated by each window's size attribute. When an address hits a window, if address translation is being performed, the new translated address is created by concatenating the window offset to the translation address. Again, the window's size attribute dictates how many bits are translated.

2.5.2 Outbound ATMUs

If the target mapping performed by the local access windows directs the transaction to one of the external peripheral interfaces (as an outbound read or write), the transaction is then mapped into that interface's external address space by outbound ATMUs associated with the external interface.

The outbound ATMUs perform the mapping from the local address space to the address space of the external peripheral interface, which may be much larger than the local space.

The outbound ATMUs also map attributes such as the transaction type and priority level.

The serial RapidIO controller has eight outbound ATMU windows plus a default window. Each PCI Express controller has four outbound ATMU windows plus a default window. If a transaction's address does not hit any of the outbound ATMU windows, the translation actions defined by the default window are used. The default window is always enabled. The outbound ATMU registers include extended translation address registers so that up to 64 bits of external address space can be supported.

2.5.3 Inbound ATMUs

The inbound ATMUs perform the address translation from the external address spaces to the local address space, attach attributes and transaction types to the transaction, and also map the transaction to its target interface.

The serial RapidIO controller has four inbound ATMU windows plus a default window. If the inbound transaction's address does not hit any of the inbound ATMU windows, the translation actions defined by the default window are used.

Each PCI Express controller has four inbound ATMU windows plus a fixed MSI ATMU window for mapping inbound message-signalled interrupt transactions to the interrupt controller (MPIC).

2.5.3.1 Illegal Interaction Between Inbound ATMUs and LAWs

Since both local access windows and inbound ATMUs map transactions to a target interface, it is essential that they not contradict one another.

For example, it is considered a programming error to have an inbound ATMU map a transaction target to the local memory space if the resulting translated local address is mapped to an external peripheral interface by a local access window. Such programming errors may result in unpredictable system deadlocks.

2.6 Configuration, Control, and Status Register (CCSR) Space

To allow for flexibility, the configuration, control, and status register space is relocatable in the local address space.

The local address map location of this register block is controlled by the configuration, control, and status registers base address register (CCSRBAR), see Accessing Configuration, Control, and Status Registers.

The default value for CCSRBAR is 00_FE00_0000h.

2.6.1 Accessing CCSR Memory from the Local Processor

When the local processor cores are used to configure CCSR space, the CCSR memory space should typically be marked as cache-inhibited and guarded.

In addition, many configuration registers affect accesses to other memory regions; therefore writes to these registers must be guaranteed to have taken effect before accesses are made to the associated memory regions.

To guarantee that the results of any sequence of writes to configuration registers are in effect, the final configuration register write should be immediately followed by a read of the same register, and that should be followed by a SYNC instruction. Then accesses can safely be made to memory regions affected by the configuration register write.

2.6.2 Accessing CCSR Memory from External Masters

In addition to being accessible by the processor cores, the configuration, control, and status registers are accessible from external interfaces.

This allows external masters on the I/O ports to configure the device.

External masters do not need to know the location of the CCSR memory in the local address map. Rather, they access this region of the local memory map through a window defined by a register in the interface programming model that is accessible to the external master from its external memory map.

The PCI Express controller's base address for accessing the local CCSR memory is selectable through the PCI Express configuration and status register base address register (PEXCSRBAR), at offset 0x10. An external PCI Express root complex host sets this register by running a PCI Express configuration transaction. Subsequent memory accesses by a PCI Express master to the PCI Express address range indicated by PEXCSRBAR are translated to the local address indicated by the current setting of CCSRBAR.

The serial RapidIO base address for accessing the local CCSR memory is selectable through the serial RapidIO LCSBA1CSR, defined in the RapidIO programming model. See Local configuration space base address 1 command and status register. An external serial RapidIO master can set the value of LCSBA1CSR with a maintenance packet. Then subsequent read and write packets whose RapidIO addresses match the window defined by LCSBA1CSR are translated to the local address range indicated by CCSRBAR.

2.6.3 Accessing Reserved Registers and Bits

Reserved registers and bits in the CCSR memory space are not guaranteed to have predictable values.

In general, reads of reserved bits return zeros, but software should not rely on the value of any reserved bit being a zero or remaining consistent.

Unless otherwise specified, when writing registers in CCSR memory space, reserved bits should be written with zeros.

Writing ones to a reserved bit may result in undefined operation.

2.6.4 Organization of CCSR Memory

The configuration, control, and status registers are grouped according to functional units.

Most functional units are allocated a 4 KB address space for registers.

Some functional units have larger address spaces as defined by their programming models. The registers for these blocks are given their own larger regions of CCSR memory.

2.6.5 CCSR Address Map

The full register address of any CCSR is comprised of the CCSR window base address, specified in CCSRBAR (default address 00_FE00_0000h), plus the functional block base address, plus the specific register's offset within that block.

Table 2-5 shows the location of the functional block base addresses for the entire CCSR space. Cross-references are provided to the CCSR maps for each individual block.

Chapter 3
Signal Descriptions

3.1 Signals Introduction

This chapter describes the external signals and is organized into the following sections:

- Overview of signals and cross-references for signals that serve multiple functions
- List of reset configuration signals
- Signal multiplexing details
- List of output signal states at reset

3.2 Signals Overview

The signals are grouped as follows:

- DDR memory controller interface signals
- Integrated Flash controller interface signals
- DUART interface signals
- I^2C interface signals
- Enhanced SPI interface signals
- Enhanced SDHC interface signals
- MPIC interface signals
- Hi-speed serial interface signals (SerDes)
- USB controller interface signals
- IEEE 1588 timestamp signals
- Ethernet management interface signals
- Ethernet controller RGMII interface signals
- DMA controller interface signals
- General-purpose input/output, system control, power management, and debug signals
- Clock, JTAG, and test signals

Note that individual chapters of this document provide details for each signal, describing each signal's behavior when the signal is asserted or negated and when the signal is an input or an output.

The following table provides a summary of the signals grouped by function. Note that the direction of signals applies for the primary signal function listed in the left-most column of the table for that row (and does not apply for the alternate function or reset configuration input signals).

Table 3-1. T4240 Signal Reference by Functional Block

Name	Description	Alternate Function(s)	No. of Signals	I/O
DDR Controller 1 see DDR Controller for more details				
D1_MDQ[0:63]	DDR controller data	-	64	I/O
D1_MECC[0:7]	DDR error correcting code	-	8	I/O
D1_MAPAR_ERR_B	Address parity error	-	1	I
D1_MAPAR_OUT	Address parity out	-	1	O
D1_MDM[0:8]/ D1_MDQS[9:17]	DDR data mask	-	9	O
D1_MDQS[0:8]	DDR data strobe	-	9	I/O
D1_MDQS[9:17]/ D1_MDM[0:8]	DDR data strobe	-	9	I/O
D1_MDQS[0:17]_B	DDR data strobe (complement)	-	18	I/O
D1_MBA[0:2]	DDR bank select	-	3	O
D1_MA[0:15]	DDR address	-	16	O
D1_MWE_B	DDR write enable	-	1	O
D1_MRAS_B	DDR row address strobe	-	1	O
D1_MCAS_B	DDR column address strobe	-	1	O
D1_MCS[0:3]_B	DDR chip select (2/DIMM)	-	4	O
D1_MCKE[0:3]	DDR clock enable	-	4	O
D1_MCK[0:3], D1_MCK[0:3]_B	DDR differential clocks (2 pairs/ DIMM)	-	8	O
D1_MODT[0:3]	DRAM On-Die Termination	-	4	O
D1_MDIC[0:1]	Driver impedance calibration	-	2	I/O
DDR Controller 2 see DDR Controller for more details				
D2_MDQ[0:63]	DDR controller data	-	64	I/O
D2_MECC[0:7]	DDR error correcting code	-	8	I/O
D2_MAPAR_ERR_B	Address parity error	-	1	I
D2_MAPAR_OUT	Address parity out	-	1	O
D2_MDM[0:8]/ D2_MDQS[9:17]	DDR data mask	-	9	O
D2_MDQS[0:8]	DDR data strobe	-	9	I/O

Table continues on the next page...

Table 3-1. T4240 Signal Reference by Functional Block (continued)

Name	Description	Alternate Function(s)	No. of Signals	I/O
D2_MDQS[9:17]/ D2_MDM[0:8]	DDR data strobe	-	9	I/O
D2_MDQS[0:17]_B	DDR data strobe (complement)	-	18	I/O
D2_MBA[0:2]	DDR bank select	-	3	O
D2_MA[0:15]	DDR address	-	16	O
D2_MWE_B	DDR write enable	-	1	O
D2_MRAS_B	DDR row address strobe	-	1	O
D2_MCAS_B	DDR column address strobe	-	1	O
D2_MCS[0:3]_B	DDR chip select (2/DIMM)	-	4	O
D2_MCKE[0:3]	DDR clock enable	-	4	O
D2_MCK[0:3], D2_MCK[0:3]_B	DDR differential clocks (2 pairs/ DIMM)	-	8	O
D2_MODT[0:3]	DRAM On-Die Termination	-	4	O
D2_MDIC[0:1]	Driver impedance calibration	-	2	I/O
DDR Controller 3 see DDR Controller for more details				
D3_MDQ[0:63]	DDR controller data	-	64	I/O
D3_MECC[0:7]	DDR error correcting code	-	8	I/O
D3_MAPAR_ERR_B	Address parity error	-	1	I
D3_MAPAR_OUT	Address parity out	-	1	O
D3_MDM[0:8]/ D3_MDQS[9:17]	DDR data mask	-	9	O
D3_MDQS[0:8]	DDR data strobe	-	9	I/O
D3_MDQS[9:17]/ D3_MDM[0:8]	DDR data strobe	-	9	I/O
D3_MDQS[0:17]_B	DDR data strobe (complement)	-	18	I/O
D3_MBA[0:2]	DDR bank select	-	3	O
D3_MA[0:15]	DDR address	-	16	O
D3_MWE_B	DDR write enable	-	1	O
D3_MRAS_B	DDR row address strobe	-	1	O
D3_MCAS_B	DDR column address strobe	-	1	O
D3_MCS[0:3]_B	DDR chip select (2/DIMM)	-	4	O
D3_MCKE[0:3]	DDR clock enable	-	4	O
D3_MCK[0:3], D3_MCK[0:3]_B	DDR differential clocks (2 pairs/ DIMM)	-	8	O
D3_MODT[0:3]	DRAM On-Die Termination	-	4	O
D3_MDIC[0:1]	Driver impedance calibration	-	2	I/O
Integrated Flash Controller see IFC Controller for more details				
IFC_AD[0:7]	IFC address/data	cfg_gpinput[0:7]	8	I/O
IFC_AD[8:15]	IFC address/data	cfg_rcw_src[0:7]	8	I/O

Table continues on the next page...

Table 3-1. T4240 Signal Reference by Functional Block (continued)

Name	Description	Alternate Function(s)	No. of Signals	I/O
IFC_AD[16:20]	IFC address/data		5	I/O
IFC_AD[21]	IFC address/data	cfg_dram_type	1	I/O
IFC_AD[22:24]	IFC address/data	-	3	I/O
IFC_AD[25:27]/ IFC_WP[1:3]_B	IFC address/data	GPIO2[25:27]	3	I/O
IFC_AD[28]	IFC address/data	GPIO2[28]	1	I/O
IFC_AD[29:31]/ IFC_RB[2:4]_B	IFC address/data	GPIO2[29:31]	3	I/O
IFC_A[26:31]	IFC address	GPIO2[18:23]	6	O
IFC_PAR[0:1]	IFC address and data parity	GPIO2[13:14]	2	I/O
IFC_PAR[2:3]	IFC address and data parity	GPIO2[16:17]	2	I/O
IFC_CS[0]_B	IFC chip select	-	1	O
IFC_CS[1:3]_B	IFC chip select	GPIO2[10:12]	3	O
IFC_CS[4:7]_B	IFC chip select	GPIO1[9:12]	4	O
IFC_WE[0]_B	IFC write enable	-	1	O
IFC_WE[2:3]_B	IFC write enable	-	2	O
IFC_BCTL	IFC buffer control	-	1	O
IFC_TE	IFC external transceiver enable	cfg_ifc_te	1	O
IFC_NDDQS	IFC DQS strobe	-	1	I/O
IFC_AVD	IFC address valid	-	1	O
IFC_CLE	IFC command latch enable	cfg_rcw_src[8]	1	O
IFC_OE_B	IFC output enable	-	1	O
IFC_WP[0]_B	IFC write protect	-	1	O
IFC_WP[1:3]_B/ IFC_AD[25:27]	IFC write protect	GPIO2[25:27]	3	I/O
IFC_RB[0:1]_B	IFC ready/busy	-	2	I
IFC_RB[2:4]_B/ IFC_AD[29:31]	IFC ready/busy	-	3	I
IFC_PERR_B	IFC parity error	GPIO2[15]	1	I
IFC_CLK[0:2]	IFC clock	-	3	O
IFC_NDDDR_CLK	IFC NAND DDR clock	-	1	O
DUART See DUART Controller for more details				
UART1_SOUT	DUART serial data out	GPIO1[15]	1	O
UART2_SOUT	DUART serial data out	GPIO1[16]	1	O
UART1_SIN	DUART serial data in	GPIO1[17]	1	I
UART2_SIN	DUART serial data in	GPIO1[18]	1	I
UART1_RTS_B/ UART3_SOUT	DUART ready to send/serial data out	GPIO1[19]	1	O
UART2_RTS_B/ UART4_SOUT	DUART ready to send/serial data out	GPIO1[20]	1	O

Table continues on the next page...

Table 3-1. T4240 Signal Reference by Functional Block (continued)

Name	Description	Alternate Function(s)	No. of Signals	I/O
UART1_CTS_B/ UART3_SIN	DUART clear to send/serial data in	GPIO1[21]	1	I
UART2_CTS_B/ UART4_SIN	DUART clear to send/serial data in	GPIO1[22]	1	I
I^2C 1 See I^2C Detailed Signal Descriptions for more details				
IIC1_SCL	I^2C serial clock	-	1	I/O
IIC1_SDA	I^2C serial data	-	1	I/O
I^2C 2 See I^2C Detailed Signal Descriptions for more details				
IIC2_SCL	I^2C serial clock	-	1	I/O
IIC2_SDA	I^2C serial data	-	1	I/O
I^2C 3 See I^2C Detailed Signal Descriptions for more details				
IIC3_SCL	I^2C serial clock	GPIO4[0]	1	I/O
IIC3_SDA	I^2C serial data	GPIO4[1]	1	I/O
I^2C 4 See I^2C Detailed Signal Descriptions for more details				
IIC4_SCL	I^2C serial clock	GPIO4[2]/ EVT[5]_B	1	I/O
IIC4_SDA	I^2C serial data	GPIO4[3]/EVT[6]_B	1	I/O
eSPI See eSPI detailed signal descriptions for more details				
SPI_MOSI	SPI master out slave in	-	1	I/O
SPI_MISO	SPI master in slave out	-	1	I
SPI_CLK	SPI clock	-	1	O
SPI_CS[0:3]_B	SPI chip select	SDHC_DAT[4:7]/GPIO2[0:3]	4	O
eSDHC See eSDHC signal descriptions for more details				
SDHC_CMD	SDHC command response	GPIO2[4]	1	I/O
SDHC_DAT[0:3]	SDHC data	GPIO2[5:8]	4	I/O
SDHC_DAT[4:7]	SDHC data	SPI_CS[0:3]_B/GPIO2[0:3]	4	I/O
SDHC_CLK	SDHC clock	GPIO2[9]	1	O
SDHC_CD_B	Card Detection	-	1	I
SDHC_WP	Card Write Protection	-	1	I
MPIC See External Signal Descriptions for more details				
IRQ[0:2]	External interrupt	-	3	I
IRQ[3:11]	External interrupt	GPIO1[23:31]	9	I
IRQ_OUT_B	Interrupt output	EVT[9]_B	1	O
SerDes 1 See External Signals Description for more details.				
SD1_TX[0:7]_P	Transmit data	-	8	O
SD1_TX[0:7]_N	Transmit data (complement)	-	8	O
SD1_RX[0:7]_P	Receive data	-	8	I
SD1_RX[0:7]_N	Receive data (complement)	-	8	I
SD1_REF1_CLK_P	SerDes 1 PLL 1 reference clock	-	1	I

Table continues on the next page...

Table 3-1. T4240 Signal Reference by Functional Block (continued)

Name	Description	Alternate Function(s)	No. of Signals	I/O
SD1_REF1_CLK_N	SerDes 1 PLL 1 reference clock (complement)	-	1	I
SD1_REF2_CLK_P	SerDes 1 PLL 2 reference clock	-	1	I
SD1_REF2_CLK_N	SerDes 1 PLL 2 reference clock (complement)	-	1	I
SerDes 2 See External Signals Description for more details.				
SD2_TX[0:7]_P	Transmit data	-	8	O
SD2_TX[0:7]_N	Transmit data (complement)	-	8	O
SD2_RX[0:7]_P	Receive data	-	8	I
SD2_RX[0:7]_N	Receive data (complement)	-	8	I
SD2_REF1_CLK_P	SerDes 2 PLL 1 reference clock	-	1	I
SD2_REF1_CLK_N	SerDes 2 PLL 1 reference clock (complement)	-	1	I
SD2_REF2_CLK_P	SerDes 2 PLL 2 reference clock	-	1	I
SD2_REF2_CLK_N	SerDes 2 PLL 2 reference clock (complement)	-	1	I
SerDes 3 See External Signals Description for more details.				
SD3_TX[0:7]_P	Transmit data	-	8	O
SD3_TX[0:7]_N	Transmit data (complement)	-	8	O
SD3_RX[0:7]_P	Receive data	-	8	I
SD3_RX[0:7]_N	Receive data (complement)	-	8	I
SD3_REF1_CLK_P	SerDes 3 PLL 1 reference clock	-	1	I
SD3_REF1_CLK_N	SerDes 3 PLL 1 reference clock (complement)	-	1	I
SD3_REF2_CLK_P	SerDes 3 PLL 2 reference clock	-	1	I
SD3_REF2_CLK_N	SerDes 3 PLL 2 reference clock (complement)	-	1	I
SerDes 4 See External Signals Description for more details.				
SD4_TX[0:7]_P	Transmit data	-	8	O
SD4_TX[0:7]_N	Transmit data (complement)	-	8	O
SD4_RX[0:7]_P	Receive data	-	8	I
SD4_RX[0:7]_N	Receive data (complement)	-	8	I
SD4_REF1_CLK_P	SerDes 4 PLL 1 reference clock	-	1	I
SD4_REF1_CLK_N	SerDes 4 PLL 1 reference clock (complement)	-	1	I
SD4_REF2_CLK_P	SerDes 4 PLL 2 reference clock	-	1	I
SD4_REF2_CLK_N	SerDes 4 PLL 2 reference clock (complement)	-	1	I
USB See USB External Signals for more details				
USB1_UDP	USB 1 data plus	-	1	I/O

Table continues on the next page...

Table 3-1. T4240 Signal Reference by Functional Block (continued)

Name	Description	Alternate Function(s)	No. of Signals	I/O
USB1_UDM	USB 1 data minus	-	1	I/O
USB1_VBUS_CLMP	USB 1 Vbus	-	1	I
USB1_UID	USB 1 ID detect	-	1	I
USB1_DRVVBUS	USB 1 drive Vbus	-	1	O
USB1_PWRFAULT	USB 1 power fault	-	1	I
USB2_UDP	USB 2 data plus	-	1	I/O
USB2_UDM	USB 2 data minus	-	1	I/O
USB2_VBUS_CLMP	USB 2 Vbus	-	1	I
USB2_UID	USB 2 ID detect	-	1	I
USB2_DRVVBUS	USB 2 drive Vbus	-	1	O
USB2_PWRFAULT	USB 2 power fault	-	1	I
USB_CLKIN	USB clock in (for both PHYs)	-	1	I
IEEE 1588 See “QorIQ Data Path Acceleration Architecture (DPAA) Reference Manual” for more details **NOTE:** The external IEEE 1588 signals are associated with the IEEE 1588 timer in FM2, which is the master timer providing the current time to FM1.				
TSEC_1588_CLK_IN	1588 clock in	GPIO3[0]	1	I
TSEC_1588_TRIG_IN1	1588 trigger in 1	GPIO3[1]	1	I
TSEC_1588_TRIG_IN2	1588 trigger in 2	GPIO3[2]	1	I
TSEC_1588_ ALARM_OUT1	1588 alarm out 1	GPIO3[3]	1	O
TSEC_1588_ ALARM_OUT2	1588 alarm out 2	GPIO3[4]	1	O
TSEC_1588_ CLK_OUT	1588 clock out	GPIO3[5]	1	O
TSEC_1588_ PULSE_OUT1	1588 pulse out 1	GPIO3[6]	1	O
TSEC_1588_ PULSE_OUT2	1588 pulse out 2	GPIO3[7]	1	O
Ethernet Management Interface 1 See “QorIQ Data Path Acceleration Architecture (DPAA) Reference Manual” and "Datasheet" for more details				
EMI1_MDC	Ethernet management data clock	-	1	O
EMI1_MDIO	Ethernet management data in/out	-	1	I/O
Ethernet management Interface 2 See “QorIQ Data Path Acceleration Architecture (DPAA) Reference Manual” and "Datasheet" for more details				
EMI2_MDC	Ethernet management data clock	-	1	O
EMI2_MDIO	Ethernet management data in/out	-	1	I/O
Ethernet Controller 1 RGMII (FMan2; MAC5) See “QorIQ Data Path Acceleration Architecture (DPAA) Reference Manual” for more details				
EC1_TXD[3:0]	EC1 transmit data	GPIO3[8:11]	4	O
EC1_TX_EN	EC1 transmit enable	GPIO3[12]	1	O

Table continues on the next page...

Table 3-1. T4240 Signal Reference by Functional Block (continued)

Name	Description	Alternate Function(s)	No. of Signals	I/O
EC1_GTX_CLK	EC1 transmit clock out	GPIO3[13]	1	O
EC1_GTX_CLK125	EC1 reference clock	-	1	I
EC1_RXD[3:0]	EC1 receive data	GPIO3[16:19]	4	I
EC1_RX_DV	EC1 receive data valid	GPIO3[14]	1	I
EC1_RX_CLK	EC1 receive clock	GPIO3[15]	1	I
Ethernet Controller 2 RGMII (FMan1; MAC5 or FMan2; MAC6) See “QorIQ Data Path Acceleration Architecture (DPAA) Reference Manual” for more details				
EC2_TXD[3:0]	EC2 transmit data	GPIO3[20:23]	4	O
EC2_TX_EN	EC2 transmit enable	GPIO3[24]	1	O
EC2_GTX_CLK	EC2 transmit clock out	GPIO3[25]	1	O
EC2_GTX_CLK125	EC2 reference clock	-	1	I
EC2_RXD[3:0]	EC2 receive data	GPIO3[28:31]	4	I
EC2_RX_DV	EC2 receive data valid	GPIO3[26]	1	I
EC2_RX_CLK	EC2 receive clock	GPIO3[27]	1	I
DMA 1 See DMA signal descriptions for more details				
DMA1_DREQ[0]_B	DMA1 channel 0 request	GPIO4[4]	1	I
DMA1_DACK[0]_B	DMA1 channel 0 acknowledge	GPIO4[5]	1	O
DMA1_DDONE[0]_B	DMA1 channel 0 done	GPIO4[6]	1	O
DMA 2 See DMA signal descriptions for more details				
DMA2_DREQ[0]_B	DMA2 channel 0 request	GPIO4[7]	1	I
DMA2_DACK[0]_B	DMA2 channel 0 acknowledge	GPIO4[8]/ EVT[7]_B	1	O
DMA2_DDONE[0]_B	DMA2 channel 0 done	GPIO4[9]/ EVT[8]_B	1	O
GPIO 1 See GPIO signal descriptions for more details				
GPIO1[9:12]	General-purpose I/O	IFC_CS[4:7]_B	4	I/O

3.3 Configuration signals sampled at reset

The signals that serve alternate functions as configuration input signals during system reset are summarized in this table. The detailed interpretation of their voltage levels during reset is described in Power-on reset configuration .

Note that throughout this document, the reset configuration signals are described as being sampled at the negation of PORESET_B. However, there is a setup and hold time for these signals relative to the rising edge of PORESET_B, as described in the chip's datasheet.

The reset configuration signals are multiplexed with other functional signals. The values on these signals during reset are interpreted to be logic one or zero, regardless of whether the functional signal name is defined as active-low. The reset configuration signals have internal pull-up resistors so that if the signals are not driven, the default value is high (a

one), as shown in the table. Some signals must be driven high or low during the reset period. For details about all the signals that require external pull-up resistors, see the datasheet.

Table 3-2. T4240 reset configuration signals

Reset configuration name	Functional interface	Functional Signal Name	Default
cfg_rcw_src[0:7]	IFC	IFC_AD[8:15]	1111 1111 [1]
cfg_rcw_src[8]	IFC	IFC_CLE	1 [1]
cfg_ifc_te	IFC	IFC_TE	1
cfg_dram_type	IFC	IFC_AD[21]	1
cfg_gpinput[0:7]	IFC	IFC_AD[0:7]	1111 1111
cfg_xvdd_sel	Power management	ASLEEP	1

1. cfg_rcw_src[0:8]=1_1111_1111 is not a valid setting; They must be set to one of the valid options defined in Reset configuration word (RCW) source

3.4 Signal multiplexing details

Due to the extensive functionality present on the chip and the limited number of external signals available, several functional blocks share signal resources through multiplexing. These signals are designated in the Alternate function(s) column of Table 3-1 . In this case when there is alternate functionality between multiple functional blocks, the signal's function is determined at the device level (rather than at the block level) typically by a reset configuration word (RCW) option. For example, the signal SPI_CS_B[0:3]/ SDHC_DAT[4:7]/GPIO2[0:3] can be utilized by either the SPI block, the eSDHC block, or by GPIO 2. Because these signals alternatively service three different functional blocks, their function is determined at the device level by RCW[SPI_BASE]. The following sections describe external signal functional selection using the RCW.

3.4.1 UART and GPIO1 signal multiplexing

For the UART signals, the following relationships apply:

- UART1 shares signals with GPIO1 and UART3
- UART2 shares signals with GPIO1 and UART4

The functionality of these signals is determined by the UART_BASE field in the reset configuration word (RCW[UART_BASE]).

Table 3-3. UART signal configuration

Signal name	Signal function	RCW[UART_BASE]or RCW[366:368]
UART1_SOUT	GPIO1[15]	000
	UART1_SOUT	011, 100, 101, 110, 111
UART1_SIN	GPIO1[17]	000
	UART1_SIN	011, 100, 101, 110, 111
UART1_RTS_B	GPIO1[19]	000, 011, 101
	UART1_RTS_B	100, 110
	UART3_SOUT	111
UART1_CTS_B	GPIO1[21]	000, 011, 101
	UART1_CTS_B	100, 110
	UART3_SIN	111
UART2_SOUT	GPIO1[16]	000, 011, 110
	UART2_SOUT	110, 101, 110, 111
UART2_SIN	GPIO1[18]	000, 011, 100
	UART2_SIN	110, 101, 111
UART2_RTS_B	GPIO1[20]	000, 011, 100, 101
	UART2_RTS_B	110
	UART4_SOUT	111
UART2_CTS_B	GPIO1[22]	000, 011, 100, 101
	UART2_CTS_B	110
	UART4_SIN	111

3.4.2 ASLEEP and GPIO1 signal multiplexing

The power management signal, ASLEEP, is shared with GPIO1[13]. The functionality of this signal is determined by the ASLEEP field in the reset configuration word (RCW[ASLEEP]).

Table 3-4. ASLEEP signal configuration

Signal name	Signal function	RCW[ASLEEP]
ASLEEP	ASLEEP	0
	GPIO1[13]	1

3.4.3 RTC and GPIO1 signal multiplexing

The clocking signal, RTC, is shared with GPIO1[14]. The functionality of this signal is determined by the RTC field in the reset configuration word (RCW[RTC]).

Table 3-5. RTC signal configuration

Signal name	Signal function	RCW[RTC]
RTC	RTC	0
	GPIO1[14]	1

3.4.4 eSDHC and GPIO2 signal multiplexing

The eSDHC interface shares signals with GPIO2. The functionality of these signals are determined by the SDHC_BASE field in the reset configuration word (RCW[SDHC_BASE]).

Table 3-6. SDHC_BASE signal configuration

Signal name	Signal function	RCW[SDHC_BASE]
SDHC_CMD	SDHC_CMD	0
	GPIO2[4]	1
SDHC_DAT[0:3]	SDHC_DAT[0:3]	0
	GPIO2[5:8]	1
SDHC_CLK	SDHC_CLK	0
	GPIO2[9]	1

3.4.5 MPIC and debug signal multiplexing

The interrupt controller (MPIC) shares a signal with debug signal EVT_B[9]. The functionality of this signal is determined by the IRQ_OUT field in the reset configuration word (RCW[IRQ_OUT]).

Table 3-7. IRQ_OUT signal configuration

Signal name	Signal function	RCW[IRQ_OUT]
IRQ_OUT_B	IRQ_OUT_B	0
	EVT_B[9]	1

3.4.6 MPIC and GPIO1 signal multiplexing

The interrupt controller (MPIC) shares signals with GPIO1. The functionality of these signals is determined by the IRQ_BASE fields in the reset configuration word (RCW[IRQ_BASE] or RCW[373:381]).

NOTE

When GPIO functionality is selected, the corresponding MPIC external interrupt vector priority registers (MPIC_EIVPRn) must have their polarity set to active high.

Table 3-8. IRQ*n* signal configuration

Signal name	Signal function	RCW[370 + n], 3 ≤ n ≤ 11
IRQ[n]	IRQ[n]	0
3 ≤ n ≤ 11	GPIO1[n+20]	1
		RCW[IRQ_EXT]

3.4.7 eSPI, eSDHC, and GPIO2 signal multiplexing

The eSPI shares signals with the eSDHC and GPIO2. The functionality of these signals is determined by the SPI_BASE field in the reset configuration word (RCW[SPI_BASE]).

Table 3-9. eSPI signal configuration

Signal name	Signal function	RCW[SPI_BASE]
SPI_CS_B[0:3]	SPI_CS_B[0:3]	00
	SDHC_DAT[4:7]	01
	GPIO2[0:3]	10

3.4.8 IFC, GPIO1, and GPIO2 signal multiplexing

The integrated Flash controller shares signals with GPIO1 and GPIO2. The functionality of these signals is determined by the IFC_GRP_[*a*]_BASE fields in the reset configuration word as described in the following table.

Table 3-10. IFC signal configuration

Signal name	Signal function	IFC_GRP_[*a*]_BASE]					
		E1	E2	D	C	B	A
IFC_CS_B[1:3]	IFC_CS_B[1:3]	0	-	-	-	-	-
	GPIO2[10:12]	1	-	-	-	-	-
IFC_CS_B[4:7]	IFC_CS_B[4:7]	-	0	-	-	-	-
	GPIO1[9:12]	-	1	-	-	-	-
IFC_PAR[0:1]	IFC_PAR[0:1]	-	-	0	-	-	-
	GPIO2[13:14]	-	-	1	-	-	-
IFC_PERR_B	IFC_PERR_B	-	-	0	-	-	-
	GPIO2[15]	-	-	1	-	-	-
IFC_PAR[2:3]	IFC_PAR[2:3]	-	-	0	-	-	-
	GPIO2[16:17]	-	-	1	-	-	-
IFC_AD[26:31]	IFC_AD[26:31]	-	-	-	0	-	-
	GPIO2[18:23]	-	-	-	1	-	-
IFC_AD[28]	IFC_AD[28]	-	-	-	-	00	-
	GPIO2[28]	-	-	-	-	01	-
IFC_AD[29:31]	IFC_AD[29:31]	-	-	-	-	00	-
	GPIO2[29:31]	-	-	-	-	01	-
	IFC_RB_B[2:4]	-	-	-	-	10	-
IFC_AD[25:27]	IFC_AD[25:27]	-	-	-	-	-	00
	GPIO2[25:27]	-	-	-	-	-	01
	IFC_WP_B[1:3]	-	-	-	-	-	10

3.4.9 IEEE 1588 and GPIO3 signal multiplexing

The IEEE 1588 interface shares signals with GPIO3. The functionality of these signals is determined by the 1588 field in the reset configuration word (RCW[1588]). The external IEEE 1588 signals are associated with the IEEE 1588 timer in FM2, which is the master timer providing the current time to FM1.

Table 3-11. IEEE 1588 signal configuration

Signal name	Signal function	RCW[1588]
TSEC_1588_CLK_IN	TSEC_1588_CLK_IN	1
	GPIO3[0]	0
TSEC_1588_TRIG_IN1	TSEC_1588_TRIG_IN1	1
	GPIO3[1]	0
TSEC_1588_TRIG_IN2	TSEC_1588_TRIG_IN2	1
	GPIO3[2]	0

Table continues on the next page...

Table 3-11. IEEE 1588 signal configuration (continued)

Signal name	Signal function	RCW[1588]
TSEC_1588_ALARM_OUT1	TSEC_1588_ALARM_OUT1	1
	GPIO3[3]	0
TSEC_1588_ALARM_OUT2	TSEC_1588_ALARM_OUT2	1
	GPIO3[4]	0
TSEC_1588_CLK_OUT	TSEC_1588_CLK_OUT	1
	GPIO3[5]	0
TSEC_1588_PULSE_OUT1	TSEC_1588_PULSE_OUT1	1
	GPIO3[6]	0
TSEC_1588_PULSE_OUT2	TSEC_1588_PULSE_OUT2	1
	GPIO3[7]	0

3.4.10 Ethernet controller 1 and GPIO3 signal multiplexing

The Ethernet controller 1 (EC1) RGMII interface shares signals with GPIO3. The functionality of these signals is determined by the EC1 field in the reset configuration word (RCW[EC1]). When RGMII is enabled for a particular MAC, it always takes precendence over SerDes-based interfaces.

Table 3-12. EC1 RGMII signal configuration

Signal name	Signal function	RCW[EC1]
EC1_TXD[3:0]	EC1_TXD[3:0] (FMan2-MAC5 RGMII)	00
	GPIO3[8:11]	10
EC1_TX_EN	EC1_TX_EN (FMan2-MAC5 RGMII)	00
	GPIO3[12]	10
EC1_GTX_CLK	EC1_GTX_CLK (FMan2-MAC5 RGMII)	00
	GPIO3[13]	10
EC1_RX_DV	EC1_RX_DV (FMan2-MAC5 RGMII)	00
	GPIO3[14]	10
EC1_RX_CLK	EC1_RX_CLK (FMan2-MAC5 RGMII)	00
	GPIO3[15]	10
EC1_RXD[3:0]	EC1_RXD[3:0] (FMan2-MAC5 RGMII)	00
	GPIO3[16:19]	10

3.4.11 Ethernet controller 2 and GPIO3 signal multiplexing

The Ethernet controller 2 (EC2) RGMII interface shares signals with GPIO3. In addition, the chip can be configured to use either Frame Manager 1 MAC5 (FMan1-MAC5) or Frame Manager 2 MAC6 (FMan2-MAC6) for EC2. The functionality of these signals is determined by the EC2 field in the reset configuration word (RCW[EC2]). When RGMII is enabled for a particular MAC, it always takes precendence over SerDes-based interfaces.

Table 3-13. EC2 RGMII signal configuration

Signal name	Signal function	RCW[EC2]
EC2_TXD[3:0]	EC2_TXD[3:0] (FMan1-MAC5 RGMII)	00
	EC2_TXD[3:0] (FMan2-MAC6 RGMII)	01
	GPIO3[20:23]	10
EC2_TX_EN	EC2_TX_EN (FMan1-MAC5 RGMII)	00
	EC2_TX_EN (FMan2-MAC6 RGMII)	01
	GPIO3[24]	10
EC2_GTX_CLK	EC2_GTX_CLK (FMan1-MAC5 RGMII)	00
	EC2_GTX_CLK (FMan2-MAC6 RGMII)	01
	GPIO3[25]	10
EC2_RX_DV	EC2_RX_DV (FMan1-MAC5 RGMII)	00
	EC2_RX_DV (FMan2-MAC6 RGMII)	01
	GPIO3[26]	10
EC2_RX_CLK	EC2_RX_CLK (FMan1-MAC5 RGMII)	00
	EC2_RX_CLK (FMan2-MAC6 RGMII)	01
	GPIO3[27]	10
EC2_RXD[3:0]	EC2_RXD[3:0] (FMan1-MAC5 RGMII)	00
	EC2_RXD[3:0] (FMan2-MAC6 RGMII)	01
	GPIO3[28:31]	10

3.4.12 I^2C3 and GPIO4 signal multiplexing

The I^2C3 interface shares signals with GPIO4. The functionality of these signals is determined by the I2C3 field in the reset configuration word (RCW[I2C3]).

Table 3-14. I2C3 signal configuration

Signal name	Signal function	RCW[I2C3]
IIC3_SCL	IIC3_SCL	00
	GPIO4[0]	01
IIC3_SDA	IIC3_SDA	00
	GPIO4[1]	01

3.4.13 I²C4, GPIO4, and Debug Signal Multiplexing

The I²C4 interface shares signals with GPIO4, and Debug. The functionality of these signals is determined by the I2C4 field in the reset configuration word (RCW[I2C4]).

Table 3-15. I2C4 Signal Configuration

Signal Name	Signal Function	RCW[I2C4]
IIC4_SCL	IIC4_SCL	00
	GPIO4[2]	01
	EVT_B[5]	10
IIC4_SDA	IIC4_SDA	00
	GPIO4[3]	01
	EVT_B[6]	10

3.4.14 DMA1 and GPIO4 signal multiplexing

DMA controller 1, channel 0 (DMA1) shares signals with GPIO4. The functionality of these signals is determined by the DMA1 field in the reset configuration word (RCW[DMA1]).

Table 3-16. DMA1 signal configuration

Signal name	Signal function	RCW[DMA1]
DMA1_DREQ_B[0]	DMA1_DREQ_B[0]	0
	GPIO4[4]	1
DMA1_DACK_B[0]	DMA1_DACK_B[0]	0
	GPIO4[5]	1
DMA1_DDONE_B[0]	DMA1_DDONE_B[0]	0
	GPIO4[6]	1

3.4.15 DMA2, debug, and GPIO4 signal multiplexing

DMA controller 2, channel 0 (DMA2) shares signals with debug and GPIO4. The functionality of these signals is determined by the DMA2 field in the reset configuration word (RCW[DMA2]).

Table 3-17. DMA2 signal configuration

Signal name	Signal function	RCW[DMA2]
DMA2_DREQ_B[0]	DMA2_DREQ_B[0]	00
	GPIO4[7]	01, 10
DMA2_DACK_B[0]	DMA2_DACK_B[0]	00
	GPIO4[8]	01
	EVT_B[7]	10
DMA2_DDONE_B[0]	DMA2_DDONE_B[0]	00
	GPIO4[9]	01
	EVT_B[8]	10

3.5 Output Signal States During Reset

When a system reset is initiated (HRESET_B or PORESET_B sampled asserted by the chip), the chip aborts all current internal and external transactions and releases all bidirectional I/O signals to a high-impedance state. See *Reset, Clocking, and Initialization* for a complete description of the reset functionality.

While the the chip is in reset, it drives HRESET_B asserted and ignores most input signals (except for the reset configuration signals) and drives most of the output-only signals to an inactive state.

Note that signals associated with the interface selected as RCW source via cfg_rcw_src[0:8] are enabled and active while the chip is in reset (that is, while HRESET_B is being driven asserted by the chip, but after PORESET_B is deasserted). This is necessary to allow the interfaces to be used for fetching configuration information from non-volatile memory devices.

Chapter 4
Reset, Clocking, and Initialization

4.1 Reset, clocking, and initialization overview

This content describes the reset, clocking, and initialization, including a definition of the reset configuration signals and the options they select.

Additionally, the configuration, control, and status registers are described. Note that other chapters in this book may describe specific aspects of initialization for individual blocks.

The reset, clocking, and control signals provide many options for operation. Additionally, many modes are selected with reset configuration signals during a power on reset (assertion of PORESET_B) and by using the reset configuration word (RCW) functionality.

4.2 External signal descriptions

The table below summarizes the external signals described in this chapter.

Table 4-3 and Table 4-4 have detailed signal descriptions, but this table contains references to additional sections that contain more information.

Table 4-1. Reset and Control Signals Summary

Signal	I/O	Description
PORESET_B	I	Power on reset input.
HRESET_B	I/O	Hard reset input. Functions as an output during initial steps in the power on reset sequence. See Power-on reset sequence for more information.
RESET_REQ_B	O	Reset request output. An internal block requests that either HRESET_B or PORESET_B be asserted.
CKSTP_OUT_B	O	Checkstop out.
ASLEEP	O	Asleep
TMP_DETECT_B	I	Tamper Detect.

Table continues on the next page...

Table 4-1. Reset and Control Signals Summary (continued)

Signal	I/O	Description
BB_TMP_DETECT_B	I	Low Power Tamper Detect.

Table 4-2. Clock Signals Summary

Signal	I/O	Description
SYSCLK	I	Primary clock input.
RTC	I	Real time clock input.
SD1_REF_CLK*n*_P/SD1_REF_CLK*n*_N SD2_REF_CLK*n*_P/SD2_REF_CLK*n*_N SD3_REF_CLK*n*_P/SD3_REF_CLK*n*_N SD4_REF_CLK*n*_P/SD4_REF_CLK*n*_N	I	SerDes high-speed interface reference clock *n*.
CLK_OUT	O	Diagnostic clock output.
DDRCLK	I	Reference clock for DDR controller.

The following sections describe the reset and clock signals in detail.

4.2.1 System control signals

The table below describes some of the system control signals. Power-on reset configuration describes the signals that also function as reset configuration signals.

Table 4-3. System control signals: Detailed signal descriptions

Signal	I/O	Description	
PORESET_B	I	Power on reset. Causes the chip to abort all current internal and external transactions and set all registers to their default values. PORESET_B may be asserted completely asynchronously with respect to all other signals.	
		State Meaning	Asserted/Negated-See Signal Descriptions and Power-on reset configuration for more information on the interpretation of the other signals during reset.
		Timing	Assertion/Negation-The chip data sheet gives specific timing information for this signal and the reset configuration signals.
HRESET_B	I/O	Hard reset. Causes the chip to abort all current internal and external transactions and set all registers to their default values. HRESET_B may be asserted completely asynchronously with respect to all other signals. HRESET_B is driven as an output during the first part of the power on reset sequence, after which, it becomes an input, allowing external devices to stall/hold the reset sequence. See Hard reset sequence for more information.	
		State Meaning	Asserted/Negated-See Signal Descriptions and Power-on reset configuration for more information on the interpretation of the other signals during reset.

Table continues on the next page...

Table 4-3. System control signals: Detailed signal descriptions (continued)

Signal	I/O	Description	
		Timing	Assertion/Negation-The chip data sheet gives specific timing information for this signal.
RESET_REQ_B	O	Reset request. Indicates to the board (system in which the chip is embedded) that a condition requiring the assertion of HRESET_B or PORESET_B has been detected.	
		State Meaning	Asserted-An event has triggered a request for either a hard reset or a power on reset. See Reset Request Status Register (DCFG_CCSR_RSTRQSR1) Negated-Indicates no reset request.
		Timing	Assertion/Negation-May occur any time. Once asserted, RESET_REQ_B does not negate until either HRESET_B or PORESET_B is asserted.
CKSTP_OUT_B	O	Checkstop out.	
		State Meaning	Asserted-Indicates that the chip is in a checkstop state. Negated-Indicates normal operation. After CKSTP_OUT_B has been asserted, it is negated after the next negation (low-to-high transition) of PORESET_B.
		Timing	Assertion-May occur at any time; may be asserted asynchronously to the input clocks. Negation-Must remain asserted until the chip has been reset with a PORESET_B.
ASLEEP	O	Power Management Signal. See External Signal Description.	
TMP_DETECT_B	I	Tamper Detect.	
BB_TMP_DETECT_B	I	Low Power Tamper Detect.	

4.2.2 External Clock Signals

The table below describes some of the external clock signals of the chip.

Note that some clock signals are specific to modules within the chip, and although some of their functionality is described here, they are defined in detail in their respective chapters.

Table 4-4. Clock External Signals-Detailed Signal Descriptions

Signal	I/O	Description	
SYSCLK	I	System clock (SYSCLK). SYSCLK is the primary clock input to the chip.	
		Timing	Assertion/Negation-See the chip data sheet for specific timing information for this signal.
RTC	I	Real time clock. May be used (optionally) to clock the time base of the cores. The RTC timing specifications are given in the chip data sheet . This signal can also be used (optionally) to clock the global timers in the programmable interrupt controller (PIC) and the IEEE 1588 Timer Module.	

Table continues on the next page...

Table 4-4. Clock External Signals-Detailed Signal Descriptions (continued)

Signal	I/O	Description	
		Timing	Assertion/Negation-See the chip data sheet for specific timing information for this signal.
SD*n*_REF_CLK*n*_P, SD*n*_REF_CLK*n*_N	I	SerDes high-speed interface differential reference clocks. These differential clock inputs are used to independently clock the banks/ports of high-speed differential signal lanes available on the chip. The SerDes reference clock timing specifications are given in the chip data sheet . See .	
		Timing	Assertion/Negation-See the chip data sheet for specific timing information for these signals.
CLK_OUT	O	Diagnostic clock output. This output may be configured to offer one of a variety of internal system clocks to external hardware for diagnostic or debug purposes. See CLK_OUT configuration.	
DDRCLK	I	DDR controller complex clock.	
USBCLK	I	Clock input for the UTMI/USB PHY. See USB external signals.	

4.3 Local Configuration Control Registers

4.3.1 Accessing Configuration, Control, and Status Registers

The memory-mapped configuration, control, and status registers (CCSRs) occupy a 16 MB region of memory.

Their location is programmable using CCSR base address register high (CCSRBARH) and CCSR base address register low (CCSRBARL); together, these registers are referred to as CCSRBAR. The default base address for the CCSRs is 0x00_FE00_0000. CCSRBARH and CCSRBARL are part of the local access block of CCSR memory, which begins at offset 0x0 from CCSRBAR. Because CCSRBAR is at offset 0x0 from the beginning of the local access registers, CCSRBAR always points to itself.

4.3.1.1 Updating CCSRBARs

Updating the CCSRBARs that relocate the entire 16 MB region of CCSR registers requires special treatment.

The effect of the update must be guaranteed to be visible by the mapping logic before an access to the new location is seen.

To ensure this happens, use the following guidelines:

- CCSRBARH and CCSRBARL should be updated during initial configuration of the device when only one host or controller has access to the device.
  - If an external host on PCI Express or RapidIO is configuring the device, it should set CCSRBARH and CCSRBARL to the desired final values before the core is released to boot.
  - If the core is initializing the device, it should set CCSRBARH and CCSRBARL to the desired final values before enabling other I/O devices to access the device.

When updating CCSRBARH and CCSRBARL, use the following sequence:

1. Place a temporary LAW over the new planned CCSRBAR space (because the CCSR space has not been moved yet, the address of the LAW register is still relative to the old CCSR space). Program the LAWAR*n*[TRGT_ID] = 0x1E (a reserved setting) for this temporary LAW. When the LAW registers for this temporary LAW are read, it forces the initial write to the CCSR space to complete. Note that this LAW is only temporary.
2. The application that is performing the update must ensure that all other cores and applications are not accessing the configuration space during the procedure.
3. Read the current CCSRBARH and CCSRBARL using load word instructions.
4. Follow this with an **isync** instruction. This forces any outstanding accesses to configuration space to completion.
5. Write the new values for CCSRBARH and CCSRBARL to their old locations.

   The CCSRBARH has a shadow register. When the CCSRBARH has a new value written it loads a CCSRBARH shadow register. When the CCSRBARL is written, the CCSRBARH shadow register contents along with the CCSRBARL value are loaded into the CCSRBARH and CCSRBARL registers, respectively.

6. Follow this with a **sync** instruction.
7. Write a 1 to the commit bit (C) of CCSRAR at the old location.
8. Follow this with a **sync** instruction.
9. The temporary LAW configured in Step 1 above should now be disabled and reused elsewhere because it is no longer needed.

4.3.2 Accessing Alternate Configuration Space

An alternate configuration space can be accessed by configuring the ALTCBARH, ALTCBARL, and ALTCAR registers.

These are intended to be used with the pre-boot loader (PBL) to allow the PBL to access a 16 MB region of the memory map. By loading the proper PBL command in the serial ROM, the base address in ALTCBARH and ALTCBARL can be combined with the 24

bits of address offset supplied from the serial ROM to generate a 40-bit address that is mapped to the target specified in ALTCAR. Thus, by configuring these registers, the PBL has access to the entire memory map, one 16 MB block at a time.

NOTE

Updates to the alternate configuration access window must be performed with care. The ALTCBARL and ALTCBARH must be written before setting ALTCAR[EN] or undefined results will occur.

While enabled, the alternate configuration space always takes precedence over the LAWs. The CoreNet Coherency Fabric (CCF) automatically disables the alternate configuration window when the PBL has completed its pre-boot initialization (PBI) process. Windows (including LAWs and the boot space translation window) can be enabled by the PBL during PBI to establish an initial address map that the cores see during their boot process.

The alternative configuration mechanism cannot be used to access external devices on the peripheral interfaces (SRIO or PCI Express). ALTCAR does not support SRIO or PCIe target IDs.

4.3.3 Boot Space Translation

The pre-boot loader can enable boot space translation, or the boot space translation can be set up by an external host when the device is configured to be in boot holdoff mode.

When each core comes out of reset, its MMU has one 4 KB page defined at 0x0_FFFF_F*nnn*. Each core begins execution with the instruction at effective address 0x0_FFFF_FFFC. To get this instruction, the core's first instruction fetch is a burst read of boot code from effective address 0x0_FFFF_FFC0. For systems in which the boot code resides at a different address, the chip provides boot space translation capability. Note that boot space translation affects transactions initiated by all cores in the same manner.

If translation is to be performed to a page outside the default boot window (8 MB at 0x0_FF80_0000 to 0x0_FFFF_FFFF), the external host or pre-boot loader must then also set up the target ID defining the target destination.

When an address falls within the range for the boot window space, boot space translation is applied (if enabled) to translate the address per Boot space translation register high (LCC_BSTRH), Boot space translation register low (LCC_BSTRL), and Boot space translation attribute register (LCC_BSTAR). If LCC_BSTAR[EN] bit is set and the access falls within the boot translation window size, a translation of the incoming address occurs. The lower address bits that represent the byte offset within the programmed size remain unchanged. The LCC_BSTRH and LCC_BSTRL are combined to form a translation address to replace the remaining upper address bits of the incoming address. The boot window location starts at address 0x0_FF80_0000 and extends to 0x0_FFFF_FFFF. The address range within the boot window that is translated by the boot space translation registers covers the region from 4 GB-BSTAR[SIZE] to 4 GB-1.

4.4 Local Configuration Control Memory Map

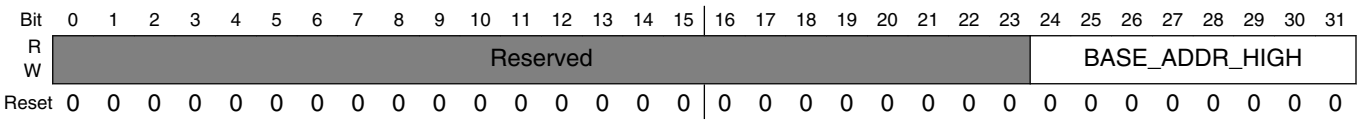
This section describes the CCSRs that control access to the configuration space, the alternate configuration space, and boot space translation as described in the previous sections.

LCC memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Configuration, control, and status registers base address register high (LCC_CCSRBARH)	32	R/W	0000_0000h	4.4.1/184
4	Configuration, control, and status registers base address register low (LCC_CCSRBARL)	32	R/W	FE00_0000h	4.4.2/184
8	Configuration, control, and status registers attribute register (LCC_CCSRAR)	32	R/W	0000_0000h	4.4.3/185
10	Alternate configuration base address register high (LCC_ALTCBARH)	32	R/W	0000_0000h	4.4.4/185
14	Alternate configuration base address register low (LCC_ALTCBARL)	32	R/W	0000_0000h	4.4.5/186
18	Alternate configuration attribute register (LCC_ALTCAR)	32	R/W	0000_0000h	4.4.6/186
20	Boot space translation register high (LCC_BSTRH)	32	R/W	0000_0000h	4.4.7/187
24	Boot space translation register low (LCC_BSTRL)	32	R/W	0000_0000h	4.4.8/187
28	Boot space translation attribute register (LCC_BSTAR)	32	R/W	01F0_000Bh	4.4.9/187

4.4.1 Configuration, control, and status registers base address register high (LCC_CCSRBARH)

Address: 0h base + 0h offset = 0h

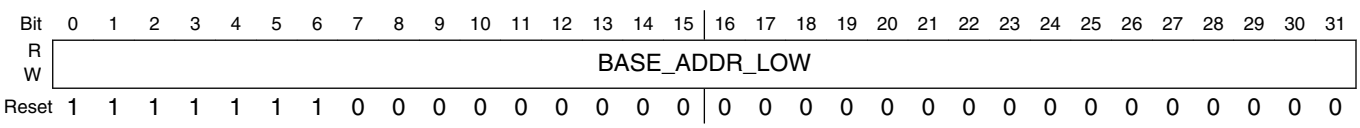


LCC_CCSRBARH field descriptions

Field	Description
0–23 -	This field is reserved. Reserved
24–31 BASE_ADDR_ HIGH	Identifies the upper portion (the 8 most significant bits) of the CCSR window base address.

4.4.2 Configuration, control, and status registers base address register low (LCC_CCSRBARL)

Address: 0h base + 4h offset = 4h



LCC_CCSRBARL field descriptions

Field	Description
0–31 BASE_ADDR_ LOW	Identifies the lower portion of the CCSR window base address. Because the CCSR base address must be aligned on a 16 MB boundary, bits 8-31 are ignored by hardware and always return 0x00_0000.

4.4.3 Configuration, control, and status registers attribute register (LCC_CCSRAR)

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	C	Reserved														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCC_CCSRAR field descriptions

Field	Description
0 C	Commit. Commits the CCSR base address configuration. Writing a 1 to this bit causes the CCSR base address programmed in CCSRBARH and CCSRBARL to take effect. When read, this bit always returns zero.
1–31 -	This field is reserved. Reserved

4.4.4 Alternate configuration base address register high (LCC_ALTCBARH)

Address: 0h base + 10h offset = 10h

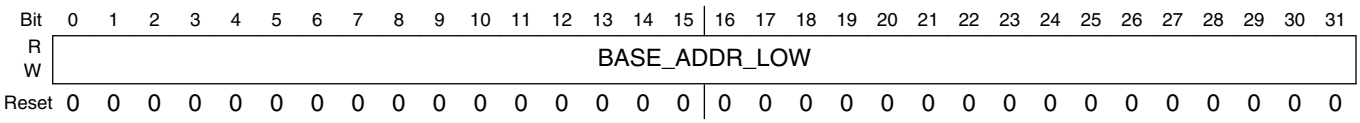
Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Reserved																												BASE_ ADDR_HIGH			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCC_ALTCBARH field descriptions

Field	Description
0–27 -	This field is reserved. Reserved
28–31 BASE_ADDR_ HIGH	Identifies the upper portion (the 4 most significant bits) of the alternate configuration window base address.

4.4.5 Alternate configuration base address register low (LCC_ALTCBARL)

Address: 0h base + 14h offset = 14h

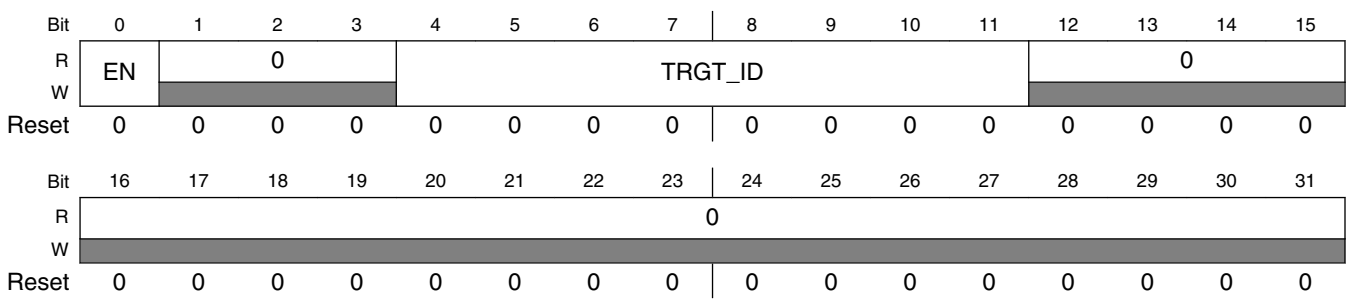


LCC_ALTCBARL field descriptions

Field	Description
0–31 BASE_ADDR_LOW	Identifies the lower portion of the alternate configuration window base address. Because the base address must be aligned on a 16 MB boundary, bits 8-31 are ignored by hardware and always return 0x00_0000.

4.4.6 Alternate configuration attribute register (LCC_ALTCAR)

Address: 0h base + 18h offset = 18h

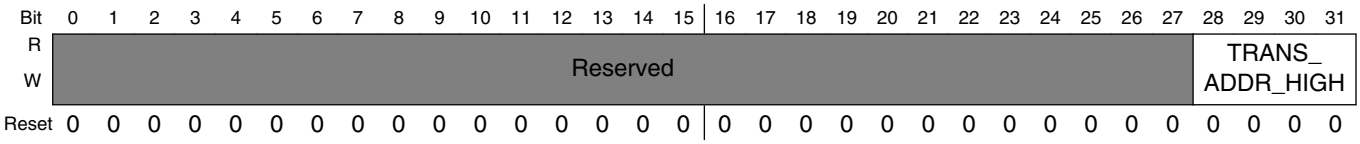


LCC_ALTCAR field descriptions

Field	Description
0 EN	Enable for alternate configuration window. The alternate configuration window has a fixed size of 16 MB. 0 Alternate configuration window is disabled. 1 Alternate configuration window is enabled.
1–3 Reserved	This read-only field is reserved and always has the value 0.
4–11 TRGT_ID	Identifies the device ID to target when a transaction hits in the 16 MB address range defined by the alternate configuration window. See Global Source and Target IDs for encodings. **NOTE:** SRIO and PEX targets are not supported.
12–31 Reserved	This read-only field is reserved and always has the value 0.

4.4.7 Boot space translation register high (LCC_BSTRH)

Address: 0h base + 20h offset = 20h

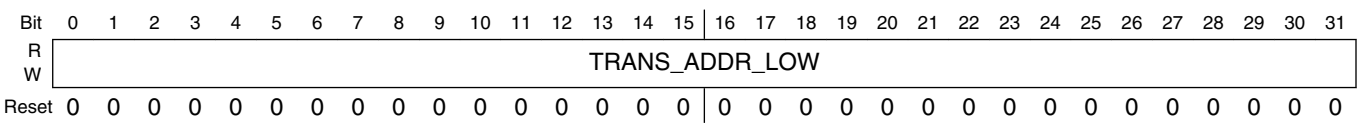


LCC_BSTRH field descriptions

Field	Description
0–27 -	This field is reserved. Reserved
28–31 TRANS_ADDR_ HIGH	Identifies the upper portion (the 4 most significant bits) of the boot space translation address.

4.4.8 Boot space translation register low (LCC_BSTRL)

Address: 0h base + 24h offset = 24h

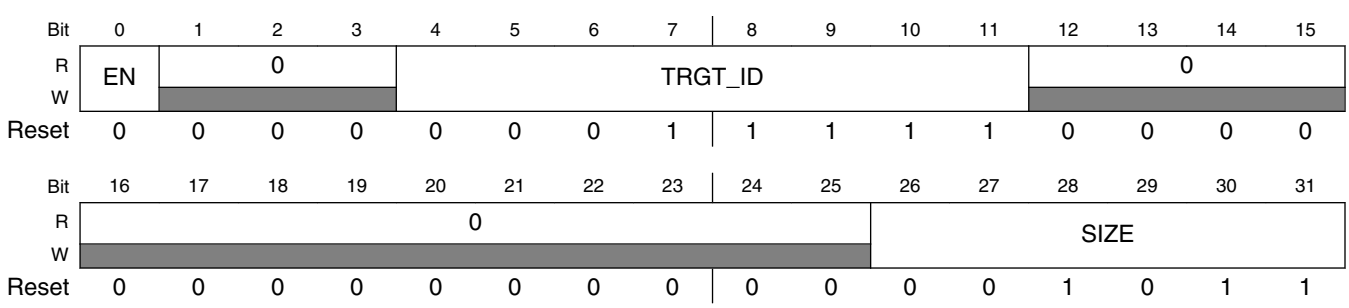


LCC_BSTRL field descriptions

Field	Description
0–31 TRANS_ADDR_ LOW	Identifies the lower portion of the boot space translation address. **NOTE:** The least significant bits of the address representing offsets within the boot space (as defined by BSTAR[SIZE]) are treated as zero by the hardware. Reading them returns zeros.

4.4.9 Boot space translation attribute register (LCC_BSTAR)

Address: 0h base + 28h offset = 28h



LCC_BSTAR field descriptions

Field	Description
0 EN	Enable for boot space translation. 0 Boot space translation is disabled. 1 Boot space translation is enabled.
1–3 Reserved	This read-only field is reserved and always has the value 0.
4–11 TRGT_ID	Identifies the destination for accesses covered by boot space translation. See Global Source and Target IDs for encodings.
12–25 Reserved	This read-only field is reserved and always has the value 0.
26–31 SIZE	Boot space translation window size. The window size is 2 $^{(SIZE+1)}$ bytes. Minimum window size is 4 KB; maximum window size is 8 MB. Example settings: 000000-001010 Reserved 001011 4 KB 001100 8 KB 001101 16 KB 010101 4 MB 010110 8 MB 010111-111111 Reserved

4.5 Clocking Memory Map

The following table summarizes the memory mapped registers which are used to configure clocking features.

Clocking memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
E_1000	Core cluster n clock control/status register (Clocking_CLKC1CSR)	32	R/W	0000_0000h	4.5.1/189
E_1010	Clock generator n hardware accelerator control/status register (Clocking_CLKCG1HWACSR)	32	R/W	0000_0000h	4.5.2/190
E_1020	Core cluster n clock control/status register (Clocking_CLKC2CSR)	32	R/W	0000_0000h	4.5.1/189
E_1030	Clock generator n hardware accelerator control/status register (Clocking_CLKCG2HWACSR)	32	R/W	0000_0000h	4.5.2/190
E_1040	Core cluster n clock control/status register (Clocking_CLKC3CSR)	32	R/W	0000_0000h	4.5.1/189

Table continues on the next page...

Clocking memory map (continued)

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
E_1050	Clock generator n hardware accelerator control/status register (Clocking_CLKCG3HWACSR)	32	R/W	0000_0000h	4.5.2/190
E_1070	Clock generator n hardware accelerator control/status register (Clocking_CLKCG4HWACSR)	32	R/W	0000_0000h	4.5.2/190
E_1090	Clock generator n hardware accelerator control/status register (Clocking_CLKCG5HWACSR)	32	R/W	0000_0000h	4.5.2/190
E_1800	PLL cluster n general status register (Clocking_PLLC1GSR)	32	R	0000_0000h	4.5.3/192
E_1820	PLL cluster n general status register (Clocking_PLLC2GSR)	32	R	0000_0000h	4.5.3/192
E_1840	PLL cluster n general status register (Clocking_PLLC3GSR)	32	R	0000_0000h	4.5.3/192
E_1860	PLL cluster n general status register (Clocking_PLLC4GSR)	32	R	0000_0000h	4.5.3/192
E_1880	PLL cluster n general status register (Clocking_PLLC5GSR)	32	R	0000_0000h	4.5.3/192
E_1A00	Platform clock domain control/status register (Clocking_CLKPCSR)	32	R/W	0000_0000h	4.5.4/194
E_1C00	Platform PLL general status register (Clocking_PLLPGSR)	32	R/W	0000_0000h	4.5.5/196
E_1C20	DDR PLL general status register (Clocking_PLLDGSR)	32	R/W	0000_0000h	4.5.6/198

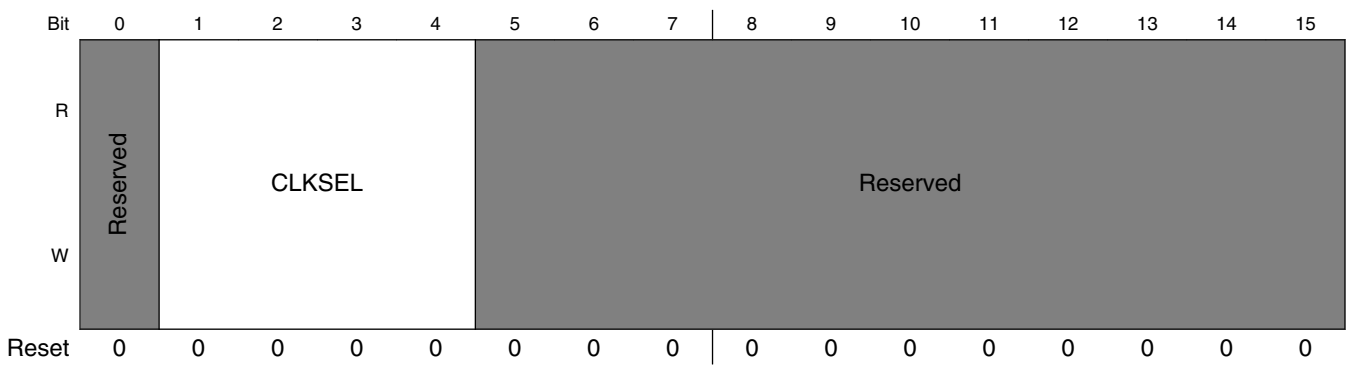
4.5.1 Core cluster n clock control/status register (Clocking_CLKC*n*CSR)

The CLKC*n*CSR registers control the clock frequency selection for each core cluster.

Table 4-5. Core cluster assignments to CLKC*n*CSR registers

Register	Cluster Group	Core Cluster
CLKC1CSR	Cluster Group A (CGA)	Core Cluster 1
CLKC2CSR	Cluster Group A (CGA)	Core Cluster 2
CLKC3CSR	Cluster Group B (CGB)	Core Cluster 3 **NOTE:** This is not supported on T4160 and T4080

Address: E_1000h base + 0h offset + (32d × i), where i=0d to 2d



Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

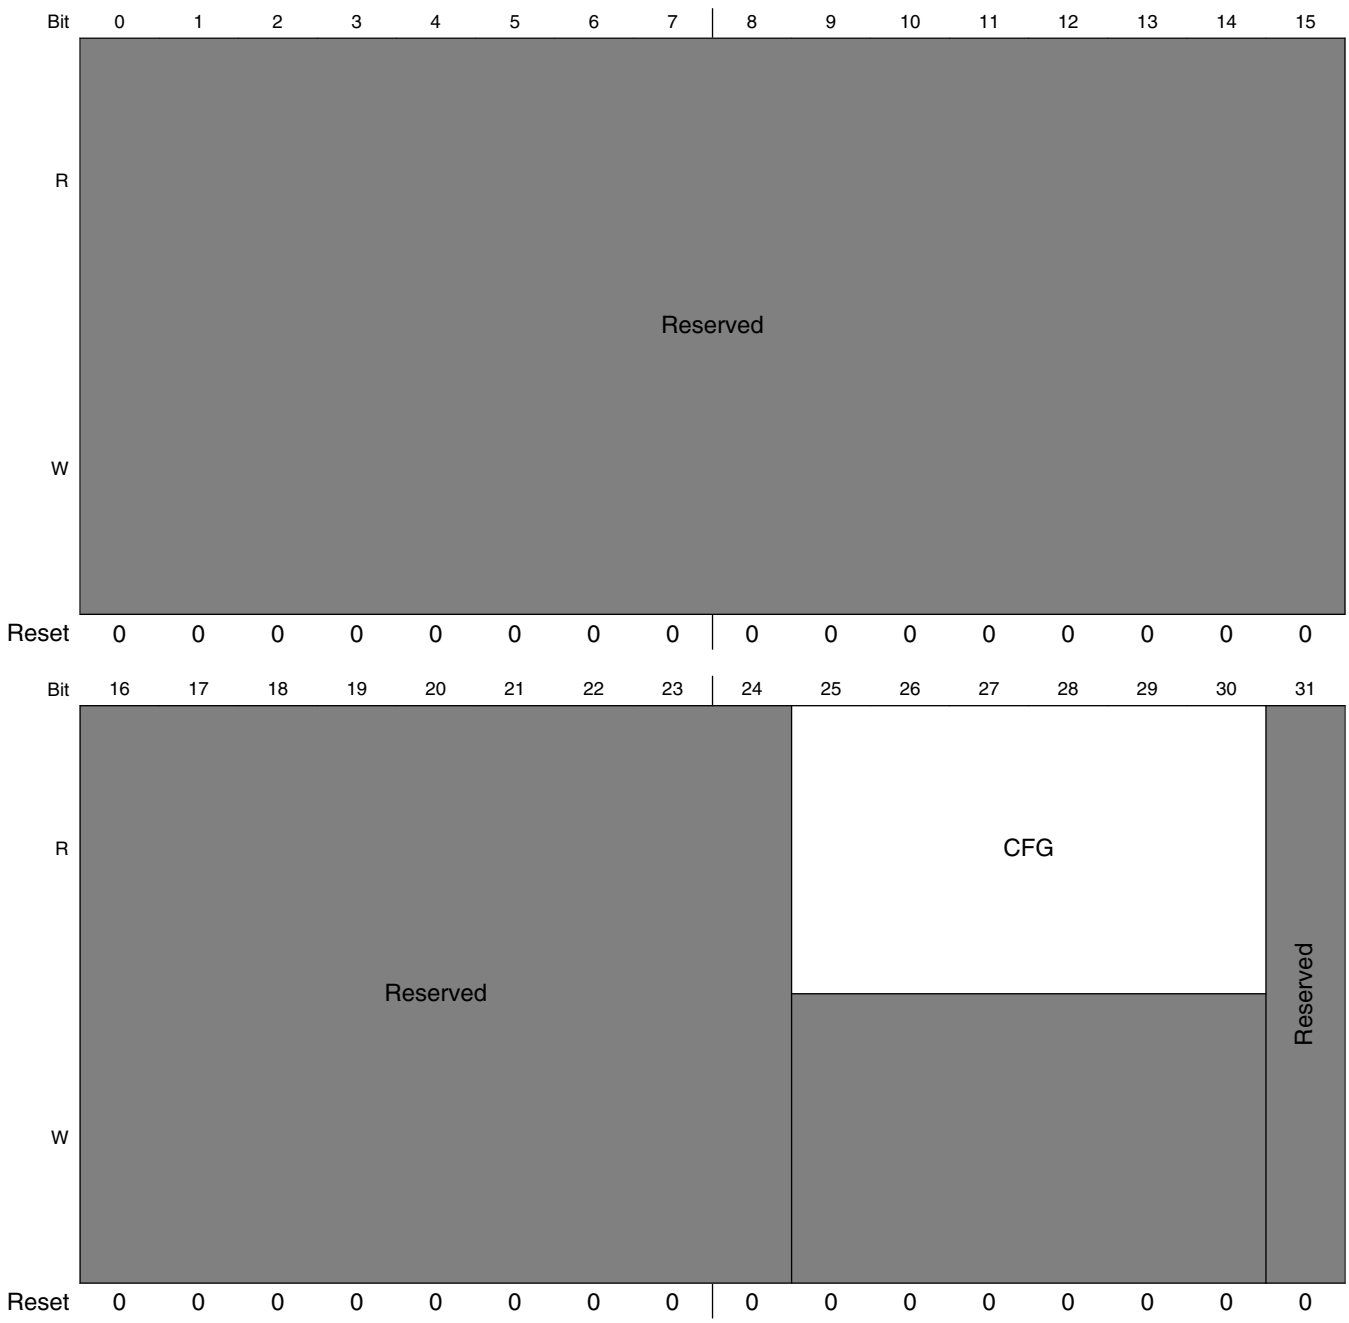
23–31 -	This field is reserved. Reserved

4.5.5 Platform PLL general status register (Clocking_PLLPGSR)

The PLLPGSR register provides information regarding the PLL's configuration.

Address: E_1000h base + C00h offset = E_1C00h



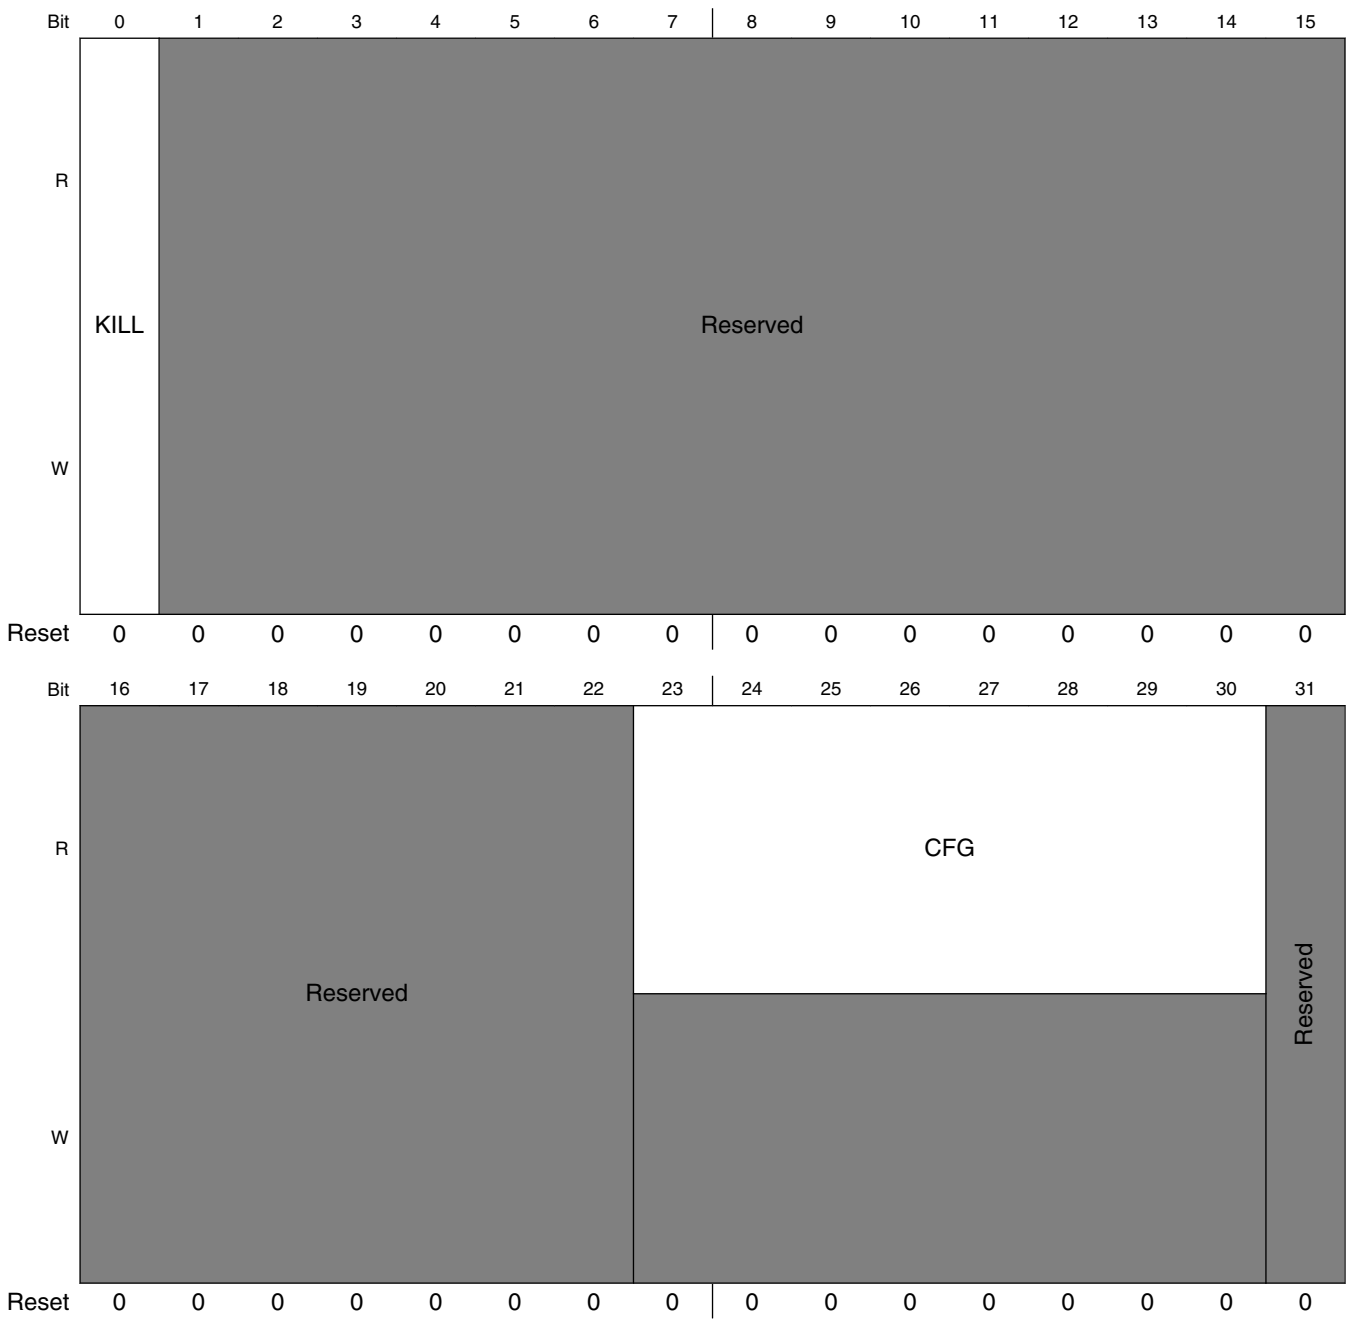
Clocking_PLLPGSR field descriptions

Field	Description
0–24 -	This field is reserved. Reserved
25–30 CFG	Reflects the current PLL multiplier configuration. Indicates the frequency for this PLL. Defined settings are from 0_0111 (7:1) through 1_0000 (16:1). All other encodings are reserved. **NOTE:** Not all ratios are supported due to frequency restrictions. Refer to the chip data sheet for the supported frequencies.
31 -	This field is reserved. Reserved

4.5.6 DDR PLL general status register (Clocking_PLLDGSR)

The PLLDGSR register provides information regarding the DDR PLL configuration.

Address: E_1000h base + C20h offset = E_1C20h



Clocking_PLLDGSR field descriptions

Field	Description
0 KILL	Writing a 1 to this bit disables the PLL. If PLL*n*GSR[CFG] indicates 0b00000, the PLL is bypassed and this bit (KILL) is set. 0 PLL is active. 1 PLL is disabled.
1–22 -	This field is reserved. Reserved
23–30 CFG	Reflects the current PLL multiplier configuration. Indicates the frequency for this PLL.
31 -	This field is reserved. Reserved

4.6 Functional description

This section describes the various ways to reset the chip, the POR sequence, the hard reset sequence, the POR configurations, the reset configuration word (RCW), and the clocking on the device.

4.6.1 Power-on reset sequence

Assertion of the external PORESET_B signal initiates the power-on reset flow.

See the chip data sheet for more information regarding power sequencing and PORESET_B input requirements.

After the negation of PORESET_B, the reset control logic begins cycling the device through its full reset and RCW configuration process. The chip asserts HRESET_B throughout the power-on reset process, including RCW configuration. Reset and RCW configuration time varies depending on the configuration source and SYSCLK frequency. Initially, the RCW source POR configuration inputs are sampled to determine the configuration source. Next, the device begins loading the RCW data. The system PLL begins to lock according to the clock ratio/mode values communicated in the RCW data. Once the PLL locks and the RCW data is loaded, HRESET_B is released by the device and the clocking unit begins distributing PLL outputs throughout the device. Pre-boot initialization is then optionally performed, and the cores are permitted to boot.

The detailed POR sequence for the device is as follows:

1. The external system logic asserts PORESET_B and power is applied to comply with the chip's data sheet .

2. PORESET_B asserted causes all registers to be initialized to their default states and most I/O drivers to be released to high impedance (some clock, clock enables, and system control signals are active).

NOTE

The common on-chip processor (COP) requires the ability to independently assert PORESET_B and TRST_B to fully control the processor. If a JTAG/COP port is used, follow the JTAG/COP interface connection recommendations given in the chip's data sheet . If the JTAG interface and COP header are not being used, it is recommended that TRST_B be tied to PORESET_B so that TRST_B is asserted when PORESET_B is asserted, ensuring that the JTAG scan chain is initialized during the power-on reset flow. See the JTAG configuration signals section in the chip's data sheet for more information.

3. The system applies a toggling SYSCLK signal and stable POR configuration inputs. At this point, SYSCLK is propagated throughout the device; the platform PLL is running in bypass mode.
4. The device begins driving HRESET_B asserted after sampling the assertion of PORESET_B.
5. External system logic negates PORESET_B after its required hold time and after POR configuration inputs have been valid for their required setup times.
6. The device samples the RCW source POR configuration inputs (cfg_rcw_src[0:*n*]) on deassertion of PORESET_B to determine the RCW source. Note that the POR configuration inputs are sampled only on a PORESET_B.
7. The device initiates and completes reset of the rest of the platform logic. Note that this platform reset step is the point where the device hard reset process (HRESET_B) begins if an external device asserts HRESET_B (assuming the device is not already sequencing through the power-on reset process).
8. Some of the I/O drivers are enabled; specifically, any signals required by the interface specified as the source of RCW data in cfg_rcw_src[0:*n*]. All of the DDR I/Os become enabled at this point (though MCKE, MCK, MODT are enabled from the beginning). The ASLEEP signal is also enabled at this point.
9. If the IFC's NAND Flash interface is configured as the RCW source, the reset block instructs the IFC to load a boot block from Flash into the internal buffer RAM of the IFC. Once complete, the reset block proceeds to instruct the Pre-Boot Loader to begin reading in RCW data. Note that if the IFC NAND Flash interface reports an ECC error, the device reset sequence is halted indefinitely, waiting for another PORESET_B or hard reset.

10. The pre-boot loader (PBL) starts loading the RCW data from the interface specified by cfg_rcw_src[0:*n*] configuration inputs and stores that 64 bytes of data to the RCWSR registers within the device configuration block. Loading time varies and depends on the source of the RCW. Hard Coded RCW Options) for more information .
11. The PLLs begin to lock.
12. The sequence then waits for the PBL RCW process to be completed (loading of all 512 bits). If the PBL reports an error during its process of loading the RCW data, the device reset sequence is halted indefinitely, waiting for another PORESET_B or hard reset.
13. The platform clock tree is then switched over and is driven by the output of the platform PLL.
14. The device stops driving HRESET_B at this point. All other I/O drivers are enabled at this point.
15. If the IFC's NAND Flash interface is:
    - configured as the pre-boot initialization source
    - the IFC's NAND Flash interface was NOT previously used as the RCW source,

    then the reset block informs the IFC to load a boot block from Flash into the internal buffer RAM of the IFC. Once complete, the IFC signals back to the reset block, and the reset block can proceed. Note that if the IFC reports an ECC error, the device reset sequence is halted indefinitely, waiting for a hard reset or PORESET_B.

16. The PBL performs pre-boot initialization, if enabled by RCW, by reading data from either the eSDHC, SPI, I^2C1, or or IFC interface and writing to CCSR space or local memory space (SRAM, DDR). If the PBL reports an error during its pre-boot initialization process, the device reset sequence is halted indefinitely, waiting for a hard reset or PORESET_B. Note that non-CCSR-mapped memory space of a module on OCN must not be the target of any pre-boot initialization.
17. Any external device optionally driving HRESET_B negates it if not done earlier. If other external devices do not release HRESET_B, the device reset sequence stalls at this point.
18. System ready state. The peripheral interfaces (serial RapidIO and PCI Express) are released to accept external requests, and the boot vector fetches by the cores are allowed to proceed unless processor booting is further held off by the boot release register (BRR) in the device configuration module. The ASLEEP signal negates synchronized to a rising edge of SYSCLK, indicating the ready state of the system. After reaching this system ready state, the ASLEEP signal transitions to the asserted state when the device enters sleep mode.

NOTE

After completing reset, software should check the SerDesx_PLLnRSTCTL[RST_DONE] field to make sure that each active SerDes PLL on the device has locked. Transactions or packet data cannot be transferred through the targeted lane(s) of the SerDes interface if the PLL associated with the lane(s) does not lock properly. Note that a SerDes PLL will not lock if the corresponding reference clock is not provided.

Figure below shows a timing diagram of the POR sequence.

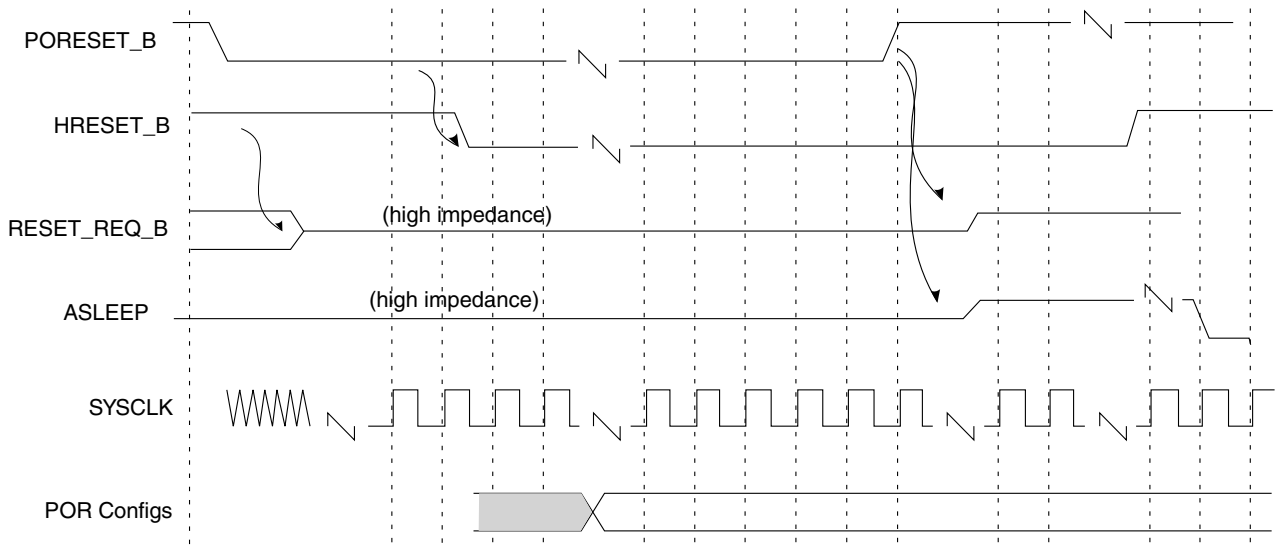


Figure 4-1. Power-on reset sequence

4.6.2 Hard reset sequence

The hard reset sequence is initiated by the external system asserting HRESET_B. Upon sampling the HRESET_B asserted, the device then begins driving HRESET itself throughout the hard reset state.

Reset and RCW configuration time varies subject to the configuration source and SYSCLK frequency. The reset configuration input signals are not sampled by a hard reset (only a power-on reset), so the device immediately begins loading RCW data and configures the device as explained in Reset configuration word (RCW). After the configuration sequence completes, the device releases the HRESET signal and exits the hard reset state. After negation is detected, a 16-cycle period is taken before testing for the presence of an external reset. The hard reset sequence begins with reset of the device at step 7 in Power-on reset sequence.

4.6.3 Power-on reset configuration

Various device functions are initialized by sampling certain signals during power on reset.

During PORESET_B, all other signal drivers connected to these signals must be in the high-impedance state.

All POR configuration signals have internal pull-up resistors so that if the desired setting is high, there is no need for a pull-up resistor on the board. See the chip data sheet for proper pull-down resistor values for POR configuration signals, when necessary.

This section describes the functions and modes configured by the POR configuration signals.

NOTE

In the following tables, the binary value 0 represents a signal pulled down to GND and a value of 1 represents a signal pulled up to that signal's corresponding V_{DD} voltage level, regardless of the sense of the functional signal name.

4.6.3.1 Reset configuration word (RCW) source

The reset configuration word (RCW) source inputs, cfg_rcw_src[0:8], are multiplexed on {IFC_AD[8:15], IFC_CLE}. These configuration inputs select the source for the RCW data as shown in the following table. The encoded values latched on these signals during POR are accessible in POR Status Register 1 [RCW_SRC], as described in POR Status Register 1 (DCFG_CCSR_PORSR1).

Table 4-8. RCW source encodings

cfg_rcw_src [0]_[1:4]_[5:8] value	RCW source
0_0000_xxxx	Reserved
0_0001_xxxx	8-bit NOR Flash cfg_rcw_src[5]: 0 Address shift “left” (most significant bits are IFC_AD[0:n-1] 1 Address shift “right” (least significant bits are IFC_AD[0:n-1] cfg_rcw_src[6:7]: 00 Reserved

1. Not valid as an IFC_MODE encoding

4.6.3.2 General-purpose input

The general-purpose inputs listed in this table are available for application-specific use.

The encoded values latched on these signals during POR are accessible in GPPORCR1[POR_CFG_VEC], as described in General-Purpose POR Configuration Register (DCFG_CCSR_GPPORCR1).

Table 4-9. General-purpose input

Functional signals	Reset configuration name	Value (binary)	General-purpose input
IFC_AD[7:0] Default (1111_1111)	cfg_gpinput[7:0]	all	Application-defined

4.6.3.3 DRAM type select

The DRAM type select input, described in this table, specifies the DDR technology and, thus, voltage (GV_{DD}) to be used with the DDR memory controllers.

The encoded value latched on this signal during POR is accessible in PORSR2[DRAM_TYPE], as described in POR Status Register 2 (DCFG_CCSR_PORSR2).

Table 4-10. DRAM type select

Functional signals	Reset configuration name	Value (binary)	DRAM type
IFC_AD21	cfg_dram_type	0	DDR3 technology (1.5 V)
(Default 1)		1	DDR3L technology (1.35 V)

4.6.3.4 SerDes XVDD voltage select

The XVDD type select input, described in this table, specifies the XVDD voltage to be used with the chip. The encoded value latched on this signal during POR is accessible in PORSR2[XVDD_SEL], as described in POR Status Register 2 (DCFG_CCSR_PORSR2).

Table 4-11. SerDes XVDD voltage select

Functional signals	Reset configuration name	Value (binary)	XVDD voltage
ASLEEP Default (1)	cfg_xvdd_sel	0	1.5 V
		1	1.35 V

4.6.3.5 IFC external transceiver enable polarity select

The IFC external transceiver enable polarity select input, described in this table, specifies the polarity of the IFC_TE output signal to accommodate external transceivers with either active-high or active-low enable inputs.

The encoded value latched on this signal during POR is accessible in PORSR1[IFC_TE]. See External transceiver enable (TE) for more information.

Table 4-12. IFC external transceiver enable polarity select

Functional signals	Reset configuration name	Value (binary)	IFC external transmitter polarity
IFC_TE	cfg_ifc_te	0	IFC drives logic 1 for TE assertion
Default (1)		1	IFC drives logic 0 for TE assertion

4.6.4 Reset configuration word (RCW)

The chip uses an external memory interface to import a subset of the reset configuration information from a memory device during reset.

Such information is called reset configuration word (RCW) data.

The pre-boot loader (PBL) loads RCW data from a non-volatile memory device interface, as specified by the RCW source configuration inputs (cfg_rcw_src[0:8]-see Reset configuration word (RCW) source for more information). See Pre-Boot Loader for details on the operation of the PBL. Note that this approach does not completely remove the necessity for at least a few power-on reset (POR) configuration signals. As noted, POR config signals are used to control RCW source information in addition to other low-level system configuration.

The logic involved is clocked directly from SYSCLK since RCW importing takes place before on-chip PLLs are configured.

The RCW is 512 bits long in order to contain all necessary configuration information for the chip. RCW data is read from external memory and written to the RCW status registers (see Reset Control Word Status Register n (DCFG_CCSR_RCWSR*n*)) contained in the Device Configuration and Pin Control module , after which the device is configured as specified in the RCW. Required format of data structure used by PBL provides details of the data structure that is required to reside in non-volatile memory.

NOTE

The chip makes all the required pins available for selected source interface for RCW. Any other multiplexing options on these pins will be overridden.

4.6.4.1 RCW Field Definitions

The following table describes the function of the individual bits of the 512-bit (64-byte) RCW data structure.

NOTE

Unless noted otherwise, any bit ranges in the table listed as reserved must be populated with 0.

Table 4-13. RCW Field Descriptions

Bit(s) (of 0-511)	Field Name	Description	Notes/comments

Table continues on the next page...

Table 4-13. RCW Field Descriptions (continued)

Bit(s) (of 0-511)	Field Name	Description	Notes/comments
168-169	SRDS_PLL_PD_S1	SerDes PLL power down - SerDes 1	This field is used to power down the SerDes 1 PLLs. Bit 168 corresponds to SerDes 1, PLL1; bit 169 corresponds to SerDes 1, PLL2. Options: 0 PLL is not powered down. If this field is set to 0, it informs RESET_REQ logic that it should assert RESET_REQ if a proper reference clock isn't applied or the SerDes PLL does not lock. 1 PLL is powered down. If this field is set to 1, it forces any data lanes selected by the protocols defined in SRDS_PRTCL_S1 that would have been used by this PLL to be powered down as well. For example, if SRDS_PRTCL_S1 selects a protocol which assigns lanes A-D to PLL1 and lanes E-H to PLL2, if PLL2's RCW bit is set to powered down, then lanes E-H are powered down. This field is ignored if the respective SRDS_PRTCL_S1 field does not use a given Serdes PLL. See Rules restricting networking SerDes PLL powerdown for more information.
170-171	SRDS_PLL_PD_S2	SerDes PLL power down - SerDes 2	This field is used to power down the SerDes 2 PLLs. Bit 170 corresponds to SerDes 2, PLL1; bit 171 corresponds to SerDes 2, PLL2. Options: 0 PLL is not powered down. If this field is set to 0, it informs RESET_REQ logic that it should assert RESET_REQ if a proper reference clock isn't applied or the SerDes PLL does not lock. 1 PLL is powered down. If this field is set to 1, it forces any data lanes selected by the protocols defined in SRDS_PRTCL_S2 that would have been used by this PLL to be powered down as well. For example, if SRDS_PRTCL_S2 selects a protocol which assigns lanes A-D to PLL1 and lanes E-H to PLL2, if PLL2's RCW bit is set to powered down, then lanes E-H are powered down. This field is ignored if the respective SRDS_PRTCL_S2 field does not use a given Serdes PLL. See Rules restricting networking SerDes PLL powerdown for more information.
172-173	SRDS_PLL_PD_S3	SerDes PLL power down - SerDes 3	This field is used to power down the SerDes 3 PLLs. Bit 172 corresponds to SerDes 3, PLL1; bit 173 corresponds to SerDes 3, PLL2. Options: 0 PLL is not powered down. If this field is set to 0, it informs RESET_REQ logic that it should assert RESET_REQ if a proper reference clock isn't applied or the SerDes PLL does not lock. 1 PLL is powered down. If this field is set to 1, it forces any data lanes selected by the protocols defined in SRDS_PRTCL_S3 that would have been used by this PLL to be powered down as well. For example, if SRDS_PRTCL_S3 selects a protocol which assigns lanes A-D to PLL1 and lanes E-H to PLL2, if PLL2's RCW bit is set to powered down, then lanes E-H are powered down. This field is ignored if the respective SRDS_PRTCL_S3 field does not use a given Serdes PLL. See Rules restricting non-networking SerDes PLL powerdown for more information.

Table continues on the next page...

Table 4-13. RCW Field Descriptions (continued)

Bit(s) (of 0-511)	Field Name	Description	Notes/comments
174-175	SRDS_PLL_PD_S4	SerDes PLL power down - SerDes 4	This field is used to power down the SerDes 4 PLLs. Bit 174 corresponds to SerDes 4, PLL1; bit 175 corresponds to SerDes 4, PLL2. Options: 0 PLL is not powered down. If this field is set to 0, it informs RESET_REQ logic that it should assert RESET_REQ if a proper reference clock isn't applied or the SerDes PLL does not lock. 1 PLL is powered down. If this field is set to 1, it forces any data lanes selected by the protocols defined in SRDS_PRTCL_S4 that would have been used by this PLL to be powered down as well. For example, if SRDS_PRTCL_S4 selects a protocol which assigns lanes A-D to PLL1 and lanes E-H to PLL2, if PLL2's RCW bit is set to powered down, then lanes E-H are powered down. This field is ignored if the respective SRDS_PRTCL_S4 field does not use a given Serdes PLL. See Rules restricting non-networking SerDes PLL powerdown for more information.
176-177	SRDS_DIV_PEX_S3	SerDes frequency divider - SerDes 3, PCI Express	This field configures the frequency of PCI Express protocols on SerDes 3. Lanes that are supporting other protocols and frequencies are unaffected by this field. Options: 00 8G (or 5G if that is the maximum for the corresponding protocol selection) 01 5G 10 2.5G 11 Reserved
178	SRDS_DIV_SRIO_S3	SerDes frequency divider - SerDes 3, Serial RapidIO	This field configures the frequency of serial RapidIO protocols on SerDes 3. Lanes that are supporting other protocols and frequencies are unaffected by this field. Options: 0 5G 1 2.5G
179	SRDS_DIV_SRIO_S4	SerDes frequency divider - SerDes 4, Serial RapidIO	This field configures the frequency of serial RapidIO protocols on SerDes 4. Lanes that are supporting other protocols and frequencies are unaffected by this field. Options: 0 5G 1 2.5G
180	SRDS_DIV_AURORA_S4	SerDes frequency divider - SerDes 4, Aurora	This field configures the frequency of Aurora protocols on SerDes 4. Lanes that are supporting other protocols and frequencies are unaffected by this field. 0 3.125G when SRDS_PRTCL_S4=16, 5G for all other values of SRDS_PRTCL_S4 1 1.5625G when SRDS_PRTCL_S4=16, 2.5G for all other values of SRDS_PRTCL_S4

Table 4-13. RCW Field Descriptions (continued)

Bit(s) (of 0-511)	Field Name	Description	Notes/comments
181-182	SRDS_DIV_PEX_S4	SerDes frequency divider - SerDes 4, PCI Express	This field configures the frequency of PCI Express protocols on SerDes 4. Lanes that are supporting other protocols and frequencies are unaffected by this field. Options: 00 8G (or 5G if that is the maximum for the corresponding protocol selection) 01 5G 10 2.5G 11 Reserved
183	Reserved		
Miscellaneous PLL-Related Configuration (Bits 184-191)			
184-191	Reserved		
Boot Configuration (Bits 192-223)			
192-195	PBI_SRC	Pre-boot initialization source. The pre-boot loader fetches address/data pairs from the selected interface for the purpose of pre-boot initialization of CCSR and/or local memory space	The following restrictions apply: • RCW and pre-boot initialization data must be loaded from the same non-volatile memory device • At most, only one given IFC option can be used for cfg_rcw_src, PBI_SRC, and BOOT_LOC. This does not mean that BOOT_LOC cannot be different from cfg_rcw_src and PBI_SRC (provided the second restriction is observed). For example, the device can be configured to load RCW and pre-boot initialization data from NAND Flash (IFC) and boot from DDR. However, the device cannot load RCW and pre-boot initialization data from NAND Flash (IFC) and boot from NOR Flash (IFC). Options: 0000 I^2C1 normal addressing (up to 256 byte ROMs) 0001 I^2C1 extended addressing 0100 SPI 16-bit addressing 0101 SPI 24-bit addressing 0110 SD/MMC 1110 IFC (The RCW field IFC_MODE configures the IFC, provided the IFC has not already been configured by the cfg_rcw_src configuration input signals, which have precedence.) 1111 disabled All other encodings are reserved.
196-200	BOOT_LOC	Boot location	Note the restrictions in PBI_SRC above. Specifically, the second restriction that at most, only one given IFC option can be selected by cfg_rcw_src, PBI_SRC, and BOOT_LOC. Options: 0_0000 PCIe1 0_0001 PCIe2 0_0010 PCIe3

Table 4-13. RCW Field Descriptions (continued)

Bit(s) (of 0-511)	Field Name	Description	Notes/comments
			0_0011 Reserved 0_1000 SRIO 1 0_1001 SRIO 2 1_0000 Memory complex 1 1_0001 Memory complex 2 1_0010 Memory complex 3 1_0100 Interleaved memory complexes 1_1000 IFC (The RCW field IFC_MODE configures the IFC, provided the IFC has not already been configured by the cfg_rcw_src configuration input signals, which have precedence.) All other encodings are reserved.
201	BOOT_HO	Boot hold off mode	Options: 0 All cores except core 0 in hold off 1 All cores in hold off
202	SB_EN	Secure boot enable	Note that secure boot is enabled if either this RCW bit is set or the Intent to Secure fuse value is set. See for more information. Options: 0 Secure boot is not enabled 1 Secure boot is enabled; boot from internal boot ROM
203-211	IFC_MODE	Integrated Flash controller mode	When PBI_SRC and/or BOOT_LOC are configured for IFC, this field selects the IFC mode for either pre-boot initialization or as the initial boot target of the core. Note that cfg_rcw_src has precedence over configuring the IFC. Valid IFC_MODE encodings are a subset of the cfg_rcw_src encodings. See Reset configuration word (RCW) source for the valid encodings for this field.
212-223	Reserved		
Clocking Configuration (Bits 224-255)			
224-226	HWA_CGA_M1_CLK_SEL	Hardware accelerator block, cluster group A, mux 1 clock select.	This controls the async clock frequency provided to the PME module. Options: 000 Synchronous mode - Synchronous to platform frequency 001 Reserved 010 Asynchronous mode - Cluster group A PLL 1 /2 011 Asynchronous mode - Cluster group A PLL 1 /3 100 Asynchronous mode - Cluster group A PLL 1 /4 101 Reserved 110 Asynchronous mode - Cluster group A PLL 2 /2 111 Asynchronous mode - Cluster group A PLL 2 /3

Table 4-13. RCW Field Descriptions (continued)

Bit(s) (of 0-511)	Field Name	Description	Notes/comments
417-418	EC1	This field configures the functionality assigned to the EC1 parallel mode pins.	Options: 00 Frame Manager 2 MAC5 RGMII 01 Reserved 10 GPIO3[8:19] 11 Reserved **NOTE:** If RGMII is to be used by the selected MAC and EC1 is set accordingly, then SGMII mode must not be enabled for that MAC. **NOTE:** To configure a MAC for SGMII operation, the EC1 bits should be configured to select GPIO.
419-420	EC2	This field configures the functionality assigned to the EC2 parallel mode pins.	Options: 00 Frame Manager 1 MAC5 RGMII 01 Frame Manager 2 MAC6 RGMII 10 GPIO3[20:31] 11 Reserved **NOTE:** If RGMII is to be used by the selected MAC and EC2 is set accordingly, then SGMII mode must not be enabled for that MAC. **NOTE:** To configure a MAC for SGMII operation, the EC2 bits should be configured to select GPIO.
421-422	I2C3	This field configures the functionality of the I2C3 pins.	Options: 00 {IIC3_SCL, IIC3_SDA} 01 {GPIO4[0:1]} 10 Reserved 11 Reserved
423-424	I2C4	This field configures the functionality of the I2C4 pins.	Options: 00 {IIC4_SCL, IIC4_SDA} 01 {GPIO4[2:3]} 10 {EVT_B[5:6]} 11 Reserved **NOTE:** EVT_B[5:6] functionality, if selected by this field, defaults to input functionality until software reconfigures to output functionality.
425-443	Reserved		
444	DMA1	This field configures the functionality of the DMA1 pins.	Options: 0 {DMA1_DREQ0_B, DMA1_DACK0_B, DMA1_DDONE0_B} 1 {GPIO4[4:6]}
445	Reserved		

Table continues on the next page...

Table 4-13. RCW Field Descriptions (continued)

Bit(s) (of 0-511)	Field Name	Description	Notes/comments
446-447	DMA2	This field configures the functionality of the DMA2 pins.	Options: 00 {DMA2_DREQ0_B, DMA2_DACK0_B, DMA2_DDONE0_B} 01 {GPIO4[7:9]} 10 {GPIO4[7], EVT_B[7:8]} **NOTE:** EVT_B[7:8] functionality, if selected by this field, defaults to input functionality until reconfigured by software to output functionality.
PLL and Clocking Configuration Expansion (Bits 448-511)			
448-505	Reserved		
506-508	HWA_CGB_M2_CLK_SEL	Hardware accelerator block, cluster group B, mux 2 clock select.	This controls the async clock frequency provided to the Frame Manager 2 module Options: 000 Reserved 001 Reserved 010 Asynchronous mode - Cluster group B PLL 2 /2 011 Asynchronous mode - Cluster group B PLL 2 /3 100 Asynchronous mode - Cluster group B PLL 2 /4 101 Platform/1 110 Asynchronous mode - Cluster group B PLL 1 /2 111 Asynchronous mode - Cluster group B PLL 1 /3 **NOTE:** For more details on frequency restrictions refer the Datasheet.
509-511	Reserved		

4.6.4.1.1 Hard Coded RCW Options

If any of the hardcoded RCW options are used, the PBL RCW loading process is bypassed and the device is automatically configured according to the specific RCW field encodings that are pre-assigned for the given hardcoded RCW option. The hardcoded RCW options can be useful if the board has no valid RCW present or if the customer is unable to load in the RCW from a non-volatile memory. Using a hardcoded RCW option allows the part to be initialized so that the desired RCW can be programmed or restored.

The hardcoded RCW option should be selected based on the system SYSCLK and DDRCLK frequency combination.

NOTE

If a hardcoded RCW option is used:

- The user should not enable the DDR controllers.
- SerDes are not available.

The user may enable the DDR controllers and use SerDes after a valid RCW is restored.

Table 4-14. Hard-Coded RCW Options

cfg_rcw_src[0:8] Encoding	Comments
0_1001_1010	Hardcoded RCW, for use with SYSCLK and DDRCLK combinations: SYSCLK: 66.7 MHz — DDRCLK: 125/133.3 MHz SYSCLK: 100 MHz — DDRCLK: 125/133.3 MHz
0_1001_1100	SYSCLK: 66.7 MHz — DDRCLK: 100 MHz
0_1001_1110	SYSCLK: 100 MHz — DDRCLK: 100 MHz SYSCLK: 125 MHz — DDRCLK: 100/125/133.3 MHz SYSCLK: 133.3 MHz — DDRCLK: 100/125/133.3 MHz

4.6.4.1.2 RCW Settings for Hard-Coded Options

After loading a hard coded RCW, the cores are kept in the boot hold off state, in which the cores are held off from booting. The boot hold off state allows an external debugger to perform initialization of configuration registers and memory before releasing the cores from boot hold off. While in boot hold off, the external debugger via JTAG would be used to program RCW data into external non-volatile memory device.

4.6.5 Clocking

The following sections describe the clocking within the chip.

4.6.5.1 IP logic clock distribution and configuration

The chip takes primary clocking input from the external SYSCLK signal. As shown in the figures below, the SYSCLK input (frequency) is multiplied using multiple phase locked loops (PLL) to create a variety of frequencies which can then be passed to a variety of internal logic, including cores and peripheral IP modules.

The DDR PLL is used to provide clocking to the DDR memory controller complexes. The DDR PLL uses the DDRCLK input clock as a reference to create a unique DDR memory controller complex clock. The DDR complex operates asynchronously with respect to the platform clock.

Note that many of the IP modules contain logic allowing software to further modify their external interface clocks within the IP module. See the applicable IP module chapter for details.

The following figures describe internal logic clock distribution along with the means to configure the various ratios and clock sources. Note that the following figures are not intended to reflect external interface clocking. Although sometimes dependent on or derived from logic clocking, a full description of external interface clocking is described within the applicable IP module chapter of this reference manual. Each of the four SerDes modules are clocked by dedicated SerDes reference clock inputs.

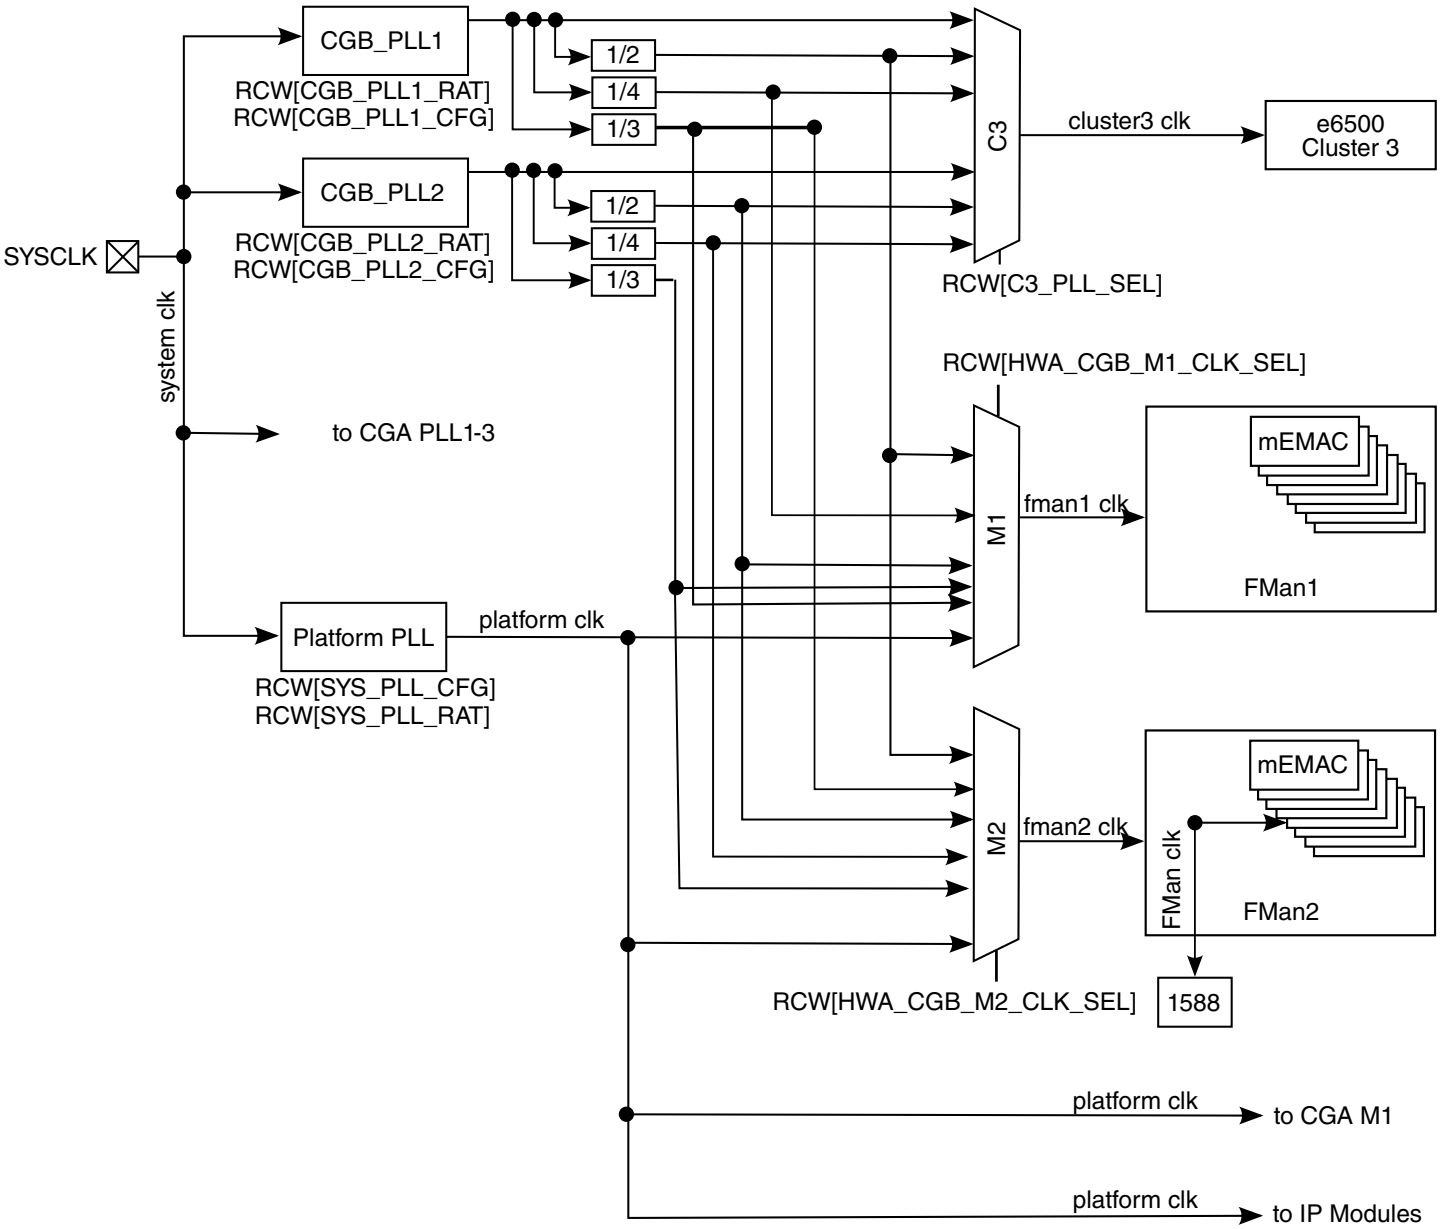

Figure 4-3. T4240 logic clock subsystem block diagram-cluster group B

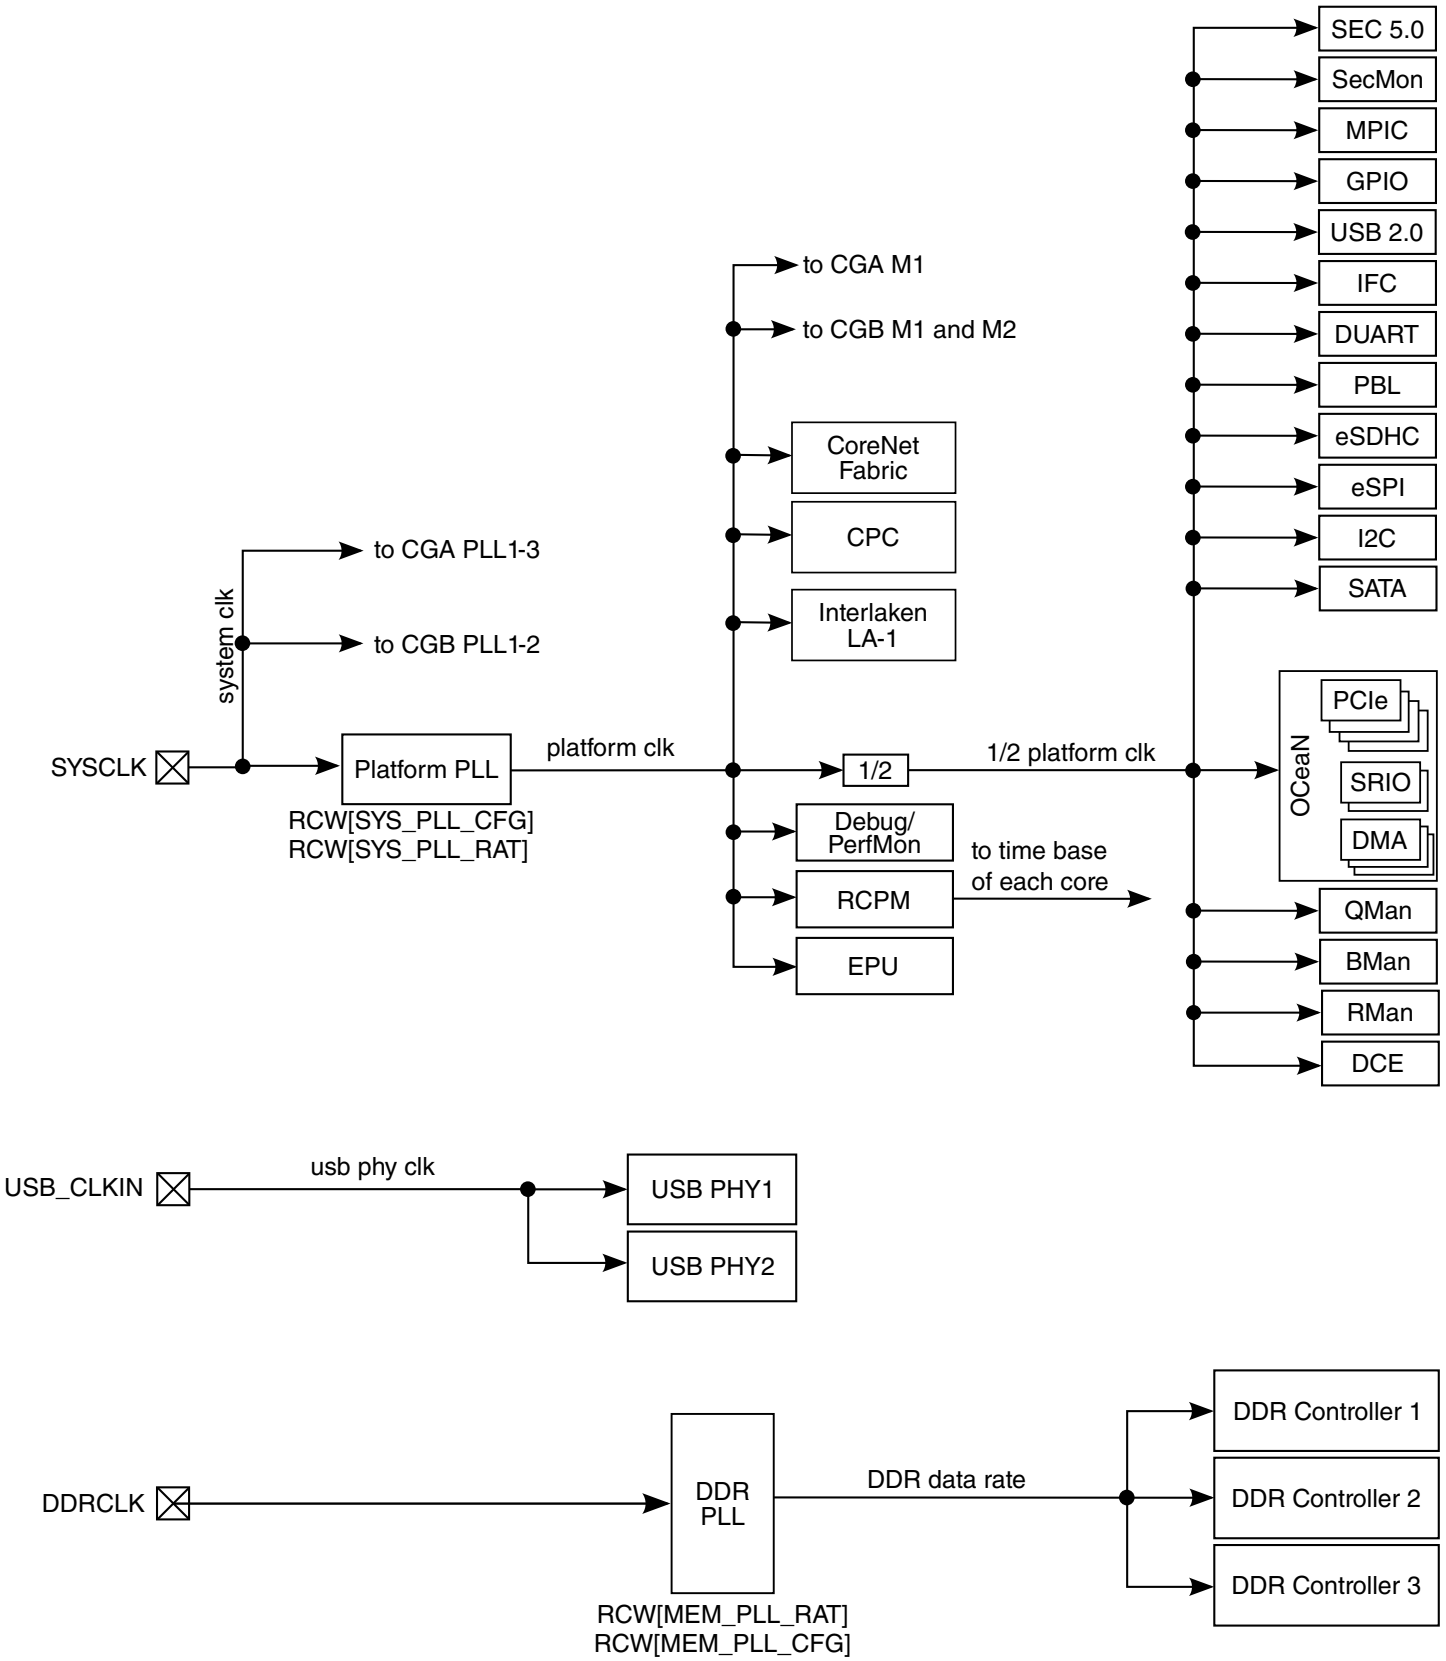

Figure 4-4. T4240 logic clock subsystem block diagram-IP modules

4.6.5.2 Dynamic frequency switching (DFS) control

Dynamic frequency switching (DFS) is supported for each core/hardware-accelerator target through software control. Each target can select from the clock frequencies generated by the PLL cluster which it is connected to. The targets can select from clocks generated by the local PLLs within the CGU or in some cases select from sources external to the CGU. Switching from one frequency to another must take place without introduction of any glitches in the clock path to each core. In order to accomplish this, a state machine is used to properly sequence the switching of clocks.

Each target's clock source is determined at POR by the RCW settings. Once the system is up and running, the CLKCnCSR[CLKSEL] register fields can be written to change each cluster's core operating frequency on-the-fly. When the CLKSEL value for any core changes, the DFS logic will detect the change and sequence the clock switch such that no glitches are introduced. The active clock is always disabled first, then the new target clock source is enabled.

Note that the user MUST wait between writes to the CLKSEL field to allow enough time for the DFS sequence to complete. Back-to-back writes to the CLKSEL field that occur too quickly may result in unpredictable behavior. The wait time should be larger than 12 SYSCLK Window in which DFS occurs.

4.6.6 Voltage ID

The overall performance boost provided by improved device integration, complexity, and a smaller transistor process technology comes with a penalty of higher leakage current. Leakage currents are present in circuitry independent of the specific speed. To guarantee maximum performance with minimum leakage current, a specific method of selecting the optimum voltage level is required to be implemented.

During manufacturing, NXP determines the voltage required to achieve the target frequency bin and programs this information into on-chip Voltage ID (VID) efuses. The VID values are accessed through the fuse status register in the device configuration module (DCFG_FUSESR). Using the VID, initialization software can program the system's voltage regulator to the appropriate value. Abstracting the on-chip voltage ID data from the interface and programming requirements of the regulator allows flexibility in selecting a solution. The power supply design section in the datasheet provides examples of system design options.

Systems must use the VID to change the voltage regulators in the system using a reliable and safe methodology. At initial power on, the system regulator must come up at the default voltage. Then, very early in the boot process, initialization software reads the value in DCFG_FUSESR and translates that value into a command sequence that will program the new voltage value for the regulator. Once the regulator has been sent the new values, allow the regulator time to change voltage and stabilize before enabling non-essential boot features and higher clock rates.

In some cases, changing voltages too fast can cause a fault or shutdown. On many recent model regulators, the voltage changes gradually and the time delay is programmable. However, some older regulators may need to be stepped by software to avoid over-current protection events.

Chapter 5
Pre-Boot Loader (PBL)

5.1 Overview

The pre-boot loader (PBL) performs configuration register reads and writes to initialize the I^2C, IFC FCM (NAND flash), eSDHC, or SPI interface, loads the RCW and pre-boot initialization commands from external memory device through I^2C, IFC FCM (NOR flash), eSDHC, or SPI, and writes data to configuration registers or memory before the local cores are permitted to boot.

The following figure shows a block diagram of PBL, showing the functional organization of the module, which includes interface command modules (ICMs) for eSDHC, I2C1, eSPI, IFC, and a common control module.

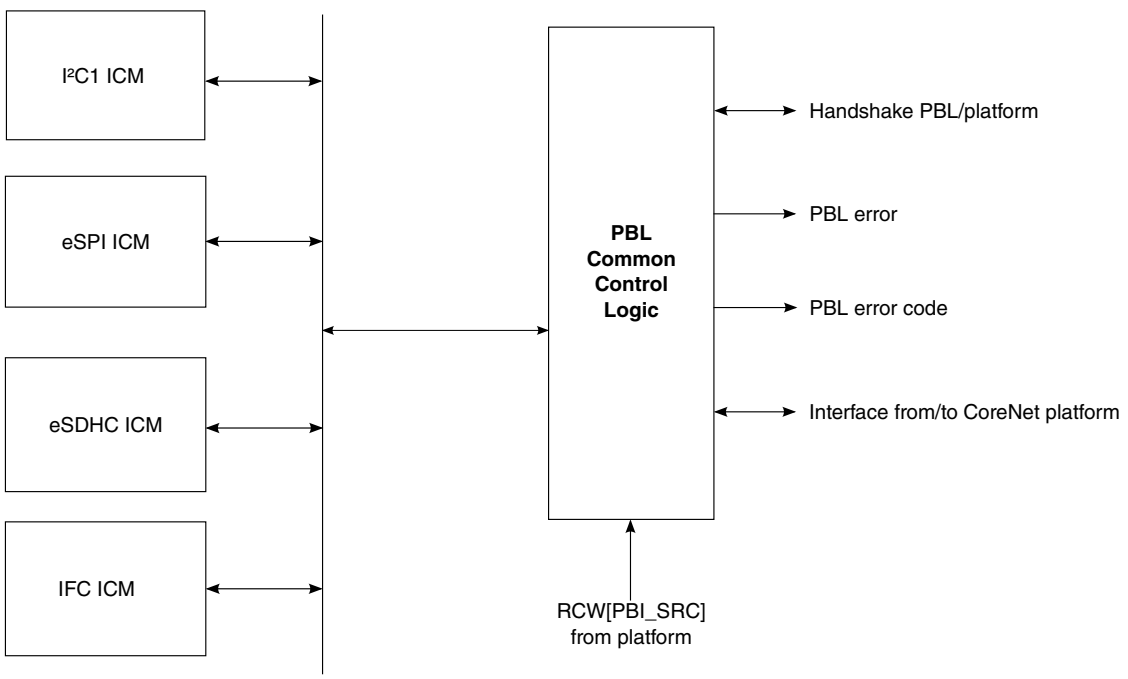

Figure 5-1. Pre-boot loader (PBL) block diagram

5.2 Features summary

PBL supports the following features:

- Initializes and loads RCW/pre-boot initialization commands from eSDHC SD/MMC interface
  - Supports multi-media card (MMC)
    - 1 bit data transfer on MMC interface
    - Compliant with version 4.2 of the specification
    - Standard capacity (< 2 GB)
    - High-capacity (> 2 GB)
  - Supports Secure Digital (SD) memory card
    - 1 bit data transfer on SD interface
    - Compliant with version 2.00 of the specification
    - Standard capacity (< 2 GB)
    - High-capacity (> 2 GB)
- Initializes and loads RCW/pre-boot initialization commands from I2C1 interface
- Initializes and loads RCW/pre-boot initialization commands from IFC FCM NAND/NOR interface
- Initializes and loads RCW/pre-boot initialization commands from eSPI interface
- Reports error upon receiving error response from each interface
- Reports error if RCW byte count is not 64 bytes
- Reports error if RCW address offset is not the specific 64 bytes aligned offset to RCW status registers (RCWSR*n*) to which RCW contents are written
- Reports error in secure boot mode if pre-boot initialization address offset is inside of protected CCSR spaces
- Reports byte count and address misalignment error during pre-boot initialization
- Reports error if PBL command is in invalid format
- Reports error if there is no response from platform when timeout counter expires

5.3 Modes of operation

PBL operates in the following modes:

- Load both RCW and pre-boot initialization commands from individual interface.
- Load RCW only.

5.4 Functional description

This section describes the following topics:

- Device configuration using reset configuration word (RCW)
- Device initialization by PBL
- Required format of data structure used by PBL
- RCW loading by PBL
- Pre-boot initialization command loading by PBL
- Reserved address space used as internal PBL commands
- Error codes
- Registers written by PBL during RCW and PBI phases
- Addressing multiple I^2C EEPROMs
- eSPI mode assumptions

5.4.1 Device configuration using reset configuration word (RCW)

The reset configuration word (RCW) data contains reset configuration information that is loaded by the PBL from a memory device during reset.

The size of the RCW is 64 bytes (512 bits). All of the data read from the RCW source is written to the RCW status registers (RCWSR*n*) in the device configuration and pin control block. See DCFG_RCWSR for more information. The RCWSRs have specific 64 bytes aligned address offsets that the PBL should ensure is written. Any address offset that is not that specific 64 bytes aligned address offset is reported by the PBL as an error to the platform, which asserts the RESET_REQ_B output pin upon receiving the error from the PBL. Refer the Reset configuration word (RCW) source section in Reset, Clocking, and Initialization chapter to see how each encoding for cfg_rcw_src selects a given source of RCW data.

5.4.2 Device initialization by PBL

The cfg_rcw_src configuration input determines the interface to use for retrieving the RCW data. Similarly, RCW[PBI_SRC] determines the interface to use for pre-boot initialization. In these cases, the PBL initializes the , I2C1, eSPI, eSDHC, or IFC FCM (NAND flash) interface before accessing the RCW or PBI commands.

Note that IFC FCM (NOR flash) does not require initialization by the PBL even though it can be selected as the source for the RCW or PBI commands. Each interface command module (ICM) inside the PBL issues CCSR space accesses to setup each interface properly. If there is an error response during initialization, the PBL reports the error to the platform.

NOTE

Only one interface can be used as the source of RCW and pre-boot initialization data. The PBL data structure must not be split across two interfaces.

5.4.2.1 CCSR registers blocked from PBL during secure boot

The following table lists the CCSR address ranges that are blocked from PBL during secure boot.

Table 5-1. CCSR registers blocked from PBL during secure boot

Address range	Size	Description
0x00_0000	4 bytes	CCSRBARH
0x00_0004	4 bytes	CCSRBARL
0x00_0008	4 bytes	CCSRAR
0x02_0000-0x02_FFFF	64 KB	PAMU partitions 1-16
0x0E_8000-0x0E_8FFF	4 KB	Security fuse processor (SFP)
0x30_0000-0x30_FFFF	64 KB	Security Engine (SEC)
0x31_4000- 0x31_4FFF	4 KB	Security monitor

5.4.3 Required format of data structure used by PBL

The RCW and pre-boot initialization commands share the same data structure format, regardless of the type of external memory device used as the source.

Table 5-2. Required format of data structure used by PBL

	0	1	2	3	4	5	6	7
Preamble (required)	1	0	1	0	1	0	1	0
	0	1	0	1	0	1	0	1
	1	0	1	0	1	0	1	0
	0	1	0	1	0	1	0	1
RCW data	ACS=0	BYTE_CNT = 000000 (64 bytes)						CONT=1
	SYS_ADDR[23-16][1]							

Table continues on the next page...

Table 5-2. Required format of data structure used by PBL (continued)

	0	1	2	3	4	5	6	7
	SYS_ADDR[15-8] [1]							
	SYS_ADDR[7-0] [1]							
	BYTE0							
	BYTE1							
	BYTE2							
	.....							
	BYTE63							
First pre-boot initialization command (optional)	ACS	BYTE_CNT						CONT=1
	SYS_ADDR[23-16]							
	SYS_ADDR[15-8]							
	SYS_ADDR[7-0]							
	BYTE0							
	BYTE1							
	BYTE2							
	.....							
	BYTE N-1 (up to 63)							
Second pre-boot initialization command (optional)	ACS	BYTE_CNT						CONT=1
	SYS_ADDR[23-16]							
	SYS_ADDR[15-8]							
	SYS_ADDR[7-0]							
	BYTE0							
	BYTE1							
	BYTE2							
	.....							
	BYTE N-1 (up to 63)							
.....								
.....								
Last pre-boot initialization command (optional)	ACS	BYTE_CNT						CONT=1
	SYS_ADDR[23-16]							
	SYS_ADDR[15-8]							
	SYS_ADDR[7-0]							
	BYTE0							
	BYTE1							
	BYTE2							
	.....							
	BYTE N-1 (up to 63)							
End command (required, special CRC check command with CONT=0)	ACS=0	BYTE_CNT = 000100 (4 bytes)						CONT=0
	SYS_ADDR[23:16] = 0x13, [2]							
	SYS_ADDR[15:8] = 0x80[2]							

Table continues on the next page...

Table 5-2. Required format of data structure used by PBL (continued)

	0	1	2	3	4	5	6	7
	SYS_ADDR[7:0] = 0x40[2]							
	CRC0							
	CRC1							
	CRC2							
	CRC3							

1. SYS_ADDR for the RCW should point to the DCFG_CCSR_RCWSR*n* register.
2. SYS_ADDR = 0x13_8040 is a PBI CRC check command (PBL block base address 0x13_8000 with offset 0x040). See Pre-boot initialization command loading by PBL for more information.

The following table provides field descriptions for the PBL data structure.

Table 5-3. PBL data structure field descriptions

Field name	Description
ACS	Alternate Configuration Space. Logic 1 for alternate configuration space. Logic 0 for CCSR Space. Note that this field must be logic 0 for the RCW data.
BYTE_CNT	Byte Count. Represents the number of bytes associated with this address/data pair. Note that an encoding of all zeros represents 64 bytes. Only power of two multiples are legal (1, 2, 4, 8, 16, 32, and 64 bytes). The associated SYS_ADDR must be aligned to the byte count of the command. 000000 64 bytes 000001 1 byte 000010 2 bytes 000100 4 bytes 001000 8 bytes 010000 16 bytes 100000 32 bytes All other encoding are reserved
CONT	Continue. This bit should be logic 1 for all commands except for the End command.
SYS_ADDR	System Address. The lowest order system address bits. Note that this permits addressability down to a byte for single byte transactions. SYS_ADDR must be aligned to the byte count of the command. The upper bits are either selected from CCSRBAR (depending on value of ACS) and then concatenated with SYS_ADDR to form the full address associated with the command.
BYTEn	Byte number *n* where *n* may range from 0 to 63. Byte 0 corresponds to address 0 relative to the SYS_ADDR (starting address), byte 1 for address 1,..., and byte 63 for address 63. Note the first command must be the RCW address/data pair and must be 64 bytes of data . Note that BYTE*n* is only present/valid in the data structure if *n* is less than the BYTE_CNT.
CRCn	Cyclic Redundancy Check data. CRC value is calculated using CRC-32 algorithm with a start value of 0xFFFF_FFFF and an XOR with 0x0000_0000. The CRC covers all bytes stored in the ROM prior to the CRC. The polynomial used is $1 + x^1 + x^2 + x^4 + x^5 + x^7 + x^8 + x^{10} + x^{11} + x^{12} + x^{16} + x^{22} + x^{23} + x^{26} + x^{32}$

5.4.4 RCW loading by PBL

If initialization of the source memory device completes without error, the PBL fetches RCW data from the source memory device and writes it to the RCW status registers (DCFG_CCSR_RCWSR*n*). See DCFG_RCWSR for more details.

The PBL reports an error and sends a corresponding error code to the platform when one of the following conditions occurs:

- No preamble is detected.
- Alternate configuration space (ACS) is selected (ACS = 1).
- The byte count (BYTE_CNT) is not 64 bytes.
- The system address (SYS_ADDR) is not the specific address offset to the RCWSR to which the RCW contents are written.
- The system does not respond before internal time-out counter (32 bit) expires.

5.4.5 Pre-boot initialization command loading by PBL

If PBI is selected by the RCW[PBI_SRC] field, the PBL PBI commands are processed and routed to CCSR, DDR, and other memory space.

The PBL reports an error and sends a corresponding error code to the platform when one of the following conditions occurs:

- CRC check error
- The byte count is not one of the supported values (1, 2, 4, 8, 16, 32, or 64 bytes). See Table 5-3 for the supported encodings. Note that if byte count is 1 or 2 bytes, the PBL expects 3 or 2 bytes of padding (zeros) after the real data.
- The system address is misaligned to the byte count.
- The system address is in an offset range of protected CCSR space. See CCSR registers blocked from PBL during secure boot, for more information.
- The system does not respond before internal time-out counter expires.
- Invalid internal PBL commands.
- Invalid End command, for example, not valid CRC command with CONT=0.

5.4.6 Reserved address space used as internal PBL commands

When a PBL command accesses the 4 KB (0x13_8000-0x13_8FFF) CCSR address space that is assigned to the PBL, the PBL treats this command entry as a PBL internal command.

There are 4 bytes allocated for each command for command parameters. The byte count must be 4 bytes and unused data must be filled with 0s.

The following table defines each PBL command.

Table 5-4. Description of PBL commands

Command name	Offset	Parameter(s)	Command description
Flush	000	N/A	Follows the previous write with a read from the same address. The purpose of this command is to ensure the previous write has taken effect. **NOTE:** Use of the FLUSH command is restricted to CCSR space. Software should use the WAIT command after commands to non-CCSR space to allow them time to complete before issuing subsequent commands to non-CCSR space.
CRC check	040	The 4 bytes of data indicate the cyclic redundancy check (CRC) value. CRC value is calculated using CRC-32 algorithm with a start value of 0xFFFF_FFFF and an XOR with 0x0000_0000.	Checks CRC for data blocks from the point where the last CRC check was performed until the data block before this CRC check command.
Jump	080	The 4 bytes of data indicate the target address for the jump destination. For I^2C/eSPI/eSDHC/NOR flash, this address is 4 bytes address relative to current address. The address after the jump is a 4 bytes aligned address. For 4 KB large page (128 pages per block) NAND flash, the higher 15 bits of address is non-bad block index relative to current block, the lower 17 bits are ignored. The address after jump is the start of target non-bad block. For 4 KB large page (64 pages per block) NAND flash, the higher 16 bits of address is non-bad block index relative to current block, the lower 16 bits are ignored. The address after jump is the start of target non-bad block. For 2 KB large page NAND flash, the higher 17 bits are used as a non-bad block index relative to current block, the lower 15 bits are ignored. The address after the jump is the start of target non-bad block. For small page NAND flash, the higher 20 bits are used as a non-bad block index relative to the current block, The lower 12 bits are ignored. The address after the jump is the start of target non-bad block.	Upon receiving this command, the PBL reads next data from address starting from jump pointer indicated by the command parameter.
Wait	0C0	The 4 bytes of data indicate the number of cycles to wait.The clock source for the wait cycle is a PBL clock cycle (platform/2).	Upon receiving this command, the PBL waits a number of cycles indicated by the command parameter before reading the next data.

5.4.7 Error codes

The PBL reports errors to the platform under various conditions. PBL error codes are also sent along with the error indication.

The platform stores the error code in the DCFG_CCSR_RSTRQPBLSR[ERR_CODE] bit. See DCFG_RSTRQPBLSR for more information.

The following table shows the encoding for each pre-boot error condition.

Table 5-5. Pre-boot error encoding

Error code[0:6]	Error condition
0x00	Reserved
0x01	I^2C timed out while waiting for I2CSR[MIF] to assert
0x02	I^2C lost arbitration
0x03	I^2C did not receive ACK during address transmit
0x04	I^2C SCL signal was stuck low at POR
0x05-0x0F	Reserved
0x10	eSPI timed out while waiting for SPIE[DON] to assert
0x11-0x22	Reserved
0x23	IFC detected error in NAND_EVTER_STAT register, NAND_EVTER_STAT can be scanned out upon receiving this error.
0x24	IFC timed out
0x25-0x3F	Reserved
0x40	eSDHC: Err_Reset_1 Indicates that eSDHC did not complete its soft-reset sequence. SYSCTL[RSTA] (offset: 0x02C, mask: 0x0100_0000) did not clear within 1 second. The bit should clear when eSDHC completes its reset sequence.
0x40	eSDHC: Err_Reset_2 Indicates that eSDHC did not complete its soft-reset sequence. SYSCTL[RSTA] (offset: 0x02C, mask: 0x0100_0000) did not clear within 1 second. The bit should clear when eSDHC completes its reset sequence.
0x41	eSDHC: Err_Card_Ins Indicates that eSDHC has not detected an inserted card. PRSSTAT[CINS] (offset: 0x024, mask: 0x0001_0000) did not set within 1 second. The bit should set when eSDHC detects that a card has been inserted.
0x42	eSDHC: Err_Cmd_Data_Rdy Indicates that eSDHC did not detect an idle command and data interface. PRSSTAT[CDIHB] (offset: 0x024, mask: 0x0000_0002) and PRSSTAT[CIHB] (offset: 0x024, mask: 0x0000_0001) did not clear within 1 second. These bits should clear when eSDHC detects an idle command and data interface.
0x42	eSDHC: Err_CMD0_Cmd_Data_Rdy

Table continues on the next page...

Table 5-5. Pre-boot error encoding (continued)

Error code[0:6]	Error condition
	Indicates that eSDHC did not detect an idle command and data interface before attempting to send CMD0. PRSSTAT[CDIHB] (offset: 0x024, mask: 0x0000_0002) and PRSSTAT[CIHB] (offset: 0x024, mask: 0x0000_0001) did not clear within 1 second. These bits should clear when eSDHC detects an idle command and data interface.
0x42	eSDHC: Err_SD_CMD8_Cmd_Data_Rdy Indicates that eSDHC did not detect an idle command and data interface before attempting to send SD CMD8. PRSSTAT[CDIHB] (offset: 0x024, mask: 0x0000_0002) and PRSSTAT[CIHB] (offset: 0x024, mask: 0x0000_0001) did not clear within 1 second. These bits should clear when eSDHC detects an idle command and data interface.
0x42	eSDHC: Err_CMD55_Cmd_Data_Rdy Indicates that eSDHC did not detect an idle command and data interface before attempting to send CMD55. PRSSTAT[CDIHB] (offset: 0x024, mask: 0x0000_0002) and PRSSTAT[CIHB] (offset: 0x024, mask: 0x0000_0001) did not clear within 1 second. These bits should clear when eSDHC detects an idle command and data interface.
0x42	eSDHC: Err_SD_ACMD41_Cmd_Data_Rdy Indicates that eSDHC did not detect an idle command and data interface before attempting to send SD ACMD41. PRSSTAT[CDIHB] (offset: 0x024, mask: 0x0000_0002) and PRSSTAT[CIHB] (offset: 0x024, mask: 0x0000_0001) did not clear within 1 second. These bits should clear when eSDHC detects an idle command and data interface.
0x42	eSDHC: Err_MMC_CMD1_Cmd_Data_Rdy Indicates that eSDHC did not detect an idle command and data interface before attempting to send MMC CMD1. PRSSTAT[CDIHB] (offset: 0x024, mask: 0x0000_0002) and PRSSTAT[CIHB] (offset: 0x024, mask: 0x0000_0001) did not clear within 1 second. These bits should clear when eSDHC detects an idle command and data interface.
0x42	eSDHC: Err_CMD2_Cmd_Data_Rdy Indicates that eSDHC did not detect an idle command and data interface before attempting to send CMD2. PRSSTAT[CDIHB] (offset: 0x024, mask: 0x0000_0002) and PRSSTAT[CIHB] (offset: 0x024, mask: 0x0000_0001) did not clear within 1 second. These bits should clear when eSDHC detects an idle command and data interface.
0x42	eSDHC: Err_SD_CMD3_Cmd_Data_Rdy Indicates that eSDHC did not detect an idle command and data interface before attempting to send SD CMD3. PRSSTAT[CDIHB] (offset: 0x024, mask: 0x0000_0002) and PRSSTAT[CIHB] (offset: 0x024, mask: 0x0000_0001) did not clear within 1 second. These bits should clear when eSDHC detects an idle command and data interface.
0x42	eSDHC: Err_MMC_CMD3_Cmd_Data_Rdy Indicates that eSDHC did not detect an idle command and data interface before attempting to send MMC CMD3. PRSSTAT[CDIHB] (offset: 0x024, mask: 0x0000_0002) and PRSSTAT[CIHB] (offset: 0x024, mask: 0x0000_0001) did not clear within 1 second. These bits should clear when eSDHC detects an idle command and data interface.
0x42	eSDHC: Err_CMD9_Cmd_Data_Rdy Indicates that eSDHC did not detect an idle command and data interface before attempting to send CMD9. PRSSTAT[CDIHB] (offset: 0x024, mask: 0x0000_0002) and PRSSTAT[CIHB] (offset: 0x024, mask: 0x0000_0001) did not clear within 1 second. These bits should clear when eSDHC detects an idle command and data interface.
0x42	eSDHC: Err_CMD7_Cmd_Data_Rdy

Table continues on the next page...

Table 5-5. Pre-boot error encoding (continued)

Error code[0:6]	Error condition
	Indicates that eSDHC did not detect an idle command and data interface before attempting to send CMD7. PRSSTAT[CDIHB] (offset: 0x024, mask: 0x0000_0002) and PRSSTAT[CIHB] (offset: 0x024, mask: 0x0000_0001) did not clear within 1 second. These bits should clear when eSDHC detects an idle command and data interface.
0x42	eSDHC: Err_CMD18_Cmd_Data_Rdy Indicates that eSDHC did not detect an idle command and data interface before attempting to send CMD18. PRSSTAT[CDIHB] (offset: 0x024, mask: 0x0000_0002) and PRSSTAT[CIHB] (offset: 0x024, mask: 0x0000_0001) did not clear within 1 second. These bits should clear when eSDHC detects an idle command and data interface.
0x42	eSDHC: Err_CMD12_Cmd_Data_Rdy Indicates that eSDHC did not detect an idle command and data interface before attempting to send CMD12. PRSSTAT[CDIHB] (offset: 0x024, mask: 0x0000_0002) and PRSSTAT[CIHB] (offset: 0x024, mask: 0x0000_0001) did not clear within 1 second. These bits should clear when eSDHC detects an idle command and data interface.
0x43	eSDHC: Err_Init_Clks Indicates that eSDHC did not complete its initialization clock sequence to the card. SYSCTL[INITA] (offset: 0x02C, mask: 0x0800_0000) did not clear within 1 second. The bit should clear when eSDHC completes transmission of initialization clocks to the card.
0x44	eSDHC: Err_CMD0_Cmd_Stat Indicates that eSDHC did not detect an error or command complete after sending CMD0. IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000), IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000), IRQSTAT[CC] (offset: 0x030, mask: 0x0000_0001) did not set within 1 second. These bits should set when eSDHC detects an error or command complete.
0x44	eSDHC: Err_SD_CMD8_Cmd_Stat Indicates that eSDHC did not detect an error or command complete after sending SD CMD8. IRQSTAT[CIE] (offset: 0x030, mask: 0x0008_0000), IRQSTAT[CEBE] (offset: 0x030, mask: 0x0004_0000), IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000), IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000), IRQSTAT[CC] (offset: 0x030, mask: 0x0000_0001) did not set within 1 second. These bits should set when eSDHC detects an error or command complete.
0x44	eSDHC: Err_CMD55_Cmd_Stat Indicates that eSDHC did not detect an error or command complete after sending CMD55. IRQSTAT[CIE] (offset: 0x030, mask: 0x0008_0000), IRQSTAT[CEBE] (offset: 0x030, mask: 0x0004_0000), IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000), IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000), IRQSTAT[CC] (offset: 0x030, mask: 0x0000_0001) did not set within 1 second. These bits should set when eSDHC detects an error or command complete.
0x44	eSDHC: Err_SD_CMD41_Cmd_Stat Indicates that eSDHC did not detect an error or command complete after sending SD ACMD41. IRQSTAT[CEBE] (offset: 0x030, mask: 0x0004_0000), IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000), IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000), IRQSTAT[CC] (offset: 0x030, mask: 0x0000_0001) did not set within 1 second. These bits should set when eSDHC detects an error or command complete.
0x44	eSDHC: Err_MMC_CMD1_Cmd_Stat Indicates that eSDHC did not detect an error or command complete after sending MMC CMD1. IRQSTAT[CEBE] (offset: 0x030, mask: 0x0004_0000), IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000), IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000), IRQSTAT[CC] (offset: 0x030, mask: 0x0000_0001) did not set within 1 second. These bits should set when eSDHC detects an error or command complete.
0x44	eSDHC: Err_CMD2_Cmd_Stat

Table continues on the next page...

Table 5-5. Pre-boot error encoding (continued)

Error code[0:6]	Error condition
	Indicates that eSDHC did not detect an error or command complete after sending CMD2. IRQSTAT[CEBE] (offset: 0x030, mask: 0x0004_0000), IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000), IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000), IRQSTAT[CC] (offset: 0x030, mask: 0x0000_0001) did not set within 1 second. These bits should set when eSDHC detects an error or command complete.
0x44	eSDHC: Err_SD_CMD3_Cmd_Stat Indicates that eSDHC did not detect an error or command complete after sending SD CMD3. IRQSTAT[CIE] (offset: 0x030, mask: 0x0008_0000), IRQSTAT[CEBE] (offset: 0x030, mask: 0x0004_0000), IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000), IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000), IRQSTAT[CC] (offset: 0x030, mask: 0x0000_0001) did not set within 1 second. These bits should set when eSDHC detects an error or command complete.
0x44	eSDHC: Err_MMC_CMD3_Cmd_Stat Indicates that eSDHC did not detect an error or command complete after sending MMC CMD3. IRQSTAT[CIE] (offset: 0x030, mask: 0x0008_0000), IRQSTAT[CEBE] (offset: 0x030, mask: 0x0004_0000), IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000), IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000), IRQSTAT[CC] (offset: 0x030, mask: 0x0000_0001) did not set within 1 second. These bits should set when eSDHC detects an error or command complete.
0x44	eSDHC: Err_CMD9_Cmd_Stat Indicates that eSDHC did not detect an error or command complete after sending CMD9. IRQSTAT[CEBE] (offset: 0x030, mask: 0x0004_0000), IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000), IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000), IRQSTAT[CC] (offset: 0x030, mask: 0x0000_0001) did not set within 1 second. These bits should set when eSDHC detects an error or command complete.
0x44	eSDHC: Err_CMD7_Cmd_Stat Indicates that eSDHC did not detect an error or command complete after sending CMD7. IRQSTAT[CIE] (offset: 0x030, mask: 0x0008_0000), IRQSTAT[CEBE] (offset: 0x030, mask: 0x0004_0000), IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000), IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000), IRQSTAT[CC] (offset: 0x030, mask: 0x0000_0001) did not set within 1 second. These bits should set when eSDHC detects an error or command complete.
0x44	eSDHC: Err_CMD18_Cmd_Stat Indicates that eSDHC did not detect an error or command complete after sending CMD18. IRQSTAT[CIE] (offset: 0x030, mask: 0x0008_0000), IRQSTAT[CEBE] (offset: 0x030, mask: 0x0004_0000), IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000), IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000), IRQSTAT[CC] (offset: 0x030, mask: 0x0000_0001) did not set within 1 second. These bits should set when eSDHC detects an error or command complete.
0x44	eSDHC: Err_CMD12_Cmd_Stat Indicates that eSDHC did not detect an error or command complete after sending CMD12. IRQSTAT[CIE] (offset: 0x030, mask: 0x0008_0000), IRQSTAT[CEBE] (offset: 0x030, mask: 0x0004_0000), IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000), IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000), IRQSTAT[CC] (offset: 0x030, mask: 0x0000_0001) did not set within 1 second. These bits should set when eSDHC detects an error or command complete.
0x45	eSDHC: Err_CMD0_Cmd_Line_Conflict Indicates that eSDHC detected a command line conflict after sending CMD0. IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000) and IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000) bits should set when eSDHC detects a command line conflict. Both bits are set for the following reason. • Command Line Conflict Error (CCE and CTOE)
0x45	eSDHC: Err_CMD8_Cmd_Line_Conflict

Table continues on the next page...

Table 5-5. Pre-boot error encoding (continued)

Error code[0:6]	Error condition
	Indicates that eSDHC detected a command line conflict after sending SD CMD8. IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000) and IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000) bits should set when eSDHC detects a command line conflict. Both bits are set for the following reason. • Command Line Conflict Error (CCE and CTOE)
0x45	eSDHC: Err_CMD55_Cmd_Line_Conflict Indicates that eSDHC detected a command line conflict after sending CMD55. IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000) and IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000) bits should set when eSDHC detects a command line conflict. Both bits are set for the following reason. • Command Line Conflict Error (CCE and CTOE)
0x45	eSDHC: Err_SD_ACMD41_Cmd_Line_Conflict Indicates that eSDHC detected a command line conflict after sending SD ACMD41. IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000) and IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000) bits should set when eSDHC detects a command line conflict. Both bits are set for the following reason. • Command Line Conflict Error (CCE and CTOE)
0x45	eSDHC: Err_MMC_CMD1_Cmd_Line_Conflict Indicates that eSDHC detected a command line conflict after sending MMC CMD1. IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000) and IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000) bits should set when eSDHC detects a command line conflict. Both bits are set for the following reason. • Command Line Conflict Error (CCE and CTOE)
0x45	eSDHC: Err_CMD2_Cmd_Line_Conflict Indicates that eSDHC detected a command line conflict after sending CMD2. IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000) and IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000) bits should set when eSDHC detects a command line conflict. Both bits are set for the following reason. • Command Line Conflict Error (CCE and CTOE)
0x45	eSDHC: Err_SD_CMD3_Cmd_Line_Conflict Indicates that eSDHC detected a command line conflict after sending SD CMD3. IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000) and IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000) bits should set when eSDHC detects a command line conflict. Both bits are set for the following reason. • Command Line Conflict Error (CCE and CTOE)
0x45	eSDHC: Err_MMC_CMD3_Cmd_Line_Conflict Indicates that eSDHC detected a command line conflict after sending MMC CMD3. IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000) and IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000) bits should set when eSDHC detects a command line conflict. Both bits are set for the following reason. • Command Line Conflict Error (CCE and CTOE)
0x45	eSDHC: Err_CMD9_Cmd_Line_Conflict Indicates that eSDHC detected a command line conflict after sending CMD9. IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000) and IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000) bits should set when eSDHC detects a command line conflict. Both bits are set for the following reason. • Command Line Conflict Error (CCE and CTOE)
0x45	eSDHC: Err_CMD7_Cmd_Line_Conflict Indicates that eSDHC detected a command line conflict after sending CMD7. IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000) and IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000) bits should set when eSDHC detects a command line conflict. Both bits are set for the following reason. • Command Line Conflict Error (CCE and CTOE)

Table continues on the next page...

Table 5-5. Pre-boot error encoding (continued)

Error code[0:6]	Error condition
0x45	eSDHC: Err_CMD18_Cmd_Line_Conflict Indicates that eSDHC detected a command line conflict after sending CMD18. IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000) and IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000) bits should set when eSDHC detects a command line conflict. Both bits are set for the following reason. • Command Line Conflict Error (CCE and CTOE)
0x45	eSDHC: Err_CMD12_Cmd_Line_Conflict Indicates that eSDHC detected a command line conflict after sending CMD12. IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000) and IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000) bits should set when eSDHC detects a command line conflict. Both bits are set for the following reason. • Command Line Conflict Error (CCE and CTOE)
0x46	eSDHC: Err_SD_CMD8_Cmd_Rsp Indicates that eSDHC detected an error with the command response for SD CMD8. IRQSTAT[CIE] (offset: 0x030, mask: 0x0008_0000), IRQSTAT[CEBE] (offset: 0x030, mask: 0x0004_0000), or IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000) bit is set for one of the following reasons. • Command Index Error (CIE) • Command End Bit Error (CEBE) • Command CRC Error (CCE)
0x46	eSDHC: Err_CMD55_Cmd_Rsp Indicates that eSDHC detected an error with the command response for CMD55. IRQSTAT[CIE] (offset: 0x030, mask: 0x0008_0000), IRQSTAT[CEBE] (offset: 0x030, mask: 0x0004_0000), or IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000) bit is set for one of the following reasons. • Command Index Error (CIE) • Command End Bit Error (CEBE) • Command CRC Error (CCE)
0x46	eSDHC: Err_SD_ACMD41_Cmd_Rsp Indicates that eSDHC detected an error with the command response for SD ACMD41. IRQSTAT[CEBE] (offset: 0x030, mask: 0x0004_0000) bit is set for the following reason. • Command End Bit Error (CEBE)
0x46	eSDHC: Err_MMC_CMD1_Cmd_Rsp Indicates that eSDHC detected an error with the command response for MMC CMD1. IRQSTAT[CEBE] (offset: 0x030, mask: 0x0004_0000) bit is set for the following reason. • Command End Bit Error (CEBE)
0x46	eSDHC: Err_CMD2_Cmd_Rsp Indicates that eSDHC detected an error with the command response for CMD2. IRQSTAT[CEBE] (offset: 0x030, mask: 0x0004_0000) or IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000) bit is set for one of the following reasons. • Command End Bit Error (CEBE) • Command CRC Error (CCE)
0x46	eSDHC: Err_SD_CMD3_Cmd_Rsp Indicates that eSDHC detected an error with the command response for SD CMD3. IRQSTAT[CIE] (offset: 0x030, mask: 0x0008_0000), IRQSTAT[CEBE] (offset: 0x030, mask: 0x0004_0000), or IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000) bit is set for one of the following reasons. • Command Index Error (CIE) • Command End Bit Error (CEBE) • Command CRC Error (CCE)

Table continues on the next page...

Table 5-5. Pre-boot error encoding (continued)

Error code[0:6]	Error condition
0x46	eSDHC: Err_MMC_CMD3_Cmd_Rsp Indicates that eSDHC detected an error with the command response for MMC CMD3. IRQSTAT[CIE] (offset: 0x030, mask: 0x0008_0000), IRQSTAT[CEBE] (offset: 0x030, mask: 0x0004_0000), or IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000) bit is set for one of the following reasons. • Command Index Error (CIE) • Command End Bit Error (CEBE) • Command CRC Error (CCE)
0x46	eSDHC: Err_CMD9_Cmd_Rsp Indicates that eSDHC detected an error with the command response for CMD9. IRQSTAT[CEBE] (offset: 0x030, mask: 0x0004_0000) or IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000) bit is set for one of the following reasons. • Command End Bit Error (CEBE) • Command CRC Error (CCE)
0x46	eSDHC: Err_CMD7_Cmd_Rsp Indicates that eSDHC detected an error with the command response for CMD7. IRQSTAT[CIE] (offset: 0x030, mask: 0x0008_0000), IRQSTAT[CEBE] (offset: 0x030, mask: 0x0004_0000), or IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000) bit is set for one of the following reasons. • Command Index Error (CIE) • Command End Bit Error (CEBE) • Command CRC Error (CCE)
0x46	eSDHC: Err_CMD18_Cmd_Rsp Indicates that eSDHC detected an error with the command response for CMD18. IRQSTAT[CIE] (offset: 0x030, mask: 0x0008_0000), IRQSTAT[CEBE] (offset: 0x030, mask: 0x0004_0000), or IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000) bit is set for one of the following reasons. • Command Index Error (CIE) • Command End Bit Error (CEBE) • Command CRC Error (CCE)
0x46	eSDHC: Err_CMD12_Cmd_Rsp Indicates that eSDHC detected an error with the command response for CMD12. IRQSTAT[CIE] (offset: 0x030, mask: 0x0008_0000), IRQSTAT[CEBE] (offset: 0x030, mask: 0x0004_0000), or IRQSTAT[CCE] (offset: 0x030, mask: 0x0002_0000) bit is set for one of the following reasons. • Command Index Error (CIE) • Command End Bit Error (CEBE) • Command CRC Error (CCE)
0x47	eSDHC: Err_SD_CMD8_Rsp_Data_Match Indicates that eSDHC did not properly communicate with the card due to a mismatch of the expected response of SD CMD8. CMDRSP0[VHS] (offset: 0x010, mask: 0x0000_0F00) was not equal to the configured SD coarse voltage or CMDRSP0[CHKPTRN] (offset: 0x010, mask: 0x0000_00FF) was not equal to the configured SD check pattern. Both fields are required to match in order to guarantee proper communication with the card.
0x47	eSDHC: Err_SD_ACMD41_Rsp_Data_Match Indicates that eSDHC did not properly communicate with the card due to a mismatch of the expected response of SD ACMD41. CMDRSP0[VDDVW] (offset: 0x010, mask: 0x00FF_FFFF) was not covered (matches at least one bit) by the configured SD fine voltage. At least one bit must match in order to guarantee proper communication with the card.
0x47	eSDHC: Err_MMC_CMD1_Rsp_Data_Match

Table continues on the next page...

Table 5-5. Pre-boot error encoding (continued)

Error code[0:6]	Error condition
	Indicates that eSDHC did not properly communicate with the card due to a mismatch of the expected response of MMC CMD1. CMDRSP0[VDDVW] (offset: 0x010, mask: 0x00FF_FFFF) was not covered (matches at least one bit) by the configured MMC voltage. At least one bit must match in order to guarantee proper communication with the card.
0x48	eSDHC: Err_SD_ACMD41_Cmd_Rsp_Timeout Indicates that eSDHC detected a timeout with the command response for SD ACMD41. IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000) bit is set for the following reason. • Command Timeout Error (CTOE)
0x48	eSDHC: Err_MMC_CMD1_Cmd_Rsp_Timeout Indicates that eSDHC detected a timeout with the command response for MMC CMD1. IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000) bit is set for the following reason. • Command Timeout Error (CTOE)
0x48	eSDHC: Err_CMD2_Cmd_Rsp_Timeout Indicates that eSDHC detected a timeout with the command response for CMD2. IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000) bit is set for the following reason. • Command Timeout Error (CTOE)
0x48	eSDHC: Err_SD_CMD3_Cmd_Rsp_Timeout Indicates that eSDHC detected a timeout with the command response for SD CMD3. IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000) bit is set for the following reason. • Command Timeout Error (CTOE)
0x48	eSDHC: Err_MMC_CMD3_Cmd_Rsp_Timeout Indicates that eSDHC detected a timeout with the command response for MMC CMD3. IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000) bit is set for the following reason. • Command Timeout Error (CTOE)
0x48	eSDHC: Err_CMD9_Cmd_Rsp_Timeout Indicates that eSDHC detected a timeout with the command response for CMD9. IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000) bit is set for the following reason. • Command Timeout Error (CTOE)
0x48	eSDHC: Err_CMD7_Cmd_Rsp_Timeout Indicates that eSDHC detected a timeout with the command response for CMD7. IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000) bit is set for the following reason. • Command Timeout Error (CTOE)
0x48	eSDHC: Err_CMD18_Cmd_Rsp_Timeout Indicates that eSDHC detected a timeout with the command response for CMD18. IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000) bit is set for the following reason. • Command Timeout Error (CTOE)
0x48	eSDHC: Err_CMD12_Cmd_Rsp_Timeout Indicates that eSDHC detected a timeout with the command response for CMD12. IRQSTAT[CTOE] (offset: 0x030, mask: 0x0001_0000) bit is set for the following reason. • Command Timeout Error (CTOE)
0x49	eSDHC: Err_SD_ACMD41_Rdy_Timeout

Table continues on the next page...

Table 5-5. Pre-boot error encoding (continued)

Error code[0:6]	Error condition
	Indicates that the card always indicates busy by examining the response of SD ACMD41. CMDRSP0[RDY] (offset: 0x010, mask: 0x8000_0000) did not set within 1 second. The bit should set when the card completes its initialization sequence.
0x49	eSDHC: Err_MMC_CMD1_Rdy_Timeout Indicates that the card always indicates busy by examining the response of MMC CMD1. CMDRSP0[RDY] (offset: 0x010, mask: 0x8000_0000) did not set within 1 second. The bit should set when the card completes its initialization sequence.
0x4A	eSDHC: Err_Rd_Buf_Rdy Indicates that eSDHC did not receive the watermark's amount (configured to 4 bytes) of data in its read buffer from CMD18. PRSSTAT[BREN] (offset: 0x024, mask: 0x0000_0800) did not set within 1 second. The bit should set when eSDHC receives the watermark's amount of data in its read buffer.
0x4B	eSDHC: Err_Data Indicates that eSDHC detected an error with the read data from CMD18. IRQSTAT[DEBE] (offset: 0x030, mask: 0x0040_0000) or IRQSTAT[DCE] (offset: 0x030, mask: 0x0020_0000) is set for one of the following reasons. • Data End Bit Error (DEBE) • Data CRC Error (DCE)
0x4C	eSDHC: Err_Data_Timeout Indicates that eSDHC detected a timeout with the read data from CMD18. IRQSTAT[DTOE] (offset: 0x030, mask: 0x0010_0000) is set for the following reason. • Data Timeout Error (DTOE)
0x4D	eSDHC: Err_Data_Reset Indicates that eSDHC did not complete its soft-reset sequence. SYSCTL[RSTD] (offset: 0x02C, mask: 0x0400_0000) did not clear within 1 second. The bit should clear when eSDHC completes its data reset sequence.
0x4E	eSDHC: Err_PBI_Timeout Indicates that pre-boot initialization (PBI) has not started within 1 second. An indication should be received when PBI starts.
0x4F	eSDHC: Reserved
0x50-0x6F	Reserved
0x70	No preamble is detected
0x71	ACS is logic 1 during RCW
0x72	Byte count is not 64 for RCW or 4 for PBL commands or 1/2/4/8/16/32/64 for pre-boot initialization commands
0x73	Misaligned address
0x74	Address is in protected space
0x75	CRC error
0x76	Time out counter expires
0x77	Unrecognized PBL commands, including unrecognized offset and invalid parameter.
0x78	Data transfer error from memory devices
0x79	Invalid end command error
0x7A	Invalid RCW or pre-boot initialization command source encoding
0x7B-0x7F	Reserved

5.4.8 Registers written by PBL during RCW and PBI phases

This section lists registers written by PBL during RCW and PBI phases.

If the interface is PBI/RCW source, the registers listed below are reset back to their POR values, when PBL is completed. Alternatively, if the registers are modified by some external source, then its value does not reset back to POR value when PBL is completed.

5.4.8.1 I^2C registers

If any of the following registers are written, they are reset back to their POR value when the PBL has completed.

- I2CFDR
- I2CCR
- I2CSR
- I2CDR
- I2CDFSRR

5.4.8.2 eSPI registers

If any of the following registers are written, they are reset back to their POR value when the PBL has completed.

- SPMODE
- SPIE
- SPCOM
- SPITF
- SPIRF
- SPMODE0

5.4.8.3 IFC registers

If any of the following registers are written, they are reset back to their POR value when the PBL has completed:

- NAND_MDR
- NANDSEQ_STRT
- NAND_EVTER_STAT

- NAND_ERATTR0
- NCFGR
- CSPR0
- CSOR0
- NAND_FIR0
- NAND_FCR0
- ROW0
- COL0
- NAND_BC

The CSOR0 register holds the pages per block information from configuration command. The CSOR0[PB] bit is read by PBL to determine the pages per block.

5.4.8.4 eSDHC registers

If any of the following registers are written, they are reset back to their POR value when the PBL has completed. The following eSDHC registers are reset by performing a software reset, asserting SYSCTL[RSTA]:

- BLKATTR
- CMDARG
- XFERTYP
- CMDRSP0
- CMDRSP2
- DATPORT
- PRSSTAT
- PROCTL
- SYSCTL
- IRQSTAT
- IRQSTATEN
- WML

5.4.9 Addressing multiple I^2C EEPROMs

When standard I^2C EEPROMs are used, it is assumed that each EEPROM holds 256 bytes of data.

After 256 bytes have been received, the PBL increments the slave address and access the next EEPROM. A maximum of eight standard I^2C EEPROMs can be used with the PBL.

Extended I^2C EEPROMs have variable sizes. However, the I^2C controller increments the slave address after 64 KB have been received. In some cases, the least significant bit of the slave address refers to a different page address on an extended EEPROM (for the larger density EEPROMs). However, the PBL should still be able to access the page successfully. Alternatively, the least significant bit may reference a second extended EEPROM on the I^2C bus. Multiple extended EEPROMs of sizes less than 64 KB are not supported (unless a jump command is used to force the PBL to the next EEPROM device).

5.4.10 eSPI mode assumptions

When eSPI is used as the PBL source, the following mode assumptions take place:

- Chip select - Uses the first chip select (CS0). PBL uses the SPMODE0 register to use CS0 during initialization.
- Supported SPI mode - Only SPI mode 0 is supported (referring to the SPI clock phase and polarity). The SPI slave device must also support SPI mode 0.
- SPI Read command - A value of 0x03 is used for the read command. The SPI slave device must decode 0x03 as a read command.

5.5 Initialization/Application information

The PBL starts searching for the first good block. It begins to fetch the PBL image at the starting address of that block. It automatically searches for the next good block should the PBL image extend past one block.

If booting from NAND, the boot image must be placed on the next 4 KB boundary. The PBL searches for the next good block should that 4 KB boundary fall on a block boundary. The PBL then loads 4 KB into the buffer.

The PBL block search routine continues to search as necessary until reaching the end of the memory device.

5.5.1 Starting addresses

The following table lists the starting addresses of data fetched from each interface.

Note that in case of IFC NAND flash, the address starts from the first good block.

Table 5-6. Starting addresses

Interface	Starting address
IFC	0x0000_0000
I^2C[1]	0x0000_0000
eSPI	0x0000_0000
eSDHC	0x0000_1000

1. The 7 bit calling address for the I^2C slave is 0x50.

5.5.2 Software restrictions

Following are the restrictions for programming the PBI commands:

- CCSRBAR cannot be updated through PBI commands. Software must wait for the cores to boot to change CCSRBAR.
- Software must issue a Flush command after updating the alternate configuration space registers (ALTCBARH, ALTCBARL, and ALTCAR) using PBI commands. This ensures that the logic has seen the update prior to any dependent writes being issued by the PBL.
- Use of the Flush command is restricted to CCSR space. Software must use the Wait command after commands to non-CCSR space to allow them time to complete before issuing subsequent commands to non-CCSR space.
- In case of IFC NAND FCM configuration, pages per block is determined by reading IFC_CSOR0 register. This IFC register holds the pages per block information from control command. Control command coming from platform must contain the valid values at POR pins.

5.5.3 Software recommendations

Following are the recommendations for programming the PBL data structure:

- A CRC check command should always be placed immediately following the RCW command to ensure that a corrupted RCW is not consumed.

Chapter 6
Secure Boot and Trust Architecture

6.1 Trust architecture objectives

T4240 supports the QorIQ Trust Architecture 2.0.

The objective of the trust architecture is to allow OEMs to prevent or strongly mitigate an attacker's ability to achieve the following attacks:

- theft of functionality,
- theft of third-party data,
- and theft of uniqueness.

These attacks are against the OEM's complete system, including both hardware and software. These systems operate in a wide variety of contexts. In addition, attackers have a broad range of motivations and skill sets. It is beyond the scope of this document to provide an exhaustive list of threats, mitigations, and contexts in which attacks might occur.

Consequently, this section focuses on trust architecture claims. This approach allows the OEM to assess how to best apply the trust architecture to mitigate attacks in a given context.

6.2 Characteristics and claims

1. Trust architecture is "opt in."
    - OEMs do not need to do anything to disable it. All trust features are enabled as the result of conscious decisions to set fuses, program registers, and perform code signing.
2. OEMs own all of the system's secrets.
    - OEMs are not dependent on NXP to provision devices, and NXP does not participate in the chain of trust for system manufacturing, deployment, or field servicing.

3. Trust architecture allows OEMs to define system security policies & configurations, which cannot be changed or bypassed by attackers.
    - Always perform secure boot
    - Access control debug interfaces
    - Detect hardware security violations
    - Soft or Hard Fail reactions to security violations
4. Trust architecture protects against unauthorized modifications to developer software and system configuration information (for example, device trees, certificates, and so on).
    - Protection consists of both prevention (secure boot) and after-the-fact detection mechanisms (for example, runtime integrity checking).
        - Secure boot detects unauthorized modifications and, when detected, prevents the unauthorized code from executing on the device.
        - Runtime integrity checking scans regions of memory for unauthorized modifications to the contents.
5. Trust architecture allows OEMs to provision system permanent secrets, which are protected against extraction or exposure.
    - Permanent secrets continue across resets of the system, and are locked out in response to security violations.
    - Trust architecture 2.0 permanent secrets include:
        - Debug Response Value (DRV)
        - One-Time Programmable Master Key (OTPMK)
6. Trust architecture allows OEMs to provision system persistent secrets which survive device resets under normal circumstances, but are capable of being cleared or rendered unusable.
    - Trust architecture 2.0 persistent secrets include:
        - Battery backed Zeroizable Master Key (ZMK)
        - Any cryptographic blobs created with the OTPMK and stored to NVRAM prior to system reset
    - Cryptographic blobs can be used to make factory installed keys, certificates, and proprietary code into persistent secrets.
7. Trust architecture allows provisioning of system ephemeral secrets, which are protected against extraction or exposure.
    - Ephemeral secrets are cleared by a security violation or system reset.
    - Trust architecture 2.0 ephemeral secrets include:
        - Job Descriptor Key Encryption Keys (JDKEKs)
        - Session keys negotiated during runtime, which are protected with the JDKEKs
        - Secrets owned by Secure World trusted applications, and stored in private on-chip or off-chip memory are also considered ephemeral.

8. Trust architecture provides high levels of separation between independent software domains.
    - The private resources of one domain must not be accessible by another domain.
    - These independent software partitions can be treated as independent security domains.
9. Trust architecture 2.0 supports anti-rollback features
    - Super Root Key revocation
    - Monotonic Counter

6.3 Non-claims

It is also important for OEMs to understand the types of attacks that NXP does not claim to prevent or strongly mitigate, so that mitigation can be taken at the system level if necessary.

1. Stronger than the underlying crypto algorithms.
    - Trust architecture's foundation rests on the strength of SHA-256, AES-256, and RSA digital signatures. If these algorithms are found to be fundamentally broken, most trust architecture claims are broken as well.
2. Preventing advanced physical attacks
    - As noted earlier, NXP recognizes that the contents of the Security Fuse Processor can be read by careful de-processing of the device. This attack destroys the QorIQ device, however cryptographic blobs protected with the OTPMK could be recovered from system memory and decrypted.
    - Memories and registers locked out or zeroized upon detection of security violations may be subject to memory remanence attacks.
    - The SEC's PKHA implements timing equalization, and the AESA implements differential power analysis resistance features; however, the effectiveness of these features has not been independently evaluated. Other side channel attack methods, against the SEC and CPUs, may be possible given sufficient motivation.
    - Operating the device outside of specified voltage, temperature, or frequency ranges can lead to unexpected failure modes. NXP has attempted to make all failure modes "fail safe," but the full range of possible glitches has not been evaluated.
    - Trust architecture incorporates tamper detection inputs, which OEMs can use to alert the device to physical attacks. Without using the Zeroizable Master Key, the highest consequence of a security violation is that the OTPMK may be locked out. Assume that attackers are capable of bypassing external tamper detection logic and rebooting the system with no hardware security violations detected.

3. Providing absolute isolation between independent software domains/security domains
   - Trust architecture's support for strong partitioning is based on access control mechanisms. If a resource is private to domain 1, domain 2 must not be able to access that resource, directly or indirectly. This is different from absolute isolation, in which domain 2 is unable to interfere with the operation of domain 1. From internal and external bus bandwidth consumption to unfiltered buffer releases, NXP knows of many scenarios in which domain 2 can interfere with domain 1.
   - Note that NXP is working within the multicore for Avionics (MCFA) working group to help bound the extent of this interference, including worst-case execution-time analysis.
4. Operating as a single-edged sword
   - Trust architecture is designed to constrain the conditions under which the system can operate. Attackers can cause security violations for the purpose of shutting down the system. Trust architecture offers configuration options allowing OEMs to make trade-offs in security violation sensitivity and consequences, but it is beyond the scope of a trust architecture device to "know" when trust is being exploited to disrupt the system. Attackers in a position to trigger security violations could be capable of causing other types of system failures.

6.4 Related resources

QorIQ Trust Architecture is not a mandatory feature; it is opt in. To minimize the information available to potential attackers, access to detailed Trust Architecture reference material is restricted to vetted customers with active programs using Trust Architecture. Contact your NXP Sales or Field Application Engineer to initiate the admission process to the NXP QorIQ Trust Architecture User's Group site.

The following table shows related resources that may be helpful.

Resource	Purpose
User Enablement for Secure Boot	These documents are periodically updated as new features are added to the Code Signing Tool and reference chain of trust. They can be found in the QorIQ device SDK, and at www.NXP.com/infocenter: Software and Tools Information Center > QorIQ SDK Documentation > Secure Boot. **NOTE:** Some of these documents are for PBL-based products, some are for non-PBL-based products. This chip is a PBL-based product.

Chapter 7
e6500 Core Integration

7.1 Introduction

This chapter provides details about how the e6500 microprocessor cores are integrated into this chip. The core provides features that the integrated chip may not implement or may implement in a more specific way.

NOTE

The following documents are necessary for understanding how to program the core:

The *EREF: A Programmer's Reference Manual for Freescale Embedded Processors* describes the instruction, register, and interrupt models, as well as other functionality defined at the architecture level and implemented on e500 family processors.

The *e6500 Core Reference Manual* describes functionality that is specific to the e6500 and that is not defined by the architecture, such as core-specific instructions, registers, and register fields. It also provides e6500-specific details about how the e6500 implements functionality that is defined by the architecture.

The *AltiVec Technology Programming Interface Manual for Power ISA Processors* describes how programmers can access AltiVec functionality from programming languages such as C and C++. The AltiVec Power ISA PIM defines a programming model for use with the AltiVec instruction set.

The *AltiVec Technology Programming Environments Manual for Power ISA Processors* is a reference guide for assembler programmers. The AltiVec Power ISA PEM uses a standardized format to describe each instruction, showing

syntax, instruction format, register translation language (RTL) code that describes how the instruction works, and a listing of which, if any, registers are affected.

7.2 Overview

The e6500 core is a low-power implementation of the resources for embedded processors defined by the Power ISA. Each core supports the simultaneous execution of two threads. The core is a 64-bit implementation and implements two sets of 64-bit general-purpose registers; however it supports accesses to 40-bit physical addresses.

The e6500 is designed to be implemented in multicore integrated devices, and many of the features are defined to support multicore implementations, in particular to partition the cores in such a way that multiple operating systems can be run with the integrated device, as shown in the following figure.

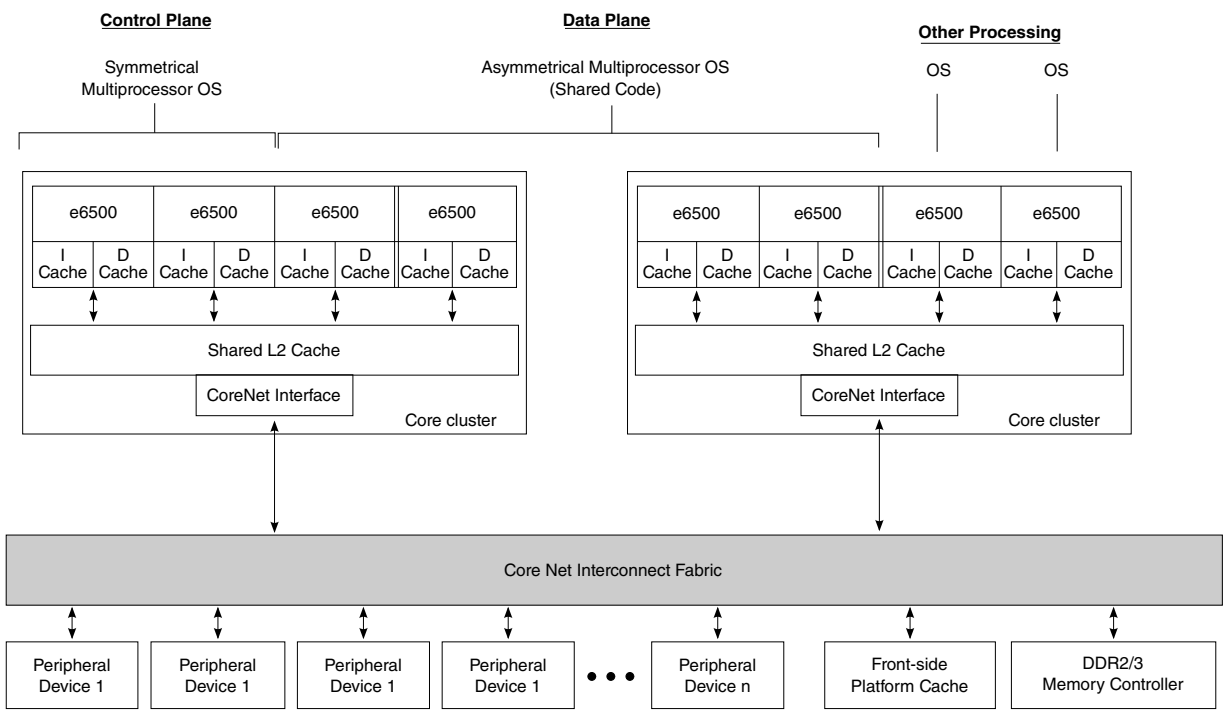

Figure 7-1. Example Partitioning Scenario of a Multicore Integrated Device(2)

The CoreNet interface provides the primary on-chip interface between the core cluster and the rest of the SoC. CoreNet is a tag-based interface fabric that provides interconnections among the cores, peripheral devices, and system memory in a multicore implementation.

The architecture defines the resources required to allow orderly and secure interactions between thread procerssors, the cores, memory, peripheral devices, and virtual machines. These include a hypervisor and guest supervisor privilege levels, that determine whether certain activities, such as memory accesses and management, cache management, and interrupt handling, are to be carried on at a system-wide level (hypervisor level) or by the operating system within a partition (guest supervisor level).

The architecture defines the resources required to allow orderly and secure interactions between the cores, memory, peripheral devices, and virtual machines. These include a hypervisor and guest supervisor privilege levels, that determine whether certain activities, such as memory accesses and management, cache management, and interrupt handling, are to be carried on at a system-wide level (hypervisor level) or by the operating system within a partition (guest supervisor level).

Each core is a multi-threaded, superscalar processor that can decode two instructions and complete two instructions per thread per clock cycle. Instructions complete in order, but can execute out of order. Execution results are available to subsequent instructions in the same thread through the rename buffers, but those results are recorded into architected registers in program order, maintaining a precise exception model.

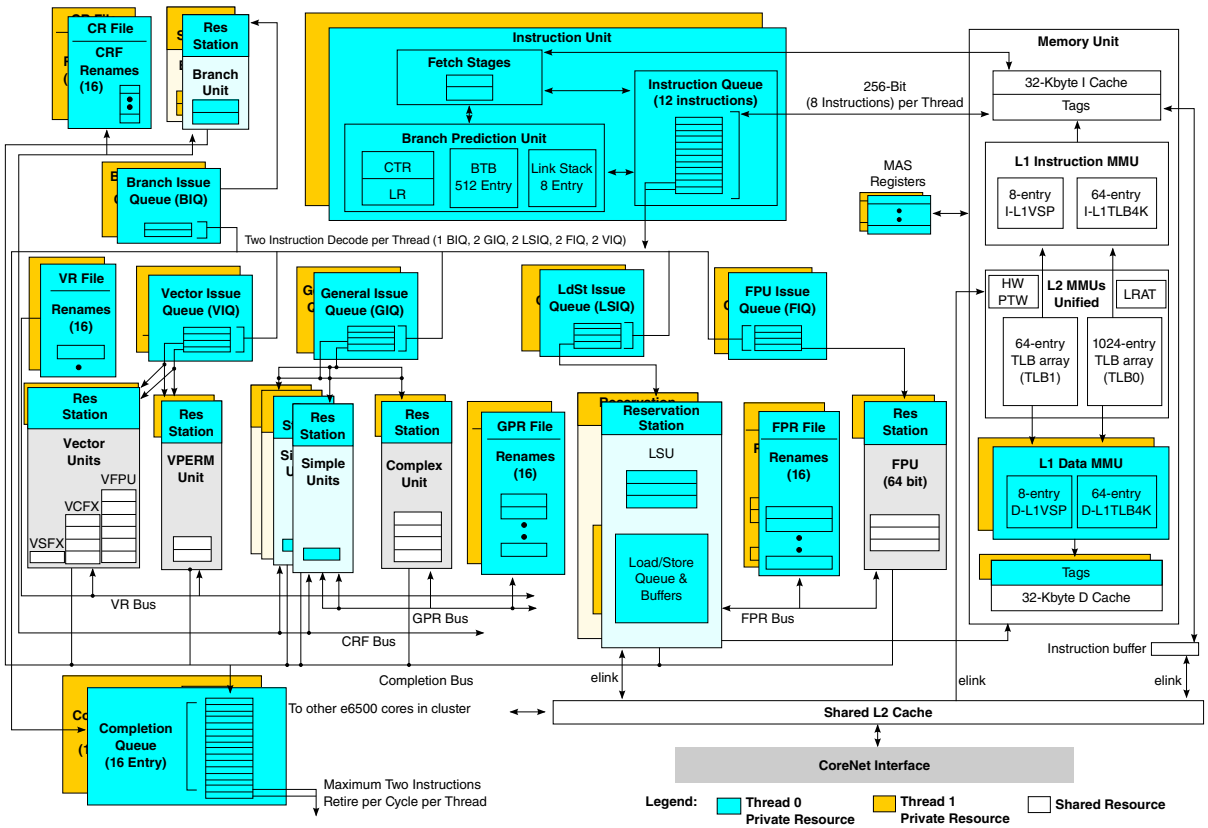

Figure 7-2. Core Block Diagram

7.3 Core and CPU clusters

This chip offers 12, high-performance, 64-bit Power Architecture, Book E-compliant cores. Each CPU core supports two hardware threads, which software views as a virtual CPU. The core CPUs are arranged in clusters of four with a shared 2 MB L2 cache.

The core subsystem includes the following features:

- Up to 1.8 GHz
- Dual-thread with simultaneous multi-threading (SMT)
  - Threading can be disabled on a per CPU basis
- 40-bit physical addressing
- L2 MMU
  - Supporting 4 KB pages
  - TLB0; 8-way set-associative, 1024-entries (4 KB pages)
  - TLB1; fully associative, 64-entry, supporting variable size pages and indirect page table entries

- Hardware page table walk
- 64-byte cache line size
- L1 caches, running at core frequency
  - 32 KB instruction, 8-way set-associative
  - 32 KB data, 8-way set-associative
  - Each with data and tag parity protection
- Hardware support for memory coherency
- Five integer units: 4 simple (2 per thread), 1 complex (integer multiply and divide)
- Two load-store units: one per thread
- Classic double-precision floating-point unit
  - Uses 32 64-bit floating-point registers (FPRs) for scalar single- and double-precision floating-point arithmetic
  - Designed to comply with IEEE Std. 754™-1985 FPU for both single and double-precision operations
- AltiVec unit
  - 128-bit Vector SIMD engine
  - 32 128-bit VR registers
  - Operates on a vector of
    - Four 32-bit integers
    - Four 32-bit single precision floating-point units
    - Eight 16-bit integers
    - Sixteen 8-bit integers
  - Powerful permute unit
  - Enhancements include: Move from GPRs to VR, sum of absolute differences operation, extended support for misaligned vectors, handling head and tails of vectors
- Supports Data Path Acceleration Architecture (DPAA) data and context "stashing" into L1 and L2 caches
- User, supervisor, and hypervisor instruction level privileges
- Addition of Elemental Barriers and "wait on reservation" instructions
- New power-saving modes including "drowsy core" with state retention and nap
  - State retention power-saving mode allows core to quickly wake up and respond to service requests
- Processor facilities
  - Hypervisor APU
  - "Decorated Storage" APU for improved statistics support
    - Provides additional atomic operations, including a "fire-and-forget" atomic update of up to two 64-bit quantities by a single access
  - Addition of Logical to Real Address translation mechanism (LRAT) to accelerate hypervisor performance
  - Expanded interrupt model

        - Improved Programmable Interrupt Controller (PIC) automatically ACKs interrupts
        - Implements message send and receive functions for interprocessor communication, including receive filtering
    - External PID load and store facility
        - Provides system software with an efficient means to move data and perform cache operations between two disjoint address spaces
        - Eliminates the need to copy data from a source context into a kernel context, change to destination address space, then copy the data to the destination address space or alternatively to map the user space into the kernel address space

The arrangement of cores into clusters with shared L2 caches is part of a major re-architecture of the QorIQ cache hierarchy. Details of the banked L2 are provided below.

- 2 MB cache with ECC protection (data, tag, & status)
    - Pipelined data array access with 2 cycle repeat rate
- 4 banks, supporting up to four concurrent accesses.
- 64-byte cache line size
- 16 way, set associative
    - Ways in each bank can be configured in one of several modes
    - Flexible way partitioning per vCPU
        - I-only, D-only, or unified
- Supports direct stashing of datapath architecture data into L2

The chip also contains up to 1.5 MB of shared L3 CoreNet Platform Cache (CPC), with the following features:

- Total 1.5 MB, implemented as three 512 KB arrays, one per DDR controller
    - ECC protection for Data, Tag and Status
    - 16-way set associative with configurable replacement algorithms
    - Allocation control for data read, data store, castout, decorated read, decorated store, instruction read and stash
    - Configurable SRAM partitioning

7.4 Chip-Specific Core Implementation Details

This section describes any aspects of the implementation of the cores that are specific to the chip. Information in this section supersedes any more general descriptions provided in either *EREF: A Programmer's Reference Manual for Freescale Embedded Processors* or the *e6500 Core Reference Manual.*

7.4.1 Benefits and Flexibility of Twelve Dual-Threaded Cores

Each core supports two hardware threads, which software views as a virtual CPU (VCPU). These VCPUs can be combined as a fully symmetric multiprocessing system on a chip, or they can be operated with variable degrees of independence to perform asymmetric multiprocessing. Full processor independence, including the ability to independently boot and reset each core, is a defining characteristic of the chip. The ability of the cores to run different operating systems, or run without an OS, provides significant flexibility in partitioning among control, data path, and applications processing. It also simplifies consolidation of functions previously spread across multiple discrete processors onto a single device.

The cores are arranged in clusters of four with a shared 2-MByte L2 cache and interface to the CoreNet interconnect fabric. The clusters reduce the amount of coherency traffic on the CoreNet interface and provide faster coherent transactions among cores in a cluster.

7.4.2 CoreNet Coherency Fabric (CCF)

The CoreNet coherency fabric (CCF) provides interconnections among the core clusters, peripheral devices, and system memory in a multicore implementation. CoreNet Coherency Fabric (CCF) describes the CCF in detail, and in particular it explains how it facilitates communication between the cores, the core platform caches (CPC), and the other blocks that comprise the coherent memory domain.

7.4.3 Reset and Clocking

Reset, Clocking, and Initialization provides information about coordination between the core and the device as part of the boot process.

The following signals are important to consider regarding the integration of the cores:

- The system clock (SYSCLK), is the primary clock input and is the clock source for the core cluster group PLLs. The core cluster group PLL outputs are assigned to specific core clusters using their associated C*n*_PLL_SEL fields in the RCW.
- The real time clock, RTC, may be used (optionally) to clock the time base of the cores. The RTC timing specifications are given in the datasheet for this chip. This signal can also be used (optionally) to clock the global timers in the programmable interrupt controller (PIC).

Core timer facilities are described in the *e6500 Core Reference Manual*.

7.4.4 Register Model Implementation Details

The device implements the core register model as defined for the core and described in the *EREF* and the *e6500 Core Reference Manual*. Details that are specific to how the core registers are implemented in the device are described in the following subsections.

7.4.4.1 Processor Version Register (PVR)

The table below lists the revision codes in the processor version register (PVR). The PVR value is source by the core processor itself. Its value is reflected in the PVR register, which is described in Processor Version Register (DCFG_CCSR_PVR). The value is also visible to software running on the core in a read-only SPR within the core, SPR287.

Table 7-1. Processor Version Register

ID	Bits	Assigned Value(Binary)	Description
PVR	[0:3]	1000	Manufacturer ID
	[4:5]	00	Reserved
	[6:9]	0001	Processor type
	[10:15]	00_0000	Processor ID
	[16:19]	0000	Process revision
	[20:23]	0001	Manufacturing revision
	[24:27]	0010	Processor major revision number
	[28:31]	0000	Processor minor revision number

7.4.4.2 System Version Register (SVR)

The SVR register, which is described in System Version Register (DCFG_CCSR_SVR), is routed to input terminals on the core as well where it is accessible as a read-only register within the core, SPR1023. This table contains the assigned values.

Table 7-2. System Version Register

ID	Bits	Assigned Value (Binary)	Description	Comments
SVR	[0:3]	1000	Manufacturer ID	Freescale
	[4:11]	0010_0100	SoC device ID	T4 Family
	[12]	n	Security	0 No security 1 Security enabled
	[13:15]	*nnn*	SoC variant ID1	000 T4240 001 T4160 or T4080
	[16:23]	nnnn_nnnn	SoC variant ID2	0000_0000 T4240 or T4160 0000_0010 T4080
	[24:27]	*nnnn*	Device major revision number	For first silicon, this is set to 0001 for major revision 1. For revison 2 this is set to 0010
	[28:31]	*mmmm*	Device minor revision number	This is set to 0000 for minor revision 0.

Table 7-3. SVR and PVR

Device	SVR	PVR
T4240 (with security)	0x8248_0020	0x8040_0120
T4240 (without security)	0x8240_0020	0x8040_0120

7.4.4.3 (Guest) Processor ID Register (PIR/GPIR)

The value in PIR/GPIR is used to distinguish processors in a system from one another. The processor control category augments this definition to make the PIR writable so software can store information specific to its needs.

In a multiprocessor system, each PIR register should be initialized at power-on-reset to a unique value. The contents of the PIR register are used as a tag for matching requested doorbell interrupts sent to the processor. Note that SPR 286 was assigned to the system version register (SVR) on some earlier devices.

Out of core reset, the PIR values for each thread are set to the following values.

NOTE

The PIR registers can be later modified if desired by Hypervisor software.

Table 7-4. PIR Values out of Reset

Physical Core	Thread	Initial PIR Value
0	0	0000_0000h
	1	0000_0001h
1	0	0000_0008h
	1	0000_0009h
2	0	0000_0010h
	1	0000_0011h
3	0	0000_0018h
	1	0000_0019h
4	0	0000_0020h
	1	0000_0021h
5	0	0000_0028h
	1	0000_0029h
6	0	0000_0030h
	1	0000_0031h
7	0	0000_0038h
	1	0000_0039h
8	0	0000_0040h
	1	0000_0041h
9	0	0000_0048h
	1	0000_0049h
10	0	0000_0050h
	1	0000_0051h
11	0	0000_0058h
	1	0000_0059h

7.4.4.4 Timer Control Register (TCR)

TCR[WRC] is defined more specifically for the implementation of the core in the integrated device, as shown in the table below.

Table 7-5. TCR[WRC] Descriptions

Bits	Name	Description
34-35	WRC	See Watchdog Timer Expiration Out to Platform.

7.4.5 Cache Model Implementation Details

The device's implemented caches can be configured and locked using instructions defined by the Power architecture and described in the *EREF* and in the *e6500 Core Reference Manual*. These instructions specify the L2 cache by setting the CT operand to 2 and the CoreNet platform cache (CPC) by setting the CT operand to 1.

Caches in a system may be specific targets of *cache stashing*, an operation initiated by the processor or other device in the system, specifying a hint that specified addresses should be prefetched into a target cache. Each cache in the system that responds to such requests has a cache identifier set by system software or predefined by hardware. For the L1 data cache, the identifier is defined in L1CSR2[DCSTASHID]. For the L2 cache, the identifier is defined in L2CSR1[L2STASHID]. A cache identifier value of 0 indicates that cache stashing operations are not accepted or performed by the cache.

NOTE

The L2 cache must have ECC enabled as follows:

- L2CSR0[L2PE] = 1
- L2ERRDIS[MBECCDIS] = 0 and L2ERRDIS[SBECCDIS] = 0

7.4.6 Interrupt Model Implementation Details

The core implements the external proxy functionality, which can be used to eliminate the need for an interrupt handler to perform a software read IACK. See the *Multicore Programmable Interrupt Controller (MPIC)* chapter for information about how this functionality is implemented on the device.

The architecture defines resources to eliminate the need from an interrupt handler responding to the assertion of the external interrupt signal, *int*, from a programmable interrupt controller (PIC) in the integrated device. The Open PIC standards define a software handshake in response to the assertion of this signal that requires the handler to read the memory-mapped IACK register, which holds interrupt vector offset bits provided by the source of the interrupt, typically one of the peripheral devices incorporated in the integrated device. In addition to providing the interrupt vector, this read also informs internal logic of the PIC to treat this interrupt source as "in-service" rather than pending and it signals the PIC to deassert its internal *int* output, making it possible for the PIC to deliver an external interrupt from another peripheral device that had been configured as higher priority

The architecture defines the external proxy register, EPR, used when the interrupt is handled at the hypervisor level, and a guest EPR, GEPR, when the interrupt is handled ar the guest supervisor level. The EPR and GEPR are SPRs, and the value that appears in

the PIC's IACK[VECTOR] fields is automatically loaded into the EPR (or GEPR), eliminating the cache-inhibited guarded load to the memory mapped IACK. The EPR is considered valid only from the time that the external input interrupt occurs until MSR[EE] is set as the result of a **mtmsr** or a return from interrupt instruction.

The interrupt proxy functionality can be enabled and disabled through the global configuration register in the PIC. See the PIC chapter in the reference manual for the integrated device for more information.

7.4.6.1 Watchdog Timer Expiration Out to Platform

Each core has an internal watchdog timer that can be configured to signal the platform upon "first" or "second" expiration; the see e6500 documentation for details. Such an indication out to the platform typically identifies runaway or faulty software or that something has gone wrong interacting with the platform.

There are four different actions taken in response to such a watchdog timer expiration depending on the value programmed in TCR[WRC] and EDBCR0[EDM] of the core:

- Internal interrupt sent over to the MPIC for WRC/WRS==01 while EDM core output == 0
- Internal interrupt sent over to the MPIC and automatic reset of that core for WRC/WRS==11 while EDM core output == 0
- Internal interrupt sent over to the MPIC and device output RESET_REQ_B is asserted to external world: WRC/WRS==10 while EDM core output == 0
- SoC specific debug action taken when WRC/WRS==01, 10, 11 while EDM core output == 1.

Note that the MPIC allows for watchdog timer expiration events from the cores to be delivered as either a regular, critical, or machine check type interrupt to a designated core. The watchdog timer expiration events from all cores are conceptually ORed to present one interrupt source to the MPIC. A status register in the MPIC records which of the cores has an expired watchdog timer status. See the *Multicore Programmable Interrupt Controller (MPIC)* chapter.

7.4.7 Performance Monitor Details

The performance monitor facility provides the ability to monitor and count predefined events such as processor clocks, misses in the instruction cache or data cache, types of instructions decoded, or mispredicted branches. The count of such events can be used to trigger the performance monitor interrupt or a Nexus event. Additional performance

monitor registers (PMRs) similar to SPRs are used to configure and track performance monitor operations. These registers are accessed with the Move to PMR and Move from PMR instructions (mtpmr and mfpmr).

Note that the core's performance monitor is separate from the SoC-level performance monitor which is similar in its design, but uses memory-mapped performance monitor registers.

The performance monitor can be configured to trigger either a performance monitor interrupt or an event to the Nexus facility when configured conditions are met.

7.4.8 Decorated Load and Store Operations

The architecture defines a set of decorated load and store instructions that allow efficient, SoC-specific operations, such as atomically sampling and updating packet-counting statistics. The SoC defines specific semantics understood by a SoC-customized resource that requires them. See Decorated Storage for more information.

The architecture defines the a set of load/store byte, half-word, and word decorated integer operations and load/store floating-point double-word instructions, which provide the EA in **r**B and the decoration in **r**A.

The Decorated Storage Notify (dsn) instruction is an address-only operation that sends a decoration without sending data.

7.4.9 Debug Features

The core provides a comprehensive, extensively integrated set of internal and external debug features to support multicore implementations:

- Debug interrupt is a separate interrupt type
- Nexus facility
- Performance monitor now provides the ability to trigger either a performance monitor interrupt or a Nexus event
- Debug resources are extensively integrated at the SoC level. Implementation-specific details about core debug resources are described in the *EREF* and the *e6500 Core Reference Manual*.

7.4.10 Power Management

The core defines registers and instructions that provide power management that is programmable from the core. See the register and instruction model chapters of the *e6500 Core Reference Manual.* Integration details are provided in the *Run Control/Power Management Unit* chapter, which describes the run control and power management (RCPM) block, which allows the device to operate at various frequencies and execution modes to optimize power consumption.

7.4.11 Dealing with Guest OS WIMGE Aliasing in a Boundedly Undefined Manner

The e6500 core uses TLB entries to map pages of real memory. Each TLB entry contains a set of attributes which describe how the core and the system should treat core accesses to that page. These are refered to as WIMGE attributes for Write-Through Required, Caching Inhibited, Guarded, and Endianess. A complete description of these attributes can be found in EREF.

In general it is required that system software regulate how accesses are performed to memory by the cores, and are generally required to ensure that each core accesses a page with the same memory attributes.

Mixing these attributes can potentially cause incoherent accesses to the memory, or can cause memory ordering failures. In order to prevent such problems, system software should ensure that caches are flushed between any access for which the W, I, or M attribute is different. For any such mismatched accesses in which the caches are not flushed, the result is undefined (except that accesses where only the W attribute differs, from the same thread, are supported and behave as described in EREF).

In a virtualized system, where a hypervisor is running one or more guest OSes, use of the LRAT may permit a guest OS to program the TLB such that WIMGE mismatched access can occur resulting in undefined behavior. In general, this would require a misbehaving OS, or a nefarious guest OS, but the end result of the undefined behavior can result in a system deadlock, thus causing a severe denial of service to other guests (partitions) in the system.

If boundedly undefined behavior is desired for mismatched WIMGE attributes (such that failures which result from such accesses are confined to the partition which initiates the accesses), hypervisor software should do one of the following:

1. Do not use the LRAT, causing all TLB write (and page table translations) to be processed by the hypervisor and the hypervisor assures that the WIMGE bits are set correctly when writing the translation.

2. Or turn off CPC sole-data. In addition, the hypervisor should guarantee that if L2 caches are removed from the coherence fabric (through configuration or by turning clusters off), that the caches are first flushed of all modified data and invalidated prior to re-enabling them.

Chapter 8
CoreNet Platform Cache (CPC)

8.1 Introduction

8.1.1 CPC Overview

The CoreNet platform cache (CPC) is a CoreNet-compliant target device that functions as a general purpose write-back cache, I/O stash and memory mapped SRAM device, or a combination of these functions.

As a general purpose cache, it manages allocations and victimizations to improve read latency and bandwidth over accesses to backing store (for example, DRAM). As an I/O stash, it can accept and allocate writes from an I/O device in order to reduce latency and improve bandwidth for future read operations to the same address. As an SRAM device, it acts as a low-latency, high-bandwidth memory that occupies a programmable address range.

The CPC connects between the CoreNet coherency fabric (CCF) and the memory controller in an inline configuration and cannot function as a lookaside cache. Therefore, the CoreNet platform cache can only cache address ranges that are present in the memory controller behind it. This limitation does not apply to SRAM, which does not have backing store.

8.1.2 Features

The CPC includes the following features:

- In-line configuration
- Support for interleaving to match memory controllers (none , 2-way or 3-way at defined address boundaries)
- 512-Kbyte, 16-way set associative, 64-byte coherency granule

- Configurable pseudo-least recently used (PLRU), streaming PLRU with aging, streaming PLRU without aging, and first-in/first-out (FIFO) replacement policies with programmable allocation policy and update options
- Support for individual line locking
- Write-back or write-through operation
- Low latency interface to memory controller including a dedicated 128-bit data bus in each direction
- Partial SRAM and partial I/O stash mode with programmable sizes
- Stashing support
  - Stashing of all transactions and sizes supported (not limited to 64-byte or 32-byte)
  - Explicit (CoreNet signalled) and implicit (address range based) stash allocation
- Support for decorated storage

8.2 CoreNet Platform Cache (CPC) Memory Map

The following table shows the memory map for the CoreNet platform cache (CPC) registers. The CPC registers are accessed by reading and writing to an address comprised of the base address (specified by the CCSRBAR), plus the CPC block base address, plus the offset of the specific register to be accessed.

CPC memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
1_0000	CPC configuration and status register 0 (CPC1_CPCCSR0)	32	R/W	0000_0000h	8.2.1/287
1_0008	CPC configuration register 0 (CPC1_CPCCFG0)	32	R	50B3_C008h	8.2.2/290
1_0010	CPC external write control register n (CPC1_CPCEWCR0)	32	R/W	0000_0000h	8.2.3/292
1_0014	CPC external write base address register n (CPC1_CPCEWBAR0)	32	R/W	0000_0000h	8.2.4/293
1_0020	CPC external write control register n (CPC1_CPCEWCR1)	32	R/W	0000_0000h	8.2.3/292
1_0024	CPC external write base address register n (CPC1_CPCEWBAR1)	32	R/W	0000_0000h	8.2.4/293
1_0100	CPC SRAM control register 1 (CPC1_CPCSRCR1)	32	R/W	0000_0000h	8.2.5/294
1_0104	CPC SRAM control register 0 (CPC1_CPCSRCR0)	32	R/W	0000_0000h	8.2.6/294
1_0200	CPC partition ID register 0 (CPC1_CPCPIR0)	32	R/W	FFFF_FFFFh	8.2.7/295
1_0208	CPC partition allocation register 0 (CPC1_CPCPAR0)	32	R/W	FFFF_FBFFh	8.2.8/296
1_020C	CPC partition way register 0 (CPC1_CPCPWR0)	32	R/W	FFFF_FFFFh	8.2.9/297
1_0210	CPC partition ID register n (CPC1_CPCPIR1)	32	R/W	0000_0000h	8.2.10/298

Table continues on the next page...

CPC memory map (continued)

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
1_0218	CPC partition allocation register n (CPC1_CPCPAR1)	32	R/W	0000_0000h	8.2.11/298

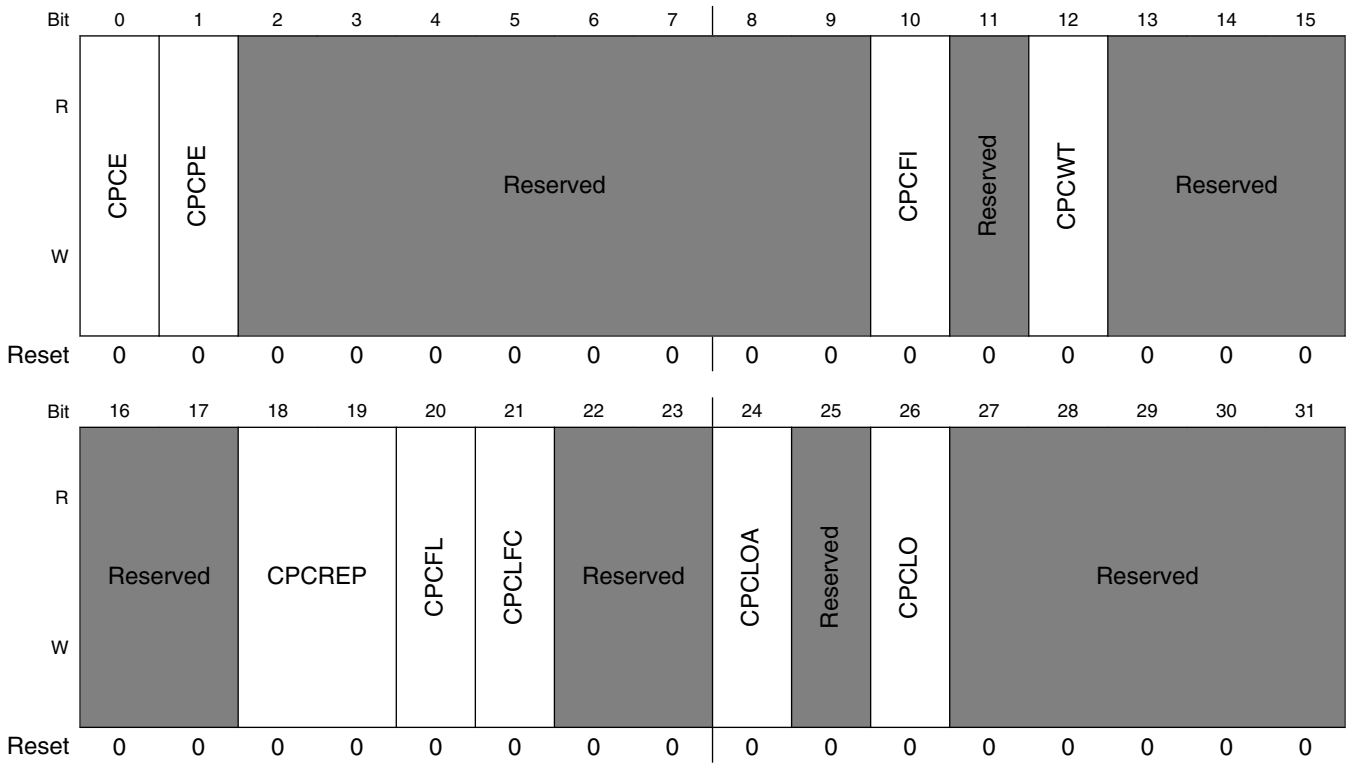
8.2.1 CPC configuration and status register 0 (CPCx_CPCCSR0)

The CPC configuration and status register (CPCCSR0) controls configuration and operation of the CPC array. The sequence for modifying CPCCSR0 can be found at Modifying CPC Control and Status Registers.

Address: Base address + 0h offset



CPCx_CPCCSR0 field descriptions

Field	Description
0 CPCE	CPC enable. Used to enable the CPC array (cache or memory-mapped SRAM). 0 CPC is disabled. All transactions will behave as if they miss in the cache. 1 CPC is enabled
1 CPCPE	CPC parity/ECC error checking enable. Used to enable error checking in the CPC arrays. This bit must be set for normal operation. **NOTE:** The value of CPCPE should not be changed after the CPC is enabled. CPCPE bit should only be set or cleared simultaneously with setting or clearing CPCE. 0 Error checking disabled 1 Error checking enabled
2–9 -	This field is reserved. Reserved

Table continues on the next page...

CPC*x*_CPCCSR0 field descriptions (continued)

Field	Description
10 CPCFI	CPC flash invalidate. Invalidation occurs regardless whether the cache is enabled or not. . **NOTE:** Attempting to set CPCFI during an invalidation operation causes undefined results; attempting to clear CPCFI during an invalidation operation is ignored. **NOTE:** Note: If CPCFI and CPCLFC are set simultaneously with the same register write operation, then the CPC flash invalidate and CPC lock flash clear functions are performed in parallel. In this case, hardware clears both the valid and lock bits, as well as all the tag and LRU bits, with a single pass through all indices, writing each entry in the CPC tag, status and victim arrays. In addition, all data arrays are cleared by writing 0s to all locations. **NOTE:** Before enabling the CPC through CPCE, the CPC tags should be cleared by setting both CPCFI and CPCLFC. This insures that all entries in the cache are invalidated and unlocked. 0 Normal operation. No cache invalidation. 1 Cache flash invalidate. A cache invalidation operation is initiated by hardware. Once complete, this bit is cleared. All the lines in the CPC that are designated as cache (that is, not SRAM) will be invalidated.
11 -	This field is reserved. Reserved
12 CPCWT	CPC write-through mode. **NOTE:** This bit must not be changed once the CPC has been enabled through the CPCE bit. The value of CPCWT must be set at the same time as CPCE. 0 CPC is operating in write-back mode. 1 CPC is operating in write-through mode.
13–17 -	This field is reserved. Reserved
18–19 CPCREP	CPC line replacement algorithm. 00 SPLRU (Streaming Pseudo Least Recently Used) with Aging. 01 FIFO (First In, First Out). 10 SPLRU (Streaming Pseudo Least Recently Used). 11 PLRU (Pseudo Least Recently Used).
20 CPCFL	CPC flush. Setting this bit initiates a CPC flush operation causing all dirty lines to be written out to backing store (memory). **NOTE:** • Writing a 1 while a flush operation is in progress is ignored. Writing a 0 during a flash clear operation is ignored. Writing a 1 to CPCFL is ignored if the CPC is not enabled (CPCE = 0). • To flush the CPC cache and ensure that no valid entries exist after the flush (that is, for the purposes of powering down or disabling) the following high level sequence of operations should be used: a. Clear all bits in CPCPAR0-CPCPAR15 to prevent new transactions from allocating in the CPC b. Set CPCCSR0[CPCFL] c. Wait for CPCCSR0[CPCFL] to be cleared by hardware d. Clear CPCCSR0[CPCE] 0 A CPC flush is not being performed. 1 Hardware initiates a CPC flush operation. This bit is cleared when the operation is complete. All lines in the CPC tag array that are dirty will be written back to backing store.

Table continues on the next page...

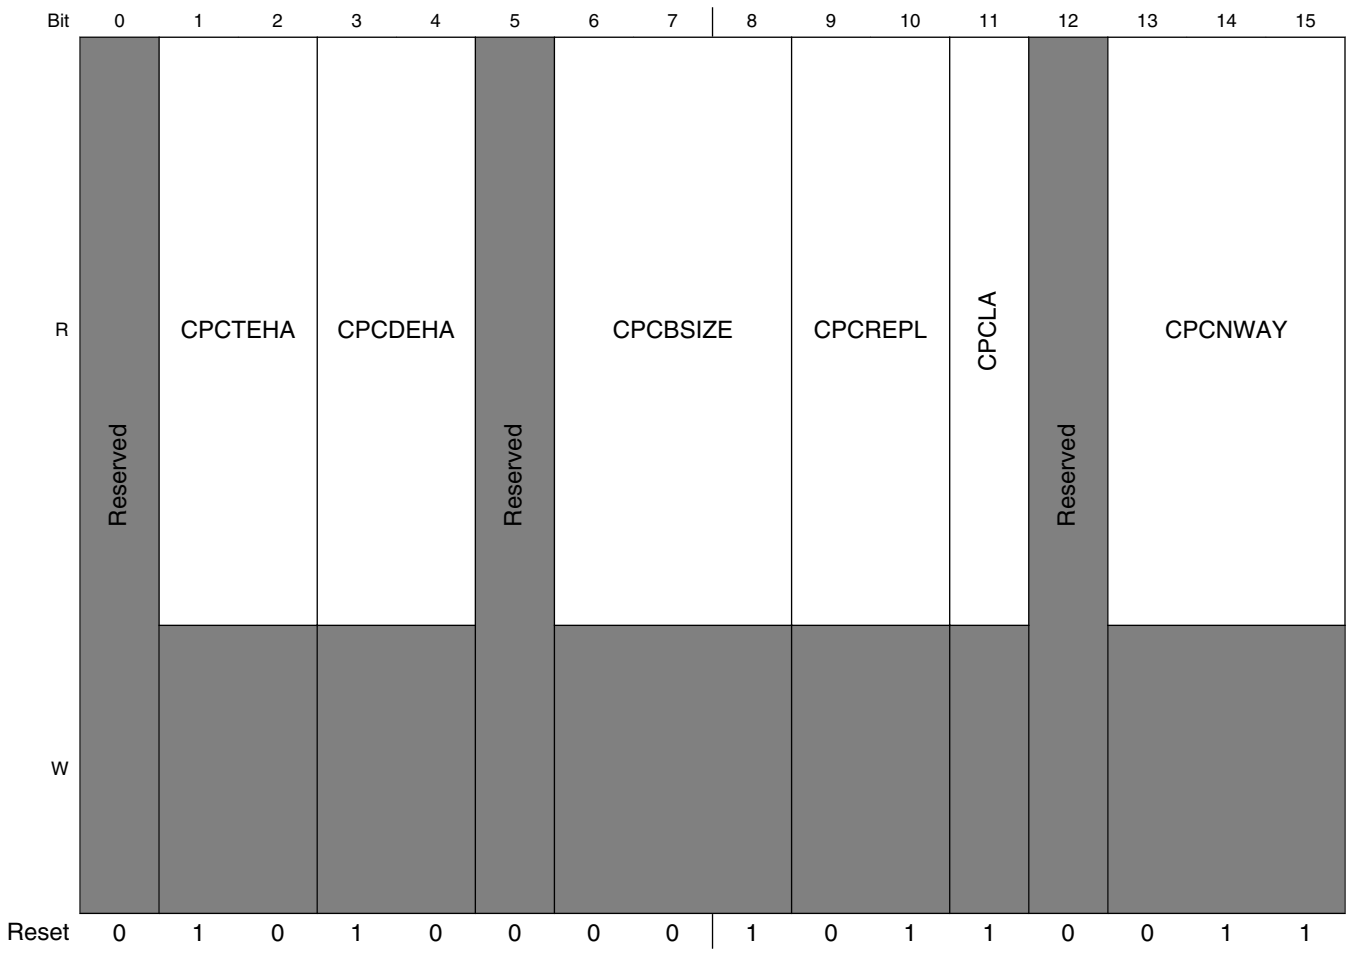
CPC*x*_CPCCSR0 field descriptions (continued)

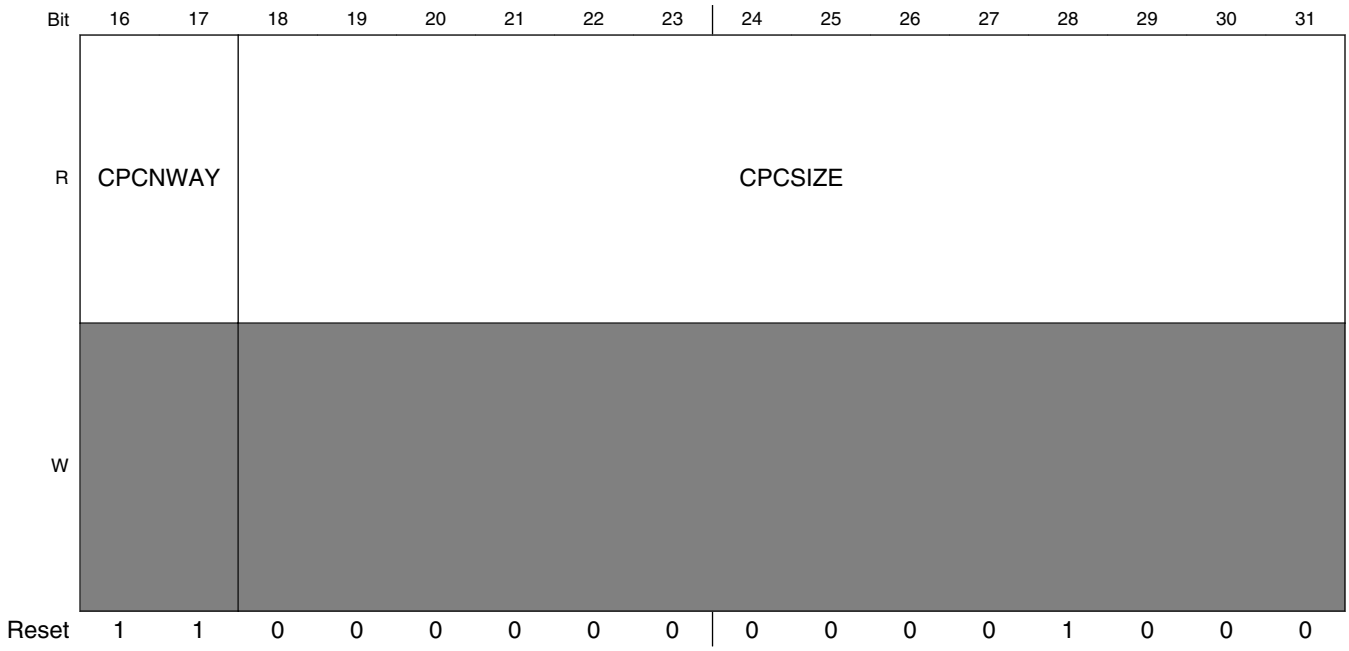
Field	Description
21 CPCLFC	CPC lock flash clear. Clearing of lock bits occurs regardless of the cache enable (CPCE) value. **NOTE:** Writing a 1 during a lock clear operation causes undefined results. Writing a 0 during a lock clear operation is ignored. **NOTE:** If CPCFI and CPCLFC are set simultaneously with the same register write operation, then the CPC flash invalidate and CPC lock flash clear functions will be performed in parallel. In this case, hardware will clear both the valid and lock bits, as well as all the tag and LRU bits, with a single pass through all indices, writing each entry in the CPC tag, status and victim arrays. In addition, all data arrays are cleared by writing 0's to all locations. **NOTE:** Before enabling the CPC through CPCCSR0[CPCE], the CPC tags should be cleared by setting both CPCCSR0[CPCFI] and CPCCSR0[CPCLFC]. This insures that all entries in the cache are invalidated and unlocked 0 No flash lock clear. . 1 Cache flash lock clear operation. A cache flash lock clear operation is initiated by hardware. Once complete, this bit is cleared. All the lines in the CPC that are designated as cache (that is, not SRAM) will clear their lock bits.
22–23 -	This field is reserved. Reserved
24 CPCLOA	CPC lock overflow allocate. Controls the behavior of a transaction that wishes to establish a coherency granule in the locked state. 0 Indicates a lock overflow condition will not replace an existing locked granule with the requested granule. 1 Indicates a lock overflow condition will replace an existing locked granule with the requested granule using the selected replacement algorithm.
25 -	This field is reserved. Reserved
26 CPCLO	CPC lock overflow. This sticky bit is set by hardware if a cache lock overflow situation is detected. Overflow conditions occur as the result of a transaction that wishes to establish a coherency granule in the cache in a locked state, but all available ways are already locked and as a result an existing locked coherency granule is replaced. 0 The cache has not encountered a lock overflow condition. 1 The cache has encountered a lock overflow condition.
27–31 -	This field is reserved. Reserved

8.2.2 CPC configuration register 0 (CPCx_CPCCFG0)

The CPC configuration register 0 (CPCCFG0) controls the initial configuration of the CPC.

Address: Base address + 8h offset





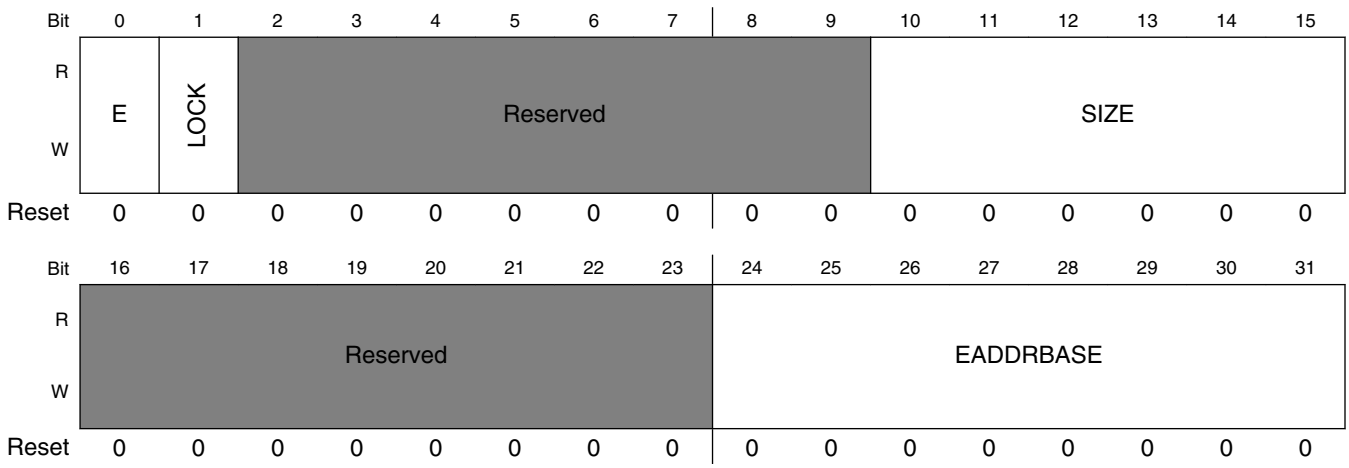
CPCx_CPCCFG0 field descriptions

Field	Description
0 -	This field is reserved. Reserved
1–2 CPCTEHA	CPC tag array error handling available. 10 Single-bit ECC correction, double-bit ECC detection available
3–4 CPCDEHA	CPC data array error handling available. 10 Single-bit ECC correction, double-bit ECC detection available
5 -	This field is reserved. Reserved
6–8 CPCBSIZE	Coherency granule size. 001 64 bytes
9–10 CPCREPL	Cache default replacement policy. 01 Pseudo LRU
11 CPCLA	Cache Line Locking APU available. The CPC responds to a CT field equal to 1. 1 Available
12 -	This field is reserved. Reserved
13–17 CPCNWAY	Cache number of ways. The actual value is the number of ways - 1. 01111 16 way set associative
18–31 CPCSIZE	Cache size in 64 Kbyte increments. A value of 1 denotes a 64-Kbyte cache 00_0000_0000_1000 512 Kbytes

8.2.3 CPC external write control register n (CPC*x*_CPCEWCR*n*)

Note that when using interleaving, the external write control registers should have the same settings.

Address: Base address + 10h offset + (16d × i), where i=0d to 1d



CPC*x*_CPCEWCR*n* field descriptions

Field	Description
0 E	Enable
1 LOCK	Lock
2–9 -	This field is reserved. Reserved
10–15 SIZE	Size of the address range used for implicit stashing. This field is used to generate an address mask that is applied to both the transaction address and the address base formed from EADDRBASE and ADDRBASE before comparing the two. The size of the address range is equal to 2^{SIZE+6}. 000000 64 bytes 000001 128 bytes 000010 256 bytes 000011 512 bytes 000100 1 Kbytes 000101 2 Kbytes 000110 4 Kbytes 000111 8 Kbytes 001000 16 Kbytes 001001 32 Kbytes 001010 64 Kbytes 001011 128 Kbytes 001100 256 Kbytes

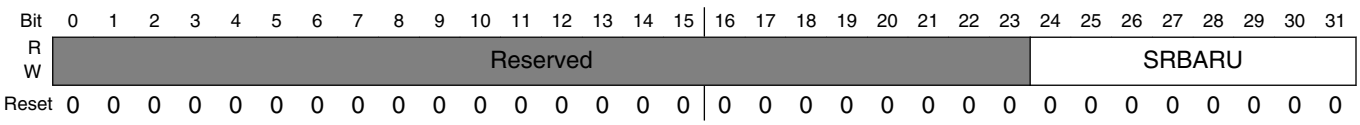
CPC*x*_CPCEWBAR*n* field descriptions

Field	Description
0–25 ADDRBASE	Base address corresponding to physical address 8:33.
26–31 -	This field is reserved. Reserved

8.2.5 CPC SRAM control register 1 (CPC*x*_CPCSRCR1)

The CPC SRAM control register 1(CPCSRCR1) determines the upper base address when the CPC is used as SRAM.

Address: Base address + 100h offset



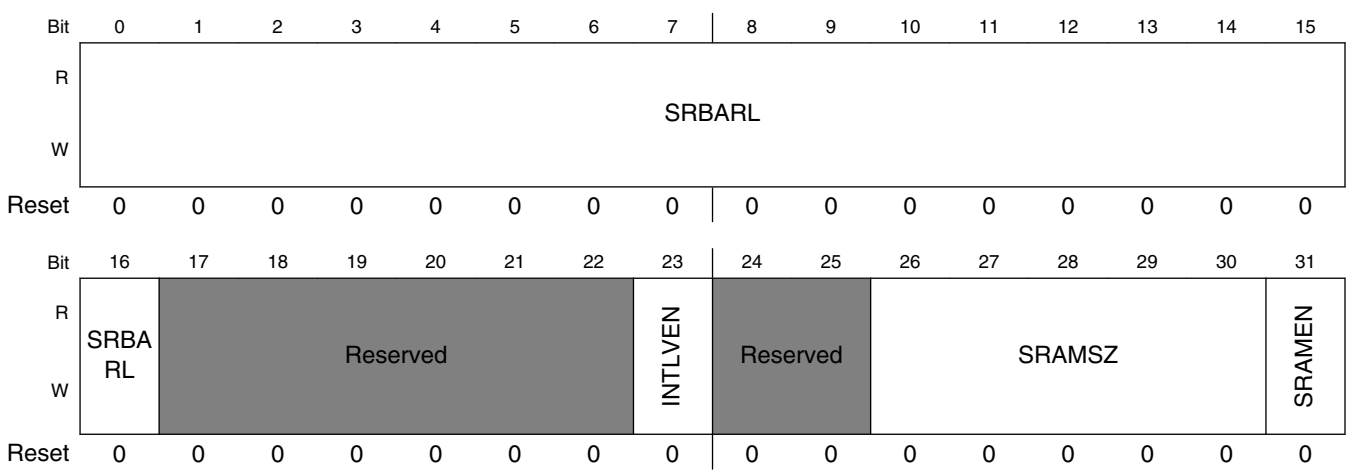
CPC*x*_CPCSRCR1 field descriptions

Field	Description
0–23 -	This field is reserved. Reserved
24–31 SRBARU	SRAM base address high. Corresponds to physical address bits 0:7.

8.2.6 CPC SRAM control register 0 (CPC*x*_CPCSRCR0)

The CPC SRAM control register 0 (CPCSRCR0) configures the CPC when it is used as SRAM.

Address: Base address + 104h offset



CPCx_CPCSRCR0 field descriptions

Field	Description
0–16 SRBARL	SRAM base address low. Corresponds to physical address bits 8:24. The base address should be aligned to the size specified in SRAMSZ.
17–22 -	This field is reserved. Reserved
23 INTLVEN	SRAM interleaving enable. **NOTE:** SRAM address interleaving is only supported when the memory controllers are interleaved on cache-line or page boundaries. 0 SRAM address interleaving is disabled 1 SRAM address interleaving is enabled. In this case, memory controller interleaving must also be enabled in the DDR controller registers. SRAM address space is interleaved at the same address boundary as the DDR controllers. These parameters are controlled by the DDR controller configuration registers.
24–25 -	This field is reserved. Reserved
26–30 SRAMSZ	SRAM size. This determines the size of the SRAM space . All other settings not shown are reserved. 00001 64 Kbytes,uses ways 14-15 for SRAM 00011 256 Kbytes,uses ways 8-15 for SRAM 00100 512 Kbytes uses ways 0-15 for SRAM
31 SRAMEN	SRAM mode enable

8.2.7 CPC partition ID register 0 (CPCx_CPCPIR0)

Address: Base address + 200h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

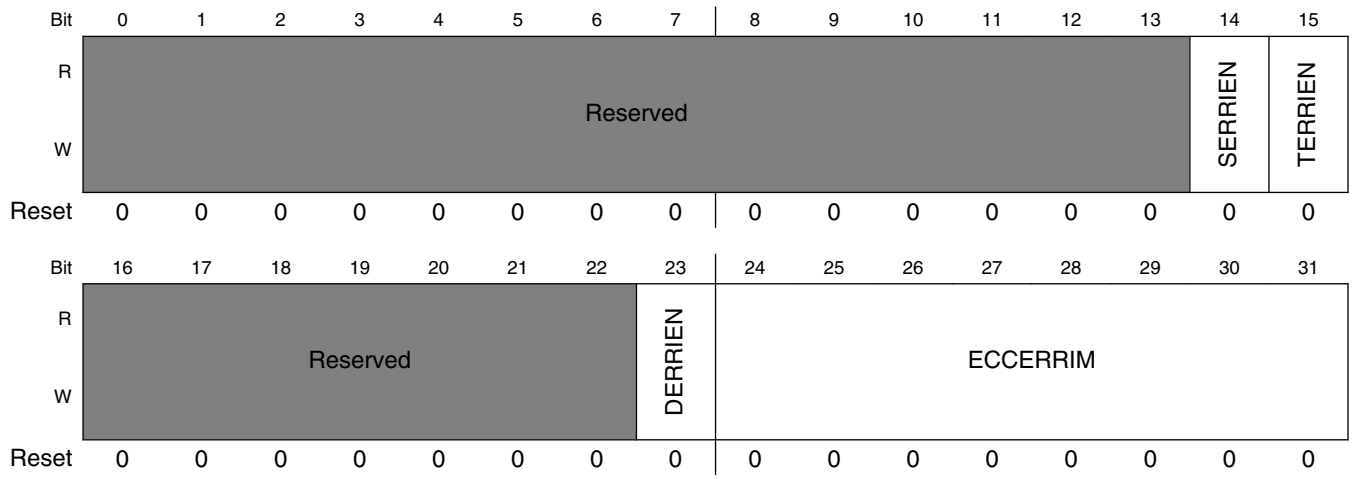
8.2.15 CPC error injection control register (CPC*x*_CPCERRINJCTL)

Address: Base address + E08h offset

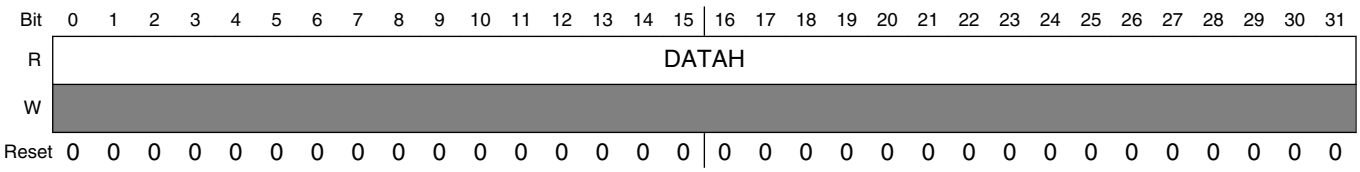


CPC*x*_CPCERRINJCTL field descriptions

Field	Description
0–13 -	This field is reserved. Reserved
14 SERRIEN	Status error injection enable. Status error injection is determined by CPCERRINJLO[23:31]; status ECC error injection is determined by the five least-significant bits of ECCERRIM (that is, CPCERRINJCTL[27:31]). 0 No status errors are injected 1 Subsequent entries written to the CPC status arrays have status or ECC bits inverted as specified in the status and ECC error injection masks.
15 TERRIEN	Tag error injection enable. Tag error injection is determined by CPCERRINJLO[7:31]; tag ECC error injection is determined by the seven least-significant bits of ECCERRIM (that is, CPCERRINJCTL[25:31]). 0 No tag errors are injected 1 Subsequent entries written to the CPC tag arrays have tag or ECC bits inverted as specified in the data and ECC error injection masks.
16–22 -	This field is reserved. Reserved
23 DERRIEN	CPC data array error injection enable. Data error injection is determined by CPCERRINJHI[0:31] and CPCERRINJLO[0:31]; data ECC error injection is determined by ECCERRIM. 0 No data errors are injected 1 Subsequent entries written to the CPC data arrays have data or ECC bits inverted as specified in the data and ECC error injection masks.
24–31 ECCERRIM	Error injection mask for the ECC bits. When DERRIEN=1, the eight ECCERRIM bits map to the eight ECC bits for each 64 bits of data. When TERRIEN=1, the low order seven ECCERRIM bits map to the seven ECC bits for each 25-bit tag. When SERRIEN=1, the low order five ECCERRIM bits map to the five ECC bits for each 9-bit tag.

8.2.16 CPC capture data high register (CPCx_CPCCAPTDATAHI)

Address: Base address + E20h offset

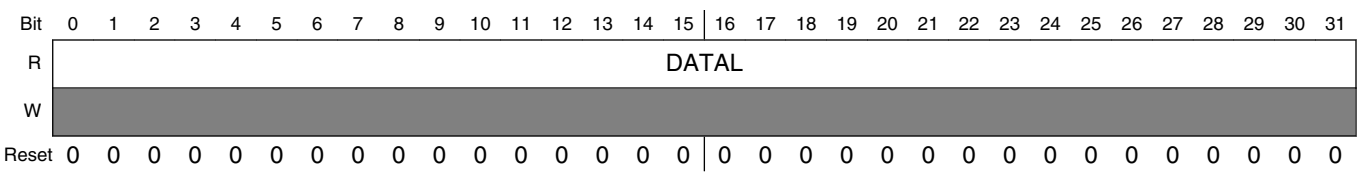


CPCx_CPCCAPTDATAHI field descriptions

Field	Description
0–31 DATAH	If error is data ECC, then bits 0-31 are the upper order 32 bits of data associated with the error. If the error is tag ECC, then bits 0-15 are zeros and bits 16-31 are the upper order 16 bits of the tag associated with the error. If the error is status ECC, then this field is all zeros.

8.2.17 CPC capture data low register (CPCx_CPCCAPTDATALO)

Address: Base address + E24h offset

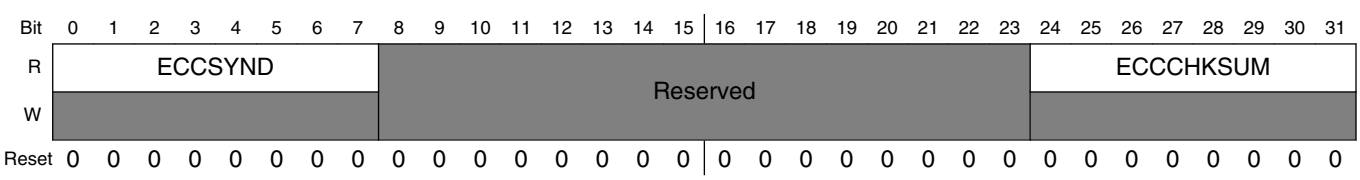


CPCx_CPCCAPTDATALO field descriptions

Field	Description
0–31 DATAL	If error is data ECC, the bits 0-31 are the lower order 32 bits of data associated with the error. If the error is tag ECC, then bits 0-16 are the lower order 17 bits of the tag associated with the error and bits 17-31 are zeros. If the error is status ECC, then bits 0-22 are zeros and bits 23-31 are the status bits associated with the error.

8.2.18 CPC capture ECC register (CPCx_CPCCAPTECC)

Address: Base address + E28h offset

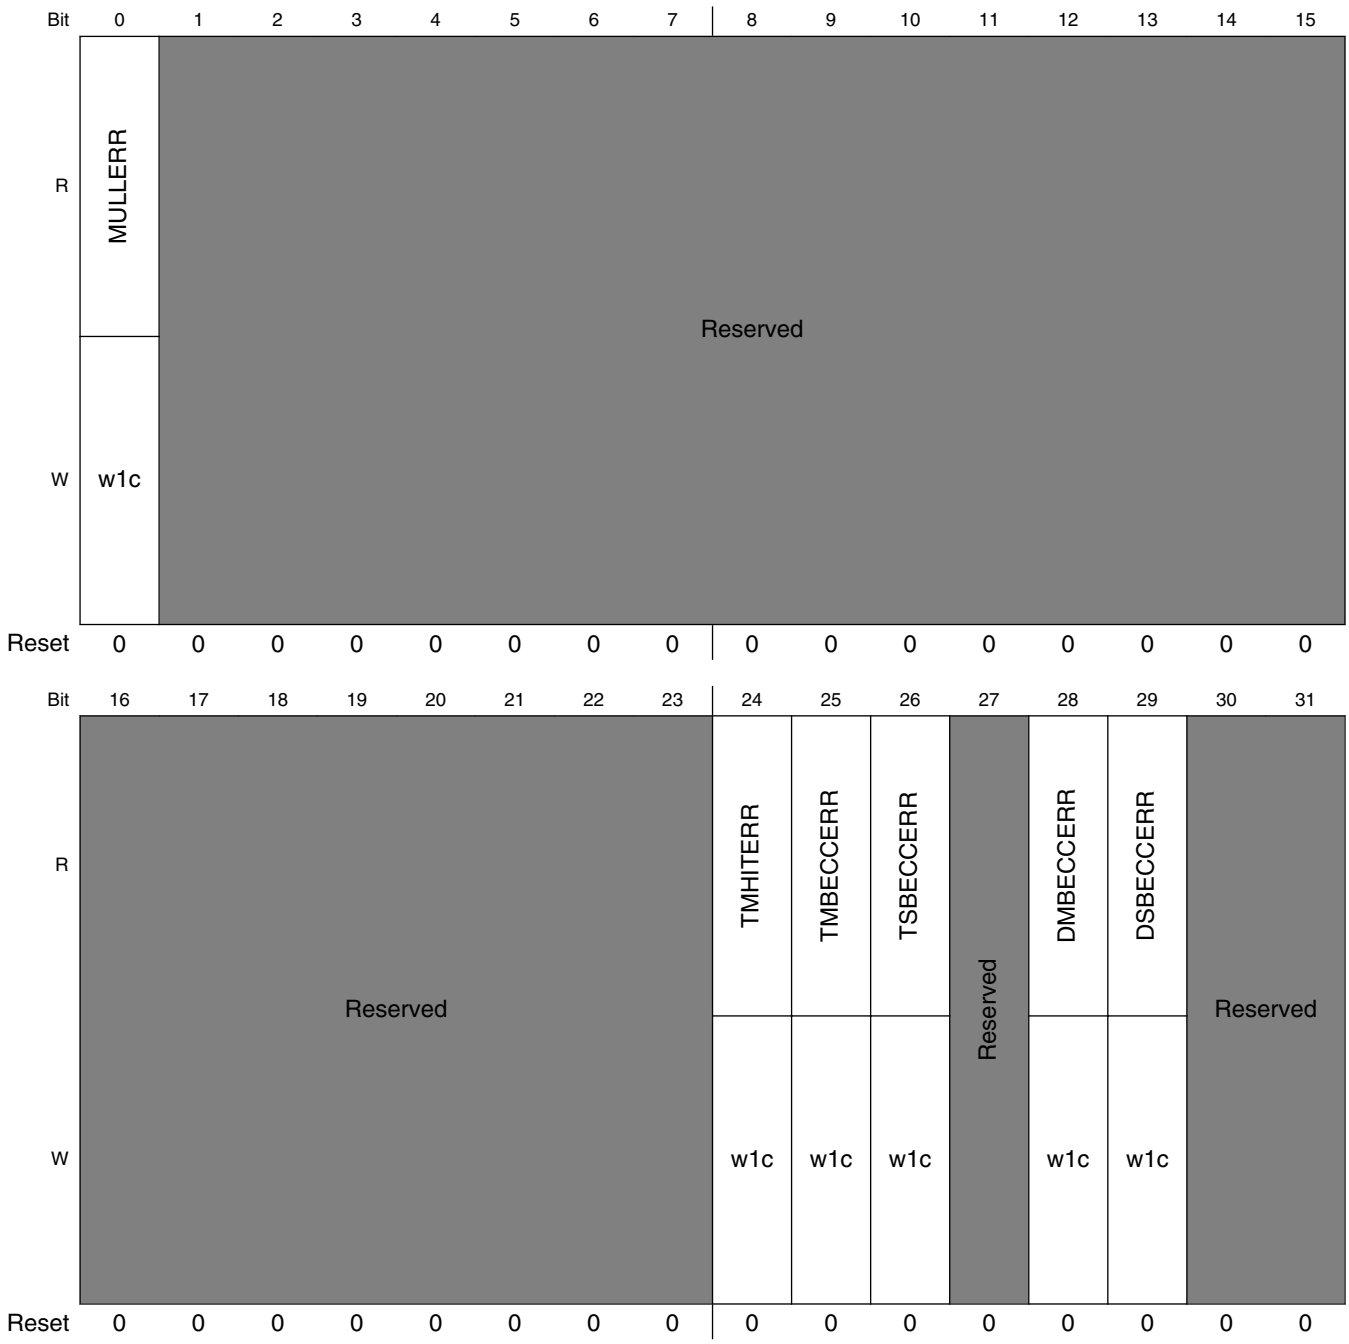


CPCx_CPCCAPTECC field descriptions

Field	Description
0–7 ECCSYND	The calculated ECC syndrome of the captured error. Tag and status ECC are left padded with 1 or 3 zeros, respectively.
8–23 -	This field is reserved. Reserved
24–31 ECCCHKSUM	The stored ECC syndrome of the captured error. Tag and status ECC are left padded with 1 or 3 zeros, respectively.

8.2.19 CPC error detect register (CPC*x*_CPCERRDET)

Address: Base address + E40h offset



CPC*x*_CPCERRDET field descriptions

Field	Description
0 MULLERR	Multiple CPC errors

Table continues on the next page...

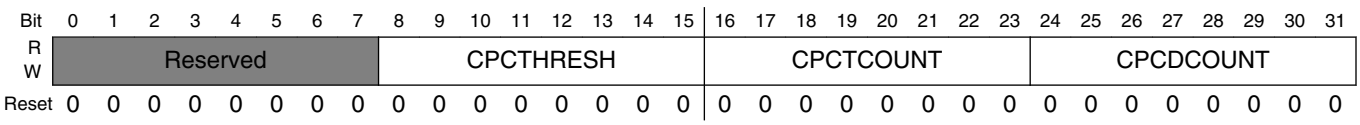
CPCx_CPCERRADDR field descriptions

Field	Description
0–31 ADDRL	Lower-order 32 bits of the physical address (PA[8:39]) associated with a captured error.

8.2.24 CPC error control register (CPCx_CPCERRCTL)

Address: Base address + E58h offset



CPCx_CPCERRCTL field descriptions

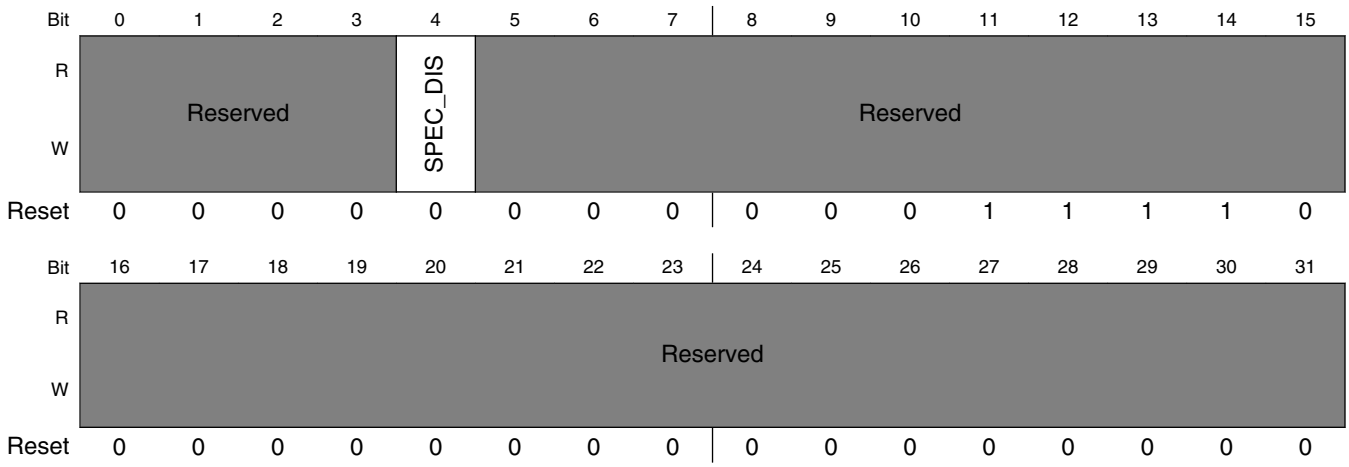
Field	Description
0–7 -	This field is reserved. Reserved
8–15 CPCTHRESH	CPC ECC single-bit error threshold. Threshold value for the number of ECC single-bit errors that are detected before reporting an error condition. CPCTHRESH is compared to CPCTCOUNT and CPCCOUNT each time a single-bit ECC error is detected. A value of 0 in this field will cause the reporting of a single bit ECC error upon the first occurrence of such an error.
16–23 CPCTCOUNT	CPC tag ECC single-bit error count. Counts ECC single-bit errors detected in the CPC tags. If CPCTCOUNT equals the ECC single-bit error threshold (CPCTHRESH), an error is reported if single-bit error reporting for tags is enabled. Software should clear this value when such an error is reported to reset the count.
24–31 CPCDCOUNT	CPC data ECC single-bit error count. Counts ECC single-bit errors detected in the CPC data. If CPCCOUNT equals the ECC single-bit error threshold (CPCTHRESH), an error is reported if single-bit error reporting for data is enabled. Software should clear this value when such an error is reported to reset the count.

8.2.25 CPC hardware debug control register 0 (CPCx_CPCHDBCR0)

NOTE

Any write to this register must maintain the default reset values for the reserved bits.

Address: Base address + F00h offset



CPCx_CPCHDBCR0 field descriptions

Field	Description
0–3 -	This field is reserved. Reserved
4 SPEC_DIS	Speculation disable 0 Read type requests speculatively pass to the memory controllers before determining whether there is a hit in the CPC. **NOTE:** This bit should be set to a 1 if the CPC SRAM is enabled and the SRAM address space does not overlap an enabled address region in the DRAM controller. 1 Read type requests must wait to determine hit in the CPC before making a memory controller request.
5–31 -	This field is reserved. Reserved

8.3 CPC Functional Description

8.3.1 Register Sections

8.3.1.1 SRAM Mode Registers

The CoreNet platform cache can be configured to use some of its ways as direct-mapped SRAM address space. The SRAM mode registers enable and configure the CPC to be used as SRAM space.

SRAM mode is enabled by CPCSRCR0[SRAMEN], the size of the SRAM address space is configured by CPCSRCR0[SRAMSZ], and the base address of the SRAM address space is specified using CPCSRCR0[SRBARL] and CPCSRCR1[SRBARU].

If DRAM addresses are interleaved (as controlled through the DDR controller configuration registers or through the CCF registers for 3-way interleaving), then SRAM address space can also be interleaved at the same address boundary by setting CPCSRCR0[INTLVEN]. If DDR is not interleaved, then SRAM address space cannot be interleaved. Enabling SRAM interleaving requires that all instances of the CPC in the system that participate in interleaving be programmed to the same SRAM size and base address. Additionally, the interleave granularity must be less than or equal to the size of an individual CPC's SRAM. Enabling SRAM interleaving effectively doubles the total SRAM address space. For 3-way interleaved SRAM, the total SRAM address space must be aligned to an address boundary equal to four times the non-interleaved CPCSRCR0[SRAMSZ] size. The interleave granularity must be less than or equal to the size of an individual CPC’s SRAM.

The CPC sends speculative requests (that is, before the CPC determines hit or miss) to the memory controller. If the CPC is configured as SRAM space, the memory controller may not respond to speculative SRAM requests that don’t hit DRAM (or may generate an error). Therefore, when the CPC is configured as SRAM and the SRAM address space does not overlap an enabled memory controller address region, disable speculative requests by setting CPCHDBCR0[SPEC_DIS]. See CPC hardware debug control register 0 (CPC_CPCHDBCR0) for more information.

8.3.1.2 Partitioning Control Registers

The CPC supports a flexible way partition/allocation control scheme. Each transaction that misses in the cache looks in a table to determine whether or not to allocate and which ways are available for allocation.

Table entries are matched by comparing Partition IDs. Allocation is then controlled dependent on transaction type and address qualifiers as well as stashing control signals.

Each partition control is composed of three registers: CPCPIR*n*, CPCPAR*n* and CPCPWR*n*. There are a total of 16 triples of these registers.

8.3.1.3 Error Registers

8.3.1.3.1 Error Detection and Reporting

Error detection for tags and data are enabled by default.

When an error is detected in the CPC the appropriate bit in the CPC error detect register (CPCERRDET) is set and, if enabled by CPCERRINTEN, a machine check interrupt is generated for software to notice and handle the error. The generation of the interrupt when an error is detected is controlled by the CPC error interrupt enable register (CPCERRINTEN). Bits in this register control whether an interrupt is to be generated based on the type and location of the error in the CPC. Software may read from the CPCERRDET and may clear bits by writing a 1 into a bit position, but cannot directly write the contents of the register. CPCERRDET is described in CPC error detect register (CPC_CPCERRDET); CPCERRINTEN is described in CPC error interrupt enable register (CPC_CPCERRINTEN).

Single-bit errors that are corrected by ECC are not reported unless the appropriate bit in the CPCERRDET register is set and the number of errors reach a threshold specified in CPCERRCTL, described in CPC error control register (CPC_CPCERRCTL).This prevents normal correctable ECC errors from generating machine check exceptions, but will still cause errors to be generated when there may be a persistent faulty condition in the CPC.

The machine check exception is generated based on the CPCERRDET status bits and CPCERRINTEN enable bits. If an CPCERRDET status bit and its corresponding CPCERRINTEN enable bit are set at the same time, a machine check exception is generated. Therefore, upon taking the machine check, software should clear CPCERRDET before setting MSR[ME], otherwise another machine check can occur when MSR[ME] is set.

8.3.1.3.2 Error Capture

When an error is detected and reported, information about the error is posted into several CPC error capture registers (CPCERRADDR, CPCERREADDR, CPCCAPTDATAHI, CPCCAPTDATALO, and CPCCAPTECC). Only the first reported error information is saved.

The error capture registers are as follows:

- CPCERRADDR and CPCERREADDR contain the physical address associated with the captured error. CPCERRADDR and CPCERREADDR are described in CPC

error extended address register (CPC_CPCERREADDR) and CPC error address register (CPC_CPCERRADDR).
- CPCCAPTDATAHI and CPCCAPTDATALO contain data or tag value associated with the captured error and are described in CPC error injection high register (CPC_CPCERRINJHI) and CPC error injection low register (CPC_CPCERRINJLO).
- CPCCAPTECC contains ECC information from the data or tag (the syndrome and the checksum) and is described in CPC capture ECC register (CPC_CPCCAPTECC).

8.3.1.3.3 Error Injection

The CPC includes support for injecting errors into the data, data ECC, tag, tag ECC, status and status ECC. This may be used to test error recovery software by deterministically creating error scenarios.

The error injection registers are as follows:

- Data error is injected into the line, according to the error injection settings in CPCERRINJHI, CPCERRINJLO, and CPCERRINJCTL, at allocation. Tag error injection is determined by CPCERRINJLO and CPCERRINJCTL, at allocation. Note that error injection enable bits in CPCERRINJCTL must be cleared by software and the CPC must be invalidated (by setting CPCCSR0[CPCFI]) before resuming CPC normal operation.
- Data, tag and status use the same error injection masks as defined by CPCERRINJHI, CPCERRINJLO and CPCERRINJCTL, but have separate error injection enables as defined in CPCERRINJCTL.
- CPCERRINJCTL, CPCERRINJLO, and CPCERRINJHI are described in CPC error injection control register (CPC_CPCERRINJCTL), CPC error injection low register (CPC_CPCERRINJLO), and CPC error injection high register (CPC_CPCERRINJHI)."

8.3.2 Line Locking

The CoreNet platform cache supports persistent cache locking as defined by NXP Book E Implementation Standards for Storage (EIS Storage). A single lock bit is associated with each coherency granule stored in the cache.

The CPC supports explicit lock and unlock commands carried through transactions. Processor master devices can use **dcbtls, dcbtstls, icbtls, dcblc, icblc** instructions to generate LoadEC and Unlock transactions that target the CPC through the respective instructions' CT field. I/O master devices can use a wider variety of transactions that support explicit stashing transaction attributes.

The CPC also supports implicit locking through specified address ranges as defined by the Stashing Control Registers. See CPC external write control register n (CPC_CPCEWCR*n*).

8.3.3 Cache Operation Instructions and Transactions

Even though the CoreNet platform cache is not directly tied to a processor, it does respect the traditional cache operation instructions through their CoreNet transaction.

dcbf instructions cause Flush transactions on CoreNet and the CPC performs the appropriate action in order to flush any dirty data to memory. **dcbi** instructions may cause Kill transactions on CoreNet and the CPC performs the appropriate action in order to invalidate the addressed coherency granule. Refer to e5500 core reference manual to get more information on how these broadcasts can be initiated.

Note that cache management transactions such as Flush, Clean, and Kill have no affect to addresses configured as SRAM.

8.3.4 Decorated Storage

The *NXP Book E Implementation Standards for Storage*, referred to as the EIS, defines an extension to the base Power Architecture instruction set called the Decorated Storage APU. This APU defines new instructions that include an attribute called a decoration that provides additional semantics for the device.

The CoreNet platform cache supports the Decorated Storage APU as defined in EIS through specially-coded CoreNet transactions. Note that the decoration does not have any direct meaning to the core itself, but is interpreted by the CPC on behalf of the memory complex. A decorated operation carries up to four parameters:

- Type of access (load, store, or notify)
- Address
- Data (for stores)
- Decoration (encoding that defines the operation)

Decorated storage is only supported to addresses mapped by big-endian memory pages. In addition, the decorated storage operations are performed only on addresses that have been marked as caching-inhibited and guarded.

8.3.4.1 Decorated Load Operations

Decorated load operations read data from the memory complex (either from the CPC data arrays or from DDR), returns it to the core, and then performs a selectable update to the data in the memory complex.

The overall flow through the data pipeline is similar to a read-modify-write (RMW) operation. The main difference is in how the new write data is generated. A decorated load operation can perform four different operations (clear, increment, decrement or set) on four different data types (1, 2, 4 or 8 bytes). The timing of these operations is the same as for RMW.

8.3.4.2 Decorated Store Operations

Decorated store operations are similar to decorated loads. The main difference is that decorated stores do not return data to the core and the update operations can perform an add and subtract (instead of just a increment or decrement) and minimum and maximum functions using data received from the core.

The timing of these operations is the same as for RMW.

Decorated store operations require that the write data be presented in the proper byte lanes as required to perform the desired operation. Table 8-1 shows the address alignment restrictions for the specific decorated store instructions. Note that the maximum and minimum functions only support one size value for each decoration value.

If a decorated store does not carry the proper address alignment for its decoration, the decorated store writes back the existing data to the memory complex (that is, it will nop).

Table 8-1 describes the decorated storage instructions with supported decorations and the operations that are performed as a result.

Table 8-1. Decorated Storage Operations

Decorated Storage Instruction	Decoration (rA)	Address Alignment Addr[60:63][1]	Update Operation[2]	Function
lbdx	0000	-	MEM(addr[ ])[0:7] = 0x00	Clear byte
	0001	-	MEM(addr[ ])[0:7] = 0xFF	Set byte
	0010	-	MEM(addr[ ])[0:7]--	Decrement byte
	0011	-	MEM(addr[ ])[0:7]++	Increment byte
lhdx	0000	-	MEM({addr[ ], 0})[0:15] = 0x0000	Clear half-word
	0001	-	MEM({addr[ ], 0})[0:15] = 0xFFFF	Set half-word

Table continues on the next page...

Table 8-1. Decorated Storage Operations (continued)

Decorated Storage Instruction	Decoration (rA)	Address Alignment Addr[60:63][1]	Update Operation[2]	Function

		1000	MEM({addr[ ], 000}) = unsigned_max(MEM({addr[ ], 000}), DIn[64:127])	
	0110	0000	MEM({addr[ ], 000}) = unsigned_min(MEM({addr[ ], 000}), DIn[0:63])	64-bit minimum with unsigned doubleword

Table continues on the next page...

Table 8-1. Decorated Storage Operations (continued)

Decorated Storage Instruction	Decoration (rA)	Address Alignment Addr[60:63][1]	Update Operation[2]	Function
		1000	MEM({addr[ ], 000}) = unsigned_min(MEM({addr[ ], 000}), DIn[64:127])	
dsn	0000	-	MEM({addr[ ], 000})[0:63]++	Doubleword increment
	0001	-	MEM({addr[ ], 00})[0:31]++	Word increment
	0010	-	MEM({addr[ ], 000})[0:63] = 0000_0000_0000_0000	Doubleword clear
	0011	-	MEM({addr[ ], 00})[0:31] = 0000_0000	Word clear

1. Addr[60:63] in this case is the core effective address, not the physical address.
2. The update operations are given as C-code equivalents. The following notes apply: exts64() represents a sign extension of the operand to 64 bits exts32() represents a sign extension of the operand to 32 bits. unsigned_max(a,b)=(a>b) ? a : b, where a and b are unsigned integers of the appropriate size unsigned_min(a,b)=(a>b) ? b : a, where a and b are unsigned integers of the appropriate size

8.3.4.3 Notify Operations

Notify is a simplification of a decorated store operation that does not require data from the core.

Because of this, only increment, decrement, set and clear functions are possible. The timing of these operations is the same as for RMW.

8.3.5 Cache/SRAM Data Clear

Upon Hard Fail condition, the security monitor drives an interrupt to the CPC that causes the CPC to immediately initiate a write of all zeros to all locations in the data arrays.

These write operations have the highest priority to the data pipeline. This operation is non-coherent and the system may be non-recoverable after this has occurred.

8.4 Initialization/Application Information

8.4.1 Supported SRAM Mode Configurations

The following table describes the supported CPC SRAM mode configurations:

Note the following interleaving rules:

- If DRAM addresses are interleaved (as controlled through the DDR controller configuration registers or through the CCF registers for 3-way interleaving), then SRAM address space can also be interleaved at the same address boundary by setting CPCSRCR0[INTLVEN].
- If DDR is not interleaved, then SRAM address space cannot be interleaved.
- Enabling SRAM interleaving requires that all instances of the CPC in the system that participate in interleaving be programmed to the same SRAM size and base address. Additionally, the interleave granularity must be less than or equal to the size of an individual CPC's SRAM.
- For 3-way interleaved SRAM, the total SRAM address space must be aligned to an address boundary equal to four times the non-interleaved CPCSRCR0[SRAMSZ] size. The interleave granularity must be less than or equal to the size of an individual CPC’s SRAM.
- If DDR memory controller interleaving is either Bank or SuperBank and CPC SRAMs are enabled then CPC1 and CPC2 SRAMs must not be interleaved.
- If DDRC1 is not used then CPC1 SRAM may be enabled as 512KB SRAM even though CPC2 SRAM is disabled (same for DDRC2 and CPC2 SRAM).

Table 8-2. Supported SRAM Mode Configurations

CPCx_CPCSRCR0						
CPC1 SRAM_EN	**CPC2 SRAM_EN**	**CPC2 SRAM_EN**	**INTLVEN**	**CPC1 SRAM_SZ**	**CPC2 SRAM_SZ**	**CPC3 SRAM_SZ**
0	0	0	don’t care	don’t care	don’t care	don’t care
1	1	1	Disabled	64 KB	64 KB	64 KB
1	1	1	Disabled	256 KB	256 KB	256 KB
1	1	1	Disabled	512 KB	512 KB	512 KB
1	1	1	2-way	64 KB	64 KB	64 KB
1	1	1	2-way	256 KB	256 KB	256 KB
1	1	1	2-way	512 KB	512 KB	512 KB
1	1	1	3-way	64 KB	64 KB	64 KB
1	1	1	3-way	256 KB	256 KB	256 KB
1	1	1	3-way	512 KB	512 KB	512 KB

The above CPC rules have one exception—when only one DDR Controller is used, the CPC on the unused controller(s) may be used as all SRAM (that is, 512 KB)

	CPCx_CPCSRCR0						
	CPC1 SRAM_EN	**CPC2 SRAM_EN**	**CPC2 SRAM_EN**	**INTLVEN**	**CPC1 SRAM_SZ**	**CPC2 SRAM_SZ**	**CPC3 SRAM_SZ**
Only DDRC1 Used	0	1	1	Disabled	don't care	512 KB	512 KB

Table continues on the next page...

	CPCx_CPCSRCR0						
	CPC1 SRAM_EN	CPC2 SRAM_EN	CPC2 SRAM_EN	INTLVEN	CPC1 SRAM_SZ	CPC2 SRAM_SZ	CPC3 SRAM_SZ
Only DDRC2 Used	1	0	1	Disabled	512 KB	don't care	512 KB
Only DDRC3 Used	1	1	0	Disabled	512 KB	512 KB	don't care

8.4.2 Programming Examples

The following section gives examples of how software should configure the CPC control registers for various scenarios.

8.4.2.1 Modifying CPC Control and Status Registers

The sequence for modifying a CPC Control and Status Register is as follows:

1. Ensure that all prior instructions and memory accesses are complete and performed before modifying the CPC register.
2. Perform a store (WIMG = 01xx) to the CPC register to set its desired value.
3. Perform a load (WIMG = 01xx) to the CPC register to push the store to the CPC and ensure it has been performed.
4. Ensure that all subsequent instruction and memory accesses wait for the load to complete, ensuring that the CPC register update has been performed before any subsequent memory accesses.

An example Power Architecture instruction sequence to update CPCCSR0 from a core follows:

1. **mbar**
2. **isync**
3. **stw** (WIMG = 01xx) CCSRBAR+CPC*n* block base address+0x000
4. **lwz** (WIMG = 01xx) CCSRBAR+CPC*n* block base address+0x000
5. **mbar**

8.4.2.2 Enabling the CPC after Power-On Reset

The CPC registers have the reset values defined in the "CoreNet Platform Cache (CPC) Memory Map". Based on these initial register values, the following procedure is performed to invalidate, configure and enable the CPC after power-on reset:

1. Set CPCCSR0[CPCFI], CPCCSR0[CPCLFC] using the same write operation
2. Wait for hardware to clear CPCCSR0[CPCFI] and CPCCSR0[CPCLFC] using a polling loop
3. Set CPC configuration registers, including CPCSRCR1, CPCSRCR0, CPCPIR*n*, CPCPAR*n*, CPCPWR*n*, CPCERRDIS, CPCERRINTEN, and CPCERRCTL
4. Set CPCCSR0 bits to desired values (notably CPCPE, CPCWT, CPCREP and CPCLOA). Note this operation can be combined with step 6.
5. Configure the LAWs and DDR controller; this must be done before enabling the CPC.
6. Set CPCCSR0[CPCE] to enable the CPC.

This procedure needs to be performed for each CPC in the system.

8.4.2.3 Changing the Configuration of an Enabled CPC

In order to change the configuration registers of a CPC that has already been enabled, it is in generally necessary to flush and disable the cache first using the following procedure:

1. Clear all bits of CPCPAR*n* (this prevents any new transactions from allocating into the CPC) using write operation.
2. Flush the CPC using one of the two following methods:
   - Harware flush: Set CPCCSR0[CPCFL] and wait for hardware to clear CPCCSR0[CPCFL] by polling
   - Software flush: perform a **dcbf** operation to each coherency granule mapped to the memory target (that is, one **dcbf** for each 64 bytes).
3. Clear all lock bits by setting CPCCSR0[CPCLFC].
4. Wait for hardware to clear CPCCSR0[CPCLFC] using a polling loop.
5. Disable the CPC by clearing CPCCSR0[CPCE].
6. Reconfigure CPC as desired.
7. Enable CPC by setting CPCCSR0[CPCE].

Common operations that require this procedure include changing CPCCSR0[CPCWT], CPCCPSR0[CPCPE], CPCPIR*n*, CPCPAR*n*, and CPCPWR*n*.

8.4.2.4 Disabling the CPC

How to disable the CPC:

To disable the CPC once it has been enabled, follow steps 1-5 of the procedure described in Changing the Configuration of an Enabled CPC.

Chapter 9
CoreNet Coherency Fabric (CCF)

9.1 CCF Introduction

This chapter provides an overview of the CoreNet coherency fabric (CCF). It describes the components of the CCF and how they are interconnected. It also describes the salient features of the platform and its components.

The CoreNet coherency fabric (CCF) is a fabric-oriented, connectivity infrastructure that enables the implementation of coherent, multicore systems. The CCF acts as a central interconnect for cores, platform-level caches, memory subsystems, peripheral devices, and I/O host bridges in the system. The CCF natively supports Power Architecture® coherency semantics.

NOTE

Please adhere to all power architecture rules. WIMG bits in the system across a physical address must be identical.

The figure below shows organization of a multicore system designed around the CCF.

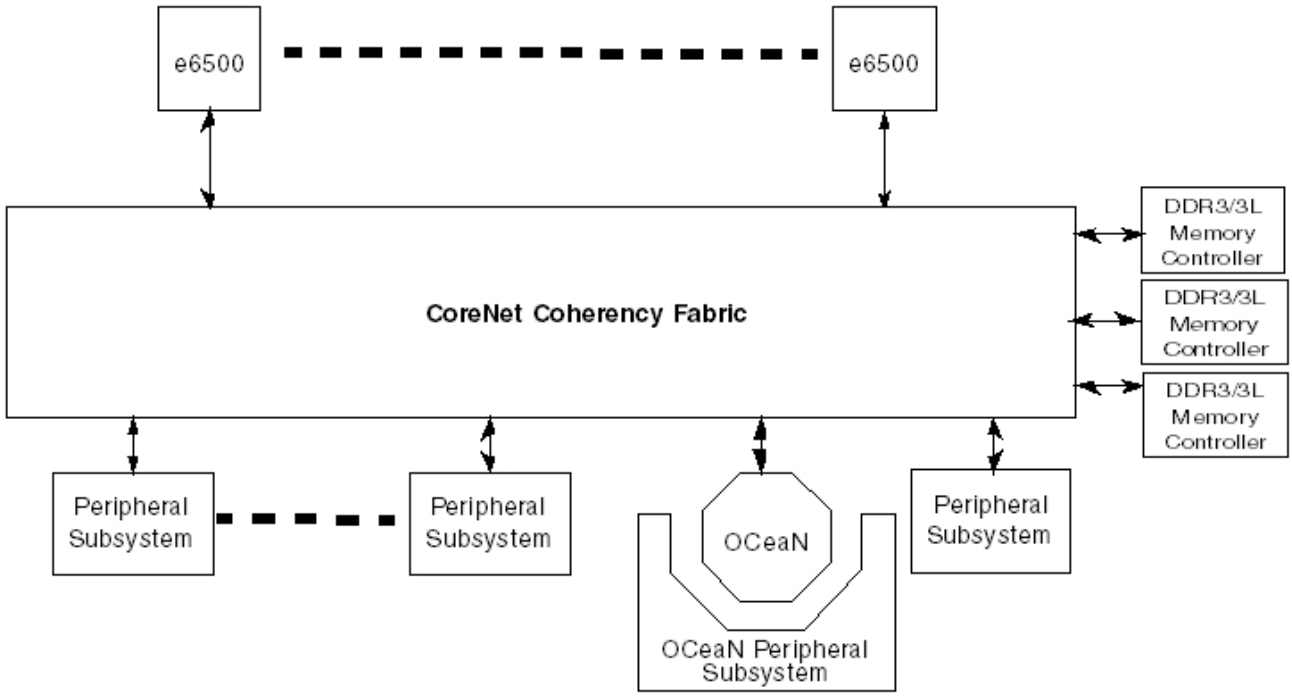

Figure 9-1. CoreNet Coherency Fabric Connectivity

9.1.1 CCF Features Summary

The CCF includes the following distinctive features:

- Multiple in-flight transactions with:
  - Concurrency of transactional progress through the system
  - Out of order completion
- Retry-free operation
  - Zero-loss utilization of system transaction processing bandwidth
- Sustainable bandwidth: 4 transactions/cycle
- Low latency data path for platform cache data
- Sustainable read bandwidth: 128 bytes (or two coherence granules - CGs) per cycle
- Power Architecture coherency semantics
  - Accelerated operation for non-coherent accesses
- 64 byte coherency granules
  - 1-8 bytes within an aligned double word, and aligned 16-byte, 32-byte, and 64-byte single copy atomic access semantics
- Rich transaction types and semantics to support:
  - All Power Architecture storage and synchronization operations
  - Inter-processor low-latency message send operations

    - RapidIO atomic operations
    - Reads and writes with semantic extensions for in-place atomic update of storage
- Transaction ordering support
    - Native support for Power Architecture ordering semantics
    - On-demand strong ordering for all "cache-inhibited" and "guarded" accesses from processors
    - Non-Power Architecture ordering support through host bridges
- Address map support
    - 32 local access windows (LAWs)
    - Boot window and CCSR spaces
    - DDR memory and SRAM interleaving support
- Logical partitioning support
    - Address-based, secure isolation of partitions and their resources
    - Coherency subdomain assignment and snoop limiting per LAW
    - Inter-partition sharing of address ranges
    - Peripheral access management unit (PAMU)
        - Capability to assign peripheral devices to logical partitions and limiting direct storage accesses (DSA) to owner partitions
        - Support for virtualized peripheral devices serving multiple partitions
        - Multiple windows per device
        - Window translation for accesses by devices
        - Transparent cache-coherent operation with PAMU tables in main memory
        - Transaction translation capability
        - Error isolation between partitions
- Three high performance memory complexes
    - Non-inclusive, in-line platform cache
        - Write-back semantics
        - Read latency optimization by keeping track of owner processors
        - I/O stashing
        - Line and way locking
        - Data delivery capability of one CG per cycle
        - Semantic extension support for cache-based atomic update of data
- Support for stashing
    - Processor cache stashing
    - Address- and attribute-based I/O stashing in platform cache
- Debug support
    - Source tracking from source to destination
    - Access triggering, filtering, and tracing
    - Event counts for performance monitoring

9.2 CoreNet Coherency Fabric (CCF) Memory Map

CCF memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

R W	Reserved											GRANULE_SIZE				
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0

CCF_MCINTLV3R field descriptions

Field	Description
0 MCI3	Memory controller three-way interleave enable **NOTE:** This field is active only if three consecutive memory controllers exist in the system and are enabled (MC1, MC2, and MC3). If MC1, MC2, and MC3 are not enabled, the function of this bit is disabled and the other interleaving modes become available. When enabling three-way interleave mode, it is imperative that all DDR memories are of the same size and configuration. If an attempt is made to use three-way interleaving using memory controllers of different sizes or configurations, indeterminate results will occur. 0 Memory controller three-way interleaving is disabled. 1 Memory controller three-way interleaving is enabled. System memory addresses are interleaved across three memory controllers on the granule basis specified in GRANULE_SIZE. Enabling three-way interleaving disables all other interleaving options across memory controllers.
1–26 -	This field is reserved. Reserved
27–31 GRANULE_SIZE	This field specifies the number of bits needed to specify a byte within a granule of memory - a naturally aligned set of $2^{GRANULE_SIZE}$ consecutively addressed bytes in DDR memory. Granule Size is the basis on which the DDR memory is interleaved. That is, all bytes within a granule are assumed to reside within a single memory controller. Different granules may be mapped to different memory controllers. **NOTE:** Values not specified are reserved and can result in undefined behavior. 01010 1 KB granule size 01100 4 KB granule size 01101 8 KB granule size

9.2.2 Snoop ID 0 Port Mapping Register (CCF_SIDMR0)

The Snoop ID n Port Mapping Registers provide a CoreNet Snoop ID to core cluster and PAMU mapping function. CoreNet transactions include an 8-bit Snoop ID [0:7]. A Snoop ID of 00h indicates an inactive Snoop ID and maps to the default SIDMR0. SIDMR0 is a read-only register. The reset value of SIDMR0 is coherent, but considered lower performing. A non-zero Snoop ID indicates a lookup into the snoop ID port mapping registers (SIDMR1-31). The Snoop ID acts as an index into these registers and extracts a core cluster and PAMU field indicating the active snoopers for this transaction. An active Snoop ID (non-zero) overrides all other implementation specific determinations for snoopers.

NOTE

Although there are 256 possible Snoop IDs, the CCF only supports bits [3:7] and thus implements 32 snoop ID port mapping registers. If any of the upper three bits (Snoop ID[0:2]) are set, the Snoop ID will alias to the 32 SIDMRs defined by Snoop ID[3:7]. If the lower bits [3:7] = 0b00000 then the default SIDMR0 is used.

Address: 1_8000h base + 200h offset = 1_8200h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

R	PAMU	Reserved														
W																
Reset	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CCF_SIDMR0 field descriptions

Field	Description
0–15 CCn	Core Cluster n. When set, a bit indicates which corresponding active core cluster to snoop for this transaction. Bit 0 corresponds to core cluster 0.
16 PAMU	Snoop PAMUs.When set, the PAMU field indicates that all PAMUs within the SoC need to be snooped for this transaction 0 Do not snoop the PAMUs. 1 Snoop all PAMUs.
17–31 -	This field is reserved. Reserved

9.2.3 Snoop ID n Port Mapping Register (CCF_SIDMR*n*)

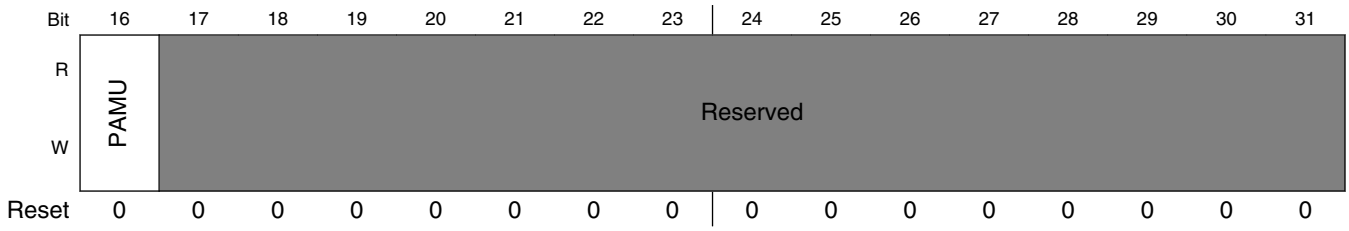
The Snoop ID n Port Mapping Registers provide a CoreNet Snoop ID to core cluster and PAMU mapping function. CoreNet transactions include an 8-bit Snoop ID [0:7]. A Snoop ID of 00h indicates an inactive Snoop ID and maps to the default SIDMR0. SIDMR0 is a read-only register. The reset value of SIDMR0 is coherent, but considered lower performing. A non-zero Snoop ID indicates a lookup into the snoop ID port mapping registers (SIDMR1-31). The Snoop ID acts as an index into these registers and extracts a core cluster and PAMU field indicating the active snoopers for this transaction. An active Snoop ID (non-zero) overrides all other implementation specific determinations for snoopers.

NOTE

Although there are 256 possible Snoop IDs, the CCF only supports bits [3:7] and thus implements 32 snoop ID port mapping registers. If any of the upper three bits (Snoop ID[0:2]) are set, the Snoop ID will alias to the 32 SIDMRs defined by Snoop ID[3:7]. If the lower bits [3:7] = 0b00000 then the default SIDMR0 is used.

Address: 1_8000h base + 204h offset + (4d × i), where i=0d to 30d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	CCn															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



CCF_SIDMR*n* field descriptions

Field	Description
0–15 CCn	Core Cluster n. When set, a bit indicates which corresponding active core cluster to snoop for this transaction. Bit 0 corresponds to core cluster 0.
16 PAMU	Snoop PAMUs.When set, the PAMU field indicates that all PAMUs within the SoC need to be snooped for this transaction 0 Do not snoop the PAMUs. 1 Snoop all PAMUs.
17–31 -	This field is reserved. Reserved

9.2.4 CSD ID 0 Port Mapping Register (CCF_CIDMR0)

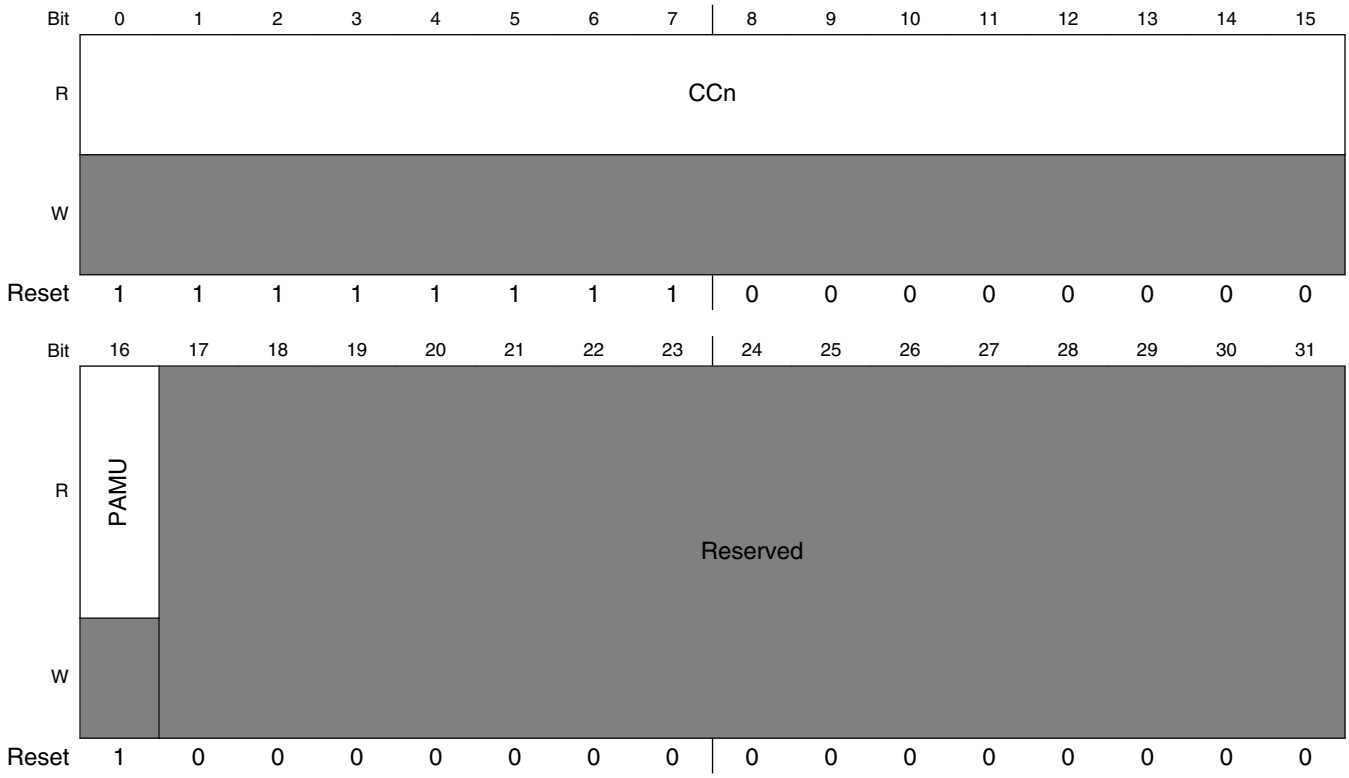
The Coherency Subdomain ID n Port Mapping Registers provide a CoreNet Coherency Subdomain ID to core cluster and PAMU mapping function. The LAW attribute registers include an 8-bit coherency subdomain ID field (LAWAR*n*[CSD_ID]). If the transaction Snoop ID is 00h, the CSD_ID obtained from the LAW hit is used to determine the valid snoopers for the transaction. The CSD_ID acts as an index into the CIDMR0-CIDMR31 registers and extracts a core cluster n field [0:15] and a PAMU field indicating the active snoopers for this transaction.

CIDMR00 is a read only register. The reset value of CIDMR0 is coherent, but considered lower performing.

NOTE

Although there are 256 possible CSDIDs, the CCF only supports 32 CIDMRs by using CSD_ID[3:7]; CSD_ID[0:2] are assumed to be inactive/zero.

Address: 1_8000h base + 600h offset = 1_8600h



CCF_CIDMR0 field descriptions

Field	Description
0–15 CCn	Core Cluster n. When set, a bit indicates which corresponding active core cluster to snoop for this transaction. Bit 0 corresponds to core cluster 0.
16 PAMU	Snoop PAMUs.When set, the PAMU field indicates that all PAMUs within the SoC need to be snooped for this transaction 0 Do not snoop the PAMUs. 1 Snoop all PAMUs.
17–31 -	This field is reserved. Reserved

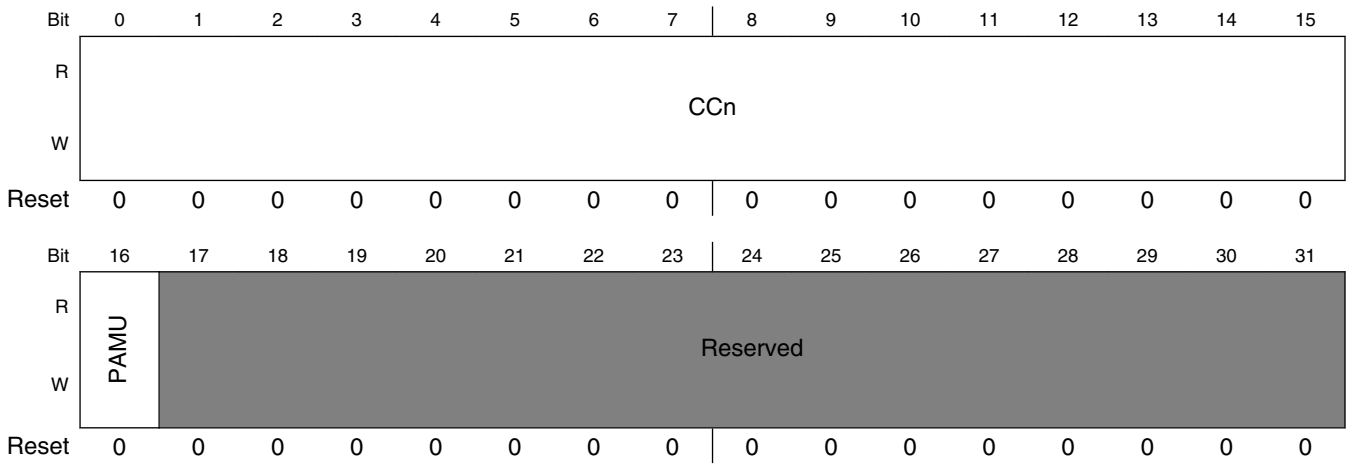
9.2.5 CSDID n Port Mapping Register (CCF_CIDMR*n*)

The Coherency Subdomain ID n Port Mapping Registers provide a CoreNet Coherency Subdomain ID to core cluster and PAMU mapping function. The LAW attribute registers include an 8-bit coherency subdomain ID field (LAWAR*n*[CSD_ID]). If the transaction Snoop ID is 00h, the CSD_ID obtained from the LAW hit is used to determine the valid snoopers for the transaction. The CSD_ID acts as an index into the CIDMR0-CIDMR31 registers and extracts a core cluster n field [0:15] and a PAMU field indicating the active snoopers for this transaction.

NOTE

Although there are 256 possible CSDIDs, the CCF only supports 32 CIDMRs by using CSD_ID[3:7]; CSD_ID[0:2] are assumed to be inactive/zero.

Address: 1_8000h base + 604h offset + (4d × i), where i=0d to 30d

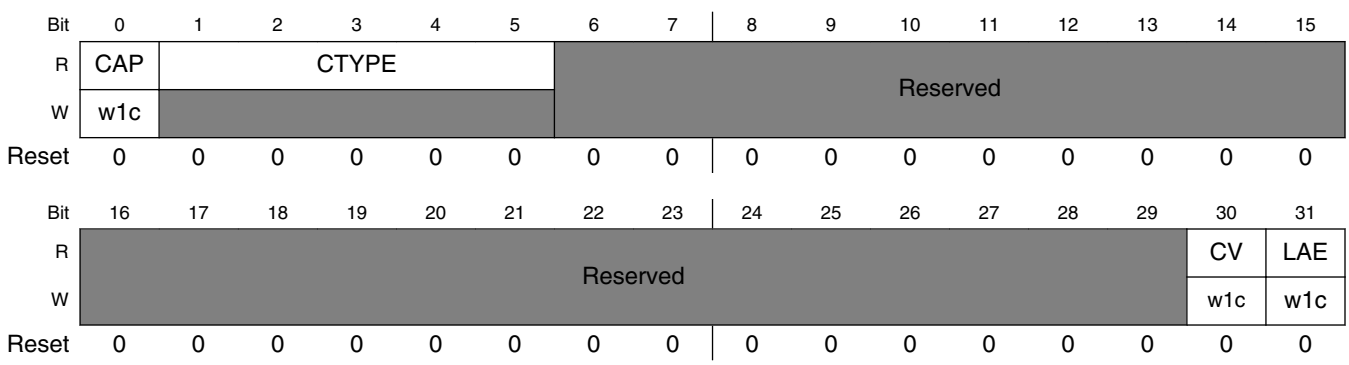


CCF_CIDMR*n* field descriptions

Field	Description
0–15 CCn	Core Cluster n. When set, a bit indicates which corresponding active core cluster to snoop for this transaction. Bit 0 corresponds to core cluster 0.
16 PAMU	Snoop PAMUs.When set, the PAMU field indicates that all PAMUs within the SoC need to be snooped for this transaction 0 Do not snoop the PAMUs. 1 Snoop all PAMUs.
17–31 -	This field is reserved. Reserved

9.2.6 CCF Error Detect Register (CCF_ERRDET)

Address: 1_8000h base + E40h offset = 1_8E40h

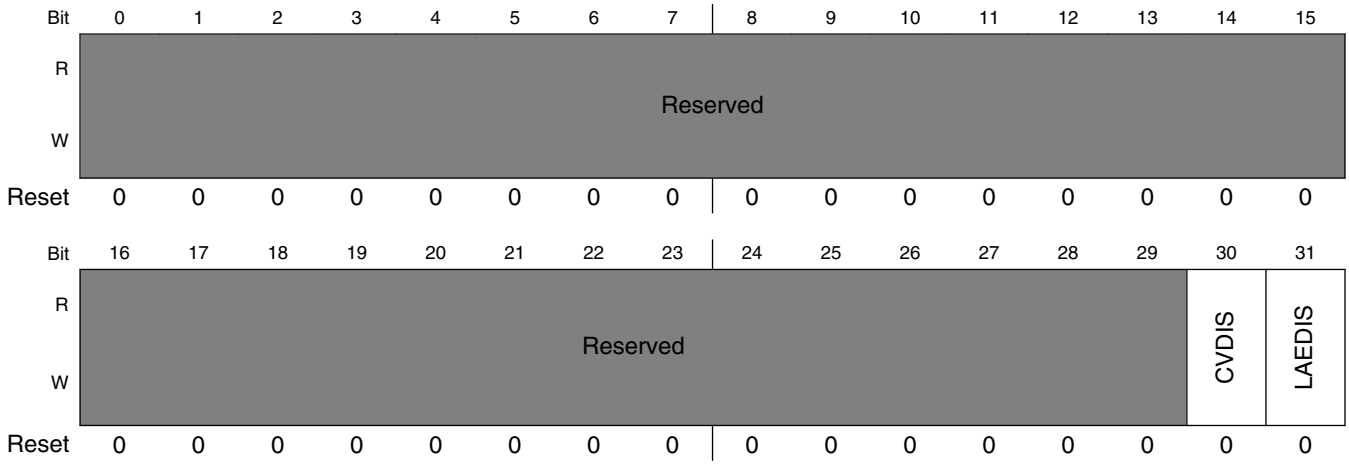


CCF_ERRDET field descriptions

Field	Description
0 CAP	Capture valid. **NOTE:** To avoid capture/detect race conditions, it is recommended that software clear CAP and the detect bit for the type of error that was captured using a single write operation. 0 The error capture registers do not contain valid error attributes. The error capture registers are armed; the next detected error will be captured and this bit will be set automatically. 1 The values in the error capture registers are valid. No new errors will be captured until software re-arms capture by writing a 1 to clear this bit.
1–5 CTYPE	Captured error type. Indicates the type of error that was captured. This value is only valid when CCF_ERRDET[CAP]=1. Cleared by writing a 1 to CCF_ERRDET[CAP]. 0x0000_0001<CTYPE decodes to the corresponding detect bit position. For example, Bit 0 set = local access error Bit 1 set = illegal coherency response error Others reserved
6–29 -	This field is reserved. Reserved
30 CV	Coherency violation. This indicates the state of the coherency granule was found to be in violation of the coherency protocol.
31 LAE	Local Access Error Cases that can generate an LAE • Local Access Window Miss. An incoming transaction misses all LAWs (except when the PBL is active). • Unavailable target ID programmed in LAW attribute register. See LAWn attribute register (LAW_LAWAR*n*) , for more information. **NOTE:** If CV and LAE occur simultaneously then the LAE Error takes precedence. **NOTE:** If CV (Bit 30) or LAE (31) was previously set and an LAE occurs it will be ignored and bit 31 will not be set. **NOTE:** If a w1c occurs at the same time as the LAE the w1c takes precedence. 0 Local Access Error has not occurred 1 Local Access Error has occurred

9.2.7 CCF Error Disable Register (CCF_ERRDIS)

Address: 1_8000h base + E44h offset = 1_8E44h

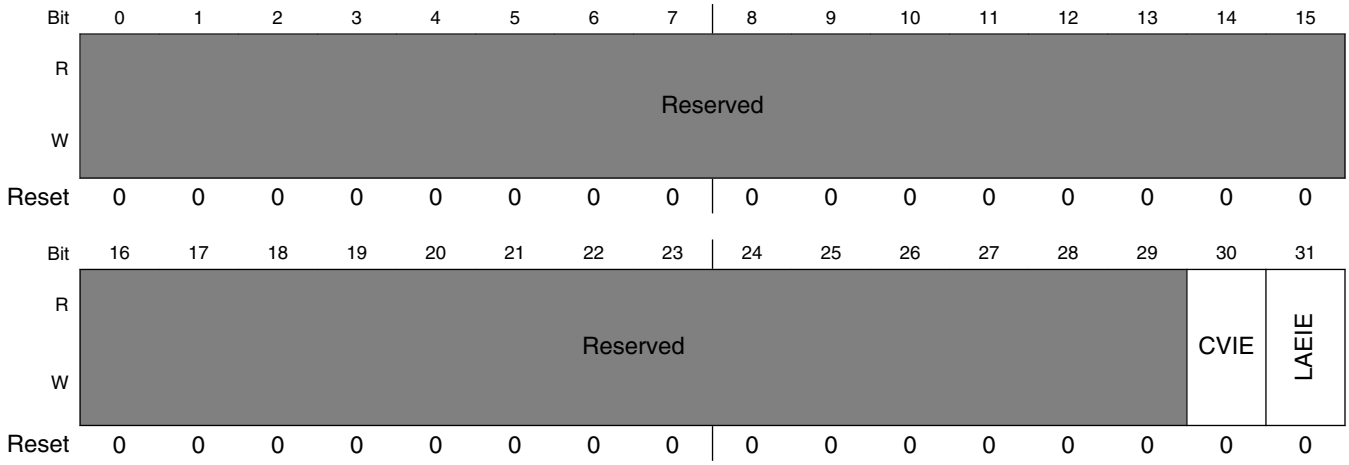


CCF_ERRDIS field descriptions

Field	Description
0–29 -	This field is reserved. Reserved
30 CVDIS	Coherency violation error disable. 0 Enable detection and capture of coherency violation errors. 1 Disable detection and capture of coherency violation errors.
31 LAEDIS	Local access error disable. 0 Enable detection and capture of local access errors. 1 Disable detection and capture of local access errors.

9.2.8 CCF Error Interrupt Enable Register (CCF_ERRINTEN)

Address: 1_8000h base + E48h offset = 1_8E48h

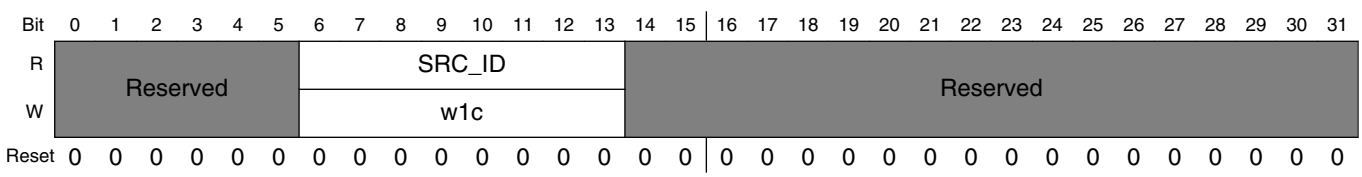


CCF_ERRINTEN field descriptions

Field	Description
0–29 -	This field is reserved. Reserved
30 CVIE	Coherency violation error interrupt enable. 0 Disable reporting of coherency violation errors as interrupts. 1 Enable reporting of coherency violation errors as interrupts.
31 LAEIE	Local access error interrupt enable. 0 Disable reporting of local access errors as interrupts. 1 Enable able reporting of local access errors as interrupts.

9.2.9 CCF Error Capture Attribute Register (CCF_CECAR)

Address: 1_8000h base + E4Ch offset = 1_8E4Ch



CCF_CECAR field descriptions

Field	Description
0–5 -	This field is reserved. Reserved

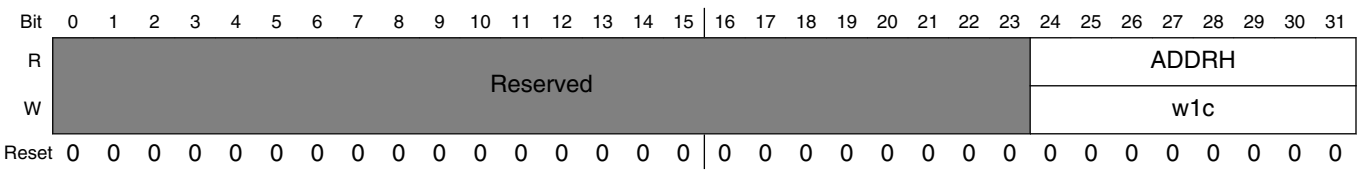
Table continues on the next page...

CCF_CECAR field descriptions (continued)

Field	Description
6–13 SRC_ID	The system transaction source ID[0:7]. See Global Source and Target IDs for valid encodings.
14–31 -	This field is reserved. Reserved

9.2.10 CCF Error Capture Address Register High (CCF_CECADDRH)

Address: 1_8000h base + E50h offset = 1_8E50h

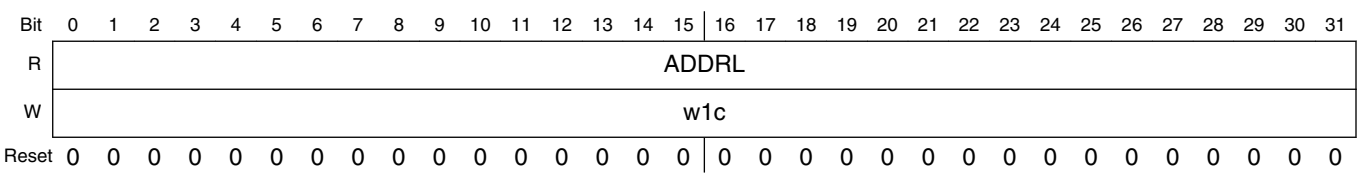


CCF_CECADDRH field descriptions

Field	Description
0–23 -	This field is reserved. Reserved
24–31 ADDRH	ADDRH contains the high-order bits[0:7]of the captured error address.

9.2.11 CCF Error Capture Address Register Low (CCF_CECADDRL)

Address: 1_8000h base + E54h offset = 1_8E54h

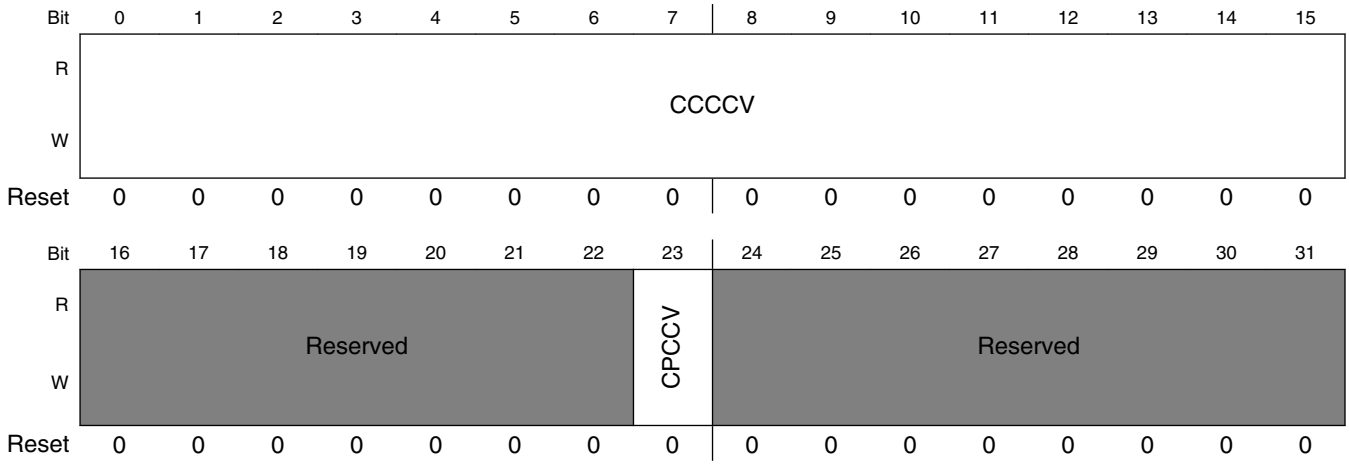


CCF_CECADDRL field descriptions

Field	Description
0–31 ADDRL	ADDRL contains the low-order bits [9:39] of the captured error address.

9.2.12 CCF Error Capture Attribute Register 2 (CCF_CECAR2)

Address: 1_8000h base + E58h offset = 1_8E58h



CCF_CECAR2 field descriptions

Field	Description
0–15 CCCCV	Core cache complex coherency violation. Bit 0 corresponds to core cache complex 0, bit 1 corresponds to core cache complex 1, and so on. A coherency violation causes 2 or more bits to be set among CCCCV and CPCCV.
16–22 -	This field is reserved. Reserved
23 CPCCV	CPC coherency violation. A coherency violation causes 2 or more bits to be set among CCCCV and CPCCV.
24–31 -	This field is reserved. Reserved

Chapter 10
Peripheral Access Management Unit (PAMU)

10.1 PAMU Introduction

This section provides an overview and features list for the peripheral access management unit (PAMU).

10.1.1 PAMU Overview

A multicore system, illustrated in Figure 10-1, consists of one or more Power Architecture processors, a system memory separate from other subsystems, and a number of I/O devices that may initiate transactions to system memory.

The processors are linked over a host domain interconnect to each other, to the system memory and to one or more I/O devices or domains. Typically, a PAMU resides astride the boundary between the coherency and I/O domains, as shown in Figure 10-1 and enforces authorization and access control over DSA operations into the coherency domain.

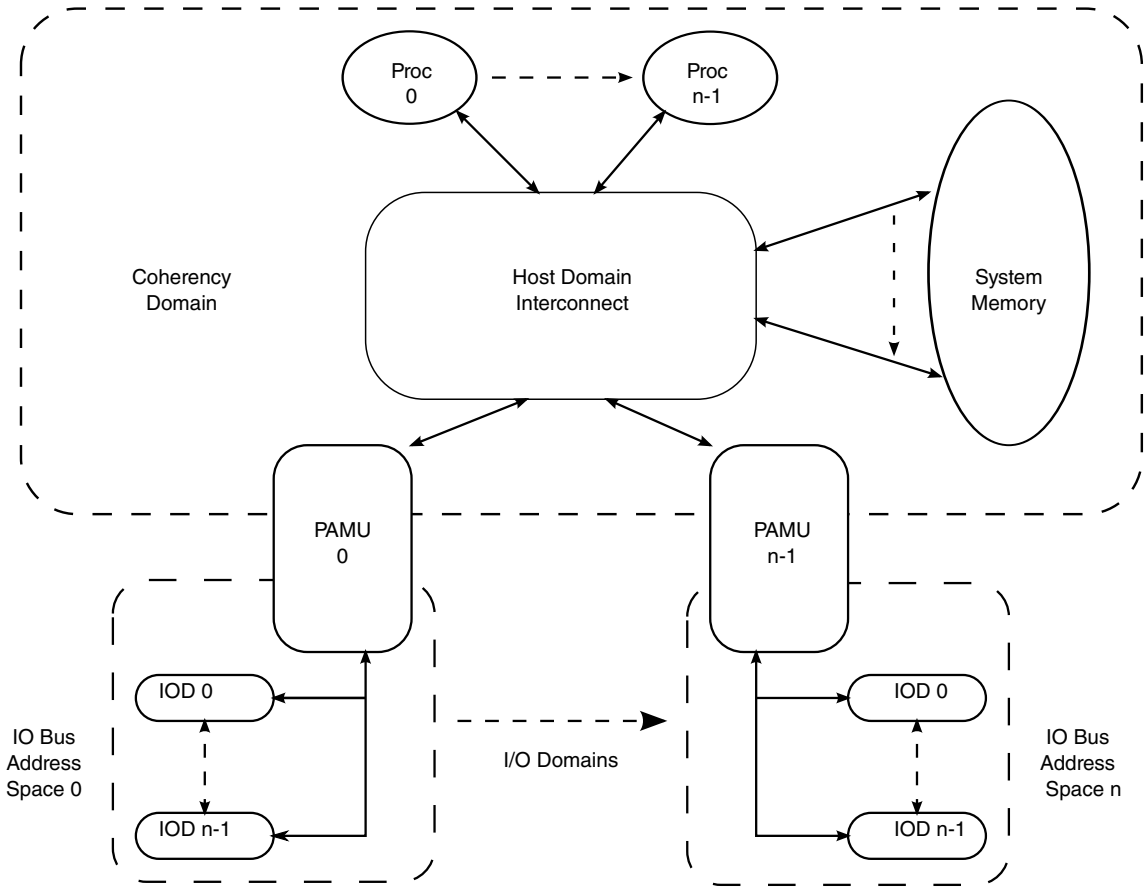


Figure 10-1. Illustration of a Multicore System

To accelerate the authorization and translation of operations, PAMU contains caches for quick lookup of memory resident data structures containing the authorization and translation attributes.

10.1.2 PAMU Features Summary

PAMU includes the following features:

- Support for authorizing DMA and peer-to-peer operations, that is, checking that the operation is originated by a valid I/O adapter, authorized to issue these operations, and that the operation is to a valid address window provided to that I/O adapter.
- Support for the access control of DMA and peer-to-peer operations, that is, allowing only the types of operations that fall within the access privileges provided to that I/O adapter.

- Support for address translation of DMA and peer-to-peer operations, that is, redirecting operations with an address in the I/O bus address space to a corresponding address in system memory space. The following address translation modes are supported:
  - No address translation
  - Window translation
- Support for operation type translation of DMA and peer-to-peer operations, that is, converting the ingress operation encoding to a corresponding egress operation encoding. The following operation translation modes are supported:
  - No Operation Translation
  - Immediate Operation Translation
  - Indexed Operation Translation for up to sixteen indexes, that is, the field is limited to OMI[0:3]
- Support for up to 4-K LIODNs, that is, signaling is limited to LIODN[4:15]
- Support for up to 256 DSA sub-windows when multiple windows are enabled, that is, the field is limited to WCE[1:3]
- Hardware coherent PAMU Look-aside caches to improve performance
  - A 32-entry, direct-mapped primary PAACT cache
  - A 128-entry, 2-way, set-associative secondary PAACT cache
  - A 4-entry, direct-mapped OMT cache
  - Support for receiving invalidating snoop operations for the PAMU look-aside caches (PLCs) from the coherency domain
  - Support for issuing PAMU fetch operations when the relevant entry is not present in the PLC
- Support for a maximum 40-bit system address space
- Support for a maximum 40-bit I/O address space
- Capability to generate interrupts
  - Access violations
  - PAMU operational errors

10.2 Data Structures Used by PAMU

The following data structures are used by the PAMU. The data structures are located in system memory and are accessed by the PAMU as necessary. These data structures are programmed by the hypervisor controlling the system.

10.2.1 Overview of Data Structures

10.2.1.1 Peripheral Access Authorization and Control Tables (PAACTs)

PAACTs are the primary data structures used by PAMU . A PAACT is a table of peripheral access authorization and control entries (PAACE).

Each PAACE defines the range of I/O bus address space that is accessible by the LIOD and the associated access capabilities.

There are two types of PAACTs: primary PAACT (PPAACT) and secondary PAACT (SPAACT).

A given physical I/O device may be able to act as one or more independent logical I/O devices (LIODs). Each such logical I/O device is assigned an identifier called logical I/O device number (LIODN).

A LIOD is allocated a contiguous portion of the I/O bus address space called the DSA window for performing DSA operations. The DSA window may optionally be divided into multiple sub-windows, each of which may be used to map to a region in system storage space. The first sub-window is referred to as the primary sub-window and the remaining are called secondary sub-windows.

A DSA window is 2^n bytes in size. Sub-windows are declared in a two-level hierarchy: a DSA window and 2^m ($n > m > 0$) sub-windows within it. There are means available to recover unused secondary windows and unused address sub-ranges (See Recovering Address Space, for more information.). The sub-windows are labeled 0 through 2^F-1. Each sub-window is of size 2^{n-m} bytes. A sub-range of size 2^k within the sub-window may be specified for mapping. The sub-range can be narrower than the default sub-window size (2^{n-m} bytes).

The access attributes of the DSA window and the primary sub-window are declared using the primary PAACE (PPAACE) and those for the secondary sub-windows are declared using secondary PAACEs (SPAACEs). Only the primary PAACE is placed in the PPAACT. The secondary PAACEs are placed consecutively in the SPAACT in the order of their labels. A pointer in the PPAACE points to the placement of the first of the SPAACEs in the SPAACT. See Figure 10-2 and Figure 10-3.

DSA operations from a LIOD may be redirected to different locations in system storage space via the mechanism of address translation via a PAACE. The attributes that define whether address translation is enabled and the type of address translation, if enabled, are contained in the PAACE.

A LIOD may have restrictions as to the type of DSA operation it is allowed to perform. The attributes that define the access permissions for that LIOD are contained in the PAACE.

Furthermore, DSA operations from a LIOD may be translated to different operation types in system storage space via the mechanism of operation translation via a PAACE. The attributes that define whether operation translation is enabled and the type of operation translation, if enabled, are contained in the PAACE. The translation may optionally refer to a data structure called operation mapping table (See Operation Mapping Table, for more information.).

A LIOD presents its LIODN along with every DSA operation issued by it. The PAMU uses the LIODN as a means to identify the relevant PPAACE and then if necessary the SPAACEs and other data structures that specify the access capabilities provided to that LIOD.

10.2.1.2 Operation Mapping Table

DSA operations from a LIOD may optionally be converted to different operation types via the mechanism of operation translation.

The conversion of operation types may be due to differences between the source and destination interconnect protocols of the DSA operation. The attributes that define operation translation is also contained in PAACE. Additional operation mapping attributes for that LIOD may be optionally contained in a operation mapping entry (OME) in the operation mapping table (OMT).

10.2.1.3 Access Capabilities Across LIODs

LIODs may be provided with a subset of the access capabilities described above as necessary.

Certain LIODs may utilize a narrower set of the mechanisms provided while other LIODs simultaneously utilize a broader or the full set of mechanisms. Hypervisor may also choose to vary, over time, the provisions for an LIOD, as application requirements and the capabilities of the system vary.

10.2.2 Structure and Contents of PAACTs

Figure 10-2 displays the placement of the PPAACT within system memory space and the arrangement of PPAACEs within the PPAACT.

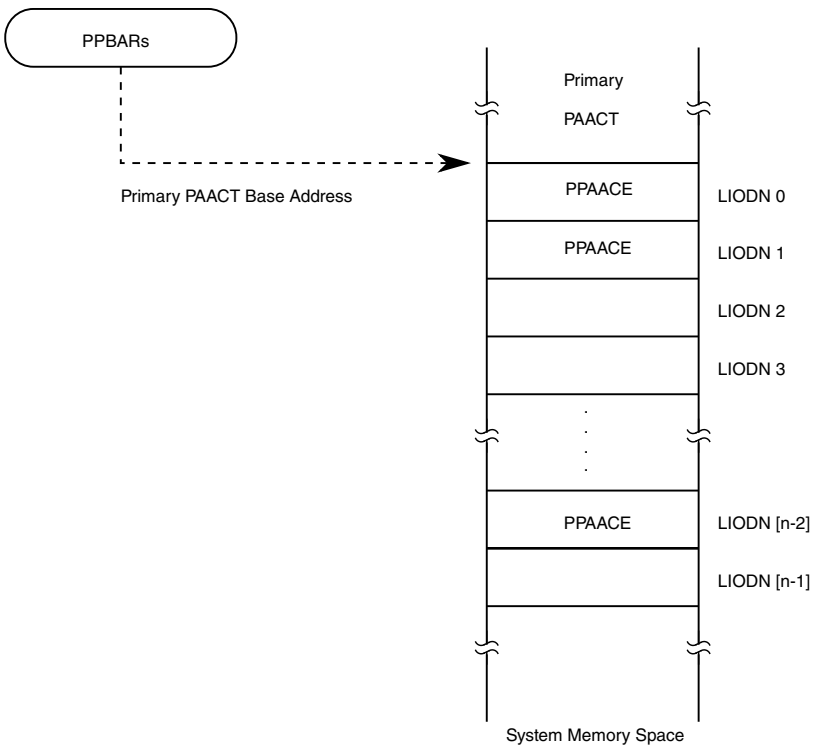

Figure 10-2. Arrangement of Primary PAACEs in System Memory Space

- The LIODN is used to index into the PPAACT to identify the PPAACE corresponding to the LIOD.
- The PPAACE located at the LIODN index of PPAACT contains fields indicating the base address and size of the DSA window for that LIOD (see Table 10-1). If the DSA window has properties that cannot be expressed in a single PAACE, multiple PAACEs are created. Fields in the PPAACE located at the LIODN index of PPAACT indicate the presence and number of multiple PAACEs for that LIOD:
  - The DSA window is divided into non-overlapping sub-windows of equal size with a PAACE containing the attributes of a sub-window.
  - The entry located at the LIODN index is called the primary PAACE. The primary PAACE contains the attributes describing the entire DSA window as well as the primary sub-window.
  - The SPAACEs are contained in the SPAACT starting at the first secondary PAACE index (FSPI) provided in the PPAACE and are arranged in linear order corresponding to the linear address order of the sub-window (see example in Figure 10-3).
  - A SPAACE describes the properties of a secondary DSA sub-window (see Table 10-2).

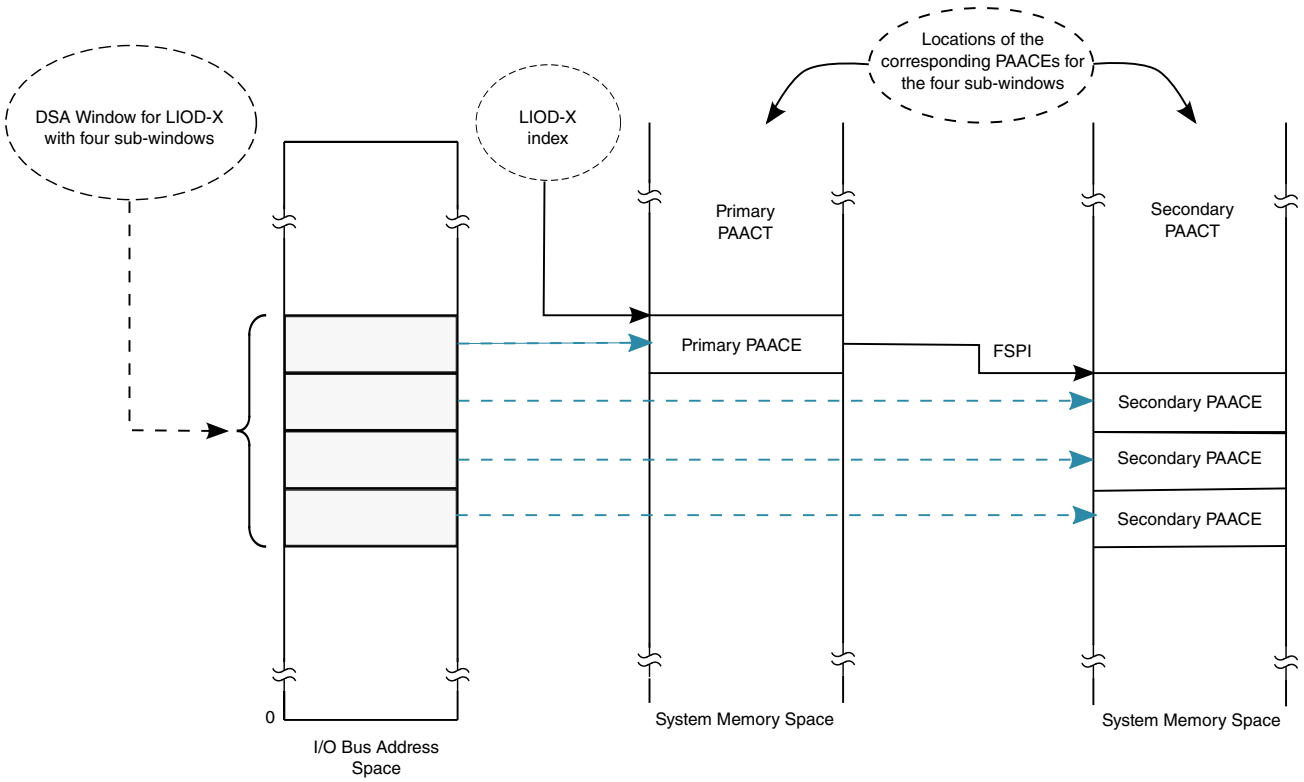

Figure 10-3. Example of DSA Sub-Windows and their Corresponding PAACEs

10.2.3 Peripheral Access Authorization and Control Entry (PAACE)

This section describes the structure and contents of a PAACE. The format of the primary PAACE data structure is shown in Table 10-1.

Fields valid in only the primary PAACE apply to the entire DSA window defined by the primary PAACE. Fields valid in both the primary and secondary PAACE apply to the DSA sub-window defined by that PAACE.

Table 10-1. Primary PAACE Format

Index Offset (hex)	Bits 0:31	Bits 32:39	Bits 40:47	Bits 48:51	Bits 52:55	Bits 56:57	Bit 58	Bit 59	Bit 60	Bit 61	Bit 62	Bit 63
00	WBA				WSE		MW	AP		-	PT	V

10.2.3.1 PAACE Offset 0x00

Describes PAACE Offset 0x00 field definitions.

Table 10-3. PAACE Offset 0x00 Field Definitions

Bits	Name	PPAACE (P) and/or SPAACE (S) Field	Description
0-51	See Notes		Notes: If primary PAACE: bits 0-51 of PAACE offset 0x00 contain the WBA.

Table continues on the next page...

Table 10-3. PAACE Offset 0x00 Field Definitions (continued)

Bits	Name	PPAACE (P) and/or SPAACE (S) Field	Description
			If secondary PAACE: bits 32-47 of PAACE offset 0x00 contain the LIODN. The rest of the bits are reserved.
0-51	WBA	P	Window Base Address These bits describe the base address of the DSA window in I/O address space. The WBA is the 52 most significant address bits of a 64-bit address aligned to the window size as described in the WSE field. The WBA field is 52 bits wide to allow for a 64-bit address aligned to the minimum 4 Kbyte window size. These bits are valid in the primary PAACE. In certain platforms, all these bits may not be required. However, enough bits must be implemented to match the largest system storage address in the platform. Reads to unimplemented high order bits must return 0.
32-47	LIODN	S	Logical I/O Device Number These bits define the LIODN for which the DSA sub-window is being described. These bits are valid in the secondary PAACE.
52-57	WSE	P	Window Size Encoding These bits identify the size of the DSA window starting from the window base address. These bits are valid in the primary PAACE and are reserved in a secondary PAACE. DSA window size is $2^{(WSE+1)}$ bytes: 0x00-0x0A Reserved (Write reserved, read returns 0) 0x0B 4 Kbytes 0x0C 8 Kbytes . . . $2^{(WSE+1)}$ bytes 0x1F 4 Gbytes 0x20 8 Gbytes . . . $2^{(WSE+1)}$ bytes 0x3F 16 Ebytes
58	MW	P	Multiple Windows This bit indicates whether the LIOD has multiple DSA sub-windows. These bits are valid in the primary PAACE and are reserved in a secondary PAACE. It is coded as follows: 0 A single DSA window exists for the LIOD. 1 Multiple DSA sub-windows exist for the LIOD. The number of sub-windows is indicated in the WCE field of the PPAACE.
59-60	AP	P and S	Access Permissions. These bits define whether access to the window described by this PAACE is permitted and if permitted, the type of permitted access. In the field description, a Query Access typically refers to read type operations where the effect of the operation does not change the values of locations or state of the system; an Update

Table continues on the next page...

Table 10-3. PAACE Offset 0x00 Field Definitions (continued)

Bits	Name	PPAACE (P) and/or SPAACE (S) Field	Description
			Access typically refers to write type operations where the effect of the operation changes the values of locations or state of the system. 00 Access denied 01 Query access only 10 Update access only 11 Access permitted for all operation types **NOTE:** If MW = 0, then AP applies to the DSA wIndow described by this PAACE; if MW = 1, then AP applies to the DSA sub-window described by this PAACE.
61	-	P and S	Reserved
62	PT	P and S	PAACE Type This bit indicates whether it is a primary or secondary PAACE. 0 Primary PAACE 1 Secondary PAACE
63	V	P and S	Valid PAACE This bit defines whether this PAACE is valid. 0 Invalid PAACE. Other PAACE fields do not contain valid information. 1 Valid PAACE. Other PAACE fields may be referenced.

10.2.3.2 PAACE Offset 0x08

Describes PAACE Offset 0x08 field definitions.

Table 10-4. PAACE Offset 0x08 Field Definitions

Bits	Name	PPAACE (P) and/or SPAACE (S) Field	Description
0-31	DA	P and S	Domain Attributes These bits define operation attributes specific to the destination domain of the operation. The contents of the DA field are further described in PAACE Domain Attributes .
32-55	IA	P and S	Implementation Attributes These bits define operation attributes that are implementation specific. For details see Implementation Attributes
56-59	WCE	P	Window Count Encoding

Table continues on the next page...

Table 10-4. PAACE Offset 0x08 Field Definitions (continued)

Bits	Name	PPAACE (P) and/or SPAACE (S) Field	Description
			These bits identify the number of DSA sub-windows for this LIOD. These bits are valid in the primary PAACE when MW is enabled and are reserved in a secondary PAACE. Window count is $2^{(WCE+1)}$ windows: 0000 2 DSA sub-windows 0001 4 DSA sub-windows . . . 1111 65536 DSA sub-windows
60-61	ATM	P and S	Address Translation Mode These bits define whether address translation is enabled for the window described by this PAACE and if enabled, the type of translation to perform. 00 No address translation. The ingress and egress operation address are the same. 01 Window address translation 10 Reserved 11 Reserved
62-63	OTM	P and S	Operation Translation Mode These bits define whether operation type translation is enabled for the window described by this PAACE and if enabled, the type of translation to perform. 00 No operation translation. The ingress and egress operation type are the same. 01 Operation translation enabled with immediate operation translation. 10 Operation translation enabled with indexed operation translation. 11 Reserved

10.2.3.2.1 PAACE Domain Attributes

Table 10-5 describes the domain attribute (DA) field of PAACE at offset 0x08-0x0B.

Table 10-5. PAACE Domain Attributes

Bits	Name	PPAACE (P) and/or SPAACE (S) Field	Description
0-15	-	-	Reserved (Write reserved; read returns 0)
16-23	SnpID	P and S	Snoop ID

Table continues on the next page...

Table 10-5. PAACE Domain Attributes (continued)

Bits	Name	PPAACE (P) and/or SPAACE (S) Field	Description
			This field may be used to identify a specific snooper or set of snoopers required for the maintenance of hardware coherency for the window described by this PAACE. This field is valid if the M bit for the PAACE is 1. If the SnpID field contains a pattern of all 0s, then all snoopers in the coherency domain must participate in the maintenance of hardware coherency. A SnpID pattern of all 0s indicates no specific snooper or set of snoopers is being specified. If the SnpID pattern is non-zero, only the snoopers defined by the SnpID field must participate in the maintenance of hardware coherency. The snoopers indicated by the non-zero SnpID pattern is implementation dependent.
24	M	P and S	Memory Coherence Required This bit defines if hardware cache coherency is to be maintained in the coherency domain for the window described by this PAACE. 0 Non-coherent memory, that is, hardware cache coherency mechanisms not required. 1 Coherent memory, that is, hardware cache coherency mechanisms required.
25-31	-	-	Reserved (Write reserved; read returns 0)

10.2.3.3 PAACE Offset 0x10

Describes PAACE Offset 0x10 field definitions.

Table 10-6. PAACE Offset 0x10 Field Definitions

Bits	Name	PPAACE (P) and/or SPAACE (S) Field	Description
0-51	TWBA	P and S	Translated Window Base Address These bits describe the translated base address in system storage space of the window described by this PAACE. The TWBA is the 52 most significant address bits of the 64-bit address, aligned to the size of the window described by this PAACE. The TWBA field is 52 bits wide to allow for a 64-bit address aligned to the minimum 4 Kbyte size of a window described by this PAACE. This field is referenced when ATM[0:1] = 01 for this PAACE.
52-57	SWSE	P and S	Sub-Window Sub-Range Encoding These bits identify the size of the sub-range of addresses within the DSA sub-window described by this PAACE, that is eligible for access and translation. This eligible sub-range

Table continues on the next page...

Table 10-6. PAACE Offset 0x10 Field Definitions (continued)

Bits	Name	PPAACE (P) and/or SPAACE (S) Field	Description
			starts from the starting address of this DSA sub-window. This field is only referenced when the MW bit is 1. The sub-range size is $2^{(SWSE+1)}$ bytes: 0x00-0x0A Reserved (Write reserved; read returns 0) 0x0B 4 Kbyte 0x0C 8 Kbyte . . . $2^{(SWSE+1)}$ bytes 0x1F 4 Gbyte 0x20 8 Gbyte . . . $2^{(SWSE+1)}$ bytes 0x3F 16Ebytes
58-63	-	-	Reserved (Write reserved; read returns 0)

10.2.3.4 PAACE Offset 0x18

Describes PAACE Offset 0x18 field definitions.

Table 10-7. PAACE Offset 0x18 Field Definitions

Bits	Name	PPAACE (P) and/or SPAACE (S) Field	Description
0-31	FSPI	P	First Secondary PAACE Index These bits identify the index location in the SPAACT of the secondary PAACE that describes the second DSA sub-window for this LIOD. These bits are valid in the primary PAACE when MW is set and are reserved in a secondary PAACE.
32-63	See Notes		**Notes:** 1. If OTM[0:1] == 01, bits 32-63 of PAACE Offset 0x18 contain IOEA, MOEA, IOEB, and MOEB respectively. If OTM[0:1] == 10, bits 48-63 of PAACE Offset 0x18 contain the OMI, bits 32-47 are reserved. 2. The following apply to ingress operation encodings: bit[0] is a qualifier indicating the operation type. bit[0] = 0 is the qualifier value reserved for all query operation types. bit[0] = 1 is the qualifier value reserved for all update operation types. The operation encoding in IOE[1:7] is implementation dependent.

Table continues on the next page...

Table 10-7. PAACE Offset 0x18 Field Definitions (continued)

Bits	Name	PPAACE (P) and/or SPAACE (S) Field	Description
			3. The following apply to egress operation encodings: bit[0] is a qualifier indicating a valid operation type. The operation encoding in EOE[1:7] is implementation dependent.
48-63	OMI	P and S	Operation Mapping Index If OTM[0:1] == 10, these bits are used to determine the relevant operation mapping entry (OME) of the OMT to be referenced for operation translation.
32-39	IOEA	P and S	Ingress Operation Encoding A If OTM[0:1] == 01, these bits define the ingress operation encoding A for which the corresponding egress encoding will be provided.
40-47	MOEA	P and S	Mapped Operation Encoding A These bits define the mapped operation encoding, including a portion of the translated egress operation encoding A (EOEA) for the ingress operation encoding A. MOEA[0] is a valid bit MOEA[1:7] contains the corresponding bits of the egress operation encoding, that is, EOEA[1:7].
48-55	IOEB	P and S	Ingress Operation Encoding B If OTM[0:1] == 01, these bits define the ingress operation encoding B for which the corresponding egress encoding will be provided.
56-63	MOEB	P and S	Mapped Operation Encoding B These bits define the mapped operation encoding, including a portion of the translated egress operation encoding B (EOEB) for the ingress operation encoding B. MOEB[0] is a valid bit MOEB[1:7] contains the corresponding bits of the egress operation encoding, that is, EOEB[1:7].

10.3 PAMU Memory Map/Register Definitions

PAMU registers reside in a 4-Kbyte block of CCSR space starting at 0x02_*n*000, where *n* is the instance of PAMU being referenced.

10.4 PAMU Memory Map

PAMU memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

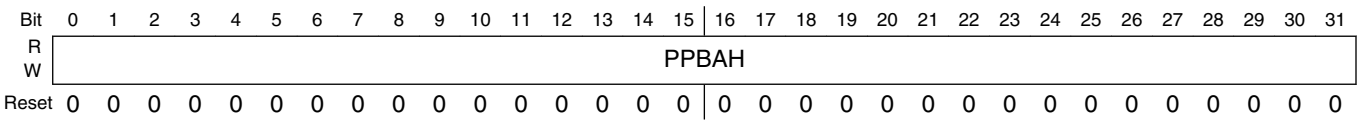
10.4.1 Primary PAACT Base Address High register (PAMUx_PPBAH)

A write to the primary PAACT Base Address High register invalidates the contents of Primary PAACT cache.

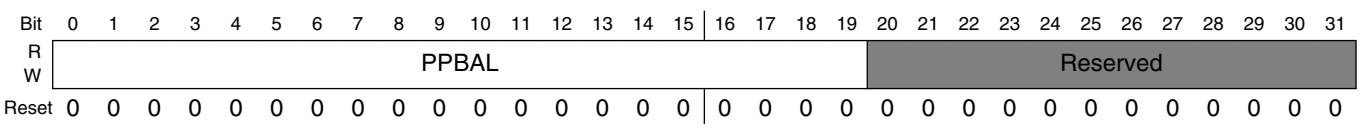


PAMUx_PPBAH field descriptions

Field	Description
0–31 PPBAH	Primary PAACT Base Address High The PPBAH is the 32 most significant bits of the 64-bit base address of the primary PAACT. **NOTE:** The most significant bits of PPBAH should have a value of 0 to be consistent with the MSA capability field as described in PAMU Capabilities register 1 (PAMU_PC1).

10.4.2 Primary PAACT Base Address Low register (PAMUx_PPBAL)

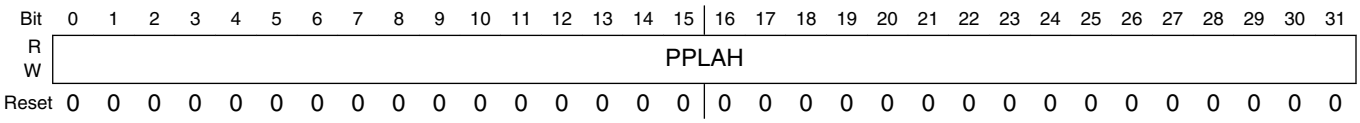
A write to the primary PAACT Base Address Low register invalidates the contents of Primary PAACT cache.



PAMUx_PPBAL field descriptions

Field	Description
0–19 PPBAL	Primary PAACT Base Address Low The PPBAL is the 20 next-significant of the 64 bits that identify the primary PAACT base address.
20–31 -	This field is reserved. Reserved. These bits are the 12 least significant base address bits of the primary PAACT base address which must be aligned to a 4-Kbyte page boundary.

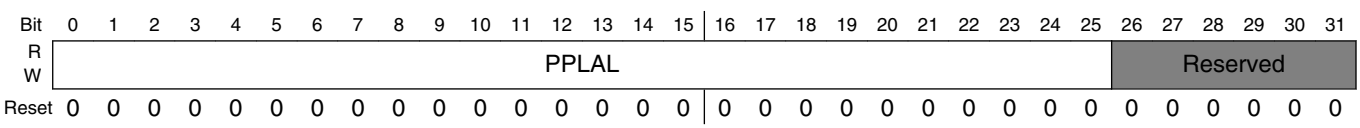
10.4.3 Primary PAACT Limit Address High register (PAMUx_PPLAH)



PAMUx_PPLAH field descriptions

Field	Description
0–31 PPLAH	Primary PAACT Limit Address High The PPLAH is the 32 most significant of the 64 address bits that identify the limit of the primary PAACT. **NOTE:** The most significant bits of PPLAH should have a value of 0 to be consistent with the MSA capability field as described in PAMU Capabilities register 1 (PAMU_PC1).

10.4.4 Primary PAACT Limit Address Low register (PAMUx_PPLAL)

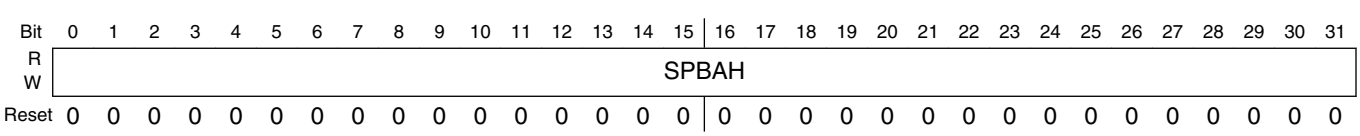


PAMUx_PPLAL field descriptions

Field	Description
0–25 PPLAL	Primary PAACT Limit Address Low The PPLAL is the 26 next-significant of the 64 bits that identify the limit of the primary PAACT. **NOTE:** The primary PAACT limit is the address of the byte following the last byte of the PPAACT.
26–31 -	This field is reserved. Reserved. These bits are the 6 least significant address bits representing the 64-byte PAACE size.

10.4.5 Secondary PAACT Base Address High register (PAMUx_SPBAH)

A write to the secondary PAACT Base Address High register invalidates the contents of secondary PAACT cache.



PAMUx_SPBAH field descriptions

Field	Description
0–31 SPBAH	Secondary PAACT Base Address High The SPBAH is the 32 most-significant of the 64 bits that identify the secondary PAACT base address. **NOTE:** The most significant bits of SPBAH should have a value of 0 to be consistent with the MSA capability field as described in PAMU Capabilities register 1 (PAMU_PC1).

10.4.6 Secondary PAACT Base Address Low register (PAMUx_SPBAL)

A write to the secondary PAACT Base Address Low register invalidates the contents of secondary PAACT cache.

PAMUx_SPBAL field descriptions

Field	Description
0–19 SPBAL	Secondary PAACT Base Address Low The SPBAL is the 20 next-significant of the 64 bits that identify the secondary PAACT base address.
20–31 -	This field is reserved. Reserved. These bits are the 12 least significant base address bits of the secondary PAACT which must be aligned to a 4-Kbyte page boundary.

10.4.7 Secondary PAACT Limit Address High register (PAMUx_SPLAH)

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PAMUx_SPLAL field descriptions

Field	Description
0–25 SPLAL	Secondary PAACT Limit Address Low The SPLAL is the 26 next-significant of the 64 bits that identify the limit of the secondary PAACT. **NOTE:** The secondary PAACT limit is the address of the byte following the last byte of the SPAACT.
26–31 -	This field is reserved. Reserved. These bits are the 6 least significant address bits representing the 64-byte PAACE size.

10.4.9 OMT Base Address High register (PAMUx_OBAH)

A write to OMT Base Address High register invalidates the contents of OMT cache.

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

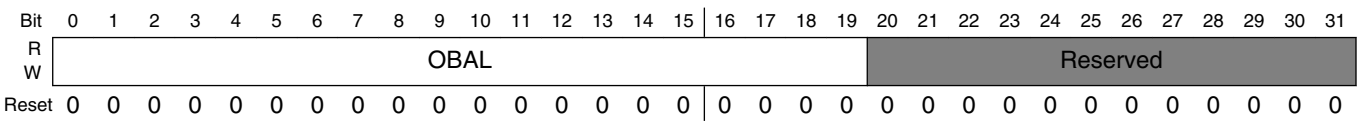
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PAMUx_OBAH field descriptions

Field	Description
0–31 OBAH	OMT Base Address High The OBAH is the 32 most significant address bits that identify the base of the OMT window. **NOTE:** The most significant bits of OBAH should have a value of 0 to be consistent with the MSA capability field as described in PAMU Capabilities 1.

10.4.10 OMT Base Address Low register (PAMUx_OBAL)

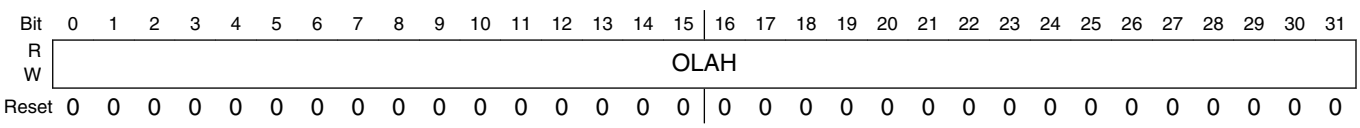
A write to OMT Base Address Low register invalidates the contents of OMT cache.



PAMUx_OBAL field descriptions

Field	Description
0–19 OBAL	OMT Base Address Low The OBAL is the next 20 least significant address bits that identify the base of the OMT window above the 12 least significant address bits representing the minimum 4-Kbyte page boundary for the base address.
20–31 -	This field is reserved. Reserved. These bits are the 12 least significant address bits a 4-Kbyte page boundary.

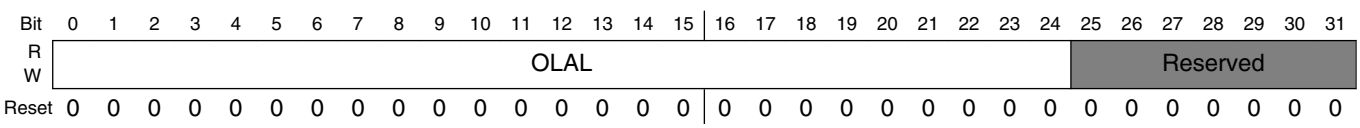
10.4.11 OMT Limit Address High register (PAMUx_OLAH)



PAMUx_OLAH field descriptions

Field	Description
0–31 OLAH	OMT Limit Address High The OLAH is the 32 most significant address bits that identify the limit of the OMT window. **NOTE:** The most significant bits of OLAH should have a value of 0 to be consistent with the MSA capability field as described in PAMU Capabilities 1.

10.4.12 OMT Limit Address Low register (PAMUx_OLAL)

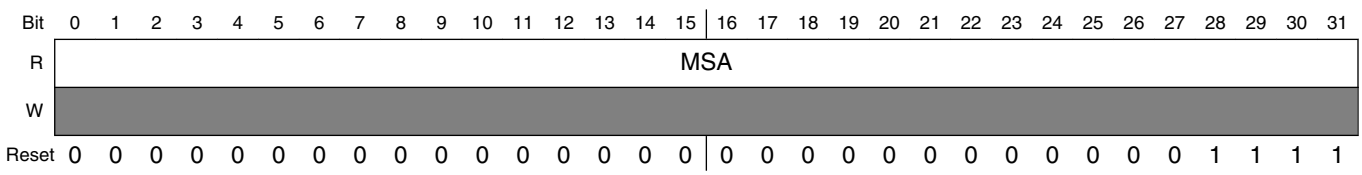


PAMUx_OLAL field descriptions

Field	Description
0–24 OLAL	OMT Limit Address Low The OLAL is the next 25 least significant address bits that identify the limit of the OMT window above the 7 least significant address bits representing the 128-byte size of an OME.
25–31 -	This field is reserved. Reserved. These bits are the 7 least significant address bits representing the 128-byte size of an OME.

10.4.13 PAMU Address Capabilities Register 1 (PAMUx_PAC1)

The PAMU address capabilities registers denote implementation parameters for a given hardware instance of the PAMU. Software must read these registers to discover the specific parameter values implemented in this instance of PAMU and utilize the information when programming the PAMU, its data structures, and related system resources.

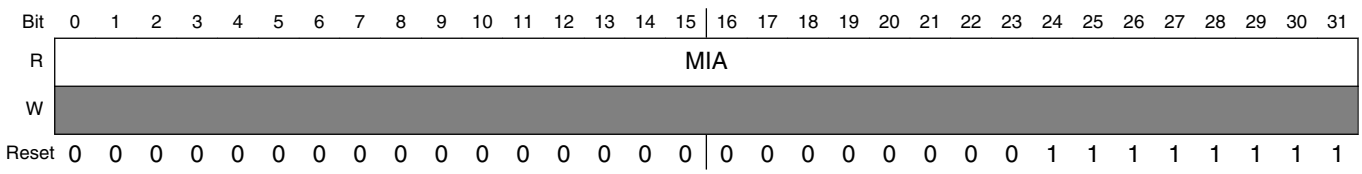


PAMUx_PAC1 field descriptions

Field	Description
0–31 MSA	Maximum System Storage Address Capability. These bits define the maximum system storage address capability of this PAMU implementation. The MSA identifies the maximum value of the 32 most-significant address bits above the 32 least-significant address bits representing 4 Gbytes. This PAMU implements only the least significant MSA number of bits of the TWBA field within a PAACE. **NOTE:** These bits do not define the maximum address capability of the system. A PAMU implementation can be used in a system where system address capability is less than or equal to maximum system-storage address capability of the PAMU. 0x0000_00FF Maximum 40-bit System Address Space

10.4.14 PAMU Address Capabilities Register 2 (PAMUx_PAC2)

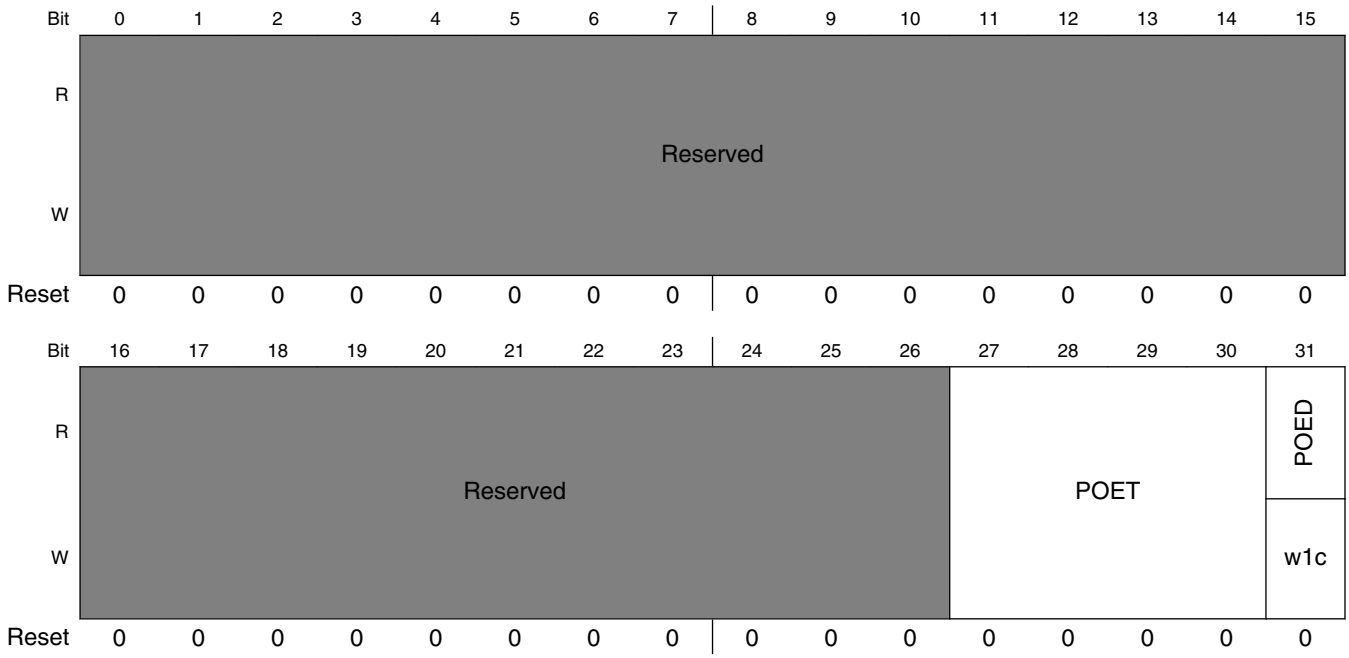
The PAMU address capabilities registers denote implementation parameters for a given hardware instance of the PAMU. Software must read these registers to discover the specific parameter values implemented in this instance of PAMU and utilize the information when programming the PAMU, its data structures, and related system resources.



PAMUx_PAC2 field descriptions

Field	Description
0–31 MIA	Maximum I/O Address Capability. These bits define the maximum I/O bus address capability of this PAMU implementation. The MIA identifies the maximum value of the 32 most-significant address bits above the 32 least-significant address bits representing 4 Gbytes. This PAMU implements only the least significant MIA number of bits of the WBA field within a PAACE. **NOTE:** In no-address-translation mode, the I/O bus address of the DSA operation is also the system storage address. Since there is no address translation, the DSA Window must be contained within the system storage space. 0x0000_00FF Maximum 40-bit I/O bus address space

10.4.15 PAMU Operation Error Status register 1 (PAMUx_POES1)



PAMUx_POES1 field descriptions

Field	Description
0–26 -	This field is reserved. Reserved
27–30 POET	PAMU Operation Error Type These bits identify the type of error encountered by the PAMU. The bits are coded as follows: 0000 PAMU fetch: bad data received 0001-0111 Reserved 1000 Unsupported ATM code requested in PAACE 1001 Unsupported OTM code requested in PAACE 1010-1111 Reserved
31 POED	PAMU Operation Error Detected This bit is set when a hardware error is encountered by PAMU. If the bit is set, the rest of the contents of the Error Status register and the contents of the Error Status and Error Address registers are valid. It is coded as follows: 0 No PAMU error 1 PAMU error detected. Software should write a 1 to clear this bit.

10.4.16 PAMU Operation Error Status register 2 (PAMUx_POES2)

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Reserved																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PAMUx_POES2 field descriptions

Field	Description
0–31 -	This field is reserved. Reserved

10.4.17 PAMU Operation Error Address High register (PAMUx_POEAH)

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	POEAH																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PAMUx_POEAH field descriptions

Field	Description
0–31 POEAH	PAMU Operation Error Address High The POEAH is the 32 most significant address bits that identify the address, in system memory space, of the PAACT, OMT location that encountered the error condition. **NOTE:** POEAH[0:27] has a value of 0x000_0000 and is consistent with the MSA capability field as described in PAMU Address Capabilities Register 1.

10.4.18 PAMU Operation Error Address Low register (PAMUx_POEAL)

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	POEAL																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

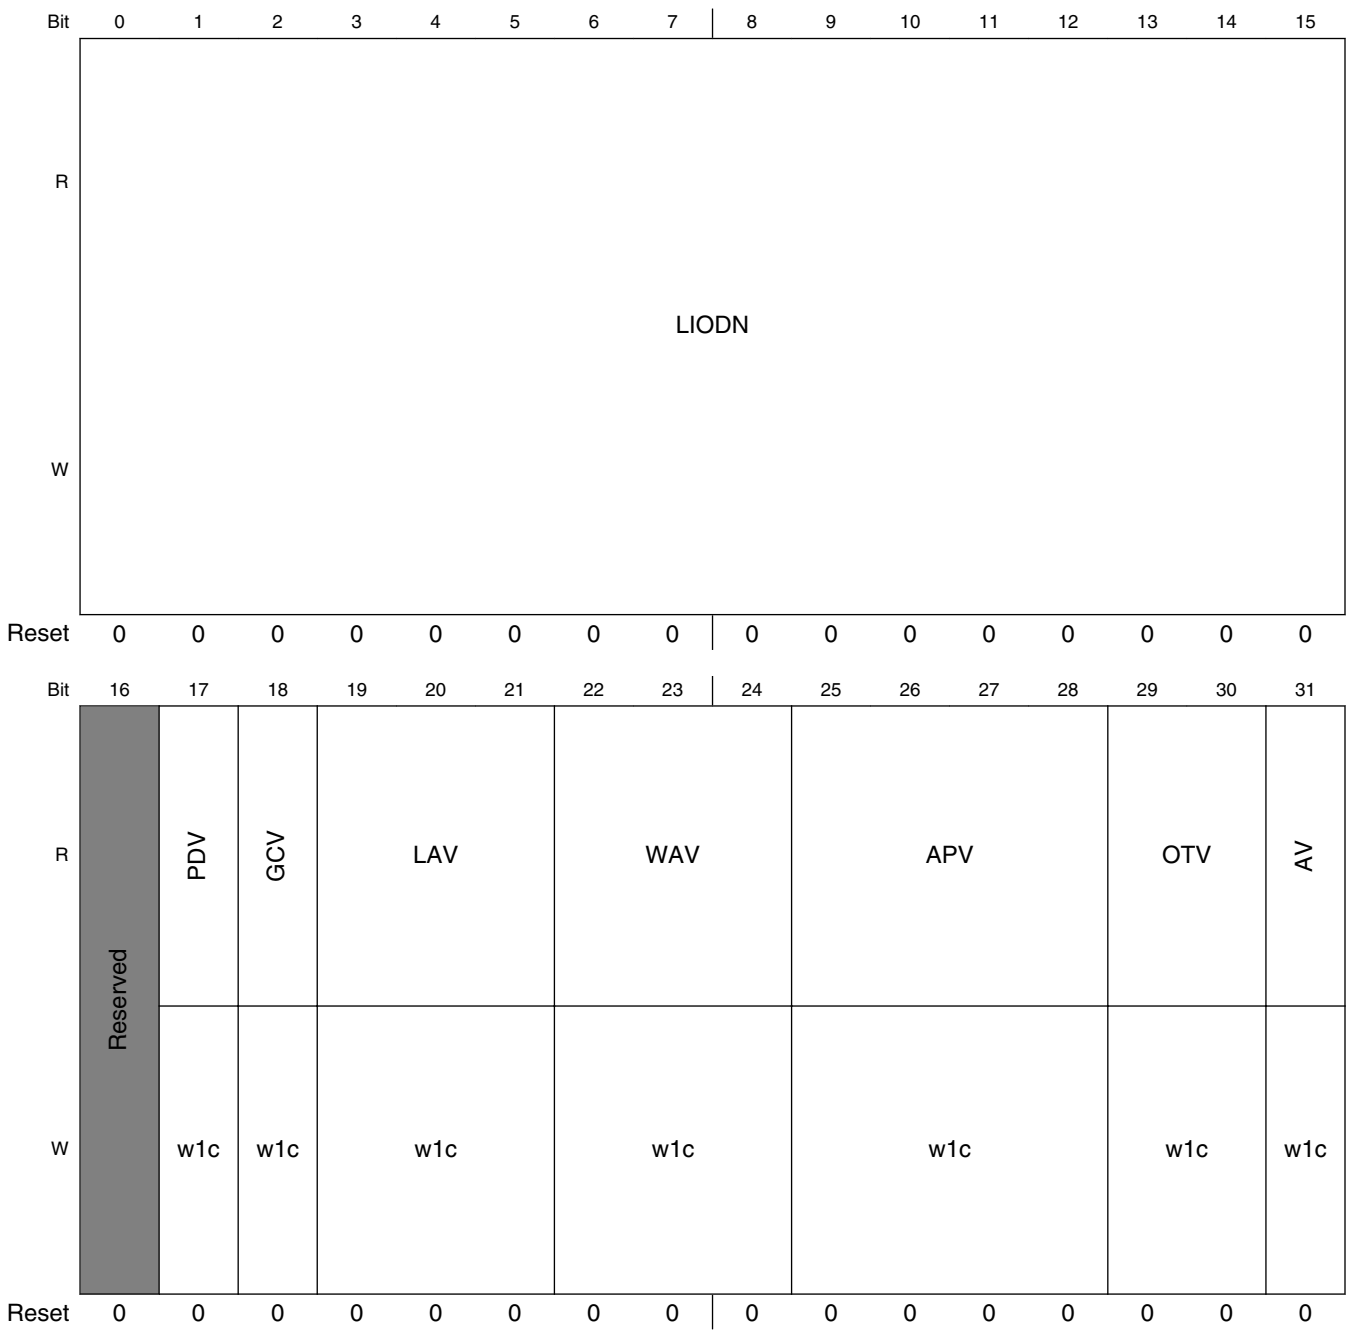
PAMUx_POEAL field descriptions

Field	Description
0–31 POEAL	PAMU Operation Error Address Low These bits define the address, in system memory space, of the PAACT or OMT location that encountered the error condition.

PAMUx_POEAL field descriptions (continued)

Field	Description
	The POEAL is the 32 least significant address bits of the address, in system memory space, that encountered the PAMU error. The granularity of the POEAL varies depending on the type of data structure that encountered the error: • For a PAACT location, the 6 least significant address bits of the POEAL has a value of 0x00, representing the PAACE size.

10.4.19 Access Violation Status register 1 (PAMUx_AVS1)



PAMUx_AVS1 field descriptions

Field	Description
0–15 LIODN	Logical I/O Device Number These bits identify the LIODN of the operation that encountered the error. **NOTE:** LIODN[0:3] has a value of 0x0 to be consistent with the ML capability field as described in PAMU Capabilities 2.
16 -	This field is reserved. Reserved
17 PDV	PAMU Disable Violation This bit identifies an access violation while the PAMU enable (PE) bit is not set (and the PAMU gate closed signal is deasserted). 0 No access violation while the PAMU enable (PE) bit is not set (and the PAMU gate closed signal is deasserted) 1 Access violation while the PAMU enable (PE) bit is not set (and the PAMU gate closed signal is deasserted)
18 GCV	Gate Closed Violation This bit identifies an access violation during assertion of PAMU gate closed bit. 0 No access violation during PAMU gate closed 1 Access violation during PAMU gate closed
19–21 LAV	LIODN Access Violation These bits identify if a LIODN access violation has occurred or the type of LIODN access violation encountered. 000 No LIODN access violation 001 LIODN access violation-LIODN index not within PPAACT 010 LIODN access violation-Secondary PAACE index not within SPAACT 011-111 reserved
22–24 WAV	Window Access Violation These bits identify if a window access violation has occurred or the type of window access violation encountered by the logical device. 000 No window access violation 001 Window access violation-Address not within valid window 010 Sub-window access violation-Address not within valid sub-range of the sub-window 011 Sub-window access violation-LIODN does not match secondary PAACE 100-111 Reserved
25–28 APV	Access Permission Violation These bits identify if an access permission violation has occurred or the type of access permission violation encountered by the logical device. **NOTE:** The APV encoding of 0001 can only be used when the MW field of the relevant PAACE is not set. Similarly, the APV encoding of 0010 can only be used when the MW field of the relevant PAACE is set. 0000 No access permission violation 0001 Window access permission violation-access denied to the DSA window 0010 Sub-window access permission violation-access denied to the DSA sub-window 0011 Reserved

Table continues on the next page...

PAMUx_AVS1 field descriptions (continued)

Field	Description
	0100 Window access type violation-illegal access type to the DSA window 0101 Sub-window access type violation-illegal access type to the DSA sub-window 0110-0111 Reserved 1000 Sub-window Access Type Violation - Access to a DSA sub-window with invalid SPAACE 1001-1111 Reserved
29–30 OTV	Operation Type Violation These bits identify if an operation type violation has occurred or the type of operation type violation encountered by the logical device. 00 No operation type violation 01 Immediate operation translation violation-IOE does not match IOA or IOB 10 Immediate operation translation violation-matched MOE valid bit not set (MOEA[0]=0 or MOEB[0]=0) 11 Indexed operation translation violation (MOEn[0]=0)
31 AV	Access Violation This bit is set when an access violation has been detected by PAMU. If the bit is set, the rest of the contents of the access violation register and the contents of the access violation address registers are valid. 0 No access violation 1 Access violation detected.

10.4.20 Access Violation Status register 2 (PAMUx_AVS2)

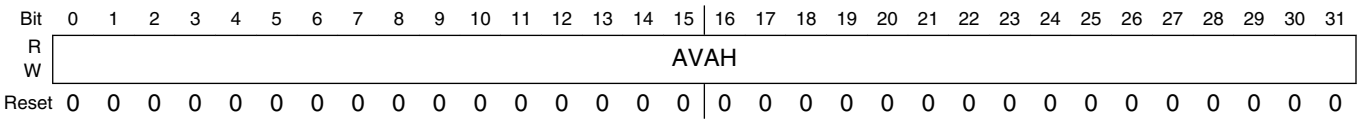
Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Reserved							OIV	IOE							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PAMUx_AVS2 field descriptions

Field	Description
0–22 -	This field is reserved. Reserved
23 OIV	Operation Index Violation OMI in PAACE refers to Operation Mapping Entry (OME) beyond the OMT limit address
24–31 IOE	Ingress Operation Encoding These bits identify the ingress operation encoding of the operation that encountered the error.

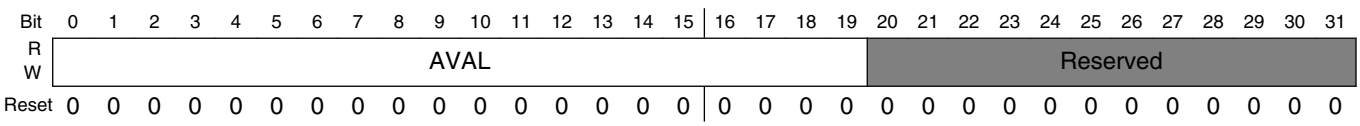
10.4.21 Access Violation Address High register (PAMUx_AVAH)



PAMUx_AVAH field descriptions

Field	Description
0–31 AVAH	Access Violation Address High The AVAH is the 32 most significant address bits that identify the address, in I/O address space, of the operation that encountered the error condition.

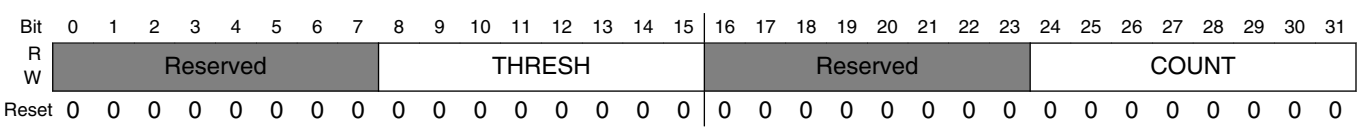
10.4.22 Access Violation Address Low register (PAMUx_AVAL)



PAMUx_AVAL field descriptions

Field	Description
0–19 AVAL	Access Violation Address Low AVAL is the 20 next-significant of the 64 bits that identify the address, in I/O address space, of the operation that encountered the error condition.
20–31 -	This field is reserved. Reserved. The 12 of the 64 bits that identify the address, in I/O address space, of the operation that encountered the error condition are not reported.

10.4.23 ECC Error Control Register (PAMUx_EECTL)



PAMUx_EECTL field descriptions

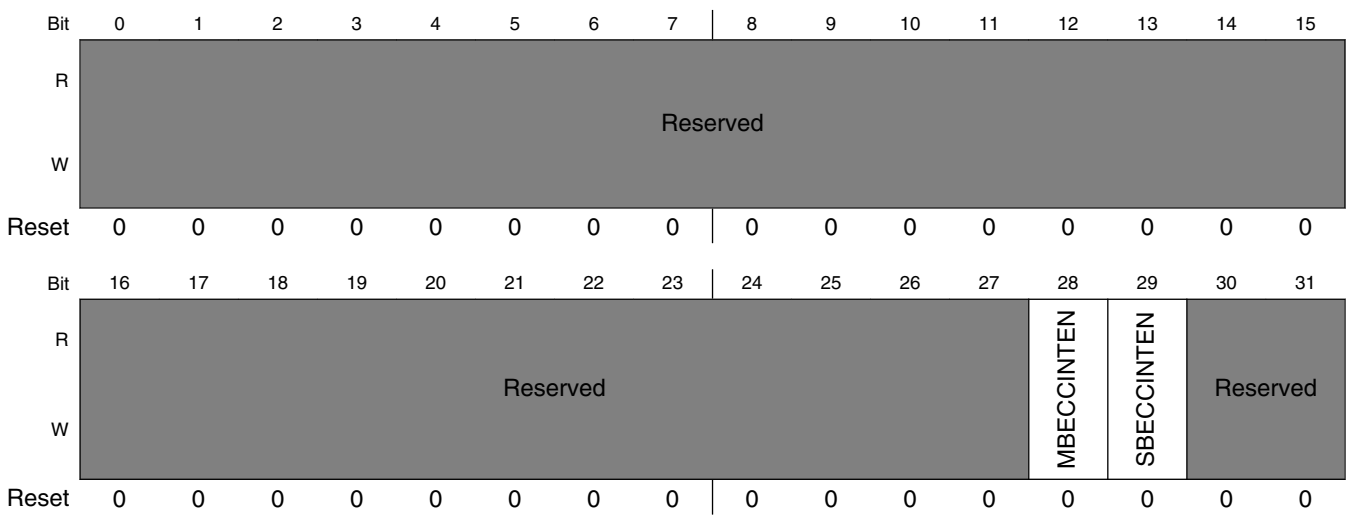
Field	Description
0–7 -	This field is reserved. Reserved
8–15 THRESH	PAMU Threshold

Table continues on the next page...

PAMUx_EECTL field descriptions (continued)

Field	Description
	Threshold value for the number of ECC single-bit error that are detected before reporting an error condition. After setting the threshold value, single bit ECC error reporting has to be enabled to report an error condition. If single bit ECC error reporting is enabled with a threshold value of 0, an error condition is reported on the first occurrence of single bit ECC error.
16–23 -	This field is reserved. Reserved
24–31 COUNT	PAMU Count Counts ECC single-bit errors detected. If COUNT is greater than or equal to THRESH then an error is reported, provided single-bit error reporting is enabled. Single bit ECC error is counted across a cache line, as a result one cache access can lead to only one single bit ECC error. Primary PAACT and secondary PAACT accesses in the same cycle can lead to a COUNT update by more than 1. Software must write zeros in bits 24-31 in order to clear the COUNT bits.

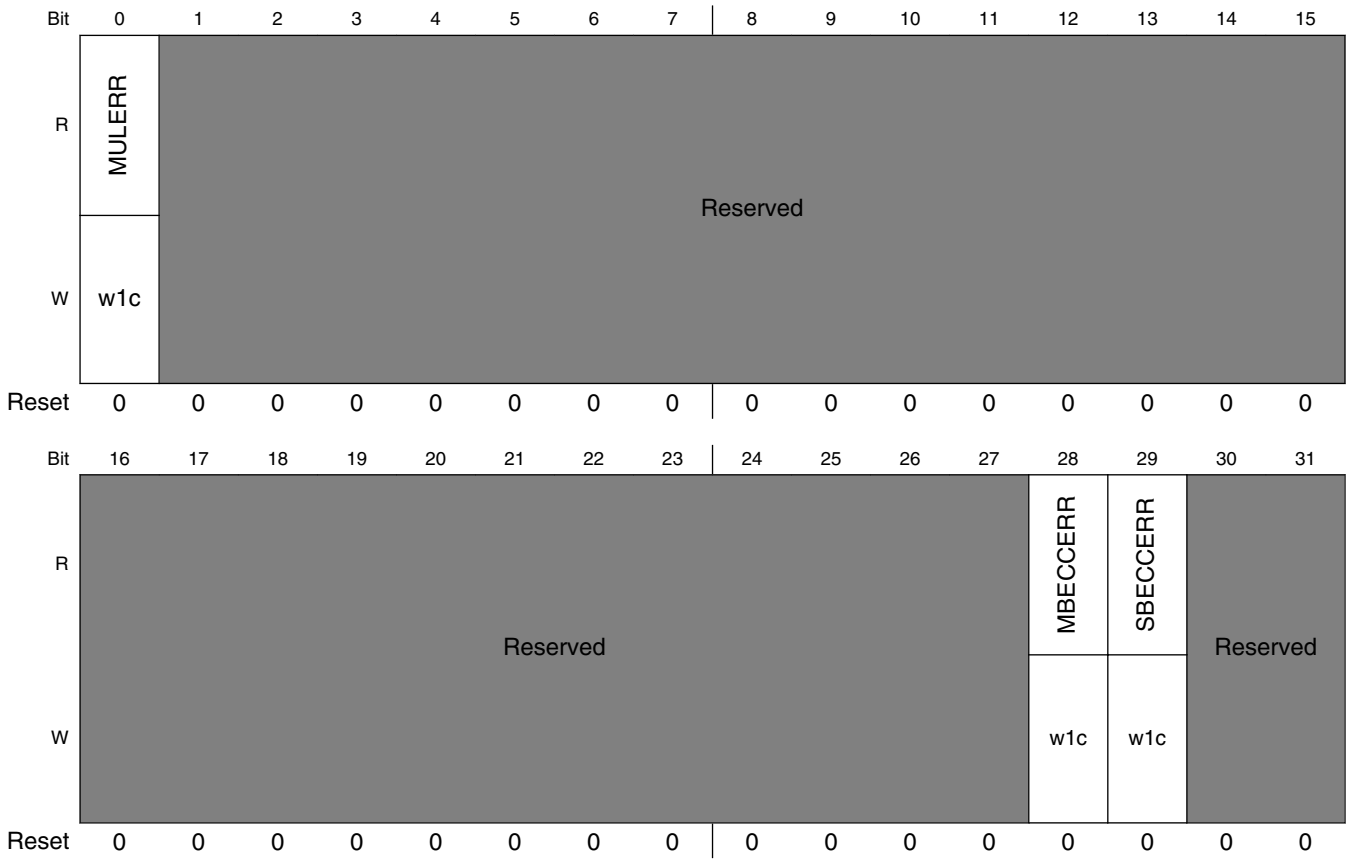
10.4.24 ECC Error Interrupt Enable Register (PAMUx_EEINTEN)



PAMUx_EEINTEN field descriptions

Field	Description
0–27 -	This field is reserved. Reserved
28 MBECCINTEN	Multiple-bit ECC error reporting enable. 0 Multiple-bit ECC error reporting disabled. 1 Multiple-bit ECC error reporting enabled.
29 SBECCINTEN	Single-bit ECC error reporting enable. 0 Single-bit ECC error reporting disabled. 1 Single-bit ECC error reporting enabled.
30–31 -	This field is reserved. Reserved

10.4.25 ECC Error Detect Register (PAMUx_EEDET)

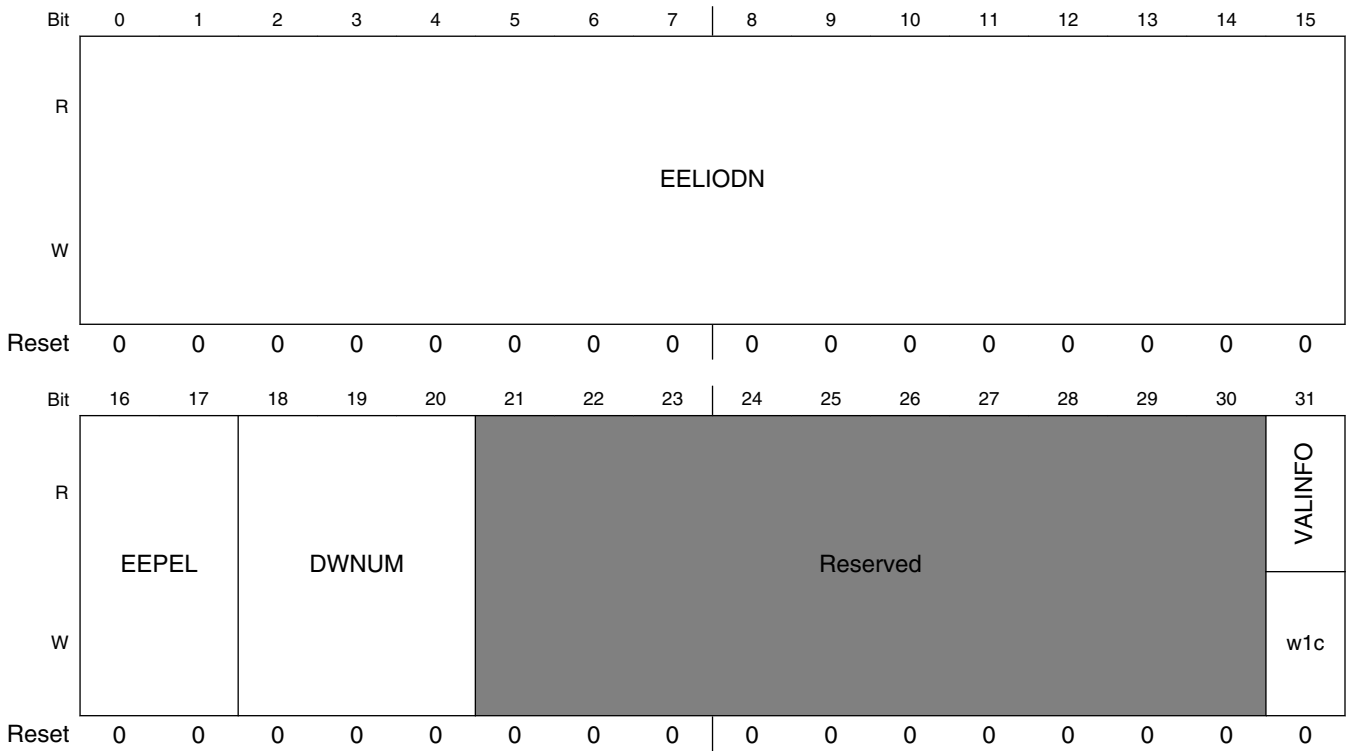


PAMUx_EEDET field descriptions

Field	Description
0 MULERR	Multiple errors. This bit is set, when multiple-bit ECC error is set and PAMU gets another multiple-bit ECC error or single-bit ECC error is set and PAMU gets another single-bit ECC error. The bit does not get set for a Primary PAACT and secondary PAACT access in the same cycle and both accesses have same type of errors. 0 Multiple errors of the same type (Multiple-bit ECC/single-bit ECC) were not detected 1 Multiple errors of the same type (Multiple-bit ECC/single-bit ECC) were detected.
1–27 -	This field is reserved. Reserved
28 MBECCERR	Multiple-bit ECC error 0 Multiple-bit ECC error was not detected. 1 Multiple-bit ECC error was detected.
29 SBECCERR	Single-bit ECC error 0 Single-bit ECC error was not detected 1 Single-bit ECC error was detected.
30–31 -	This field is reserved. Reserved

10.4.26 ECC Error Attributes Register (PAMUx_EEATTR)

If ECC errors are detected for the primary PAACT cache and secondary PAACT cache in the same cycle, the primary PAACT cache information is captured in the EEATTR, EEAHI, EEALO, EEDHI, and EEDLO registers.



PAMUx_EEATTR field descriptions

Field	Description
0–15 EELIODN	Logical I/O Device Number These bits identify the LIODN of the operation that encountered the ECC error. **NOTE:** LIODN[0:3] has a value of 0x0 to be consistent with the ML capability field as described in PAMU Capabilities 2.
16–17 EEPEL	PAMU Error Location. These bits identify the location of the error encountered by the PAMU. For cases, where an error is detected in the primary PAACT cache and secondary PAACT cache in the same cycle, EEPEL will be set to 00. 00 Error detected in primary PAACT cache 01 Error detected in secondary PAACT cache 10 Reserved 11 Error detected in OMT cache
18–20 DWNUM	Double word number. Indicates the double-word number within the cache line where the ECC error was detected. Example: 0x1: Indicates double word 1

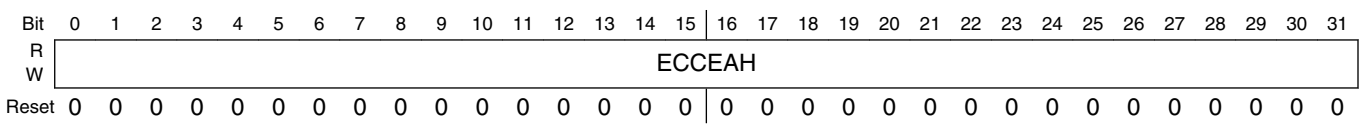
Table continues on the next page...

PAMUx_EEATTR field descriptions (continued)

Field	Description
21–30 -	This field is reserved. Reserved
31 VALINFO	PAMU ECC error attribute register valid 0 PAMU ECC error attribute register contains no valid information or no enabled errors were detected. 1 PAMU ECC error attribute register contains information of the first detected error that has reporting enabled. Software must clear this bit to unfreeze error capture so error detection hardware can overwrite the capture address/data/attributes for a newly detected error.

10.4.27 ECC Error Address High (PAMUx_EEAHI)

If ECC errors are detected for the primary PAACT cache and secondary PAACT cache in the same cycle, the primary PAACT cache information is captured in the EEATTR, EEAHI, EEALO, EEDHI, and EEDLO registers.

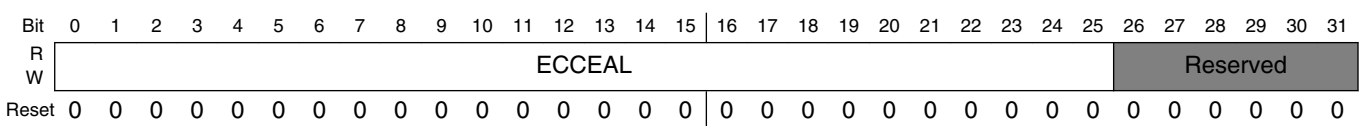


PAMUx_EEAHI field descriptions

Field	Description
0–31 ECCEAH	ECC Error Address High The ECCEAH is the 32 most significant address bits that identify the address that encountered an ECC error while reading from the cache.

10.4.28 ECC Error Address Low (PAMUx_EEALO)

If ECC errors are detected for the primary PAACT cache and secondary PAACT cache in the same cycle, the primary PAACT cache information is captured in the EEATTR, EEAHI, EEALO, EEDHI, and EEDLO registers.



PAMUx_EEALO field descriptions

Field	Description
0–25 ECCEAL	ECC Error Address Low

Table continues on the next page...

PAMUx_EEALO field descriptions (continued)

Field	Description
	ECCEAL is the next 26 least significant address bits that identify the address that encountered an ECC error while reading from the cache.
26–31 -	This field is reserved. Reserved

10.4.29 ECC Error Data High (PAMUx_EEDHI)

If ECC errors are detected for the primary PAACT cache and secondary PAACT cache in the same cycle, the primary PAACT cache information is captured in the EEATTR, EEAHI, EEALO, EEDHI, and EEDLO registers.

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	DATAHI

PAMUx_EEDHI field descriptions

Field	Description
0–31 DATAHI	ECC Error Data High High-order bits for data presenting an ECC error. Data[0:31].

10.4.30 ECC Error Data Low (PAMUx_EEDLO)

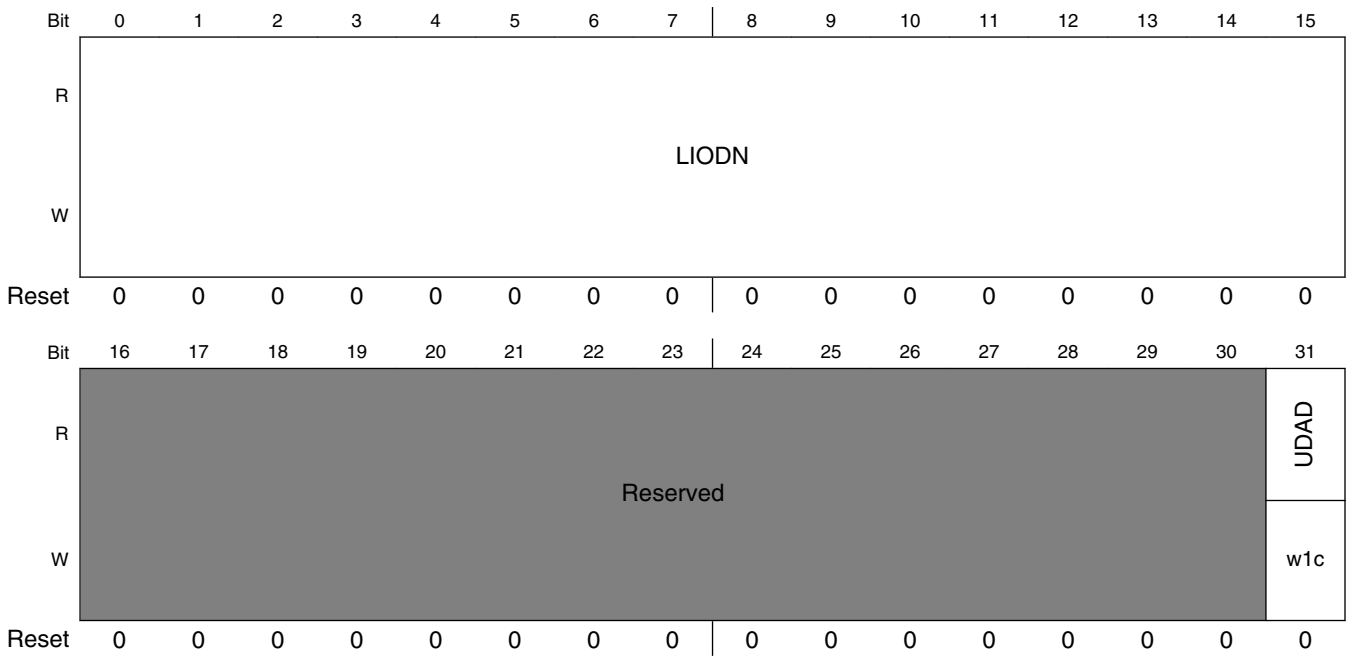
If ECC errors are detected for the primary PAACT cache and secondary PAACT cache in the same cycle, the primary PAACT cache information is captured in the EEATTR, EEAHI, EEALO, EEDHI, and EEDLO registers.

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	DATALO																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PAMUx_EEDLO field descriptions

Field	Description
0–31 DATALO	ECC Error Data Low Low-order bits for data presenting an ECC error. Data[32:63].

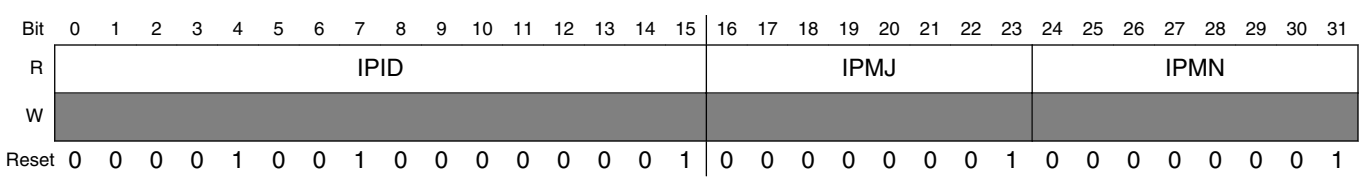
10.4.31 Unauthorized device access detection register (PAMUx_UDAD)



PAMUx_UDAD field descriptions

Field	Description
0–15 LIODN	Logical I/O device number. These bits identify the LIODN of the operation that encountered the unauthorized device access. **NOTE:** LIODN[0:3] has a value of 0x0 to be consistent with the ML capability field as described in PAMU Capabilities 2.
16–30 -	This field is reserved. Reserved
31 UDAD	Unauthorized device access detected. This bit is set when an unauthorized device access has been detected by the PAMU (LIODN index not pointing to a valid PPAACE). If the bit is set, the rest of the contents of the Unauthorized Device Access Detection register are valid. 0 No Unauthorized Device Access Detected 1 Unauthorized Device Access Detected.Software must write 1 in order to clear the pin.

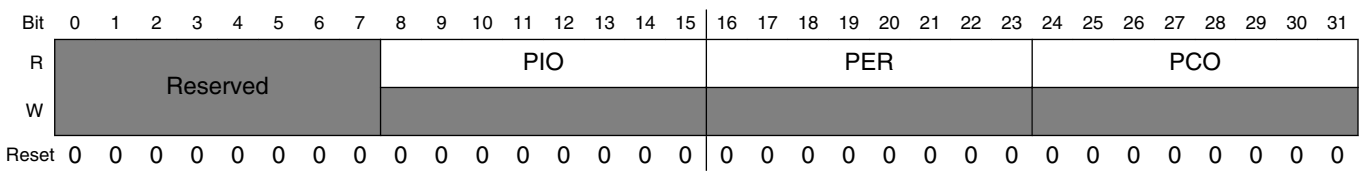
10.4.32 PAMU Revision register 1 (PAMUx_PR1)



PAMUx_PR1 field descriptions

Field	Description
0–15 IPID	IP block ID. These bits provide the IP block ID. For PAMU, the value is 0x0901.
16–23 IPMJ	Major revision. These bits provide the major revision number for PAMU.
24–31 IPMN	Minor revision. These bits provide the minor revision number for PAMU.

10.4.33 PAMU Revision register 2 (PAMUx_PR2)

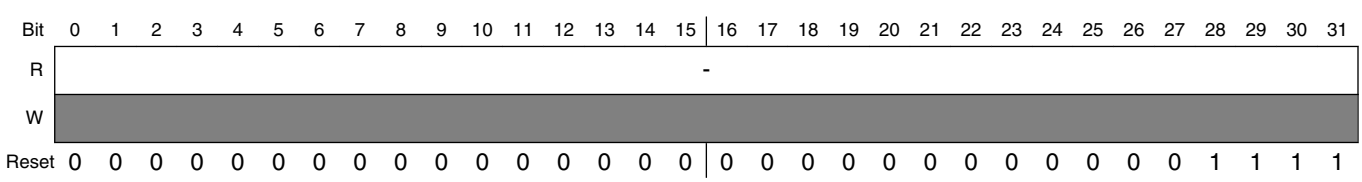


PAMUx_PR2 field descriptions

Field	Description
0–7 -	This field is reserved. Reserved
8–15 PIO	PAMU Integration Options. These bits provide information on the integration options for PAMU.
16–23 PER	PAMU ECO Revision. These bits provide information on the ECO Revision Number for PAMU.
24–31 PCO	PAMU Configuration Options. These bits provide information on the configuration options for PAMU.

10.4.34 PAMU Capabilities register 1 (PAMUx_PC1)

The fields in the PAMU capabilities registers denote implementation parameters for a given hardware instance of PAMU. Software must read these registers to discover the specific parameter values implemented in this instance of PAMU and utilize the information when programming the PAMU, its data structures, and related system resources.

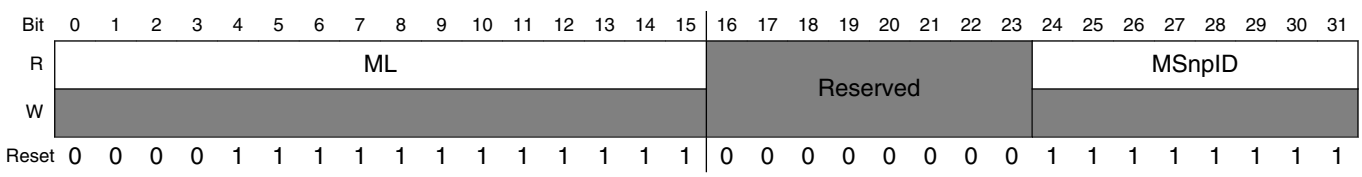


PAMUx_PC1 field descriptions

Field	Description
0–31 -	Reserved

10.4.35 PAMU Capabilities register 2 (PAMUx_PC2)

The fields in the PAMU capabilities registers denote implementation parameters for a given hardware instance of PAMU. Software must read these registers to discover the specific parameter values implemented in this instance of PAMU and utilize the information when programming the PAMU, its data structures, and related system resources.

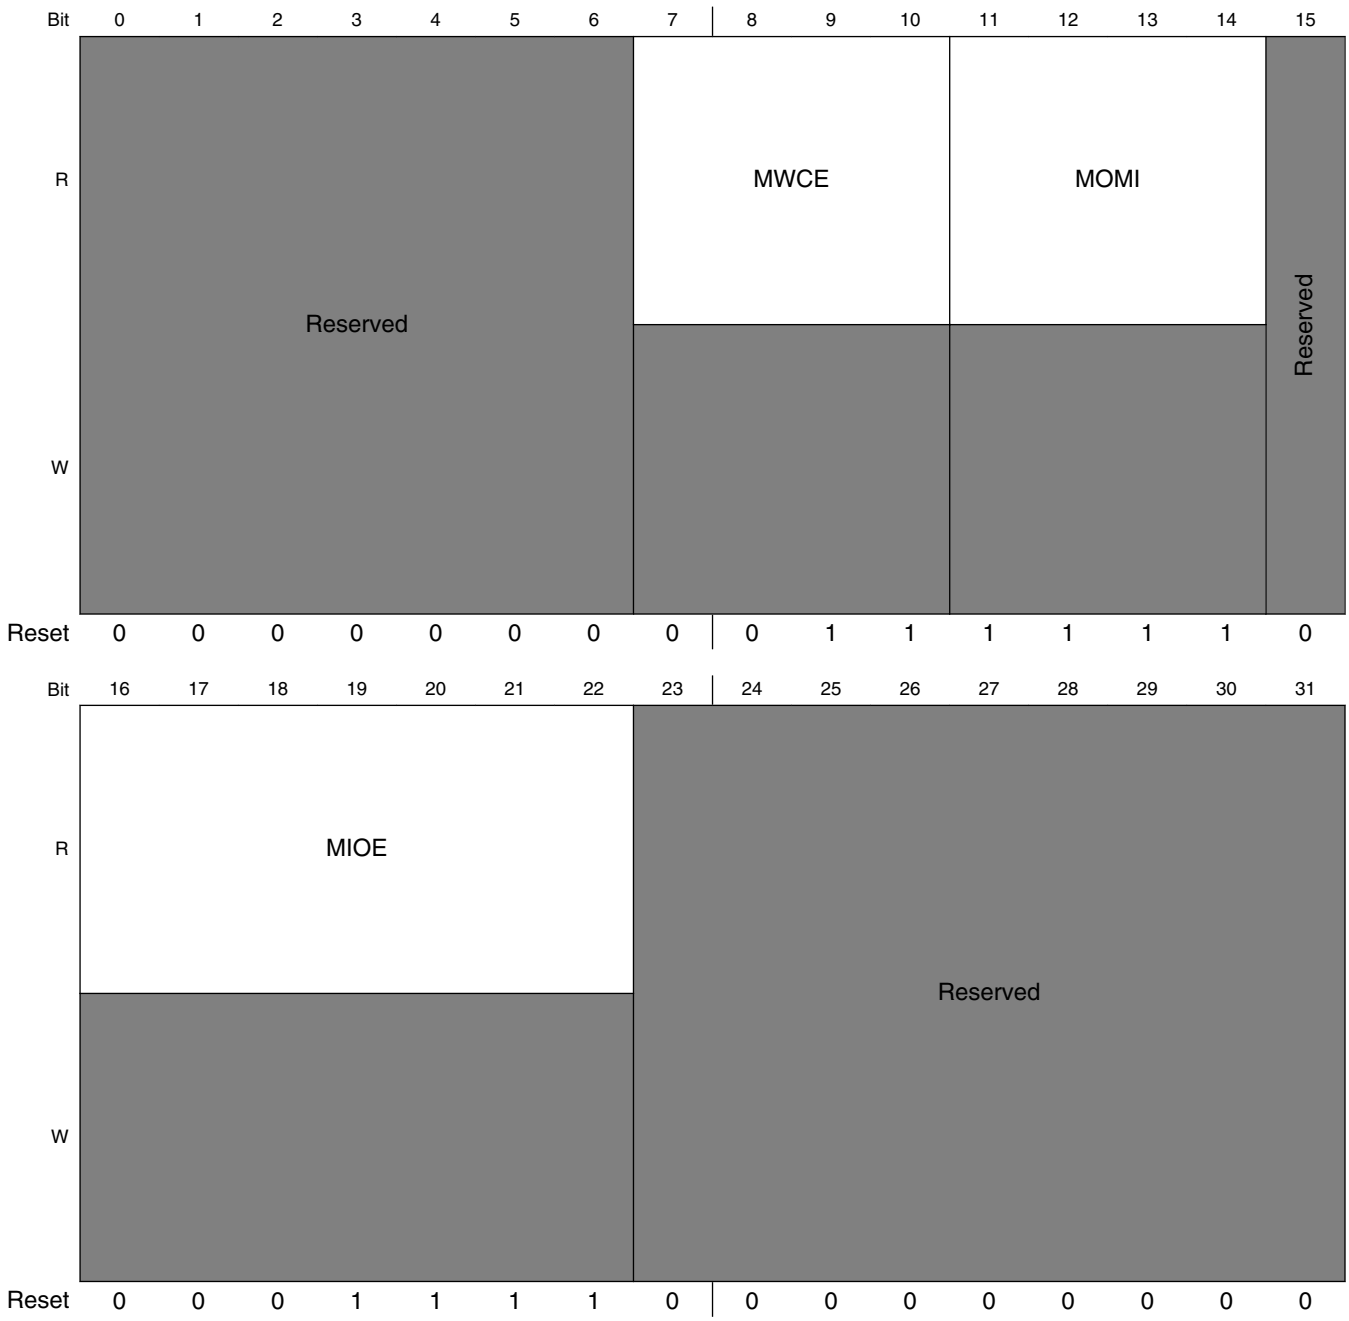


PAMUx_PC2 field descriptions

Field	Description
0–15 ML	Maximum LIODN. These bits define the maximum number of bits of LIODN supported by this PAMU instance. This field is specified as a 16-bit vector, with the sub-vector of the supported number of bits set to 1. Examples: 0x00FF Maximum 8-bit LIODN capability 0x0FFF Maximum 12-bit LIODN capability
16–23 -	This field is reserved. Reserved
24–31 MSnpID	Maximum Snoop ID. These bits define the maximum Snoop ID capability of the system or the maximum Snoop ID that PAMU can signal to the Host/Coherency Domain. This field is specified as a 8-bit vector, with the sub-vector of the supported number of bits set to 1. The bits are coded as follows: 0x0F Maximum 4-bit Snoop ID or the capability for up to 16 unique Snoop IDs 0x1F Maximum 5-bit Snoop ID or the capability for up to 32 unique Snoop IDs 0xFF Maximum 8-bit Snoop ID or the capability for up to 256 unique Snoop IDs

10.4.36 PAMU Capabilities register 3 (PAMUx_PC3)

The fields in the PAMU capabilities registers denote implementation parameters for a given hardware instance of PAMU. The software must read these registers to discover the specific parameter values implemented in this instance of PAMU and utilize the information when programming PAMU, its data structures, and related system resources.

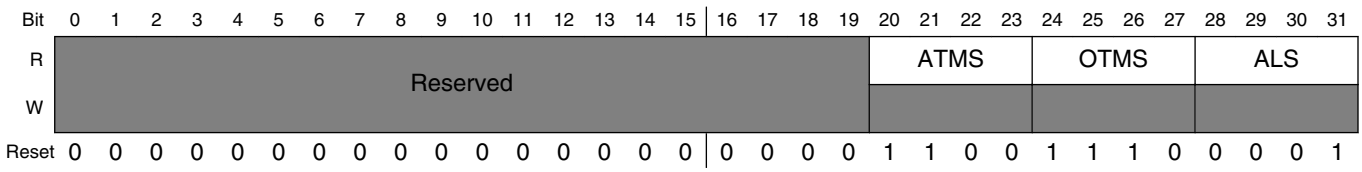


PAMUx_PC3 field descriptions

Field	Description
0–6 -	This field is reserved. Reserved
7–10 MWCE	Maximum Window Count Encoding. These bits define the maximum number of DSA sub-windows available to a LIODN. The window count identifies the maximum number of secondary PAACEs that the PAMU accesses to perform authorization and access control services. The maximum window count is $2^{(MWCE+1)}$ windows. **NOTE:** MWCE affects the maximum value of the WCE field in a PAACE that can be handled by this PAMU instance. Example: 0x3 Maximum 16 window count capability
11–14 MOMI	Maximum Operation Mapping Index. These bits define the number of least significant bits of the OMI field in a PAACE that are accessed and used as OMT index by this instance of PAMU. This field is specified as a 4-bit vector, with the sub-vector of the supported number of bits set to 1. The field thus defines the maximum number of operation mapping entries available to a LIODN for indexed operation type translation. **NOTE:** MOMI affects the maximum index value of the OMI field of a PAACE that can be handled by this PAMU instance. The bits are coded as follows: 0001 Indicates a maximum 2 OME capability 0011 Indicates a maximum 4 OME capability 0111 Indicates a maximum 8 OME capability 1111 Indicates a maximum 16 OME capability
15 -	This field is reserved. Reserved
16–22 MIOE	Maximum Ingress Operation Encoding. These bits define the number of least significant bits of an ingress operation encoding (IOE) that are used as an index into an OME to obtain an EOE mapping by this instance of PAMU. This field is specified as a 7-bit vector, with the sub-vector of the supported number of bits set to 1. **NOTE:** The field defines the maximum number of IOEs available to an LIODN for operation type translation through this PAMU instance. Example: 0x0F Indicates a maximum 16 IOE capability
23–31 -	This field is reserved. Reserved

10.4.37 PAMU Capabilities register 4 (PAMUx_PC4)

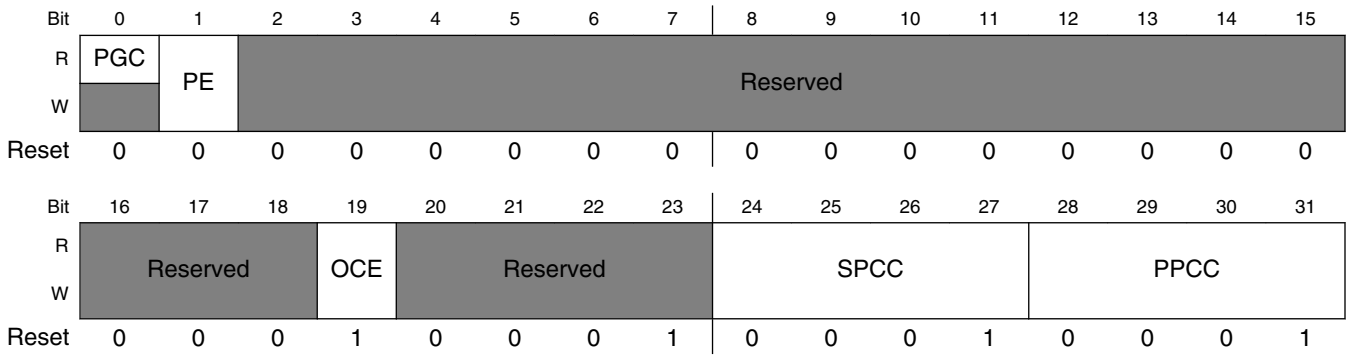
The fields in the PAMU capabilities registers denote implementation parameters for a given hardware instance of PAMU. The software must read these registers to discover the specific parameter values implemented in this instance of PAMU and utilize the information when programming PAMU, its data structures, and related system resources.



PAMUx_PC4 field descriptions

Field	Description
0–19 -	This field is reserved. Reserved
20–23 ATMS	ATM Support. These bits identify the address translation mode(s) supported by this instance of PAMU. The bits are coded as follows: Bit 20, when set, indicates that no address translation mode is supported by this PAMU. Bit 21, when set, indicates that window address translation mode is supported by this PAMU. Bits 22-23 are reserved. Example: 1100 Indicates PAMU support for the following address translation modes: No Address Translation. Window Address Translation.
24–27 OTMS	OTM Support. These bits identify the operation translation mode(s) supported by this instance of PAMU. The bits are coded as follows: Bit 24, when set, indicates that no operation translation mode is supported by this PAMU. Bit 25, when set, indicates that immediate operation translation mode is supported by this PAMU. Bit 26, when set, indicates that indexed operation translation mode is supported by this PAMU. Bit 27 is reserved. Example: 1110 Indicates PAMU support for the following operation translation modes: No Operation Translation Immediate Operation Translation Indexed Operation Translation
28–31 ALS	Architecture Level Support. These bits identify the version(s) of the PAMU architecture supported by this revision of the PAMU implementation. 0001 Indicates PAMU support for PAMU architecture Version 1.0 only

10.4.38 PAMU Control register (PAMUx_PC)



PAMUx_PC field descriptions

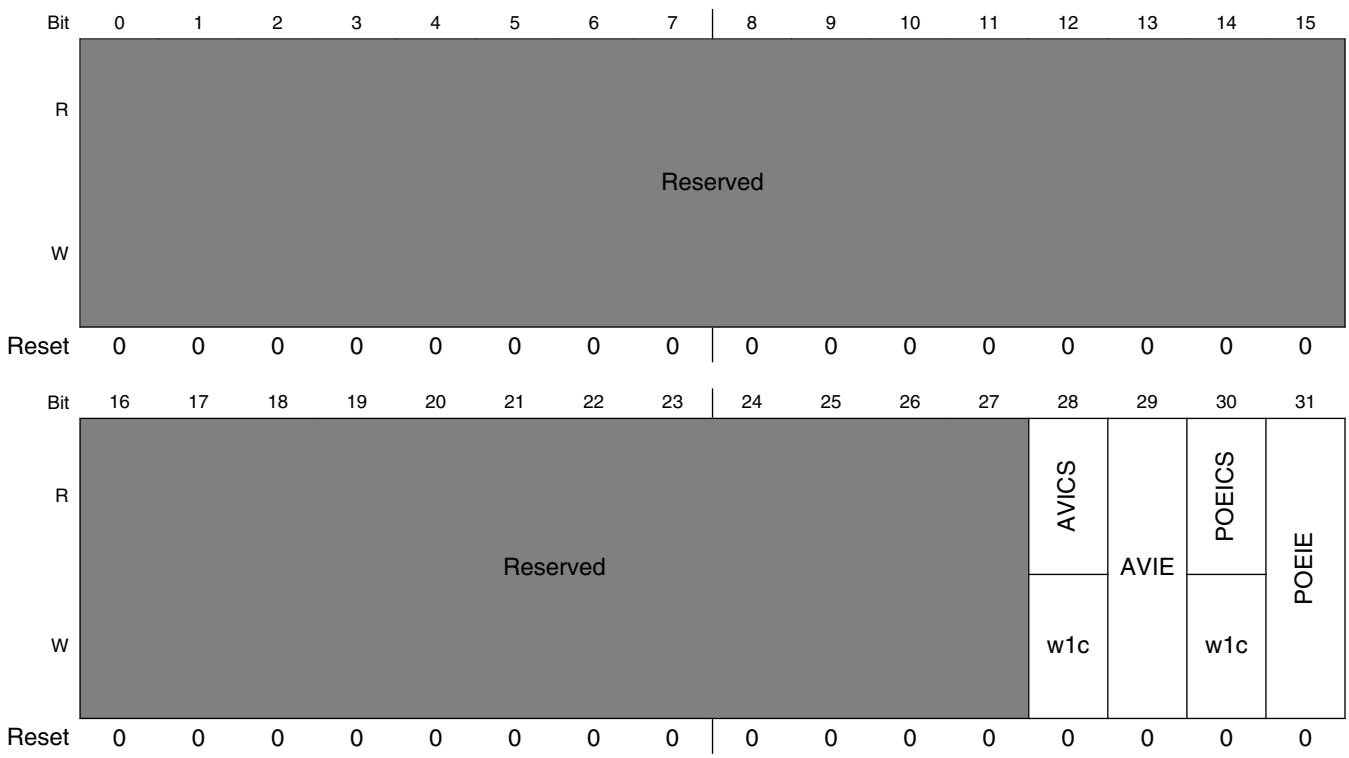
Field	Description
0 PGC	PAMU Gate Closed 0 PAMU gate open. PAMU may allow peripheral accesses, subject to authorization and access control. 1 PAMU gate closed. PAMU blocks all peripheral accesses.
1 PE	PAMU Enable This bit controls whether PAMU performs authorization and translation functions. This is to be set by software after setting up the authorization and translation data structures, PAMU and devices (including the setting of LIODNs). **NOTE:** • If PGC is set, or if PE is cleared, all peripheral accesses are blocked. • If PGC is cleared and PE is set, peripheral accesses are allowed based on the LIODN signaled with the access capabilities permitted for the LIOD. 0 PAMU Disabled 1 PAMU Enabled
2–18 -	This field is reserved. Reserved
19 OCE	OMT Cache Enable These bits define the OMT cache enable bit. 0 OMT cache disabled 1 OMT cache enabled
20–23 -	This field is reserved. Reserved
24–27 SPCC	Secondary PAACT Cache Control These bits, SPCC[0:3], define the properties of the secondary PAACT cache. SPCC[0:2] are reserved. SPCC[3] is the cache enable bit. 0 Secondary PAACT cache disabled 1 Secondary PAACT cache enabled

Table continues on the next page...

PAMUx_PC field descriptions (continued)

Field	Description
28–31 PPCC	Primary PAACT Cache Control These bits, PPCC[0:3], define the properties of the primary PAACT cache. PPCC[0:2] are reserved. PPCC[3] is the cache enable bit. 0 Primary PAACT cache disabled 1 Primary PAACT cache enabled

10.4.39 PAMU Interrupt Control and Status register (PAMUx_PICS)



PAMUx_PICS field descriptions

Field	Description
0–27 -	This field is reserved. Reserved
28 AVICS	Access Violation Interrupt Control and Status This bit provides status on whether the access violation interrupt pin is asserted and controls whether the access violation interrupt pin is to be deasserted. 0 Access violation interrupt pin is deasserted 1 Access violation interrupt pin is asserted.

Table continues on the next page...

PAMUx_PICS field descriptions (continued)

Field	Description
29 AVIE	Access Violation Interrupt Enable This bit identifies if an access violation interrupt is to be asserted. 0 No interrupt asserted if an access violation is detected 1 Access violation interrupt pin asserted if an access violation is detected
30 POEICS	PAMU Operation Error Interrupt Control and Status This bit provides status on whether the operation error interrupt pin is asserted and controls whether the operation error interrupt pin is to be deasserted. 0 Operation error interrupt pin is deasserted 1 Operation error interrupt pin is asserted.
31 POEIE	PAMU Operation Error Interrupt Enable This bit identifies if an operation error interrupt is to be asserted. 0 No interrupt asserted if an operation error is detected 1 Operation error interrupt pin asserted if an operation error is detected

10.5 PAMU Functional Description

The following is a brief description of the set-up requirements and sequence of events involving processing of DSA operations by PAMU.

10.5.1 System Set-Up for PAMU Operation

System software, for example, a Hypervisor, enumerates these physical I/O devices with one or more Logical I/O Device Numbers (LIODN).

Hypervisor then creates PPAACT and if necessary SPAACT and OMT in system memory (see Data Structures Used by PAMU).

After setting up the data structures, PAMU CCSRs are programmed, including the locations of the above data structures. After a PAMU is programmed, it is enabled to process DSA operations.

NOTE

Depending on reset configuration, the PAMUs may default to PAMU bypass mode. The PAMU bypass enable register in the device configuration module (DCFG_PAMUBYPENR) controls enabling and disabling PAMU bypass mode for each PAMU. PAMU bypass mode must be disabled for PAMU to authorize and translate transactions. See PAMU Bypass Mode

or No Operation Translation Mode for more information about PAMU bypass mode and PAMU Bypass Enable Register (DCFG_CCSR_PAMUBYPENR) for more information about disabling PAMU bypass mode.

10.5.2 Steps in Processing of DSA Operations by PAMU

Figure 10-4 illustrates the data structures and actions associated with processing of a DSA operation by PAMU.

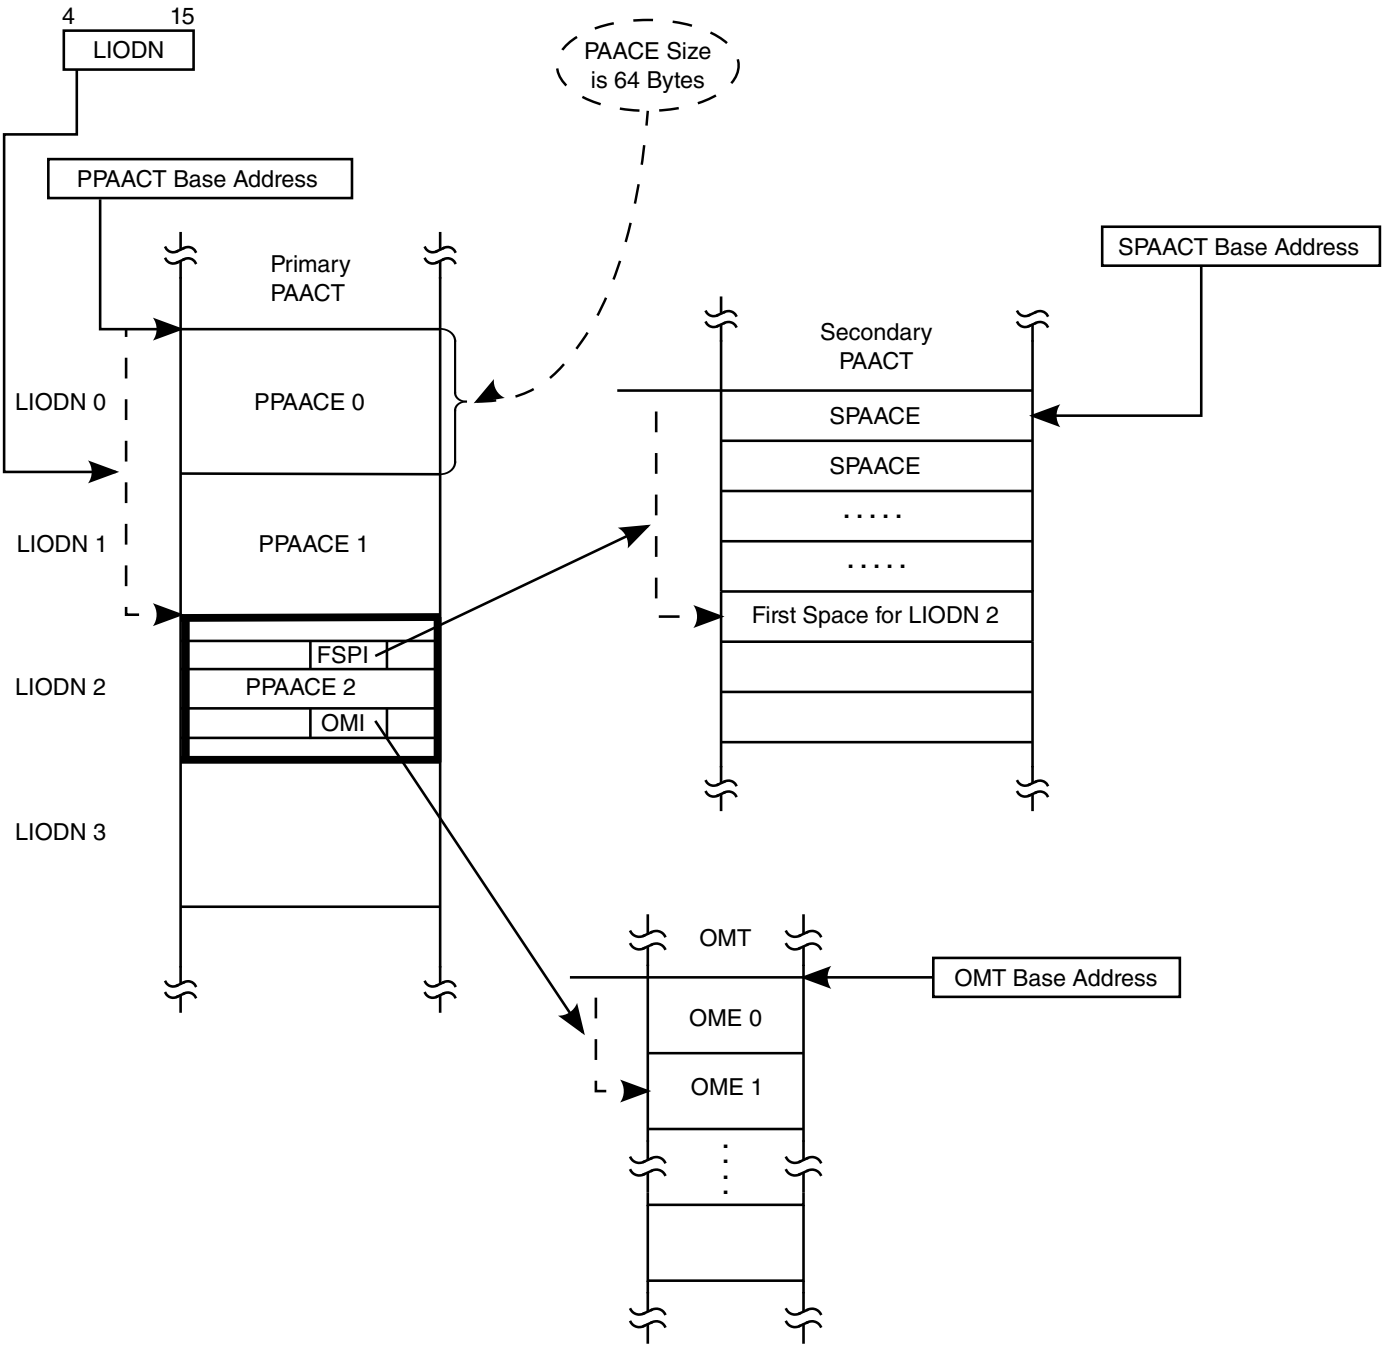


Figure 10-4. PAMU Operation flow overview

- An operation from a logical I/O device arrives at the entrance of the coherency domain. The operation carries with it the LIODN representing that logical device.
- PAMU uses the LIODN to look up the relevant PPAACE in the PPAACT cache.
- In the case of a cache-miss, PAMU will fetch the necessary data structure from the PPAACT in system memory.

- The contents of the PPAACE indicate if additional data structures have to be referenced to obtain all the necessary authorization and translation attributes for the operation by that LIODN to a particular DSA window.
- A secondary PAACE is accessed if the address accessed is beyond the primary sub-window.
- If the access falls beyond the windows assigned to the LIOD, it is considered an access violation.
- An OME is accessed optionally based on the value of the OTM. The base address of the operation mapping table (OMT) and the operation mapping index (OMI) contained in the PAACE are used to access the entry.
- The translated transaction type and operation is returned for forwarding to the destination domain.

The next section describes the above steps in greater detail.

10.5.3 Detailed Description of PAMU Actions

This section describes in detail the handling of DSA operations by PAMU.

10.5.3.1 PAMU Gate Closed and PAMU Enable Check

In secure boot mode, or if the PAMU Gate Closed (PGC) bit is set to 1, the PAMU will block all peripheral accesses through assertion of access violation regardless of the PAMU Enable (PE) bit setting and regardless of the signaled LIODN.

- If a PAMU lookup request were to be issued while the PGC bit is set to 1, an access violation is detected and bits are set in the relevant CCSRs (see PAMU Operation Error Address High register (PAMU_POEAH), through Access Violation Address Low register (PAMU_AVAL)).
  - The access violation (AV) detected bit is set.
  - The Gate Closed Violation (GCV) bit is set to indicate the peripheral access is not allowed.
  - The LIODN and DSA Address encountering the access violation is logged.

If the PGC bit is not asserted and the PE bit is not set, the PAMU will block all peripheral accesses regardless of the signaled LIODN.

If the PGC bit is not asserted and the PE bit is set, the PAMU will provide authorization and translation services for all peripheral accesses based on the signaled LIODN. Description of this flow is detailed in subsequent sections, starting with section PPAACT Request Range Check. This setting is recommended once all authorization and translation data structures have been set up in system memory space.

If secure boot and trust architecture is not enabled, the PAMU Gate Closed (PGC) bit can be cleared.

Table 10-8. PAMU Gate Closed and PAMU Enable Check

PAMU Gate Closed	PAMU Enable	PAMU Authorizing	Comments
0	0	Yes	Access Violation
0	1	Yes	Normal Operation
1	X	Yes	Access Violation

10.5.3.2 PPAACT Request Range Check

The following describes the manner in which the PAMU lookup request is checked to see if it falls within a valid range:

- During a PAMU lookup request, the LIODN of the operation is signaled along with the rest of the information that describes the DSA operation (address, operation type, and so on).
- The PPAACT base address programmed in the PPBARs (see Primary PAACT Base Address High register (PAMU_PPBAH), and Primary PAACT Base Address Low register (PAMU_PPBAL)) along with the LIODN as offset is used to generate the PPAACE address.
- The PPAACE address is checked against the PPAACT limit address programmed in the PPLARs (see sections Primary PAACT Limit Address High register (PAMU_PPLAH), and Primary PAACT Limit Address Low register (PAMU_PPLAL)).
- A PPAACE address higher than the PPAACT limit address is due to an erroneously or illegally signaled LIODN. An access violation has been detected and bits are set in the relevant CCSRs (see Access Violation Status register 1 (PAMU_AVS1), through Access Violation Address Low register (PAMU_AVAL)):
  - The access violation (AV) detected bit is set.
  - The LIODN access violation (LAV) bits are set to indicate the LIODN index is not within the PPAACT.
  - The LIODN and DSA address encountering the access violation is logged.

10.5.3.3 PPAACT Cache Lookup

The following describes the flow of a PPAACT cache lookup and the manner in which the information is used by the cache:

- During a PAMU lookup request, the LIODN of the operation is signaled along with the rest of the information that describes the DSA operation (address, operation type, and so on).
  - The LIODN is used to index into the PPAACT cache.
- The PPAACT base address programmed in the PPBARs (see Primary PAACT Base Address High register (PAMU_PPBAH), and Primary PAACT Base Address Low register (PAMU_PPBAL)) along with the LIODN offset is used to generate the PPAACE address.
  - A match of the PPAACE address against the stored tag of a valid entry indicates a cache hit while a mismatch indicates a cache miss. If the tag does not match, a cache miss has occurred.
- If a cache-hit occurs, ECC bits are computed for the contents of the PAACE and these ECC bits are compared against the ECC bits stored along with the PAACE. Mismatched ECC bits, indicates an ECC error.

10.5.3.4 PAMU Fetch Request

Fetch requests are issued to retrieve the relevant PAACE or OME from system memory. These requests are also issued when cache misses occur.

10.5.3.5 Primary PAACE Processing

The primary PAACE is processed for authorization, access control and optionally, translation:

- The WBA and WSE fields of the PPAACE are used to determine if the address of the DSA operation is within a valid window in the I/O bus address space.
  - If the operation is not within a valid window, an access violation has been detected and several bits are set in the relevant CCSRs (see Access Violation Status register 1 (PAMU_AVS1), through Access Violation Address Low register (PAMU_AVAL)):
    - The access violation (AV) detected bit is set.

        - The window access violation (WAV) bits are set to indicate a window access violation has occurred.
        - The LIODN and DSA address encountering the access violation is logged.
- The MW field of the PPAACE is used to determine if DSA sub-windows exist.
    - The WCE field indicates the number of DSA sub-windows if DSA sub-windows exist.
- The least significant WSE+1 bits of the DSA address represent its offset (DSA window offset or DWO) within the LIOD's DSA window.
- The Sub-window index (SWI) is the most significant WCE+1 bits of the DWO.
- If the MW bit is set and if SWI = 0, then PPAACE is being accessed. In this case the SWSE field of the PPAACE is used to check if the DSA address is valid, that is, it falls within the defined sub-range.
    - If the address of the DSA operation is not within the sub-range, an access violation has been detected and bits are set in the relevant CCSRs (see Access Violation Status register 1 (PAMU_AVS1), through Access Violation Address Low register (PAMU_AVAL)):
        - The access violation (AV) detected bit is set.
        - The window access violation (WAV) bits are set to indicate a sub-window access violation has occurred.
        - The LIODN and DSA address encountering the access violation is logged.
    - If the address of a DSA operation is valid, the access permission (AP) field of the PPAACE is used to determine if the DSA operation is from a valid LIOD that has permission to issue transactions to system storage space. If the AP indicates access is denied or if the specific type of access is not permitted, bits are set in the relevant CCSRs (see Access Violation Status register 1 (PAMU_AVS1), through Access Violation Address Low register (PAMU_AVAL)):
        - The access violation (AV) detected bit is set.
        - The LIODN and DSA address encountering the access violation is logged.
        - The access permission violation (APV) bits are set to indicate the type of violation that has occurred:
            - If AP indicates that access is denied, either the DSA operation has signaled an invalid LIODN or this LIOD does not have access permissions to this system storage space, that is, the DSA window or sub-window has not been provided to the LIOD assigned the LIODN. The APV bits are set to indicate access has been denied to either the DSA window or sub-window.
            - The AP field of the entry is also used to determine if the type of operation is within the access privileges for that LIOD. Bit 0 of the IOE of the operation is compared against the permitted operation type(s) identified in the AP field. If the type of DSA operation is not permitted,

the APV bits are set to indicate an illegal access type to either the DSA window or sub-window.

- If SWI != 0, the PAACE being referenced is a SPAACE. See SPAACE Access and Processing.
- Details on how address translation is performed is detailed in Address Translation Service.
- Details on how the DSA operation type is processed is detailed in OMT Access and Service.

10.5.3.6 SPAACE Access and Processing

If SWI != 0, the DSA address indicates that the relevant PAACE is a SPAACE, and the PAMU will perform a lookup on the SPAACT as follows:

If the PPAACE indicates multiple window capability and the window count is n, then:

- The attributes for the DSA sub-window defined by addresses where SWI = 0 are contained in the PPAACE.
- The attributes for the DSA sub-window defined by addresses where SWI = 1 are contained in the SPAACE located at the FSPI of SPAACT.
- The attributes for the DSA sub-window defined by addresses where SWI = 2 are contained in the SPAACE located at the FSPI + 1.
- The attributes for the DSA sub-window defined by addresses where SWI = *n* - 1 (n > 1) are contained in the SPAACE located at the FSPI + (n-2).

See Figure 10-3 for an example illustration for n = 4.

The PAMU also performs an SPAACT range check based on the address of the SPAACE being accessed (see SPAACT Request Range Check).

10.5.3.6.1 SPAACT Request Range Check

The following describes the manner in which the SPAACE address is checked to see if it falls within a valid range:

- The SPAACE address is checked against the SPAACT limit address programmed in the SPLARs (see Secondary PAACT Limit Address High register (PAMU_SPLAH), and Secondary PAACT Limit Address Low register (PAMU_SPLAL)).
- A SPAACE address higher than the SPAACT limit address is due to an erroneous or illegal DSA address. An access violation has been detected and bits are set in the relevant CCSRs (see Access Violation Status register 1 (PAMU_AVS1), through Access Violation Address Low register (PAMU_AVAL)):
  - The access violation (AV) detected bit is set.

- The window access violation (WAV) bits are set to indicate a sub-window access violation has occurred.
- The LIODN and DSA address encountering the access violation is logged.

10.5.3.6.2 SPAACT Cache Lookup Request

SPAACT cache lookup requests are issued to retrieve the relevant SPAACE from the SPAACT cache.

- If the lookup results in a cache hit, the ECC status is checked.
  - If the ECC status indicates an error, bits are set in the relevant CCSRs (see ECC Error Control Register (PAMU_EECTL), through ECC Error Data Low (PAMU_EEDLO)).
- If the lookup response indicates a cache-miss, the SPAACE fetch request is issued.

10.5.3.6.3 Secondary PAACE Processing

Lists secondary PAACE processing:

- The SWSE field of the SPAACE is used to determine if the address of the DSA operation is within a valid sub-range in the I/O bus address space.
  - If the operation is not within the valid sub-range within the DSA sub-window, an access violation has been detected and bits are set in the relevant CCSRs (see Access Violation Status register 1 (PAMU_AVS1), through Access Violation Address Low register (PAMU_AVAL)):
    - The access violation (AV) detected bit is set.
    - The window access violation (WAV) bits are set to indicate a sub-window access violation has occurred.
    - The LIODN and DSA Address encountering the access violation is logged.
- If the address of a DSA operation is within the valid sub-range within the DSA sub-window, the Access Permission (AP) field of the SPAACE is used to determine if the DSA operation is from a valid LIOD that has permission to issue transactions to system storage space. If the AP indicates access is denied or if the specific type of access is not permitted, bits are set in the relevant CCSRs (see Access Violation Status register 1 (PAMU_AVS1), through Access Violation Address Low register (PAMU_AVAL)):
  - The access violation (AV) detected bit is set.
  - The LIODN and DSA Address encountering the access violation is logged.
  - The Access Permission Violation (APV) bits are set to indicate the type of violation that has occurred:

- If AP indicates that access is denied, this LIOD does not have access permissions to the DSA sub-window. The APV bits are set to indicate access has been denied to the DSA sub-window.
- The AP field of the entry is also used to determine if the type of operation is within the access privileges for that LIOD. IOE[0] of the operation is compared against the permitted operation type(s) identified in the AP field. If the type of DSA operation is not permitted, the APV bits are set to indicate an illegal access type to the DSA sub-window.

- Details on how address translation is performed is detailed in Address Translation Service.
- Details on how the DSA operation type is processed is detailed in OMT Access and Service.

10.5.3.7 Address Translation Service

The address of the DSA operation issued by the LIOD falls within the I/O address space. This section describes the mechanisms to direct DSA operations in I/O address space to the corresponding locations in system storage space.

When a valid PAACE is referenced for a DSA operation from a LIOD, the DSA address translation mode field of the PAACE is used to determine if the additional step of address translation is needed for that DSA operation. There can be two types of encodings indicated in the ATM field, as follows:

- No address translation mode
- Window address translation mode

10.5.3.7.1 No Address Translation Mode

If the address range of system storage space is equal to or less than the address range of the I/O address space, and a particular LIOD has the addressing capability to access the address range of system storage space, then the no address translation Mode may be enabled because the LIOD does not have any addressability limitations to locations in system storage space.

The following describes how no address translation mode is achieved for DSA operations:

- The I/O bus address of the DSA operation is also the system storage address.
- Because there is no address translation, the DSA window must be contained within the system storage space.
- Figure 10-5 shows an example of DSA operations with no address translation.

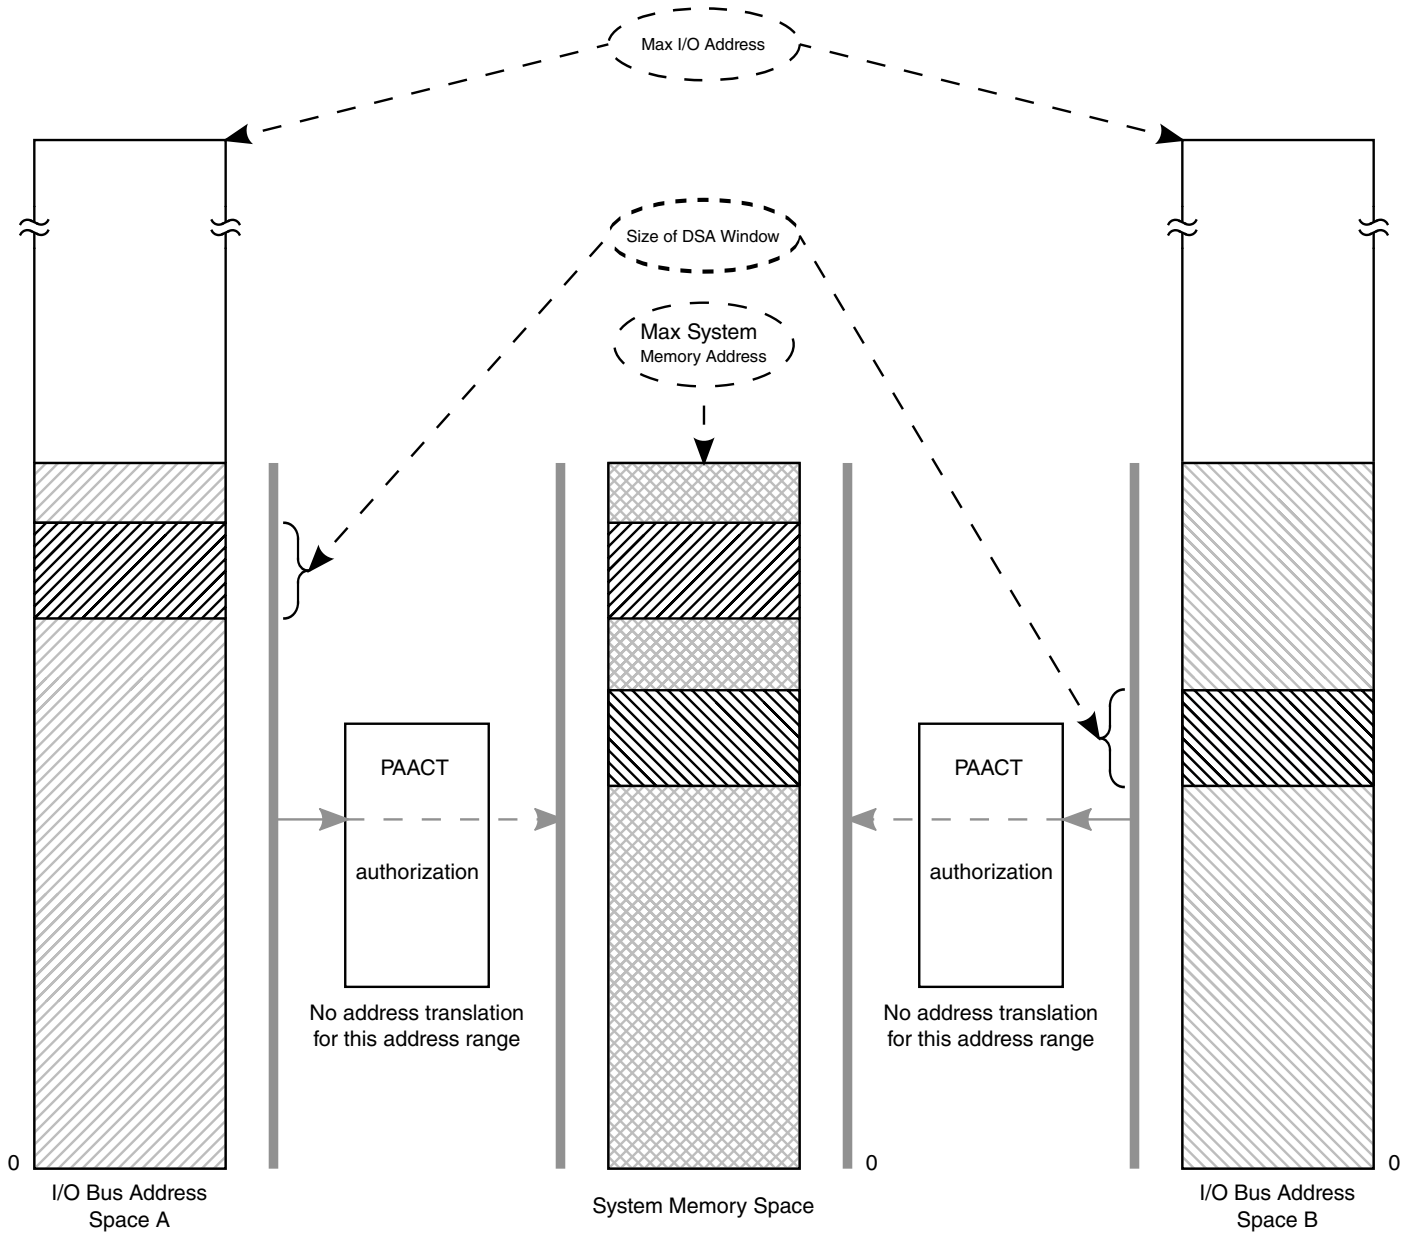

Figure 10-5. DSA Operations with No Address Translation

10.5.3.7.2 Window Address Translation Mode

Window address translation allows the capability for a LIOD to direct DSA operations to a contiguous DSA window in I/O bus address space that get translated to a contiguous window of the same size in system storage space.

While no address translation mode implies that the system address is identical to the I/O bus address, with window address translation mode the DSA window can be located anywhere in the I/O bus address space including an address range where the addressing width of the I/O bus address space is larger than that defined for system storage space.

The following describes how DSA operations are achieved when window address translation is enabled:

- The TWBA field of the PAACE defines the base address of the DSA window in system storage space (see Figure 10-7). As mentioned in Table 10-6, TWBA is aligned to the size to the window described by the PAACE:
- If MW is disabled, the size of the window is indicated by the WSE field of the PAACE
- If MW is enabled, the size of the window is indicated by the SWSE field of the PAACE
- The window size is also used to determine which bits of the I/O bus address used in the DSA operation will be retained in the system storage address (also shown in Figure 10-7). because the minimum window size is 4 Kbytes, the 4-Kbyte address offset is always retained.
- Figure 10-7 shows an illustration of DSA operations with window address translation.

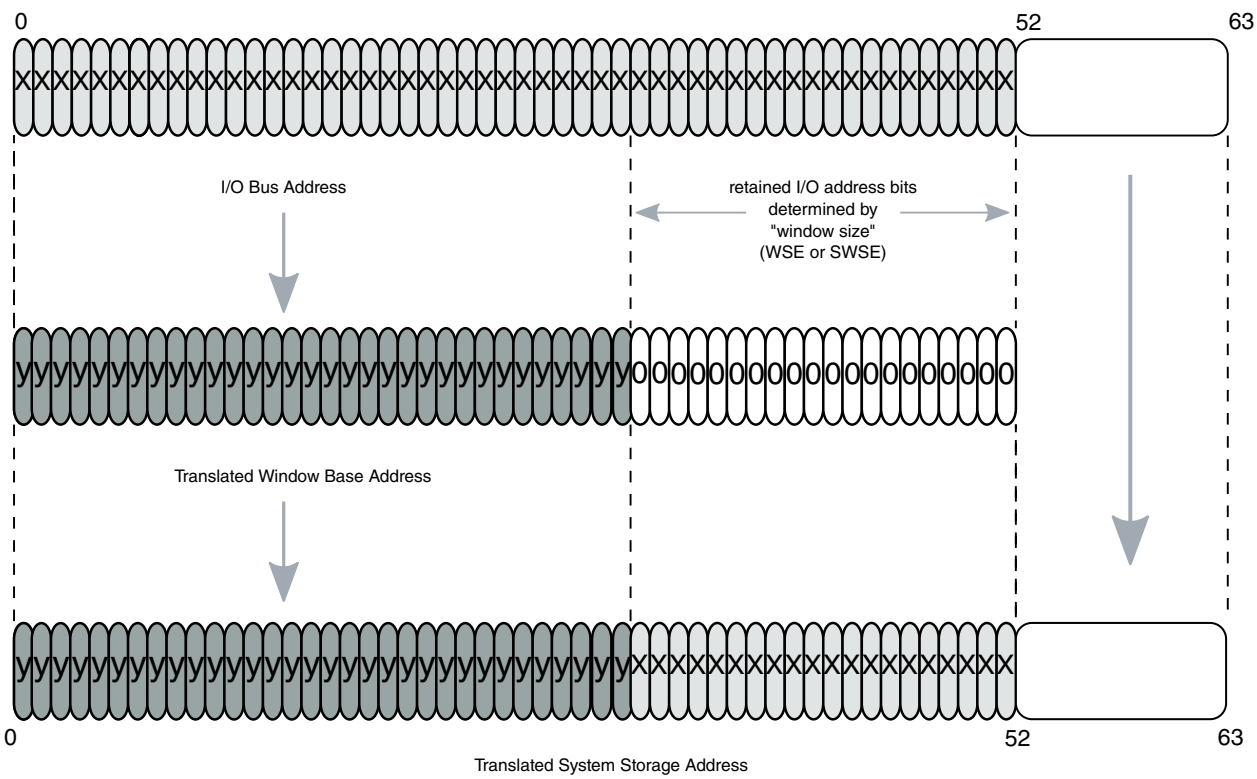

Figure 10-6. Window Address Translation

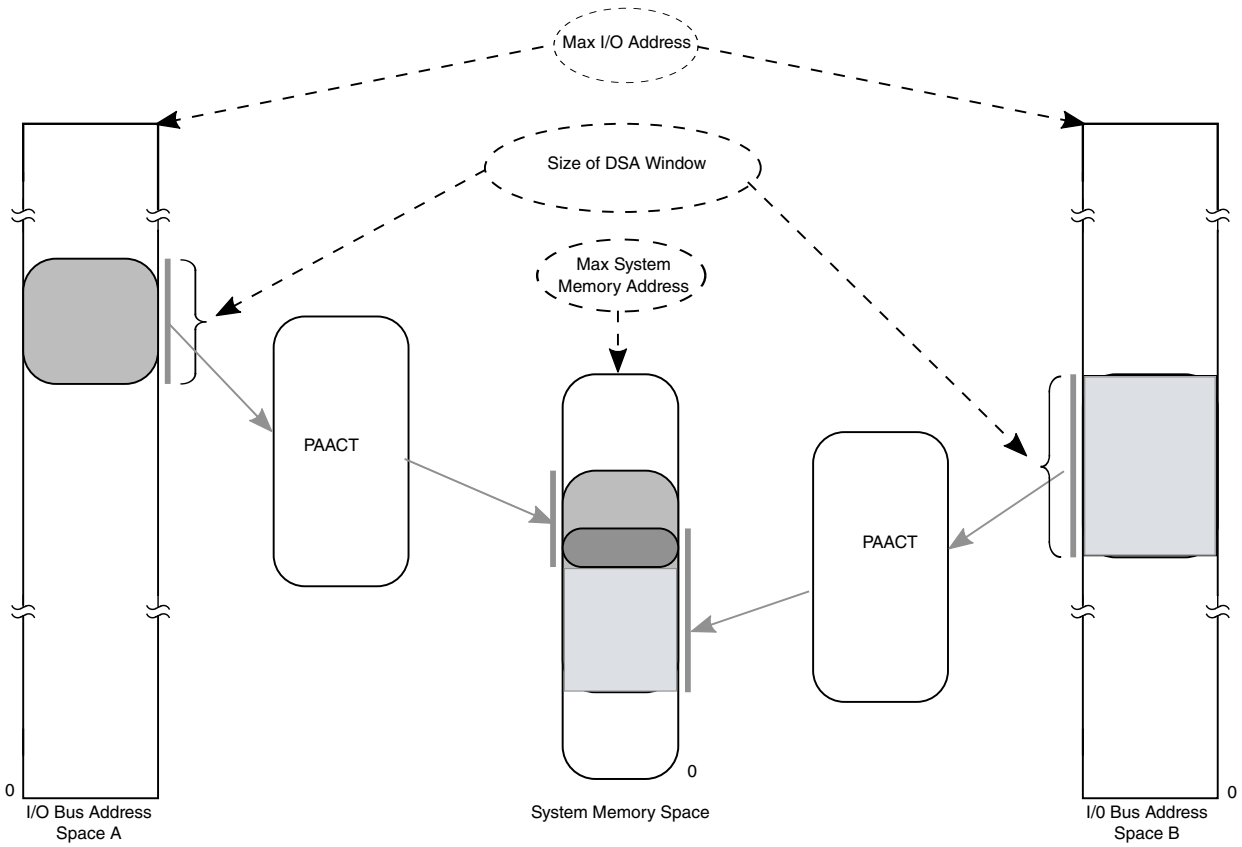

Figure 10-7. DSA Operations with Window Address Translation

10.5.3.8 OMT Access and Service

A DSA operation issued by a LIOD has an ingress operation encoding. This section describes the mechanisms to check a DSA operation's ingress operation encoding and optionally remap the encoding to a corresponding egress operation encoding.

When a valid PAACE is referenced for a DSA operation from a LIOD, the Operation Translation Mode field of the entry is used to determine the type of operation translation needed for that DSA operation. There can be three types of encodings indicated in the OTM field, as follows:

- No operation translation
- Immediate translation mode
- Indexed translation mode

10.5.3.8.1 No Operation Translation

If the source and destination protocols of the DSA operation are the same or the same ingress and egress encodings can be used to express the operation types, No operation translation may be required.

The following describes how no address translation mode is achieved for DSA operations:

- The I/O operation type of the DSA operation is also the operation type of the interconnect protocol in system storage space, or the I/O operation encoding can also be used to express the operation encoding in system storage space.

10.5.3.8.2 Operation Type Translation

The translation process starts by the PAMU-resident hardware encoding an incoming DSA operation type.

The output of the encode function is a 8-bit code called the ingress operation encoding. As mentioned in PAACE Offset 0x18, bit 0 of the ingress operation encoding is the operation type qualifier:

- If IOE[0] is a 0, the DSA operation's ingress transaction is a query type of operation.
- If IOE[0] is a 1, the DSA operation's ingress transaction is a update type of operation.

The ingress operation types and their corresponding encodings to the least significant 7-bits of the IOE is I/O domain specific.

Immediate Translation Mode

The following describes DSA operation mapping when OTM indicates immediate translation mode:

- If the IOE matches the encoding contained in the IOEA field of the PAACE:
  - bit-0 of the MOEA field of the PAACE indicates whether the field contains a valid egress operation encoding.
  - If bit-0 of the MOEA field is set, MOEA[1:7] contains the corresponding egress operation encoding A (EOEA).
  - If bit-0 of the MOEA field is not set, an access violation has been detected.
- If the IOE matches the encoding contained in the IOEB field of the PAACE:
  - bit-0 of the MOEB field of the PAACE indicates whether the field contains a valid egress operation encoding.

    - If bit-0 of the MOEB field is set, MOEB[1:7] contains the corresponding egress operation encoding B (EOEB).
    - If bit-0 of the MOEB field is not set, an access violation has been detected.
- If the IOE does not match both IOEA and IOEB, an access violation has been detected.

Indexed Translation Mode

The following describes DSA operation mapping when OTM indicates indexed translation mode:

- The contents of the OMI field of the PAACE are used to index into the relevant OME off the OMT base address[1] (see example in Figure 10-8).
- The least significant 7-bits of the IOE is used to index into the OME to obtain the relevant MOE to be used[2] .
- The selected MOE contains the egress operation encoding[3]
    - bit-0 of the MOE field indicates whether field contains a valid egress operation encoding.
    - If bit-0 of the MOE field is set, MOE[1:7] contains the corresponding egress operation encoding (EOE).
    - If bit-0 of the MOE field is not set, an access violation has been detected.

1. PAMU caches the OMT to improve translation performance.
2. Thus, in the limit, up to 128 operation types may be translated.
3. A system could consolidate all operation mappings into a single global OMT with various PAACEs using appropriate indices into the table via their OMI fields.

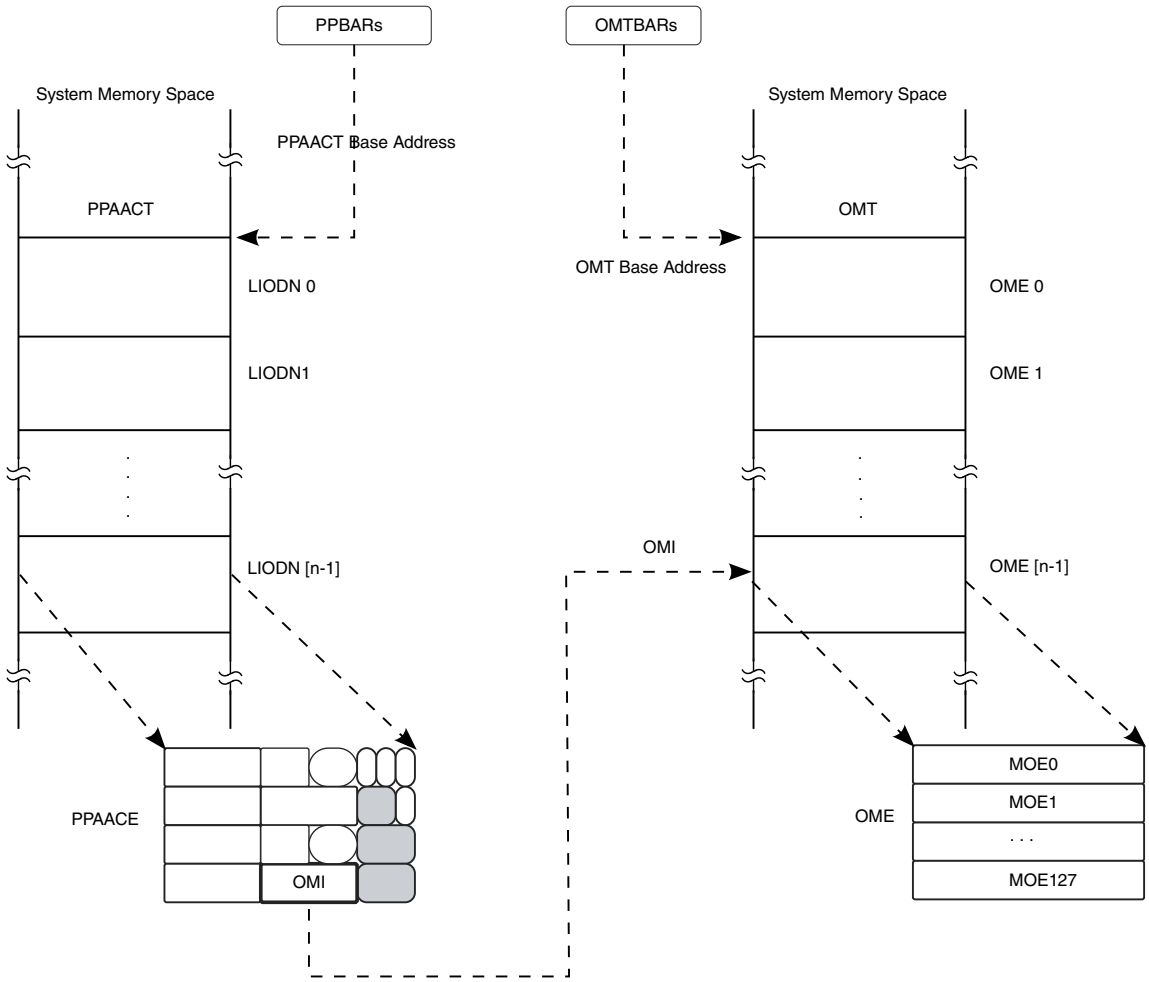

Figure 10-8. PPAACE to OME mapping in System Memory Space

10.5.3.8.3 OMT Cache Access

If the operation translation mode indicates that accessed location requires indexed operation translation performed, the PAMU will perform a lookup on the OMT cache:

- The OMT base address programmed in the OMTBARs see OMT Base Address Low register (PAMU_OBAL) and OMT Base Address High register (PAMU_OBAH) along with the OMI offset contained in the PAACE is used to determine the OME address.
- The MOMI-indicated least significant bits of the OMI are used to index into the OMT cache.
- The valid bit at the OMI index location is used to determine whether the relevant OME is in the cache.

- On a cache miss, the PAMU accesses the OME address from the system memory.
- The MIOE-indicated least significant bits of the IOE are used to index into the OME to determine the 8-bit MOE and the EOE within it.

10.5.3.9 Access Violation

As described in previous sections, during the process of authorizing and checking access permissions, PAMU may detect access violations.

In addition to logging relevant error information in the access violation CCSRs (see Access Violation Status register 1 (PAMU_AVS1), through Access Violation Address Low register (PAMU_AVAL)), the following actions may also be incurred.

- An interrupt is optionally asserted based on the setup in the interrupt mapping CCSR (see PAMU Interrupt Control and Status register (PAMU_PICS)).
- For DSA operations encountering access violations, the system terminates write operations and return 0s for read operations.

10.6 PAMU Initialization/Application Information

This section describes system/software configuration and set-up of the data structures and PAMU for system implementations. This section also describes system/software interactions of the data structures and PAMU during run-time operation.

10.6.1 System Set-Up

Before the LIODs can initiate DSA operations in the system, the Hypervisor must do the following:

- Create the necessary data structures: PAACTs and OMTs in system memory.
- Set up the PAMU (see Setting Up PAMU).
- Program the corresponding LIODNs for the LIODs. Hypervisor assigns a unique LIODN to a given LIOD of a given I/O domain.

10.6.1.1 Setting Up PAMU

Each PAMU has CCSRs (see PAMU Memory Map) that Hypervisor must either enable or program with the relevant locations of the data structures in system memory space:

- The base and limit addresses of the memory-resident tables accessed by PAMU are programmed. Note that a PAMU instance can access at most one instance of each of these tables at a time.
  - The primary PAACT base and limit address registers, PPBARs and PPLARs, are programmed with the relevant locations of the PPAACT.
  - The secondary PAACT base and limit address registers, SPBARs and SPLARs, are programmed with the relevant locations of the SPAACT.
  - The OMT base and limit address registers, OMTBARs and OMTLARs, are programmed with the relevant locations of the PPAACT.
- The PAMU control register is programmed to enable the necessary caches resident in the PAMU hardware.
- As the last step, the PAMU enable bit in PAMU CCSR space must be set by Hypervisor. PAMU will now enforce authorization, translation, or access control based on the signaled LIODN.

10.6.1.2 Power-On Reset

Coming out of reset, Hypervisor must program PAMU configuration registers (PPBARs, PPLARs, SPBARs, SPLARs, OMTBARs, OMTLARs, PC) before enabling PAMU.

After programming PAMU configuration registers, Hypervisor must enable PAMU by setting PE bit in PAMU control register.

10.6.2 System with Multiple PAMUs

Each PAMU may have access to authorization and access control data structures that are unique to that PAMU. Alternatively, each PAMU may have access to a common set of authorization and access control data structures. These considerations influence how each PAMU is set up.

While multiple PAMUs may share common settings in terms of accessing data structures in system memory space, the control and status registers are unique to each PAMU. For example, the error control and status registers log error information unique to each PAMU.

10.6.2.1 PAACT Locations

If the desired setup is a single set of peripheral access, authorization, and control tables (PAACTs) that are accessed by all PAMUs in the system, each PAMU would be programmed with the same primary base address and limit locations and the same secondary base address and limit locations in the corresponding CCSRs.

If the desired setup is a unique set of PAACTs for access by each PAMU in the system, each PAMU would be programmed with unique primary base address and limit locations and unique secondary base address and limit locations corresponding to the unique primary and secondary PAACT locations in system address space.

10.6.2.2 OMT Locations

Similar to the PAACT setup described in PAACT Locations, either the desired setup is a single operation mapping table (OMT) that is accessed by all PAMUs in the system, or a unique table for access by each PAMU in the system.

Accordingly, all PAMUs would either be programmed with the same base address and limit locations or each PAMU would be programmed with a unique base address and limit locations corresponding to the unique OMT location in system address space.

Note that it is possible for multiple PAMUs to have unique OMT base and limit addresses programmed but have the same PPAACT base and limit address and SPAACT base and limit address programmed. This would allow for protocol specific operation translation capabilities unique to the protocol being bridged while accessing a single set of PAACT and associated data structures that contain the authorization, access control, and address translation properties unique to each LIODN.

10.6.2.3 Location of PAACT and OMT Data Structures

Regardless of whether there is a single set of PAACTs or OMT common to all PAMUs or PAACTs or OMT unique to each PAMU, these structures must be placed in one contiguous window for efficiency in the hardware coherency mechanisms.

The single window is defined in a LAW that has the coherency sub-domain identifier (CSDId) field of the LAW set up in a manner that includes the relevant PAMUs in the coherency sub-domain. PAMU Cache Coherency, provides details on the setup and use of CSDId towards maintaining coherency.

10.6.3 Peer-to-Peer I/O Operations

The memory map of the system must be set up in a particular manner for authorization, access control and translation services to be made available for peer-to-peer I/O operations:

- The source peer I/O device issues an operation to I/O address space.
- CCSRs across the hierarchy relating to address decode and/or routing are set up such that the operation is sent upstream from the I/O to the host/coherency domain.
- System interface on receiving the operation performs a PAMU lookup.
- PAMU authorizes the operation and checks the access permissions.
- The translated address provided by PAMU is the address of the operation in system memory space.
- The operation with the translated system address is forwarded to the system.
- System address of the operation decodes to a LAW that identifies the peer I/O device as the destination of the operation.
- The system forwards the operation to the relevant target device.
- CCSRs across the hierarchy relating to address decode and/or routing, including the target ID designation, are set up such that the operation is sent downstream from the host/coherency domain to the destination peer I/O device.
- As a result, the destination peer I/O device receives an operation that has had authorization, access control and translation services performed.

10.6.4 PAMU Cache Coherency

The presence of caches in PAMU is transparent to application software. However, hardware coherency mechanisms are applied in order for PAMU to maintain coherent copies of the PAACT or OMT data structures in system memory.

There are system setup considerations for maintaining coherent caches:

- A mastering agent, for example, a CPU, accesses either the PAACT or OMT locations in system memory.
- The system performs address decode to determine the particular LAW to be referenced for the access.
- The relevant LAW contains the coherency sub-domain identifier (CSDId) which in turn identifies all ports that are to be snooped by that operation.
- Because this access is to a PAACT or OMT location, CSDId must be set up to include ports that have PAMUs present.

10.6.5 Quiescing I/O Devices

10.6.5.1 Quiescing I/O Devices for Table/Entry Updates

While PAMU maintains coherent copies of the system memory resident data structures, a race condition still exists when device activity causes PAMU to reference in the PAMU cache a stale copy of the data structure.

This is because the cache invalidating operations, related to the data structure update activity, is still in flight in the system/platform and has not reached PAMU before PAMU references the cache.

Therefore, when system software, for example, a Hypervisor, updates or moves either the PAACT or OMT locations, the software should ensure that there are no peripheral devices performing operations that require the referencing of those data structures. It may do so by quiescing the activities of the relevant I/O devices.

10.6.5.2 Quiescing I/O Devices for Enabling PAMU and its Caches

When system software, for example, a Hypervisor, enables PAMU (see PAMU Control register (PAMU_PC)) or enables one or more of its caches, the software should ensure that there are no peripheral devices performing operations that require the referencing of PAMU and its caches.

Therefore, software should quiesce activity by I/O devices that would cause a PAMU lookup to occur.

10.6.6 Locality of References

The efficiency of the PPAACT, SPAACT, and OMT caches depends on how the LIODNs are enumerated, the placement of entries in system memory space, and the size of the DSA window.

10.6.6.1 Spatial Locality

The benefits associated with spatial locality of references apply to both the locality of LIODNs that accompany the different transactions flowing toward the same PAMU as well as the locality of the addresses contained within the transactions themselves:

- Enumerating LIODNs under a particular PAMU in linear order reduces the likelihood of thrashing of PPAACEs stored in the PPAACT cache.
- Placing the secondary PAACEs for one LIODN in linear order with respect to other LIODNs under the same PAMU reduces the likelihood of thrashing of SPAACEs stored in the SPAACT cache.

10.6.6.2 Temporal Locality

Achieving temporal locality of references in the caches is more a function of the size of the DSA window described by the PAACE.

With the maximum transfer size in the coherency domain being 64-bytes, even the minimum 4 Kbyte granularity allowed by the architecture for a PAACE window size results in 64 references to the same PAACE for the case of a 4 Kbyte DSA access. Assigning window sizes larger than 4 Kbyte to a PAACE will result in a correspondingly higher temporal locality of reference for PAACEs stored in the PAMU cache.

10.6.7 Recovering Address Space

The architecture has several fields and settings defined as a 2^n (power-of-two) value.

These values may lead to consumption of a larger address space than desired, either I/O address space or system memory space. However, it is possible to recover unallocated address space.

10.6.7.1 Primary PAACT Address Window

While LIODN is defined as a 2^n (power-of-two) value, implementations that have less than 2^n LIODNs can have system software set up the primary PAACT limit address registers to the location in system memory space following the 64-byte index location indicated by the last valid LIODN value.

10.6.7.2 Secondary PAACT Address Window

While the locations of secondary PAACEs are determined by the FSPI index in each PPAACE, system software can set up the secondary PAACT limit address registers to the location in system memory space following the last SPAACE index location of the last valid LIODN that has multiple sub-window capability.

10.6.7.3 Secondary Sub-Windows and PAACEs

The number of sub-windows for a particular LIODN is a function of the window count encoding (WCE) field in the primary PAACE, defined as a 2^n (power-of-two) value.

Correspondingly, the number of secondary sub-windows and SPAACEs to be accessed for that LIODN is (2^n - 1). The secondary sub-windows described by the SPAACEs start with the SPAACE at the FSPI index location in the SPAACT that describes the first secondary sub-window. Subsequent sub-windows are described by subsequent SPAACEs after the SPAACE at the FSPI index location.

Implementations that have less than (2^n - 1) secondary sub-windows, and therefore less than (2^n - 1) SPAACEs for a particular LIODN can have that LIODN programmed into the LIODN field for only the required number of SPAACEs. This allows for the recoverability of the I/O bus address space for unallocated sub-windows for that LIODN. This also allows for the recoverability of SPAACE index locations in the SPAACT.

10.6.8 Data Structure Size and Alignment

While the Architecture describes the size of a PAACE as being 64-bytes and OME as being 128-bytes, the PAMU implementation only references the defined 32-bytes of the PAACE data structure and 16-bytes of the OME data structure.

However, in order to maintain programming model consistency with the architecture across multiple generations of PAMU implementations, software must maintain the 64-byte and 128-byte address alignment for the PAACE and OME data structures respectively.

10.7 PAMU Setup

10.7.1 PAMU Operation Encoding

The specification allows for several methods to achieve the ingress and egress operation encoding (IOE & EOE) from the source and destination interconnect protocols. For this chip, an implementation-specific decode table will be used to achieve both the ingress and egress operation types (see Figure 10-9):

- The IOE is acquired from an SoC-specific Ingress Decode Table (IDT) that identifies the operation type that generate a particular IOE.
- The EOE is an index into an SoC-specific Egress Decode Table (EDT) that elaborates the CoreNet transaction type to be generated.

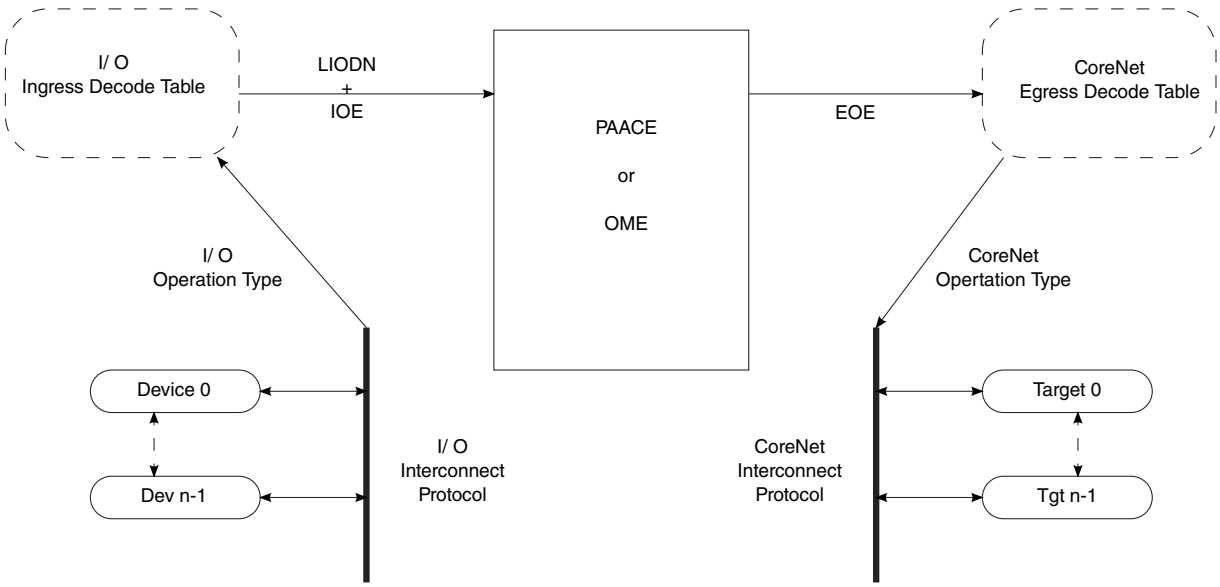

Figure 10-9. Illustration: Generation of Ingress and Egress Operation Encodings

10.7.1.1 Ingress Operation Encoding (IOE)

Table 10-9 describes the ingress operation encodings that are issued on the PAMU Lookup Interface.

Table 10-9. PAMU Ingress Operation Encodings

Ingress Operation Encoding [0:7]	Name	Description
0_000_0000	READ	Read
1_000_0001	WRITE	Write
1_000_0010	EREAD0	Enhanced Read Type 0
1_000_0011	EWRITE0	Enhanced Write Type 0
1_000_0100	DIRECT0	Directive Type 0
1_000_0101	EREAD1	Enhanced Read Type 1
1_000_0110	EWRITE1	Enhanced Write Type 1
1_000_0111	DIRECT1	Directive Type 1
1_000_1100	RAC	Read with Atomic Clear
1_000_1101	RAS	Read with Atomic Set
1_000_1110	RAD	Read with Atomic Decrement

Table continues on the next page...

Table 10-9. PAMU Ingress Operation Encodings (continued)

Ingress Operation Encoding [0:7]	Name	Description
1_000_1111	RAI	Read with Atomic Increment
All other encodings are reserved		

10.7.1.2 Egress Operation Encodings

Table 10-10 describes the egress operation encodings that are issued on the PAMU Lookup Response Interface. The EOEs are indexes into CoreNet commands.

NOTE

EOE[0] is not referenced for the Egress Decode Table. This is because EOE[0] == MOE[0] which determines if the EOE is valid in either the PAACE or OME.

Table 10-10. PAMU Egress Decode Table[1]

EOE [1:7]	Description
READ (000_0000)	Read
WRITE (000_0001)	Write
RAC (000_1100)	Read with Atomic Clear
RAS (000_1101)	Read with Atomic Set
RAD (000_1110)	Read with Atomic Decrement
RAI (000_1111)	Read with Atomic Increment
LDEC (001_0000)	Load External Cache
LDECL (001_0001)	Load External Cache with Stash Lock
LDECPE (001_0010)	Load External Cache with Preferred Exclusive
LDECPEL (001_0011)	Load External Cache with Preferred Exclusive and Lock
LDECFE (001_0100)	Load External Cache with Forced Exclusive
LDECFEL (001_0101)	Load External Cache with Forced Exclusive and Lock
RSA (001_0110)	Read with Stash Allocate
RSAU (001_0111)	Read with Stash Allocate and Unlock
READI (001_1000)	Read with Invalidate
RWNITC (001_1001)	Read with No Intention to Cache
WCI (001_1010)	Write Cache Inhibited

Table continues on the next page...

Table 10-10. PAMU Egress Decode Table[1] (continued)

EOE [1:7]	Description
WWSA (001_1011)	Write with Stash Allocate
WWSAL (001_1100)	Write with Stash Allocate and Lock
WWSOT (001_1101)	Write with Stash or Target
WWSOTL (001_1110)	Write with Stash Allocate and Lock or Target
All other encodings are reserved	

1. Stashing capability is restricted to 64-byte operations in the chip. Operations < 64 bytes will not have the stash portion of the operation performed.

2. While CoreNet supports all sizes for Atomic Operations, the chip will only support 1,2,4, and 8 byte sizes. See CoreNet Platform Cache (CPC) for resultant behavior when EOE mappings do not fall within these size constraints.

10.7.1.3 IOE to EOE Translations

Due to operation semantics at the source interconnect protocol, only certain ingress operation encodings can map in a seamless manner to an egress operation encoding in order to achieve the same operation semantics at the destination interconnect protocol (CoreNet for PAMU).

10.7.1.3.1 PAMU Bypass Mode or No Operation Translation Mode

Only the basic command set is supported when PAMU is in Bypass Mode. Thus basic Read and Write operations are supported. In the case of SRIO, the Read Atomic Operations are supported as well.

The same basic command set is supported when PAMU is not bypassed but the PAACE entry for that LIODN indicates No Operation Translation has been enabled. Unsupported enhanced IOEs map to reserved EOEs that are used by hardware to detect that an unsupported IOE was encountered while No Operation Translation Mode was enabled.

Table 10-11 shows the default IOE to EOE mappings that occur when PAMU is in bypass mode or when the PAACE entry for an LIODN indicates No Operation Translation has been enabled.

Table 10-11. Default IOE to EOE mappings: PAMU Bypass Mode or No Operation Translation Mode

IOE	EOE
Basic Commands	
READ	READ
WRITE	WRITE

Table continues on the next page...

Table 10-11. Default IOE to EOE mappings: PAMU Bypass Mode or No Operation Translation Mode (continued)

IOE	EOE
RAC	RAC
RAS	RAS
RAD	RAD
RAI	RAI
Enhanced Commands- Unsupported	
EREAD0	EREAD0
EWRITE0	EWRITE0
DIRECT0	DIRECT0
EREAD1	EREAD1
EWRITE1	EWRITE1
DIRECT1	DIRECT1

Table 10-12 shows the CoreNet operations that can be achieved when PAMU is in bypass mode or when the PAACE entry for an LIODN indicates No Operation Translation has been enabled. Issuance of operations by an LIODN outside of that listed in Table 10-12 can be achieved only when an OMT has been created with the relevant mappings and the relevant PAACE entry for that LIODN has the Immediate or Indexed Operation Translation Mode enabled (see Immediate and Indexed Operation Translation Modes).

Table 10-12. Default CoreNet operations in PAMU Bypass Mode or No Operation Translation Mode

Description
Read
Write
Read with Atomic Clear
Read with Atomic Set
Read with Atomic Decrement
Read with Atomic Increment

10.7.1.3.2 Immediate and Indexed Operation Translation Modes

Table 10-13 shows the permitted EOEs for particular IOEs for Immediate and Indexed Operation Translation.

Table 10-13. Permitted IOE to EOE translations for Immediate and Index Operation Translation

IOE	EOE
READ, EREAD0, EREAD1	READ, RAC, RAD, RAS, RAI, RSA, RSAU, READI, RWNITC
WRITE, EWRITE0, EWRITE1	WRITE, WCI, WWSA, WWSAL, WWSOT, WWSOTL
DIRECT0, DIRECT1	LDEC, LDECL, LDECPE, LDECPEL, LDECFE, LDECFEL
RAC	RAC
RAS	RAS
RAD	RAD
RAI	RAI

10.7.2 Domain Attributes

10.7.2.1 Constrained Domain Attribute

Table 10-14 describes a domain attribute field constraint in this chip.

Table 10-14. Domain Attributes constrained

Bits	Name	PPAACE (P) and/or SPAACE (S) Field	Description
16-23	SnpID	P & S	Snoop ID While PAMU in this chip can access an 8-bit Snoop ID Domain Attribute from the PAACE, the CoreNet Coherency Fabric (CCF) in the chip supports up to 32 Snoop IDs Therefore, only SnpID[3:7] is supported.

10.7.3 Implementation Attributes

Table 10-15 describes the SoC definition of Implementation Attributes fields of PAACE Offset 0x0C through 0x0E.

Table 10-15. Implementation Attributes

Bits	Name	PPAACE (P) and/or SPAACE (S) Field	Description
0-7	-	-	Reserved
8-15	CID	P and S	Cache ID These bits define the cache identifier. This field may be used to identify a specific cache entity for the window described by this PAACE. These bits are used for explicit stashing where CID identifies the specific destination.
16-23	-	-	Reserved

10.7.4 Operation Mapping Table (OMT)

For this chip, OMI can be up to 4 bits supporting 16 OMEs. Each OME can contain up to 16 valid bytes supporting 16 MOEs.

Because an OME can have at most 16 valid bytes in the 128-byte OME, PAMU fetches 16 bytes of data after a OMT cache miss. Invalidation will only invalidate one entry out of the 4 entries in the OMT cache. Each entry will hold 128 bits of data.

Chapter 11
DDR Memory Controller

11.1 DDR Introduction

The three fully programmable DDR SDRAM controllers support most JEDEC standard x4, x8, x16 DDR3/3L memories available. In addition, unbuffered and registered DIMMs are supported. However, mixing different memory types or unbuffered and registered DIMMs in the same system is not supported. Built-in error checking and correction (ECC) ensures very low bit-error rates for reliable high-frequency operation. Dynamic power management and auto-precharge modes simplify memory system design. A large set of special features, including ECC error injection, support rapid system debug.

NOTE

In this chapter, the word 'bank' refers to a physical bank specified by a chip select; 'logical bank' refers to one of the four or eight sub-banks in each SDRAM chip. A sub-bank is specified by the 3 bits on the bank address (MBA) pins during a memory access.

The figure below is a high-level block diagram of the DDR memory controller with its associated interfaces.

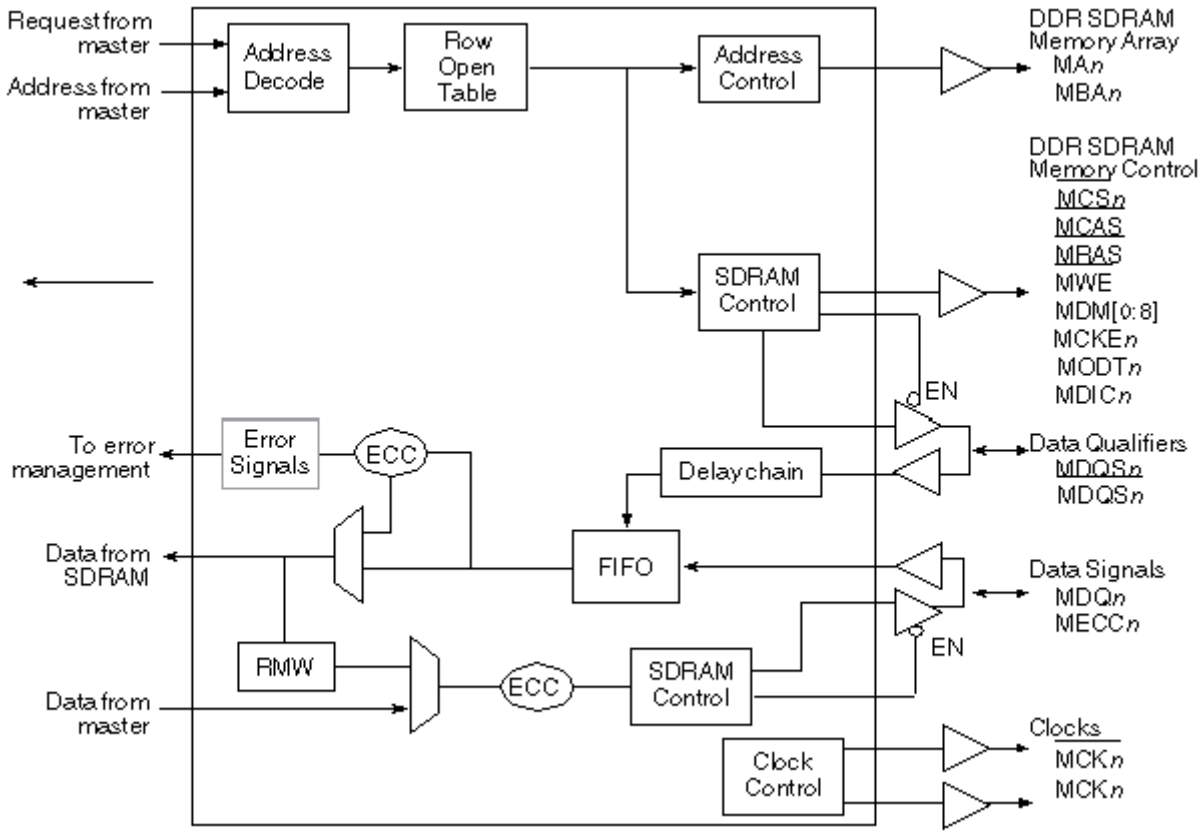

Figure 11-1. DDR Memory Controller Simplified Block Diagram

11.2 DDR Features

The DDR memory controller includes these distinctive features:

- Support for DDR3/3L SDRAM
- Three independent controllers
- 64-/72-bit SDRAM data bus, 32-/40-bit SDRAM for DDR3/3L
- Programmable settings for meeting all SDRAM timing parameters
- The following SDRAM configurations are supported:
  - As many as four physical banks (chip selects), each bank independently addressable
  - 64-Mbit to 8 -Gbit devices depending on internal device configuration with x4/x8/x16 data ports
  - Unbuffered and registered DIMMs
- Chip select interleaving support
- Partial array self refresh support
- Controller interleaving support

- Support for data mask signals and read-modify-write for sub-double-word writes. Note that a read-modify-write sequence is only necessary when ECC is enabled.
- Support for double-bit error detection and single-bit error correction ECC (8-bit check word across 64-bit data)
- Support for address parity for registered DIMMs
- Open page management (dedicated entry for each logical bank)
- Automatic DRAM initialization sequence or software-controlled initialization sequence
- Automatic DRAM data initialization
- Interrupt driven rapid clear of memory
- Write leveling supported for DDR3 memories
- Support for up to eight posted refreshes
- Memory controller clock frequency of two times the SDRAM clock with support for sleep power management
- Support for error injection

11.2.1 DDR Modes of Operation

The DDR memory controller supports the following modes:

- Dynamic power management mode. The DDR memory controller can reduce power consumption by negating the SDRAM CKE signal when no transactions are pending to the SDRAM.
- Auto-precharge mode. Clearing DDR_SDRAM_INTERVAL[BSTOPRE] causes the memory controller to issue an auto-precharge command with every read or write transaction. Auto-precharge mode can be enabled for separate chip selects by setting CS *n*_CONFIG[AP_ *n*_EN].

11.3 DDR External Signal Descriptions

This section provides descriptions of the DDR memory controller's external signals. It describes each signal's behavior when the signal is asserted or negated and when the signal is an input or an output.

Note that this device has three DDR memory controllers. The same set of signals exist on each DDR controllers. The signals are differentiated by the Dn_ in front of the signal names. When a DDR signal is discussed specifically elsewhere in this book it is referred to without the Dn_ prefix. For example, the D1_MDQ[0], D2_MDQ[0], and D3_MDQ[0] signals are all referred to as just MDQ[0].

11.3.1 DDR Signals Overview

Memory controller signals are grouped as follows:

- Memory interface signals
- Clock signals
- Debug signals

The following table shows how DDR memory controller external signals are grouped. The device datasheet has a pinout diagram showing pin numbers. It also lists all electrical and mechanical specifications.

Table 11-1. DDR Memory Interface Signal Summary

Name	Function/Description	Reset	Pins	I/O
MAPAR_ERR_B	Address Parity Error	One	1	I
MAPAR_OUT_B	Address Parity Out	Zero	1	O
MDQ[0:63]	Data bus	All zeros	64	I/O
MDQS[0:8]	Data strobes	All zeros	9	I/O
MDQS[0:8]_B	Complement data strobes	All ones	9	I/O
MDQS[9:17]_B	Complement data strobes for x4 support	All ones	9	I/O
MECC[0:7]	Error checking and correcting	All zeros	8	I/O
MCAS_B	Column address strobe	One	1	O
MA[15:0]	Address bus	All zeros	16	O
MBA[2:0]	Logical bank address	All zeros	3	O
MCS[0:3]_B	Chip selects	All ones	4	O
MWE_B	Write enable	One	1	O
MRAS_B	Row address strobe	One	1	O
MDM[0:8]	Data mask; MDQSL[0:8] in x4 mode.	All zeros	9	O
MCK[0:3]	DRAM clock outputs	All zeros	4	O
MCK[0:3]_B	DRAM clock outputs (complement)	All zeros	4	O
MCKE[0: 3]	DRAM clock enable	All zeros	4	O
MODT[0: 3]	DRAM on-die termination	All zeros	4	O
MDIC[0:1]	Driver impedance calibration	b10	2	I/O
MDQS[9:17]_B	Complement data strobes for x4 support	All ones	9	I/O

The table below shows the memory address signal mappings.

Table 11-2. Memory Address Signal Mappings

Signal Name (Outputs)		JEDEC DDR DIMM Signals (Inputs)
msb	MA15	A15

Table continues on the next page...

Table 11-2. Memory Address Signal Mappings (continued)

Signal Name (Outputs)		JEDEC DDR DIMM Signals (Inputs)
	MA14	A14
	MA13	A13
	MA12	A12
	MA11	A11
	MA10	A10 (AP for DDR)
	MA9	A9
	MA8	A8
	MA7	A7
	MA6	A6
	MA5	A5
	MA4	A4
	MA3	A3
	MA2	A2
	MA1	A1
lsb	MA0	A0
msb	MBA2	MBA2
	MBA1	MBA1
lsb	MBA0	MBA0

11.3.2 DDR Detailed Signal Descriptions

The following sections describe the DDR SDRAM controller input and output signals, the meaning of their different states, and relative timing information for assertion and negation.

11.3.2.1 Memory Interface Signals

The following table describes the DDR controller memory interface signals.

Table 11-3. Memory Interface Signals-Detailed Signal Descriptions

Signal	I/O	Description	
Dn_MDQ[0:63]	I/O	Data bus. Both input and output signals on the DDR memory controller.	
	O	As outputs for the bidirectional data bus, these signals operate as described below.	
		State Meaning	Asserted/Negated - Represent the value of data being driven by the DDR memory controller.
		Timing	Assertion/Negation - Driven with valid data during writes to memory.

Table continues on the next page...

Table 11-3. Memory Interface Signals-Detailed Signal Descriptions (continued)

Signal	I/O	Description	
			High impedance - No READ or WRITE command is in progress; data is not being driven by the memory controller or the DRAM.
	I	As inputs for the bidirectional data bus, these signals operate as described below.	
		State Meaning	Asserted/Negated - Represents the state of data being driven by the external DDR SDRAMs.
		Timing	Assertion/Negation - The DDR SDRAM drives data during a READ transaction. High impedance - No READ or WRITE command in progress; data is not being driven by the memory controller or the DRAM.
Dn_MDQS[0:8]/ Dn_MDQS[0:8]_ B,MDQS[9:17]_ B	I/O	Data strobes. Inputs with read data, outputs with write data. The data strobes must be differential. Note that the MDQS[9:17] IOs are only used if DDR_SDRAM_CFG_2[X4_EN] is set. Also refer to the MDM signal descriptions for the true data strobes used in x4 mode.	
	O	As outputs, the data strobes are driven by the DDR memory controller during a write transaction.	
		State Meaning	Asserted/Negated - Driven high when positive capture data is transmitted and driven low when negative capture data is transmitted. Centered in the data "eye" for writes; coincident with the data eye for reads. Treated as a clock. Data is valid when signals toggle. See Table 11-7 for byte lane assignments.
		Timing	Assertion/Negation - If a WRITE command is registered at clock edge n, data strobes at the DRAM assert centered in the data eye on clock edge n + 1. See the JEDEC DDR SDRAM specification for more information.
	I	As inputs, the data strobes are driven by the external DDR SDRAMs during a read transaction. The data strobes are used by the memory controller to synchronize data latching.	
		State Meaning	Asserted/Negated - Driven high when positive capture data is received and driven low when negative capture data is received. Centered in the data eye for writes; coincident with the data eye for reads. Treated as a clock. Data is valid when signals toggle. See Table 11-7 for byte lane assignments.
		Timing	Assertion/Negation - If a READ command is registered at clock edge n, and the latency is programmed in TIMING_CFG_1[CASLAT] to be *m* clocks, data strobes at the DRAM assert coincident with the data on clock edge *n* + *m*. See the JEDEC DDR SDRAM specification for more information.
Dn_ MECC[0:7]	I/O	Error checking and correcting codes. Input and output signals for the DDR controller's bidirectional ECC bus.	
	O	As normal mode outputs the ECC signals represent the state of ECC driven by the DDR controller on writes. See Error Checking and Correcting (ECC) for more details.	
		State Meaning	Asserted/Negated - Represents the state of ECC being driven by the DDR controller on writes.
		Timing	Assertion/Negation - Same timing as MDQ High impedance - Same timing as MDQ
	I	As inputs, the ECC signals represent the state of ECC driven by the SDRAM devices on reads.	
		State Meaning	Asserted/Negated - Represents the state of ECC being driven by the DDR SDRAMs on reads.
		Timing	Assertion/Negation - Same timing as MDQ High impedance - Same timing as MDQ
Dn_ MA[15:0]	O	Address bus. Memory controller outputs for the address to the DRAM. MA[15:0] carry 16 of the address bits for the DDR memory interface corresponding to the row and column address bits. MA0 is the lsb of the address output from the memory controller.	

Table continues on the next page...

Table 11-3. Memory Interface Signals-Detailed Signal Descriptions (continued)

Signal	I/O	Description	
		State Meaning	Asserted/Negated - Represents the address driven by the DDR memory controller. Contains different portions of the address depending on the memory size and the DRAM command being issued by the memory controller. See Table 11-10 for a complete description of the mapping of these signals.
		Timing	Assertion/Negation - The address is always driven when the memory controller is enabled. It is valid when a transaction is driven to DRAM (when MCS n is active). High impedance - When the memory controller is disabled
Dn_ MBA[2:0]	O	Logical bank address. Outputs that drive the logical (or internal) bank address pins of the SDRAM. Each SDRAM supports four or eight addressable logical sub-banks. Bit zero of the memory controller's output bank address must be connected to bit zero of the SDRAM's input bank address. MBA0, the least-significant bit of the three bank address signals, is asserted during the mode register set command to specify the extended mode register.	
		State Meaning	Asserted/Negated - Selects the DDR SDRAM logical (or internal) bank to be activated during the row address phase and selects the SDRAM internal bank for the read or write operation during the column address phase of the memory access. Table 11-10 describes the mapping of these signals in all cases.
		Timing	Assertion/Negation - Same timing as MAn High impedance - Same timing as MAn
Dn_MCAS_B	O	Column address strobe. Active-low SDRAM address multiplexing signal. MCAS_B is asserted for read or write transactions and for mode register set, refresh, and precharge commands.	
		State Meaning	Asserted - Indicates that a valid SDRAM column address is on the address bus for read and write transactions. See Table 11-16 for more information on the states required on MCAS_B for various other SDRAM commands. Negated - The column address is not guaranteed to be valid.
		Timing	Assertion/Negation - Assertion and negation timing is directed by the values described in DDR SDRAM timing configuration 0 (DDR_TIMING_CFG_0)DDR SDRAM timing configuration 1 (DDR_TIMING_CFG_1)DDR SDRAM timing configuration 2 (DDR_TIMING_CFG_2) and DDR SDRAM timing configuration 3 (DDR_TIMING_CFG_3). High impedance - MCAS_B is always driven unless the memory controller is disabled.
Dn_MRAS_B	O	Row address strobe. Active-low SDRAM address multiplexing signal. Asserted for activate commands. In addition; used for mode register set commands and refresh commands.	
		State Meaning	Asserted - Indicates that a valid SDRAM row address is on the address bus for read and write transactions. See Table 11-16 for more information on the states required on MRAS_B for various other SDRAM commands. Negated - The row address is not guaranteed to be valid.
		Timing	Assertion/Negation - Assertion and negation timing is directed by the values described in DDR SDRAM timing configuration 0 (DDR_TIMING_CFG_0)DDR SDRAM timing configuration 1 (DDR_TIMING_CFG_1)DDR SDRAM timing configuration 2 (DDR_TIMING_CFG_2) and DDR SDRAM timing configuration 3 (DDR_TIMING_CFG_3). High impedance - MRAS_B is always driven unless the memory controller is disabled.
Dn_ MCS[0:3]_B	O	Chip selects. Four chip selects supported by the memory controller.	
		State Meaning	Asserted - Selects a physical SDRAM bank to perform a memory operation as described in Chip select n memory bounds (DDR_CS*n*_BNDS) and Chip select n configuration (DDR_CS*n*_CONFIG)." The DDR controller asserts one of the MCS_B [0:3]signals to begin a memory cycle. Negated - Indicates no SDRAM action during the current cycle.

Table continues on the next page...

Table 11-3. Memory Interface Signals-Detailed Signal Descriptions (continued)

Signal	I/O	Description	
		Timing	Assertion/Negation - Asserted to signal any new transaction to the SDRAM. The transaction must adhere to the timing constraints set in TIMING_CFG_0-TIMING_CFG_3. High impedance - Always driven unless the memory controller is disabled.
Dn_ MWE_B	O	Write enable. Asserted when a write transaction is issued to the SDRAM. This is also used for mode registers set commands and precharge commands.	
		State Meaning	Asserted - Indicates a memory write operation. See Table 11-16 for more information on the states required on MWE_B for various other SDRAM commands. Negated - Indicates a memory read operation.
		Timing	Assertion/Negation - Similar timing as MRAS_B and MCAS_B. Used for write commands. High impedance - MWE_B is always driven unless the memory controller is disabled.
Dn_MDM[0:8]	O	DDR SDRAM data output mask. Masks unwanted bytes of data transferred during a write. They are needed to support sub-burst-size transactions (such as single-byte writes) on SDRAM where all I/O occurs in multi-byte bursts. MDM0 corresponds to the most significant byte (MSB) and MDM7 corresponds to the LSB, while MDM8 corresponds to the ECC byte. Table 11-7 shows byte lane encodings. If DDR_SDRAM_CFG_2[X4_EN] is set, then these pins will act as the true data strobes for the lower nibble of each byte. For example, MDM0/MDQS9_B would be associated with DQ[4:7] in this mode. In this mode, the timings will match what is shown for the MDQS[0:8] IO	
		State Meaning	Asserted - Prevents writing to DDR SDRAM. Asserted when data is written to DRAM if the corresponding byte(s) should be masked for the write. Note that the MDMn signals are active-high for the DDR controller. MDMn is part of the DDR command encoding. Negated - Allows the corresponding byte to be read from or written to the SDRAM.
		Timing	Assertion/Negation - Same timing as MDQx as outputs. High impedance - Always driven unless the memory controller is disabled.
Dn_MODT[0: 3]	O	On-Die termination. Memory controller outputs for the ODT to the DRAM. MODT[0: 3]represents the on-die termination for the associated data, data masks, ECC, and data strobes.	
		State Meaning	Asserted/Negated - Represents the ODT driven by the DDR memory controller.
		Timing	Assertion/Negation - Driven in accordance with JEDEC DRAM specifications for on-die termination timings. It is configured through the CS n _CONFIG[ODT_RD_CFG] and CS n _CONFIG[ODT_WR_CFG] fields. High impedance - Always driven.
Dn_MDIC[0:1]	I/O	Driver impedance calibration. Note that the MDIC signals require the use of 237-Ω precision 1% resistors; MDIC0 must be pulled to GND, while MDIC1 must be pulled to GV_{DD}. See DDR Control Driver Register 2 (DDR_DDRCDR_2) for more information on these signals.	
		State Meaning	These pins are used for automatic calibration of the DDR IOs.
		Timing	These will be driven for four DRAM cycles at a time while the DDR controller is executing the automatic driver compensation.
Dn_MAPAR_ERR_B	I	Address parity error. Reflects whether an address parity error has been detected by the DRAM. This signal is active low.	
		State Meaning	Asserted - An error has been detected. Negated - An error has not been detected.

Table continues on the next page...

Table 11-3. Memory Interface Signals-Detailed Signal Descriptions (continued)

Signal	I/O	Description	
		Timing	Assertion/Negation - Driven by the registered DDR3 DIMMs 3 DRAM cycles after the parity bit has been driven by the memory controller. This error signal should be held valid for 2 DRAM cycles.
Dn_MAPAR_OUT_B	O	Address parity out. Driven by the memory controller as the parity bit calculated across the address and command bits. Even parity is used, and parity is not calculated for the MCKE[0:3], MODT[0:3], or MCS[0:3]_B signals.	
		State Meaning	Asserted - The parity bit is high. Negated - The parity bit is low.
		Timing	Assertion/Negation - Will be issued one DRAM cycle after the chip select for each command.

11.3.2.2 Clock Interface Signals

The following table contains the detailed descriptions of the clock signals of the DDR controller.

Table 11-4. Clock Signals-Detailed Signal Descriptions

Signal	I/O	Description	
MCK[0:3], MCK_B [0:3]	O	DRAM clock outputs and their complements. See Clock Distribution."	
		State Meaning	Asserted/Negated-The JEDEC DDR SDRAM specifications require true and complement clocks. A clock edge is seen by the SDRAM when the true and complement cross.
		Timing	Assertion/Negation-Timing is controlled by the DDR_SDRAM_CLK_CNTL register at offset 0x130.
MCKE[0: 3]	O	Clock enable. Output signals used as the clock enables to the SDRAM. MCKE[0: 3] can be negated to stop clocking the DDR SDRAM. The MCKE signals should be connected to the same rank of memory as the corresponding MCS_B and MODT signals. For example, MCKE[0] should be connected to the same rank of memory as MCS_B[0] and MODT[0].	
		State Meaning	Asserted-Clocking to the SDRAM is enabled. Negated-Clocking to the SDRAM is disabled and the SDRAM should ignore signal transitions on MCK or MCK_B. MCK/MCK_B are don't cares while MCKE[0: 3] are negated.
		Timing	Assertion/Negation-Asserted when DDR_SDRAM_CFG[MEM_EN] is set. Can be negated when entering dynamic power management or self refresh. Will be asserted again when exiting dynamic power management or self refresh. High impedance-Always driven.

11.4 DDR Memory Map/Register Definition

The table below shows the register memory map for the DDR memory controller.

DDR memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
8000	Chip select n memory bounds (DDR1_CS0_BNDS)	32	R/W	0000_0000h	11.4.1/444
8008	Chip select n memory bounds (DDR1_CS1_BNDS)	32	R/W	0000_0000h	11.4.1/444
8010	Chip select n memory bounds (DDR1_CS2_BNDS)	32	R/W	0000_0000h	11.4.1/444
8018	Chip select n memory bounds (DDR1_CS3_BNDS)	32	R/W	0000_0000h	11.4.1/444
8080	Chip select n configuration (DDR1_CS0_CONFIG)	32	R/W	0000_0000h	11.4.2/445
8084	Chip select n configuration (DDR1_CS1_CONFIG)	32	R/W	0000_0000h	11.4.2/445
8088	Chip select n configuration (DDR1_CS2_CONFIG)	32	R/W	0000_0000h	11.4.2/445
808C	Chip select n configuration (DDR1_CS3_CONFIG)	32	R/W	0000_0000h	11.4.2/445
80C0	Chip select n configuration 2 (DDR1_CS0_CONFIG_2)	32	R/W	0000_0000h	11.4.3/447
80C4	Chip select n configuration 2 (DDR1_CS1_CONFIG_2)	32	R/W	0000_0000h	11.4.3/447
80C8	Chip select n configuration 2 (DDR1_CS2_CONFIG_2)	32	R/W	0000_0000h	11.4.3/447
80CC	Chip select n configuration 2 (DDR1_CS3_CONFIG_2)	32	R/W	0000_0000h	11.4.3/447
8100	DDR SDRAM timing configuration 3 (DDR1_TIMING_CFG_3)	32	R/W	0000_0000h	11.4.4/449
8104	DDR SDRAM timing configuration 0 (DDR1_TIMING_CFG_0)	32	R/W	0011_0005h	11.4.5/452
8108	DDR SDRAM timing configuration 1 (DDR1_TIMING_CFG_1)	32	R/W	0000_0000h	11.4.6/455
810C	DDR SDRAM timing configuration 2 (DDR1_TIMING_CFG_2)	32	R/W	0000_0000h	11.4.7/459
8110	DDR SDRAM control configuration (DDR1_DDR_SDRAM_CFG)	32	R/W	0200_0000h	11.4.8/462
8114	DDR SDRAM control configuration 2 (DDR1_DDR_SDRAM_CFG_2)	32	R/W	0000_0000h	11.4.9/465
8118	DDR SDRAM mode configuration (DDR1_DDR_SDRAM_MODE)	32	R/W	0000_0000h	11.4.10/468
811C	DDR SDRAM mode configuration 2 (DDR1_DDR_SDRAM_MODE_2)	32	R/W	0000_0000h	11.4.11/469
8120	DDR SDRAM mode control (DDR1_DDR_SDRAM_MD_CNTL)	32	R/W	0000_0000h	11.4.12/469
8124	DDR SDRAM interval configuration (DDR1_DDR_SDRAM_INTERVAL)	32	R/W	0000_0000h	11.4.13/473
8128	DDR SDRAM data initialization (DDR1_DDR_DATA_INIT)	32	R/W	0000_0000h	11.4.14/473
8130	DDR SDRAM clock control (DDR1_DDR_SDRAM_CLK_CNTL)	32	R/W	0200_0000h	11.4.15/474
8148	DDR training initialization address (DDR1_DDR_INIT_ADDR)	32	R/W	0000_0000h	11.4.16/475
814C	DDR training initialization extended address (DDR1_DDR_INIT_EXT_ADDRESS)	32	R/W	0000_0000h	11.4.17/476
8160	DDR SDRAM timing configuration 4 (DDR1_TIMING_CFG_4)	32	R/W	0000_0000h	11.4.18/477

Table continues on the next page...

DDR memory map (continued)

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
8164	DDR SDRAM timing configuration 5 (DDR1_TIMING_CFG_5)	32	R/W	0000_0000h	11.4.19/481

11.4.1 Chip select n memory bounds (DDR*x*_CS*n*_BNDS)

The chip select bounds registers (CS*n*_BNDS) define the starting and ending address of the memory space that corresponds to the individual chip selects. Note that the size specified in CS*n*_BNDS should equal the size of physical DRAM. Also, note that EA*n* must be greater than or equal to SA*n*.

If chip select interleaving is enabled, all fields in the lower interleaved chip select will be used, and the other chip selects' bounds registers will be unused. For example, if chip selects 0 and 1 are interleaved, all fields in CS0_BNDS will be used, and all fields in CS1_BNDS will be unused.

Address: Base address + 0h offset + (8d × i), where i=0d to 3d

DDR*x*_CS*n*_BNDS field descriptions

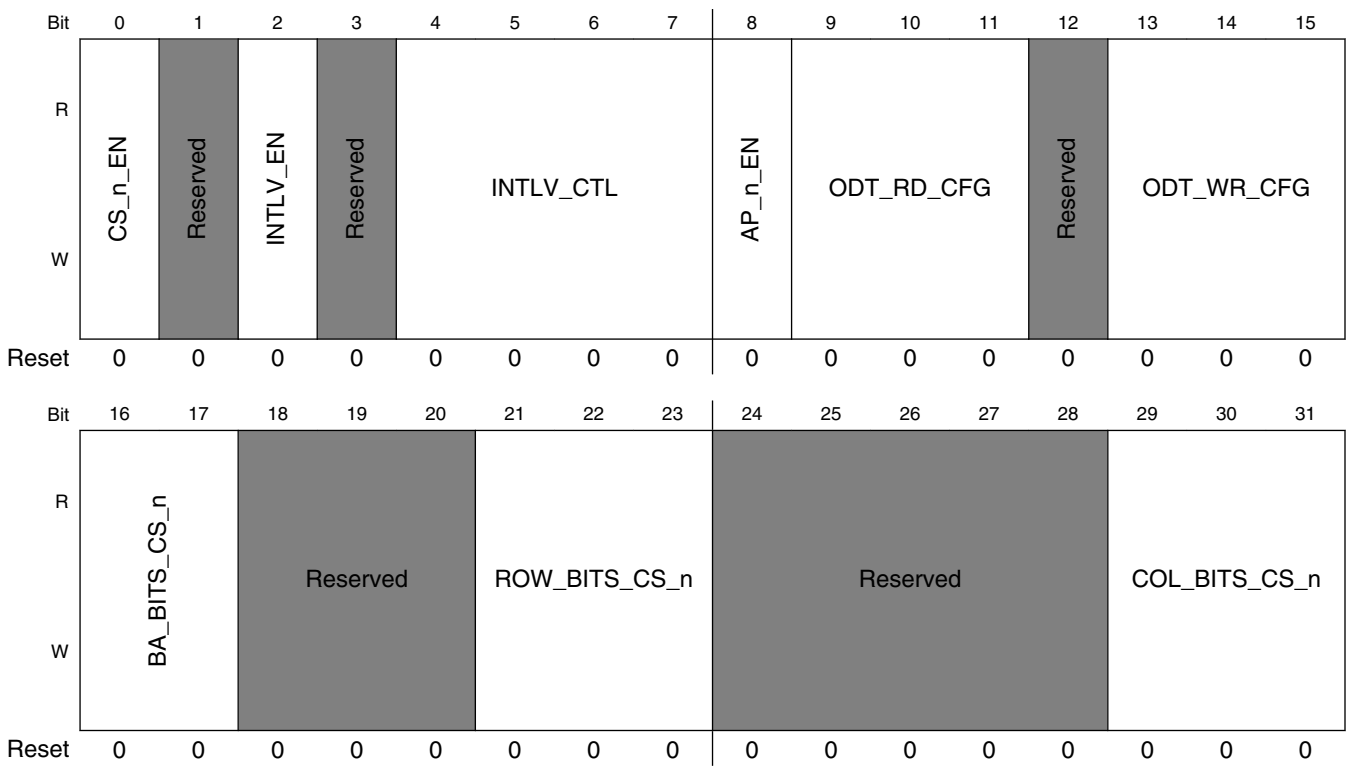
Field	Description
0–15 SAn	Starting address for chip select (bank) *n. This value is compared against the 16 msbs of the 40-bit address.*
16–31 EAn	Ending address for chip select (bank) n. This value is compared against the *16* msbs of the 40-bit address.

11.4.2 Chip select n configuration (DDR*x*_CS*n*_CONFIG)

The chip select configuration registers (CS*n*_CONFIG) enable the DDR chip selects and set the number of row and column bits used for each chip select. These registers should be loaded with the correct number of row and column bits for each SDRAM. Because CS*n*_CONFIG[ROW_BITS_CS_*n*, COL_BITS_CS_*n*] establish address multiplexing, the user should take great care to set these values correctly.

If chip select interleaving is enabled, then all fields in the lower interleaved chip select will be used, and the other registers' fields will be unused, with the exception of the ODT_RD_CFG and ODT_WR_CFG fields. For example, if chip selects 0 and 1 are interleaved, all fields in CS0_CONFIG will be used, but only the ODT_RD_CFG and ODT_WR_CFG fields in CS1_CONFIG will be used.

Address: Base address + 80h offset + (4d × i), where i=0d to 3d



DDR*x*_CS*n*_CONFIG field descriptions

Field	Description
0 CS_n_EN	Chip select n enable 0 Chip select *n*is not active 1 Chip select *n*is active and assumes the state set in CS*n*_BNDS.

Table continues on the next page...

DDRx_CSn_CONFIG field descriptions (continued)

Field	Description
1 -	This field is reserved. Reserved
2 INTLV_EN	Memory controller interleave enable Note: This field is only available in CS0_CONFIG. If memory controller interleaving is enabled, then the data bus widths must be programmed identically for the 2 memory controllers. If this bit is set, INTLV_CTL must be set to select the bit(s) used to control interleaving. 0 No interleaving 1 Interleaving between 2 memory controllers
3 -	This field is reserved. Reserved
4–7 INTLV_CTL	Interleaving control-Controls the bit(s) used to select the memory controller when memory controller interleaving is enabled (INTLV_EN is set) Note: This field is only available in CS0_CONFIG. 0000 Cache line interleaving. In this mode, bit 33 of the 40-bit physical address is used to select the memory controller. 0001 Page interleaving. In this mode, the bit used to select the controller is the bit to the left of the highest-order column bits. 0010 Bank interleaving. In this mode, the bit used to select the controller is the bit to the left of the bank select bits, which are to the left of the highest-order column bits. 0011 Super-bank interleaving. Super-bank interleaving should only be used if chip select interleaving is enabled. In this mode, the decoded address bit to the left of the chip select interleaved bit(s) is used for the memory controller interleaving. 0100-1111 Reserved
8 AP_n_EN	Chip select n auto-precharge enable 0 Chip select *n*will only be auto-precharged if global auto-precharge mode is enabled (DDR_SDRAM_INTERVAL[BSTOPRE] = 0). 1 Chip select *n*will always issue an auto-precharge for read and write transactions.
9–11 ODT_RD_CFG	ODT for reads configuration. Note that CAS latency plus additive latency must be at least 3 cycles for ODT_RD_CFG to be enabled. Values not shown are reserved. 000 Never assert ODT for reads 001 Assert ODT only during reads to CS*n* 010 Assert ODT only during reads to other chip selects 011 Assert ODT only during reads to other DIMM modules. It is assumed that CS0 and CS1 are on the same DIMM module, whereas CS2 and CS3 are on a separate DIMM module. 100 Assert ODT for all reads 101 Assert ODT only during transactions to same DIMM 110 Assert ODT only during transactions to own CS and other DIMM. 111 Assert ODT only during transactions to other CS in same DIMM.
12 -	This field is reserved. Reserved
13–15 ODT_WR_CFG	ODT for writes configuration. Note that write latency plus additive latency must be at least 3 cycles for ODT _WR_CFG to be enabled. Values not shown are reserved.

Table continues on the next page...

DDR*x*_CS*n*_CONFIG field descriptions (continued)

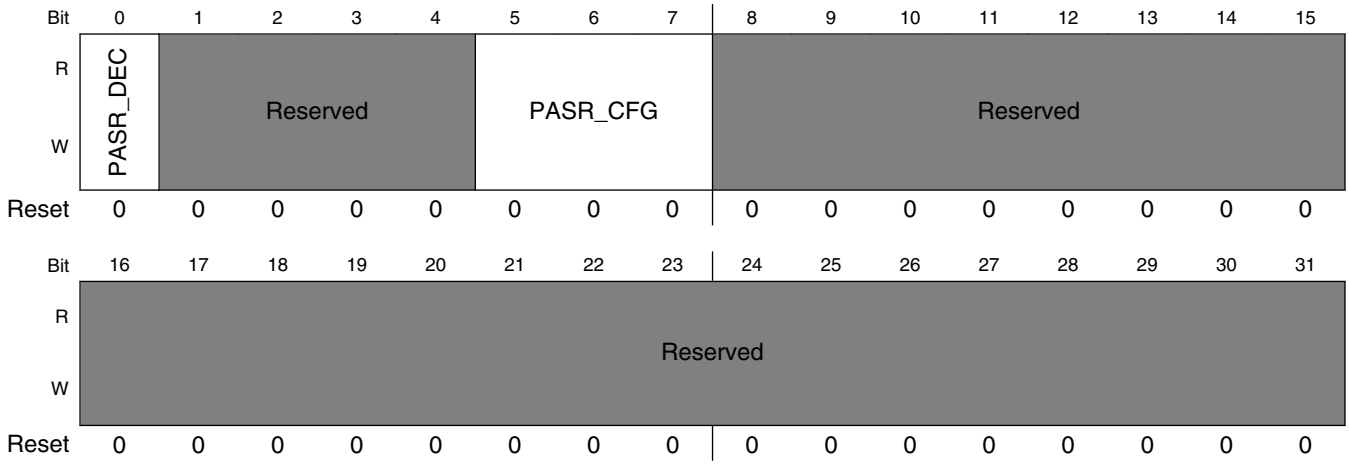
Field	Description
	000 Never assert ODT for writes 001 Assert ODT only during writes to CS*n* 010 Assert ODT only during writes to other chip selects 011 Assert ODT only during writes to other DIMM modules. It is assumed that CS0 and CS1 are on the same DIMM module, whereas CS2 and CS3 are on a separate DIMM module. 100 Assert ODT for all writes 101 Assert ODT only during transactions to same DIMM 110 Assert ODT only during transactions to own CS and other DIMM. 111 Assert ODT only during transactions to other CS in same DIMM.
16–17 BA_BITS_CS_n	Number of bank bits for SDRAM on chip select*n*. These bits correspond to the sub-bank bits driven on MBA*n* in Table 11-10 and Table 11-11. 00 2 logical bank bits 01 3 logical bank bits 10-11 Reserved
18–20 -	This field is reserved. Reserved
21–23 ROW_BITS_CS_n	Number of row bits for SDRAM on chip select*n*. See Table 11-10 and Table 11-11 for details. Values not shown are reserved. 000 12 row bits 001 13 row bits 010 14 row bits 011 15 row bits 100 16 row bits
24–28 -	This field is reserved. Reserved
29–31 COL_BITS_CS_n	Number of column bits for SDRAM on chip select n. For DDR, the decoding is as follows: 000 8 column bits 001 9 column bits 010 10 column bits 011 11 column bits 100-111 Reserved

11.4.3 Chip select n configuration 2 (DDR*x*_CS*n*_CONFIG_2)

The chip select configuration (CS*n*_CONFIG_2) registers enable the partial array self refresh address decode in each chip select.

If chip select interleaving is enabled, then all fields in the lower interleaved chip select will be used, and the other registers' fields will be unused.

Address: Base address + C0h offset + (4d × i), where i=0d to 3d



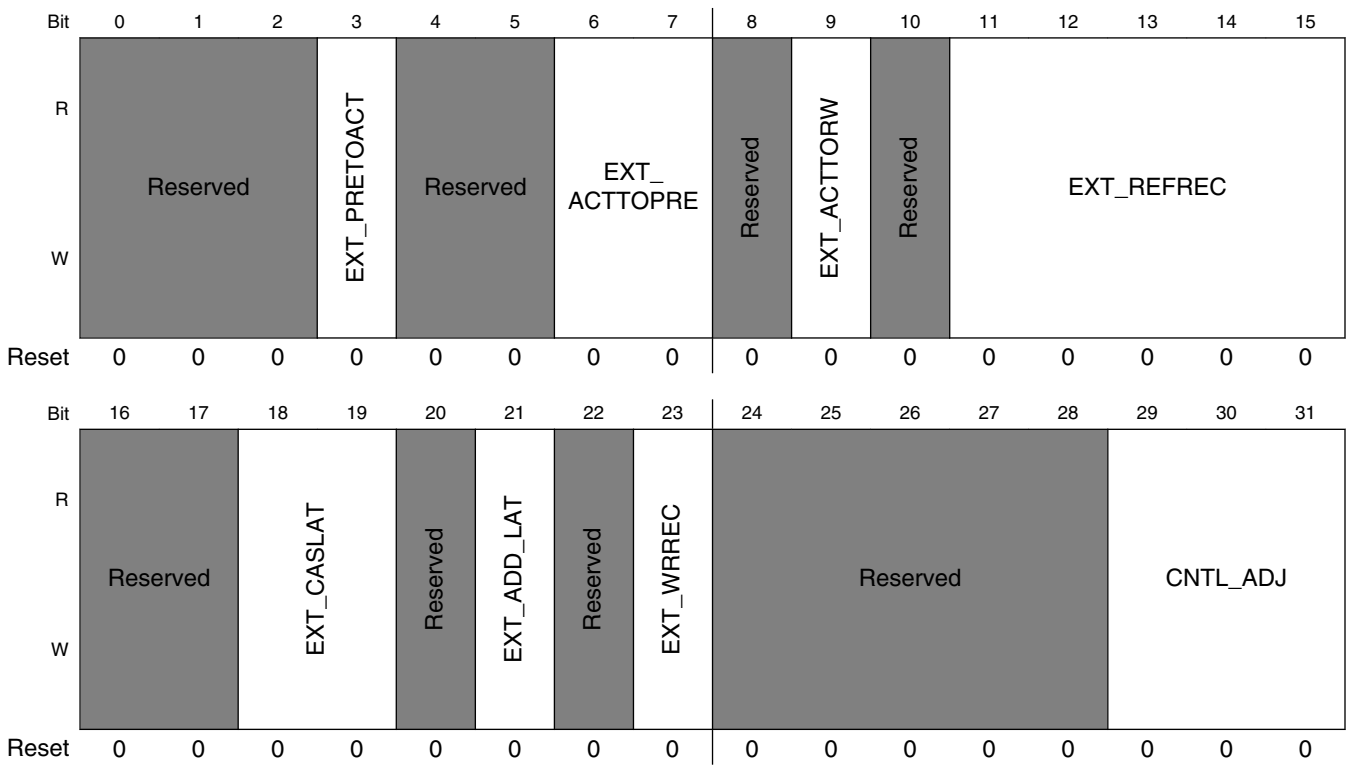
DDRx_CSn_CONFIG_2 field descriptions

Field	Description
0 PASR_DEC	Partial array decoding. This bit can be used to enable the same address decoding used for partial array self refresh without modifying the values written to the DRAM mode registers. If this decoding is desired without enabling partial array self refresh, then this bit should be used. Note that if PASR_CFG is a non-zero value, then this bit will be ignored. 0 Normal address decoding is used, unless PASR_CFG is non-zero. 1 Address decoding typically used for partial array self refresh will be used (Refer to DDR SDRAM Address Multiplexing for details on decoding).
1–4 -	This field is reserved. Reserved
5–7 PASR_CFG	Partial array self refresh config. Controls the bits that will be placed on MA[2:0] during the write to the EMRS(2) register when the automatic hardware DRAM initialization is used (DDR_SDRAM_CFG[BI] is cleared when DDR_SDRAM_CFG[MEM_EN] is set). If this field is a non-zero value, then it will override the least significant 3 bits in DDR_SDRAM_MODE_2[ESDMODE2] during the automatic initialization for chip select n. In addition, if a non-zero value is programmed in this field, then the address decode for chip select n will be optimized for partial array self refresh, as shown in DDR SDRAM Address Multiplexing. 000 Partial array self refresh is disabled 001-111 Partial array self refresh is enabled per JEDEC specifications. Overriding the least significant 3 bits of EMRS or EMRS(2) is only supported for DDR3/3L memory types.
8–31 -	This field is reserved. Reserved

11.4.4 DDR SDRAM timing configuration 3 (DDRx_TIMING_CFG_3)

DDR SDRAM timing configuration register 3 sets the extended refresh recovery time, which is combined with TIMING_CFG_1[REFREC] to determine the full refresh recovery time.

Address: Base address + 100h offset



DDRx_TIMING_CFG_3 field descriptions

Field	Description
0–2 -	This field is reserved. Reserved
3 EXT_PRETOACT	Extended precharge-to-activate interval (t_{RP}). Determines the number of clock cycles from a precharge command until an activate or refresh command is allowed. This field is concatenated with TIMING_CFG_1[PRETOACT] to obtain a 5-bit value for the total precharge to activate time. 0 0 clocks 1 16 clocks
4–5 -	This field is reserved. Reserved
6–7 EXT_ACTTOPRE	Extended Activate to precharge interval (t_{RAS}). Determines the number of clock cycles from an activate command until a precharge command is allowed. This field is concatenated with

Table continues on the next page...

DDRx_TIMING_CFG_3 field descriptions (continued)

Field	Description
	TIMING_CFG_1[ACTTOPRE] to obtain a 6-bit value for the total activate to precharge. Note that a 6-bit value of 00_0000 is the same as a 6-bit value of 01_0000. Both values represent 16 cycles. 00 0 clocks 01 16 clocks 10 32 clocks 11 48 clocks
8 -	This field is reserved. Reserved
9 EXT_ACTTORW	Extended activate to read/write interval for SDRAM (t_{RCD}). Controls the number of clock cycles from an activate command until a read or write command is allowed. This field is concatenated with TIMING_CFG_1[ACTTORW] to obtain a 5-bit value for the total activate to read/write time.
10 -	This field is reserved. Reserved
11–15 EXT_REFREC	Extended refresh recovery time (t_{RFC}). Controls the number of clock cycles from a refresh command until an activate command is allowed. This field is concatenated with TIMING_CFG_1[REFREC] to obtain an 9-bit value for the total refresh recovery. Note that hardware adds an additional 8 clock cycles to the final, 9-bit value of the refresh recovery. t_{RFC} = {EXT_REFREC || REFREC} + 8, such that t_{RFC} is calculated as follows: 00000 0 clocks 00001 16 clocks 00010 32 clocks 00011 48 clocks 00100 64 clocks 00101 80 clocks 00110 96 clocks 00111 112 clocks 01000 128 clocks 01001 144 clocks 01010 160 clocks 01011 176 clocks 01100 192 clocks 01101 208 clocks 01110 224 clocks 01111 240 clocks 10000 256 clocks 10001 272 clocks 10010 288 clocks 10011 304 clocks 10100 320 clocks 10101 336 clocks 10110 352 clocks 10111 368 clocks 11000 384 clocks 11001 400 clocks 11010 416 clocks 11011 432 clocks

Table continues on the next page...

DDRx_TIMING_CFG_3 field descriptions (continued)

Field	Description
	11100 448 clocks 11101 464 clocks 11110 480 clocks 11111 496 clocks
16–17 -	This field is reserved. Reserved
18–19 EXT_CASLAT	Extended MCAS_B latency from READ command. Number of clock cycles between registration of a READ command by the SDRAM and the availability of the first output data. If a READ command is registered at clock edge n and the latency is m clocks, data is available nominally coincident with clock edge *n* + *m*. This field is concatenated with TIMING_CFG_1[CASLAT] to obtain a 5-bit value for the total CAS latency. Note that the value of this field is added to the programmed value in TIMING_CFG_1[CASLAT]. The largest total CAS latency supported is 20 clocks. 00 0 clocks 01 8 clocks 10 16 clocks 11 Reserved
20 -	This field is reserved. Reserved
21 EXT_ADD_LAT	Extended Additive Latency. The additive latency must be set to a value less than TIMING_CFG_1[ACTTORW]. Note that the value of this field is added to the programmed value in TIMING_CFG_2[ADD_LAT]. The largest total additive latency supported is 19 clocks. 0 0 clocks 1 16 clocks
22 -	This field is reserved. Reserved
23 EXT_WRREC	Extended last data to precharge minimum interval (t_{WR}). Determines the number of clock cycles from the last data associated with a write command until a precharge command is allowed. If DDR_SDRAM_CFG_2[OBC_CFG] is set, then this field needs to be programmed to (t_{WR} + 2 cycles). This field is concatenated with TIMING_CFG_1[WRREC] to obtain a 5-bit value for the total write recovery time. 0 0 clocks 1 16 clocks
24–28 -	This field is reserved. Reserved
29–31 CNTL_ADJ	Control Adjust. Controls the amount of delay to add to the lightly loaded control signals w/ respect to all other DRAM address and command signals. The signals affected by this field are MODT[0:3], MCS[0:3]_B, and MCKE[0:3] 000 MODT[0:3], MCS[0:3]_B, and MCKE[0:3] will be launched aligned with the other DRAM address and control signals. 001 MODT[0:3], MCS[0:3]_B, and MCKE[0:3] will be launched 1/4 DDR clock cycle later than the other DRAM address and control signals. 010 MODT[0:3], MCS[0:3]_B, and MCKE[0:3] will be launched 1/2 DDR clock cycle later than the other DRAM address and control signals. 011 MODT[0:3], MCS[0:3]_B, and MCKE[0:3] will be launched 3/4 DDR clock cycle later than the other DRAM address and control signals.

Table continues on the next page...

DDRx_TIMING_CFG_3 field descriptions (continued)

Field	Description
	100 MODT[0:3], MCS[0:3]_B, and MCKE[0:3] will be launched 1 DDR clock cycle later than the other DRAM address and control signals. 101 MODT[0:3], MCS[0:3]_B, and MCKE[0:3] will be launched 5/4 platform cycles later than the other DRAM address and control signals. 110-111 Reserved

11.4.5 DDR SDRAM timing configuration 0 (DDRx_TIMING_CFG_0)

DDR SDRAM timing configuration register 0 sets the number of clock cycles between various SDRAM control commands.

Address: Base address + 104h offset

DDRx_TIMING_CFG_0 field descriptions

Field	Description
0–1 RWT	Read-to-write turnaround (t_{RTW}). Specifies how many extra cycles will be added between a read to write turnaround. If 0 clocks is chosen, then the DDR controller will use a fixed number based on the CAS latency and write latency. Choosing a value other than 0 adds extra cycles past this default calculation. As a default the DDR controller will determine the read-to-write turnaround as CL - WL + BL/2 + 2. In this equation, CL is the CAS latency rounded up to the next integer, WL is the programmed write latency, and BL is the burst length. This field is concatenated with TIMING_CFG_4[EXT_RWT] to obtain a 3-bit value for the total read-to-write turnaround 00 0 clocks 01 1 clock 10 2 clocks 11 3 clocks
2–3 WRT	Write-to-read turnaround. Specifies how many extra cycles will be added between a write to read turnaround. If 0 clocks is chosen, then the DDR controller will use a fixed number based on the, read latency, and write latency. Choosing a value other than 0 adds extra cycles past this default calculation. As a default, the DDR controller will determine the write-to-read turnaround as WL - CL + BL/2 + 1. In this equation, CL is the CAS latency rounded down to the next integer, WL is the programmed write latency, and BL is the burst length. This field is concatenated with TIMING_CFG_4[EXT_WRT] to obtain a 3-bit value for the total write-to-read turnaround 00 0 clocks 01 1 clock

Table continues on the next page...

DDRx_TIMING_CFG_0 field descriptions (continued)

Field	Description
	10 2 clocks 11 3 clocks
4–5 RRT	Read-to-read turnaround. Specifies how many extra cycles will be added between reads to different chip selects. As a default, 3 cycles will be required between read commands to different chip selects. Extra cycles may be added with this field. Note: If 8-beat bursts are enabled, then 5 cycles will be the default. This field is concatenated with TIMING_CFG_4[EXT_RRT] to obtain a 3-bit value for the total read-to-read turnaround. 00 0 clocks 01 1 clock 10 2 clocks 11 3 clocks
6–7 WWT	Write-to-write turnaround. Specifies how many extra cycles will be added between writes to different chip selects. As a default, 2 cycles will be required between write commands to different chip selects. Extra cycles may be added with this field. Note: If 8-beat bursts are enabled, then 4 cycles will be the default. This field is concatenated with TIMING_CFG_4[EXT_WWT] to obtain a 3-bit value for the total write-to-write turnaround 00 0 clocks 01 1 clock 10 2 clocks 11 3 clocks
8–11 ACT_PD_EXIT	Active powerdown exit timing (t_{XP}). Specifies how many clock cycles to wait after exiting active powerdown before issuing any command. 0000 Reserved 0001 1 clock 0010 2 clocks 0011 3 clocks 0100 4 clocks 0101 5 clocks 0110 6 clocks 0111 7 clocks 1100 8 clocks 1101 9 clocks 1110 10 clocks 1111 11 clocks 1100 12 clocks 1101 13 clocks 1110 14 clocks 1111 15 clocks
12–15 PRE_PD_EXIT	Precharge powerdown exit timing (t_{XP}). Specifies how many clock cycles to wait after exiting precharge powerdown before issuing any command. This field is concatenated with TIMING_CFG_0[EXT_PRE_PD_EXIT] to obtain a 6-bit value for the total precharge powerdown exit timing. 0000 Reserved 0001 1 clock 0010 2 clocks

Table continues on the next page...

DDRx_TIMING_CFG_0 field descriptions (continued)

Field	Description
	0011 3 clocks 0100 4 clocks 0101 5 clocks 0110 6 clocks 0111 7 clocks 1000 8 clocks 1001 9 clocks 1010 10 clocks 1011 11 clocks 1100 12 clocks 1101 13 clocks 1110 14 clocks 1111 15 clocks
16–17 EXT_PRE_PD_EXIT	Extended precharge powerdown exit timing (t_{XP}). Specifies how many clock cycles to wait after exiting precharge powerdown before issuing any command. Note the decoding for this field is not a straight decode. This field is concatenated with TIMING_CFG_0[PRE_PD_EXIT] to obtain a 6-bit value for the total precharge powerdown exit timing. 00 0 clocks 01 16 clocks 10 32 clocks 11 48 clocks
18–26 -	This field is reserved. Reserved
27–31 MRS_CYC	Mode register set cycle time (t_{MRD}, t_{MOD}). Specifies the number of cycles that must pass after a Mode Register Set command until any other command. This should be set to the greater of $t_{MRS\ and\ tMOD)}$. 00000 Reserved 00001 1 clock 00010 2 clocks 00011 3 clocks 00100 4 clocks 00101 5 clocks 00110 6 clocks 00111 7 clocks 01000 8 clocks 01001 9 clocks 01010 10 clocks 01011 11 clocks 01100 12 clocks 01101 13 clocks 01110 14 clocks 01111 15 clocks 10000 16 clocks 10001 17 clocks 10010 18 clocks 10011 19 clocks 10100 20 clocks

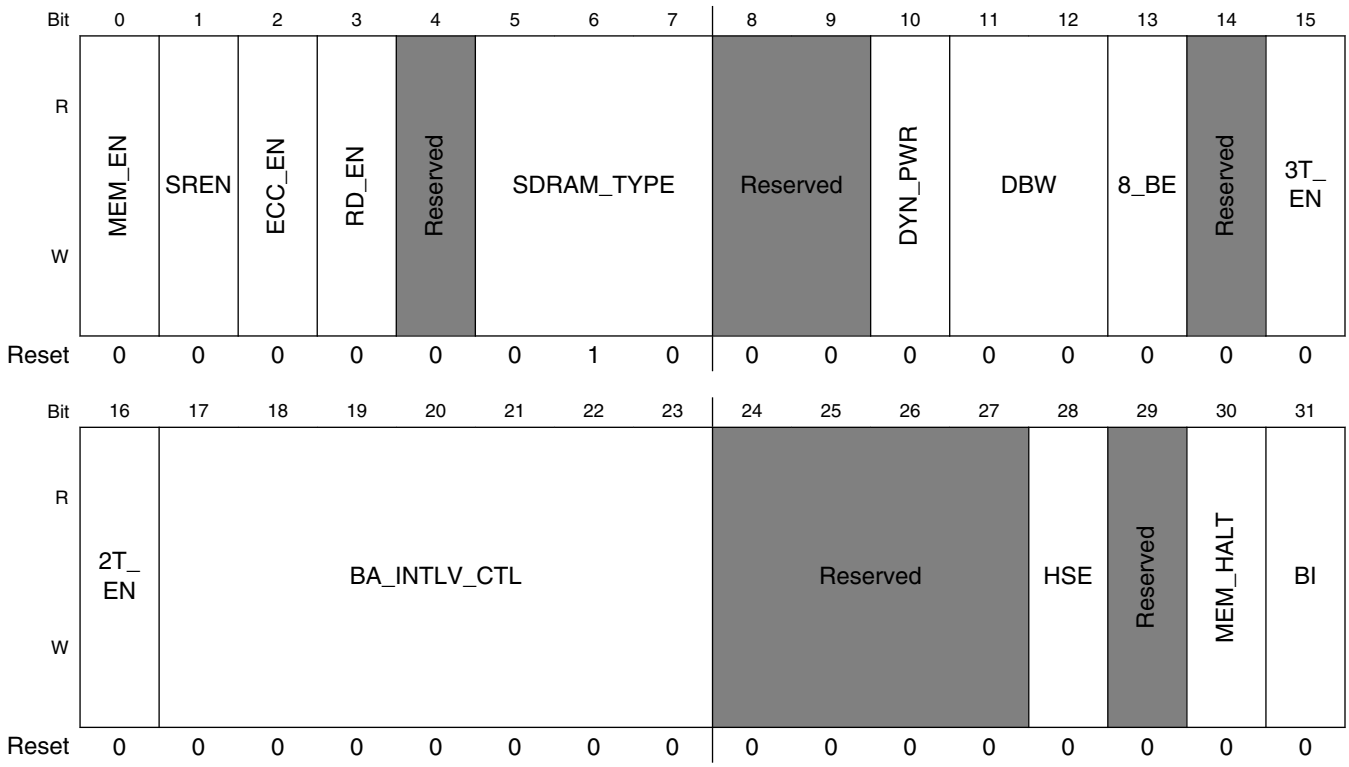
26–31 FOUR_ACT	Window for four activates (t_{FAW}). This is applied to DDR3 with eight logical banks only. **NOTE:** If tFAW requires FOUR_ACT to be set higher than the supported values, then TIMING_CFG_1[ACTTOACT] should be programmed to avoid a t_{FAW} violation. This can be done by programming -> TIMING_CFG_1[ACTTOACT] = rounded_up[max(tRRD, tFAW/4)]. 000000 Reserved 000001 1 cycle 000010 2 cycles 000011 3 cycles 000100 4 cycles ... 011110 30 cycles 011111 31 cycles 100000 32 cycles 100001 33 cycles 100010 - 111111 Reserved

11.4.8 DDR SDRAM control configuration (DDRx_DDR_SDRAM_CFG)

The DDR SDRAM control configuration register enables the interface logic and specifies certain operating features such as self refreshing, error checking and correcting, registered DIMMs, and dynamic power management.

Address: Base address + 110h offset



DDRx_DDR_SDRAM_CFG field descriptions

Field	Description
0 MEM_EN	DDR SDRAM interface logic enable. **NOTE:** The DDRC must be programmed before the corresponding Local Access Windows are programmed and enabled for the DDR target(s). 0 SDRAM interface logic is disabled. 1 SDRAM interface logic is enabled. Must not be set until all other memory configuration parameters have been appropriately configured by initialization code.
1 SREN	Self refresh enable (during sleep). 0 SDRAM self refresh is disabled during sleep. Whenever self-refresh is disabled, the system is responsible for preserving the integrity of SDRAM during sleep. 1 SDRAM self refresh is enabled during sleep.

Table continues on the next page...

DDRx_DDR_SDRAM_CFG field descriptions (continued)

Field	Description
2 ECC_EN	ECC enable. Note that uncorrectable read errors may cause an interrupt. 0 No ECC errors are reported. No ECC interrupts are generated. 1 ECC is enabled.
3 RD_EN	Registered DIMM enable. Specifies the type of DIMM used in the system. Note that RD_EN and 2T_EN must not both be set at the same time. 0 Indicates unbuffered DIMMs. 1 Indicates registered DIMMs.
4 -	This field is reserved. Reserved
5–7 SDRAM_TYPE	Type of SDRAM device to be used. This field will be used when issuing the automatic hardware initialization sequence to DRAM via Mode Register Set and Extended Mode Register Set commands. Default value is 111 designating DDR3 SDRAM. 000-110 Reserved 111 DDR3 SDRAM
8–9 -	This field is reserved. Reserved
10 DYN_PWR	Dynamic power management mode 0 Dynamic power management mode is disabled. 1 Dynamic power management mode is enabled. If there is no ongoing memory activity, the SDRAM CKE signal is negated.
11–12 DBW	DRAM data bus width. 00 64-bit bus is used. 01 32-bit bus is used. 10 Reserved 11 Reserved
13 8_BE	8-beat burst enable. 0 4-beat bursts are used on the DRAM interface. This is only supported if DDR_SDRAM_CFG_2[OBC_CFG] is also set. 1 8-beat bursts are used on the DRAM interface.
14 -	This field is reserved. Reserved
15 3T_EN	Enable 3T timing. This field cannot be set if DDR_SDRAM_CFG[2T_EN] is also set. This field cannot be used with a 32-bit bus if 4-beat bursts are used. 0 1T timing is enabled if 2T_EN is cleared. The DRAM command/address are held for only 1 cycle on the DRAM bus. 1 3T timing is enabled. The DRAM command/address are held for 3 full cycles on the DRAM bus for every DRAM transaction. However, the chip select is only held for the third cycle. **NOTE:** 3T timing may not be used with 4-beat bursts, unless DDR_SDRAM_CFG_2[OBC_CFG] is set.
16 2T_EN	Enable 2T timing. This field should not be set if DDR_SDrAM_CFG[3T_EN] is set. Note that RD_EN and 2T_EN must not both be set at the same time.

Table continues on the next page...

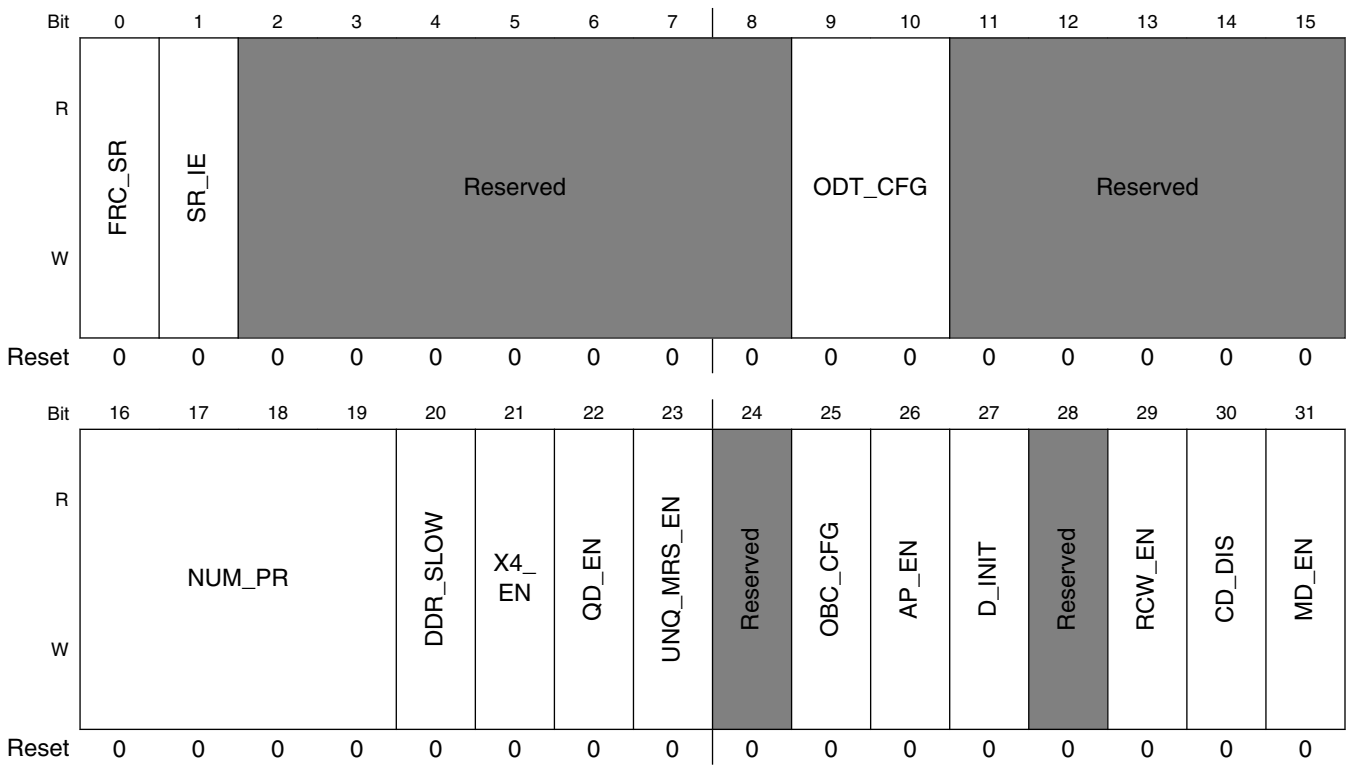
DDRx_DDR_SDRAM_CFG field descriptions (continued)

Field	Description
	0 1T timing is enabled if 3T_EN is cleared. The DRAM command/address are held for only 1 cycle on the DRAM bus. 1 2T timing is enabled. The DRAM command/address are held for 2 full cycles on the DRAM bus for every DRAM transaction. However, the chip select is only held for the second cycle.
17–23 BA_INTLV_CTL	Bank (chip select) interleaving control. Set this field only if you wish to use bank interleaving. ('*x*' denotes a don't care bit value. All unlisted field values are reserved.) 0000000 No external memory banks are interleaved 1000000 External memory banks 0 and 1 are interleaved 0100000 External memory banks 2 and 3 are interleaved 1100000 External memory banks 0 and 1 are interleaved together and banks 2 and 3 are interleaved together xx00100 External memory banks 0 through 3 are all interleaved together
24–27 -	This field is reserved. Reserved
28 HSE	Global half-strength override Sets I/O driver impedance to calibrate to half strength. This calibrated impedance will be used by the MDIC, address/command, data, and clock impedance values, but only if automatic hardware calibration is enabled and the corresponding group's software override is disabled in the DDR control driver register, described in DDR Control Driver Register 1 (DDR_DDRCDR_1) and DDR Control Driver Register 2 (DDR_DDRCDR_2). 0 I/O driver impedance will be calibrated to full strength. 1 I/O driver impedance will be calibrated to half strength.
29 -	This field is reserved. Reserved
30 MEM_HALT	DDR memory controller halt. When this bit is set, the memory controller will not accept any new data read/write transactions to DDR SDRAM until the bit is cleared again. This can be used when bypassing initialization and forcing MODE REGISTER SET commands through software. 0 DDR controller will accept new transactions. 1 DDR controller will finish any remaining transactions, and then it will remain halted until this bit is cleared by software.
31 BI	Bypass initialization See DDR training initialization address (DDR_DDR_INIT_ADDR) for details on avoiding ECC errors in this mode. 0 DDR controller will cycle through initialization routine based on SDRAM_TYPE 1 Initialization routine will be bypassed. Software is responsible for initializing memory through DDR_SDRAM_MD_CTRL register. If software is initializing memory, then the MEM_HALT bit can be set to prevent the DDR controller from issuing transactions during the initialization sequence. Note that the DDR controller will not issue a DLL reset to the DRAMs when bypassing the initialization routine, regardless of the value of DDR_SDRAM_CFG[DLL_RST_DIS]. If a DLL reset is required, then the controller should be forced to enter and exit self refresh after the controller is enabled.

11.4.9 DDR SDRAM control configuration 2 (DDRx_DDR_SDRAM_CFG_2)

The DDR SDRAM control configuration register 2 provides more control configuration for the DDR controller.

Address: Base address + 114h offset



DDRx_DDR_SDRAM_CFG_2 field descriptions

Field	Description
0 FRC_SR	Force self refresh 0 DDR controller will operate in normal mode. 1 DDR controller will enter self-refresh mode.
1 SR_IE	Self-refresh interrupt enable. The DDR controller can be placed into self refresh mode by forcing the PIC to assert *sie0*. This is considered a panic interrupt by the DDR controller, and it will enter self refresh as soon as possible. DDR_SDRAM_CFG[SREN] must also be set if the panic interrupt will be used. 0 DDR controller will not enter self-refresh mode if panic interrupt is asserted. 1 DDR controller will enter self-refresh mode if panic interrupt is asserted.
2–8 -	This field is reserved. Reserved

Table continues on the next page...

DDRx_DDR_SDRAM_CFG_2 field descriptions (continued)

Field	Description
9–10 ODT_CFG	ODT configuration. This field defines how ODT will be driven to the on-chip IOs. See DDR Control Driver Register 1 (DDR_DDRCDR_1) and DDR Control Driver Register 2 (DDR_DDRCDR_2) which define the termination value that will be used. 00 Never assert ODT to internal IOs 01 Reserved 10 Assert ODT to internal IOs only during reads to DRAM 11 Reserved
11–15 -	This field is reserved. Reserved
16–19 NUM_PR	Number of posted refreshes. This will determine how many posted refreshes, if any, can be issued at one time. Note that if posted refreshes are used, then this field, along with DDR_SDRAM_INTERVAL[REFINT], must be programmed such that the maximum t_{ras} specification cannot be violated. 0000 Reserved 0001 1 refresh will be issued at a time 0010 2 refreshes will be issued at a time 0011 3 refreshes will be issued at a time 0100 4 refreshes will be issued at a time 0101 5 refreshes will be issued at a time 0110 6 refreshes will be issued at a time 0111 7 refreshes will be issued at a time 1000 8 refreshes will be issued at a time 1001-1111 Reserved
20 DDR_SLOW	DDR Slow Frequency. Indicates to the controller if it will be run at a lower frequency. 0 The DDR controller will be run at DDR-1250 or higher. 1 The DDR controller will be run less than DDR-1250.
21 X4_EN	x4 DRAM enable. Determines if x4 memories will be used. If using these memories, then 1 DQS/DQS_B pair will be used for every 4 bits of data. Note that mixed systems using x4 and x8/x16 devices are not supported. 0 x8 or x16 memories are used such that 1 DQS/DQS_B pair is used per byte of data. 1 x4 memories are used such that 1 DQS/DQS_B pair is used per every 4 bits of data. Note that data masks are not used when this bit is set. Therefore, any transaction that is not a multiple of 8 beats (or 4 beats if DDR_SDRAM_CFG_2[OBC_CFG is set) will require a read-modify-write transaction. This functionality is independent of the value of DDR_SDRAM_CFG[ECC_EN].
22 QD_EN	Quad-rank enable. Determines if a quad-ranked DIMM is used. This bit should also be set if quad-stacked discrete memory chips are used. 0 Quad-ranked DIMMs are not used. 1 Quad-ranked DIMMs are used. The controller will internally swap CKE[1] and CKE[2], along with MODT[1] and MODT[2].
23 UNQ_MRS_EN	Unique MRS Enable. Determines if the DDR_SDRAM_MODE_{3..8} registers will be used when initializing the memories for chip selects 1, 2, and 3. These can be used to provide unique values to the Mode Registers of the DRAM to allow different termination values for each rank.
24 -	This field is reserved. Reserved

Table continues on the next page...

DDRx_DDR_SDRAM_CFG_2 field descriptions (continued)

Field	Description
25 OBC_CFG	On-The-Fly Burst Chop Configuration. Determines if on-the-fly Burst Chop will be used. This bit should only be set if DDR3 memories are used. If on-the-fly Burst Chop mode is not used with DDR3 memories, then fixed Burst Chop mode may be used if the proper turnaround times are programmed into TIMING_CFG_0 and TIMING_CFG_4. DDR_SDRAM_CFG[8_BE] should be cleared for both on-the-fly Burst Chop mode or fixed Burst Chop mode when using a 64-bit data bus with DDR3 memories. 0 On-the-fly Burst Chop mode is disabled. Fixed burst lengths as defined in DDR_SDRAM_CFG[8_BE] are used. If fixed Burst Chop will be used (with DDR3 memories), then DDR_SDRAM_CFG[8_BE] should be cleared. 1 On-the-fly Burst Chop mode will be used. DDR_SDRAM_CFG[8_BE] should be cleared for on-the-fly Burst Chop mode. DDR_SDRAM_CFG[DBW] should also be cleared for on-the-fly Burst Chop mode
26 AP_EN	Address Parity Enable. Determines if address parity will be generated and checked for the address and control signals when using registered DIMMs. If address parity is used, the MAPAR_OUT and MAPAR_ERR_B pins will be used to drive the parity bit and to receive errors from the open-drain parity error signal. Even parity will be used, and parity will be generated for the MA[15:0], MBA[2:0], MRAS_B, MCAS_B, MWE_B signals. Parity will not be generated for the MCKE[0:3], MODT[0:3], or MCS[0:3]_B signals. Note that address parity should not be used for non-zero values of TIMING_CFG_3[CNTL_ADJ]. 0 Address parity will not be used 1 Address parity will be used
27 D_INIT	DRAM data initialization This bit is set by software, and it is cleared by hardware. If software sets this bit before the memory controller is enabled, the controller will automatically initialize DRAM after it is enabled. This bit will be automatically cleared by hardware once the initialization is completed. This data initialization bit should only be set when the controller is idle. 0 There is not data initialization in progress, and no data initialization is scheduled 1 The memory controller will initialize memory once it is enabled. This bit will remain asserted until the initialization is complete. The value in DDR_DATA_INIT register will be used to initialize memory.
28 -	This field is reserved. Reserved
29 RCW_EN	Register Control Word Enable. If DDR3 registered DIMMs are used, it may be necessary to write the register control words before issuing commands to DRAM. If this bit is set, the controller will write the register control words after DDR_SDRAM_CFG[MEM_EN] is set, unless DDR_SDRAM_CFG[BI] is set. The register control words will be written with the values in DDR_SDRAM_RCW_1 and DDR_SDRAM_RCW_2. 0 Register control words will not be automatically written during DRAM initialization 1 Register control words will be automatically written during DRAM initialization. This bit should only be set if DDR3 registered DIMMs are used, and the default settings need to be modified.
30 CD_DIS	Corrupted Data Disable. If this bit is set, then the corrupted data feature will be disabled. When the corrupted data feature is enabled, the DDR controller will inverted the generated ECC code for any beat of data which is known to have corrupted data. When a read to the corrupted data is later generated, the ERR_DETECT[CDE] error will be set if error reporting is enabled. 0 Corrupted data is enabled 1 Corrupted data is disabled
31 MD_EN	Mirrored DIMM Enable. Some DDR3 DIMMs will be mirrored, where certain MA and MBA pins are mirrored on one side of the DIMM. When this bit is set, the controller will know to swap these signals before transmitting to the DRAM. The controller will assume that CS1 and CS3 are the 'mirrored' ranks of memory. The following signals are mirrored (MBA[0] vs. MBA[1]; MA[3] vs. MA[4]; MA[5] vs. MA[6]; MA[7] vs. MA[8]).

Table continues on the next page...

DDRx_DDR_SDRAM_CFG_2 field descriptions (continued)

Field	Description
	0 Mirrored DIMMs are not used 1 Mirrored DIMMs are used

11.4.10 DDR SDRAM mode configuration (DDRx_DDR_SDRAM_MODE)

The DDR SDRAM mode configuration register sets the values loaded into the DDR's mode registers.

Address: Base address + 118h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	ESDMODE																SDMODE															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRx_DDR_SDRAM_MODE field descriptions

Field	Description
0–15 ESDMODE	Extended SDRAM mode. Specifies the initial value loaded into the DDR SDRAM extended mode register. The range and meaning of legal values is specified by the DDR SDRAM manufacturer. When this value is driven onto the address bus (during the DDR SDRAM initialization sequence), MA[0] presents the lsb of ESDMODE, which, in the big-endian convention shown in the figure, corresponds to ESDMODE[15]. The msb of the SDRAM extended mode register value must be stored at ESDMODE[0]. The value programmed into this field is also used for writing MR1 during write leveling for DDR3, although the bits specifically related to the write leveling scheme are handled automatically by the DDR controller. Even if DDR_SDRAM_CFG[BI] is set, this field is still used during write leveling. The write leveling enable bit should be cleared by software in this field.
16–31 SDMODE	SDRAM mode. Specifies the initial value loaded into the DDR SDRAM mode register. The range of legal values is specified by the DDR SDRAM manufacturer. When this value is driven onto the address bus (during DDR SDRAM initialization), MA[0] presents the lsb of SDMODE, which, in the big-endian convention shown in the figure, corresponds to SDMODE[15]. The msb of the SDRAM mode register value must be stored at SDMODE[0]. Because the memory controller forces SDMODE[7] to certain values depending on the state of the initialization sequence, (for resetting the SDRAM's DLL) the corresponding bits of this field are ignored by the memory controller. Note that SDMODE[7] is mapped to MA[8].

11.4.11 DDR SDRAM mode configuration 2 (DDRx_DDR_SDRAM_MODE_2)

The DDR SDRAM mode 2 configuration register sets the values loaded into the DDR's extended mode 2 and 3 registers.

Address: Base address + 11Ch offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	ESDMODE2																ESDMODE3															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRx_DDR_SDRAM_MODE_2 field descriptions

Field	Description
0–15 ESDMODE2	Extended SDRAM mode 2. Specifies the initial value loaded into the DDR SDRAM extended 2 mode register. The range and meaning of legal values is specified by the DDR SDRAM manufacturer. When this value is driven onto the address bus (during the DDR SDRAM initialization sequence), MA[0] presents the lsb bit of ESDMODE2, which, in the big-endian convention shown in the register figure, corresponds to ESDMODE2[15]. The msb of the SDRAM extended mode 2 register value must be stored at ESDMODE2[0].
16–31 ESDMODE3	Extended SDRAM mode 3. Specifies the initial value loaded into the DDR SDRAM extended 3 mode register. The range of legal values of legal values is specified by the DDR SDRAM manufacturer. When this value is driven onto the address bus (during DDR SDRAM initialization), MA[0] presents the lsb of ESDMODE3, which, in the big-endian convention shown in the figure, corresponds to ESDMODE3[15]. The msb of the SDRAM extended mode 3 register value must be stored at ESDMODE3[0].

11.4.12 DDR SDRAM mode control (DDRx_DDR_SDRAM_MD_CNTL)

The DDR SDRAM mode control register allows the user to carry out the following tasks:

- Issue a mode register set command to a particular chip select
- Issue an immediate refresh to a particular chip select
- Issue an immediate precharge or precharge all command to a particular chip select
- Force the CKE signals to a specific value

Before issuing a command via the DDR_SDRAM_MD_CNTL register, the DDR interface should be idle. This can be done by setting DDR_SDRAM_CFG[MEM_HALT] and disabling refreshes by clearing DDR_INTERVAL[REFINT]. If there are memory contents that need to be preserved during this time, then software should also force any required refresh commands while DDR_INTERVAL[REFINT] is cleared.

The accompanying table shows the user how to set the fields of this register to accomplish the above tasks.

NOTE

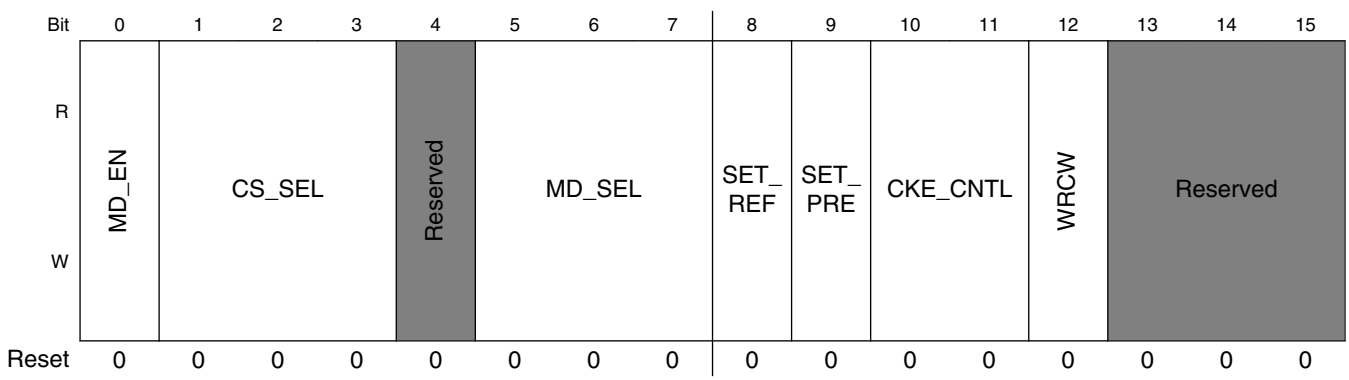
Note that MD_EN, SET_REF, and SET_PRE are mutually exclusive; only one of these fields can be set at a time.

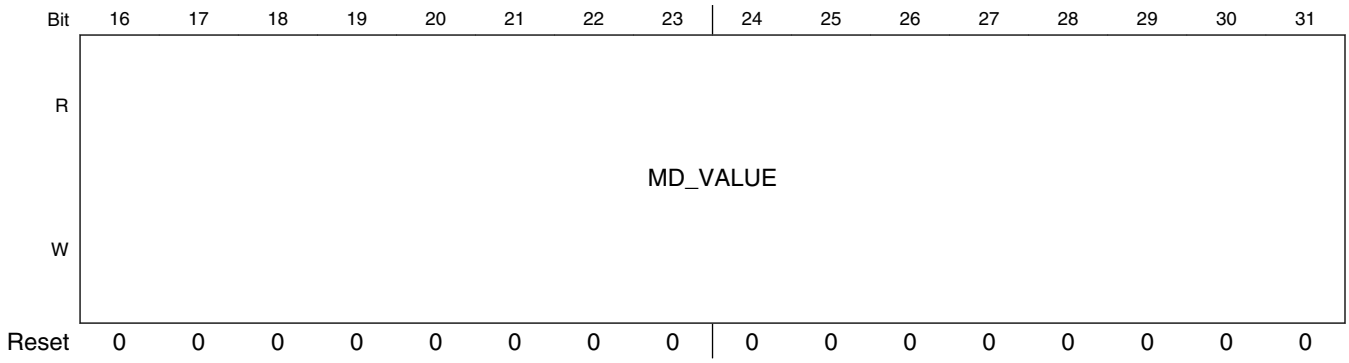
The following table shows how DDR_SDRAM_MD_CNTL fields should be set for each of the tasks described above.

Table 11-5. Settings of DDR_SDRAM_MD_CNTL Fields

Field	Mode Register Set	Refresh	Precharge	Clock Enable Signals Control
MD_EN	1	0	0	-
SET_REF	0	1	0	-
SET_PRE	0	0	1	-
CS_SEL	Chooses chip select (CS)			-
MD_SEL	Select mode register. See DDR SDRAM mode control (DDR_DDR_SDRAM_MD_CNTL).	-	Selects logical bank	-
MD_VALUE	Value written to mode register	-	Only bit 5 is significant. See DDR SDRAM mode control (DDR_DDR_SDRAM_MD_CNTL).	-
CKE_CNTL	0	0	0	See DDR SDRAM mode control (DDR_DDR_SDRAM_MD_CNTL).

Address: Base address + 120h offset





DDRx_DDR_SDRAM_MD_CNTL field descriptions

Field	Description
0 MD_EN	Mode enable. Setting this bit specifies that valid data in MD_VALUE is ready to be written to DRAM as one of the following commands: • MODE REGISTER SET • EXTENDED MODE REGISTER SET • EXTENDED MODE REGISTER SET 2 • EXTENDED MODE REGISTER SET 3 The specific command to be executed is selected by setting MD_SEL. In addition, the chip select must be chosen by setting CS_SEL.MD_EN is set by software and cleared by hardware once the command has been issued. 0 Indicates that no mode register set command needs to be issued. 1 Indicates that valid data contained in the register is ready to be issued as a mode register set command.
1–3 CS_SEL	Select chip select. Specifies the chip select that will be driven active due to any command forced by software in DDR_SDRAM_MD_CNTL. 000 Chip select 0 is active 001 Chip select 1 is active 010 Chip select 2 is active 011 Chip select 3 is active 100 Chip select 0 and chip select 1 are active 101 Chip select 2and chip select 3 are active 110-111 Reserved
4 -	This field is reserved. Reserved
5–7 MD_SEL	Mode register select. MD_SEL specifies one of the following: • During a mode select command, selects the SDRAM mode register to be changed • During a precharge command, selects the SDRAM logical bank to be precharged. A precharge all command ignores this field. • During a refresh command, this field is ignored. Note that MD_SEL contains the value that will be presented onto the memory bank address pins (MBA*n*) of the DDR controller. 000 MR 001 EMR 010 EMR2 011 EMR3

Table continues on the next page...

DDRx_DDR_SDRAM_MD_CNTL field descriptions (continued)

Field	Description
8 SET_REF	Set refresh. Forces an immediate refresh to be issued to the chip select specified by DDR_SDRAM_MD_CNTL[CS_SEL]. This bit will be set by software and cleared by hardware once the command has been issued. 0 Indicates that no refresh command needs to be issued. 1 Indicates that a refresh command is ready to be issued.
9 SET_PRE	Set precharge. Forces a precharge or precharge all to be issued to the chip select specified by DDR_SDRAM_MD_CNTL[CS_SEL]. This bit will be set by software and cleared by hardware once the command has been issued. 0 Indicates that no precharge all command needs to be issued. 1 Indicates that a precharge all command is ready to be issued.
10–11 CKE_CNTL	Clock enable control. Allows software to globally clear or set the all CKE signals issued to DRAM. Once software has forced the value driven on CKE, that value will continue to be forced until software clears the CKE_CNTL bits. At that time, the DDR controller will continue to drive the CKE signals to the same value forced by software until another event causes the CKE signals to change (that is, self refresh entry/exit, power down entry/exit). 00 CKE signals are not forced by software. 01 CKE signals are forced to a low value by software. 10 CKE signals are forced to a high value by software. 11 Reserved
12 WRCW	Write register control word. If software sets this bit, then a register control word will be written by asserting the selected chip selects while providing the programmed data on the MA and MBA signals. The RAS, CAS, and WE will remain deasserted during this write The MD_EN field should also be set to force a register control word write. This should only be set if DDR3 registered DIMM s are used, and the register needs to be configured. If DDR_SDRAM_MD_CNTL is used to write RCW2 specifically, then software must guarantee that the timing parameter, t-STAB, is met before future accesses to the controller are allowed. In addition, DDR_SDRAM_MD_CNTL register cannot be used to write the RCWs if write leveling will be used, since write leveling is run automatically before DDR_SDRAM_MD_CNTL can be used to force RCW writes. 0 Indicates that a register control word write will not be issued if MD_EN is set. 1 Indicates that a register control word write will be issued if MD_EN is set.
13–15 -	This field is reserved. Reserved
16–31 MD_VALUE	Mode register value. This field, which specifies the value that will be presented on the memory address pins of the DDR controller during a mode register set command, is significant only when this register is used to issue a mode register set command or a precharge or precharge all command. For a mode register set command, this field contains the data to be written to the selected mode register. For a precharge command, only bit five is significant: 0 Issue a precharge command; MD_SEL selects the logical bank to be precharged 1 Issue a precharge all command; all logical banks are precharged

11.4.13 DDR SDRAM interval configuration (DDRx_DDR_SDRAM_INTERVAL)

The DDR SDRAM interval configuration register sets the number of DRAM clock cycles between bank refreshes issued to the DDR SDRAMs. In addition, the number of DRAM cycles that a page is maintained after it is accessed is provided here.

Address: Base address + 124h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	REFINT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Reserved		BSTOPRE													
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRx_DDR_SDRAM_INTERVAL field descriptions

Field	Description
0–15 REFINT	Refresh interval. Represents the number of memory bus clock cycles between refresh cycles. Depending on DDR_SDRAM_CFG_2[NUM_PR], some number of rows are refreshed in each DDR SDRAM physical bank during each refresh cycle. The value for REFINT depends on the specific SDRAMs used and the interface clock frequency. Refreshes will not be issued when the REFINT is set to all 0s. This field is concatenated with TIMING_CFG_4[EXT_REFINT] to obtain a 17-bit value for the total refresh interval.
16–17 -	This field is reserved. Reserved
18–31 BSTOPRE	Precharge interval. Sets the duration (in memory bus clocks) that a page is retained after a DDR SDRAM access. If BSTOPRE is zero, the DDR memory controller uses auto-precharge read and write commands rather than operating in page mode. This is called global auto-precharge mode.

11.4.14 DDR SDRAM data initialization (DDRx_DDR_DATA_INIT)

The DDR SDRAM data initialization register provides the value that will be used to initialize memory if DDR_SDRAM_CFG2[D_INIT] is set.

Address: Base address + 128h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	INIT_VALUE																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRx_DDR_DATA_INIT field descriptions

Field	Description
0–31 INIT_VALUE	Initialization value. Represents the value that DRAM will be initialized with if DDR_SDRAM_CFG2[D_INIT] is set.

11.4.15 DDR SDRAM clock control (DDRx_DDR_SDRAM_CLK_CNTL)

The DDR SDRAM clock control configuration register provides a 1/16-cycle clock adjustment.

Address: Base address + 130h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Reserved					CLK_ADJUST					Reserved

11.4.16 DDR training initialization address (DDRx_DDR_INIT_ADDR)

The DDR SDRAM initialization address register provides the address that will be used for the data strobe to data skew adjustment and automatic CAS_B to preamble calibration after POR.

When the default value is used (that is, address 0x0), all chip selects are considered for the training. If DDR_INIT_ADDR is set to any value other than the default value of address zero, then only the first chip select will be trained. When multiple chip selects are used and DQS/DQ skew is not common between chip selects/ranks, then the default address value of 0x0 is be recommended to obtain the best timing margins.

After the skew adjustment, this address will contain bad ECC data. This is not important at POR, as all of memory should be subsequently initialized if ECC is enabled (either by software or through the use of DDR_SDRAM_CFG_2[D_INIT]).

If an HRESET_B has been issued after the DRAM is in self-refresh mode, however, memory is not initialized, so this address should be written to using an 8- or 32-byte transaction to avoid possible ECC errors if this address could later be accessed.

Address: Base address + 148h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DDRx_DDR_INIT_ADDR field descriptions

Field	Description
0–31 INIT_ADDR	Initialization address. Represents the address that will be used for the data strobe to data skew adjustment and automatic CAS to preamble calibration at POR. This address will be written to during the initialization sequence.

11.4.17 DDR training initialization extended address (DDRx_DDR_INIT_EXT_ADDRESS)

The DDR SDRAM initialization extended address register provides the extended address that will be used for the data strobe to data skew adjustment and automatic CAS_B to preamble calibration after POR.

Address: Base address + 14Ch offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	UIA	Reserved														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Reserved								INIT_EXT_ADDR							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

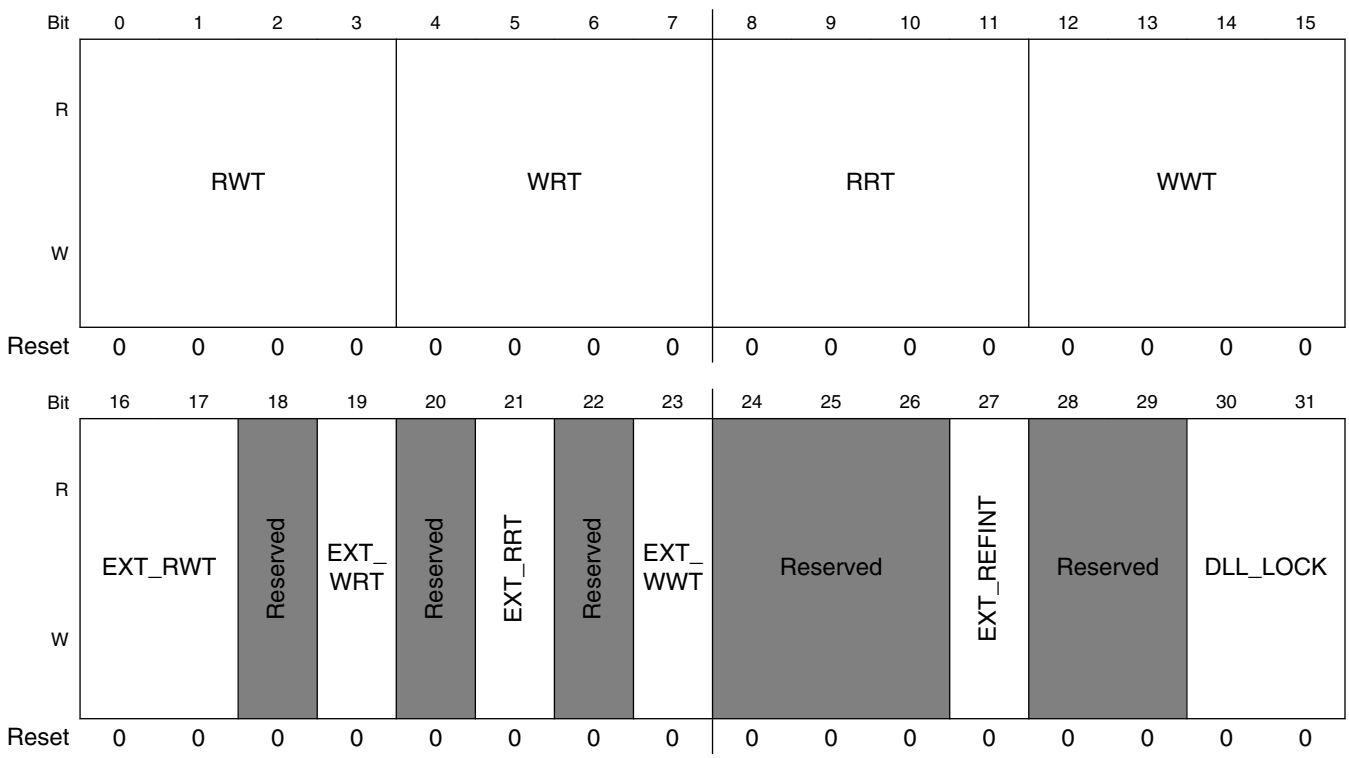
DDRx_DDR_INIT_EXT_ADDRESS field descriptions

Field	Description
0 UIA	Use initialization address. 0 Use the default address for training sequence as calculated by the controller. This will be the first valid address in each enabled chip select. 1 Use the initialization address programmed in DDR_INIT_ADDR and DDR_INIT_EXT_ADDR. This may not be used if memory controller interleaving is enabled via CS0_CONFIG[INTLV_EN], unless all enabled chip selects are also interleaved together.
1–23 -	This field is reserved. Reserved
24–31 INIT_EXT_ADDR	Initialization extended address. Represents the extended address that will be used for the data strobe to data skew adjustment and automatic CAS_B to preamble calibration at POR. This extended address will be written to during the initialization sequence.

11.4.18 DDR SDRAM timing configuration 4 (DDRx_TIMING_CFG_4)

The DDR SDRAM timing configuration 4 register provides additional timing fields required to support DDR3 memories.

Address: Base address + 160h offset



DDRx_TIMING_CFG_4 field descriptions

Field	Description
0–3 RWT	Read-to-write turnaround for same chip select. Specifies how many cycles will be added between a read to write turnaround for transactions to the same chip select. If a value of 0000 is chosen, then the DDR controller will use the value used for transactions to different chip selects, as defined in TIMING_CFG_0[RWT]. This field can be used to improve performance when operating in burst-chop mode by forcing transactions to the same chip select to use extra cycles, while transaction to different chip selects can utilize the tri-state time on the DRAM interface. Regardless of the value that is set in this field, the value defined by TIMING_CFG_0[RWT] will also be met before issuing a write command. 0000 Default 0001 1 clock 0010 2 clocks 0011 3 clocks 0100 4 clocks 0101 5 clocks 0110 6 clocks 0111 7 clocks

Table continues on the next page...

DDRx_TIMING_CFG_4 field descriptions (continued)

Field	Description
	1000 8 clocks 1001 9 clocks 1010 10 clocks 1011 11 clocks 1100 12 clocks 1101 13 clocks 1110 14 clocks 1111 15 clocks
4–7 WRT	Write-to-read turnaround for same chip select. Specifies how many cycles will be added between a write to read turnaround for transactions to the same chip select. If a value of 0000 is chosen, then the DDR controller will use the value used for transactions to different chip selects, as defined in TIMING_CFG_0[WRT]. This field can be used to improve performance when operating in burst-chop mode by forcing transactions to the same chip select to use extra cycles, while transaction to different chip selects can utilize the tri-state time on the DRAM interface. Regardless of the value that is set in this field, the value defined by TIMING_CFG_0[WRT] will also be met before issuing a read command. 0000 Default 0001 1 clock 0010 2 clocks 0011 3 clocks 0100 4 clocks 0101 5 clocks 0110 6 clocks 0111 7 clocks 1000 8 clocks 1001 9 clocks 1010 10 clocks 1011 11 clocks 1100 12 clocks 1101 13 clocks 1110 14 clocks 1111 15 clocks
8–11 RRT	Read-to-read turnaround for same chip select. Specifies how many cycles will be added between reads to the same chip select. If a value of 0000 is chosen, then 2 cycles will be required between read commands to the same chip select if 4-beat bursts are used (4 cycles will be required if 8-beat bursts are used). Note that DDR3 does not support 4-beat bursts. However, this field may be used to add extra cycles when burst-chop mode is used, and the DDR controller must wait 4 cycles for read-to-read transactions to the same chip select. 0000 BL/2 clocks 0001 BL/2 + 1 clock 0010 BL/2 + 2 clocks 0011 BL/2 + 3 clocks 0100 BL/2 + 4 clocks 0101 BL/2 + 5 clocks 0110 BL/2 + 6 clocks 0111 BL/2 + 7 clocks 1000 BL/2 + 8 clocks 1001 BL/2 + 9 clocks

11.4.21 DDR ZQ calibration control (DDRx_DDR_ZQ_CNTL)

The DDR ZQ Calibration Control register provides the enable and controls required for ZQ calibration when using DDR3 SDRAM devices.

There is a limitation for various DRAM timing parameters when ZQ calibration is used. The factors involved in this limitation are DDR_ZQ_CNTL[ZQOPER], DDR_ZQ_CNTL[ZQCS], TIMING_CFG_1[PRETOACT], TIMING_CFG_1[REFREC], DDR_SDRAM_INTERVAL[REFINT], and the number of chip selects enabled. If the following condition is true:

[((DDR_ZQ_CNTL[ZQOPER] + DDR_ZQ_CNTL[ZQCS])* (# enabled chip selects)) +

TIMING_CFG_1[PRETOACT] +

TIMING_CFG_1[REFREC] + $2t_{CK}$] > (DDR_SDRAM_INTERVAL[REFINT]),

then it is possible that one refresh will be skipped when the controller is exiting self refresh. If this is an issue, then posted refreshes could be used to extend the refresh interval. Another alternative is to use the DDR_SDRAM_MD_CNTL register to force an extra refresh to each chip select after exiting self refresh mode. However, DDR3 timing parameters for most devices/frequencies will not allow for a refresh to be missed.

Address: Base address + 170h offset

DDRx_DDR_SDRAM_RCW_2 field descriptions

Field	Description
0–3 RCW8	Register Control Word 8. Represents the value that will be placed on MBA[1], MBA[0], MA[4], and MA[3] during writes to register control word 8.

Table continues on the next page...

DDRx_DDR_SDRAM_RCW_2 field descriptions (continued)

Field	Description
4–7 RCW9	Register Control Word 9. Represents the value that will be placed on MBA[1], MBA[0], MA[4], and MA[3] during writes to register control word 9.
8–11 RCW10	Register Control Word 10. Represents the value that will be placed on MBA[1], MBA[0], MA[4], and MA[3] during writes to register control word 10.
12–15 RCW11	Register Control Word 11. Represents the value that will be placed on MBA[1], MBA[0], MA[4], and MA[3] during writes to register control word 11.
16–19 RCW12	Register Control Word 12. Represents the value that will be placed on MBA[1], MBA[0], MA[4], and MA[3] during writes to register control word 12.
20–23 RCW13	Register Control Word 13. Represents the value that will be placed on MBA[1], MBA[0], MA[4], and MA[3] during writes to register control word 13.
24–27 RCW14	Register Control Word 14. Represents the value that will be placed on MBA[1], MBA[0], MA[4], and MA[3] during writes to register control word 14.
28–31 RCW15	Register Control Word 15. Represents the value that will be placed on MBA[1], MBA[0], MA[4], and MA[3] during writes to register control word 15.

11.4.26 DDR write leveling control 2 (DDRx_DDR_WRLVL_CNTL_2)

The DDR Write Leveling Control 2 register provides controls for write leveling, as it is supported for DDR3 memory devices. This register specifically defines the starting points for the individual data strobes.

NOTE

For each field WRLVL_START_n, a setting of 0000 is not recommended; it disables the per-byte write level start time selection. It is recommended to select proper individual delay for each byte lane based on board skews.

Address: Base address + 190h offset

11.4.28 DDR SDRAM mode configuration 3 (DDRx_DDR_SDRAM_MODE_3)

The DDR SDRAM mode configuration register 3 sets the values loaded into the DDR's mode registers. This register is used specifically for chip select 1 if DDR_SDRAM_CFG_2[UNQ_MRS_EN] is set.

Address: Base address + 200h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	ESDMODE																SDMODE															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRx_DDR_SDRAM_MODE_3 field descriptions

Field	Description
0–15 ESDMODE	Extended SDRAM mode. Specifies the initial value loaded into the DDR SDRAM extended mode register for chip select 1 if DDR_SDRAM_CFG_2[UNQ_MRS_EN] is set. The range and meaning of legal values is specified by the DDR SDRAM manufacturer. When this value is driven onto the address bus (during the DDR SDRAM initialization sequence), MA[0] presents the lsb of ESDMODE, which, in the big-endian convention shown in the register figure, corresponds to ESDMODE[15]. The msb of the SDRAM extended mode register value must be stored at ESDMODE[0]. The value programmed into this field is also used for writing MR1 during write leveling for DDR3, although the bits specifically related to the write leveling scheme are handled automatically by the DDR controller. Even if DDR_SDRAM_CFG[BI] is set, this field is still used during write leveling. The write leveling enable bit should be cleared by software in this field.
16–31 SDMODE	SDRAM mode. Specifies the initial value loaded into the DDR SDRAM mode register for chip select 1 if DDR_SDRAM_CFG_2[UNQ_MRS_EN] is set. The range of legal values is specified by the DDR SDRAM manufacturer. When this value is driven onto the address bus (during DDR SDRAM initialization), MA[0] presents the lsb of SDMODE, which, in the big-endian convention shown in the register figure, corresponds to SDMODE[15]. The msb of the SDRAM mode register value must be stored at SDMODE[0]. Because the memory controller forces SDMODE[7] to certain values depending on the state of the initialization sequence, (for resetting the SDRAM's DLL) the corresponding bits of this field are ignored by the memory controller. Note that SDMODE[7] is mapped to MA[8].

11.4.29 DDR SDRAM mode configuration 4 (DDRx_DDR_SDRAM_MODE_4)

The DDR SDRAM mode configuration register 4 sets the values loaded into the DDR's extended mode 2 and 3 registers. This register is used specifically for chip select 1 if DDR_SDRAM_CFG_2[UNQ_MRS_EN] is set.

Address: Base address + 204h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DDRx_DDR_SDRAM_MODE_4 field descriptions

Field	Description
0–15 ESDMODE2	Extended SDRAM mode 2. Specifies the initial value loaded into the DDR SDRAM extended 2 mode register for chip select 1 if DDR_SDRAM_CFG_2[UNQ_MRS_EN] is set. The range and meaning of legal values is specified by the DDR SDRAM manufacturer. When this value is driven onto the address bus (during the DDR SDRAM initialization sequence), MA[0] presents the lsb bit of ESDMODE2, which, in the big-endian convention shown in the register figure, corresponds to ESDMODE2[15]. The msb of the SDRAM extended mode 2 register value must be stored at ESDMODE2[0].
16–31 ESDMODE3	Extended SDRAM mode 3. Specifies the initial value loaded into the DDR SDRAM extended 3 mode register for chip select 1 if DDR_SDRAM_CFG_2[UNQ_MRS_EN] is set. The range of legal values of legal values is specified by the DDR SDRAM manufacturer. When this value is driven onto the address bus (during DDR SDRAM initialization), MA[0] presents the lsb of ESDMODE3, which, in the big-endian convention shown in the register figure, corresponds to ESDMODE3[15]. The msb of the SDRAM extended mode 3 register value must be stored at ESDMODE3[0].

11.4.30 DDR SDRAM mode configuration 5 (DDRx_DDR_SDRAM_MODE_5)

The DDR SDRAM mode configuration register 5 sets the values loaded into the DDR's mode registers. This register is used specifically for chip select 2 if DDR_SDRAM_CFG_2[UNQ_MRS_EN] is set.

Address: Base address + 208h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DDRx_DDR_SDRAM_MODE_5 field descriptions

Field	Description
0–15 ESDMODE	Extended SDRAM mode. Specifies the initial value loaded into the DDR SDRAM extended mode register for chip select 2 if DDR_SDRAM_CFG_2[UNQ_MRS_EN] is set. The range and meaning of legal values is specified by the DDR SDRAM manufacturer. When this value is driven onto the address bus (during the DDR SDRAM initialization sequence), MA[0] presents the lsb of ESDMODE, which, in the big-endian convention shown in the register figure, corresponds to ESDMODE[15]. The msb of the SDRAM extended mode register value must be stored at ESDMODE[0]. The value programmed into this field is also used for writing MR1 during write leveling for DDR3, although the bits specifically related to the write leveling scheme are handled automatically by the DDR controller. Even if DDR_SDRAM_CFG[BI] is set, this field is still used during write leveling. The write leveling enable bit should be cleared by software in this field.
16–31 SDMODE	SDRAM mode. Specifies the initial value loaded into the DDR SDRAM mode register for chip select 2 if DDR_SDRAM_CFG_2[UNQ_MRS_EN] is set. The range of legal values is specified by the DDR SDRAM manufacturer. When this value is driven onto the address bus (during DDR SDRAM initialization), MA[0] presents the lsb of SDMODE, which, in the big-endian convention shown in the register figure, corresponds to SDMODE[15]. The msb of the SDRAM mode register value must be stored at SDMODE[0]. Because the memory controller forces SDMODE[7] to certain values depending on the state of the initialization sequence, (for resetting the SDRAM's DLL) the corresponding bits of this field are ignored by the memory controller. Note that SDMODE[7] is mapped to MA[8].

11.4.31 DDR SDRAM mode configuration 6 (DDR*x*_DDR_SDRAM_MODE_6)

The DDR SDRAM mode configuration register 6 sets the values loaded into the DDR's extended mode 2 and 3 registers. This register is used specifically for chip select 2 if DDR_SDRAM_CFG_2[UNQ_MRS_EN] is set.

Address: Base address + 20Ch offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DDRx_DDRDSR_2 field descriptions (continued)

Field	Description
30 RPD_ST	Rapid clear of memory start. See DDR Rapid Clear of Memory for more information. 0 The rapid clear of memory function has not been started. 1 The rapid clear of memory function has started. During the rapid clear of memory, writes to the DDR memory mapped registers will not affect the register contents. This bit is cleared by software writing a 1.
31 RPD_END	Rapid clear of memory end. See DDR Rapid Clear of Memory," for more information. 0 The rapid clear of memory function has not ended. 1 The rapid clear of memory function has completed. This bit is cleared by software writing a 1.

11.4.36 DDR Control Driver Register 1 (DDRx_DDRCDR_1)

DDRCDR_1 sets the hardware DDR driver calibration enable, the ODT termination value for IOs, and the software override enables for address/command and data bus signals. The combined DDRCDR_1[ODT] and DDRCDR_2[ODT] set the on-die-termination values in the memory controller for the data bus signals. Hardware DDR driver calibration must be enabled by setting DDRCDR_1[DHC_EN]. MDIC[0:1] pins are required to be connected to proper calibration resistors. The proper value and connection of the MDIC resistor are specified in the corresponding device datasheet.

The global half-strength override field DDR_SDRAM_CFG[HSE] or software overrides in DDRCDR_1 or DDRCDR_2 registers determine whether the DDR drivers calibrate to full-strength or half-strength. The software overrides in DDRCDR_1 or DDRCDR_2 registers take precedence over the DDR_SDRAM_CFG[HSE] setting.

NOTE

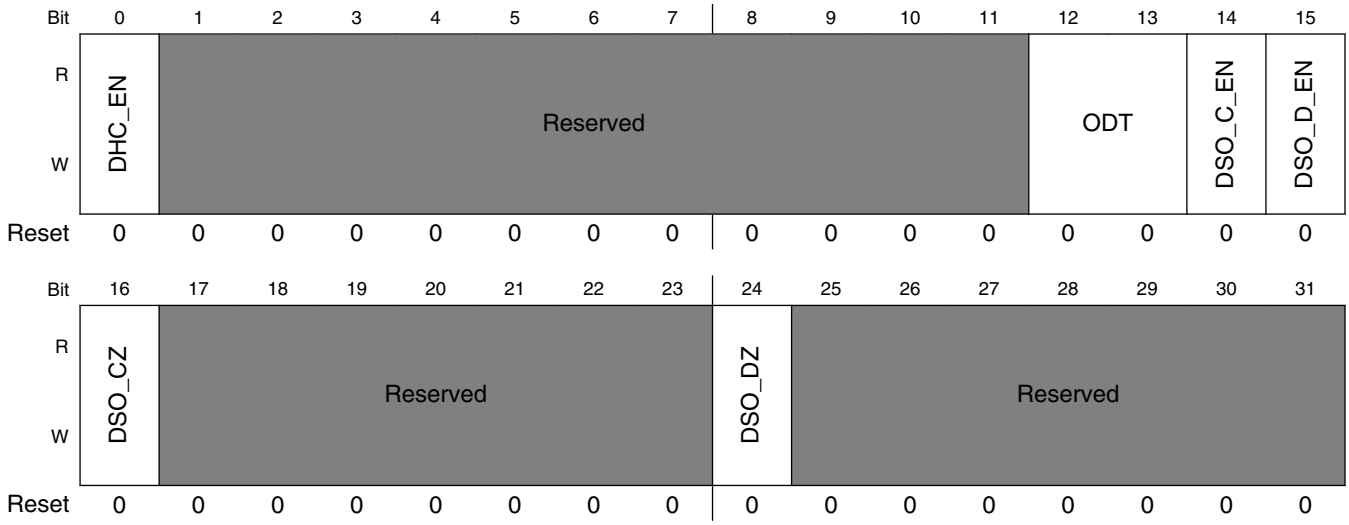
All driver calibration related registers should be set 500 µs before the DDR controller is enabled (that is, before DDR_SDRAM_CFG[MEM_EN] is set).

The table below lists the valid impedance override values. Note that the drivers may be calibrated to either full-strength or half-strength.

Table 11-6. Valid Impedance Override Values

Driver impedance	Impedance Override Value
Highest	0
Lowest	1

Address: Base address + B28h offset



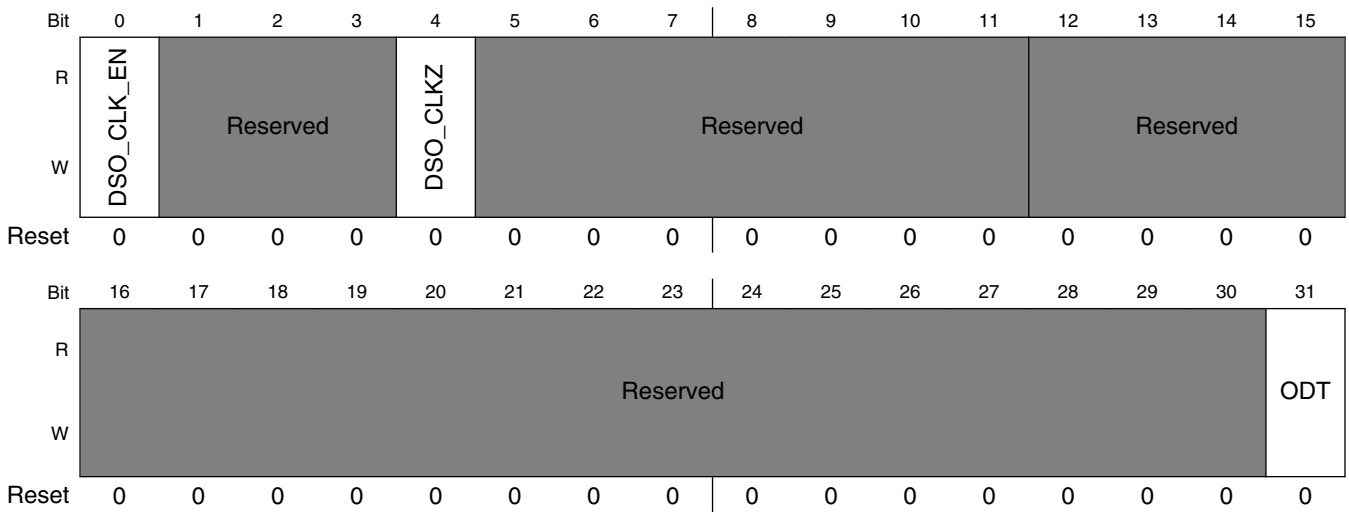
DDRx_DDRCDR_1 field descriptions

Field	Description
0 DHC_EN	DDR driver hardware compensation enable
1–11 -	This field is reserved. Reserved. These bits are writeable, but they are unused.
12–13 ODT	ODT termination value for IOs. This is combined with DDRCDR_2[ODT] to determine the termination value. Below is the termination based on concatenating these two fields. Note that the order of concatenation is (from left to right) DDRCDR_1[ODT], DDRCDR_2[ODT] **NOTE:** All other settings reserved 000 Termsel off 001 120 Ω 011 75 Ω 101 60 Ω 111 46 Ω
14 DSO_C_EN	Driver software override enable for address/command
15 DSO_D_EN	Driver software override enable for data
16 DSO_CZ	DDR driver software command impedance override
17–23 -	This field is reserved. Reserved. These bits are writeable, but they are unused.
24 DSO_DZ	Driver software data impedance override
25–31 -	This field is reserved. Reserved. These bits are writeable, but they are unused.

11.4.37 DDR Control Driver Register 2 (DDRx_DDRCDR_2)

The DDRCDR_2 sets the driver software override enable for clocks, and the DDR clocks driver P/N impedance.

Address: Base address + B2Ch offset



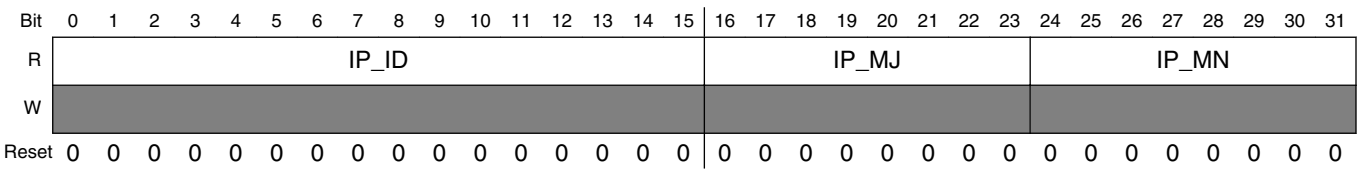
DDRx_DDRCDR_2 field descriptions

Field	Description
0 DSO_CLK_EN	Driver software override enable for clocks
1–3 -	This field is reserved. Reserved
4 DSO_CLKZ	Driver software clocks impedance override
5–11 -	This field is reserved. Reserved. These bits are writeable, but they are unused.
12–30 -	This field is reserved. Reserved
31 ODT	ODT termination value for IOs. This is combined with DDRCDR_2[ODT] to determine the termination value. Below is the termination based on concatenating these two fields. Note that the order of concatenation is (from left to right) DDRCDR_1[ODT], DDRCDR_2[ODT] 000 Termsel off 001 120 Ω 011 75 Ω 101 60 Ω 111 47 Ω

11.4.38 DDR IP block revision 1 (DDRx_DDR_IP_REV1)

The DDR IP block revision 1 register provides read-only fields with the IP block ID, along with major and minor revision information.

Address: Base address + BF8h offset



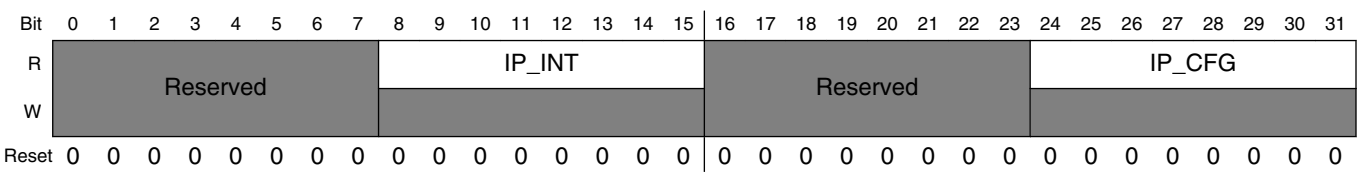
DDRx_DDR_IP_REV1 field descriptions

Field	Description
0–15 IP_ID	IP block ID. For the DDR controller, this value is 0x0002.
16–23 IP_MJ	Major revision. This is currently set to 0x04.
24–31 IP_MN	Minor revision. This is currently set to 0x07.

11.4.39 DDR IP block revision 2 (DDRx_DDR_IP_REV2)

The DDR IP block revision 2 register provides read-only fields with the IP block integration and configuration options.

Address: Base address + BFCh offset



DDRx_DDR_IP_REV2 field descriptions

Field	Description
0–7 -	This field is reserved. Reserved
8–15 IP_INT	IP block integration options

Table continues on the next page...

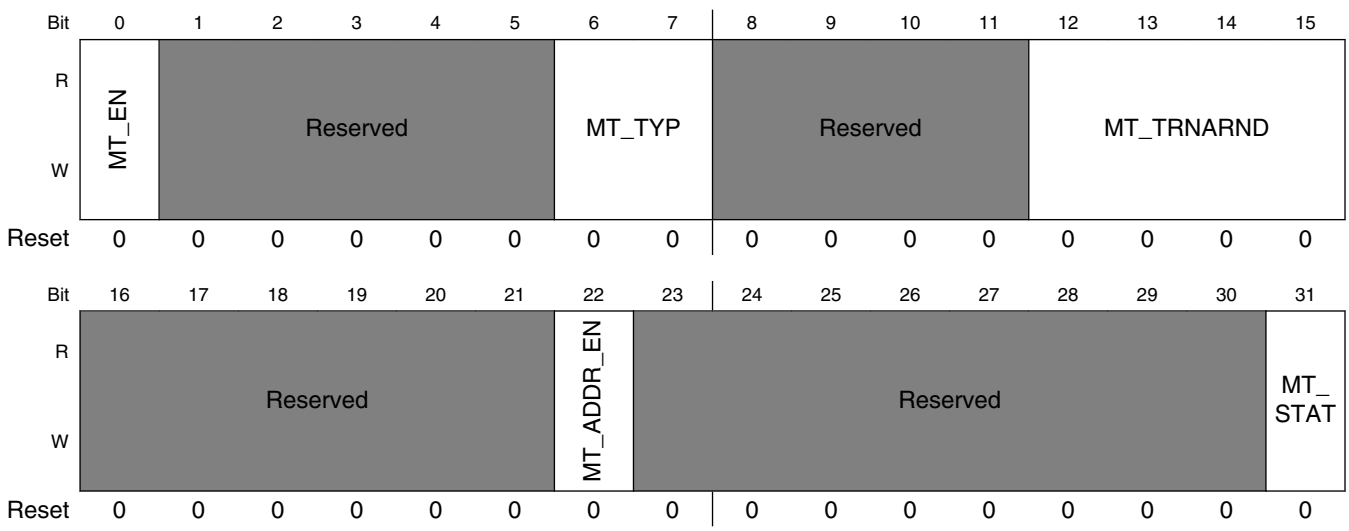
DDRx_DDR_IP_REV2 field descriptions (continued)

Field	Description
16–23 -	This field is reserved. Reserved
24–31 IP_CFG	IP block configuration options

11.4.40 DDR Memory Test Control Register (DDRx_DDR_MTCR)

The DDR Memory Test Control Register provides the enable and controls for an automatic memory test.

Address: Base address + D00h offset



DDRx_DDR_MTCR field descriptions

Field	Description
0 MT_EN	Memory Test Enable. This bit can be set by software to enable the memory test. Based on the value of MT_TYP, the controller will either issue writes only, reads only, or it will issue writes and reads.The memory controller will issue transactions throughout all of memory, as defined by the CSn_CONFIG and CSn_BNDS registers. The memory controller will check the data during this test. In addition, the ERR_DETECT register should be read by software if ECC is enabled after the memory test to ensure there were no ECC errors. If an ECC error is detected, the error capture registers will hold the address, data, and attributes captured for the first fail. If there is no ECC error and the test failed (for a data miscompare), then the capture registers will hold information for the transaction that caused the first data miscompare. Note that transactions with ECC errors will take priority in the capture registers. Hardware will clear MT_EN after the memory test is complete. This bit can be set before DDR_SDRAM_CFG[MEM_EN] is set, or it can be set again after the memory controller has been enabled. **NOTE:** The memory test may not be used if memory controller interleaving has been enabled via CS0_CONFIG[INTLV_EN] and DDR_MTCR[MT_TRNARND]=0000.

Table continues on the next page...

DDRx_DDR_MTCR field descriptions (continued)

Field	Description
	0 Memory test has been disabled. 1 Memory test has been enabled. Hardware will clear this bit when it is complete.
1–5 -	This field is reserved. Reserved
6–7 MT_TYP	Memory Test Type. This field will determine if the memory test will issue writes only, reads only, or both writes and reads. Note that the 'read only' test should not be used unless memory has already been initialized. 00 Memory test will issue writes and reads. 01 Memory test will issue writes only. 10 Memory test will issue reads only. 11 Reserved
8–11 -	This field is reserved. Reserved
12–15 MT_TRNARND	Memory Test Turnaround. This field determines how many writes will be issued during the memory test before the reads to the same addresses will be issued. This can be used to allow longer streams of writes/reads, and it can be used to test the write->read and read->write turnarounds in a stressful manner. This field is only relevant if MT_TYP is set to 2'b00. 0000 Entire memory will be written before read transactions are issued. 0001 Total write/read streams will be 1 transaction each. 0010 Total write/read streams will be 2 transactions each. 0011 Total write/read streams will be 4 transactions each. 0100-1111 Reserved
16–21 -	This field is reserved. Reserved
22 MT_ADDR_EN	Memory Test Address Range Enable. If this bit is set, then the address range defined in the DDR_MT_ST_EXT_ADDR, DDR_MT_ST_ADDR, DDR_MT_END_EXT_ADDR, and DDR_MT_END_ADDR registers will be used. **NOTE:** Please note the following restriction when using this field to limit the address range to be tested: For any individual test, neither the starting address (DDR_MT_ST_EXT_ADDR || DDR_MT_ST_ADDR) nor the ending address (DDR_MT_END_EXT_ADDR || DDR_MT_END_ADDR) can be less than that used during the previous test. 0 Full memory range defined by CSn_BNDS registers will be used for the memory test. 1 Memory range defined by DDR_MT_ST_EXT_ADDR, DDR_MT_ST_ADDR, DDR_MT_END_EXT_ADDR, and DDR_MT_END_ADDR is used.
23–30 -	This field is reserved. Reserved
31 MT_STAT	Memory Test Status. After hardware clears MT_EN, this bit will be set if there was a fail. If there is a fail during the memory test (that is, a data miscompare), then this bit will be set at the same time that MT_EN is cleared. Software can clear this bit after it has been set. 0 No fail has been detected. 1 A data miscompare was detected during the memory test.

11.4.41 DDR Memory Test Pattern n Register (DDR*x*_DDR_MTP*n*)

The DDR memory test pattern n register provides the data pattern that will be written during the nth set of 32-bits of each 40-byte memory test pattern. This is used when DDR_MTCR[MT_EN] is set to enable the memory write/read test.

NOTE

Memory test read compares data that is written in this register.

Address: Base address + D20h offset + (4d × i), where i=0d to 9d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DDR*x*_DDR_MTP*n* field descriptions

Field	Description
0–31 DDR_PATT	This 32-bit pattern will be used during the memory test if enabled via DDR_MTCR[MT_EN]. This memory test will write/read a programmable 40-byte pattern. The 10 DDR_MTPn registers will create the 40-byte pattern that is used.

11.4.42 DDR Memory Test Start Extended Address (DDR*x*_DDR_MT_ST_EXT_ADDR)

The DDR memory test start extended address register provides the extended address that will be used with DDR_MTCR[MT_ADDR_EN] is set.

Address: Base address + D60h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DDRx_DDR_MT_ST_ADDR field descriptions

Field	Description
0–31 MT_ST_ADDR	This field represents the starting address that will be used when MTCR[MT_ADDR_EN] is set. **NOTE:** Please note the following restriction when using DDR_MTCR[MT_ADDR_EN] to limit the address range to be tested: For any individual test, neither the starting address (DDR_MT_ST_EXT_ADDR || DDR_MT_ST_ADDR) nor the ending address (DDR_MT_END_EXT_ADDR || DDR_MT_END_ADDR) can be less than that used during the previous test.

11.4.44 DDR Memory Test End Extended Address (DDRx_DDR_MT_END_EXT_ADDR)

The DDR memory test end extended address register provides the extended address that will be used with DDR_MTCR[MT_ADDR_EN] is set.

NOTE

Please note the following restriction when using DDR_MTCR[MT_ADDR_EN] to limit the address range to be tested:

For any individual test, neither the starting address (DDR_MT_ST_EXT_ADDR || DDR_MT_ST_ADDR) nor the ending address (DDR_MT_END_EXT_ADDR || DDR_MT_END_ADDR) can be less than that used during the previous test.

DDR*x*_DATA_ERR_INJECT_LO field descriptions

Field	Description
0–31 EIML	Error injection mask low data path. Used to test ECC by forcing errors on the low word of the data path. Setting a bit causes the corresponding data path bit to be inverted on memory bus writes.

11.4.48 Memory data path error injection mask ECC (DDR*x*_ECC_ERR_INJECT)

The memory data path error injection mask ECC register sets the ECC mask, enables errors to be written to ECC memory, and allows the ECC byte to mirror the most significant data byte. In addition, a single address parity error may be injected through this register.

Address: Base address + E08h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table continues on the next page...

DDRx_ECC_ERR_INJECT field descriptions (continued)

Field	Description
15 APIEN	Address parity error injection enable. This bit will be cleared by hardware after a single address parity error has been injected. 0 Address parity error injection disabled. 1 Address parity error injection enabled.
16–21 -	This field is reserved. Reserved
22 EMB	ECC mirror byte 0 Mirror byte functionality disabled. 1 Mirror the most significant data path byte onto the ECC byte.
23 EIEN	Error injection enable 0 Error injection disabled. 1 Error injection enabled. This applies to the data mask bits, the ECC mask bits, and the ECC mirror bit. Note that error injection should not be enabled until the memory controller has been enabled via DDR_SDRAM_CFG[MEM_EN].
24–31 EEIM	ECC error injection mask. Setting a mask bit causes the corresponding ECC bit to be inverted on memory bus writes.

11.4.49 Memory data path read capture high (DDR*x*_CAPTURE_DATA_HI)

The memory data path read capture high register stores the high word of the read data path during error capture.

Address: Base address + E20h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DDRx_CAPTURE_DATA_LO field descriptions

Field	Description
0–31 ECLD	Error capture low data path. Captures the low word of the data path when errors are detected.

11.4.51 Memory data path read capture ECC (DDRx_CAPTURE_ECC)

The memory data path read capture ECC register stores the ECC syndrome bits that were on the data bus when an error was detected.

Address: Base address + E28h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	ECE																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

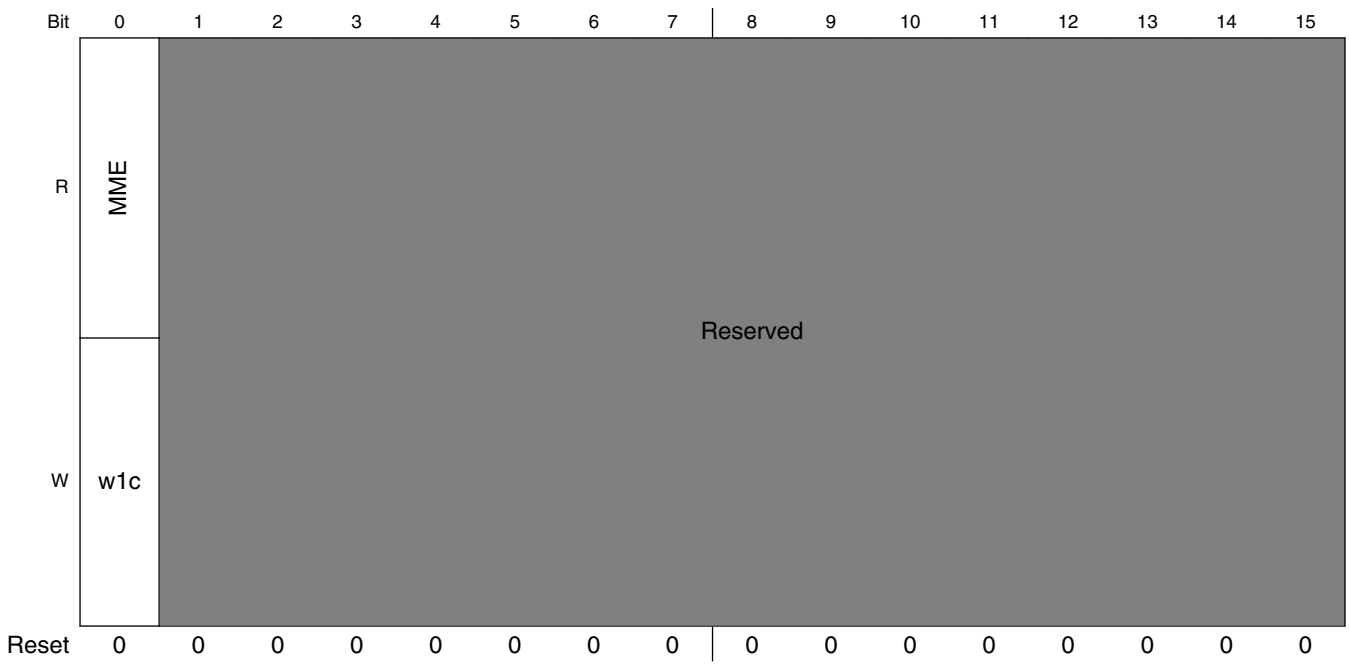
DDRx_CAPTURE_ECC field descriptions

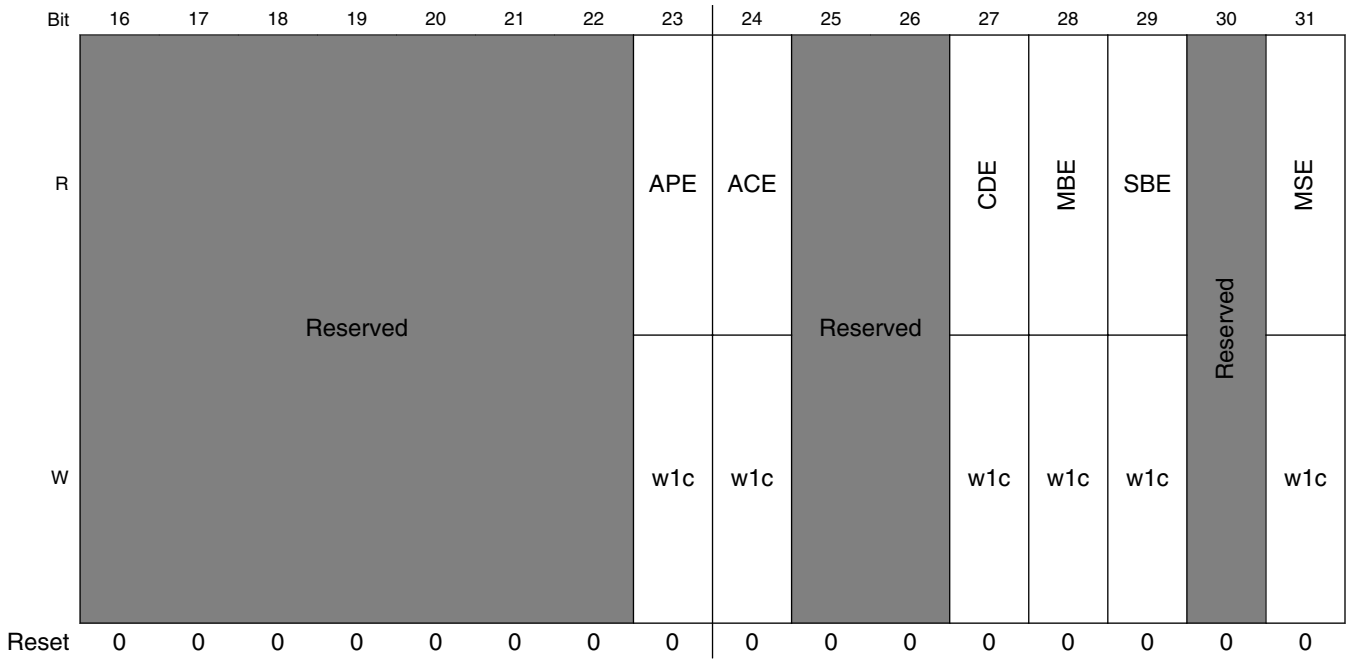
Field	Description
0–31 ECE	Error capture ECC. Captures the ECC bits on the data path whenever errors are detected. 64-bit mode: In 64-bit mode, only 24:31 should be used, although 0:7, 8:15, and 16:23 show the 8-bit ECC code replicated. • 0:7 should be ignored • 8:15 should be ignored • 16:23 should be ignored • 24:31 all 64 bits 32-bit mode: • 0:7 should be ignored • 8:15 8-bit ECC for the 32 bits in beats 0, 2, 4, 6 in 32-bit bus mode • 16:23 should be ignored • 24:31 8-bit ECC for the 32 bits in beats 1, 3, 5, 7 in 32-bit bus mode

11.4.52 Memory error detect (DDR*x*_ERR_DETECT)

The memory error detect register stores the detection bits for multiple memory errors, single- and multiple-bit ECC errors, and memory select errors. It is a read/write register. A bit can be cleared by writing a one to the bit. System software can determine the type of memory error by examining the contents of this register. If an error is disabled with ERR_DISABLE, the corresponding error is never detected or captured in ERR_DETECT.

Address: Base address + E40h offset





DDRx_ERR_DETECT field descriptions

Field	Description
0 MME	Multiple memory errors. This bit is cleared by software writing a 1. 0 Multiple memory errors of the same type were not detected. 1 Multiple memory errors of the same type were detected.
1–22 -	This field is reserved. Reserved
23 APE	Address parity error. This bit is cleared by software writing a 1. 0 An address parity error has not been detected. 1 An address parity error has been detected.
24 ACE	Automatic calibration error. This bit is cleared by software writing a 1. 0 An automatic calibration error has not been detected. 1 An automatic calibration error has been detected.
25–26 -	This field is reserved. Reserved
27 CDE	Corrupted data error. This bit is cleared by software writing a 1. 0 A corrupted data error has not been detected. 1 A corrupted data error has been detected. This bit will be set if the actual ECC is inverted from the expected ECC during a read command. The memory controller will intentionally invert the ECC code if DDR_SDRAM_CFG_2[CD_DIS] is cleared when corrupted data is written to memory. The ERR_DETECT[MBE] bit will also be set when a corrupted data error is detected. Note it is also possible for a 2-bit data error to cause the ECC code to become inverted, which would either mask a corrupted data error or cause a normal multi-bit error to also appear as a corrupted data error.
28 MBE	Multiple-bit error. This bit is cleared by software writing a 1.

Table continues on the next page...

DDRx_ERR_DETECT field descriptions (continued)

Field	Description
	0 A multiple-bit error has not been detected. 1 A multiple-bit error has been detected.
29 SBE	Single-bit ECC error. This bit is cleared by software writing a 1. 0 The number of single-bit ECC errors detected has not crossed the threshold set in ERR_SBE[SBET]. 1 The number of single-bit ECC errors detected crossed the threshold set in ERR_SBE[SBET].
30 -	This field is reserved. Reserved
31 MSE	Memory select error. This bit is cleared by software writing a 1. 0 A memory select error has not been detected. 1 A memory select error has been detected.

11.4.53 Memory error disable (DDRx_ERR_DISABLE)

The memory error disable register allows selective disabling of the DDR controller's error detection circuitry. Disabled errors are not detected or reported.

Address: Base address + E44h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

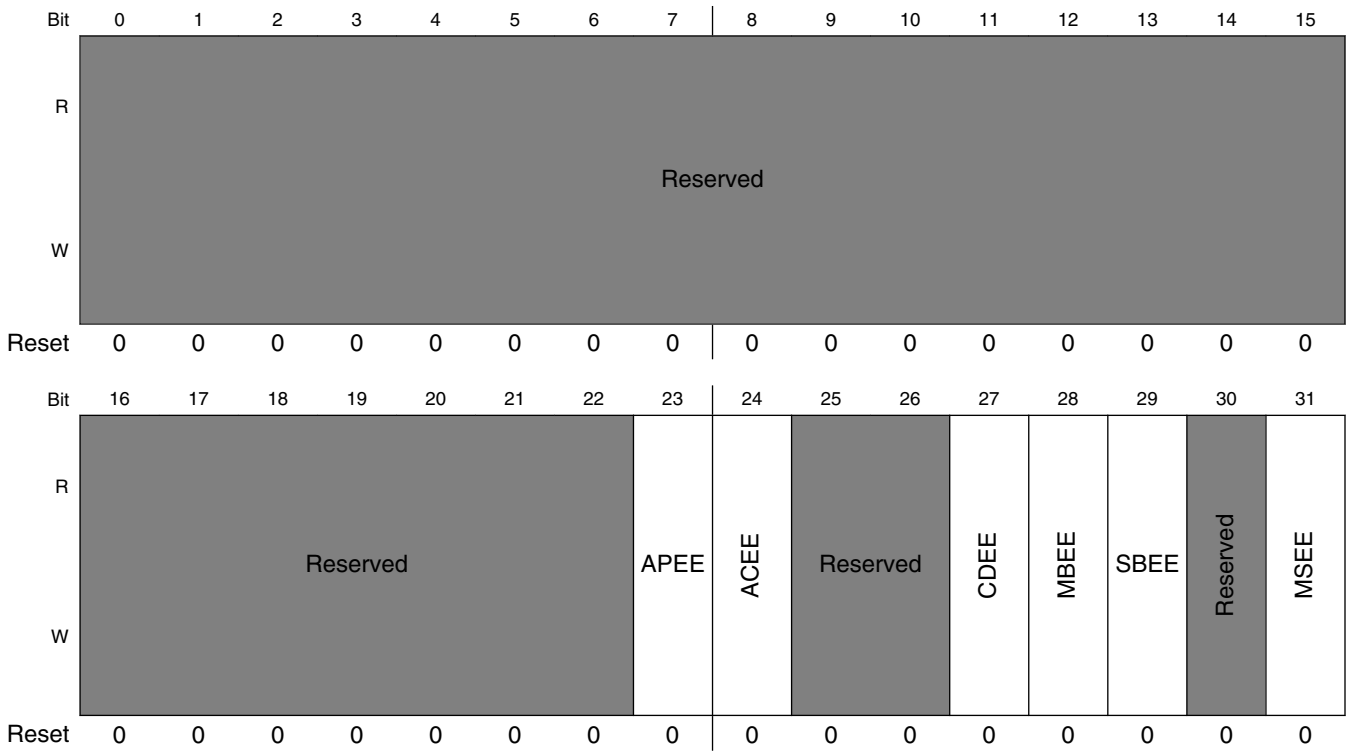
DDRx_ERR_DISABLE field descriptions

Field	Description
0–22 -	This field is reserved. Reserved
23 APED	Address parity error disable 0 Address parity errors are detected if (DDR_SDRAM_CFG2[AP_EN] is set. They are reported if ERR_INT_EN[APEE] is set. 1 Address parity errors are not detected or reported.
24 ACED	Automatic calibration error disable 0 Automatic calibration errors are enabled. 1 Automatic calibration errors are disabled.
25–26 -	This field is reserved. Reserved
27 CDED	Corrupted data error disable 0 Corrupted data error checking is enabled. 1 Corrupted data error checking is disabled.
28 MBED	Multiple-bit ECC error disable 0 Multiple-bit ECC errors are detected if DDR_SDRAM_CFG[ECC_EN] is set. They are reported if ERR_INT_EN[MBEE] is set. See Error Management for more information.MBED must be zero and ERR_INT_EN[MBEE] and ECC_EN must be one to ensure that an interrupt is generated. 1 Multiple-bit ECC errors are not detected or reported.
29 SBED	Single-bit ECC error disable 0 Single-bit ECC errors are enabled. 1 Single-bit ECC errors are disabled.
30 -	This field is reserved. Reserved
31 MSED	Memory select error disable 0 Memory select errors are enabled. 1 Memory select errors are disabled.

11.4.54 Memory error interrupt enable (DDRx_ERR_INT_EN)

The memory error interrupt enable register enables ECC interrupts or memory select error interrupts. When an enabled interrupt condition occurs, the internal *int_b* signal is asserted to the programmable interrupt controller (PIC).

Address: Base address + E48h offset



DDRx_ERR_INT_EN field descriptions

Field	Description
0–22 -	This field is reserved. Reserved
23 APEE	Address parity error interrupt enable 0 Address parity errors cannot generate interrupts. 1 Address parity errors generate interrupts.

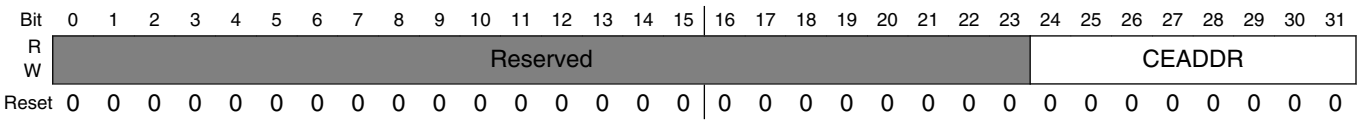
DDRx_CAPTURE_ADDRESS field descriptions

Field	Description
0–31 CADDR	Captured address. Captures the 32 lsbs of the transaction address when an error is detected.

11.4.57 Memory error extended address capture (DDRx_CAPTURE_EXT_ADDRESS)

The memory error extended address capture register holds the four most significant transaction bits when an error is detected.

Address: Base address + E54h offset



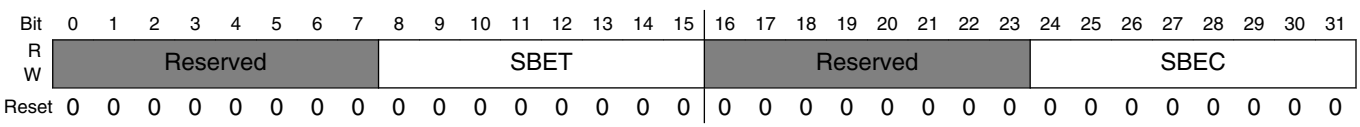
DDRx_CAPTURE_EXT_ADDRESS field descriptions

Field	Description
0–23 -	This field is reserved. Reserved
24–31 CEADDR	Captured extended address. Captures the 8 msbs of the transaction address when an error is detected

11.4.58 Single-Bit ECC memory error management (DDRx_ERR_SBE)

The single-bit ECC memory error management register stores the threshold value for reporting single-bit errors and the number of single-bit errors counted since the last error report. When the counter field reaches the threshold, it wraps back to the reset value (0). If necessary, software must clear the counter after it has managed the error.

Address: Base address + E58h offset



DDRx_ERR_SBE field descriptions

Field	Description
0–7 -	This field is reserved. Reserved
8–15 SBET	Single-bit error threshold. Establishes the number of single-bit errors that must be detected before an error condition is reported.
16–23 -	This field is reserved. Reserved

Table continues on the next page...

DDRx_ERR_SBE field descriptions (continued)

Field	Description
24–31 SBEC	Single-bit error counter. Indicates the number of single-bit errors detected and corrected since the last error report. If single-bit error reporting is enabled, an error is reported and an interrupt is generated when this value equals SBET. SBEC is automatically cleared when the threshold value is reached.

11.5 DDR Functional Description

The DDR SDRAM controller controls processor and I/O interactions with system memory. It provides support for JEDEC-compliant DDR3/3L SDRAMs. The memory system allows a wide range of memory devices to be mapped to any arbitrary chip select, and support is provided for registered DIMMs and unbuffered DIMMs. However, registered DIMMs cannot be mixed with unbuffered DIMMs.

The figure below is a high-level block diagram of the DDR memory controller. Requests are received from the internal mastering device and the address is decoded to generate the physical bank, logical bank, row, and column addresses. The transaction is compared with values in the row open table to determine if the address maps to an open page. If the transaction does not map to an open page, an active command is issued.

The memory interface supports as many as four physical banks of 64-/72-bit wide or 32-/40bit bit wide memory. Bank sizes up to 16 Gbytes are supported, providing up to a maximum of 64 Gbytes of DDR main memory.

Programmable parameters allow for a variety of memory organizations and timings. Optional error checking and correcting (ECC) protection is provided for the DDR SDRAM data bus. Using ECC, the DDR memory controller detects and corrects all single-bit errors within the 64- or 32- -bit data bus, detects all double-bit errors within the 64- or 32- bit data bus, and detects all errors within a nibble. The controller allows as many as 32 pages to be open simultaneously. The amount of time (in clock cycles) the pages remain open is programmable with DDR_SDRAM_INTERVAL[BSTOPRE].

Note that the examples below show x8 memory devices. If x4 memory devices are used (enabled via DDR_SDRAM_CFG_2[X4_EN]), then there will be 1 clock pair used with each nibble. For example, DQS0/DQS0_B will be the data strobes associated with DQ[0:3], and DM0/DQS9_B will be the data strobes associated with DQ[4:7].

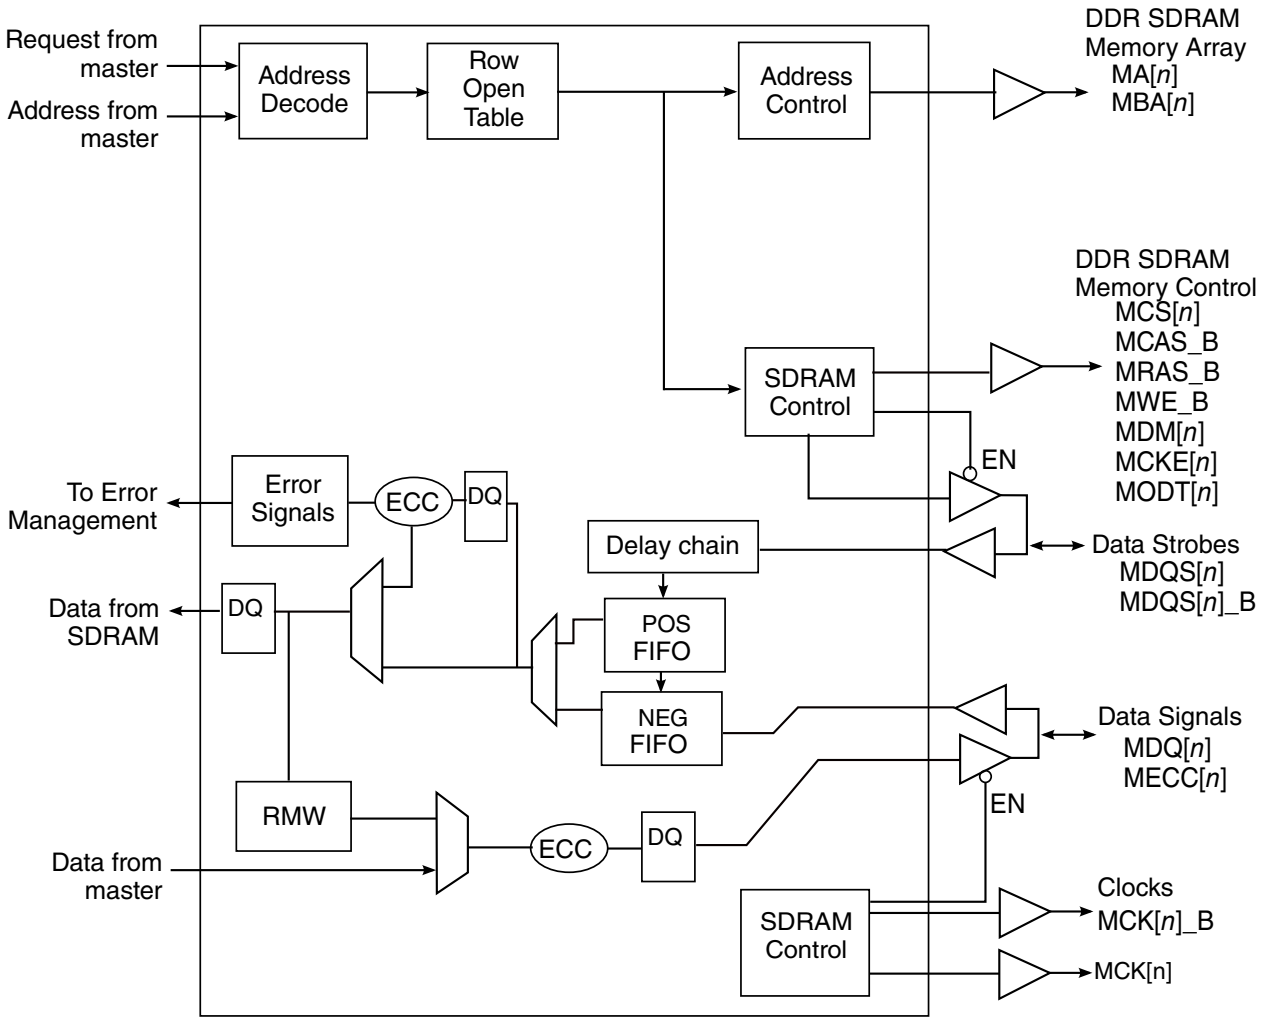


Figure 11-2. DDR Memory Controller Block Diagram

Read and write accesses to memory are burst oriented; accesses start at a selected location and continue for a programmed number of higher locations (4 or 8) in a programmed sequence. Accesses to closed pages start with the registration of an ACTIVE command followed by a READ or WRITE. (Accessing open pages does not require an ACTIVE command.) The address bits registered coincident with the activate command specifies the logical bank and row to be accessed. The address coincident with the READ or WRITE command specify the logical bank and starting column for the burst access.

The data interface is source synchronous, meaning whatever sources the data also provides a clocking signal to synchronize data reception. These bidirectional data strobes (MDQS[0:8]) are inputs to the controller during reads and outputs during writes. The DDR SDRAM specification requires the data strobe signals to be centered within the data tenure during writes and to be offset by the controller to the center of the data tenure during reads. This delay is implemented in the controller for both reads and writes.

When ECC is enabled, 1 clock cycle is added to the read path to check ECC and correct single-bit errors. ECC generation does not add a cycle to the write path.

The address and command interface is also source synchronous, although 1/8 cycle adjustments are provided for adjusting the clock alignment.

The figure below shows an example DDR SDRAM configuration with four logical banks.

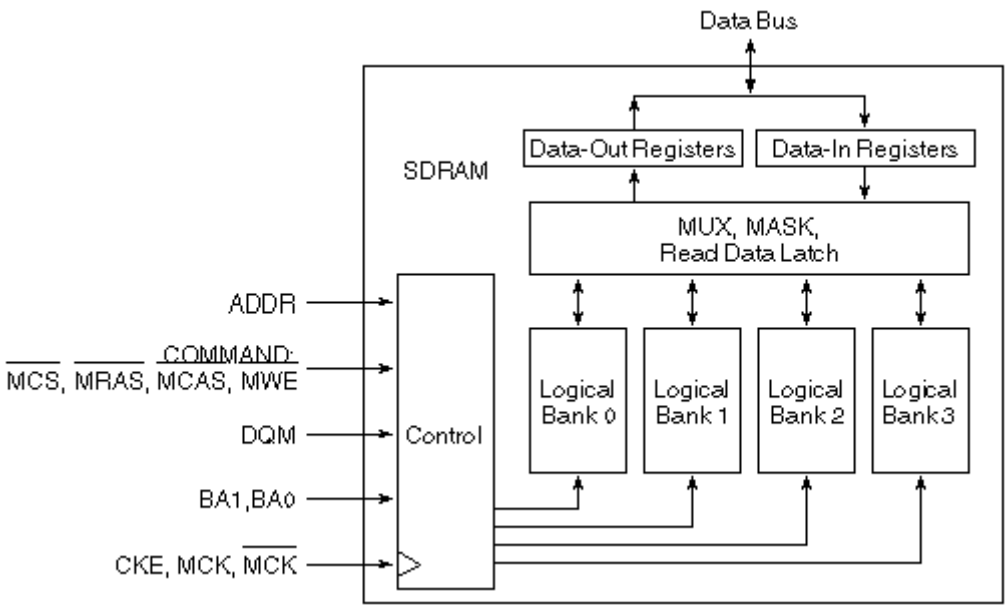

Figure 11-3. Typical Dual Data Rate SDRAM Internal Organization

The figure below shows some typical signal connections.

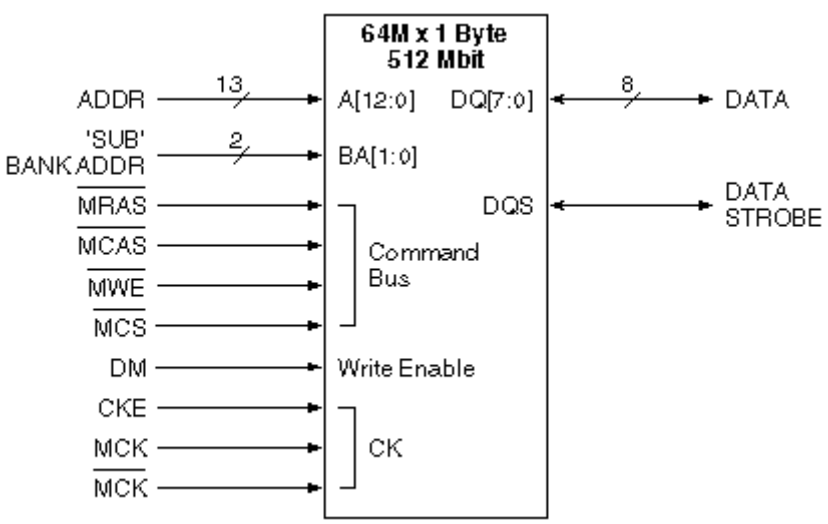

Figure 11-4. Typical DDR SDRAM Interface Signals

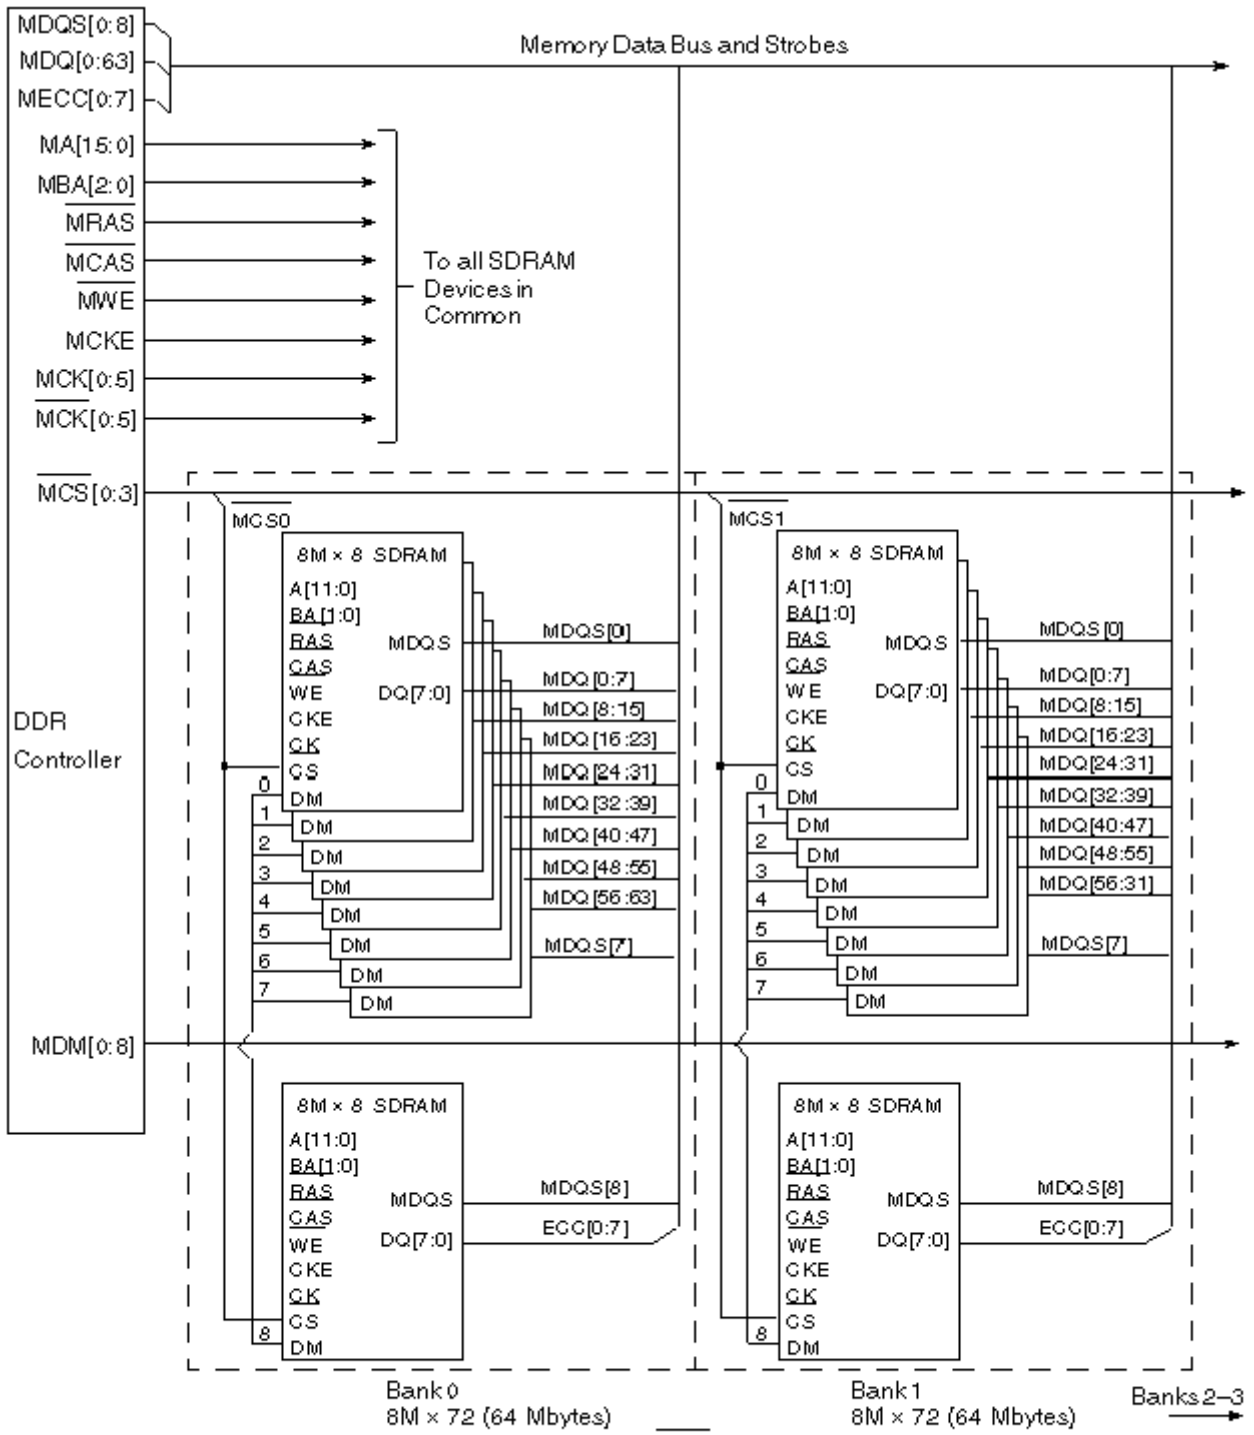
The figure below shows an example DDR SDRAM configuration with four physical banks each comprised of nine 8M x 8 DDR modules for a total of 256 Mbytes of system memory. One of the nine modules is used for the memory's ECC checking function. Certain address and control lines may require buffering. Analysis of the device's AC timing specifications, desired memory operating frequency, capacitive loads, and board routing loads can assist the system designer in deciding signal buffering requirements. The DDR memory controllerdrives 16 address pins, but in this example the DDR SDRAM devices use only 12 bits.



1. All signals are connected in common (in parallel) except for MCS[0:3], MCK[0:5], MDM[0:8], and the data bus signals.
2. Each of the MCS[0:3] signals correspond with a separate physical bank of memory.
3. Buffering may be needed if large memory arrays are used.
4. MCK[0:5] may be apportioned among all memory devices. Complementary bus is not shown.

Figure 11-5. Example 256-Mbyte DDR SDRAM Configuration

Error Management explains how the DDR memory controller handles errors.

11.5.1 DDR SDRAM interface operation

The DDR memory controller supports many different DDR SDRAM configurations. SDRAMs with different sizes can be used in the same system. 16 multiplexed address signals and three logical bank select signals support device densities from 64 Mbits to 8 Gbits. Four chip select (CS_B) signals support up to two DIMMs of memory. The DDR SDRAM physical banks can be built from standard memory modules or directly-attached memory devices. The data path to individual physical banks is 64 or 32 bits wide, 72 or 40 bits with ECC. The DDR memory controller supports physical bank sizes from 16 MB to 4 GB. The physical banks can be constructed using x 8, x16 (with 1 DQS per data byte) memory devices. The memory technologies supported are 64 Mbits, 128 Mbits, 256 Mbits, 512 Mbits, 1 Gbit , 2 Gbits, 4 Gbits and 8Gbits. Nine data qualifier (DQM) signals provide byte selection for memory accesses.

NOTE

An 8-bit DDR SDRAM device has a DQM signal and eight data signals (DQ[0:7]). A 16-bit DDR SDRAM device has two DQM signals associated with specific halves of the 16 data signals (DQ[0:7] and DQ[8:15]).

When ECC is enabled, all memory accesses are performed on double-word boundaries (that is, all DQM signals are set simultaneously). However, when ECC is disabled, the memory system uses the DQM signals for byte lane selection when using x8 or x16 devices.

This table shows the DDR memory controller's relationships between data byte lane0-7 , MDM[0:7], MDQS[0:7], and MDQ[0:63] when DDR SDRAM memories are used with x8 or x16 devices.

Table 11-7. Byte-lane-to-data relationship for x8 and x16 devices

Data byte lane	Data bus mask	Data bus strobe	Data bus 64-bit mode
0 (MSB)	MDM[0]	MDQS[0]/MDQS[0]_B	MDQ[0:7]
1	MDM[1]	MDQS[1]/MDQS[1]_B	MDQ[8:15]

7 (LSB)	N/A	MDM[7]/MDQS[16]_B	MDQ[60:63]

11.5.1.1 Supported DDR SDRAM Organizations

Although the DDR memory controller multiplexes row and column address bits onto 16 16 memory address signals and 3 logical bank select signals, a physical bank may be implemented with memory devices requiring fewer than 31 address bits. The physical bank may be configured to provide from 12 to 16 row address bits, plus 3 logical bank-select bits and from 8-11 column address bits.

The table below describes DDR SDRAM device configurations supported by the DDR memory controller.

Table 11-9. Supported DDR3 SDRAM Device Configurations

SDRAM Device	Device Configuration	Row x Column x Sub-bank Bits	64-Bit Bank Size	Four Banks of Memory
512 Mbits	128 Mbits x 4	13 x 11 x 3	1 Gbyte	4 Gbytes
512 Mbits	64 Mbits x 8	13 x 10 x 3	512 Mbytes	2 Gbytes
512 Mbits	32 Mbits x 16	12 x 10 x 3	256 Mbytes	1 Gbyte

Table continues on the next page...

Table 11-9. Supported DDR3 SDRAM Device Configurations (continued)

SDRAM Device	Device Configuration	Row x Column x Sub-bank Bits	64-Bit Bank Size	Four Banks of Memory
1 Gbits	256 Mbits x 4	14 x 11 x 3	2 Gbytes	4 Gbytes
1 Gbits	128 Mbits x 8	14 x 10 x 3	1 Gbyte	4 Gbytes
1 Gbits	64 Mbits x 16	13 x 10 x 3	512 Mbytes	2 Gbytes
2 Gbits	512 Mbits x 4	15 x 11 x 3	4 Gbytes	16 Gbytes
2 Gbits	256 Mbits x 8	15 x 10 x 3	2 Gbytes	8 Gbytes
2 Gbits	128 Mbits x 16	14 x 10 x 3	1 Gbyte	4 Gbytes
4 Gbits	1 Gbit x 4	16 x 11 x 3	8 Gbytes	32 Gbytes
4 Gbits	512 Mbits x 8	16 x 10 x 3	4 Gbytes	16 Gbytes
4 Gbits	256 Mbits x 16	15 x 10 x 3	2 Gbytes	8 Gbytes
8 Gbits	2 Gbits x 4	16 x 12 x 3	16 Gbytes	64 Gbytes
8 Gbits	1 Gbit x 8	16 x 11 x 3	8 Gbytes	32 Gbytes
8 Gbits	512 Mbits x 16	16 x 10 x 3	4 Gbytes	16 Gbytes

If a transaction request is issued to the DDR memory controller and the address does not lie within any of the programmed address ranges for an enabled chip select, a memory select error is flagged. Errors are described in detail in Error Management."

By using a memory-polling algorithm at power-on reset or by querying the JEDEC serial presence detect capability of memory modules, system firmware uses the memory-boundary registers to configure the DDR memory controller to map the size of each bank in memory. The memory controller uses its bank map to assert the appropriate MCSn_B signal for memory accesses according to the provided bank starting and ending addresses. The memory banks are not required to be mapped to a contiguous address space.

11.5.2 DDR SDRAM Address Multiplexing

The tables below show the address bit encodings for each DDR SDRAM configuration. The address presented at the memory controller signals MA[15 :0] use MA[15] as the msb and MA[0] as the lsb. Also, MA[10] is used as the auto-precharge bit in DDR3 mode for reads and writes, so the column address can never use MA[10].

Chip select interleaving is supported for the memory controller, and is programmed in DDR_SDRAM_CFG[BA_INTLV_CTL]. Interleaving is supported between chip selects 0 and 1 or chip selects 2 and 3. In addition, interleaving between all four chip selects can be enabled. When interleaving is enabled, the chip selects being interleaved must use the same size of memory. If two chip selects are interleaved, then 1 extra bit in the address decode is used for the interleaving to determine which chip select to access. If four chip selects are interleaved, then two extra bits are required in the address decode.

Table 11-12 illustrates examples of address decode when interleaving between two chip selects, and Table 11-13 shows examples of address decode when interleaving between four chip selects.

Partial Array Self Refresh (PASR) can be enabled for any chip select using the CS*n*_CONFIG_2[PASR_CFG] fields. If PASR is enabled for a given chip select, then the sub-bank and row decode will be swapped, and the sub-bank will be decoded as the most significant portion of the DRAM address, as shown in Table 11-14. If chip select interleaving and PASR are enabled for a chip select, then the interleaved chip select bit will be placed immediately to the left of the column decode, as shown in Table 11-15.

11.5.3 JEDEC Standard DDR SDRAM Interface Commands

The following section describes the commands and timings the controller uses when operating in DDR3 mode.

All read or write accesses to DDR SDRAM are performed by the DDR memory controller using JEDEC standard DDR SDRAM interface commands. The SDRAM device samples command and address inputs on rising edges of the memory clock; data is sampled using both the rising and falling edges of DQS. Data read from the DDR SDRAM is also sampled on both edges of DQS.

The following DDR SDRAM interface commands (summarized in Table 11-16) are provided by the DDR controller. All actions for these commands are described from the perspective of the SDRAM device.

- Row activate-Latches row address and initiates memory read of that row. Row data is latched in SDRAM sense amplifiers and must be restored by a precharge command before another row activate occurs.
- Precharge-Restores data from the sense amplifiers to the appropriate row. Also initializes the sense amplifiers in preparation for reading another row in the memory array, (performing another activate command). Precharge must occur after read or write, if the row address changes on the next open page mode access.
- Read-Latches column address and transfers data from the selected sense amplifier to the output buffer as determined by the column address. During each succeeding clock edge, additional data is driven without additional read commands. The amount of data transferred is determined by the burst size which defaults to 4.
- Write-Latches column address and transfers data from the data pins to the selected sense amplifier as determined by the column address. During each succeeding clock edge, additional data is transferred to the sense amplifiers from the data pins without

additional write commands. The amount of data transferred is determined by the data masks and the burst size, which is set to four by the DDR memory controller.

- Refresh (similar to MCAS_B before MRAS_B)-Causes a row to be read in all logical banks (JEDEC SDRAM) as determined by the refresh row address counter. This refresh row address counter is internal to the SDRAM. After being read, the row is automatically rewritten in the memory array. All logical banks must be in a precharged state before executing a refresh. The memory controller also supports posted refreshes, where several refreshes may be executed at once, and the refresh interval may be extended.
- Mode register set (for configuration)-Allows setting of DDR SDRAM options. These options are: MCAS_B latency, additive latency (for DDR3), write recovery (for DDR3), burst type, and burst length. MCAS_B latency may be chosen as provided by the preferred SDRAM (some SDRAMs provide MCAS_B latency {1,2,3}, some provide MCAS_B latency {1,2,3,4,5}, etc.). Burst type is always sequential. Although some SDRAMs provide burst lengths of 1, 2, 4, 8, and page size, this memory controller supports a burst length of 4. A burst length of 8 is supported for DDR3 memory only. The mode register set command is performed by the DDR memory controller during system initialization. Parameters such as mode register data, MCAS_B latency, burst length, and burst type, are set by software in DDR_SDRAM_MODE[SDMODE] and transferred to the SDRAM array by the DDR memory controller after DDR_SDRAM_CFG[MEM_EN] is set. If DDR_SDRAM_CFG[BI] is set to bypass the automatic initialization, then the MODE registers can be configured through software via use of the DDR_SDRAM_MD_CNTL register.
- Self refresh (for long periods of standby)-Used when the device is in standby for very long periods of time. Automatically generates internal refresh cycles to keep the data in all memory banks refreshed. Before execution of this command, the DDR controller will place all logical banks in a precharged state.

Table 11-16. DDR SDRAM Command Table

Operation	CKE Prev.	CKE Current	MCS_B	MRAS_B	MCAS_B	MWE_B	MBA	MA10	MA
Activate	H	H	L	L	H	H	Logical bank select	Row	Row
Precharge select logical bank	H	H	L	L	H	L	Logical bank select	L	X
Precharge all logical banks	H	H	L	L	H	L	X	H	X
Read	H	H	L	H	L	H	Logical bank select	L	Column
Read with auto-precharge	H	H	L	H	L	H	Logical bank select	H	Column
Write	H	H	L	H	L	L	Logical bank select	L	Column

Self refresh	H	L	L	L	L	H	X	X	X

11.5.4 DDR SDRAM Interface Timing

For single-beat reads, the DDR memory controller performs a four- (or eight-) beat burst read, but ignores the last three (or seven) beats. Single-beat writes are performed by masking the last three (or seven) beats of the four- (or eight-) beat burst using the data mask MDM[0:8]. If ECC is disabled, writes smaller than double words are performed by appropriately activating the data mask. If ECC is enabled, the controller performs a read-modify write.

NOTE

If a second read or write is pending, reads shorter than four beats are not terminated early even if some data is irrelevant.

To accommodate available memory technologies across a wide spectrum of operating frequencies, the DDR memory controller allows the setting of the intervals defined in the table below with granularity of one memory clock cycle, except for CASLAT, which can be programmed with 1/2 clock granularity.

Table 11-17. DDR SDRAM Interface Timing Intervals

Timing Intervals	Definition
ACTTOACT	The number of clock cycles from a bank-activate command until another bank-activate command within a physical bank. This interval is listed in the AC specifications of the SDRAM as t_{RRD}.
ACTTOPRE	The number of clock cycles from an activate command until a precharge command is allowed. This interval is listed in the AC specifications of the SDRAM as t_{RAS}.
ACTTORW	The number of clock cycles from an activate command until a read or write command is allowed. This interval is listed in the AC specifications of the SDRAM as t_{RCD}.
BSTOPRE	The number of clock cycles to maintain a page open after an access. The page open duration counter is reloaded with BSTOPRE each time the page is accessed (including page hits). When the counter expires, the open page is closed with a SDRAM precharge bank command as soon as possible.
CASLAT	Used in conjunction with additive latency to obtain the READ latency. The number of clock cycles between the registration of a READ command by the SDRAM and the availability of the first piece of output data. If a READ command is registered at clock edge *n*, and the read latency is *m* clocks, the data is available nominally coincident with clock edge $n + m$.

Table continues on the next page...

Table 11-17. DDR SDRAM Interface Timing Intervals (continued)

Timing Intervals	Definition
PRETOACT	The number of clock cycles from a precharge command until an activate or a refresh command is allowed. This interval is listed in the AC specifications of the SDRAM as t_{RP}.
REFINT	Refresh interval. Represents the number of memory bus clock cycles between refresh cycles. Depending on DDR_SDRAM_CFG_2[NUM_PR], some number of rows are refreshed in each SDRAM bank during each refresh cycle. The value of REFINT depends on the specific SDRAMs used and the frequency of the interface as t_{RP}.
REFREC	The number of clock cycles from the refresh command until an activate command is allowed. This can be calculated by referring to the AC specification of the SDRAM device. The AC specification indicates a maximum refresh to activate interval in nanoseconds. This field is also combined with TIMING_CFG_3[EXT_REFREC]
WR_DATA_DELAY	Provides different options for the timing between a write command and the write data strobe. This allows write data to be sent later than the nominal time to meet the SDRAM timing requirement between the registration of a write command and the reception of a data strobe associated with the write command. The specification dictates that the data strobe may not be received earlier than 75% of a cycle, or later than 125% of a cycle, from the registration of a write command. This parameter is not defined in the SDRAM specification. It is implementation-specific, defined for the DDR memory controller in TIMING_CFG_2.
WRREC	The number of clock cycles from the last beat of a write until a precharge command is allowed. This interval, write recovery time, is listed in the AC specifications of the SDRAM as t_{WR}.
WRTORD	Last write pair to read command. Controls the number of clock cycles from the last write data pair to the subsequent read command to the same bank as t_{WTR}.

The value of the above parameters (in whole clock cycles) must be set by boot code at system start-up (in the TIMING_CFG_0, TIMING_CFG_1, TIMING_CFG_2, and TIMING_CFG_3 registers as described in DDR SDRAM timing configuration 0 (DDR_TIMING_CFG_0)DDR SDRAM timing configuration 1 (DDR_TIMING_CFG_1)DDR SDRAM timing configuration 2 (DDR_TIMING_CFG_2) and DDR SDRAM timing configuration 3 (DDR_TIMING_CFG_3)) and be kept in the DDR memory controller configuration register space.

The following figures show SDRAM timing for various types of accesses. System software is responsible (at reset) for optimally configuring SDRAM timing parameters. The programmable timing parameters apply to both read and write timing configuration. The configuration process must be completed and the DDR SDRAM initialized before any accesses to SDRAM are attempted.

Figure 11-6 through Figure 11-8 show DDR SDRAM timing for various types of accesses; see Figure 11-7 for a burst read operation, Figure 11-6 for a single-beat write operation, and Figure 11-8 for a burst write operation. Note that all signal transitions occur on the rising edge of the memory bus clock and that single-beat read operations are identical to burst-reads. These figures assume the CLK_ADJUST is set to 1/2 DRAM cycle, an additive latency of 0 DRAM cycles is used, and the write latency is 1 DRAM cycle.

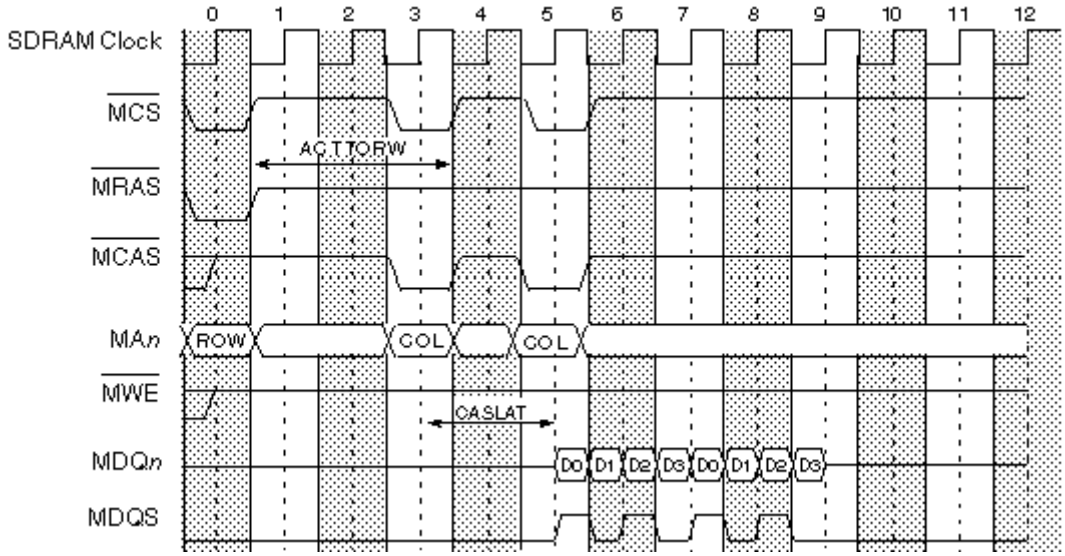

Figure 11-6. DDR SDRAM Burst Read Timing-ACTTORW = 3, MCAS_B Latency = 2

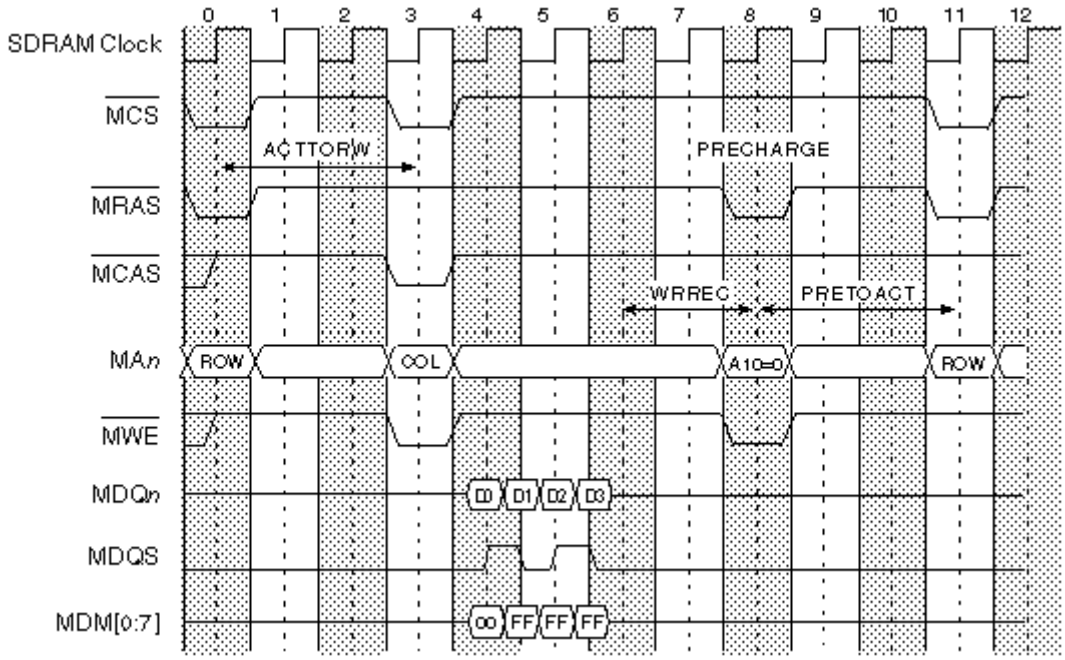

Figure 11-7. DDR SDRAM Single-Beat (Double Word) Write Timing-ACTTORW = 3

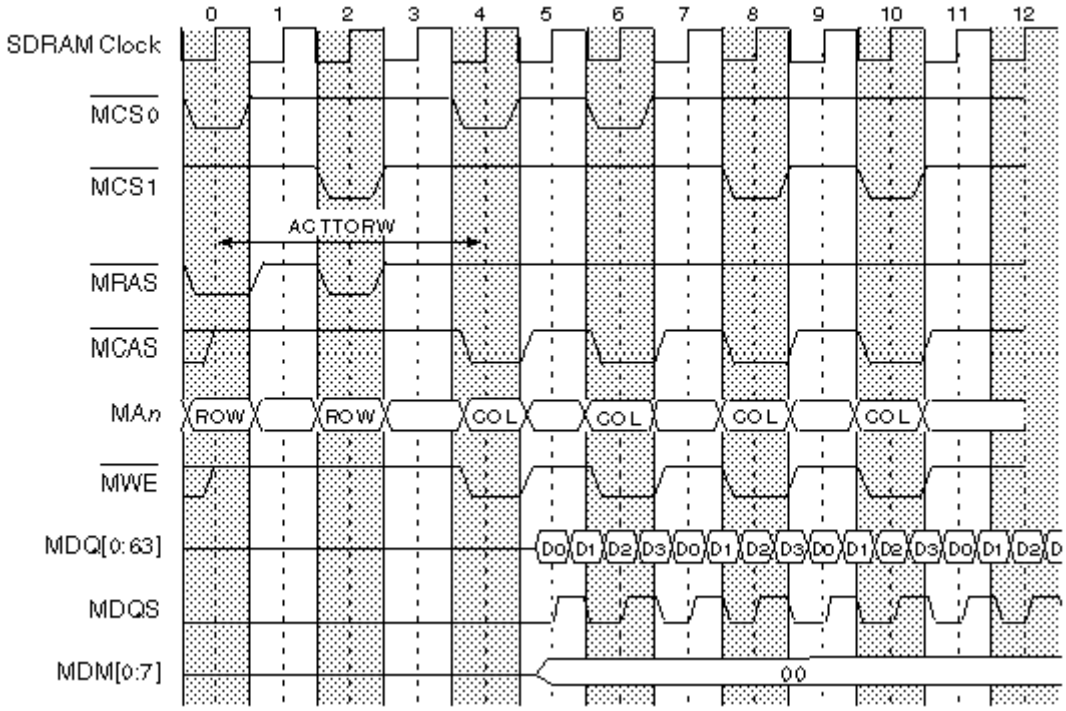

Figure 11-8. DDR SDRAM 4-Beat Burst Write Timing-ACTTORW = 4

11.5.4.1 Clock Distribution

- If running with many devices, zero-delay PLL clock buffers, JEDEC-JESD82 standard, should be used. These buffers were designed for DDR applications.
- A 72 bit x 64 Mbytes DDR bank has 9-byte-wide DDR chips, resulting in 18 DDR chips in a two-bank system. In this case, each MCK/MCK_B signal pair should drive exactly nine devices.
- PCB traces for DDR clock signals should be short, all on the same layer, and of equal length and loading.
- DDR SDRAM manufacturers provide detailed information on PCB layout and termination issues.

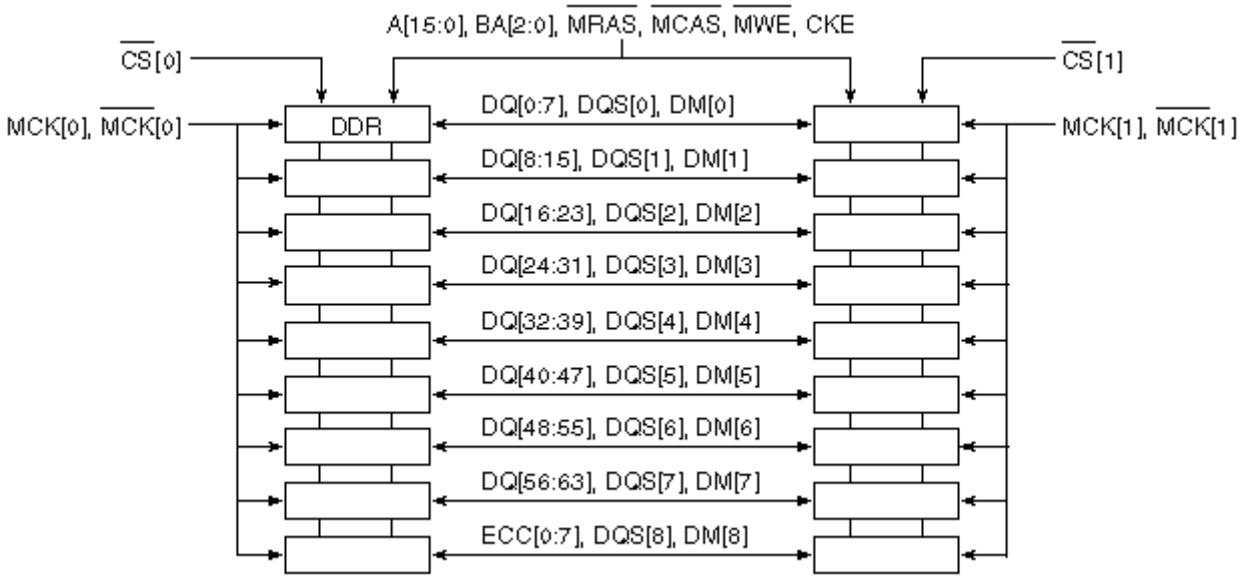

Figure 11-9. DDR SDRAM Clock Distribution Example for x8 DDR SDRAMs

11.5.5 DDR SDRAM Mode-Set Command Timing

The DDR memory controller transfers the mode register set commands to the SDRAM array, and it uses the setting of TIMING_CFG_0[MRS_CYC] for the Mode Register Set cycle time.

The figure below shows the timing of the mode-set command. The first transfer corresponds to the ESDMODE code; the second corresponds to SDMODE. The Mode Register Set cycle time is set to 2 DRAM cycles.

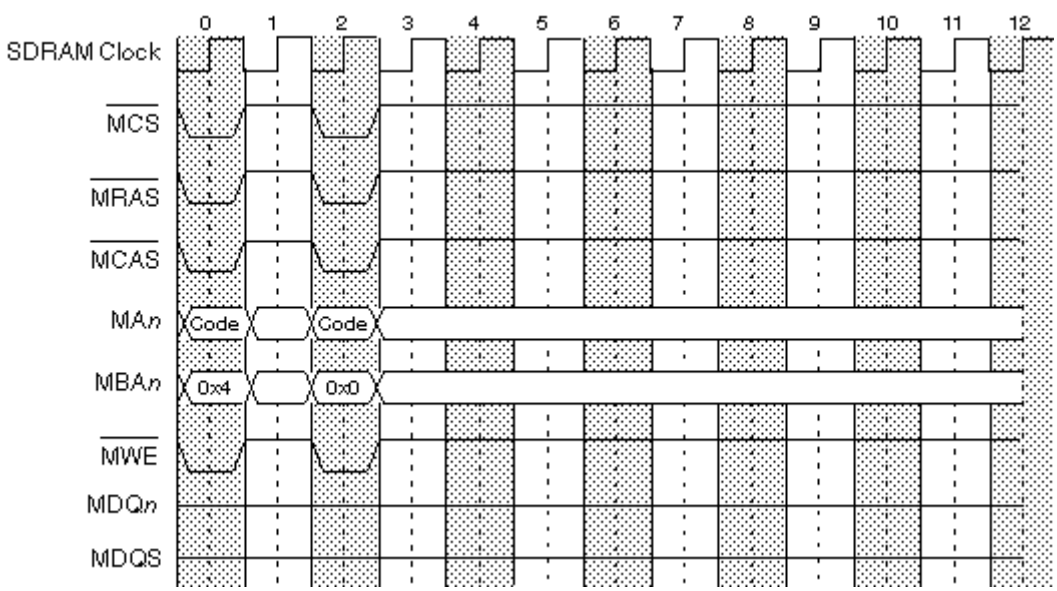

Figure 11-10. DDR SDRAM Mode-Set Command Timing

11.5.6 DDR SDRAM Registered DIMM Mode

To reduce loading, registered DIMMs latch the DDR SDRAM control signals internally before using them to access the array. Setting DDR_SDRAM_CFG[RD_EN] compensates for this delay on the DIMMs' control bus by delaying the data and data mask writes (on SDRAM buses) by an extra SDRAM clock cycle.

NOTE

Application system board must assert the reset signal on DDR memory devices until software is able to program the DDR memory controller configuration registers, and must deassert the reset signal on DDR memory devices before DDR_SDRAM_CFG[MEM_EN] is set. This ensures that the DDR memory devices are held in reset until a stable clock is provided and, further, that a stable clock is provided before memory devices are released from reset.

The figure below shows the registered DDR SDRAM DIMM single-beat write timing.

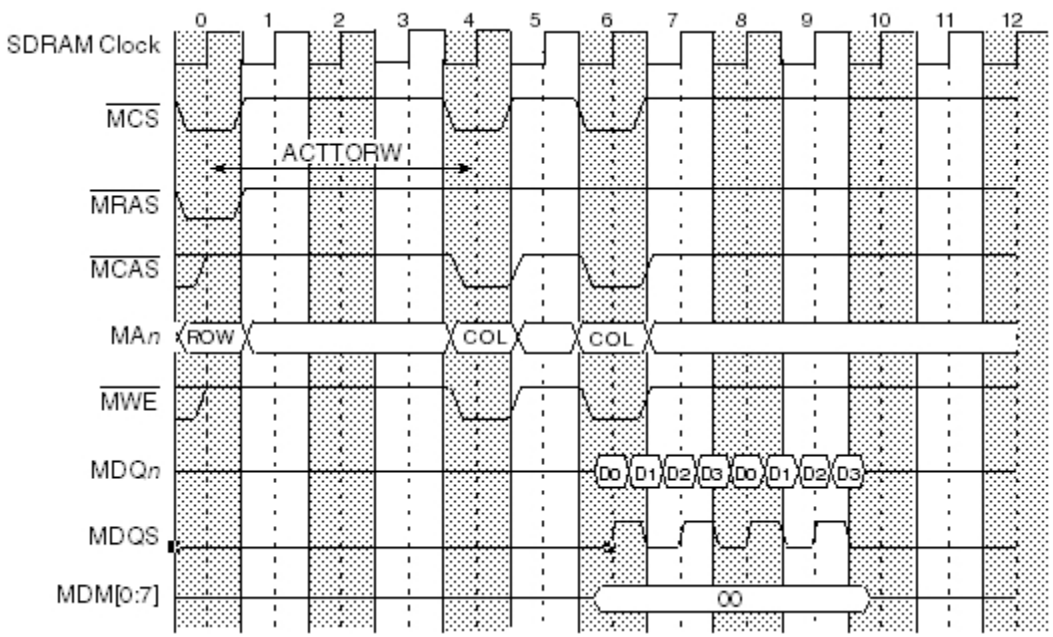

Figure 11-11. Registered DDR SDRAM DIMM Burst Write Timing

11.5.7 DDR SDRAM Write Timing Adjustments

The DDR memory controller facilitates system design flexibility by providing a write timing adjustment parameter, write data delay, (TIMING_CFG_2[WR_DATA_DELAY]) for data and DQS. The DDR SDRAM specification requires DQS be received no sooner than 75% of an SDRAM clock period-and no later than 125% of a clock period-from the capturing clock edge of the command/address at the SDRAM. The WR_DATA_DELAY parameter may be used to meet this timing requirement for a variety of system configurations, ranging from a system with one DIMM to a fully populated system with two DIMMs.
TIMING_CFG_2[WR_DATA_DELAY] specifies how much to delay the launching of DQS and data from the first clock edge occurring one SDRAM clock cycle after the command is launched. The delay increment step sizes are in 1/4 SDRAM clock periods starting with the default value of 0.

The figure below shows the use of the WR_DATA_DELAY parameter.

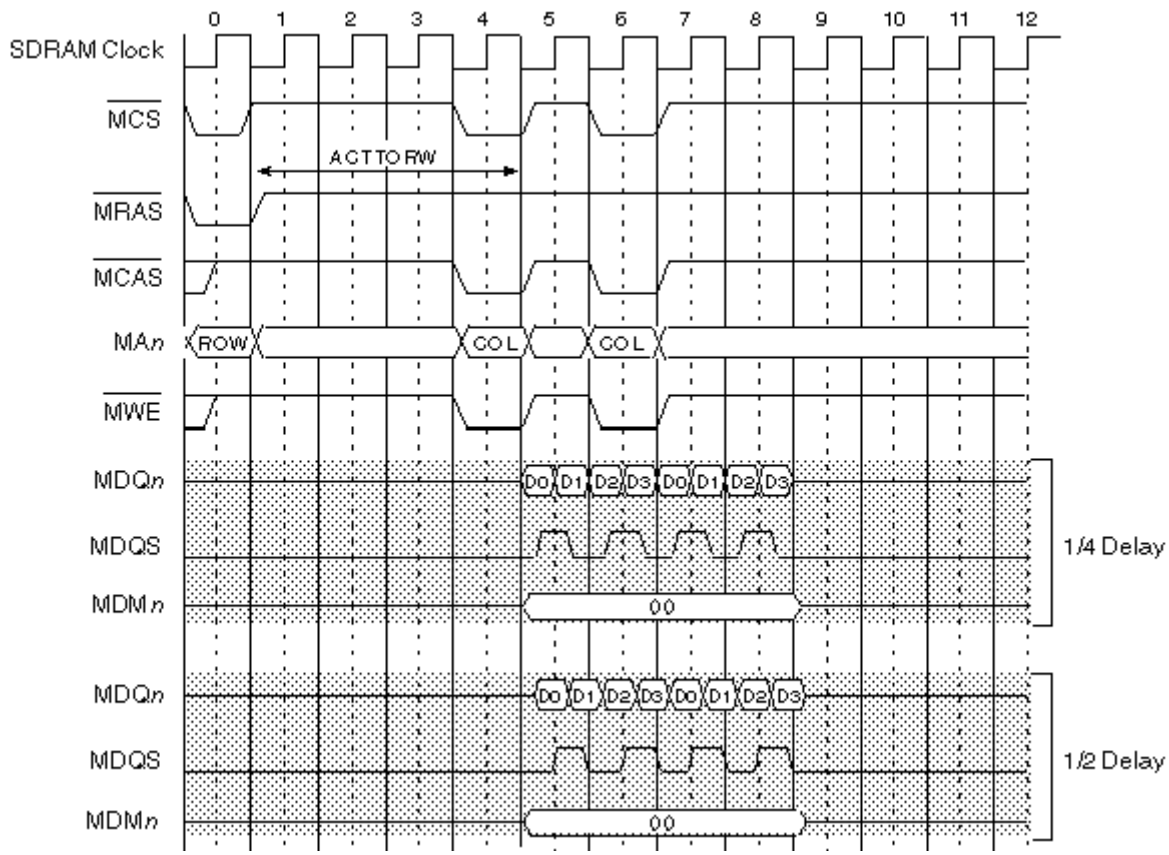

Figure 11-12. Write Timing Adjustments Example for Write Latency = 1

11.5.8 DDR SDRAM Refresh

The DDR memory controller supports auto-refresh and self-refresh. Auto refresh is used during normal operation and is controlled by the DDR_SDRAM_INTERVAL[REFINT] value; self-refresh is used only when the DDR memory controller is set to enter a sleep power management state. The REFINT value, which represents the number of memory bus clock cycles between refresh cycles, must allow for possible outstanding transactions to complete before a refresh request is sent to the memory after the REFINT value is reached. If a memory transaction is in progress when the refresh interval is reached, the refresh cycle waits for the transaction to complete. In the worst case, the refresh cycle must wait the number of bus clock cycles required by the longest programmed access. To ensure that the latency caused by a memory transaction does not violate the device refresh period, it is recommended that the programmed value of REFINT be less than that required by the SDRAM.

When a refresh cycle is required, the DDR memory controller does the following:

1. Completes all current memory requests.
2. Closes all open pages with a PRECHARGE-ALL command to each DDR SDRAM bank with an open page (as indicated by the row open table).
3. Issues one or more auto-refresh commands to each DDR SDRAM bank (as identified by its chip select) to refresh one row in each logical bank of the selected physical bank.

The auto-refresh commands are staggered across the four possible banks to reduce the system's instantaneous power requirements. Two sets of auto refresh commands will be issued on consecutive cycles when the memory is fully populated with two DIMMs. The initial PRECHARGE-ALL commands are also staggered in two groups for convenience. It is important to note that when entering self-refresh mode, only one refresh command is issued simultaneously to all physical banks. For this entire refresh sequence, no cycle optimization occurs for the usual case where fewer than four banks are installed. After the refresh sequence completes, any pending memory request is initiated after an inactive period specified by TIMING_CFG_1 [REFREC] and TIMING_CFG_3[EXT_REFREC]. In addition, posted refreshes are supported to allow the refresh interval to be set to a larger value.

11.5.8.1 DDR SDRAM Refresh Timing

Refresh timing for the DDR SDRAM is controlled by the programmable timing parameter TIMING_CFG_1 [REFREC], which specifies the number of memory bus clock cycles from the refresh command until a logical bank activate command is allowed. The DDR memory controller implements bank staggering for refreshes, as shown in this figure (TIMING_CFG_1 [REFREC] = 10 in this example).

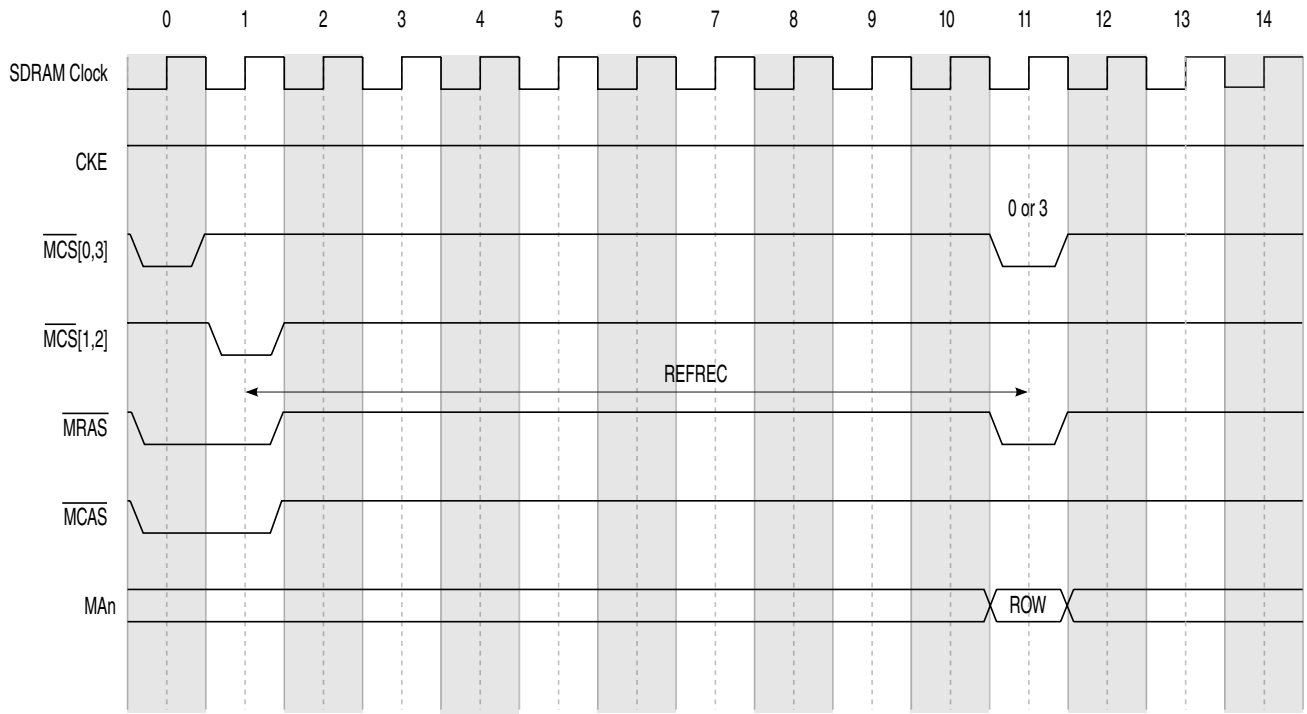

Figure 11-13. DDR SDRAM Bank Staggered Auto Refresh Timing

NOTE

Although the figure shows the controller activating bank 0 or 3 after the refresh recovery interval has expired in cycle 11, the controller could activate bank 1 or 2 instead of bank 0 or 3.

System software is responsible for optimal configuration of TIMING_CFG_1 [REFREC] and TIMING_CFG_3[EXT_REFREC] at reset. Configuration must be completed before DDR SDRAM accesses are attempted.

11.5.8.2 DDR SDRAM Refresh and Power-Saving Modes

In full-on mode, the DDR memory controller supplies the normal auto refresh to SDRAM. In sleep mode, the DDR memory controller can be configured to take advantage of self-refreshing SDRAMs or to provide no refresh support. Self-refresh support is enabled with the SREN memory control parameter.

Table 11-18 summarizes the refresh types available in each power-saving mode.

Table 11-18. DDR SDRAM Power-Saving Modes Refresh Configuration

Power Saving Mode	Refresh Type	SREN
Sleep	Self	1
	None	-

Note that in the absence of refresh support, system software must preserve DDR SDRAM data (such as by copying the data to disk) before entering the power-saving mode.

The dynamic power-saving mode uses the CKE DDR SDRAM pin to dynamically power down when there is no system memory activity. The CKE pin is negated when both of the following conditions are met:

- No memory refreshes are scheduled
- No memory accesses are scheduled

CKE is reasserted when a new access or refresh is scheduled or the dynamic power mode is disabled. This mode is controlled with DDR_SDRAM_CFG[DYN_PWR_MGMT].

Dynamic power management mode offers tight control of the memory system's power consumption by trading power for performance through the use of CKE. Powering up the DDR SDRAM when a new memory reference is scheduled causes an access latency penalty, depending on whether active or precharge powerdown is used, along with the settings of TIMING_CFG_0[ACT_PD_EXIT] and TIMING_CFG_0[PRE_PD_EXIT]. A penalty of 1 cycle is shown in the figure below .

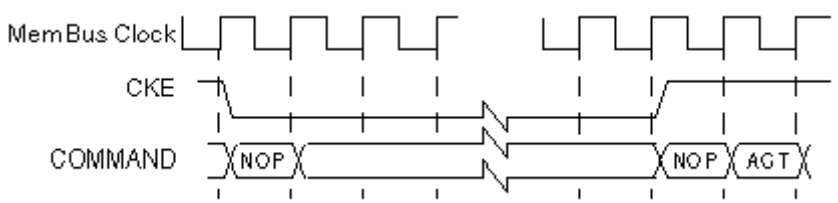

Figure 11-14. DDR SDRAM Power-Down Mode

11.5.8.2.1 Self-Refresh in Sleep Mode

The entry and exit timing for self-refreshing SDRAMs is shown in these figures.

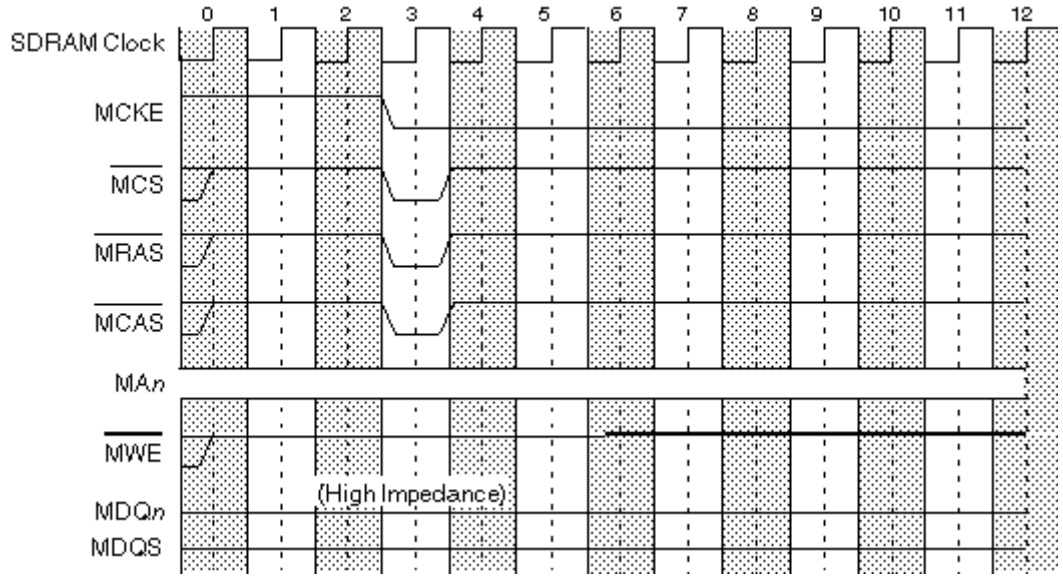

Figure 11-15. DDR SDRAM Self-Refresh Entry Timing

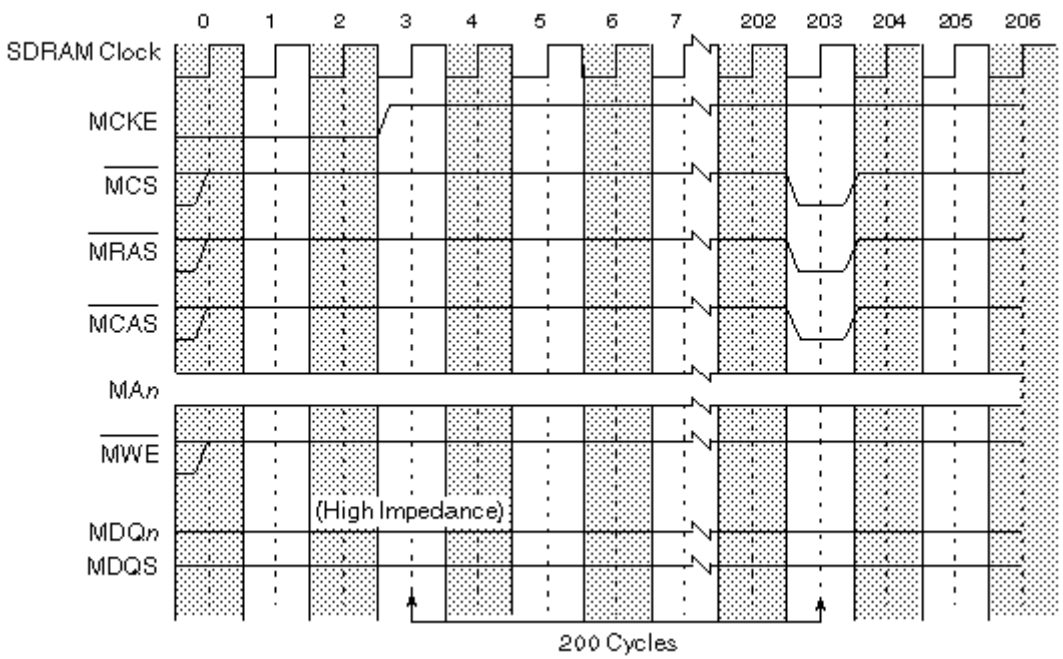

Figure 11-16. DDR SDRAM Self-Refresh Exit Timing

11.5.9 DDR Data Beat Ordering

Transfers to and from memory are always performed in four- or eight-beat bursts (four beats = 32 bytes when a 64-bit bus is used). For transfer sizes other than four or eight beats, the data transfers are still operated as four- or eight-beat bursts. If ECC is enabled and either the access is not doubleword aligned or the size is not a multiple of a doubleword, a full read-modify-write is performed for a write to SDRAM. If ECC is disabled or both the access is doubleword aligned with a size that is a multiple of a doubleword, the data masks (MDM[0:8] (MDM[0:4] for 32-bit bus) can be used to prevent the writing of unwanted data to SDRAM. The DDR memory controller also uses data masks to prevent all unintended full double words from writing to SDRAM. For example, if a write transaction is desired with a size of one double word (8 bytes), then the second, third, and fourth beats of data are not written to DRAM.

All writes for DDR3 mode will be aligned to beat 0 of the DRAM.

11.5.10 Page Mode and Logical Bank Retention

The DDR memory controller supports an open/closed page mode with an allowable open page for each logical bank of DRAM used. In closed page mode for DDR SDRAMs, the DDR memory controller uses the SDRAM auto-precharge feature, which allows the controller to indicate that the page must be automatically closed by the DDR SDRAM after the READ or WRITE access. This is performed by using MA[10] of the address during the COMMAND phase of the access to enable auto-precharge. Auto-precharge is non-persistent in that it is either enabled or disabled for each individual READ or WRITE command. It can, however, be enabled or disabled separately for each chip select.

When the DDR memory controller operates in open page mode, it retains the currently active SDRAM page by not issuing a precharge command. The page remains opens until one of the following conditions occurs:

- Refresh interval is met.
- The user-programmable DDR_SDRAM_INTERVAL[BSTOPRE] value is exceeded.
- There is a logical bank row collision with another transaction that must be issued.

Page mode can dramatically reduce access latencies for page hits. Depending on the memory system design and timing parameters, using page mode can save two to three clock cycles for subsequent burst accesses that hit in an active page. Also, better performance can be obtained by using more banks, especially in systems which use many different channels. Page mode is disabled by clearing DDR_SDRAM_INTERVAL[BSTOPRE] or setting CS n_CONFIG[AP_ nEN].

11.5.11 Error Checking and Correcting (ECC)

The DDR memory controller supports error checking and correcting (ECC) for the data path between the core master and system memory. The memory detects all double-bit errors, detects all multi-bit errors within a nibble, and corrects all single-bit errors. Other errors may be detected, but are not guaranteed to be corrected or detected. Double-bit errors are always reported when error reporting is enabled. When a single-bit error occurs, the single-bit error counter register is incremented, and its value compared to the single-bit error trigger register. An error is reported when these values are equal. The single-bit error registers can be programmed such that minor memory faults are corrected and ignored, but a catastrophic memory failure generates an interrupt.

For writes that are smaller than 64 bits, the DDR memory controller performs a double-word read from system memory of the address for the write (checking for errors), and merges the write data with the data read from memory. Then, a new ECC code is generated for the merged double word. The data and ECC code is then written to memory. If a multi-bit error is detected on the read, the transaction completes the read-modify-write to keep the DDR memory controller from hanging. However, the corrupt data is masked on the write, so the original contents in SDRAM remain unchanged.

The syndrome encodings for the ECC code are shown in Table 11-19 and Table 11-20.

Table 11-19. DDR SDRAM ECC Syndrome Encoding

11.5.12 Error Management

The DDR memory controller detects four different kinds of errors: training, single-bit, multi-bit, and memory select errors. The following discussion assumes all the relevant error detection, correction, and reporting functions are enabled as described in Memory error interrupt enable (DDR_ERR_INT_EN)Memory error disable (DDR_ERR_DISABLE) and Memory error detect (DDR_ERR_DETECT)."

Single-bit errors are counted and reported based on the ERR_SBE value. When a single-bit error is detected, the DDR memory controller does the following:

- Corrects the data
- Increments the single-bit error counter ERR_SBE[SBEC]
- Generates an critical interrupt if the counter value ERR_SBE[SBEC] equals the programmable threshold ERR_SBE[SBET]
- Completes the transaction normally

If a multi-bit error is detected for a read, the DDR memory controller logs the error and generates an error interrupt (if enabled, as described in Memory error disable (DDR_ERR_DISABLE)"). Another error the DDR memory controller detects is a memory select error, which causes the DDR memory controller to log the error and generate an critical interrupt (if enabled, as described in Memory error detect (DDR_ERR_DETECT)"). This error is detected if the address from the memory request does not fall into any of the enabled, programmed chip select address ranges. For all memory select errors, the DDR memory controller does not issue any transactions onto the pins after the first read has returned data strobes. If the DDR memory controller is not using sample points, then a dummy transaction is issued to DDR SDRAM with the first enabled chip select. In this case, the source port on the pins is forced to 0x1F to show the transaction is not real. Table 11-21 shows the errors with their descriptions. The final error the memory controller detects is the automatic calibration error. This error is set if the memory controller detects an error during its training sequence.

Table 11-21. Memory Controller Errors

Category	Error	Descriptions	Action	Detect Register
Notification	Single-bit ECC threshold	The number of ECC errors has reached the threshold specified in the ERR_SBE.	The error is reported via machine check or an error interrupt if enabled.	The error control register only logs read versus write, not full type
Access Error	Multi-bit ECC error	A multi-bit ECC error is detected during a read, or read-modify-write memory operation.		
	Memory select error	Read, or write, address does not fall within the address range of any of the memory banks.		

11.5.13 DDR Rapid Clear of Memory

Upon Hard Fail condition, the security monitor drives an interrupt to the DDR controller indicating the memory needs to be cleared, the DDR controller will clear all of memory defined by the CS*n*_BNDS registers for all enabled chip selects. DDRDSR_2[RPD_ST] will be set once the DDR controller begins clearing memory. At this time, writes to the DDR CCSR space are not allowed to modify the register values. Once the rapid clear of memory sequence is complete, writes to the DDR registers may proceed. The DDRDSR_2[RPD_EN] bit is provided so software can determine when the rapid clear of memory sequence is complete and can therefore update registers again. Software can clear the RPD_ST and RPD_EN bits after the rapid memory clear is complete.

11.6 Initialization/Application Information

NOTE

The DDRC must be programmed before the corresponding Local Access Windows are programmed and enabled for the DDR target(s).

System software must configure the DDR memory controller, using a memory polling algorithm at system start-up, to correctly map the size of each bank in memory. Then, the DDR memory controller uses its bank map to assert the appropriate MCSn_B signal for memory accesses according to the provided bank depths. System software must also configure the DDR memory controller at system start-up to appropriately multiplex the row and column address bits for each bank. Refer to row-address configuration in Chip select n configuration (DDR_CS*n*_CONFIG). Address multiplexing occurs according to these configuration bits.

At system reset, initialization software (boot code) must set up the programmable parameters in the memory interface configuration registers. See DDR Memory Map/ Register Definition for more detailed descriptions of the configuration registers. These parameters are shown in the table below.

Table 11-22. Memory Interface Configuration Register Initialization Parameters

Name	Description	Parameter		Section/Page

11.6.1 Programming Summary

Depending on the memory type used, certain fields must be programmed differently. The table below illustrates the differences in certain fields for different memory types. Note: This table does not list all fields that must be programmed.

Table 11-23. DDR3 Programming Summary

Parameter	Description	Summary	Section
AP*n* _EN	Chip Select *n*Auto Precharge Enable	Can be used to place chip select *n*in auto precharge mode	
ODT_RD_CFG	Chip Select ODT Read Configuration	Can be enabled to assert ODT if desired. This could be set differently depending on system topology. However, systems with only 1 chip select will typically not use ODT when issuing reads to the memory.	
ODT_WR_CFG	Chip Select ODT Write Configuration	Can be enabled to assert ODT if desired. This could be set differently depending on system topology. However, ODT will typically be set to assert for the chip select that is getting written to (value would be set to 001).	
PRETOACT	Precharge to Activate Timing	Should be set according to the specifications for the memory used (t_{RP})	
ACTTOPRE	Activate to Precharge Timing	Should be set, along with the Extended Activate to Precharge Timing, according to the specifications for the memory used (t_{RAS})	
ACTTORW	Activate to Read/Write Timing	Should be set according to the specifications for the memory used (t_{RCD})	

Table continues on the next page...

Table 11-23. DDR3 Programming Summary (continued)

Parameter	Description	Summary	Section
CASLAT	CAS Latency	Should be set, along with the Extended CAS Latency, to the desired CAS latency	
REFREC	Refresh Recovery	Should be set, along with the Extended Refresh Recovery, to the specifications for the memory used (T_{RFC})	
WRREC	Write Recovery	Should be set according to the specifications for the memory used (t_{WR}). If DDR_SDRAM_CFG_2[OBC_CFG] is set, then this should be programmed to t_{WR} + 2 DRAM cycles.	
ACTTOACT	Activate A to Activate B	Should be set according to the specifications for the memory used (t_{RRD})	
WRTORD	Write to Read Timing	Should be set according to the specifications for the memory used (t_{WTR}) If DDR_SDRAM_CFG_2[OBC_CFG] is set, then this should be programmed to t_{WTR} + 2 DRAM cycles.	
ADD_LAT	Additive Latency	Should be set to the desired additive latency. This must be set to a value less than TIMING_CFG_1[ACTTORW]	
WR_LAT	Write Latency	Should be set to the desired write latency. Note that DDR3 SDRAMs do not necessarily require the write latency to equal the CAS latency minus 1 cycle. The minimum WR_LAT that can be used in 1T timing mode is 5 cycles if DDR_RATE=0	
RD_TO_PRE	Read to Precharge Timing	Should be set according to the specifications for the memory used (t_{RTP}). Time between read and precharge for non-zero value of additive latency (AL) is a minimum of AL + t_{RTP} cycles. If DDR_SDRAM_CFG_2[OBC_CFG] is set, then this should be programmed to t_{RTP} + 2 DRAM cycles.	
CKE_PLS	Minimum CKE Pulse Width	Should be set according to the specifications for the memory used (t_{CKE})	
FOUR_ACT	Four Activate Window	Should be set according to the specifications for the memory used (t_{FAW}).	
RD_EN	Registered DIMM Enable	If registered DIMMs are used, then this field should be set to 1	
8_BE	8-beat burst enable	Set to 1 for fixed 8-beat burst mode. Set to 0 for on-the-fly burst chop mode and ensure DDR_SDRAM_CFG_2[OBC_CFG] = 1. If this is set to 0, then other requirements in TIMING_CFG_4 will be needed to ensure t_{CCD} is met.	
2T_EN	2T Timing Enable	In heavily loaded systems, this can be set to 1 to gain extra timing margin on the interface at the cost of address/ command bandwidth.	
ODT_CFG	ODT Configuration	Can be set for termination at the IOs according to system topology. Typically, if ODT is enabled, then the internal IOs should be set up for termination only during reads to DRAM.	
OBC_CFG	On-The-Fly Burst Chop Configuration	Can be set to 1 if on-the-fly burst chop will be used. This is expected to give the best performance in DDR3 mode. This feature can only be used if a 64-bit data bus is used.	

Table continues on the next page...

Table 11-23. DDR3 Programming Summary (continued)

Parameter	Description	Summary	Section
RWT	Read-to-write turnaround for same chip select (in TIMING_CFG_4)	This can be used to force a longer read-to-write turnaround time when accessing the same chip select. This is useful for burst chop mode, as there are some timing requirements to the same chip select that still must be met.	
WRT	Write-to-read turnaround for same chip select (in TIMING_CFG_4)	This could be used to force a certain turnaround time between a write and read to the same chip select. This is useful for burst chop mode. However, it is expected that TIMING_CFG_1[WRTORD] will be programmed appropriately such that TIMING_CFG_4[WRT] can be set to 0000.	
RRT	Read-to-read turnaround for same chip select (in TIMING_CFG_4)	Should typically be set to 0100 in burst chop mode (on-the-fly or fixed).	
WWT	Write-to-write turnaround for same chip select (in TIMING_CFG_4)	Should typically be set to 0100 in burst chop mode (on-the-fly or fixed).	
ZQ_EN	ZQ Calibration Enable	Should be set to 1. The other fields in DDR_ZQ_CNTL should also be programmed appropriately based on the DRAM specifications.	
WRLVL_EN	Write Leveling Enable	Can be set to 1 if write leveling is desired. Otherwise the value used in TIMING_CFG_2[WR_DATA_DELAY] will be used to shift all bytes during writes to DRAM. If write leveling will be used, all other fields in DDR_WRLVL_CNTL should be programmed appropriately based on the DRAM specifications.	
BSTOPRE	Burst To Precharge Interval	Can be set to any value, depending on the application. Auto precharge can be enabled by setting this field to all 0s.	

11.6.2 Supported DDR Interleaving Configurations

Considering the options for chip select, cache line, page, bank, and super-bank interleaving, the DDR controllers could potentially support hundreds of combinations, many of which are of limited utility. For this reason, only a subset of the possible combinations are supported. The following table describes the supported DDR interleaving configurations.

NOTE

If only one memory controller is being used, any non-reserved bank (chip select) interleaving (DDR_SDRAM_CFG[BA_INTLV_CTL]) setting may be selected. However, if multiple memory controllers are being used, the bank (chip select) interleaving

(DDR_SDRAM_CFG[BA_INTLV_CTL]) settings of all controllers must be the same.

Table 11-24. Supported DDR Interleaving Configurations

1. When more than one chip select is present in each of the two memory controllers only chip select 0 (CS0) or the chip selects that are bank interleaved with CS0 will be available after memory controller interleaving. For example, MC1 and MC2 each has CS0 and CS1 and. CS0 and CS1 of each memory controller are not interleaved. After memory controller interleaving between MC1 and MC2, only the combined memory space of CS0 or two controllers would be interleaved and available for access. The CS1 or each of the controllers that do not participate in the memory controller interleaving are not available or accessible.

11.6.3 DDR SDRAM Initialization Sequence

After configuration of all parameters is complete, system software must set DDR_SDRAM_CFG[MEM_EN] to enable the memory interface. Note that 200 µs (500 µs for DDR3) must elapse after DRAM clocks are stable (DDR_SDRAM_CLK_CNTL[CLK_ADJUST] is set and any chip select is enabled) before MEM_EN can be set, so a delay loop in the initialization code may be necessary if software is enabling the memory controller. If DDR_SDRAM_CFG[BI] is not set, the DDR memory controller will conduct an automatic initialization sequence to the memory, which will follow the memory specifications. If the bypass initialization mode is used, then software can initialize the memory through the DDR_SDRAM_MD_CNTL register.

NOTE

It is recommended to check DDR_ERR_DETECT after initialization has completed, assuming it has been cleared

before. If any error is reported in DDR_ERR_DETECT due to the initialization procedure, the initialization has failed and the memory interface cannot be considered stable for use.

11.6.4 Using Forced Self-Refresh Mode to Implement a Battery-Backed RAM System

This section describes the options offered by this device to support battery-backed main memory.

11.6.4.1 Hardware Based Self-Refresh Scheme

An external voltage sense device can be connected to this device through one of the external interrupt lines IRQ*n*. The external interrupt from the voltage sensor would then be steered through the programmable interrupt controller (MPIC) to the internal SoC interrupt event signal, *sie0*. Note that the *sie0* signal must remain high until power is removed. Also note that *sie0* is sent to all DDR controllers at the same time.

If DDR_SDRAM_CFG_2[SR_IE] is set, the *sie0* signal from the interrupt controller is then automatically detected by the DDR controller, which immediately causes main memory to enter self-refresh mode. See DDR SDRAM control configuration 2 (DDR_DDR_SDRAM_CFG_2) for further information on this bit.

These fields in the appropriate registers in the MPIC must be set for self refresh to function:

- EIVPR*n*[PRIORITY] should be set to 0xF (highest priority)
- EILRn[INTTGT] should be set to route the incoming signal to *sie0*

See External interrupt n (IRQn) vector/priority register (MPIC_EIVPR*n*) and External interrupt n (IRQn) level register (MPIC_EILR*n*) for descriptions of these registers.

11.6.4.2 Software Based Self-Refresh Scheme

The DDR controller also has a software-programmable bit, DDR_SDRAM_CFG_2[FRC_SR], that immediately puts main memory into self-refresh mode. See DDR SDRAM control configuration 2 (DDR_DDR_SDRAM_CFG_2) for a description of this register.

It is expected that a critical interrupt routine triggered by an external voltage sensing device will have time to set this bit.

11.6.4.3 Bypassing Re-initialization During Battery-Backed Operation

The DDR controller offers an initialization bypass feature (DDR_SDRAM_CFG[BI]), which system designers may use to prevent re-initialization of main memory during system power-on following an abnormal shutdown. See DDR SDRAM control configuration (DDR_DDR_SDRAM_CFG) for information on this bit and DDR training initialization address (DDR_DDR_INIT_ADDR) for a discussion of avoiding possible ECC errors in this mode.

Note that the DDR controller will automatically wait 200 DRAM cycles before issuing any command after the assertion of MCKE[0:3] when this mode is used.

Chapter 12
Integrated Flash Controller (IFC)

12.1 IFC overview

The integrated flash controller (IFC) is used to interface with external asynchronous NAND flash, asynchronous NOR flash, SRAM, generic ASIC memory and EPROM.

It has eight chip-selects, to which a maximum of eight flash devices can be attached, although only one of these can be accessed at any given time.

The IFC handles pin multiplexing to the internal system bus based on the selected controller (NAND, NOR, GPCM, or generic ASIC). To save pins at the chip level, multiplexing of address pins can be done on the data bus using an address valid signal (AVD). The BCH error-correction algorithm is used to correct the error bits while reading from a NAND device.

This figure shows the block diagram of IFC.

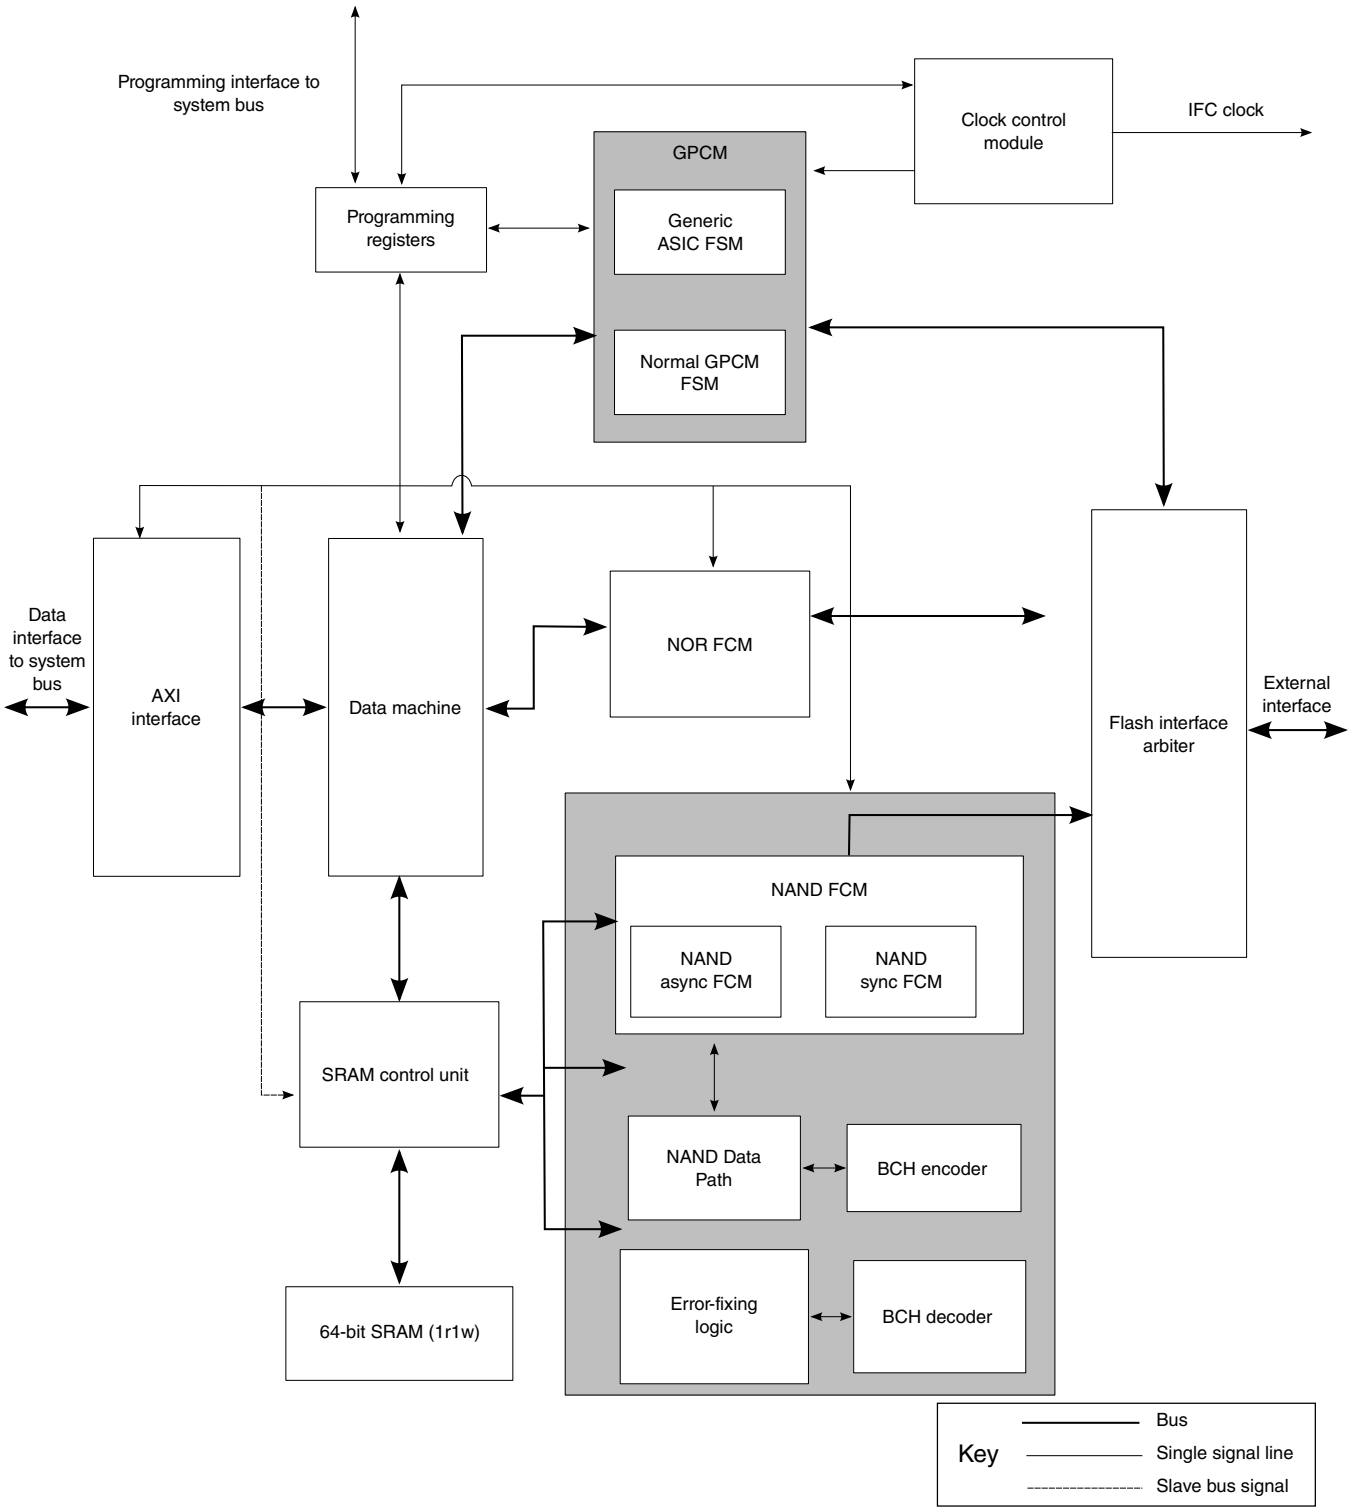

Figure 12-1. IFC block diagram

12.1.1 IFC features summary

The IFC supports both general and controller-specific features.

The general features of the IFC include the following:

- Flash controller with eight chip-selects
- Supports error and debug registers
- Functional muxing of pins between NAND, NOR, and GPCM
- Supports memory banks of sizes up to 4 GB (for NOR and GPCM)
- Write-protection capability (for NAND and NOR)
- Provision of software reset
- External transceiver enable/disable control on a per-bank basis

12.1.1.1 NAND flash features

The IFC features a NAND flash controller.

- x8 NAND flash interface
- Support for ONFI-2.2 asynchronous interface (8-/16-bit) and mandatory commands
- BCH code for 4-bit and 8-bit error correction per sector of 512 bytes (using GF-2^{13} Galois field) and 24 and 40-bit ECC per sector of 1 KB (using GF- 2^{14} Galois field):
  - For a 512-byte page and 16-byte spare region, 4-bit error correction is supported
  - For a 2 KB page and 64-byte spare region, 4-bit error correction is supported
  - For a 4 KB page width:
    - For 128-byte spare region, 4-bit error correction is supported
    - For 210-, 218-, and 224-byte spare regions, 4- or 8-bit error correction is supported
    - Spare size of minimum 176 bytes (8 for BBI + 4x42 for ECC bytes), 4-, 8-, or 24-bit BCH
    - Spare size of minimum 288 bytes (8 for BBI + 4x70 for ECC bytes), 4-, 8-, 24-, or 40-bit BCH
  - For an 8 KB page width:
    - At least 136(8 + 128) bytes of spare region is required for bad block information and ECC bytes, 4-bit BCH
    - 8 KB page, at least 264(8 + 256) bytes of spare region required for bad block information and ECC bytes, 4-bit or 8-bit BCH
    - Spare size of minimum 344 bytes (8 for BBI + 8x42 for ECC bytes), 4-, 8-, or 24-bit BCH
    - Spare size of minimum 568 bytes (8 for BBI + 8x70 for ECC bytes), 4-, 8-, 24-, or 40-bit BCH
  - For all ECC modes (4/8/24/40), parity bytes are stored at offset 08h in a spare region
- ECC generation/checking is optional
- Flexible timing control to allow interfacing with proprietary NAND devices

- Supports SLC and MLC flash devices with configurable page sizes of up to 8 KB
- Supports advance NAND commands such as cache, copy-back, and multi-plane programming
- Supports five RDY_B/BSY_B signals
- Programmable command and data transfer sequences of up to 15 steps
- Configurable block-size
- Interrupt for error handling and flash command completion event
- Internal SRAM of 9 KB
    - Memory-mapped
    - Can be configured as boot RAM
    - Acts as data buffer for normal operation
- Boot chip-select (CS0) available after system reset, with a boot block size of 8 KB for execute-in-place boot loading from NAND flash
- Supports flash devices of a magnitude of terabytes
    - By using 32 bit row address, 4 Giga pages of NAND flash can be accessed

12.1.1.2 NOR flash features

The IFC features a NOR flash controller.

- Compatible with asynchronous NOR flash (synchronous burst-read not supported)
- Provides memory-mapped interfacing to NOR
- Supports an address data multiplexed (ADM) NOR device
- Flexible timing control allows interfacing with proprietary NOR devices (WE_B controlled writes only)
- Boot chip-select (CS0) is available at system reset
- Data bus width of 16/32-bits
- Burst size in NOR is governed by system bus size and length

12.1.1.3 GPCM and GASIC features

The IFC's general-purpose, chip-select Controller (GPCM) supports operation in either normal or generic ASIC modes.

Normal GPCM features include the following:

- Support for x8-/16-/32-bit devices
- Compatible with general-purpose addressable device, such as SRAM and ROM
- External clock is generated with programmable division ratio (2, 3, 4, ... up to 16)
- Output enable signal (OE_B)
- Write enable signal(s) (WE_B)

- Even/odd parity data bus support
- External access termination signal (IFCTA_B)
- Programmable burst support

Generic ASIC features include the following:

- Support for x8-/16-/32-bit devices
- Address and data are shared on I/O bus
- The following address and data sequences are supported on the I/O bus:
  - 32-bit I/O: AD
  - 16-bit I/O: AADD
  - 8-bit I/O: AAAADDDD
- Configurable even/odd parity on address/data bus
- Parity-error detection

12.1.2 IFC modes of operation

The IFC contains one NAND controller, one NOR flash controller, and one GPCM/ generic-ASIC controller.

It can be programmed such that all eight memory banks can work with NAND, NOR, and GPCM/generic-ASIC interfaces as required. However, only one memory bank can be active at any given time.

12.2 External signal descriptions

This section provides both general and detailed information on the chip's external signals.

This table provides an overview of the chip's external signals, and the following table then provides a much more detailed description of the signals.

Table 12-1. Signal properties

Chip signal name	IFC signal name	Alternate Functions	Mode	Description / Function	Number of signals	I/O
IFC_AD[0:31]	AD[0:31]	AD[0:31]	NAND FCM	I/O Bus for Asynchronous NAND	32	I/O
		AD[0:31]	NOR FCM	Bidirectional Data Bus for NOR. During AVD assertion, this bus will

Table 12-1. Signal properties (continued)

Chip signal name	IFC signal name	Alternate Functions	Mode	Description / Function	Number of signals	I/O
				carry address bits. Address LSB or MSB will be governed by CSOR[ADM_SHFT_MODE]		
		AD[0:31]	GPCM	Bidirectional data bus for GPCM. For external address latching, this bus is used to carry address MSBs.		
		AD[0:31]	GASIC	Bidirectional shared address/ data bus for GASIC.		
IFC_A[26:31]	ADDR[26:31]	-	-	Dedicated address bus used by NOR and GPCM mode	6	O
IFC_PAR[0:3]	PAR[0:3]	PAR[0:3]	GPCM	Parity data	4	I/O
		PAR[0:3]	GASIC	Parity address and data		
IFC_CS[0:7]_B	CE/CS[0:7]_B	-	-	Chip Selects	8	O
IFC_WE0_B	WE0_B	NRWE_B	NOR FCM	NOR Write Enable	1	O
		GPWE0_B	GPCM	GPCM Write Byte Select 0		
		SOF_L_B	GASIC	Start of frame indication for Generic ASIC		
		NDWE_B	Async	NAND Write Enable		
IFC_BCTL	BCTL	-	-	Data buffer control	1	O
IFC_TE	TE	-	-	External Transceiver Enable/Disable Control	1	I/O
IFC_AVD	ALE/AVD	NDALE	NAND FCM	NAND Address Latch Enable	1	O
		NRAVD	NOR FCM	NOR External Address Latch Enable/AVD		

Table continues on the next page...

Table 12-1. Signal properties (continued)

Chip signal name	IFC signal name	Alternate Functions	Mode	Description / Function	Number of signals	I/O
		GPALE	GPCM	GPCM External Address Latch Enable		
IFC_CLE	CLE	NDCLE	NAND FCM	NAND Command Latch Enable	1	O
		GPWE1_B	GPCM	GPCM Write Byte Select 1		
IFC_WE2_B	WE2_B	GPWE2_B	GPCM	GPCM Write Byte Select 2	1	O
		NRAVD_B	NOR FCM	Address Valid Signal for ADM NOR (Timing is same as NRAVD except opposite polarity)		
IFC_WE3_B	WE3_B	-	GPCM	GPCM Write Byte Select 3	1	O
IFC_OE_B	OE_B	NROE_B	NOR FCM	NOR Output Enable	1	O
		GPOE_B	GPCM	GPCM Output Enable		
		RW_L_B	GASIC	GASIC Read/ Write Indication		
		NDRE_B	Async	NAND Read Enable		
IFC_WP[0:3]_B	WP[0:3]_B	NDWP[0:3]_B	NAND FCM	Per chip select based NAND Write Protect	4	O
IFC_RB[0:4]_B	RB[0:4]_B	NAND FCM	NAND Ready/ Busy Input	5	I	
		NRRB[0:4]_B	NOR FCM			NOR Ready Busy Input
		IFCTA[0:4]_B	GPCM			GPCM External Termination
		RDY_L[0:4]_B	GASIC			GASIC Ready Indication
IFC_PERR_B	PERR_L_B	PERR_L_B	GASIC	Parity error from Generic ASIC	1	I
IFC_CLK[0:2]	CLK[0:2]	-	-	External IFC clock	3	O

This table describes the external signals in detail.

Table 12-2. Detailed signal description

Signal	I/O	Description	
AD[0:*n*]	I/O	Multiplexed address/data bus.	
		State meaning	Asserted/Negated - During the assertion of AVD, AD[0:*n*] are driven with the address for the access to follow. External logic should propagate the address on AD[0:*n*]while AVD is asserted and latch the address upon negation of AVD. After it is negated, AD[0:*n*] are either driven by write data or are switched to an input to sample read data driven by an external device. Following the last data transfer of a write access, AD[0:*n*] are released to a high-impedance state. For exact functionality, behavior, and timings, refer to detailed waveform and timing diagrams within the specific interface.
ADDR[*n*:*m*]	O	Non-multiplexed address bus.	
		State meaning	Asserted/Negated - It is a non-multiplexed address bus which carries address MSBs or LSBs depending on CSOR[ADM_SHFT_MODE].
ALE	O	External Address Latch Enable (NAND) External Address Valid Signal (NOR) External Address Latch Enable(GPCM) Control signal for an external address latch, which allows address and data to be multiplexed on the device pins	
		State meaning	Asserted - Latch enable is asserted with the address at the beginning of each memory controller transaction. The number of cycles for which it is asserted is governed by the FTIM0_CSn[EADC] field. Negated - The exact timing of the negation of AVD is controlled by the FTIM0_CSn[EAHC] field. Note that no other control signals are asserted during the assertion of AVD.
AVD_B	O	Active low address valid signal for the address latch in NOR devices.	
		State meaning	Timing is same as AVD signal except opposite polarity.
CS[0:*n*]_B	O	Chip-Select; mutually exclusive chip-selects are available.	
		State meaning	Asserted/Negated - Used to enable each specific memory device connected to the IFC. CS_B[0] corresponds to the chip-select for memory bank 0, which has the memory type and attributes defined by CSPR0 and FTIM0_CS0.
WE[0:n]_B	O	NAND write enable, NOR write enable, GPCM write byte select 0, GASIC start of frame.	
		State meaning	Asserted/Negated - Used to control the data write cycles on NOR/NAND flash. For GPCM it validates its corresponding byte number on the data bus. For GASIC it indicates start of a transaction frame.
CLE	O	NAND Command latch enable, GPCM write byte select 1 which is WE[1]_B.	
		State meaning	Asserted/Negated - It enables the command cycle on NAND flash. For GPCM it validates 1st byte(AD [8:15]) on data bus.
OE_B	O	NAND read enable, NOR output enable, GPCM output enable, GASIC Read/Write Enable and is valid only when SOF_L_B is asserted.	
		State meaning	Asserted/Negated - It enables data read cycles on NOR, NAND, and GPCM devices. For GASIC, it indicates whether the transaction is read or write. High value on this indicates read operation while low value indicates write.

Table continues on the next page...

Table 12-2. Detailed signal description (continued)

Signal	I/O	Description	
WP[0:*n*]_B	O	Per chip select based non-muxed NAND Write Protect Output. GPCM write byte select its corresponding byte number on the data bus. Note that if chip has multiplexed single WP_B pin to different chip selects connecting different NAND devices, then same value must be programmed in corresponding CSPRn[WP] bit field sharing same WP_B pin. It is required as NAND device expects TWW wait time for any toggling in WP_B pin.	
		State meaning	Asserted/Negated - It protects NAND flash from accidental erasure or program when asserted low. For GPCM it validates the corresponding byte number on data bus.
RB[0:*n*]_B	I	NAND ready busy for all the chip-selects, NOR Read Busy, GPCM External Termination of Access, GASIC Ready Indication. Valid after the completion of address phase till it asserts.	
		State meaning	Asserted/Negated - It indicates the ready busy status of the flash operation. It is used to stall the controller operation when the flash is indicating busy. For GPCM this input is used for termination of current access. For GASIC it indicates that the current GASIC transaction is accepted by device and the host can start the next transaction.
BCTL	O	Data buffer control. Buffer control is disabled by FTIM0_CS0[BCTLD] field.	
		State meaning	Asserted/Negated - The BCTL pin normally functions as a write (High)/read (Low) direction control for the external data buffer used in the AD lines (bidirectional bus). Default value of BCTL is high (write direction).
TE	I/O	External transceiver enable/disable. This pin acts as an input during reset and should be weakly pulled up/down so as to disable the external transceiver during that time. After reset, the IFC drives TE with the value configured in CSPRn[TE] as per the selected chip select. When none of the CS pins are selected, TE is driven High-Z from the IFC (the external transceiver will be disabled by the appropriate external pull device).	
		State meaning	Asserted/Negated - The TE pin functions as an enable/disable for an external transceiver connected to the AD lines. In asserted state, it enables the external transceiver and when negated, disables the transceiver.
PAR[0:*n*]	I/O	GPCM data bus parity, GASIC address bus parity.	
		State meaning	Asserted/Negated - For GPCM during Write a parity bit is generated for each data byte sent over the bus. Unused byte lanes have undefined parity. For GASIC a parity bit is sent for each address and data byte sent over the AD bus.
PERR_L_B	I	GASIC parity error indication. PERR_B is sampled a configurable number of IFC_CLK cycles after the assertion of SOF_L_B.	
		State meaning	Asserted/Negated - Parity error is indicated by GASIC for wrong parity sent for address and data bytes.
CLK[0:*n*]	O	IFC external clock.	
		State meaning	This is an external clock derived from the IFC module input clock. Division ratio is programmable (using CCR register).

12.2.1 Internal connectivity of WP/RB signal

The IFC supports one write protect and one ready/busy signal per chip select. The available write protect and ready/busy signals are mapped to the eight chip selects that the IFC supports.

The chip supports one dedicated write protect signal (IFC_WP0_B), three multiplexed write protect pins (IFC_WP[1:3]_B), two dedicated ready/busy signals (IFC_RB[0:1]_B) and three multiplexed ready/busy signals IFC_RB[2:4]_B.

NOTE

The internal connectivity of WP/RB signal depends on the IFC mode selected by RCW[IFC_MODE].

12.2.1.1 Internal connectivity of WP signal

For the 28-/32-bit address mode, the write protect signal (WP0_B) is sourced by the logical OR of all the eight write protect signals from the IFC block which corresponds to chip selects 0-7.

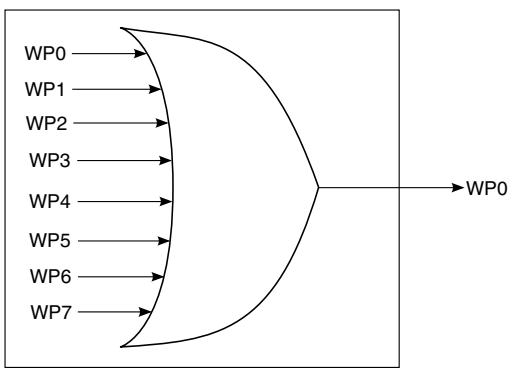

Figure 12-2. Internal connectivity of WP signal for 28-/32-bit address mode

For the 25-bit address mode, the first three write protect signals WP_B[0:2] are directly sourced by the three write protect signals from the IFC block which correspond to chip selects 0-2, respectively. The fourth write protect signal (WP_B[3]) is sourced by the logical OR of the remaining five write protect signals from the IFC block which correspond to chip selects 3-7. This allows for some flexibility in controlling write protection to individual or groups of NAND flash devices.

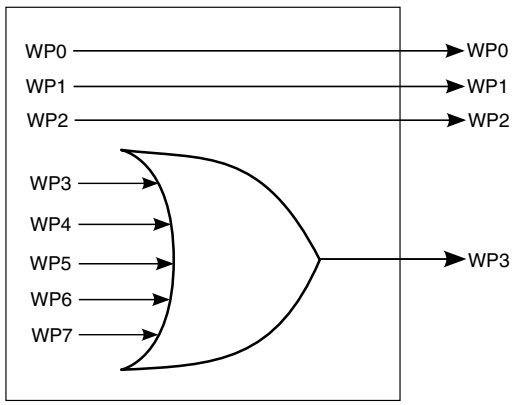

Figure 12-3. Internal connectivity of WP signal for 25-bit address mode

12.2.1.2 Internal connectivity of RB signal

For the 32-bit address mode, RB1_B is directly routed to the ready/busy inputs of the IFC block which correspond to chip select 1.

The first ready/busy signal RB0_B is routed to the ready/busy inputs of the IFC block which correspond to chip selects 0 and 2-7. In these modes of operation, this overall solution allows for one bank of flash to be fully optimized from a performance perspective, while leaving one additional ready/busy for one or more ASICs or lower performance tier of flash devices.

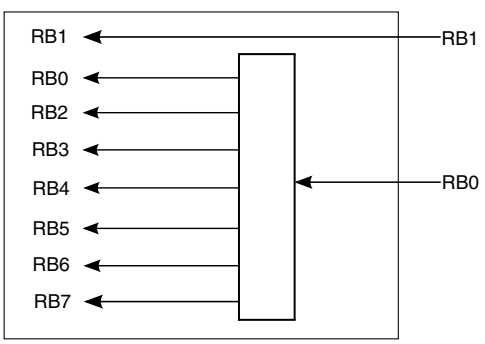

Figure 12-4. Internal connectivity of RB signal for 32-bit address mode

For the 25-/28-bit address mode, RB[0:3]_B is directly routed to the ready/busy inputs of the IFC block which correspond to chip selects 0-3. The fifth ready/busy signal RB4_B is routed to the ready/busy inputs of the IFC block which correspond to chip selects 4-7. This configuration allows for four banks of flash to be fully optimized from a performance perspective, while leaving one additional ready/busy for one or more ASICs or lower performance tier of flash devices.

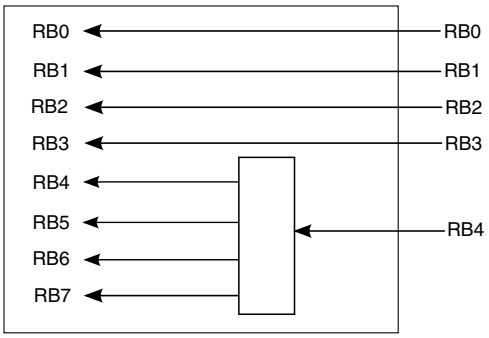

Figure 12-5. Internal connectivity of RB signal25-/28-bit address mode

12.3 IFC memory map/register definition

The IFC is allocated 8 KB of memory-mapped space. The memory map is divided into two parts (4 KB each):

- Common registers shared by NAND, NOR, and GPCM FCM
- Specific registers defined for the NAND FCM, NOR FCM (IFC global), and GPCM FCM (IFC run time) exclusively

IFC memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

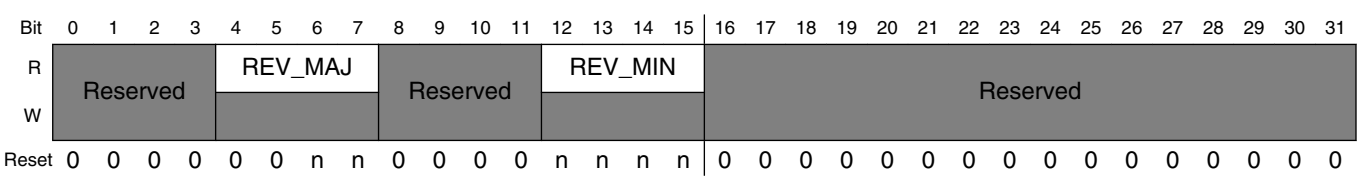
12.3.1 IFC Revision Control register (IFC_REV)

This register represents the revision number of the IFC.

Address: 12_4000h base + 0h offset = 12_4000h



IFC_REV field descriptions

Field	Description
0–3 -	This field is reserved.

Table continues on the next page...

IFC_REV field descriptions (continued)

Field	Description
4–7 REV_MAJ	Major Revision. It represents the major revision of IFC
8–11 -	This field is reserved.
12–15 REV_MIN	Minor Revision. It represents the minor revision of IFC.
16–31 -	This field is reserved.

12.3.2 Extended Chip Select Property registers (IFC_CSPR*n*_EXT)

The extended chip select property register (CSPRn_EXT) contains the extended base address, that is, the most significant bits (msb) of the base address.

Address: 12_4000h base + Ch offset + (12d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Reserved																								BA_EXT							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IFC_CSPR*n*_EXT field descriptions

Field	Description
0–23 -	This field is reserved.
24–31 BA_EXT	Extended Base Address: This field contains the msbs of the base address. Complete base address can be represented by concatenating CSPRn_EXT[BA_EXT] and CSPR*n*[BA] fields. Each chip selects's base register value is compared to the address on the address bus to determine if the master is accessing a memory bank controlled by the IFC. Address decoding is performed by using the address mask bit in AMASK*n*[AM] field more details of decoding is given in AMASK register description.

12.3.3 Chip-select Property register n (IFC_CSPR*n*)

The chip-select property register (CSPR*n*) contains the base address and memory attributes for each bank.

NOTE

CSPR0: Only chip-select 0 is used for booting. PS, MSEL[1], and TE is obtained from the configuration word when boot_load/rcw_load occurs. V will be set for CSPR0 when boot_load/rcw_load occurs with valid port size.

Address: 12_4000h base + 10h offset + (12d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	BA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R W	Reserved							PS		WP	Reserved			MSEL		V
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IFC_CSPR*n* field descriptions

Field	Description
0–15 BA	Base Address: Each base register value is compared to the address on the address bus to determine if the master is accessing a memory bank controlled by the IFC. Used with the address mask bit.
16–22 -	This field is reserved.
23–24 PS	Port Size-Specifies the port size of this memory region. For CSPR0, PS is configured through reset configuration word as loaded during power on reset. For all other banks the value is reset to 00 (port size not defined). 00 Reserved 01 8 bit 10 16 bit 11 32 bit
25 WP	Write Protect: **NOTE:** 1. This bit is valid only for NAND and NOR; for GPCM this bit should not be set. **NOTE:** 2. If CS0 is used for booting from NAND or NOR, CSPR0[WP] will be set (write protected). Software must clear this bit after completing the boot operation to permit write operations on CS0 0 Read and write accesses are allowed. 1 Only read accesses are allowed. The memory controller does not assert chip-select on write cycles to this memory bank for NOR flash. (Refer Write protect for more details)
26–28 -	This field is reserved.
29–30 MSEL	Machine Select 00 NOR flash 01 NAND flash 10 GPCM 11 Reserved
31 V	Valid: Indicates that the contents of CSPRn are valid. 1 Bank is valid 0 Bank is invalid

12.3.4 Address Mask register (IFC_AMASK*n*)

The address mask (AMASKn) registers contains the 16-bit address mask field for all four memory banks. The selected 16-bit address mask field masks corresponding CSPR*n*[BA] fields. The 16 lsbs of the 32-bit internal address do not participate in bank address matching in selecting a bank for access. Masking address bits independently allows external devices of different size address ranges to be used. Address mask bits can be set or cleared in any order in the field, allowing a resource to reside in more than one area of the address map.

The table below shows memory bank size from 64 KB to 4 GB.

Table 12-3. Memory Bank Sizes in Relation to Address Mask

AM	Memory Bank Size
0000_0000_0000_0000	4 GBytes
1000_0000_0000_0000	2 Gbytes

Field	Description
0–15 AM	16-bit Address mask corresponding to memory bank
16–31 -	This field is reserved.

12.3.5 Chip-Select Option register - NAND Flash Mode (IFC_CSOR*n*_NAND)

The following figure shows the CSOR*n* fields when CSPR*n*[MSEL] selects the NAND flash mode.

NOTE

- CSOR0 is the only chip-select used for booting.
- ECC_DEC_EN, ECC_MODE[0:1], and PGS are obtained from the configuration word when boot_load/rcw_load occurs.
- For boot time RAL value, see NAND asynchronous mode boot mechanism (the default is set to max assuming that the device will ignore extra address cycles).

Address: 12_4000h base + 130h offset + (12d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
19–24 -	This field is reserved.
25–26 NOR_MODE	Type of the NOR device hooked at CS*n*. 00 Simple asynchronous NOR (ALE is asserted before CE_B) 01 Internal latch based AVD NOR device (ALE is asserted after CE_B) Others Reserved
27–29 TRHZ	Time for read enable high to output high impedance (Z). Number of clocks required for memory to go in high Z after read enable deassertion. If IFC is accessing NOR flash for read operation, then after last byte read NOR FSM must wait for these many clock cycles so that there is no contention on external buffer. Others Reserved 000 Wait for 20 IP Clocks 001 Wait for 40 IP Clocks 010 Wait for 60 IP Clocks 011 Wait for 80 IP Clocks 100 Wait for 100 IP Clocks
30 -	This field is reserved.
31 BCTLD	Buffer control disable. This bit signifies presence or absence of external buffer. If buffer is absent then this bit should be set to 1. 0 BCTL is actively driven by IFC based on direction of access. 1 BCTL is set to its default value (high) irrespective of direction of access.

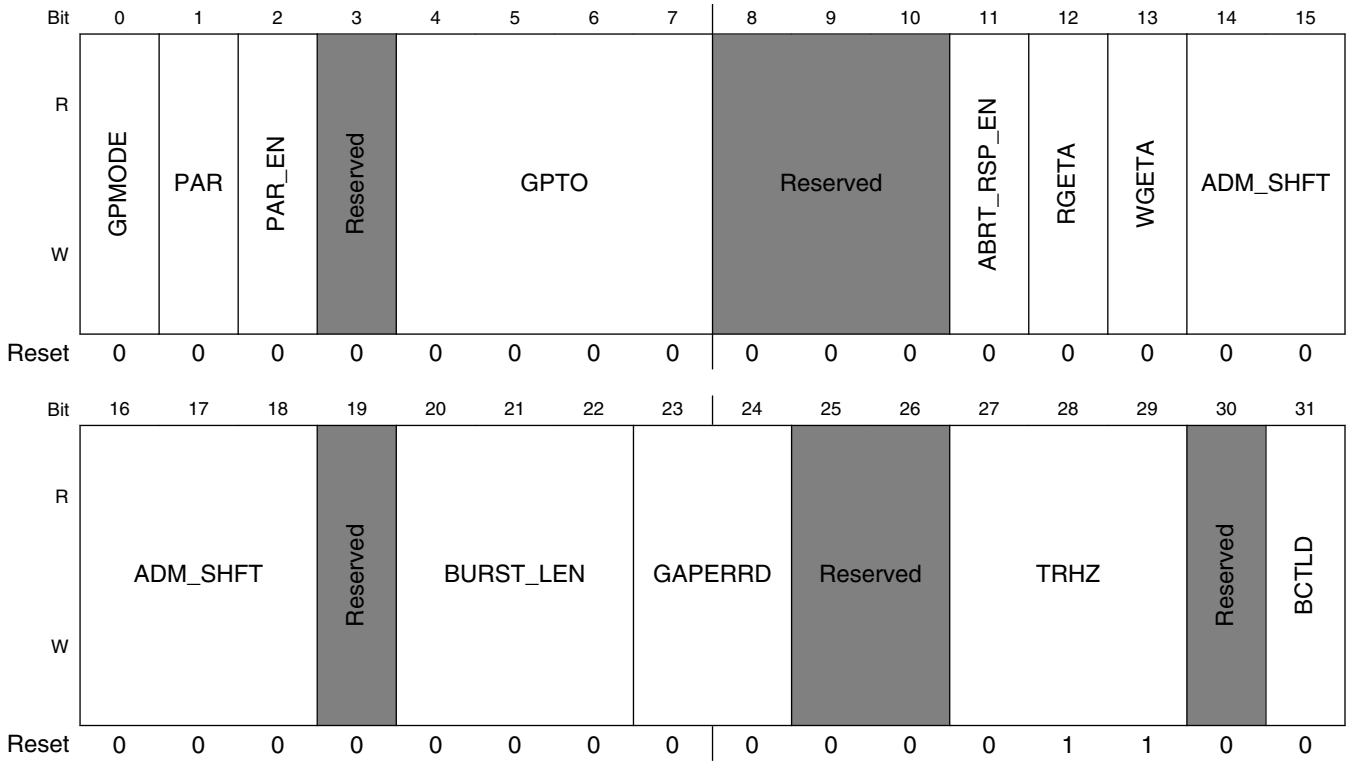
12.3.7 Chip-Select Option register - GPCM (IFC_CSOR*n*_GPCM)

The CSCOR*n* can work in following two modes:

- Normal GPCM
- Generic ASIC

The following figure shows the CSOR*n* fields when CSPR*n*[MSEL] selects the GPCM mode.

Address: 12_4000h base + 130h offset + (12d × i), where i=0d to 7d



IFC_CSOR*n*_GPCM field descriptions

Field	Description
0 GPMODE	GPCM Mode of operation: 0 Normal GPCM operation 1 Generic ASIC mode operation
1 PAR	Parity mode. 0 Odd Parity 1 Even Parity
2 PAR_EN	Parity checking enable/disable: 0 Parity checking disabled over the received data 1 Parity checking enabled over the received data
3 -	This field is reserved.
4–7 GPTO	GPCM Timeout Count: For normal GPCM, the timeout occur only when read data/write data transaction is external transaction acknowledgement based and IFCTA signal has not come. In Generic ASIC mode timeout occurs when RDY_L has not come for the number of IP clks cycles defined by this register field. 0000 256 cycles of IFC module input clocks 0001 512 cycles of IFC module input clocks 0010 1024 cycles of IFC module input clocks 0011 2048 cycles of IFC module input clocks 0100 4096 cycles of IFC module input clocks

Table continues on the next page...

IFC_CSOR*n*_GPCM field descriptions (continued)

Field	Description
	0101 8192 cycles of IFC module input clocks 0110 16,384 cycles of IFC module input clocks 0111 32,768 cycles of IFC module input clocks 1000 65,536 cycles of IFC module input clocks 1001 131,072 cycles of IFC module input clocks 1010 262,144 cycles of IFC module input clocks 1011 524,288 cycles of IFC module input clocks 1100 1,048,576 cycles of IFC module input clocks 1101 2,097,152 cycles of IFC module input clocks 1110 4,194,304 cycles of IFC module input clocks 1111 8,388,608 cycles of IFC module input clocks
8–10 -	This field is reserved.
11 ABRT_RSP_EN	Abort Error Response Enable. An error response will be sent for read transaction if the transaction is aborted by IFCTA_B when REGTA is programmed in abort mode. This bit is valid only for normal GPCM mode. 0 No error response will be sent. 1 Error response will be sent for abort.
12 RGETA	GPCM external access termination mode for read access. **NOTE:** This bit is valid only for normal GPCM Mode. 0 Abort mode. IFCTA_B signal acts as abort signal. GPCM read access is terminated internally by the controller at the expiry of TRAD counter unless aborted externally (If IFCTA_B asserts before the expiry of TRAD counter access will be terminated). Error will be reported in GPCM_EVTER_STAT[ABER] register. 1 Acknowledgement mode. IFCTA_B acts as acknowledgement/data qualifier signal. GPCM read access is acknowledged by external pin IFCTA_B and only it can complete the read access. If it is not asserted within CSOR[GPTO] time, GPCM_EVTER_STAT[TOER] will be set.
13 WGETA	GPCM external access termination mode for write access: **NOTE:** This bit is valid only for normal GPCM Mode. 0 Abort mode. GPCM write access is terminated if IFCTA_B asserts before expiry of TWP counter in case of single beat transaction. If IFCTA_B is asserted during burst write the current transaction is aborted and only after deassertion of IFCTA_B it will be resumed. Details are given in Normal GPCM program operation, Figure 12-43. Note that in abort mode no error is reported for write transaction. 1 Acknowledgement mode: GPCM write access is acknowledged/qualified by external pin IFCTA_B assertion. If it is not asserted within CSOR[GPTO] time, GPCM_EVTER_STAT[TOER] will be set
14–18 ADM_SHFT	Address data multiplexing shift: Left shift the flash address by this value and assign it to address data multiplexed bus (AD[0:15]) ifc_data. By this method, the address msbs will be assigned to address data muxed bus that can be latched by asserting the AVD/ALE signal. **NOTE:** This shifting is only valid in normal GPCM mode. Others Reserved 00000 No shift

Table continues on the next page...

IFC_CSOR*n*_GPCM field descriptions (continued)

Field	Description
	00001 Left shift addr[0:31] by 1 and assign it to AD[0:31] 00010 Left shift ifc_addr by 2 00011 Left shift ifc_addr by 3 00100 Left shift ifc_addr by 4 00101 Left shift ifc_addr by 5 00110 Left shift ifc_addr by 6 00111 Left shift ifc_addr by 7 01000 Left shift ifc_addr by 8 01001 Left shift ifc_addr by 9 01010 Left shift ifc_addr by 10 01011 Left shift ifc_addr by 11 01100 Left shift ifc_addr by 12 01101 Left shift ifc_addr by 13 01110 Left shift ifc_addr by 14 01111 Left shift ifc_addr by 15 10000 Left shift ifc_addr by 16 10001 Left shift ifc_addr by 17 10010 Left shift ifc_addr by 18 10011 Left shift ifc_addr by 19 10100 Left shift ifc_addr by 20
19 -	This field is reserved.
20–22 BURST_LEN	GPCM burst length. It defines the maximum number of beats that will be sent/received in one burst cycle. This is programmed in terms of port-size transfer. For example, if the port size is 2 bytes and burst_length is 2, then the total of 8 bytes will be transferred in one burst cycle (that is, 4 beats of data transfers and each data transfer of 2 bytes). This is valid only in normal GPCM mode. 000 Non-burst mode 001 2 010 4 011 8 100 16 101 32 110 64 111 128
23–24 GAPERRD	Generic ASIC parity error indication delay. Represents the delay (in terms of number of IFC_CLK) between the indication of parity error for address and write data with respect to start of frame (SOF_L). 00 1 IFC_CLK delayed 01 2 IFC_CLK delayed 10 3 IFC_CLK delayed 11 4 IFC_CLK delayed
25–26 -	This field is reserved.
27–29 TRHZ	Time for read enable high to output high impedance (Z)- Number of clocks required for memory to go in high Z after read enable deassertion.

Table continues on the next page...

IFC_CSOR*n*_GPCM field descriptions (continued)

Field	Description
	If IFC is accessing for read operation, then after last byte read wait for these many clock cycles so that there is no contention on external bus. Others Reserved 000 Wait for 20 IFC module input clocks 001 Wait for 40 IFC module input clocks 010 Wait for 60 IFC module input clocks 011 Wait for 80 IFC module input clocks 100 Wait for 100 IFC module input clocks
30 -	This field is reserved.
31 BCTLD	Buffer control disable. This bit signifies presence or absence of external buffer. If buffer is absent then this bit should be set to 1. 0 BCTL is actively driven by IFC based on direction of access. 1 BCTL is set to its default value (high) irrespective of direction of access.

12.3.8 Extended Chip-Select Option register - NAND Flash Mode (IFC_CSOR*n*_EXT)

The figure below shows the CSOR*n*_EXT fields when CSPR*n*[MSEL] selects the NAND flash mode.

NOTE

CSOR*n*_EXT register is reserved if CSPR*n*[MSEL] is in NOR/GPCM mode.

Address: 12_4000h base + 134h offset + (12d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Field	Description
0–20 -	This field is reserved.
21–31 SPARE_BYTES_CSn	No. of bytes in spare region. This filed is applicable only when corresponding CSOR*n*[SPRZ] is 3'h110. Others Reserved. 0x000 0 Spare region bytes 0x001 1 Spare region byte ... 0x400 1024 spare region bytes 0x7FE 2046 spare region bytes

12.3.9 Flash Timing register 0 for Chip Select *n* - NAND flash async mode (IFC_FTIM0_CS*n*_NAND)

The flash timing registers define the flash interface timings. These register fields are defined differently depending on the machine type (NOR/NAND/GPCM) selected for that bank by CSPR*n*[MSEL] field. Timing registers are provided separately for each chip-select. Timing parameter are in terms of IFC module input clock cycles. More details about the register field is given in section Programming model for flash interface timing .

NOTE

- Timing values of FTIM0, FTIM1, FTIM2, and FTIM3 registers for chip-select 0 in NAND/NOR flash mode will be loaded at boot_load/rcw_load by the parameters passed.
- If CSOR_EXTn[AUTO_TIM_PARAMS_SEL] is set, then the values returned on reading the FTIM0, FTIM1, FTIM2, FTIM3 registers will be the ones calcuated automatically by IFC (based on CSOR_EXTn[MODE_FREQ] and the Clock divsion ratio) and not the ones programmed in the FTIM registers. This is valid only when CSORn[NAND_MODE] = 2'b01, 2'b10, 2'b11.
- The TRP value loaded during RCW/boot load is taken as (TRAD +2) input clocks.
- For normal GPCM mode (write transaction) all the three timing parameters (that is, TEAHC, TACSE, and TCS) should not be programmed zero together.
- For normal GPCM mode (read transaction) all the three timing parameters (that is, TEAHC, TACSE, and TACO) should not be programmed zero together.

During NAND and NOR boot, default values of FTIM*n*CS0 must be as shown in below table.

Table 12-4. Default values of FTIM*n*CS0 during boot

FTIMnCS0	Value during NAND RCW and boot	Value during NOR RCW	Value during NOR boot
FTIM0_CS0	181C_0C10	2002_0202	4005_0405
FTIM1_CS0	5454_141E	1B00_0E0E	5000_2828
FTIM2_CS0	0410_501C	0208_1C0A	0380_8034
FTIM3_CS0	2C00_0000	0000_0000	0000_0000

The following figure shows the FTIM0_CS*n* fields when CSPR*n*[MSEL] selects the NAND flash mode and CSOR*n*[NAND MODE] selects NAND flash async mode.

Address: 12_4000h base + 1C0h offset + (48d × i), where i=0d to 7d

IFC_FTIM3_CS*n*_GPCM field descriptions

Field	Description
0–5 TAAD	GPCM address access delay. This timing parameter is required for read cycles when GPCM is working in burst mode, that is, burst length is programmed to a non-zero value. The first data beat of a burst is sampled after TRAD time of OE assertion; subsequent beat data are sampled after TAAD time of the previous sample pulse. The same timing is used for sending the new address of the beat. The second address is sent after TRAD time of OE assertion and subsequent address beats are sent after TAAD time of the last beat. This is programmed in terms of IFC module input clock but should always be a mupltiple of IFC_CLK. This is valid only for normal GPCM mode. 000000 Reserved 000001 1 IFC module input clock 000010 2 IFC module input clocks ... 111111 63 IFC module input clocks
6–31 -	This field is reserved.

IFC_RB_STAT field descriptions

Field	Description
0 RB0	Ready Busy input from CS0. This register field represents the status of RB_B signal of CS0 sampled by IFC at every clock. 0 Device connected at CS0 is driving RB_B signal as Busy 1 Device connected at CS0 is driving RB_B signal as Ready.

Table continues on the next page...

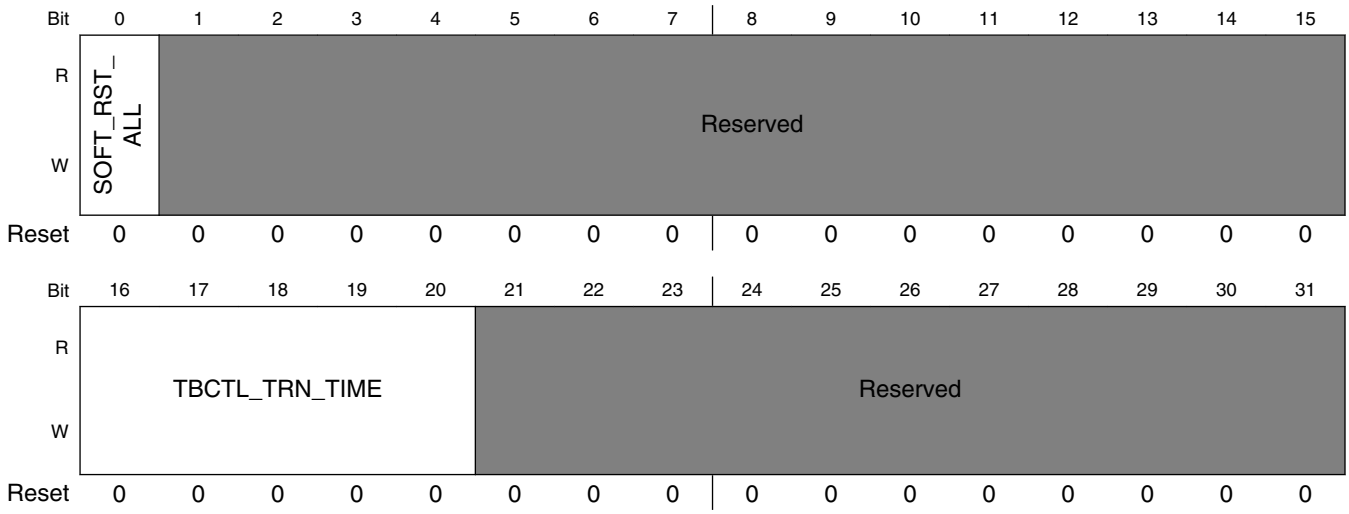
IFC_RB_STAT field descriptions (continued)

Field	Description
1 RB1	Ready Busy input from CS1 This register field represents the status of RB_B signal of CS1 sampled by IFC at every clock. 0 Device connected at CS1 is driving RB_B signal as Busy 1 Device connected at CS1 is driving RB_B signal as Ready.
2 RB2	Ready Busy input from CS2 This register field represents the status of RB_B signal of CS2 sampled by IFC at every clock. 0 Device connected at CS2 is driving RB_B signal as Busy 1 Device connected at CS2 is driving RB_B signal as Ready.
3 RB3	Ready Busy input from CS3 This register field represents the status of RB_B signal of CS3 sampled by IFC at every clock. 0 Device connected at CS3 is driving RB_B signal as Busy 1 Device connected at CS3 is driving RB_B signal as Ready.
4 RB4	Ready Busy input from CS4 This register field represents the status of RB_B signal of CS4 sampled by IFC at every clock. 0 At least one of the device connected at CS4-CS7 is busy 1 All devices connected to CS4-CS7 are ready
5 RB5	Ready Busy input from CS5 This register field represents the status of RB_B signal of CS5 sampled by IFC at every clock. 0 At least one of the device connected at CS4-CS7 is busy 1 All devices connected to CS4-CS7 are ready
6 RB6	Ready Busy input from CS6 This register field represents the status of RB_B signal of CS6 sampled by IFC at every clock. 0 At least one of the device connected at CS4-CS7 is busy 1 All devices connected to CS4-CS7 are ready
7 RB7	Ready Busy input from CS7 This register field represents the status of RB_B signal of CS7 sampled by IFC at every clock. 0 At least one of the device connected at CS4-CS7 is busy 1 All devices connected to CS4-CS7 are ready
8–31 -	This field is reserved.

12.3.26 General Control register (IFC_GCR)

The reset value of this field is passed through parameter.

Address: 12_4000h base + 40Ch offset = 12_440Ch



IFC_GCR field descriptions

Field	Description
0 SOFT_RST_ALL	Software Reset All: It is used to reset the whole IFC hardware (NAND, NOR, and GPCM). With this reset only the event/error status registers of IFC will be cleared. Programming registers will retain their value. The software reset mechanism is implemented such that IFC will send the pending transactions on system bus with good response. In case of pending read transaction, garbage data will be supplied back. Once the whole IFC is in IDLE state, the software can clear this bit. IFC hardware stops software from clearing this bit till all the processing has been done and IFC hardware is in idle state. If this bit is set, hardware will clear it once reset operation is completed. Software should poll this bit to get cleared before initiating any new transaction. 0 No Software reset 1 Assert Software reset
1–15 -	This field is reserved.
16–20 TBCTL_TRN_TIME	It represents the turnaround time of external buffer in terms of number of IFC module input clock cycles. BCTL should be kept high for these many clock cycles before issuing a write transaction after a read on flash interface. See Data buffer control (BCTL) for more details.
21–31 -	This field is reserved.

12.3.27 Common Event and Error Status register (IFC_CM_EVTER_STAT)

Common event and error status register (CM_EVTER_STAT) indicates the cause of an error or event that cannot be classified in NAND, NOR, and GPCM.

Address: 12_4000h base + 418h offset = 12_4418h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1–31 -	This field is reserved.

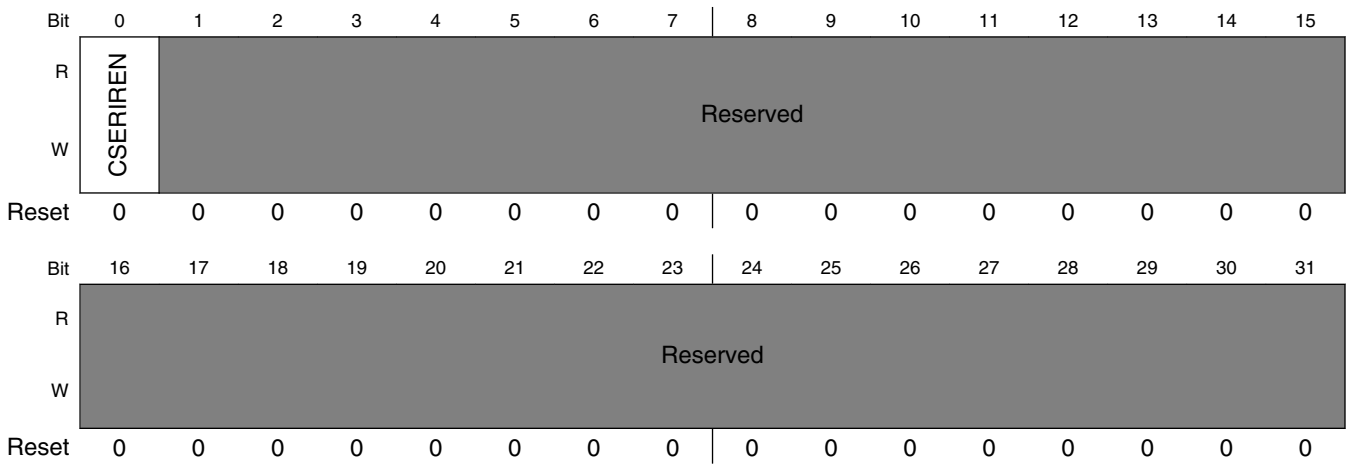
12.3.29 Common Event and Error Interrupt Enable register (IFC_CM_EVTER_INTR_EN)

Common event and error interrupt enable register (CM_EVTER_INTR_EN) is used to enable/disable the generation of interrupt signals corresponding to common error and event reporting. Software must clear pending events and errors in CM_EVTER_STAT register before enabling the interrupts.

Address: 12_4000h base + 430h offset = 12_4430h



IFC_CM_EVTER_INTR_EN field descriptions

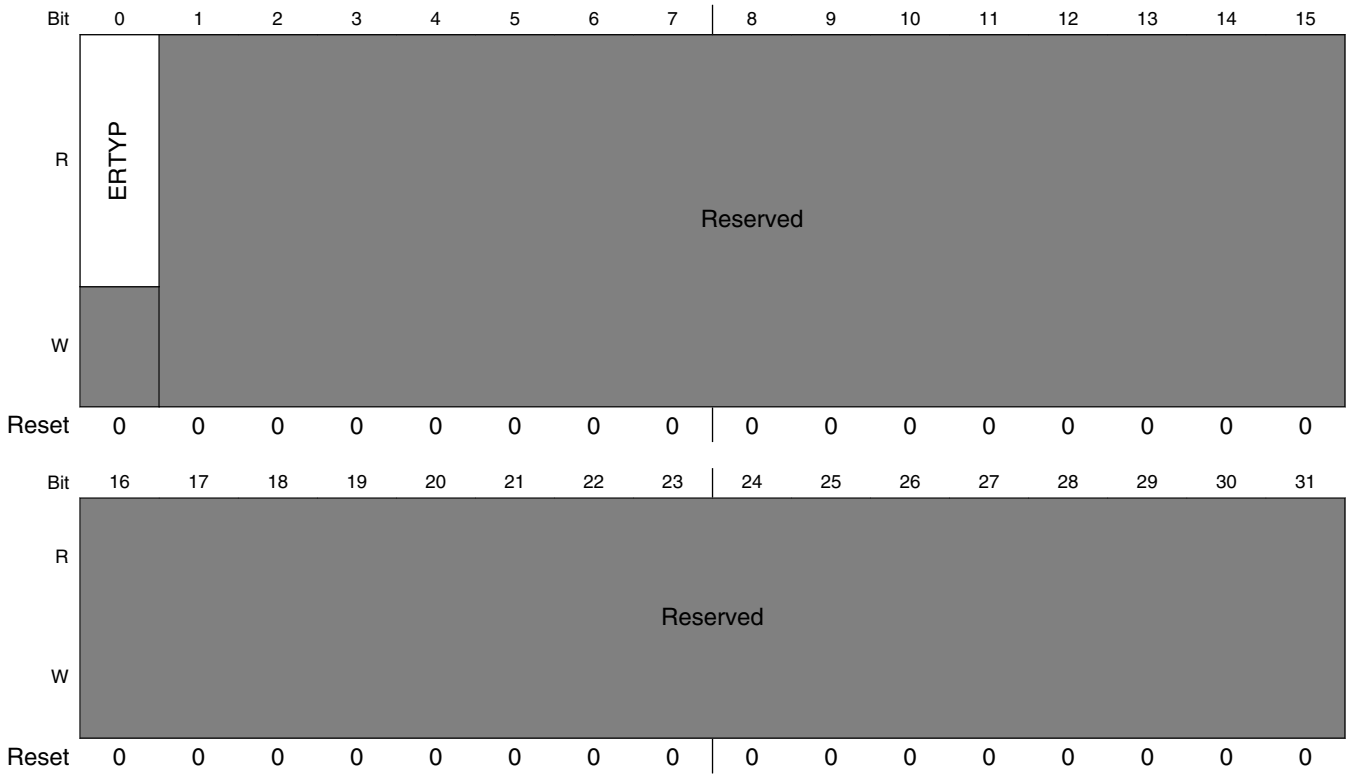
Field	Description
0 CSERIREN	Chip-Select Error Interrupt Enable 0 Chip-Select Error Interrupt Disabled 1 Chip-Select Error Interrupt Enabled
1–31 -	This field is reserved.

12.3.30 Common Transfer Error Attributes register 0 (IFC_CM_ERATTR0)

These registers store the attribute corresponding to the first transaction on which common error occured.

Common transfer error attribute register 0 (CM_ERATTR0) is used to register the transaction attributes corresponding to the first common error occured.

Address: 12_4000h base + 43Ch offset = 12_443Ch



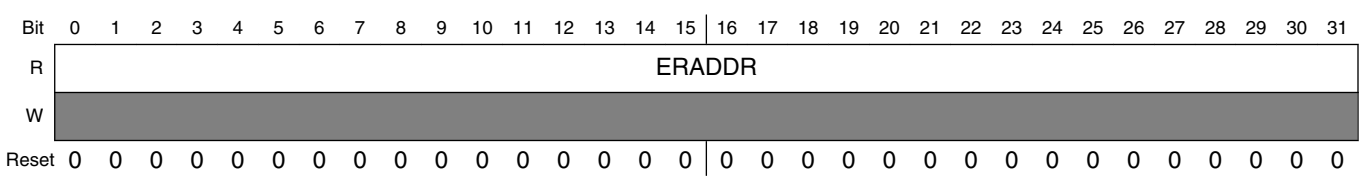
IFC_CM_ERATTR0 field descriptions

Field	Description
0 ERTYP	Transaction type of the error 0 Write Transaction 1 Read Transaction
1–31 -	This field is reserved.

12.3.31 Common Transfer Error Attributes register 1 (IFC_CM_ERATTR1)

Common transfer error attribute register1 (CM_ERATTR1) is used to register the transaction address corresponding to the first error.

Address: 12_4000h base + 440h offset = 12_4440h

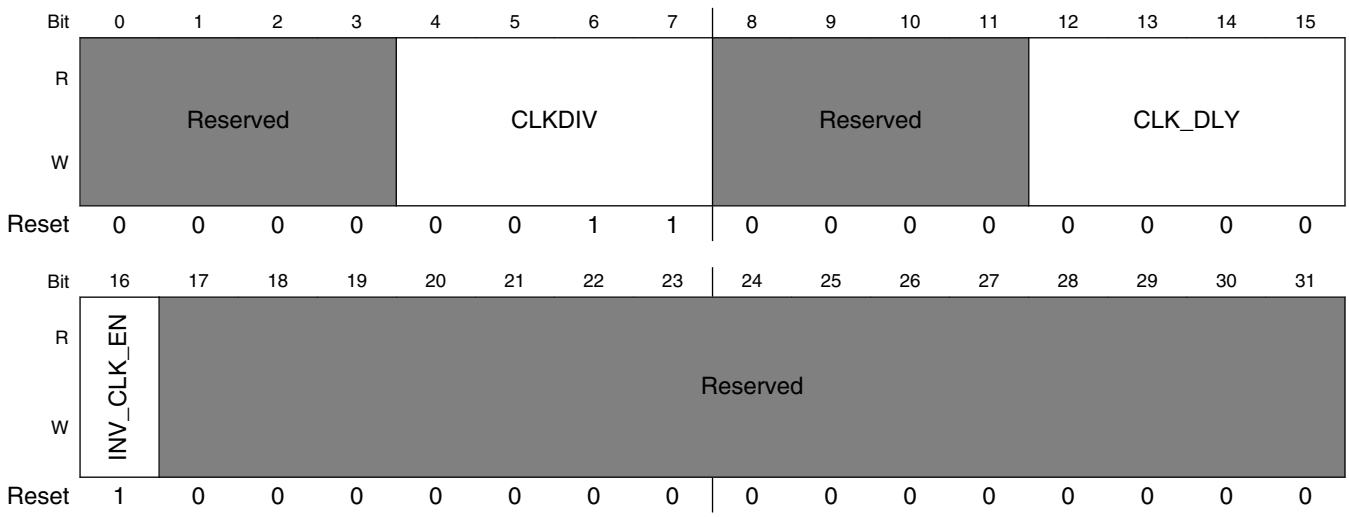


IFC_CM_ERATTR1 field descriptions

Field	Description
0–31 ERADDR	32 bits of transaction address corresponding to error transaction

12.3.32 Clock Control register (IFC_CCR)

Address: 12_4000h base + 44Ch offset = 12_444Ch



IFC_CCR field descriptions

Field	Description
0–3 -	This field is reserved.
4–7 CLKDIV	Clock division ratio: This field is used to generate the IFC clock from the IFC module input clock. The IFC clock is sent out after inverting it according to the INV_CLK_EN setting. 0000 Reserved 0001 Divide by 2 0010 Divide by 3 0011 Divide by 4 0100 Reserved 0101 Divide by 6 0110 Reserved 0111 Divide by 8 1000 Reserved 1001 Reserved 1010 Reserved 1011 Divide by 12 1100 Reserved 1101 Reserved

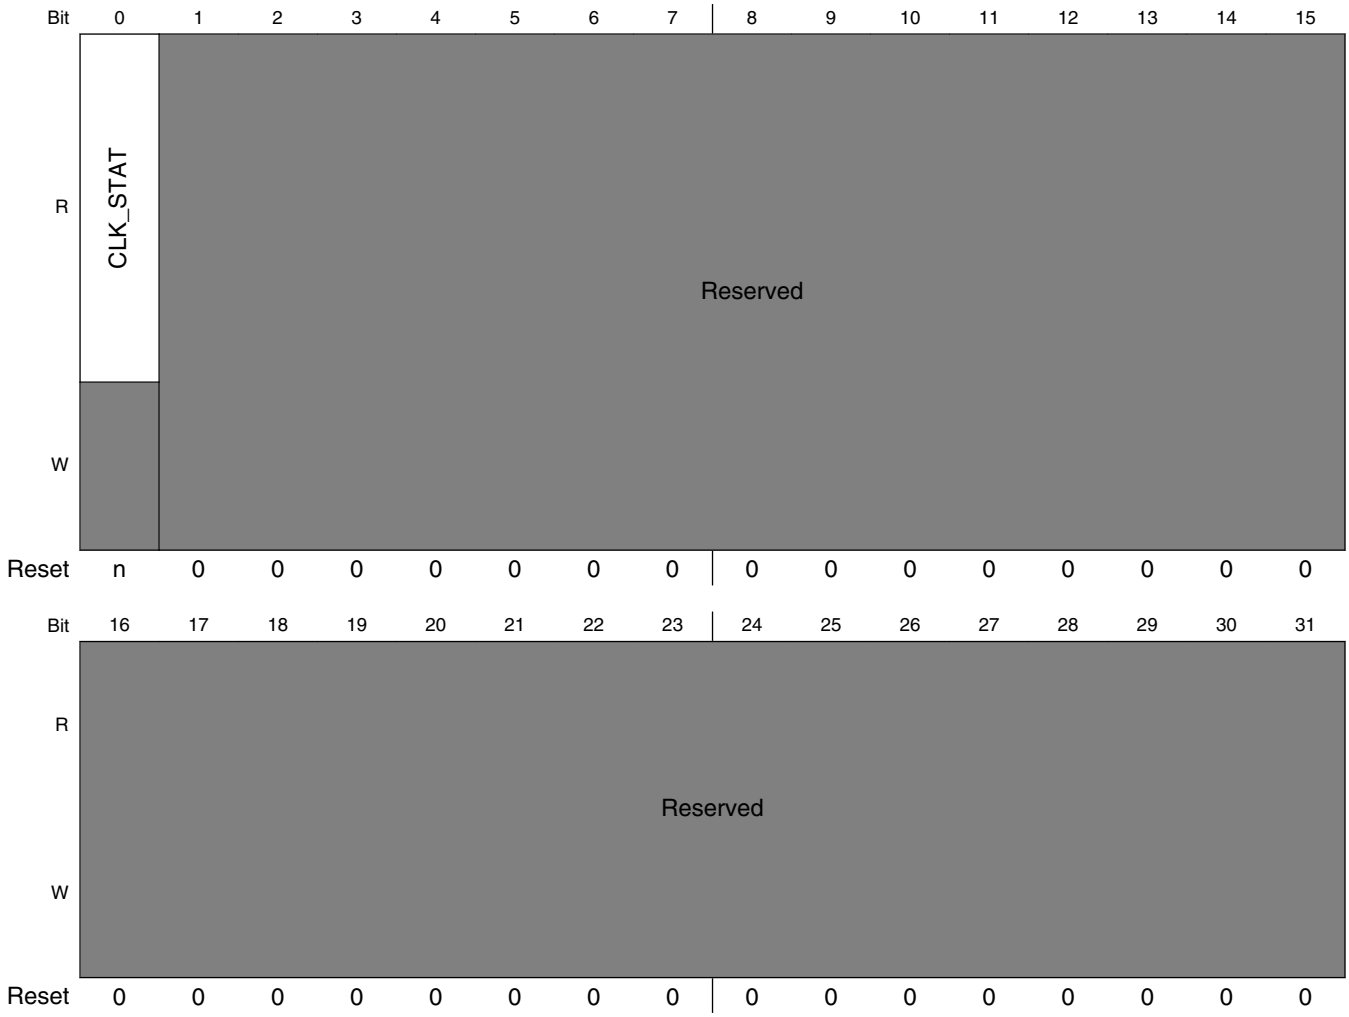
Table continues on the next page...

IFC_CCR field descriptions (continued)

Field	Description
	1110 Reserved 1111 Divide by 16
8–11 -	This field is reserved.
12–15 CLK_DLY	IFC Clock Delay This field specifies the number of IFC module input clocks by which external clock is delayed. 0000 No delay 0001 1 IFC module input clocks delay introduced 0010 2 IFC module input clocks delay introduced ... 1111 15 IFC module input clocks delay introduced
16 INV_CLK_EN	IFC Clock Inversion This field specifies whether IFC clock is inverted before sending out. 0 IFC clock is not inverted 1 IFC clock is inverted
17–31 -	This field is reserved.

12.3.33 Clock Status register (IFC_CSR)

Address: 12_4000h base + 450h offset = 12_4450h



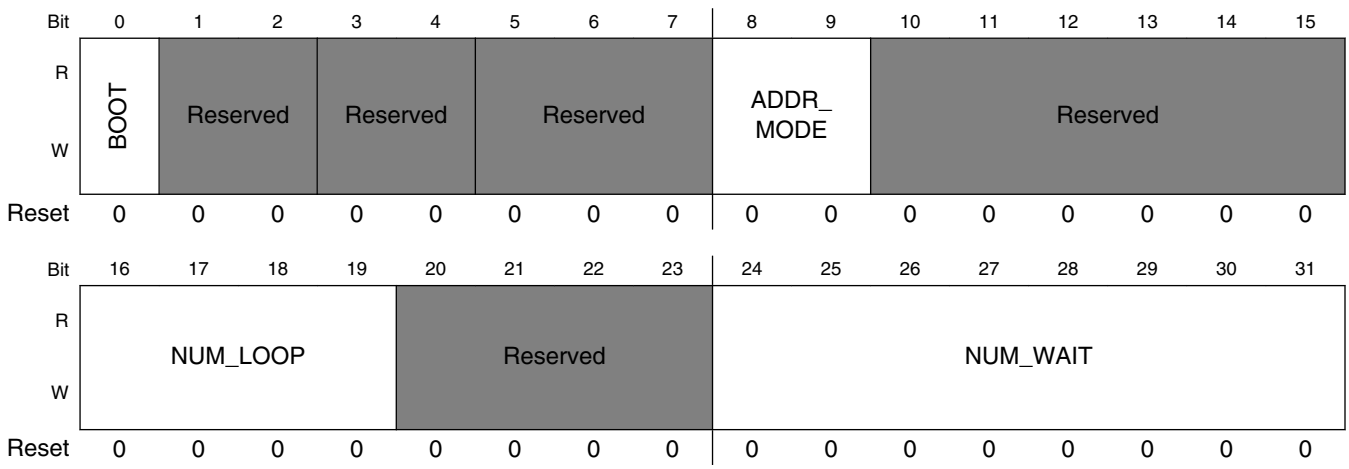
IFC_CSR field descriptions

Field	Description
0 CLK_STAT	Clock Status. This bit is cleared by hardware in case any of the field of CCR is changed. It is again set when external clock is stable. New GPCM operation can be initiated only after clock is stable for new CLK_DIV ratio. 0 Clock is unstable 1 Clock is stable
1–31 -	This field is reserved.

12.3.34 NAND Configuration register (IFC_NCFGR)

A separate 1 KB memory-mapped region is assigned to NAND-specific registers.

Address: 12_4000h base + 1000h offset = 12_5000h



IFC_NCFGR field descriptions

Field	Description
0 BOOT	NAND flash auto-boot load mode: During system boot from NAND flash, this bit remains set to alter the use of the FCM buffer RAM. Software should clear BOOT once FCM is to be restored for normal operation. Setting BOOT without auto-boot in progress only alters the mapping of the buffer RAM. 0 NAND FCM is operating in normal functional mode, with a 16-KB FCM buffer RAM. In this case normal SRAM buffer mapping applies. 1 Flash is accessed in boot mode. SRAM buffer mapping gets changed and whole 8 KB NAND flash main area in the buffer looks as contiguous linear addressable memory region. This bit is set by hardware when por_cfg_rcw_load or por_cfg_boot_load occurs with NAND as bootable device.
1–2 -	This field is reserved.
3–4 -	This field is reserved.
5–7 -	This field is reserved.
8–9 ADDR_MODE	Addressing Mode: Applicable for the current active CS. Applicable only with opcodes CA0 and RA0. Others Reserved 00 ROW0/COL0, ROW0+1/COL0, ROW0+2/COL0 and so on, in each iteration defined by NUM_LOOP field (Incremental by Page Size) 01 ROW0/COL0 addresses in first iteration, ROW1/COL1 address in second iteration, ROW2/COL2 address in third iteration, ROW3/COL3 address in fourth iteration

Table continues on the next page...

IFC_NCFGR field descriptions (continued)

Field	Description
10–15 -	This field is reserved.
16–19 NUM_LOOP	Number of loop iterations of FIR sequences for multipage operations FIR sequence will execute lopping by NUM_LOOP's time. **NOTE:** 1 NUM_LOOP value should be programmed carefully as it is restricted by SRAM buffer size. We support 16-page operation for small page, 4-page operation for large page of size 2 KB and 2-page operations for 4 KB page size. Hence NUM_LOOP value of 0000-1111 is only valid for small page; for 2 KB page size NUM_LOOP 0000-0011 are valid values; and for 4-KB page size NUM_LOOP value 0000 and 0001 are valid. **NOTE:** 2 For ADDR_MODE = 01, NUM_LOOP should not exceed 4. **NOTE:** 3 Ensure that separate SRAM buffers should be allocated during consecutive runs of NUM_LOOP else the data from the previous iteration will be overwritten and produce incorrect results. 0000 1 time execution of FIR sequence 0001 2 time execution of FIR sequence 0010 3 time execution of FIR sequence 0011 4 time execution of FIR sequence 0100 5 time execution of FIR sequence 0101 6 time execution of FIR sequence 0110 7 time execution of FIR sequence 0111 8 time execution of FIR sequence 1000 9 time execution of FIR sequence 1001 10 time execution of FIR sequence 1010 11 time execution of FIR sequence 1011 12 time execution of FIR sequence 1100 13 time execution of FIR sequence 1101 14 time execution of FIR sequence 1110 15 time execution of FIR sequence 1111 16 time execution of FIR sequence
20–23 -	This field is reserved.
24–31 NUM_WAIT	Number of wait cycles It represents the count value for which FCM will wait when used with opcode NWAIT in FIR. The value specified in this register represents the number of IFC module input clock cycles. Minimum value to be programmed is 2.

12.3.35 NAND Flash Command register 0 (IFC_NAND_FCR0)

The NAND flash command registers hold up to 8 NAND flash EEPROM command bytes that may be referenced by opcodes in NAND_FIR during FCM operation. The values of the commands should follow the manufacturer's datasheet for the relevant NAND flash.

Address: 12_4000h base + 1014h offset = 12_5014h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

8–15 CMD5	General purpose FCM flash command byte 5. Opcodes in FIR that issue command index 5write CMD5 to the NAND flash command/data bus.
16–23 CMD6	General purpose FCM flash command byte 6. Opcodes in FIR that issue command index 6 write CMD6 to the NAND flash command/data bus.
24–31 CMD7	General purpose FCM flash command byte 7. Opcodes in FIR that issue command index 7 write CMD7 to the NAND flash command/data bus

12.3.37 Flash Row Address register n (IFC_ROW*n*)

ROW*n* registers are used for addressing the NAND flash memory. These registers are used as per the field NCFGR1[ADDR_MODE]. ROW*n* register holds the row address to be issued on NAND flash interface using address phase. CSOR*n*[RAL] field determines the number of bits to be issued to the flash from ROW register during row address phase.

Address: 12_4000h base + 103Ch offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

IFC_ROW*n* field descriptions

Field	Description
0–31 RA	Row Address This register holds the row address to be issued on flash during row address phase

12.3.38 Flash COL Address register n (IFC_COL*n*)

COL*n* registers are used for addressing the NAND FLASH memory. These registers are used as per the field NCFGR1[ADDR_MODE]. The following holds the column address to be issued to flash during address phase. CSOR*n*[PGS] field determines the number of bits to be issued to flash from COL register during column address phase.

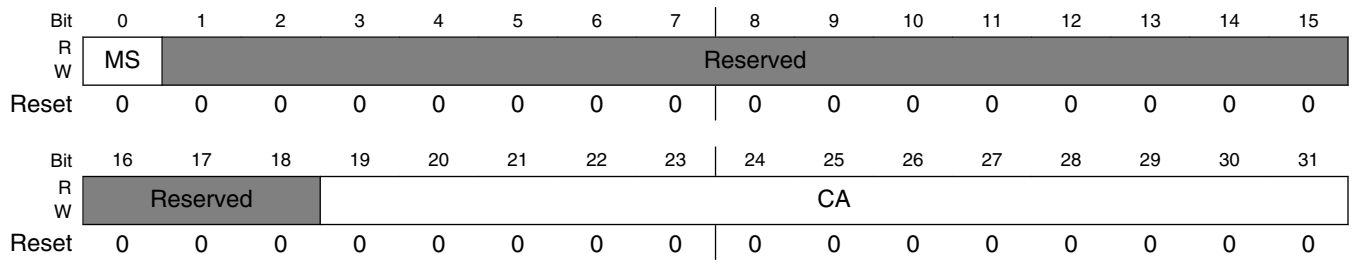
For small-page size, that is, 512 Bytes, the four lsbs of ROW*n* register is used to select the IFC buffer for data transfer to/from IFC buffer to/from flash. It indexes the page in NAND flash EEPROM at the current block, and locates the corresponding transfer buffer in the FCM buffer RAM.

The four lsbs of RA index, 1 of the 16, 1-KB buffers in the FCM buffer RAM as follows:

- 0000-The page is transferred to/from FCM buffer 0, address offsets 0x0000-0x03FF
- 0001-The page is transferred to/from FCM buffer 1, address offsets 0x0400-0x07FF
- 0010-The page is transferred to/from FCM buffer 2, address offsets 0x0800-0x0BFF
- 0011-The page is transferred to/from FCM buffer 3, address offsets 0x0C00-0x0FFF
- 0100-The page is transferred to/from FCM buffer 4, address offsets 0x1000-0x13FF
- 0101-The page is transferred to/from FCM buffer 5, address offsets 0x1400-0x17FF
- 0110-The page is transferred to/from FCM buffer 6, address offsets 0x1800-0x1BFF
- 0111-The page is transferred to/from FCM buffer 7, address offsets 0x1C00-0x1FFF

- 1000-The page is transferred to/from FCM buffer 8, address offsets 0x2000-0x23FF
- 1001-The page is transferred to/from FCM buffer 9, address offsets 0x2400-0x27FF
- 1010-The page is transferred to/from FCM buffer 10, address offsets 0x2800-0x2BFF
- 1011-The page is transferred to/from FCM buffer 11, address offsets 0x2C00-0x2FFF
- 1100-The page is transferred to/from FCM buffer 12, address offsets 0x3000-0x33FF
- 1101-The page is transferred to/from FCM buffer 13, address offsets 0x3400-0x37FF
- 1110-The page is transferred to/from FCM buffer 14, address offsets 0x3800-0x3BFF
- 1111-The page is transferred to/from FCM buffer 15, address offsets 0x3C00-0x3FFF

Address: 12_4000h base + 1044h offset + (16d × i), where i=0d to 3d



IFC_COL*n* field descriptions

Field	Description
0 MS	Main/spare region locator.: **NOTE:** In the case that NAND_BC[BC] = 0, MS is treated as 0. 0 Data is transferred to/from the main region of the SRAM buffer; that is, the first 512 bytes of the buffer are used. 1 Data is transferred to/from the spare region of the SRAM buffer; that is, the second 512 bytes of the buffer are used, but only an initial 16 bytes of spare region are defined.
1–18 -	This field is reserved.
19–31 CA	Column Address This register holds the column address to be issued on flash during column address phase. CA indexes the first byte to transfer to/from the main or spare region of the NAND flash EEPROM and corresponding transfer buffer. In the case that NAND_BC[BC] = 0, CA is treated as 0. For MS = 0, CA can range 0x0000-0x1FF; for MS = 1, CA can range 0x000-0x00F. For a 16-bit port size, the least significant bit of the Column Address is assumed to be zero; hence, the Column Address remains a byte index at all times.

12.3.39 Flash COL Address register for 2 KB Large-Page Device (IFC_COL*n*_2KB)

For large-page size of 2 KB, two lsbs of ROW*n* register are used to select the IFC buffer for data transfer to/from IFC buffer to/from flash. It indexes the page in NAND flash EEPROM at the current block, and locates the corresponding transfer buffer in the FCM buffer RAM.

The two lsbs of RA index one of the four 4-KB buffers in the FCM buffer RAM as follows:

- 00-The page is transferred to/from FCM buffer 0, address offsets 0x0000-0x0FFF
- 01-The page is transferred to/from FCM buffer 1, address offsets 0x1000-0x1FFF
- 10-The page is transferred to/from FCM buffer 2, address offsets 0x2000-0x2FFF
- 11-The page is transferred to/from FCM buffer 3, address offsets 0x3000-0x3FFF

Address: 12_4000h base + 1044h offset + (16d × i), where i=0d to 3d

IFC_COL*n*_2KB field descriptions

Field	Description
0 MS	Main/spare region locator. In the case that NAND_BC[BC] = 0, MS is treated as 0. 0 Data is transferred to/from the main region of the SRAM buffer; that is, the first 2048 bytes of the buffer are used. 1 Data is transferred to/from the spare region of the SRAM buffer; that is, the second 2048 bytes of the buffer are used, but only an initial 64 bytes of spare region are defined.
1–18 -	This field is reserved.
19–31 CA	Column Address This register holds the column address to be issued on flash during column address phase. CA indexes the first byte to transfer to/from the main or spare region of the NAND flash EEPROM and corresponding transfer buffer. In the case that NAND_BC[BC] = 0, CA is treated as 0. For MS = 0, CA can range 0x000-0x7FF; for MS = 1, CA can range 0x000-0x03F. For a 16-bit port size, the least significant bit of the Column Address is assumed to be zero; hence, the Column Address remains a byte index at all times.

12.3.40 Flash COL Address register for 4 KB Large-Page Device (IFC_COL*n*_4KB)

For large-page size of 4 KB, lsb of ROW*n* register is used to select the IFC buffer for data transfer to/from IFC buffer to/from flash. It indexes the page in NAND flash EEPROM at the current block, and locates the corresponding transfer buffer in the FCM buffer RAM.

The lsb of RA indexes one of the two 8 KB buffers in the FCM buffer RAM as follows:

- 0-The page is transferred to/from FCM buffer 0, address offsets 0x0000-0x1FFF
- 1-The page is transferred to/from FCM buffer 1, address offsets 0x2000-0x3FFF

Address: 12_4000h base + 1044h offset + (16d × i), where i=0d to 3d

IFC_COL*n*_4KB field descriptions

Field	Description
0 MS	Main/spare region locator. In the case that NAND_BC[BC] = 0, MS is treated as 0. 0 Data is transferred to/from the main region of the SRAM buffer; that is, the first 4096 bytes of the buffer are used. 1 Data is transferred to/from the spare region of the SRAM buffer; that is, the second 4096 bytes of the buffer are used, but only an initial 64 bytes of spare region are defined.
1–18 -	This field is reserved.
19–31 CA	Column Address This register holds the column address to be issued on flash during column address phase. CA indexes the first byte to transfer to/from the main or spare region of the NAND flash EEPROM and corresponding transfer buffer. In the case that NAND_BC[BC] = 0, COL is treated as 0. For MS = 0, CA can range 0x000-0xFFF; for MS = 1, CA can range 0x000- CSOR*n*[SPRZ]. For a 16-bit port size, the least significant bit of the Column Address is assumed to be zero; hence, the Column Address remains a byte index at all times.

12.3.41 Flash COL Address register for 8 KB Large-Page Device (IFC_COL*n*_8KB)

For large-page size of 8 KB, lsb of ROW*n* register is used to select the IFC buffer for data transfer to/from IFC buffer to/from flash. It indexes the page in NAND flash EEPROM at the current block, and locates the corresponding transfer buffer in the FCM buffer RAM.

The lsb of RA indexes one of the two 8 KB buffers in the FCM buffer RAM as follows:

- 0-The page is transferred to/from FCM buffer 0, address offsets 0x0000-0x1FFF
- 1-The page is transferred to/from FCM buffer 1, address offsets 0x2000-0x3FFF
- Only single 8 KB page can be accessed using SRAM buffer.

Address: 12_4000h base + 1044h offset + (16d × i), where i=0d to 3d

IFC_COL*n*_8KB field descriptions

Field	Description
0 MS	Main/spare region locator. In the case that NAND_BC[BC] = 0, MS is treated as 0. 0 Data is transferred to/from the main region of the SRAM buffer; that is, the first 4096 bytes of the buffer are used. 1 Data is transferred to/from the spare region of the SRAM buffer; that is, the second 8192 bytes of the buffer are used, but only an initial CSOR[SPRZ] bytes of spare region are defined. Maximum addressable bytes in sprae region buffer are 1024 bytes with this page size.
1–18 -	This field is reserved.
19–31 CA	Column Address This register holds the column address to be issued on Flash during column address phase. CA indexes the first byte to transfer to/from the main or spare region of the NAND flash E2PROM and corresponding transfer buffer. In the case that NAND_BC[BC] = 0, COL is treated as 0. For MS = 0, CA can range 0x000-0x1FFF; for MS = 1, CA can range 0x000- CSOR[SPRZ]. For a 16 bit port size the least significant bit of the column address is assumed to be zero, hence, the column address remains a byte index at all times.

12.3.42 Flash Byte Count register for NAND Flash (IFC_NAND_BC)

This register defines the NAND flash data block transfer size.

Address: 12_4000h base + 1108h offset = 12_5108h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	Reserved																BC															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

IFC_NAND_BC field descriptions

Field	Description
0–17 -	This field is reserved.
18–31 BC	Byte count determines how many bytes are transferred by the flash controller during data read (RBCD) or data write (WBCD) opcodes. In case of partial page operations, the value programmed in this field must be aligned to the port size of the device. Thus, if the bank port size is 16 bits, the lsb bit of BC (that is, bit 31) is ignored. The first byte accessed in the NAND flash is located by the COLn register, and successive bytes are transferred until BC bytes have been counted If BC = 0, an entire flash page and its spare region will be transferred by FCM, in which case COL*n*[MS] and COL*n*[CA] are treated as zero regardless of their values. **NOTE:** BC = 0 is the only setting that permits flash controller to generate and check ECC.

12.3.43 NAND Flash Instruction register 0 (IFC_NAND_FIR0)

The following flash instruction registers hold the instructions. When any operation on a selected bank is triggered and the FIR is programmed by the user, flash controller executes 6-bit opcode at a time until all the opcodes have been fetched from all the FIR registers. There are three such registers provided for the application. A total of 15 instructions can be programmed for FLASH operations.

NAND flash instruction register0 holds first five opcodes.

Table 12-5. Instruction Opcodes

Opcode encoding (6 bits)	Opcode name	Description
0x00	NOOP	No-operation and end of operation sequence
0x01	CA0	Issue current column address (CA) as set in COL0
0x02	CA1	Issue current column address as set in COL1
0x03	CA2	Issue current column address as set in COL2

Table continues on the next page...

Table 12-5. Instruction Opcodes (continued)

Opcode encoding (6 bits)	Opcode name	Description
0x04	CA3	Issue current column address as set in COL3
0x05	RA0	Issue current row address as set in ROW0
0x06	RA1	Issue current row address as set in ROW1
0x07	RA2	Issue current row address as set in ROW2
0x08	RA3	Issue current row address as set in ROW3
0x09	CMD0	Issue command from NAND_FCR0[CMD0]
0x0A	CMD1	Issue command from NAND_FCR0[CMD1]
0x0B	CMD2	Issue command from NAND_FCR0[CMD2]
0x0C	CMD3	Issue command from NAND_FCR0[CMD3]
0x0D	CMD4	Issue command from NAND_FCR1[CMD4]
0x0E	CMD5	Issue command from NAND_FCR1[CMD5]
0x0F	CMD6	Issue command from NAND_FCR1[CMD6]
0x10	CMD7	Issue command from NAND_FCR1[CMD7]
0x11	CW0	Wait for TWBE time, poll R/B to return high or time-out (depends upon IFC_NANDCR[FTOCNT]), then issue command from NAND_FCR0[CMD0]
0x12	CW1	Wait for TWBE time, poll R/B to return high or time-out (depends upon IFC_NANDCR[FTOCNT]), then issue command from NAND_FCR0[CMD1]
0x13	CW2	Wait for TWBE time, poll R/B to return high or time-out (depends upon IFC_NANDCR[FTOCNT]), then issue command from NAND_FCR0[CMD2]
0x14	CW3	Wait for TWBE time, poll R/B to return high or time-out (depends upon IFC_NANDCR[FTOCNT]), then issue command from NAND_FCR0[CMD3]
0x15	CW4	Wait for TWBE time, poll R/B to return high or time-out (depends upon IFC_NANDCR[FTOCNT]), then issue command from NAND_FCR1[CMD4]
0x16	CW5	Wait for TWBE time, poll R/B to return high or time-out (depends upon IFC_NANDCR[FTOCNT]), then issue command from NAND_FCR1[CMD5]
0x17	CW6	Wait for TWBE time, poll R/B to return high or time-out (depends upon IFC_NANDCR[FTOCNT]), then issue command from NAND_FCR1[CMD6]
0x18	CW7	Wait for TWBE time, poll R/B to return high or time-out (depends upon IFC_NANDCR[FTOCNT]), then issue command from NAND_FCR1[CMD7]
0x19	WBCD	Write BC bytes of data from current FCM buffer to flash device
0x1A	RBCD	Wait for R/B_B to return high or time-out (depends upon IFC_NANDCR[FTOCNT]), then Read BC bytes of data from flash device into current FCM RAM buffer
0x1B	BTRD	Same as RBCD except in this case deassertion of read enable will happen once the read data has been sampled (same as boot read)

Table continues on the next page...

Table 12-5. Instruction Opcodes (continued)

Opcode encoding (6 bits)	Opcode name	Description
0x1C	RDSTAT	Wait for TWHRE (Async) time, then Read one byte/two bytes (8b/16b port) of data from flash device into RS0 and RS1 field of FSR.
0x1D	NWAIT	Wait for NCFGR[NUM_WAIT] Clock cycles
0x1E	WFR	Wait for TWBE time, poll Ready
0x1F	SBRD	Wait for R/B to return high or time-out (depends upon IFC_NANDCR[FTOCNT]), then Read 8/16 bits of data from NAND flash memory into the NAND_MDR register. COLn register will determine the location from where the data will be fetched in a given page. Deassertion of read enable will happen once the read data has been sampled. With this opcode NAND_BC register field value will be ignored. Although the value is ignored, it is mandatory that the NAND_BC register hold a non-zero value else the Column Address would be treated as 0 (refer Flash COL Address register n (IFC_COL*n*))
0x20	UA	Issue current row address as set in ROW3 The SRAM Buffer used for data transfers is always Buffer 0
0x21	RB	Wait for TWHRE (Async) time, then Read BC bytes of data from flash device into current FCM RAM buffer. Deassertion of read enable will happen once the read data has been sampled

Field	Description
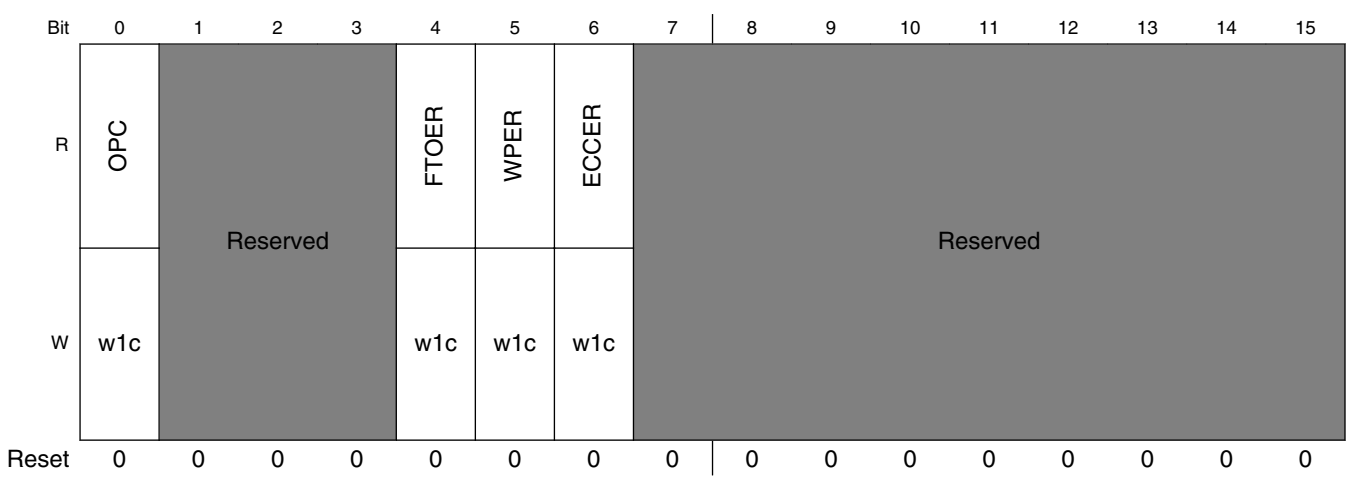
14 AUTO_CPB	Automatic copyback Writing 1 to this register bit triggers automatic copy back operation **NOTE:** The FIR sequence executed is {CW0, CA0, RA0, CMD1, CW2, CA1, RA1, CMD3, CW4, RDSTAT, and NOOP}
15–16 -	This field is reserved.
17 AUTO_RD	Automatic read operation Writing 1 to this register bit triggers automatic read operation **NOTE:** The FIR sequence executed is: For small-page device: {CW0, CA0, RA0, RBCD, NOOP} For large-page device: {CW0, CA0, RA0, CMD1, RBCD, NOOP}
18–19 -	This field is reserved.
20 AUTO_STAT_RD	Automatic status read Writing 1 to this register bit triggers automatic read status **NOTE:** The FIR sequence executed is {CW0, RDSTAT, NOOP}
21–31 -	This field is reserved.

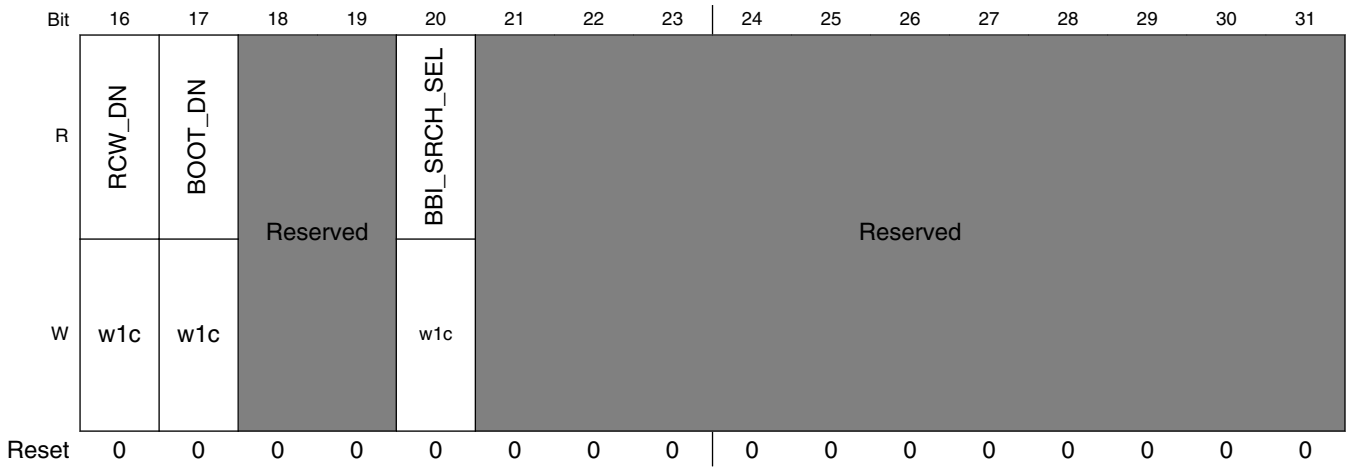
12.3.48 NAND Event and Error Status register (IFC_NAND_EVTER_STAT)

NAND event and error status register (NAND_EVTER_STAT) indicates the cause of an error or event corresponding to NAND flash.

The following figure shows the register fields. It is write-1-to-clear register.

Address: 12_4000h base + 116Ch offset = 12_516Ch





IFC_NAND_EVTER_STAT field descriptions

Field	Description
0 OPC	NAND flash operation complete event. OPC indicates that all instructions in FIR has been executed. **NOTE:** 1. The software should not poll this bit during auto boot. Instead RCW_DN/ BOOT_DN should be used. However, software must clear this bit post auto boot. **NOTE:** 2. This bit is set even if a flash timeout, ECC or write protect error occurs. For example, if a flash timeout error is detected for a read operation intiated on the NAND flash memory device, IFC will dump BC bytes worth of garbage data from the NAND flash interface into the internal SRAM and set this bit. Similarly, in case of NAND write protect error, IFC asserts chip select and sends the program data to NAND device, it is device which ignores the data as write protect signal is asserted. User must wait for operation completion (poll for OPC bit getting set) even in case of timeout before initiating next operation. As the transaction goes into NAND, OPC will be set at the end of FIR execution. OPC bit indicates that all the instructions in the FIRs have been executed. Also, it implies that OPC should be polled first and then FSR for completion. 0 NAND flash operation is not complete 1 NAND flash operation completed
1–3 -	This field is reserved.
4 FTOER	Flash timeout error 0 No flash interface timeout 1 Flash interface timeout occured
5 WPER	Write protect error **NOTE:** Error is asserted when the write operation starts executing on the flash interface. 0 No write protect error 1 A write is attempted to the memory bank which is write protected
6 ECCER	ECC error **NOTE:** With the clearing of this error status bit, the ECCSTAT0/1/2/3 register contents will also be cleared.

Table continues on the next page...

IFC_NAND_EVTER_STAT field descriptions (continued)

Field	Description
	0 No uncorrectable ECC Error occured on page read operation 1 Uncorrectable ECC error occured in page read operation
7–15 -	This field is reserved.
16 RCW_DN	This bit is set when one flash page has been read from the flash device and written into the SRAM buffer during RCW load. It is write-1-to-clear bit and can be cleared by software after RCW loading. This event does not have any corresponding event enable and interrupt enable bit.
17 BOOT_DN	This event is set when 8 KB flash data has been read from the flash device and written into the SRAM buffer during BOOT load. It is write-1-to-clear bit and can be cleared by software after BOOT loading. This events will not have any corresponding event enable and interrupt enable bit.
18–19 -	This field is reserved.
20 BBI_SRCH_SEL	Bad Block Indicator search select: This status register bit represents the location of bad block indication in each block of NAND flash device connected at chip-select0. This field will be updated with input port value por_cfg_bbi_srch_sel when por_cfg_boot_load /por_cfg_rcw_load pulse occurs. 0 Read bad block indicator (BBI) corresponding to page0 and page1 of each block of the NAND flash device connected at chipselect 0, to identify the first good block during auto-boot 1 Read bad block indicator (BBI) corresponding to page0 and the last page of each block of the NAND flash device connected at chipselect 0, to identify the first good block during auto-boot
21–31 -	This field is reserved.

12.3.49 NAND Page Read Completion Event Status register (IFC_PGRDCMPL_EVT_STAT)

NAND flash page read completion event register indicates the status of the pages read from NAND flash and stored in SRAM buffer. 16 bits of this register represent 16 sectors each of 512 bytes (used in ECC decoding). There can be 1, 4, 8, and 16 sectors in each page of size 512 bytes, 2 KB, 4 KB, and 8 KB . Event interrupt will be generated if one complete page has been written in SRAM buffer (when ecc_dec_en = 0) or when one complete page has been fixed in the SRAM after decoding (ecc_dec_en = 1). Software can read the corresponding page whose data has been completely written in SRAM (ECC fixed) and clear the corresponding bits in this register.

24/40-bit ECC is computed on 1 KB sector and applicable for 4 KB and 8 KB page sizes. However the definition of this register remains same except the fact that 512 is the byte size and not the sector size.

NOTE

The register gets cleared when software clears the OPC bit in NAND_EVTER_STAT register. Even if per page event interrupt is used for reading the data from SRAM,

NAND_EVTER_STAT[OPC] is the true indication of NAND operation completion.

The following figure shows the register fields. It is write-1-to-clear register.

Address: 12_4000h base + 1174h offset = 12_5174h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	SEC_DONE																Reserved															
W	w1c																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

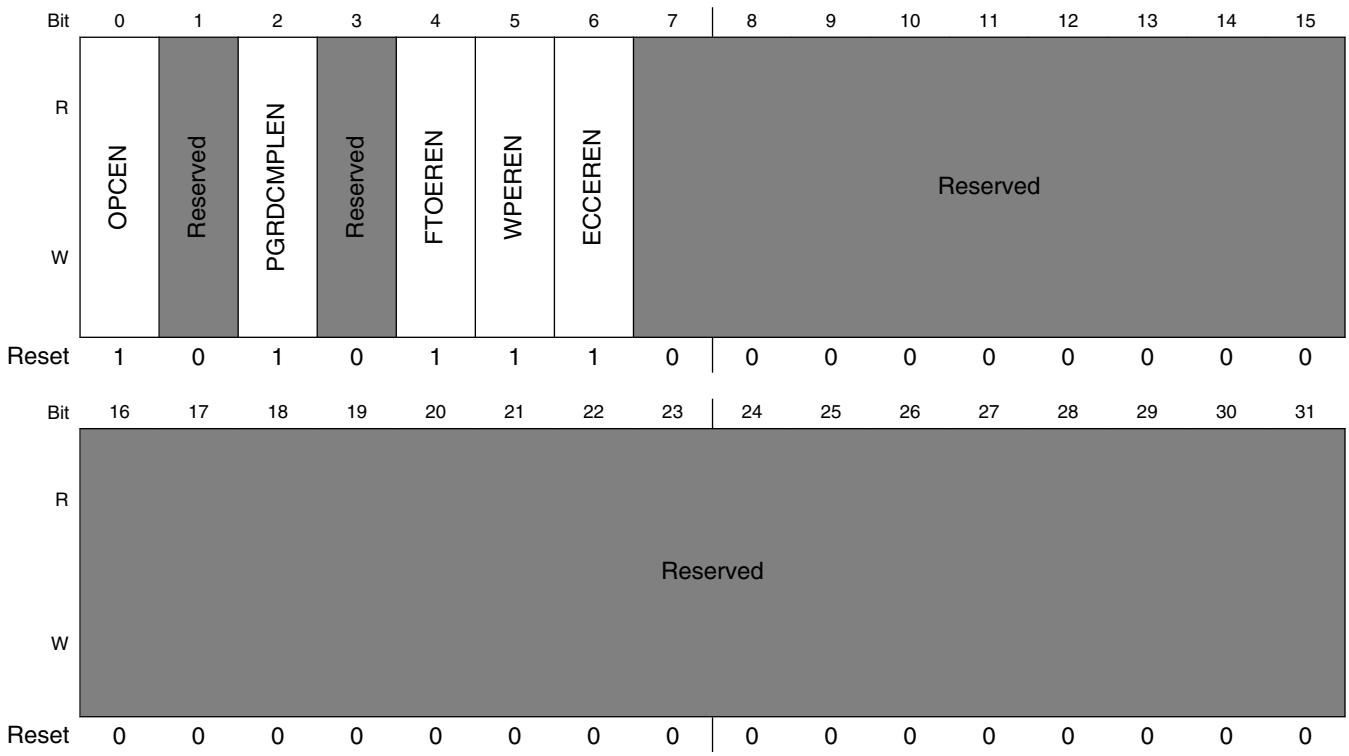
IFC_PGRDCMPL_EVT_STAT field descriptions

Field	Description
0–15 SEC_DONE	For small page: Each of the 16 bits of this field represent one small page read data completion status Bit 0 set-Page 0 done, that is, flash read data is completely written and fixed in SRAM buffer Bit 1 set-Page 1 done Bit 2 set-Page 2 done Bit 3 set-Page 3 done ... Bit15 Set-Page 15 done For 2KB Page: SRAM buffer can accommodate 4 page (2KB) each containing four 512 byte sectors SEC_DONE[0:3] = 4'b1111: Page 0 done SEC_DONE[4:7] = 4'b1111: Page 1 done SEC_DONE[8:11] = 4'b1111: Page 2 done SEC_DONE[12:15] = 4'b1111: Page 3 done For 4KB Page: SRAM buffer can accommodate 2 page (4KB) each containing eight 512 byte sectors SEC_DONE[0:7] = 8'b1111_1111: Page 0 done SEC_DONE[8:15] = 8'b1111_1111: Page 1 done For 8KB Page: Only one page can be buffered in SRAM. SEC_DONE[0:15] = 16'b 1111_1111_1111_1111: Single page of 8KB done. **NOTE:** Event interrupt will be generated when one complete page read is done. Software has to read the corresponding page from SRAM buffer and clear the bits from this register. For example if page size is 2 KB and page 0 is being written in SRAM buffer, then SEC_DONE[0:15] will be 16'HF000, now software has to write the data 16'HF000 in this register to clear it.
16–31 -	This field is reserved.

12.3.50 NAND Event and Error Enable register (IFC_NAND_EVTER_EN)

Event and Error Enable Register (NAND_EVTER_EN) is used to enable/disable the logging of event and error indication in the NAND_EVTER_STAT and PGRDCMPL_EVT_STAT registers.

Address: 12_4000h base + 1180h offset = 12_5180h



IFC_NAND_EVTER_EN field descriptions

Field	Description
0 OPCEN	NAND flash operation complete event enable 0 NAND flash operation complete event is disabled 1 NAND flash operation completed event is enabled
1 -	This field is reserved.
2 PGRDCMPLEN	NAND flash page read completion event enable 0 Per page read event disable 1 Event will be generated on per page flash read operation completion. Status about the page whose data is available in sram buffer is given by PGRDCMPL_EVT_STAT register.

Table continues on the next page...

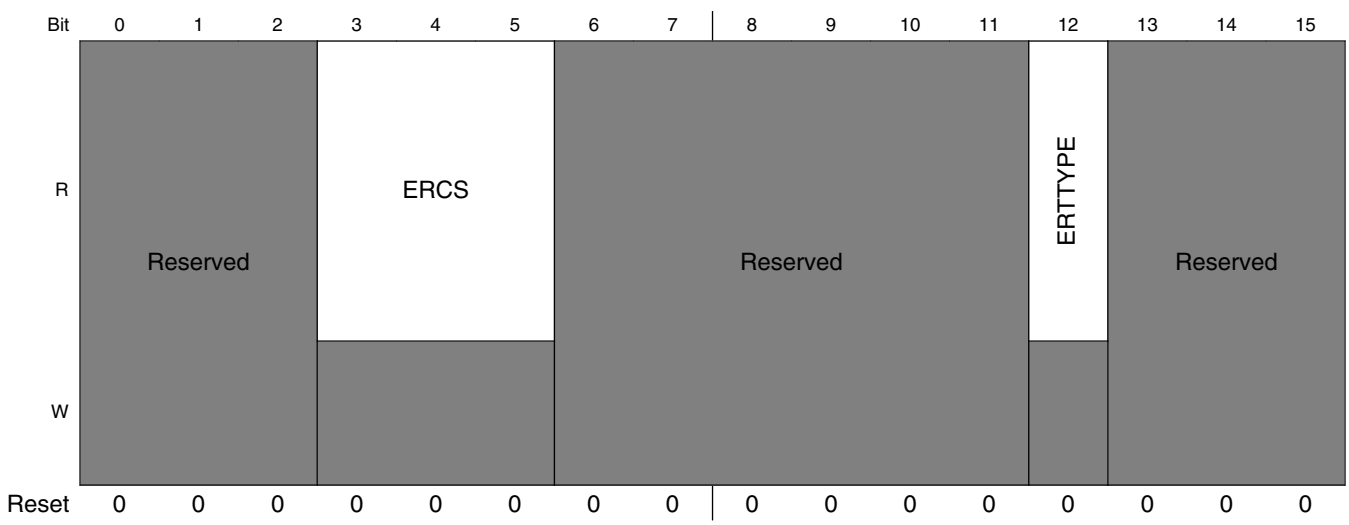
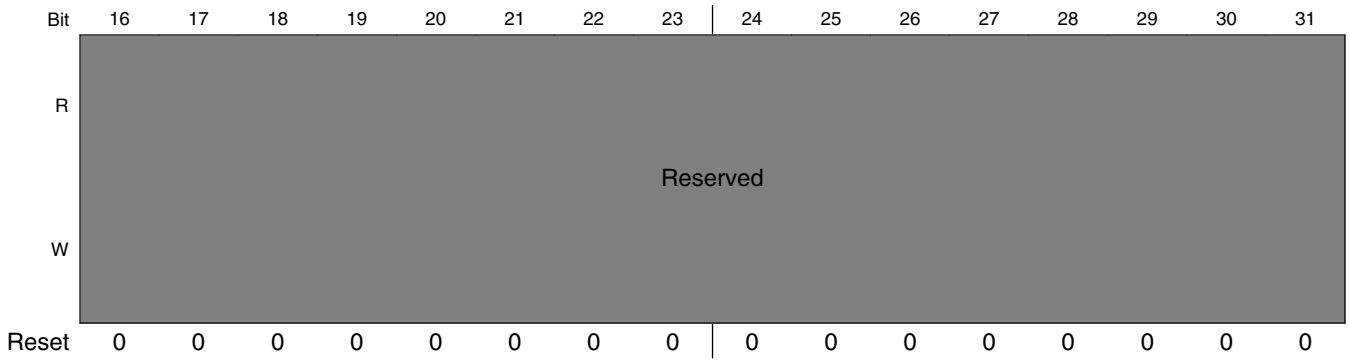
12.3.52 NAND Transfer Error Attributes register 0 (IFC_NAND_ERATTR0)

Transfer error attribute register 0 (NAND_ERATTR0) is used to register the transaction attributes corresponding to the first error.

These registers store the attribute corresponding to the first transaction on which an error occured.

Address: 12_4000h base + 1198h offset = 12_5198h





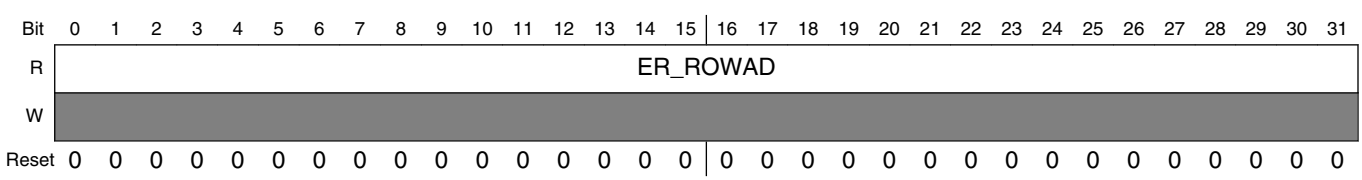
IFC_NAND_ERATTR0 field descriptions

Field	Description
0–2 -	This field is reserved.
3–5 ERCS	Chip-Select Corresponding to NAND Error 000 Bank0 001 Bank1 010 Bank2 ... 111 Bank7
6–11 -	This field is reserved.
12 ERTTYPE	Transaction type of NAND error 0 Write 1 Read
13–31 -	This field is reserved.

12.3.53 NAND Transfer Error Attributes register 1 (IFC_NAND_ERATTR1)

Transfer error attribute register (NAND_ERATTR1) is used to register the transaction address corresponding to the first error.

Address: 12_4000h base + 119Ch offset = 12_519Ch



IFC_NAND_ERATTR1 field descriptions

Field	Description
0–31 ER_ROWAD	Row address corresponding to error transaction

12.3.54 NAND Flash Status register (IFC_NAND_FSR)

Flash status register (NAND_FSR) contains read status data from NAND flash.

Address: 12_4000h base + 11E0h offset = 12_51E0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

IFC_NAND_FSR field descriptions

Field	Description
0–7 RS0	First byte of data read from read status operation
8–15 RS1	Second byte of data read from read status operation
16–31 -	This field is reserved.

12.3.55 ECC Status and Result of Flash Operation register 0 (IFC_ECCSTAT0)

ECC status registers are used to store the number of ECC errors occured on read operation. It has different meanings for 4/8 and 24/40 bit ECC Modes as the sector size is different for 4/8 and 24/40 bit modes.

ECC is computed on sector basis, and in the SRAM buffer there can be 16 such sectors of 512 byte each for 4 and 8 bit ECC (Galois field GF-2 ^{13}) and 8 sectors of 1 KB each for 24 and 40 bit ECC (Galois Field 2 ^{14}). Hence, each field of these registers represents number of errors in each sector. Depending on the page index mapped in the SRAM buffer, the corresponding field in the ECCSTAT0 will be updated.

As SRAM buffer can have 8 sectors of 1KB each, only the first eight register fields in ECCSTAT0/1 registers are defined with width 6 to represent 24 and 40 bit ECC along with 4 and 8 bit ECC.

NOTE

1. These registers will be updated whenever decoder is enable (ECC_DEC_EN =1'b1) irrespective of ECC Error Event Indication is enabled or not (ECCEREN).
2. With the clearing of NAND_EVTER_STAT[ECCER] register bit the contents of ECCSTAT0/1/2/3 registers will also be cleared. These registers will also be cleared with soft_reset.
3. For every NAND sequence start, all the ECCSTAT registers will be cleared. It is implemented in order to flush the previously logged information.

Address: 12_4000h base + 11E8h offset = 12_51E8h

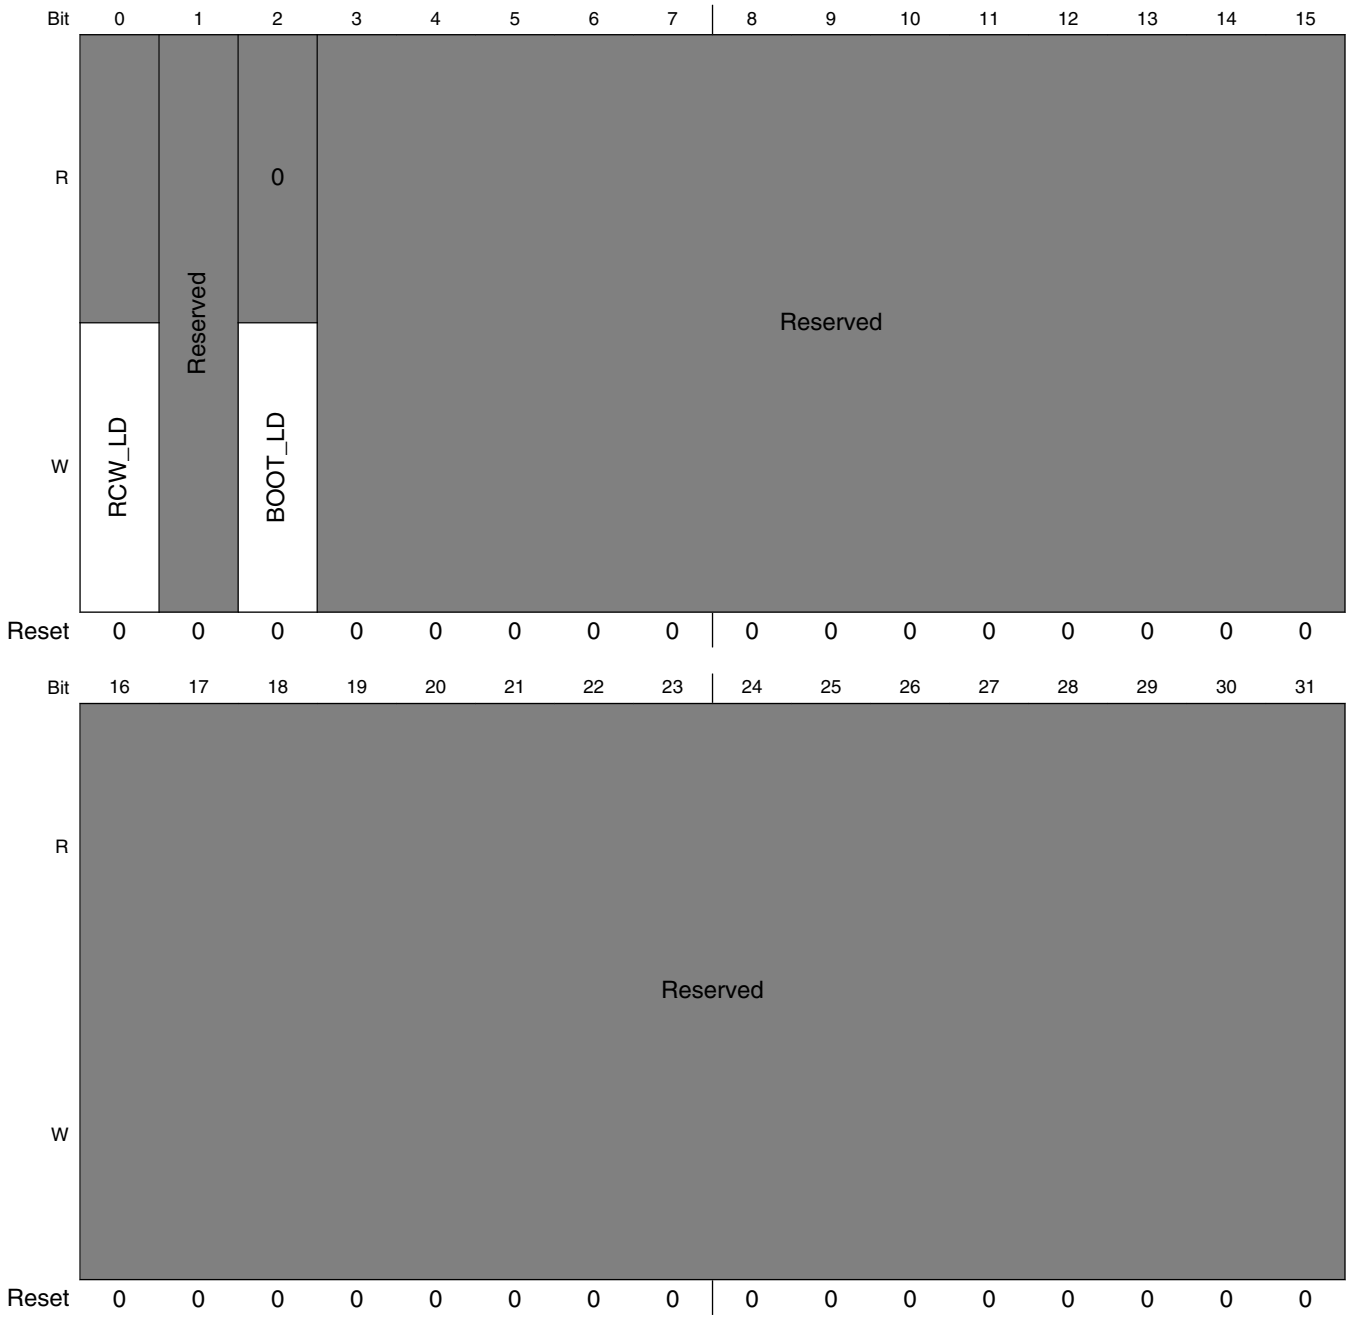
12.3.60 NAND Autoboot Trigger register (IFC_NAND_AUTOBOOT_TRGR)

This register is used to trigger the booting on the NAND flash. This register is provided if por_cfg_rcw_load and por_cfg_boot_load signals are not coming through the pins for the booting. The user can use this register to achieve the same boot functionality as described in NAND asynchronous mode boot mechanism .

It is a self-clearing register; hence, the user just has to write 1 in appropriate field to trigger the auto-boot operation and hardware will clear it.

Address: 12_4000h base + 1284h offset = 12_5284h



IFC_NAND_AUTOBOOT_TRGR field descriptions

Field	Description
0 RCW_LD	RCW Load **NOTE:** The values on the various por_cfg pins should be driven valid when this bit is set. 0 No RCW loading 1 Trigger RCW load from NAND flash (same functionality that can be achieved by sending pulse on por_cfg_rcw_load)

Table continues on the next page...

IFC_NAND_AUTOBOOT_TRGR field descriptions (continued)

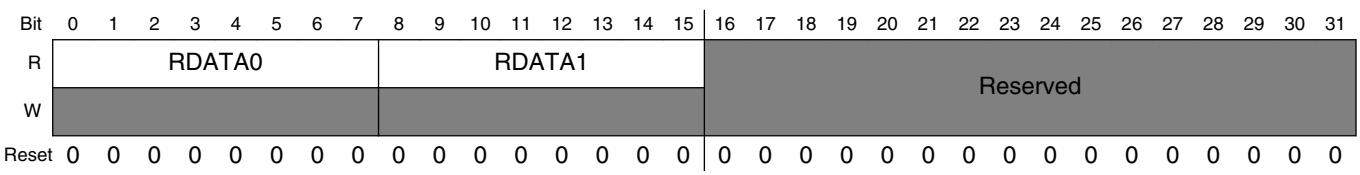
Field	Description
1 -	This field is reserved.
2 BOOT_LD	BOOT Load **NOTE:** The values on the various por_cfg pins should be driven valid when this bit is set. 0 No BOOT loading 1 Trigger autoboot loading from NAND flash (same functionality that can be achieved by sending pulse on por_cfg_boot_load)
3–31 -	This field is reserved.

12.3.61 NAND Flash Memory Data register (IFC_NAND_MDR)

This register is used to store one beat of data read from NAND flash memory when opcode, "SBRD" is used in the FIR register. This register is provided for reading 1 or 2 bytes of data from 8- or 16-bit NAND flash. The location from where the data gets fetched can be controlled by column register (COL*n*). When NAND FIR is programmed with opcode "SBRD", IFC always reads 1/2 bytes of data irrespective of the value of BC (no. of bytes) programmed in NAND_BC register.

Also note that the read data fetched from NAND flash is only stored in this register and SRAM buffer does not get updated as this opcode is intended for register access only.

Address: 12_4000h base + 128Ch offset = 12_528Ch



IFC_NAND_MDR field descriptions

Field	Description
0–7 RDATA0	1st read data byte when opcode SBRD is used for read
8–15 RDATA1	Second read data byte when opcode SBRD is used for read (only valid for 16 bit NAND flash)
16–31 -	This field is reserved.

12.3.62 NOR Event and Error Status register (IFC_NOR_EVTER_STAT)

As with NAND FCM, 1 KB memory-mapped region is allocated for the NOR-specific registers. This section describes these registers.

NOR event and error status register (NOR_EVTER_STAT) indicates the cause of an error or event corresponding to NOR flash.

The following figure shows the register fields. It is write-1-to-clear register.

Address: 12_4000h base + 1400h offset = 12_5400h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

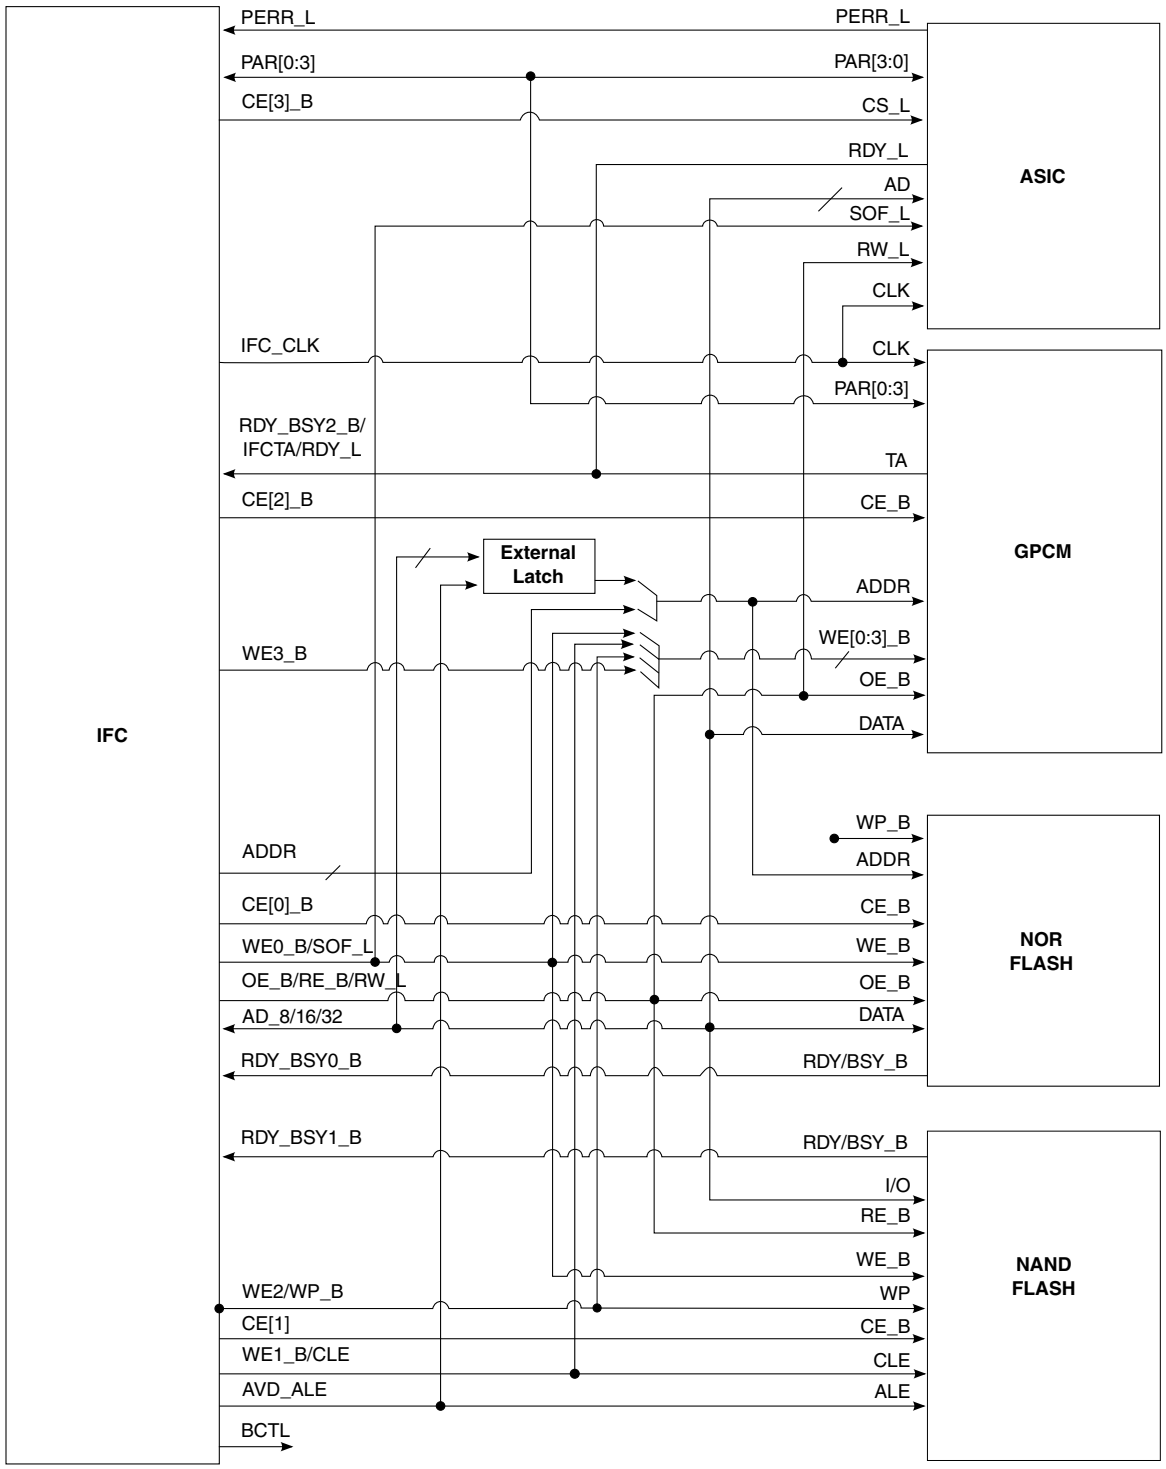
12.4 IFC functional description

The IFC is used to interface with external asynchronous NAND flash, asynchronous NOR flash, SRAM, EPROM, and generic ASIC devices.

To achieve this functionality, the logic is partitioned in independent flash control machines (FCMs) in the IFC to control the timings of NAND flash, NOR flash, and GPCM separately. Eight independent chip-selects are provided, but they all share the same pins; hence, only one memory can be accessed at a time based on the machine-select bits of the chip-select property register for that bank (CSPR*n*[MSEL]). If a bank match occurs, the corresponding machine (NAND, NOR, or GPCM) takes ownership of the external signals that control the access and maintains control until the transaction ends.

This figure is a functional block diagram of the flash memory interface and its signal muxing.



NOTE: All interfaces and signals are not necessarily supported. Refer to the "Features" and "Exteranl signal description" sections for the features and signals supported on this device.

Figure 12-6. Flash memory interface and muxing

The IFC supports the following types of flash control machines (FCMs):

- NOR FCM provides interfacing with NOR flash memories that have a 8-/16-/32-bit-wide data bus. NOR FCM-controlled banks are used primarily for booting (direct memory-mapped) and code storage.
- The NAND FCM interfaces to NAND flash EEPROMs with 8- and 16-bit data buses. If NAND is chosen as the booting device, after reset, the NAND FCM can load boot code into SRAM buffer for execution. Following boot, the NAND FCM provides a flexible instruction sequencer that allows a user-defined command, address, and data transfer sequence of up to 15 steps to be executed against a memory-mapped buffer RAM. An advance ECC algorithm (BCH codes) is implemented to correct up to 4-/8-bit errors per sector of 512 bytes and 24/40 bit erros per 1KB sector.
- GPCM provides an interface to simple, synchronous, memory-mapped devices.

Each memory bank can be assigned to any of these types of machines through the machine-select bits of the chip-select property register for that chip-select (CSPRn[MSEL]).

12.4.1 General architecture

The basic architecture of the IFC allows bank selection through address decoding and address/data pin muxing.

12.4.1.1 Bank selection through address decoding

Banks can be selected via address decoding.

The defined base addresses are written to CSPR*n*[BA] and CSPR*n*_EXT[BA_EXT], while the corresponding address masks are written to AMASK*n*[AM]. Each time a local system access is requested, the internal transaction address is compared with each bank. Address decoding logic is explained in Address Mask register (IFC_AMASK*n*). If a match is found on a memory controller bank, the attributes defined in the CSPR*n* and CSOR*n* for that bank are used to control the memory access. If a match is found in more than one bank, the lowest-numbered bank handles the memory access (that is, bank 0 has priority over bank 1).

12.4.1.2 Address/Data pin muxing for external address latch

There are various pin-muxing schemes available at the IFC interface.

The IFC provides muxing of the address and data bits on the same bus (AD), where the muxing is controlled by the AVD/ALE signal. There are two modes supported to supply, either address msbs (most significant bits) or lsbs (least significant bits) on AD bus. Chip-select register field CSOR*n*[ADM_SHFT_MODE] determines the mode of address-data pin muxing for the chip. The pin-muxing modes are described in Mode 0 pin muxing (CSOR*n*[ADM_SHFT_MODE] = 0) and Mode 1 pin muxing (CSOR*n*[ADM_SHFT_MODE] = 1).

12.4.1.2.1 Mode 0 pin muxing (CSOR*n*[ADM_SHFT_MODE] = 0)

In this mode of muxing, the IFC supplies the most significant bit (msb) of the address bits on the AD bus. Register field CSORn[ADM_SHFT] controls the amount of address shift to align the msb of address with AD[0]. This shift can be utilized to align the msb of system address with the AD[0] signal during address phase (when AVD/ALE is asserted).

An application of this mode is an external latched-based system where the AVD/ALE signal is connected to the latch enable such that external latch latches the address msb coming through the AD bus during AVD/ALE assertion. This mode is used to connect conventional NOR devices (having dedicated address and data pins) as well as GPCM-based interfaces.

In this mode, system address is left shifted by CSORn[ADM_SHFT] shift value and assigned to AD[0:31]. The address msb will be assigned to data bus msb (AD[0]). The shifted address can be latched by external latch at the falling edge of AVD/ALE.

The system address directly gets assigned to the IFC address bus (ADDR [0:31]) irrespective of the ADM_SHFT value. The least significant bit (lsb) can be retrieved from the ADDR bus. ADDR[31] will carry the lsb of the system address.

To interface with a x16 NOR device, the address lsb must be left unconnected on the board.

For a chip that has a 16-bit AD bus and an 11-bit ADDR bus, which needs to be interfaced with a memory of 8-bit port width and 128 MB memory size (requiring a 27-bit address), the following figure shows how system address bits are placed during IFC address phase (AVD/ALE assertion) with a CSORn[ADM_SHFT] value of 5.

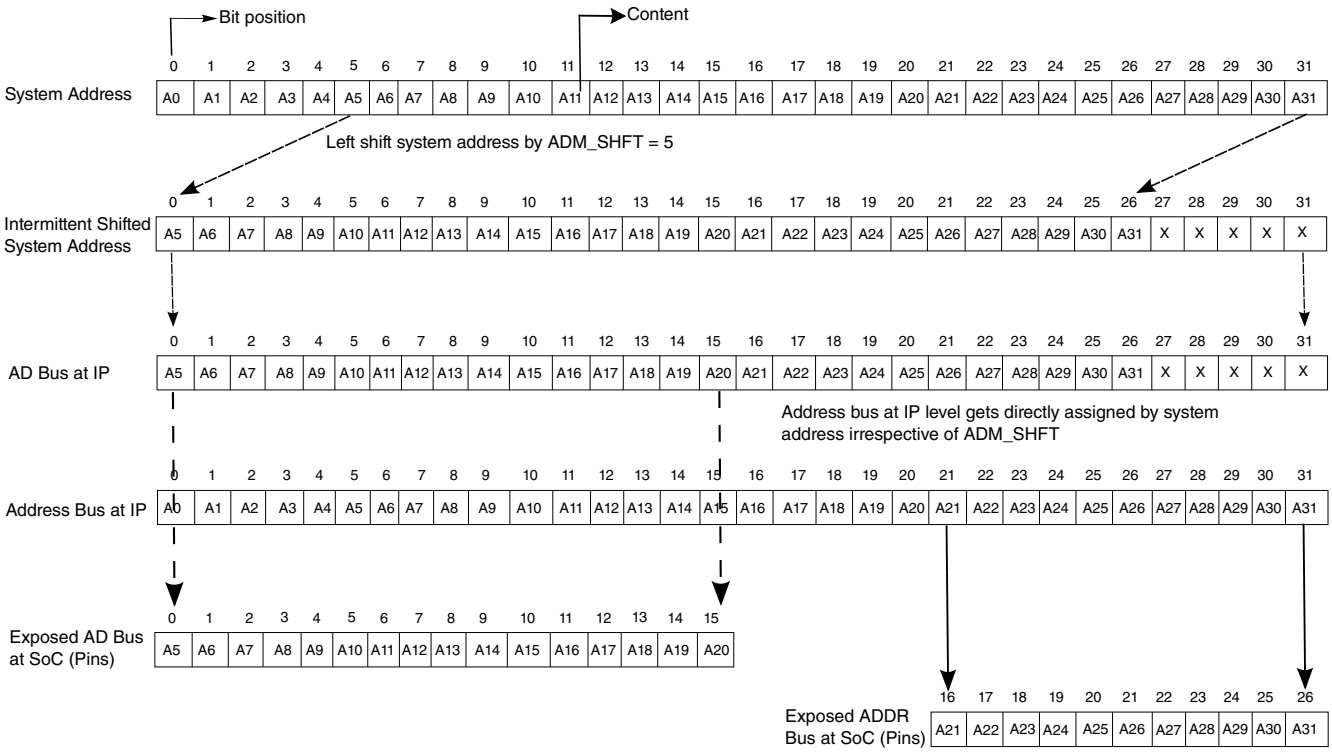


Figure 12-7. System address assignment with CSORn[ADM_SHFT]= 5 for ADM MODE 0

These figures show a x8 and x16 memory connection for the configuration given above, where the shift value is 5.

NOTE

These figures are intended to be examples only and may show ADDR pins that are not supported.

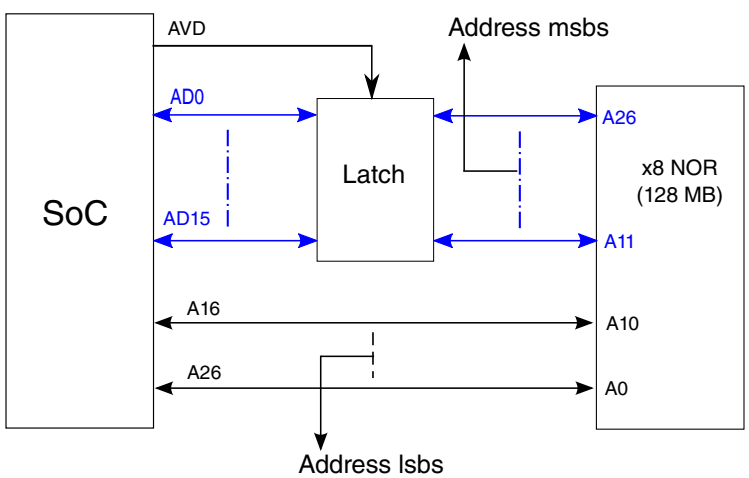

Figure 12-8. Connection of x8 NOR for ADM MODE 0

For a x16 memory connection, since the memory expects a 26-bit word address, the address lsb is left unconnected at the board to supply the word address.

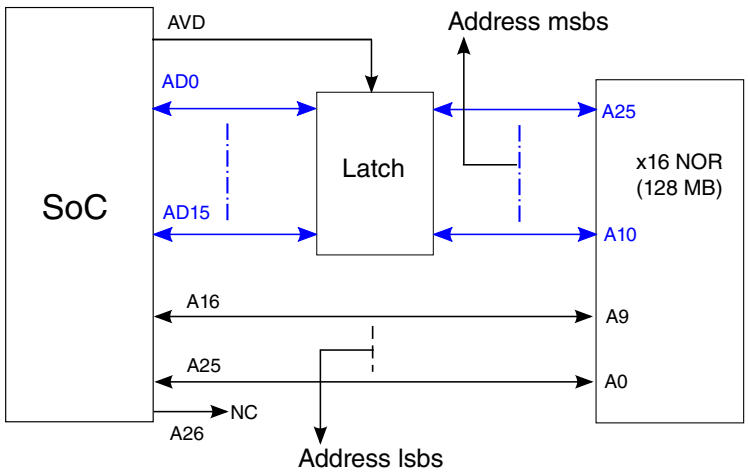

Figure 12-9. Connection of x16 NOR for ADM MODE 0

12.4.1.2.2 Mode 1 pin muxing (CSOR*n*[ADM_SHFT_MODE] = 1)

In this mode of muxing, the IFC supplies the address least significant bit (lsb) on the AD bus. CSORn[ADM_SHFT] controls the address shift to align the system address lsb with AD[0]. In this mode, the ADDR bus carries the address most significant bit (msb). This mode is used to interface address data multiplexed (ADM) NOR devices (internal latch-based).

Connection in this mode should be treated as a special case since the board connectivity is in decrementing (reverse) bit order, as shown in following examples.

This is done to simplify the board connection for the ADM NOR as these devices expect the lsb to get latched at their internal latch with the assertion of AVD_B. In this mode, the system address remains the same and the IFC internally rearranges (based on the port size) the data bus in order to maintain the same data image for both the conventional NOR (external latched-based) as well as the ADM NOR (internal latch-based). This data rearrangement is performed internally within the IFC during both the read and write phases because the board connection for ADM NOR is opposite of the conventional (non-ADM) NOR devices. This mode is valid only for NOR mode of operation and not for GPCM.

Unlike in CSOR*n*[ADM_SHFT_MODE] = 0, there is no need to leave the ADDR lsb unconnected on the board to supply word address to memory for x16- and x32-bit memories. The reason is that the lsb are now carried by the AD bus, which cannot be left unconnected since they carry the data during the data phase. Therefore, the logic is implemented in such a way that the IFC does a necessary address shift internally to supply word addresses to memory.

Example 1: The chip has exposed a 32-bit AD bus and x8 ADM NOR of 128 MB is connected through it.

In this example, ADM_SHFT does not have any role as the chip has not exposed the ADDR bus and all address bits are available through the AD bus.

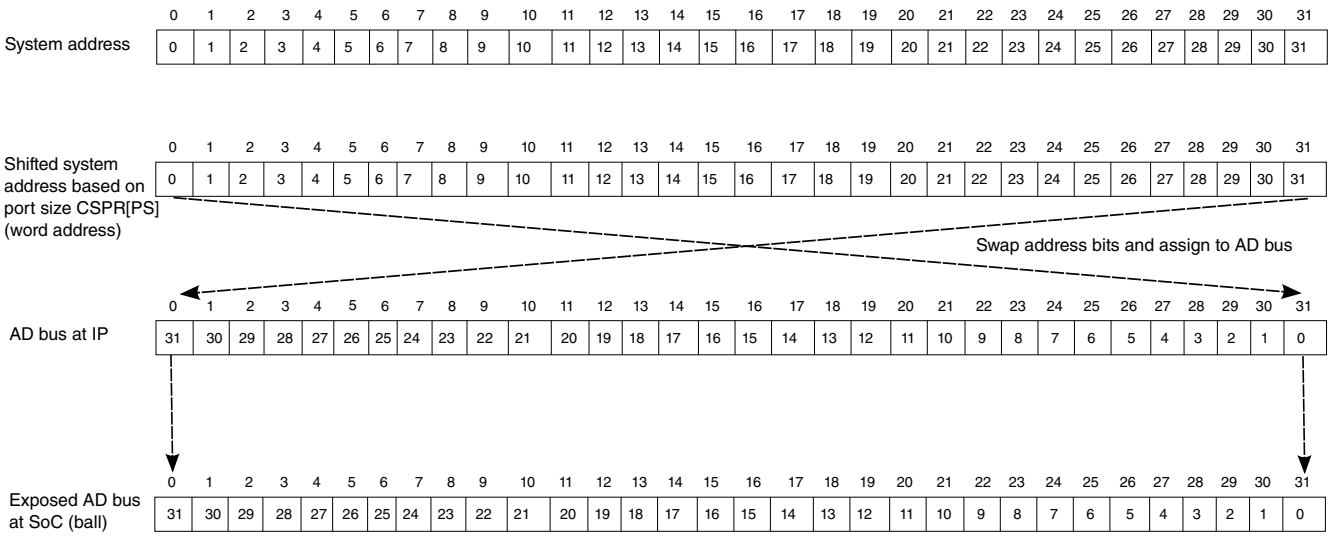

Figure 12-10. Example 1 - System address assignment to the AD bus for ADM MODE 1

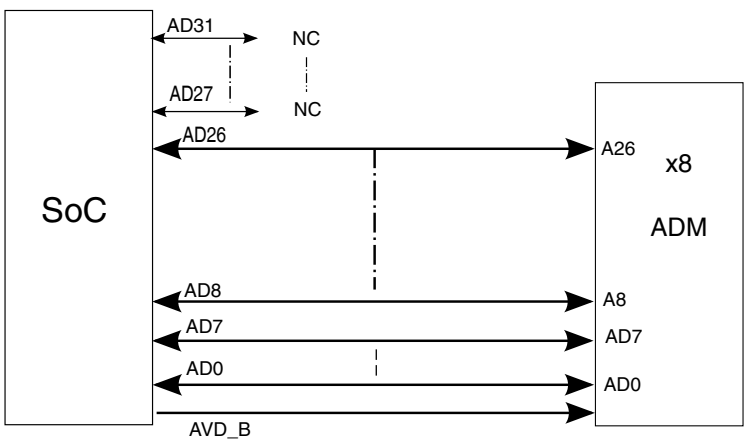

Figure 12-11. Example 1 - Connection of x8 ADM NOR for ADM MODE 1

NOTE

The board connections are in decrementing (reverse) bit order for the ADM NOR only.

Example 2: The chip has exposed a 32-bit AD bus and x16 ADM NOR of 128 MB is connected through it.

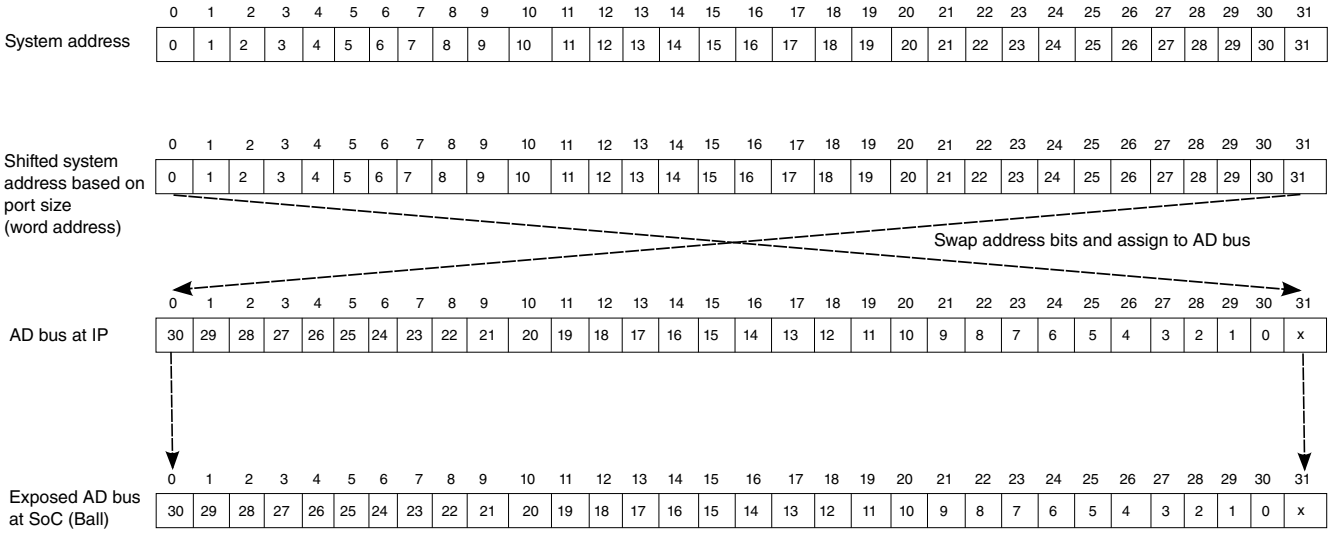

Figure 12-12. Example 2 - System address assignment to the AD bus for ADM MODE 1

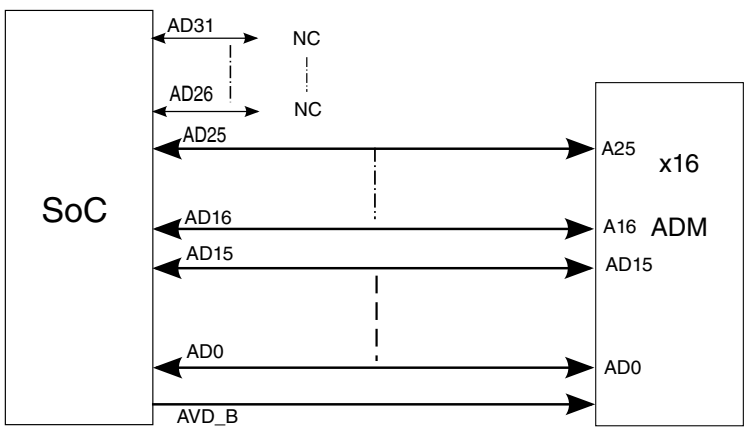

Figure 12-13. Example 2 - Connection of x16 ADM NOR for ADM MODE 1

Based on the port size, the address is generated such that the proper word address goes to the memory, unlike conventional NOR (ADM MODE 0). The lsb cannot be left unconnected as they are carried by AD[0] and is also used in the data phase.

Example 3: The chip has exposed a 16-bit AD bus, 11-bit ADDR bus, and x8 ADM NOR of 128 MB is connected through it.

In this example, ADM_SHFT=5 is required to align the system address msb with the right-most ADDR index as shown in the figure below.

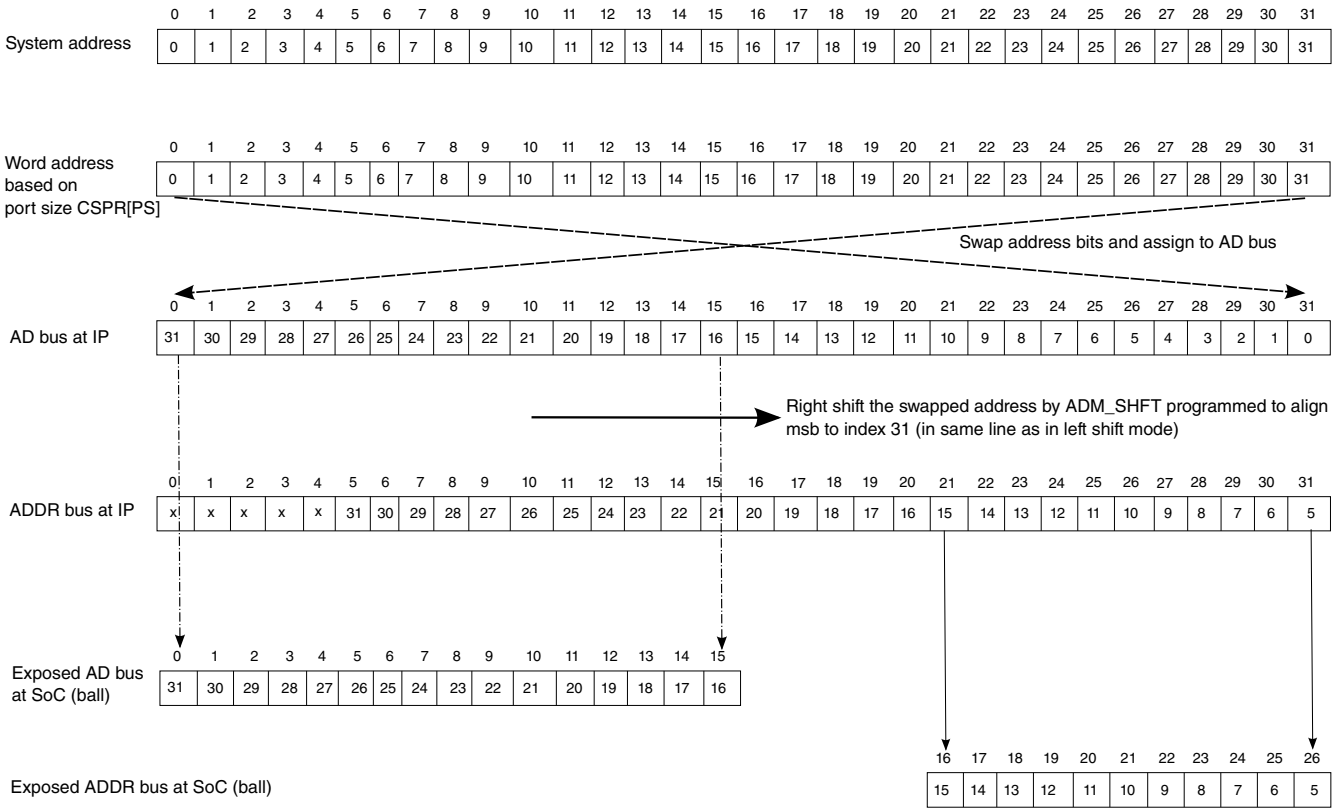

Figure 12-14. Example 3 - System address assignment to the AD and ADDR bus for ADM MODE 1

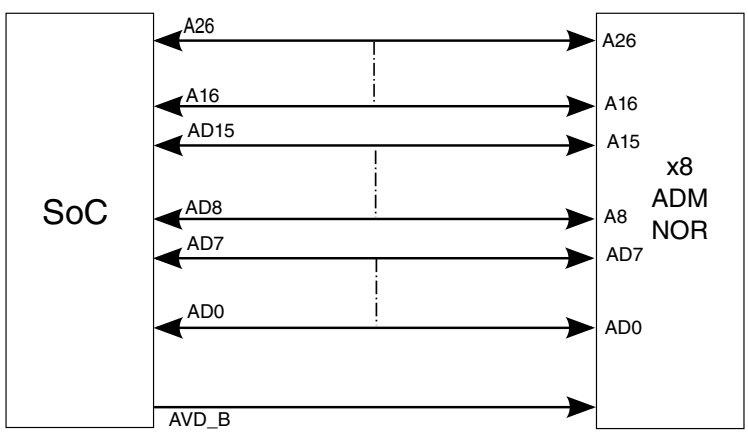

Figure 12-15. Example 3 - Connection of x8 ADM NOR for ADM MODE 1

Example 4: The chip has exposed a 16-bit AD bus, 11-bit ADDR bus, and x16 ADM NOR of 128 MB is connected through it.

In this example, ADM_SHFT=5 is required to align the system address msb with the right-most ADDR index as shown below.

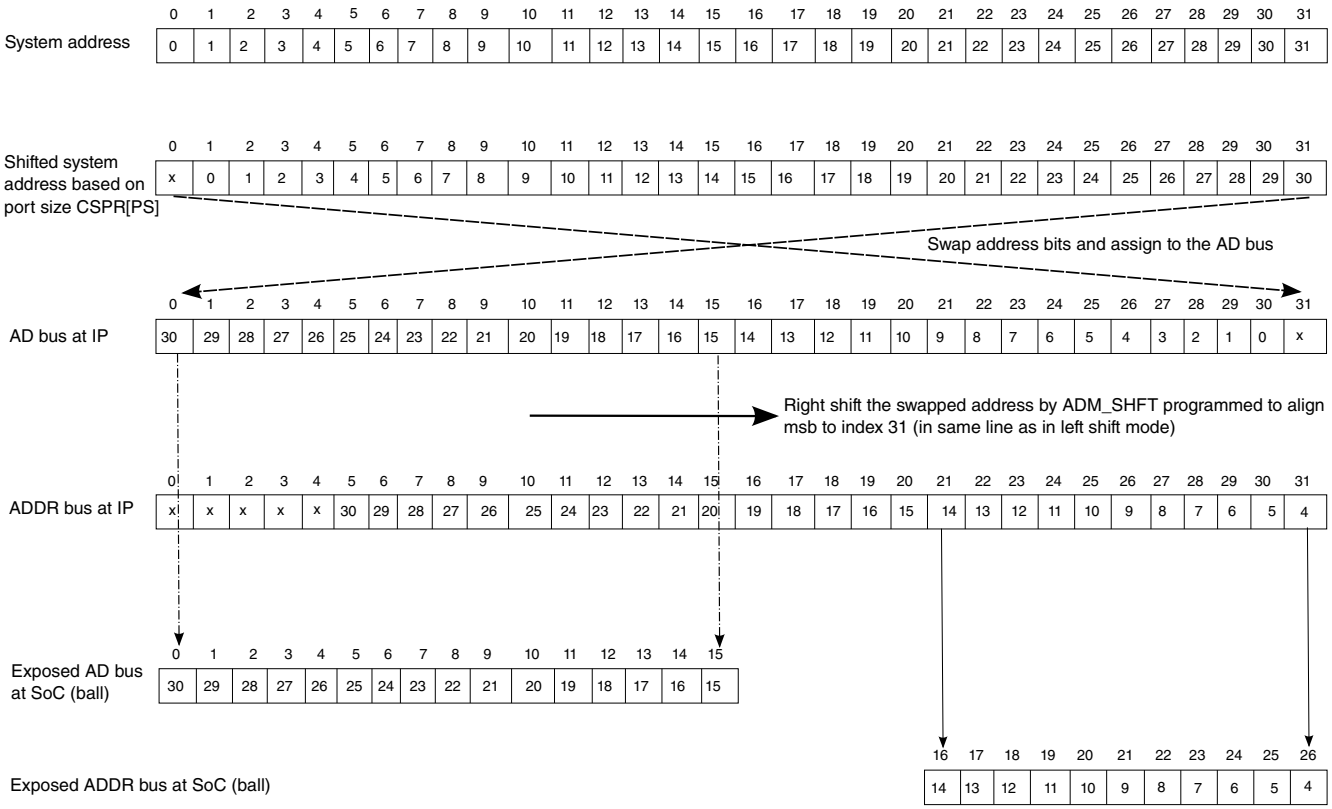

Figure 12-16. Example 4 - System address assignment to AD and ADDR bus for ADM MODE 1

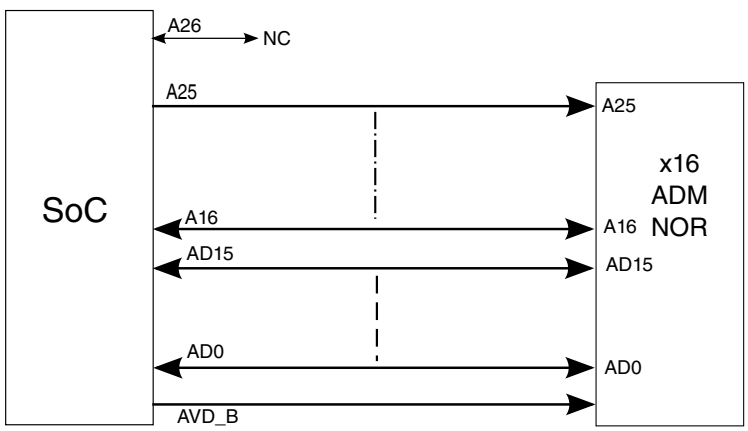

Figure 12-17. Example 4 - Connection of x16 ADM NOR for ADM MODE 1

NOTE

Timing of AVD and AVD_B is same. Both are generated by the same logic except they are opposite in polarity. If the chip is only exposing AVD and not exposing AVD_B, then it can be generated by using an on-board inverter and can be used for interfacing with ADM NOR.

12.4.2 Programming model for flash interface timing

The IFC follows a counter-based approach to generate the required timings on the flash side.

Programming registers (FTIM*n*) are provided that correspond to the various flash timing parameters. The values to be programmed in these registers are in terms of the number of IFC input clock-cycles derived by the following formula:

Timing counter value = [{Flash Timing Parameter(ns) x IFC module input clock frequency (MHz)} + 1000 - 1] / 1000

In this approach, counters running at the IFC module input clock generate the appropriate values for the flash interface signals depending on the value programmed in the Timing Registers (FTIM0-FTIM3). These timing registers must be programmed per the values specified in the flash device datasheet mapped to the waveforms shown in NAND asynchronous mode timings, Unmuxed (parallel) asynchronous NOR read timings, and Simple asynchronous NOR write timings.

12.4.3 Booting methods

Booting can be performed from NAND or NOR flash on the IFC.

- NOR is directly memory-mapped, so booting from NOR can be done as simple read operations without any special arrangements. Default timing parameters are loaded with the assertion of rcw_load/boot_load, details of this requirement is explained in NOR boot.
- NAND is not directly memory-mapped, so the boot code is loaded first into an SRAM buffer from where the code can be executed. See NAND flash control machine for more information about booting from NAND.

The flash timing registers (Flash Timing register 0 for Chip Select *n* - NAND flash async mode (IFC_FTIM0_CS*n*_NAND) through Flash Timing register 3 for Chip Select n - NAND Flash Mode (IFC_FTIM3_CS*n*_NAND)) that control chip-select 0 have default values corresponding to the slowest-mode devices to guarantee boot.

Reset initialization is performed by the reset controller and the default configuration is determined by cfg_rcw_src and/or RCW settings.

12.4.4 Software reset handling

Software reset requires that software read and clear specific registers.

Software follows these steps as part of software reset handling:

1. Read all the event and error status registers.
2. Clear the NANDSEQ_STRT register.
3. Clear the NAND_AUTOBOOT_TRGR register.
4. Apply soft reset.

After the soft reset has been applied, the hardware automatically clears all the event and error status registers. None of the other registers are reset. Therefore, the initial configuration done by the software is preserved.

12.4.4.1 System bus handling

Any pending transactions on the system bus are terminated with a valid response.

During software reset assertion, providing a good response that corresponds to the pending transaction on the IFC helps prevent a corresponding interrupt. The core expects an error interrupt whenever there is an error response from the system bus. Therefore, in the case of a software reset and an error response is provided, the core goes into a hang state because there is no corresponding interrupt. If there are pending read transactions, the garbage data is supplied back; if there is a pending write transaction, the data is not written in the memory.

The hardware does not allow the software to clear the soft reset bit until all pending transactions on the system bus have been gracefully terminated (with a good response). When there are no more transactions pending on the system bus, the hardware allows the software to clear the soft reset bit.

12.4.4.2 Flash interface handling

All the state machines (NAND, NOR, GPCM, and GASIC) are reset to the idle state.

All related FIFOs and registers are flushed, so the flash interface would be in the idle state.

12.4.5 Data buffer control (BCTL)

The IFC provides a data buffer control signal (BCTL) that can be disabled (remain high) by setting CSOR*n*[BCTLD]. BCTL should be used to signify the write direction when high.

NOTE

BCTL is a static value; it cannot be programmed on the fly.

If the access is a write, BCTL remains high for the whole duration. However, if the access is a read, BCTL is negated (low) so that the memory device is able to drive the bus. Note that the default (reset and bus idle) value of BCTL is also high.

While accessing slow memories, the data driven by the flash is available on the bus after deassertion of read enable. To avoid bus contention, BCTL remains low (read mode) for the time defined by the CSORn[TRHZ] field.

Apart from CSORn[TRHZ], another signal timing that requires attention during the external buffer control is buffer turn-around. The external buffer takes time to reverse the direction of the shared I/O bus. This situation is more relevant when a read is followed by a write. To handle this, GCR[TBCTL_TRN_TIME] is defined, which represents the time for which BCTL remains high before starting another flash access. The timings are shown in the following figures.

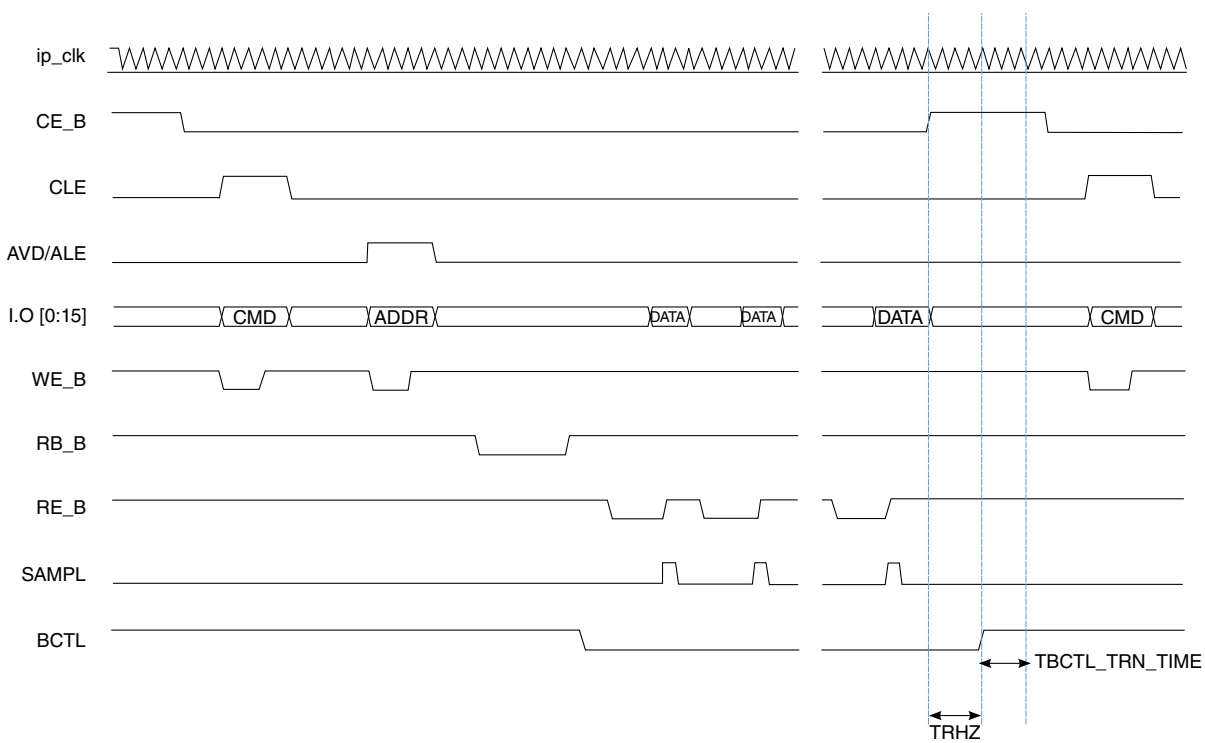

Figure 12-18. BCTL signal in NAND read followed by any other operation

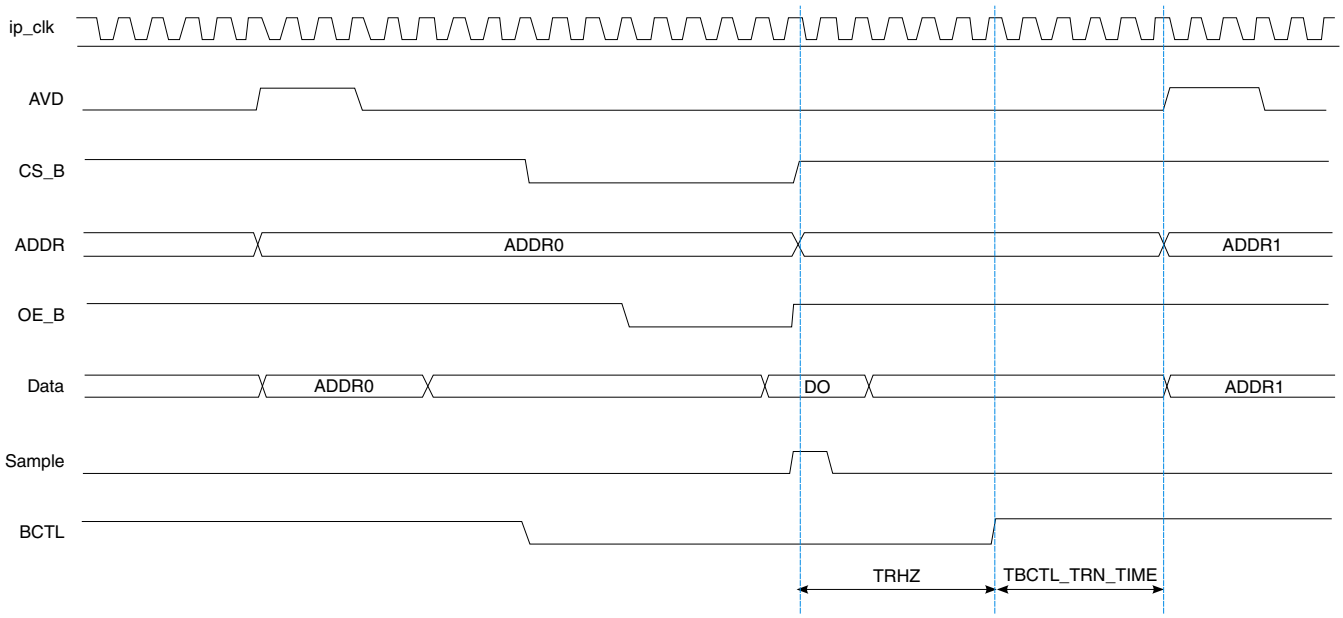

Figure 12-19. BCTL signal in NOR read followed by any other operation

12.4.6 External transceiver enable (TE)

This signal is used to enable/disable the external transceiver depending on whether a slow/fast memory is connected to the bank servicing the current request.

If various fast/slow memories are connected to different banks of the IFC, the AD bus may become loaded due to sharing. Such a scenario results in poor rise/fall times and therefore limits the speed of operation of fast memories given their strict timing requirements. To address this issue, fast memories should be segregated from the slower memories using an external transceiver that is connected to the AD bus. In these scenarios, the IFC provides the configurable transceiver enable (TE) pin.

12.4.6.1 Transceiver enable during boot

The IFC can be used for booting after reset.

The IFC can obtain the TE value, which is used during booting, in the following ways:

- By sampling the TE pin.

  In this scenario, the TE pin acts as an input during reset. During this time, the external transceiver should not drive anything onto the AD bus (that is, keep it tristated). This is accomplished by connecting a weak pull up/down resistor on the TE pin so that the external transceiver is disabled. With rcw_load/boot_load, the IFC

samples the TE pin in order to know the polarity of external transceiver's enable pin. With rcw_load/boot_load, the value stored in CSPR0[TE] as the default value will be opposite of the polarity of external transceiver's enable pin. Therefore, the polarity of external transceiver's enable pin is configurable with the help of pull up/down resistors.

Table 12-6. Programming of CSPRn[TE]

Transceiver Enable (TE) Input	Value of CSPRn[TE]	
	Slow Memory	Fast Memory
Active low	0	1
Active high	1	0

- By the chip booting from fast/slow device

  If boot source is a fast device and connected directly to chip (without transceiver), then the chip should drive the IFC_TE signal such that IFC disables external transceiver.

  For booting from slower devices where transceiver is present in the connectivity, then the chip should drive the IFC_TE signal such that IFC enables external transceivers.

12.4.6.2 Transceiver enable post-boot

After booting, and during normal read/write transactions, the TE pin acts as an output pin.

The configuration of this pin is done on a per-bank basis using CSPRn[TE] bits:

- If a transaction hits bank n, the logic specified by CSPRn[TE] appears on the TE pin when CS*n* gets selected by a flash interface arbitration.
- If no CS*n* is selected, the default (board tied) value appears on the TE pin. (By default, the transceiver is disabled.)

This table shows how CSPR*n*[TE] should be programmed depending on polarity of the transceiver's enable pin and type of memory connected to that particular bank.

Table 12-7. Programming of CSPRn[TE]

External transceiver input	Value of CSPRn[TE]	
	Slow memory	Fast memory
Active low	0	1
Active high	1	0

12.4.6.3 Transceiver enable example

In this scenario, three chip-selects are used.

The connections are as follows:

- CS0: Slow device
- CS1: Fast device
- CS2: Slow device

Because the transceiver used in this scenario has an active-low enable (TOE), the programming of the CSPRn[TE] should be:

- 0 when a slow device is connected to the corresponding bank (to enable the transceiver).
- 1 when a fast device is connected to the corresponding bank (to disable the transceiver).

Therefore, configuration would be as follows:

- CSPR0[TE] = 0
- CSPR1[TE] = 1
- CSPR2[TE] = 0

12.5 NAND flash control machine

The NAND flash control machine (FCM) provides an interface to parallel-bus NAND flash devices.

12.5.1 NAND flash asynchronous mode

For connections between an 8-bit port size NAND flash EEPROM and the IFC in FCM mode, commands, address bytes, and data are all transferred on AD[0:7] with WE_B asserted for transfers written to the chip, or RE_B asserted for transfers read from the chip. IFC signals CLE and AVD/ALE to determine whether writes are of the type command (only CLE asserted), address (only AVD/ALE asserted), or write data (neither CLE nor AVD/ALE asserted).

For connection to a 16-bit NAND flash EEPROM to IFC in FCM mode, the high byte of data appear on AD[0:7], whereas the commands, address bytes, and the low byte of 16-bit data is placed on AD[8:15] during read and write data transfers.

12.5.2 Write protect

NAND/NOR flash devices come with an input pin, write-protect (WP_B), used to protect the flash data from any write.

Register bit CSPR*n*[WP] per chip-select indicates whether or not write accesses are allowed on the particular chip-select.

If a NOR device is connected and a write transaction arrives to a write-protected chip-select, then do not assert chip-select on the NOR flash device and consume the transaction internally. Hence, the protection is controlled by software and the IFC hardware. A write protect error is also generated.

When NAND operation is triggered and IFC detects transition of IFC_CSPRn[WP] from its previous value then it inserts idle cycles on the interface for TWW time where CS_B and WP_B are asserted as shown in figure below.

As a NAND device is not directly memory-mapped like a NOR device and is accessed through the instruction register (FIR), hence there is no prior information of the type of operation to be performed on the NAND. Thus, assert chip-select even if the device is write-protected and expect the device to ignore the write data sent.

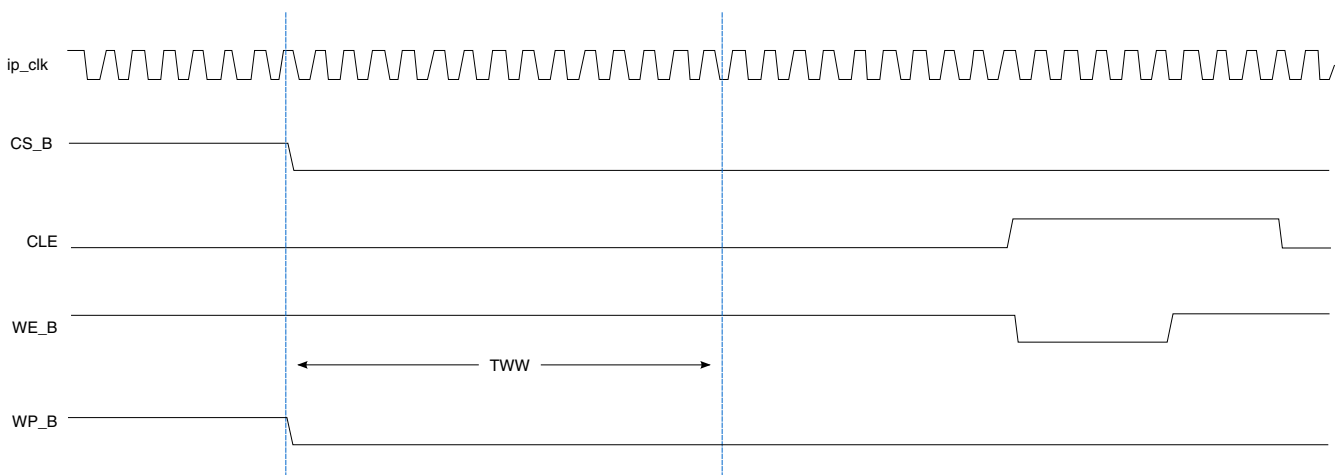

Figure 12-20. Write-protect timing in NAND asynchronous mode

12.5.3 SRAM buffer

Read and write accesses to IFC banks controlled by NAND FCM do not access attached NAND flash EEPROMs directly. Rather, these accesses read and write the buffer RAM (a single, shared 16-KB space internal to the IFC and mapped by the base address of every NAND FCM bank).

Even though each NAND FCM-controlled bank has a different base address to differentiate it, all accesses to such banks access the same buffer space. External IFC signals, such as AVD/ALE and CS*n*, do not assert upon accesses to the buffer RAM.

- To perform a page-read operation from a NAND flash device, software initializes the FCM command, mode, and address registers, and triggers the read operation on a particular bank by setting the bit in NANDSEQ_STRT register. FCM executes the sequence of op-codes held in FIR, reading data from the flash device into the shared buffer RAM. While this read is taking place, software should not access buffer RAM. After loading the complete page on buffer RAM ECC decoding can be performed if it is enabled. Once all the errors have been fixed and if operation completion interrupt is enabled, an interrupt is generated. When FCM has completed its last command, buffer RAM can be read.
- To perform a page-write operation, the software writes data into the SRAM buffer. Then, the software initializes the FCM command, mode, and address registers and triggers the write operation on a particular BANK by setting the bit in NANDSEQ_STRT register. FCM will execute the sequence of op-codes held in FIR, writing the data from shared buffer RAM to the flash device. While this write is taking place, the software is free to write data in other buffers of the FCM buffer RAM.

By programming NCFGR[NUM_LOOP] field, the NAND FCM can be used for multi-page read and write operation. A maximum of 16 pages (for 512-byte page), 4 pages (2-KB page), and 2-page (4-KB page) can be used for multi-page operation. Operation completion interrupt will be sent only after completing last page operation.

12.5.3.1 Guidelines for SRAM buffer for NAND access

Guidelines for SRAM buffer for NAND access are as follows:

- The IFC supports only one operation at a time on the NAND flash; that is, the user can either read data from the SRAM buffer for a NAND flash read or write data in the SRAM buffer for a NAND flash-write.
- NAND program: The user must fill the complete program data in the IFC's SRAM buffer before setting the trigger on the IFC to start the data transfer from the SRAM buffer to the NAND flash. When the trigger is set to transfer the data to a NAND

device, the SRAM buffer must not be accessed for either read or write. Accessing the SRAM buffer during this time may result in undesirable outcome. The user must wait for the current program operation to complete before accessing the SRAM buffer for the next operation.

- NAND read: When the trigger is set in the IFC, the read data coming from the NAND device is stored in an SRAM buffer. In this operation, the SRAM buffer should not be accessed until the event-completion flag is set.

12.5.3.2 Buffer layout and page mapping for 512-byte page NAND flash

The FCM buffer space is divided into 1-KB buffers for 512-byte-page devices (CSOR*n*[PGS] = 00), mapped as shown in the figure below.

The EEPROM's page numbered P is associated with buffer number (P mod 16), where P = ROW*n*. Because the bank size set by AMASK*n*[AM] is greater than 16 KB, an identical image of the FCM buffer RAM appears replicated every 16 KB throughout the bank address space.

In the case where NAND_BC[BC] = 0, FCM transfers an entire page, comprising the 512-byte main region followed by the 16-byte spare region; the 496-byte reserved region is not accessed and remains undefined for software. However, for commands given a specific byte-count in NAND_BC[BC], COL*n*[MS] locates the starting address in either the main region (MS = 0) or the spare region (MS = 1).

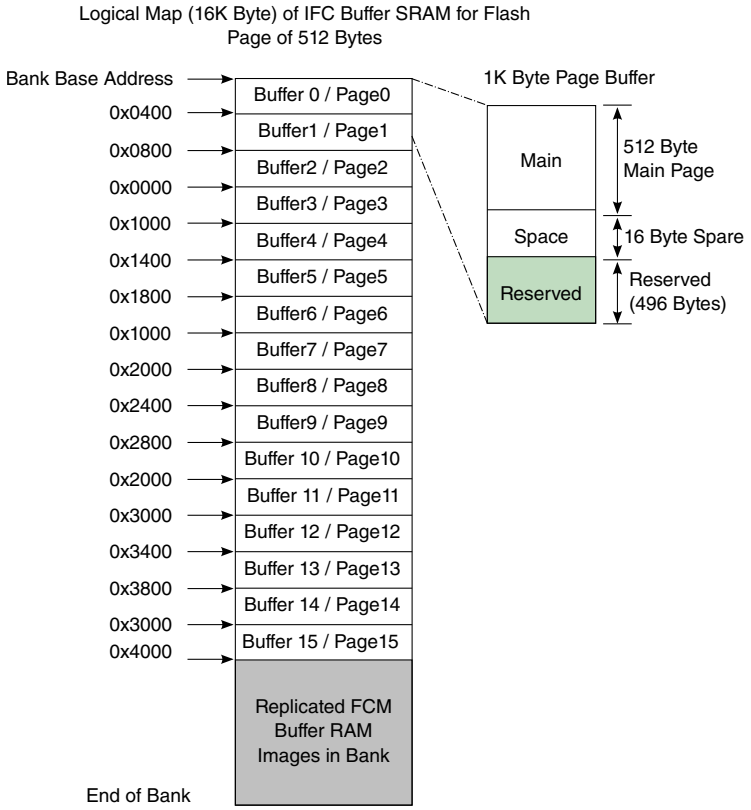

Figure 12-21. SRAM buffer layout for 512-byte page device

12.5.3.3 Buffer layout and page mapping for 2-KB page NAND flash

The FCM buffer space is divided into four 4 KB buffers for 2-KB page devices (CSOR*n*[PGS] = 01).

Each page in a 2 KB-page NAND flash comprises 2112 bytes, where 2048 bytes appear as main-region data and 64 bytes as spare-region data. The EEPROM's page numbered P is associated with buffer number (P mod 4), where P = ROW*n*. Because the bank size set by AMASK*n*[AM] is greater than 16 KB, an identical image of the FCM buffer RAM appears replicated every 16 KB throughout the bank address space.

If NAND_BC[BC] = 0, the FCM transfers an entire page comprising the 2048-byte main region followed by the 64-byte spare region; the 1984-byte reserved region is not accessed, and remains undefined for software. However, for commands given a specific byte count in NAND_BC[BC], COL*n*[MS] locates the starting address in either the main region (MS = 0) or the spare region (MS = 1). When different IFC banks control both page devices, a 4 KB-page buffer must be assigned to either the first four or last four 512-byte page buffers.

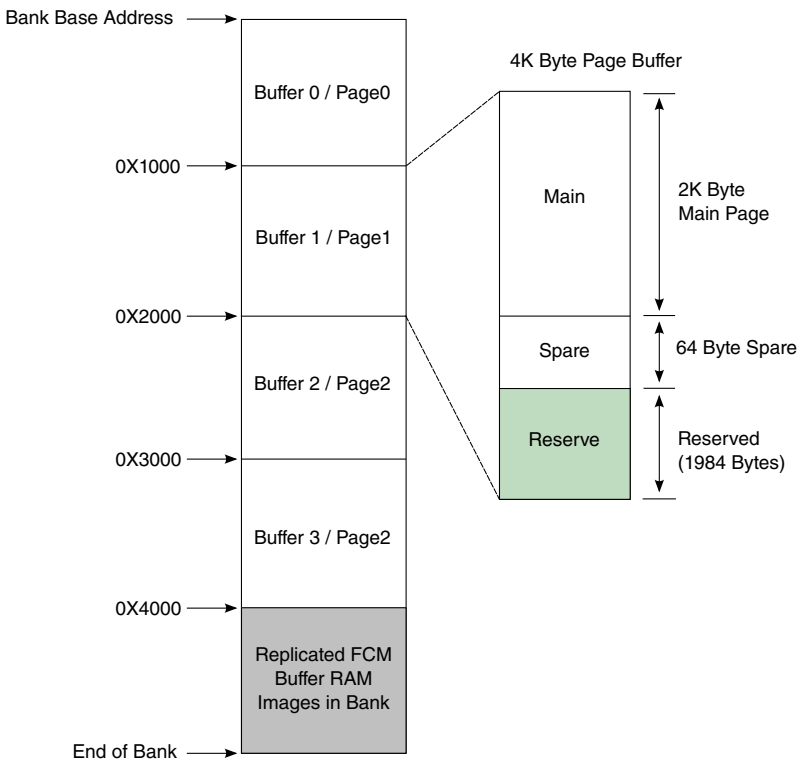

Figure 12-22. SRAM buffer layout for 2-KB page device

12.5.3.4 Buffer layout and page mapping for 4 KB page NAND flash

The FCM buffer space is divided into two 8 KB buffers for 4 KB-page devices (CSOR*n*[PGS] = 10).

Each page in a NAND flash comprises 4224 bytes, where 4096 bytes appear as main region data and 128 bytes as spare region data. The EEPROM's page numbered P is associated with buffer number (P mod 2), where P = ROW*n*. Because the bank size set by AMASK*n*[AM] is greater than 16 KB, an identical image of the FCM buffer RAM appears replicated every 16 KB throughout the bank address space.

If NAND_BC[BC] = 0, FCM transfers an entire page comprising the 4096-byte main region followed by the CSOR*n*[SPRZ]-byte spare region.

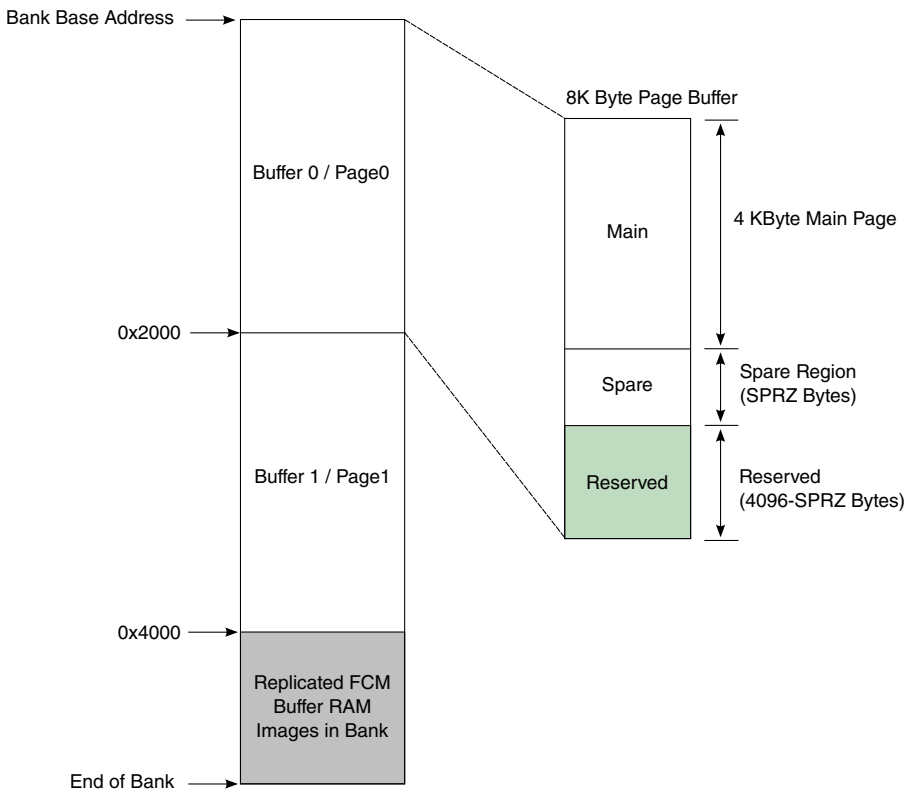

Figure 12-23. SRAM buffer layout for 4 KB-page device

12.5.3.5 Buffer layout and page mapping for 8 KB page NAND flash

The FCM buffer space is divided into single 8 KB buffers for 8 KB large-page devices (CSOR*n*[PGS] = 11).

Each page in a large-page NAND flash comprises 8192 + spare region bytes, where 8192 bytes appear as main region data, and spare region bytes appear as spare region data. Because the bank size set by AMASK*n*[AM] will be greater than 16 KB, an identical image of the FCM buffer RAM appears replicated every 16 KB throughout the bank address space.

If NAND_BC[BC] = 0, the FCM transfers an entire page comprising the 8192-byte main region followed by the CSORn[SPRZ]-byte spare region.

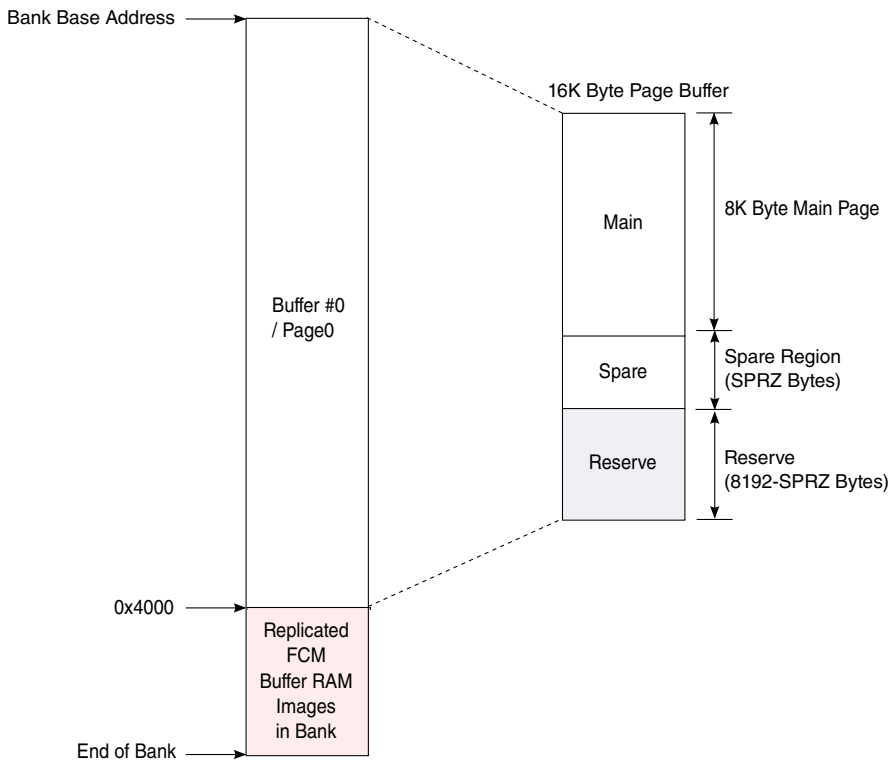

Figure 12-24. SRAM buffer layout for 8 KB-page device

12.5.3.6 SRAM buffer initialization requirement

Set NCFGR[SRAM_INIT_EN] bit to initialize the SRAM before initiating the first program operation. See NAND Configuration register (IFC_NCFGR) for details.

12.5.4 Use of ECC algorithms

BCH encoder and decoder algorithms are implemented to detect and correct up to 4/8 bits in each 512-byte sector and 24/40 bits in each 1 KB sector.

A Galois Field 2^{13} is used for the encoding and decoding of 4- and 8-bit ECC and a Galois field 2^{14} is used for 24-/40-bit ECC.

12.5.4.1 Generating Galois field elements

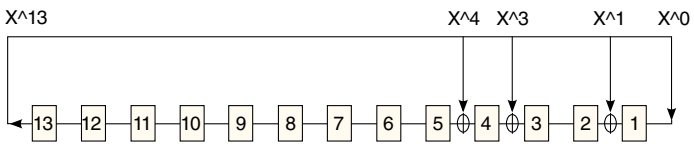
The Galois field elements can be generated by shifting the LFSR.

The following primitive polynomials are used for the computation of respective field elements.

Galois Field 2^{13} field elements

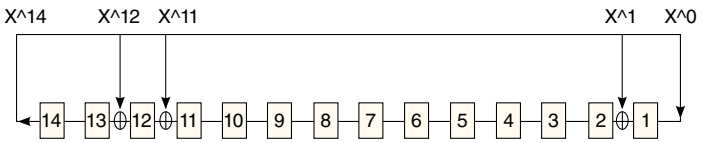
As shown in this figure, the field elements can be generated by shifting the LFSR. Each state of LFSR represents the field element.

P(x) = 11011000000001 in binary form and $1+x+x^3+x^4+x^{13}$in polynomial form.



Galois Field 2^{14} field elements

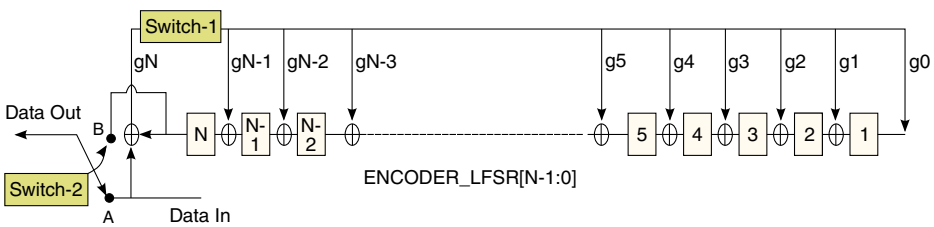
Primitive polynomial P(x) = 110000000001101; that is, $1 + x + x^{11} + x^{12} + x^{14}$



12.5.4.2 BCH encoding

This section describes BCH encoding scheme.

This figure represents the encoder implementation.



- 4-bit ECC: g(x) = 1101010101100001110101011100001000001100010010100010 1
- 8-bit ECC:

1011001101110001011100011010000000001101100000000011001000011010011111

- 40-bit ECC:
  g(x)=1110000011101110011001100111111011010010111001110100001100000000000011100111111000100111100000000010100011011101010001110110110101110101000111100101111111000011010110101001000001100110001110100011110101001101000001100110110111011110101011010001111110000100111001000011110100101100101111101001110111011011011000010101101110001001001110001011111110110100111011010000000101011101010001011001110110101010110100000010000110011000011001010010111111110001101110110010001110110001111111100111000000111110110100010110000011111010110011010010100110011101111

In each of the generator polynomial binary forms mentioned above, the msb represents the lowest polynomial power (g0) and the lsb represents highest polynomial power (gN). The following LFSR can be used for BCH encoding.

In encoding, operation data corresponding to a sector is given to the LFSR. During this time, the following events occur:

- Switch 1 is closed and switch 2 is in the down position (A) to allow the transfer of data to the output.
- After the transfer of a sector's data, switch 1 is opened and switch 2 is moved to the up position (B).
- Now N parity bits can be read out from the LFSR. ENCODER_LFSR[N-1] represents the first parity bit out and ENCODER_LFSR[0] the last parity bit.
  - The value of N is 52, 104, 336 and 560 for 4-, 8-, 24- and 40-bit ECC.

When the IFC accesses the NAND flash device for a read operation, it performs a BCH detection algorithm and indicates how many bit errors were detected and corrected. The number of errors per sector gets registered in the ECCSTAT0/1/2/3 registers. For 24- and 40-bit ECC, only ECCSTAT0/1 are valid as only 8 sectors of 1 KB is possible for SRAM buffer.

ECC is kept in spare region of page at offset 08h. BCH ECC bytes are first written to the SRAM buffer and then to the NAND flash device. During program, the user can read the ECC bytes by reading the appropriate locations in the SRAM buffer.

During encoding, ECC is always calculated for 512-byte data for 4-/8-bit ECC and 1 KB data for 24-/40-bit ECC. CSORn[ECC_MODE] can be used to select 4-/8-/24-/40-bit correction mode, and CSORn[ECC_ENC_EN] and CSORn[ECC_DEC_EN] can be used to enable/disable the ECC logic.

If the encoder is enabled to calculate the ECC, then the data to the encoder is fed in the following manner:

- 16 bits are fed to the encoder every other clock cycle
- The encoder processes the bits in the following manner:
  - Bit #15 (d0), bit #14 (d1), bit #13 (d2), ... , bit #0 (d15), that is, bit #15 is the first bit to enter the encoder
  - Parity bit #0 (p0) is the first parity bit which comes out of the encoder

This table explains the manner in which the data and parity bits are stored in the 16-bit NAND flash memory for 4-bit encoding/decoding.

NOTE

- Even when storing data in an 8-bit NAND flash memory, the manner in which the data is fed to the encoder remains unchanged.
- The data to the decoder also needs to be fed in the same manner.

Note that pn_m, such that

- n = sector number (0, 1, 2, 3), where:
  - Sector 0: d0 to d4095
  - Sector 1: d4096 to d8191
  - Sector 2: d8192 to d12287
  - Sector 3: d12288 to d16383
- m = parity bit number, where:
  - 4-bit ECC: 0 to 51 (12 bits padded to 0 to align the number of parity bytes to the 8 bytes boundary)
  - 8-bit ECC: 0 to 104 (24 bits padded to 0 to align the number of parity bytes to the 8 bytes boundary)

During decoding, the full page is loaded into buffer RAM from flash and then decoding begins. This is required because the BCH decoder can work when a sector's data and corresponding ECC bytes are supplied to the decoder.

For 4-bit correction, 8 parity bytes, 8-bit correction 16 parity bytes, 24-bit correction 42 parity bytes, and 40-bit correction 70 parity bytes per sector are required. These parity bytes are stored in the spare region of the page at offset 08h. For small pages, only 4-bit mode is allowed. For a 2 KB page, four sectors of 512 bytes each can be present in the main region; hence a total of 4x8= 32 parity bytes are store at offset 08h. For a 4 KB page size, eight sectors of 512 bytes each can be present; hence 8x8 =64 parity bytes are required for 4-bit mode and 128 bytes for 8-bit mode.

In 24- and 40-bit mode, the parity information is stored adjacent to each other in the spare region; that is, the ECC bytes will be placed one after another. With 24-/40-bit ECC mode, there is no need to pad 0 bits in order to align it to the 8-byte boundary, unlike the padding that is performed with the 4-/8-bit ECC mode.

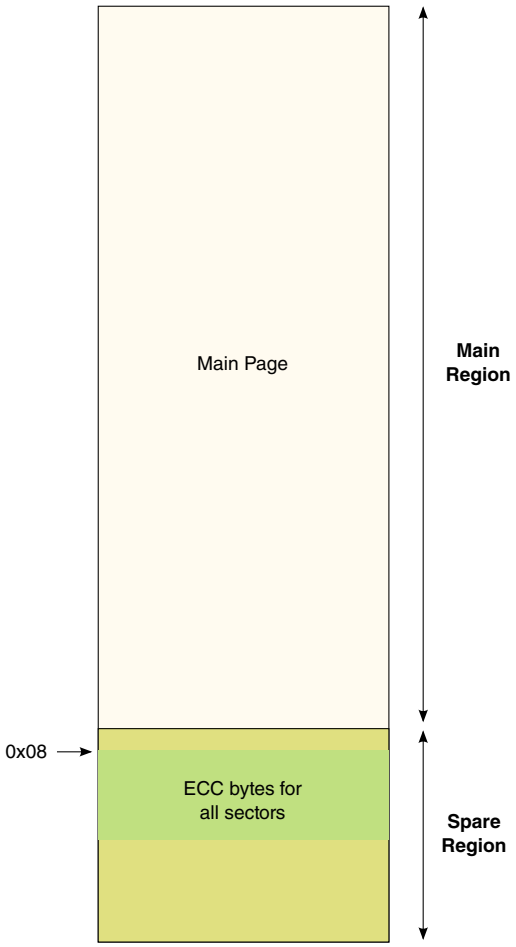

Figure 12-25. ECC arrangement on a page

For example, there is a memory of 4 KB page size and a 24-bit ECC is needed to protect it. A 4 KB page size memory will have four sectors of 1 KB each. The encoder will generate 42 bytes of parity information for each sector. Therefore, there will be a total of 42x4 = 168 ECC bytes. All 168 bytes are placed in the spare region of the NAND flash at offset 08h: { Sector-1 {P0, P1,...P335}, Sector-2 {P0,P1,...P335}, Sector-3 {P0, P1,...P335}, Sector-4 {P0,P1,...P335} } from offset 08h where P0 is the first parity bit coming out from encoder and P335 the last bit. The data and parity feeding and arrangement for all the modes remains same and as shown in Table 12-10.

This figure represents the logical flow of encoding and decoding operation during program and read. During program, ECC bytes are also written back in SRAM. During read, first, all data bytes corresponding to a page are written in SRAM buffer, and then the decoding starts on sector basis. At any time, only one operation can be performed on the NAND; that is, it can only be either read or programmed.

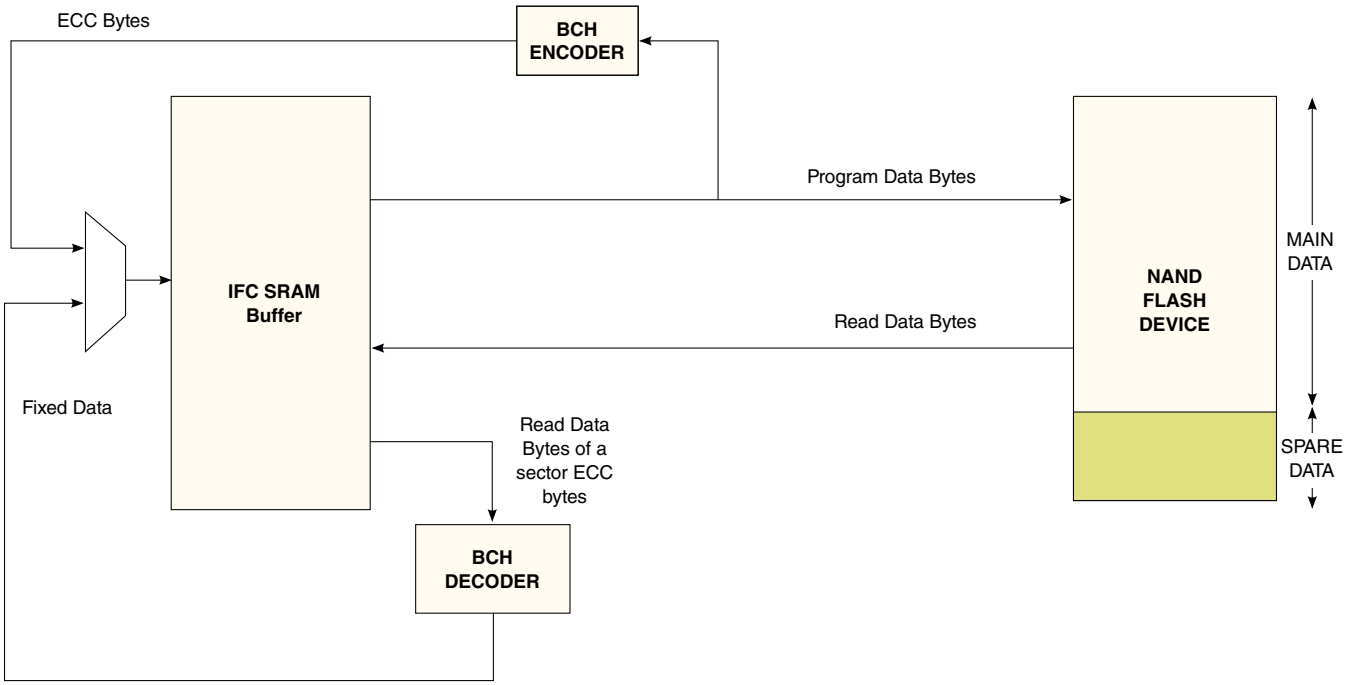

Figure 12-26. BCH encoding/decoding during flash program/read

NOTE

The BCH encoder and decoder should be enabled only when performing full-page operations. If there are partial page operations, the encoder and decoder should be disabled.

NOTE

The IFC computes the ECC only for the main region data (as the ECC is not computed for the spare region). The decoder detects and corrects 4/8 bits of error on the main region data and the corresponding ECC bytes stored.

12.5.5 Programming the NAND FCM

The NAND FCM performs operations on the NAND flash interface based on the values programmed in the common and NAND register spaces.

The user is expected to program the following registers with the appropriate values before triggering the NAND FCM operation:

- Chip-select option registers
- Flash timing registers
- General control register
- NAND configuration register
- NAND flash command registers

- Flash row and column address registers
- NAND flash byte count register
- NAND flash instruction registers
- NAND chip-select register
- NAND event and error interrupt enable register (in case an interrupt needs to be generated)
- NAND control register

When all the above registers have been programmed, the NAND FCM can then be triggered through the NAND operation sequence start register.

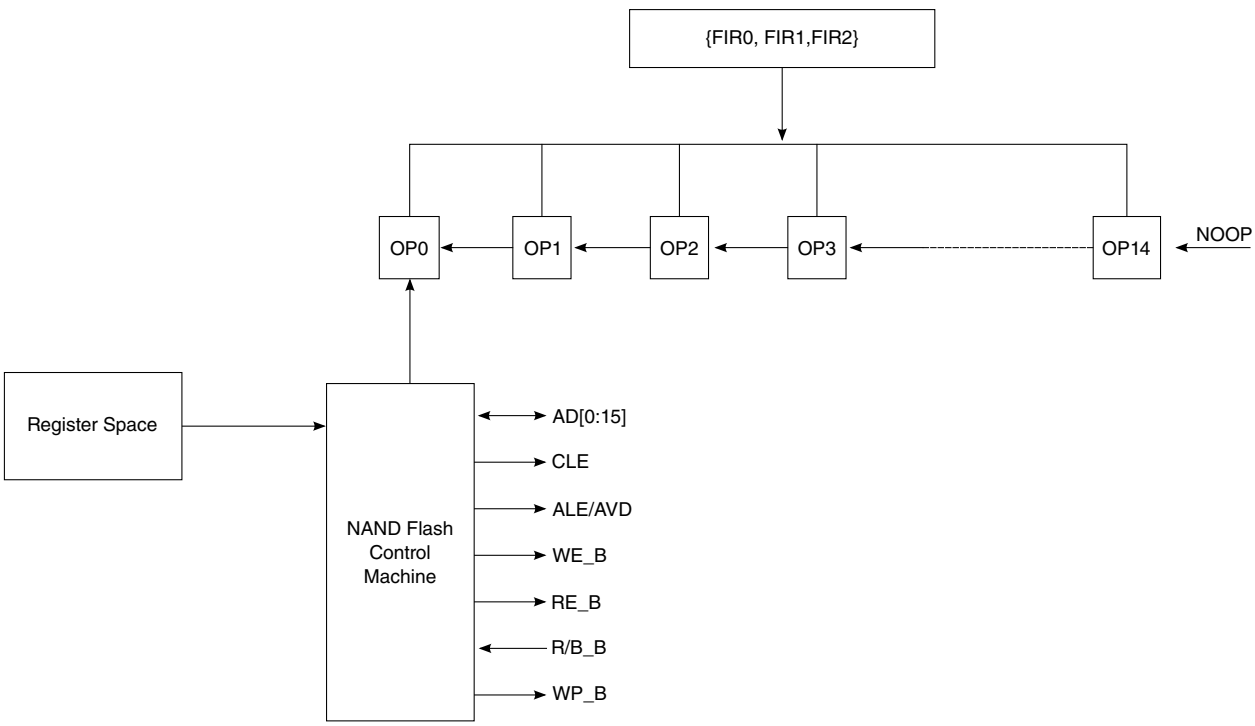

Figure 12-27. FCM instruction sequence mechanism

NOTE

User must use the WFR opcode at the end of NAND FIR programming to probe the RDY_B/BSY_B signal before end of operation. Status poll is also recommended after every write or erase command.

12.5.5.1 FCM command instructions

There are different types of command instructions.

- Commands that issue immediately (CMD0-CMD7)

    - Asynchronous mode: These commands write a single command byte by asserting CLE and WE_B while driving an 8-bit command on the AD[0:7]/ AD[8:15] (8-/16-bit port) bus. The opcode CMD*n* sources its command byte from the field FCR[CMD*n*]. Therefore, up to eight different commands can be issued in any instruction sequence.
- Commands that wait for RB_B to be sampled high before issuing (CW0-CW7)
    - Asynchronous mode: These commands first poll the RB_B signal to be sampled high before writing a single command write on the AD[0:7]/AD[8:15] (8-/16-bit port) bus sourced from FCR[CMDn] for opcode CW*n*. It is necessary to use CW*n* opcodes whenever the memory is expected to be in the busy state (such as following a page read, block erase or program operation) and therefore, initially unresponsive to commands.

Consult the manufacturer's datasheet to determine the values to be programmed into the FCR register and whether a given command in the sequence is expected to initiate device busy behavior.

12.5.5.2 FCM address instructions

Address instructions are used to issue addresses to the NAND flash device.

- Asynchronous mode: A complete address is formed by a sequence of 1 or more bytes, each written onto AD[0:7]/AD[8:15] (8-bit/16-bit port) with AVD/ALE and WE_B asserted together.

12.5.5.3 FCM data read instructions

Read data instructions assert RE_B repeatedly to transfer one or more bytes of read data from the NAND flash device.

The different types of data read instructions provided are as follows:

- Read BC bytes of data from the NAND flash device into the internal SRAM
    - Asynchronous mode: This instruction reads NAND_BC[BC] into the current FCM SRAM buffer addressed. The data driven by the NAND flash device is sampled on the basis of the TRAD timing parameter and the RE_B is asserted for a time period equivalent to the TRP timing parameter. If NAND_BC[BC] = 0, an entire page (including the main and the spare regions) is transferred in a burst.
- Read BC bytes of data from the NAND flash device into the internal SRAM during boot

- Asynchronous mode: This instruction reads NAND_BC[BC] into the current FCM SRAM buffer addressed. The data driven by the NAND flash device is sampled on the basis of the TRAD timing parameter and the RE_B is deasserted once the read data has been sampled by the NAND FCM. If NAND_BC[BC] = 0, an entire page (including the main and the spare regions) is transferred in a burst. This instruction can also be used for non-boot applications wherein the RE_B signal needs to be asserted until the read data has been sampled.

- Read the NAND flash device status
  - Asynchronous mode: This instruction performs a status read operation on the NAND flash device. The status returned by the device is stored in the NAND_FSR register.
- Read data into the MDR register
  - Asynchronous mode: This instruction reads 8/16 bits of data from a given page in the NAND flash device (based upon the column address programmed) into the MDR register.

12.5.5.4 FCM data write instructions

Write data instructions assert WE repeatedly to transfer program data to the NAND flash device.

- Asynchronous mode: Write data instructions assert WE repeatedly to transfer 1 or more bytes of program data to the NAND flash device. If NAND_BC[BC] = 0, an entire page (including the main and the spare regions) is transferred in a burst.

12.5.6 Looping FIR sequences

The loop feature provides the flexibility to loop certain FIR sequences (such as program, read, and erase) a finite number of times based on the value programmed in NCFGR[NUM_LOOP].

The row and column addresses sent to the NAND flash device during a loop operation depend on NCFGR[ADDR_MODE]. For a more detailed description of the addresses performed on the NAND flash device for every subsequent execution of the FIR sequence during a loop operation, see NAND Configuration register (IFC_NCFGR).

NOTE

For this feature to correctly execute, it is important to note that the opcodes programmed in the FIR sequence corresponding to the column and row addresses should always be CA0 and RA0. Therefore, it is recommended that only one type of operation

(such program/read/erase) be performed through a loop sequence.

12.5.7 NAND asynchronous mode timings

This section describes the basic NAND flash timing waveforms and the programmable timing parameters.

Figure 12-28 explains the NAND program cycle; Figure 12-29 and Figure 12-30 explain the basic read cycle waveforms and corresponding timing parameters for NON-EDO and EDO mode flash. Non-EDO mode corresponds to ONFi2.0 async mode 0/1/2/3 while EDO mode corresponds to ONFi mode 4/5.

12.5.7.1 NAND asynchronous mode program data timing

This figure shows the NAND flash program.

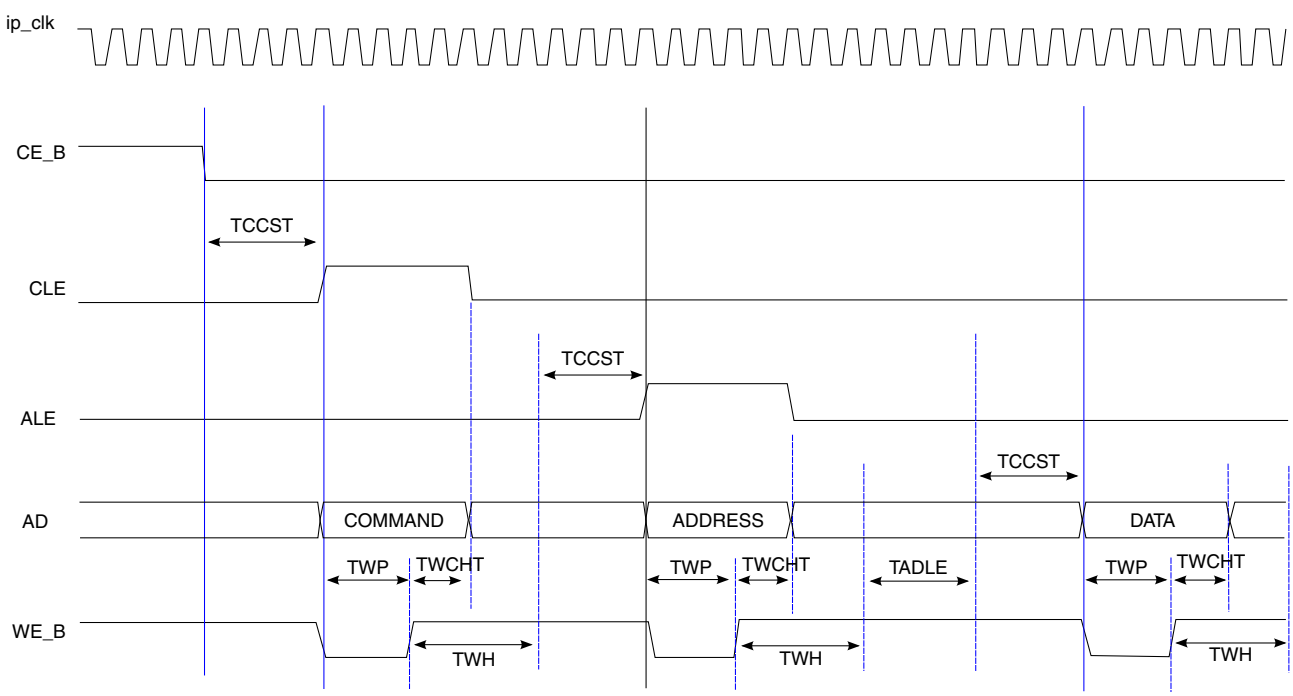

Figure 12-28. NAND flash program

12.5.7.2 NAND asynchronous mode read data timing

This figure shows the NAND flash read.

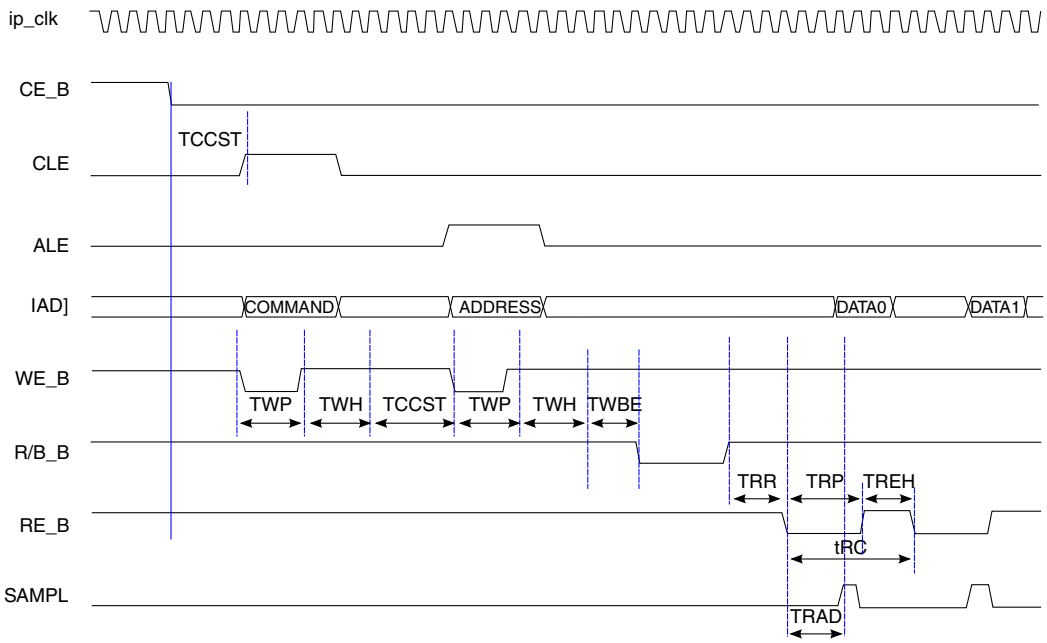

Figure 12-29. NAND flash read

12.5.7.3 NAND asynchronous mode calculating read data window width

Calculating the read data window width can be done in several ways.

- Non-EDO mode NAND
  - The window size for the received data is calculated as t_{RP} - t_{REA} + t_{RHOH}.
- EDO mode NAND
  - The window size for the received data (except the last data beat) is calculated as t_{REH} - (t_{REA} - t_{RP}) + t_{RLOH}.
  - The window size for last data beat received is calculated as t_{RHOH} - (t_{REA} - t_{RP}).

Based on these calculations, the minimum size of the data window width is 9 ns (for EDO ONFi mode 5). To support this data window width, a minimum of 333 MHz for the IFC module input clock is required. By increasing the value of timing parameter t_{RP}, that is, the RE pulse width, the data window size can be increased.

NOTE

The read cycle time should satisfy this condition: ((t_{RP} + t_{REH})≥ t_{RCmin}). If the sum of the t_{RPmin} and the t_{REHmin} values specified by the datasheet is less than the t_{RCmin} (from the datasheet), it is

then recommended that the t_{RPmin} value be increased to meet the t_{RCmin} timing requirement. This is recommended because increasing the t_{RPmin} value causes the data window size to increase.

Read data sampling time (TRAD) represents the read data sampling time on the NAND. The value should be programmed where the sampling at the IFC should be done at the center of the received data eye. Its value can be calculated as [T_{REAmax} (from NAND datasheet) + 2 x board delay + 1/2 received data window size]. If in EDO mode, the user should choose the TRAD value corresponding to the smaller data window calculated using the two formulae explained above for EDO.

NOTE

For EDO mode, the value of TRAD should always be less than t_{RP} + t_{REH}. If the board delay value used in the TRAD calculation results in this condition to not be met, the user may not be able to run the interface at the EDO mode frequency. In this situation, the read timing should be relaxed by increasing t_{RP} value to access the NAND device at a slower speed.

12.5.7.4 NAND asynchronous mode read data sampling approach

The IFC follows the approach in which the timing parameters are programmable.

The IFC logic runs at the IFC module input clock and can generate these timings on the flash interface through the programmed value in the timing registers. Based on the timing values as given in the ONFi 2.0 spec for each mode, received data window width is calculated (as explained in the previous section).

12.5.7.5 NAND asynchronous mode read status timing

This figure shows NAND read status timing.

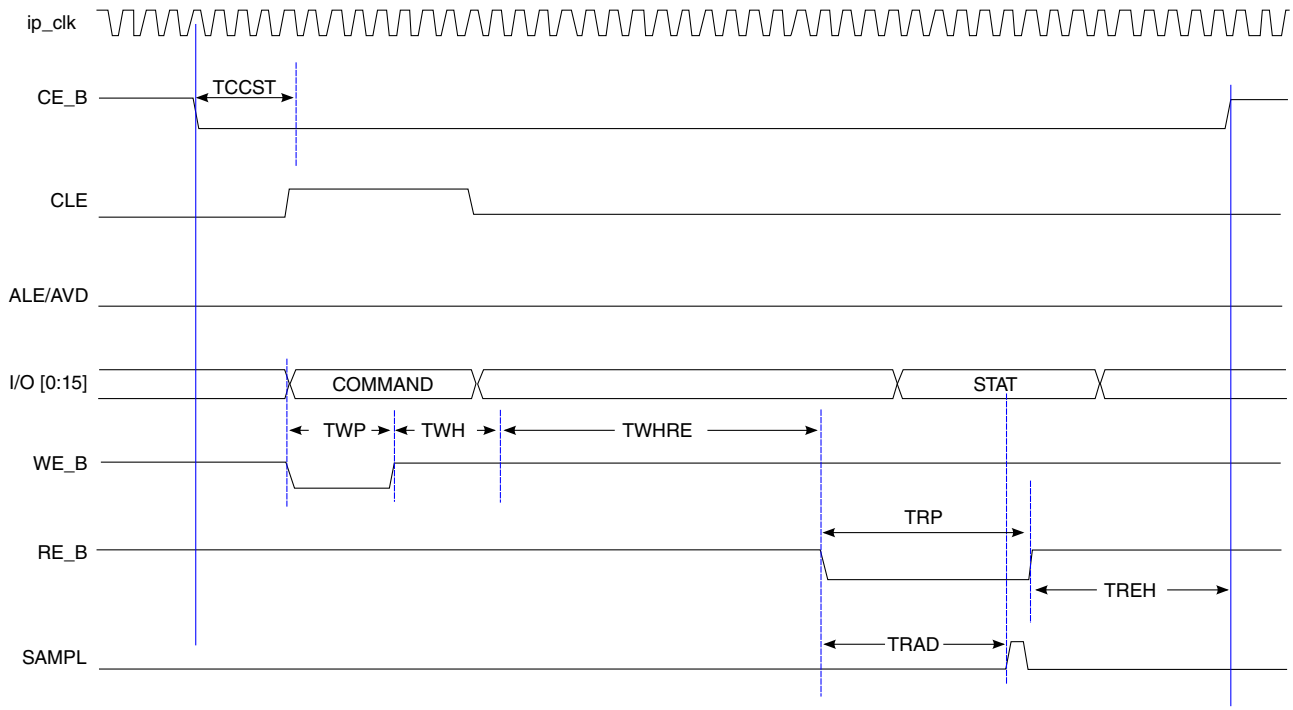

Figure 12-30. NAND status read

12.5.8 NAND asynchronous mode boot mechanism

If the FCM is selected as the boot ROM controller from power-on-reset configuration, the IFC automatically loads up to 8 KB of boot code from BANK0 to the NAND FCM buffer RAM depending on the RCW load or BOOT load indication.

The CPU can execute boot code directly from the FCM buffer RAM, but must ensure that any further data read from the NAND flash EEPROM is transferred under software control in order to continue the bootstrap process.

As AMASK0[AM] is initially cleared during reset, all the CPU fetches to the IFC access the FCM buffer RAM. First, 8 KB of SRAM holds the valid boot data, which appears in the memory map as a 8 KB RAM. No NAND flash spare regions are mapped during boot, therefore only 8 KB of contiguous, main-region data loaded from the first pages of the boot block (good block), are accessible in IFC bank 0, as indicated in this figure. In boot mode, addresses coming to SRAM buffer from system bus wraps at 8 KB physical address boundary.

The software must clear NCFGR[BOOT] to enable the logical to physical address mapping.

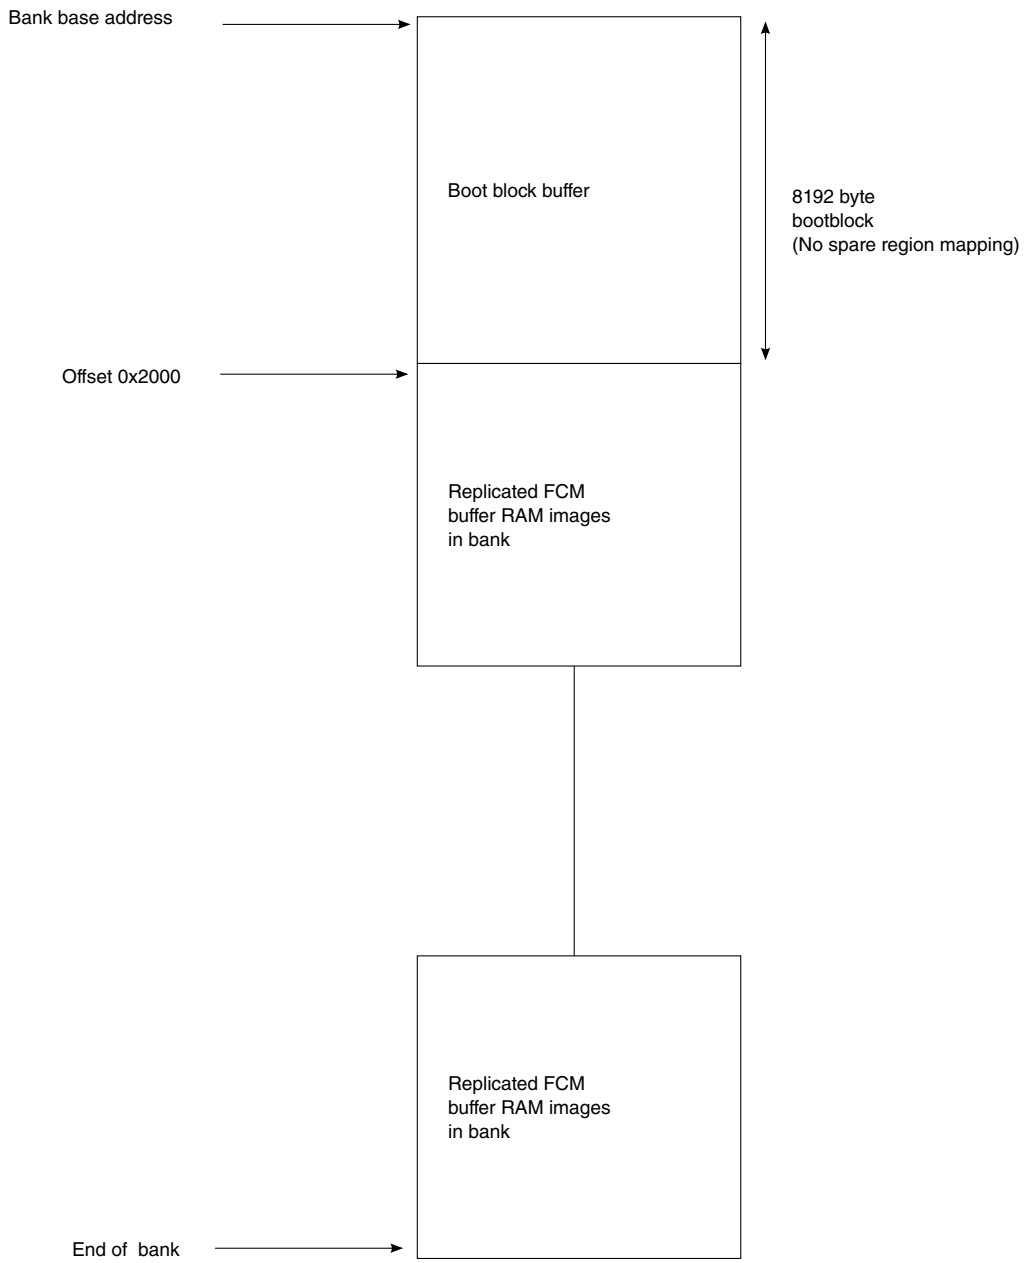

Figure 12-31. FCM buffer RAM map during boot

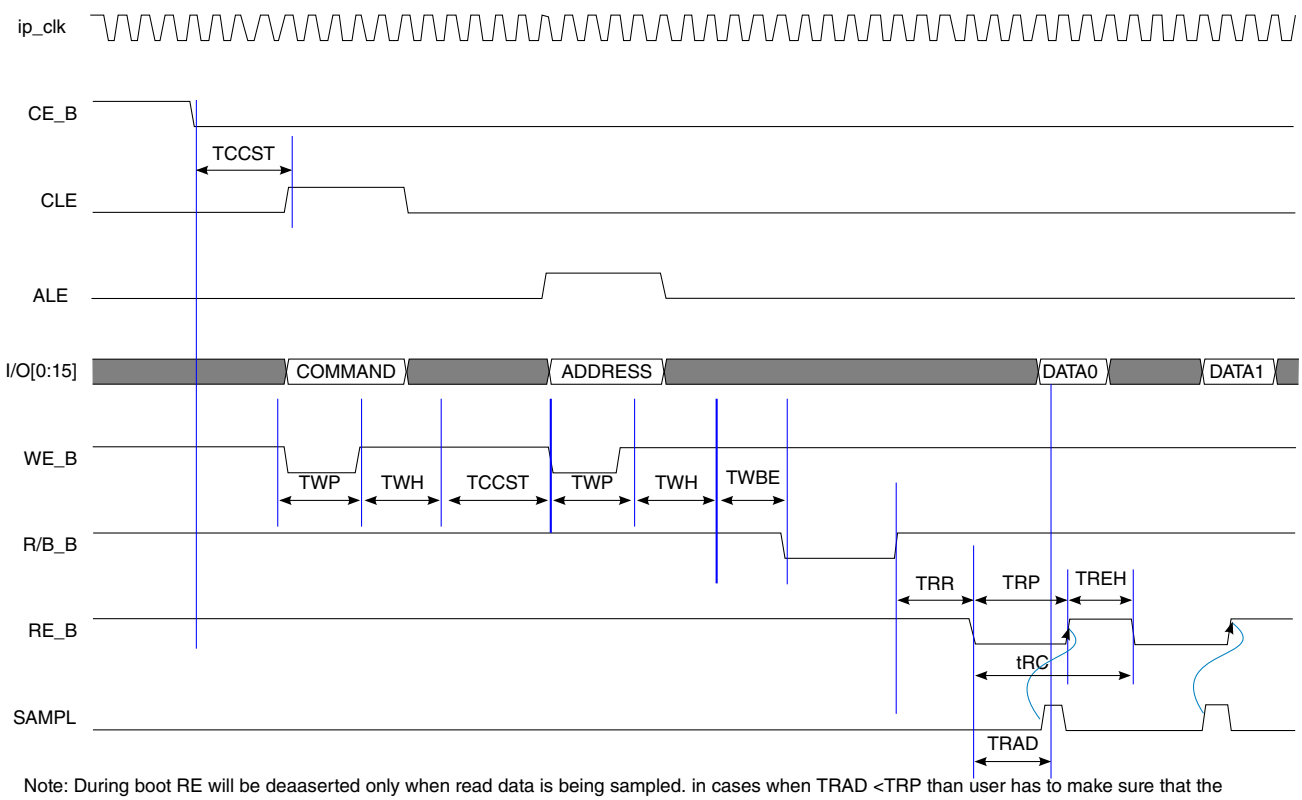
The IFC employs the counter-based read data sampling approach as described earlier. Here, the read data sampling is determined by the counter value whose initial value is determined by the *NAND Flash Specification* and the IFC module input clock , however there can be two different clocks for boot; if the system PLL is not locked, the RCW clock will be coming to the IFC and the counter values for read data sampling will be

governed by this clock frequency; otherwise the IFC would receive the IFC module input clock post-system PLL lock for boot, which results in a different value of the timing counters.

These two clock frequencies are passed as parameters into the IFC during instantiation. Based on this, the IFC initializes timing parameters corresponding to the slowest mode of asynchronous NAND device (ONFi Mode-0) during boot. During normal operation, timing parameters can be programmed as per the device specification. Read data sampling is governed by read access time of NAND flash and board delay. This value is represented by timing parameter FTIM2_CS0[TRAD]. It can be initialized by the device by passing the TRAD parameter during instantiation.

During boot, the read data sampling mechanism is slightly different than normal read to assure booting. Also, the read-enable signal remains asserted (low) until the data gets sampled, while in normal read operation the read-enable can be de-asserted. This mechanism ensures that there is no case where the read data cannot be sampled by the IFC as data retains its state until the time read enable is asserted.



Note: During boot RE will be deaaserted only when read data is being sampled. in cases when TRAD <TRP than user has to make sure that the value programmed in TRAD should be max of [TRAD, TRP].

Figure 12-32. Read data sampling during boot

12.5.8.1 NAND asynchronous mode boot process

The steps below describe the boot process:

1. After receiving rcw_load or boot_load input signals, the IFC commences automatic boot block loading if the FCM is selected as the boot ROM location. Small-page (512-byte page) or large-page (2/4/8-Kbyte page), 8-bit or 16-bit NAND flash devices can be used for boot loading when enabled with CS0. With rcw_load or boot_load indication, the CSPR0[WP] bit also is set. With this bit set, the IFC drives WP_B low on the IFC output during boot accesses to prevent accidental erasure of the NAND flash boot ROM. Software needs to clear the CSPR0[WP] bit to commence normal write operation on CS0 after finishing the booting process.
2. The NAND FCM issues a reset command to the NAND device and then begins searching for a valid boot block from block 0.
3. The NAND FCM reads the spare regions of the first two pages or the first and the last page (depending upon pof_cfg_bbi_srch_sel) of the current block, checking the bad block indication (BI) bytes to validate the block for reading. BI bytes must hold the value 0xFF for the page to be considered readable.
   - For small-page (512-byte page) devices, the BI is a single-byte read from spare region byte offset 5 (8-bit port size). For a 16-bit port size device, the BI is a single byte read from spare region byte offset 11. The IFC supports booting from a 16-bit port size device only when no ECC is stored in the spare region, that is, the boot block is guaranteed to be good.
   - For large-page (2/4/8-Kbyte page) devices, the BI is a single-byte read from spare region byte offset 0 (8-bit port size), or two-bytes read from spare region byte offsets 0 and 1 (16-bit port size).

   If either of the above-mentioned pages of the current block are marked invalid, then the boot block index is incremented by 1 and the FCM repeats step 3. The IFC will continue searching for a bootable block indefinitely; therefore, at least one block must be marked valid for boot loading to proceed. At the conclusion of the boot block search, the value of ROW0 points to the boot block.
4. The FCM optionally checks the ECC at boot time depending on configuration selected during reset (por_cfg).
5. The FCM reads entire pages from the boot block until /8 Kbytes have been saved to the FCM buffer RAM when booting via the IFC NAND FCM. ECC errors are corrected if possible. If the FCM is unable to correct the ECC errors, the IFC signals an unrecoverable error by asserting the boot_err signal.
6. The CPU now commences fetching instructions in random order, from the FCM buffer RAM. Boot software must clear NCFGR1[BOOT] to enable normal operation of FCM.

NOTE

During boot, the IFC performs a total of 5/6 address cycles, based on whether the NAND flash device used for booting is a small-page (512-byte page) or a large-page (2/4/8-Kbyte page) device. It is expected that the NAND flash device used to boot will ignore any excess address cycles which it may not need.

The following table describes the hard-coded FIR sequences used during auto-boot operation from the NAND flash.

Table 12-11. FIR sequences used during boot

FIR sequence	Description
{CMD3, NOOP}, where CMD3 = 0xFF	Issue soft reset to NAND device
{CW1, CA0, RA0, BTRD, NOOP}, where CW1 = 0x50	Partial page read from small-page device for bad block indicator read (good block search)
{CW0, CA0, RA0), BTRD, NOOP}, where CW0 = 0x00	Full page read from small-page device fom boot page read
{CW0, CA0, RA0, CMD2, BTRD, NOOP}, where CW0 = 0x00, CMD2=0x30	Partial page read from large-page device for bad block indicator read (good block search)
{CW0, CA0, RA0, CMD2, BTRD, NOOP}, where CW0 = 0x00, CMD2= 0x30	Full page read from large-page device fom boot page read

NOTE

Since fixed values of commands are used for read during auto-boot operations, only NAND flash devices supporting the commands mentioned in the above table can be used for auto-boot read operations.

12.6 NOR flash control machine

The NOR FCM allows an interface to asynchronous, simple, and internal latch-based NOR flash devices.

12.6.1 NOR boot

For NOR boot, CS0 is the boot chip-select.

Before fetching the first instruction from the NOR flash, the IFC flash timing registers are loaded with default timing parameters.

12.6.2 Unmuxed (parallel) asynchronous NOR read timings

The figures show the read cycle and burst read cycle timing diagrams.

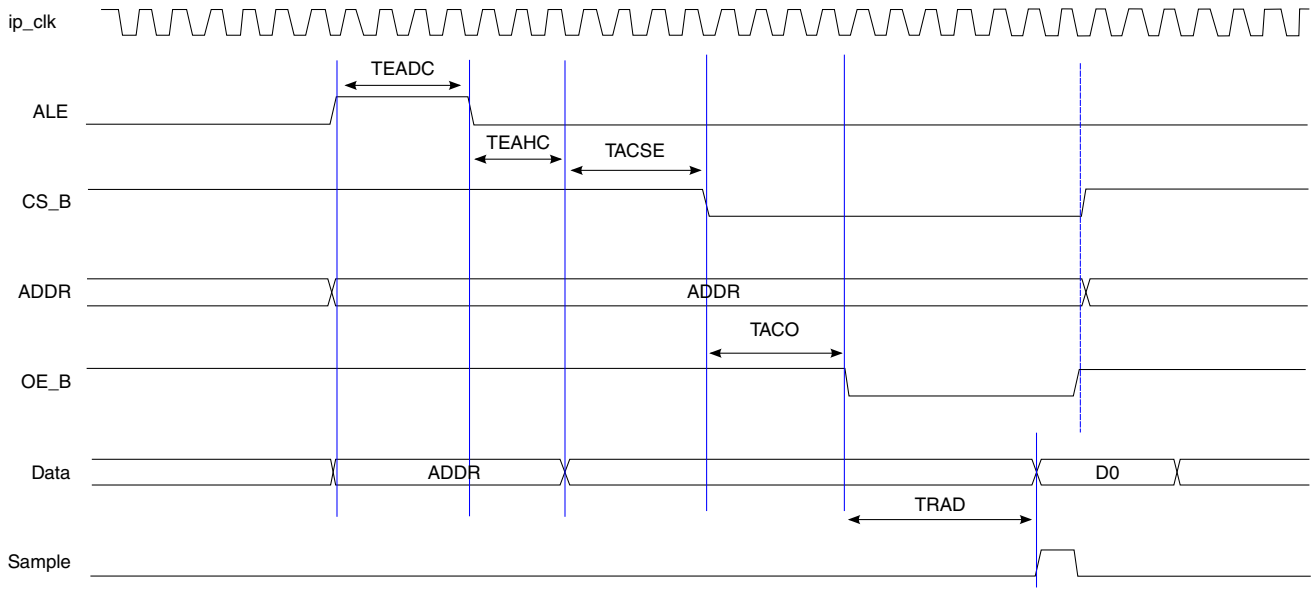


Figure 12-33. Read cycle timing

This figure shows the write cycle timing diagram.

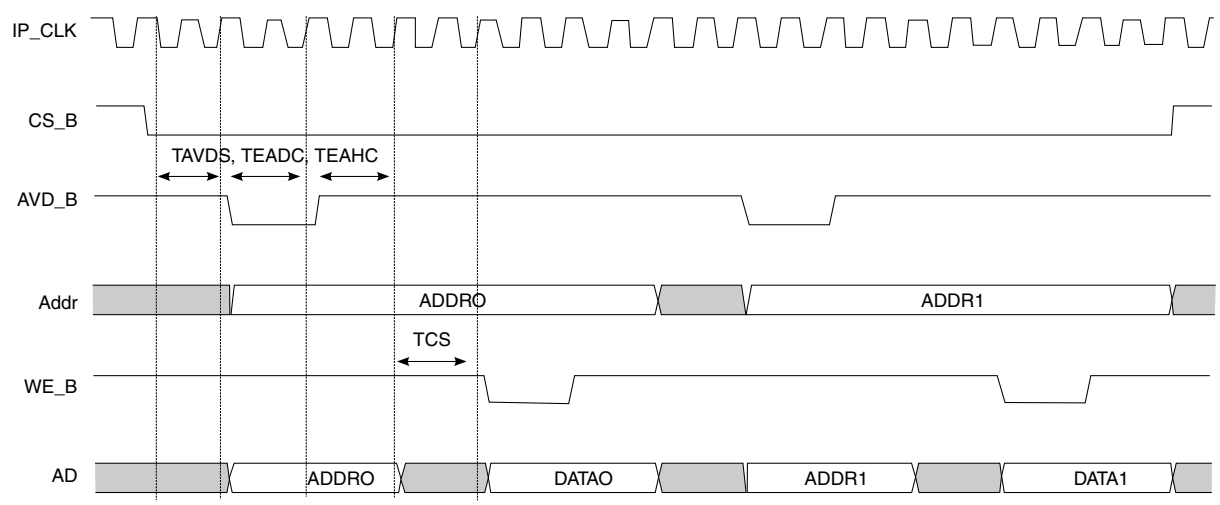

Figure 12-38. Write cycle timing

12.7 General purpose chip-select machine (GPCM)

The GPCM controller has two modes of operation: normal GPCM and generic ASIC.

Only one mode is operational at a time per chip select. The mode is selected by the value programmed in GPMODE field of CSOR*n*_GPCM register.

12.7.1 Normal GPCM mode of operation

The figure below explains the interface of the IFC to a device connected through the normal GPCM FCM.

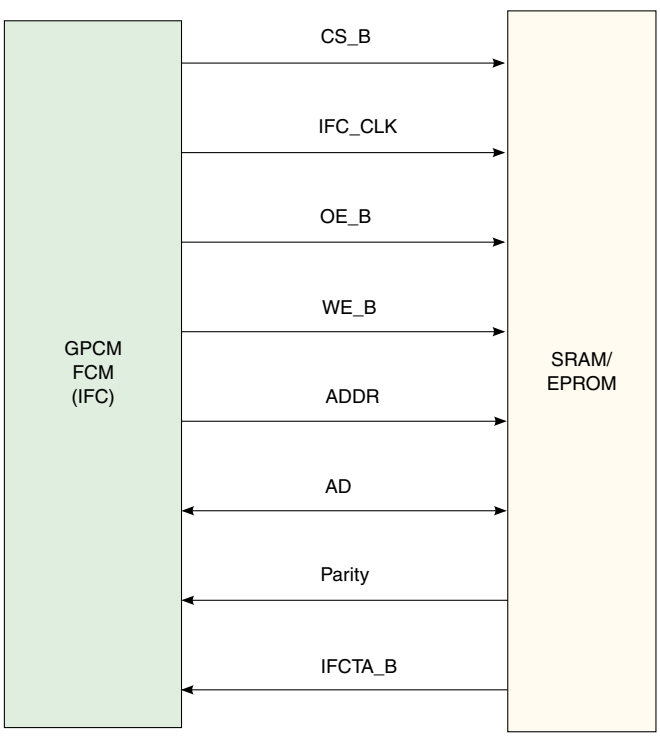

Figure 12-39. Normal GPCM interface

12.7.1.1 Normal GPCM program operation

In normal GPCM, the write transaction depends on the register field CSORn[WGETA].

The following options, through an internal counter or through an external device giving an access termination signal, are explained below.

12.7.1.1.1 Normal GPCM internal counter-based program operation

Transactions are based on control-signal timings that are programmed in the flash timing registers for GPCM mode (IFC_FTIM*x*_CS*n*_GPCM) when CSOR*n*[WGETA]=0.

Assertion of AVD/ALE is aligned to the rising edge of ifc_launch_clk (an internal clock), after that all the timing parameters are in terms of the IFC module input clock (ip_clk). IFC_CLK is external clock which goes to the device and it is generated by inverting ifc_launch_clk.

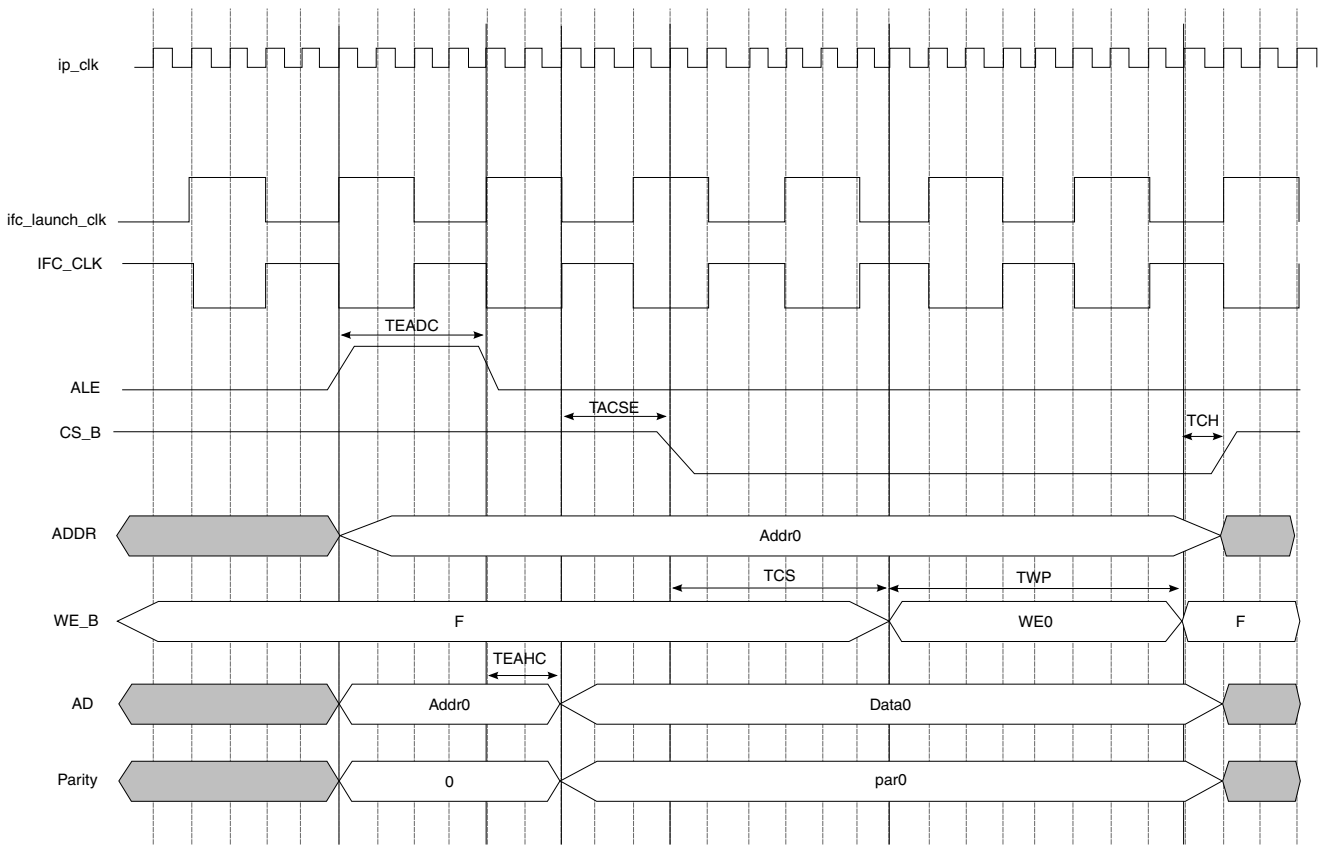

Figure 12-40. Normal GPCM program operation - non-burst mode

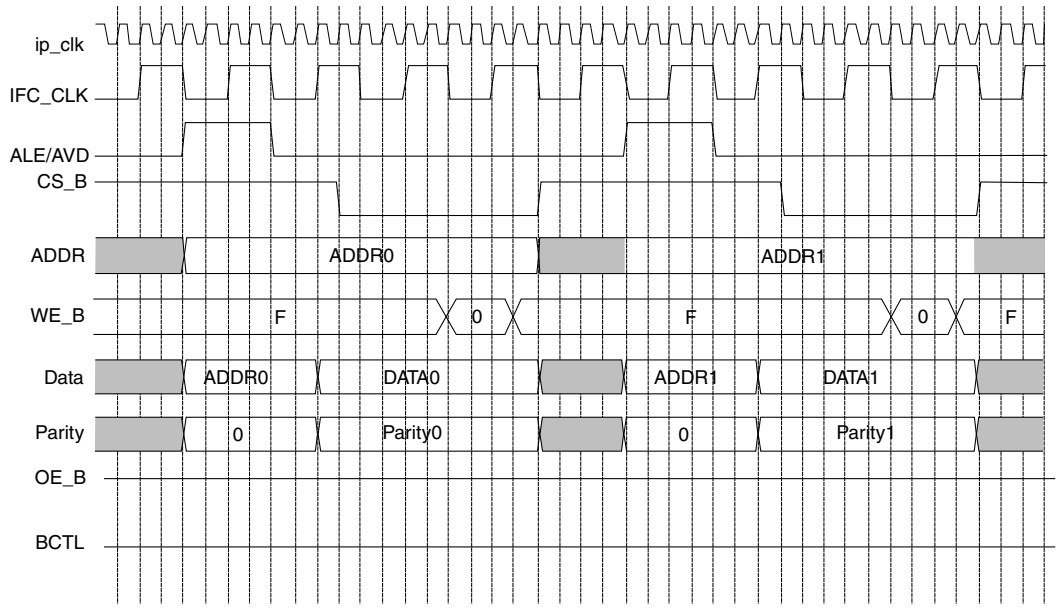

Figure 12-41. Normal GPCM back-to-back program operation

In burst mode, the next data and next address are sent after one TWP period (the amount of time between address/data cycles). If IFCTA_B is deasserted and the burst is controlled by the timing parameter programmed in FTIM registers, the burst will continue until either the burst length is reached or complete data is transferred. If the number of bytes of data to be transferred is less than programmed burst length multiplied by port size, then the burst will be terminated before the programmed maximum number of burst transfers.

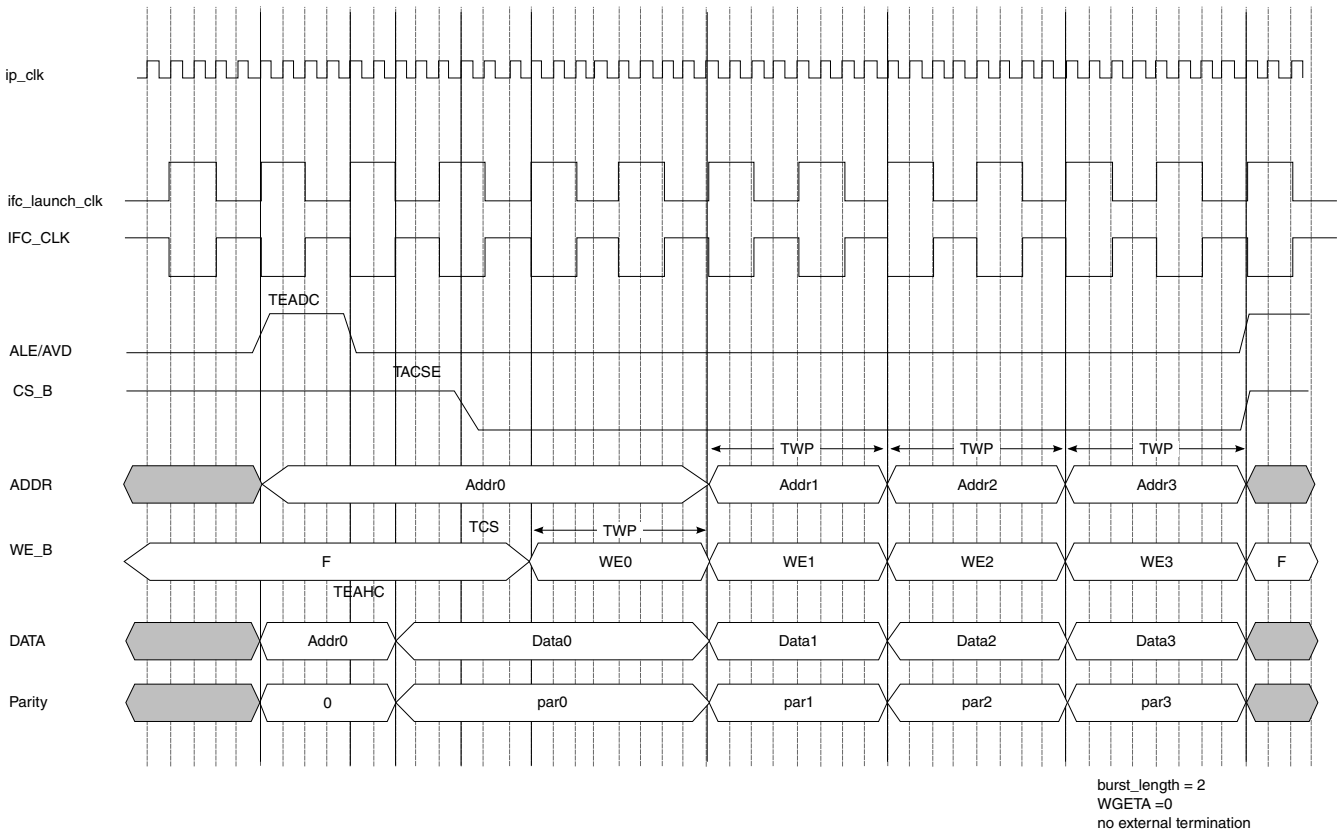

Figure 12-42. Normal GPCM program operation - burst mode

For a normal timing-based transaction, CSOR*n*[RGETA]=0. If the access is aborted by IFCTA_B and there is remaining data to be transferred, the current burst is terminated and a new burst transaction is launched. Ongoing burst terminates at the next rising edge of ifc_launch_clk after the assertion of IFCTA_B. The next burst's starting address is the last burst address + the number of bytes that needed to be transferred in the last burst.

$Address_{n+1} = Address_n$ + (number of bytes for current burst)

The next burst starts only after deassertion of IFCTA_B. This is registered as an abort error in the status register and all transaction attributes are locked.

Since IFCTA_B is synchronized through asynchronous FIFO, bus termination occurs only after a synchronization delay of IFCTA_B. IFCTA_B should be asserted for at least one IFC_CLK cycle if it is synchronous (that is, meeting setup and hold time); otherwise, asynchronous IFCTA_B should be asserted for a minimum of two IFC_CLK cycles.

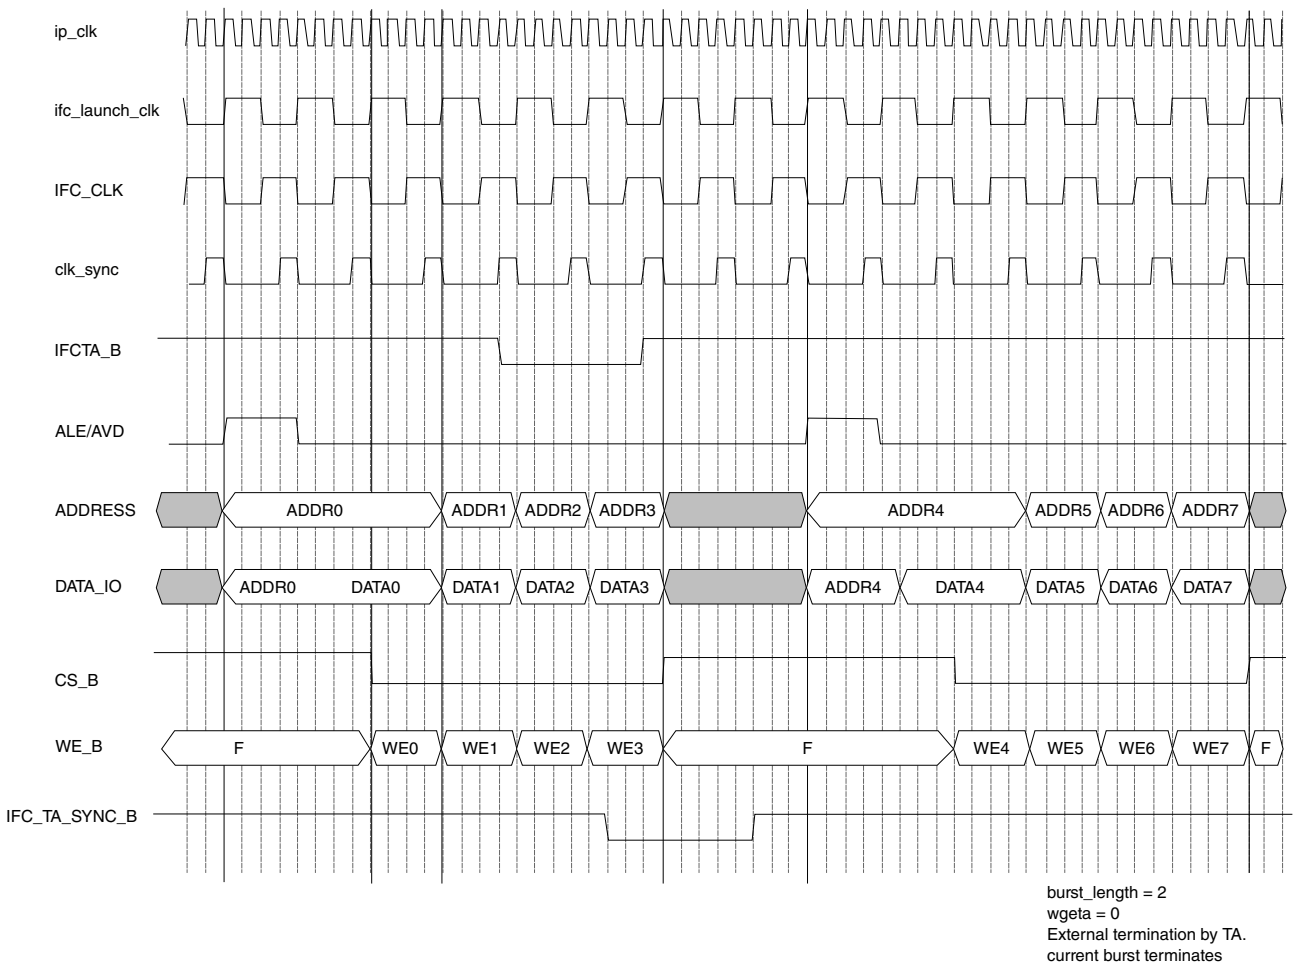

Figure 12-43. Normal GPCM program operation - transaction aborted

12.7.1.1.2 Normal GPCM external termination-based program operation

When WGETA is set, the next address and data are sent only after sampling the rising edge of IFCTA_B or after timeout (as defined in register CSORn[GPTO]).

IFCTA_B is synchronized to the IFC module input clock through asynchronous FIFO and only after the rising edge of IFCTA_B, the new beat is sent over the interface. The next data and address beat is sent in sync with the positive edge of ifc_launch_clk. The last beat of the last burst completes at the next rising edge of ifc_launch_clk after assertion of IFCTA_B, without waiting for deassertion of IFCTA_B and CS_B is deasserted.

If transaction size is greater than GPCM port size, the transaction will be split into multiple port size accesses. For non-burst mode, the last split is terminated at the rising edge of ifc_launch_clk after assertion of IFCTA_B or after timeout. For other splits, IFC waits for IFC_TA deassertion and not available for further transactions until IFC_TA is deasserted.

As IFCTA_B is synchronized through asynchronous FIFO, bus termination occurs only after the synchronization delay of the IFCTA_B signal. IFCTA_B should be asserted for at least one IFC_CLK cycle if it is synchronous (that is, meeting setup and hold time); otherwise, if it is asynchronous, IFCTA_B should be asserted for a minimum of two IFC_CLK cycles.

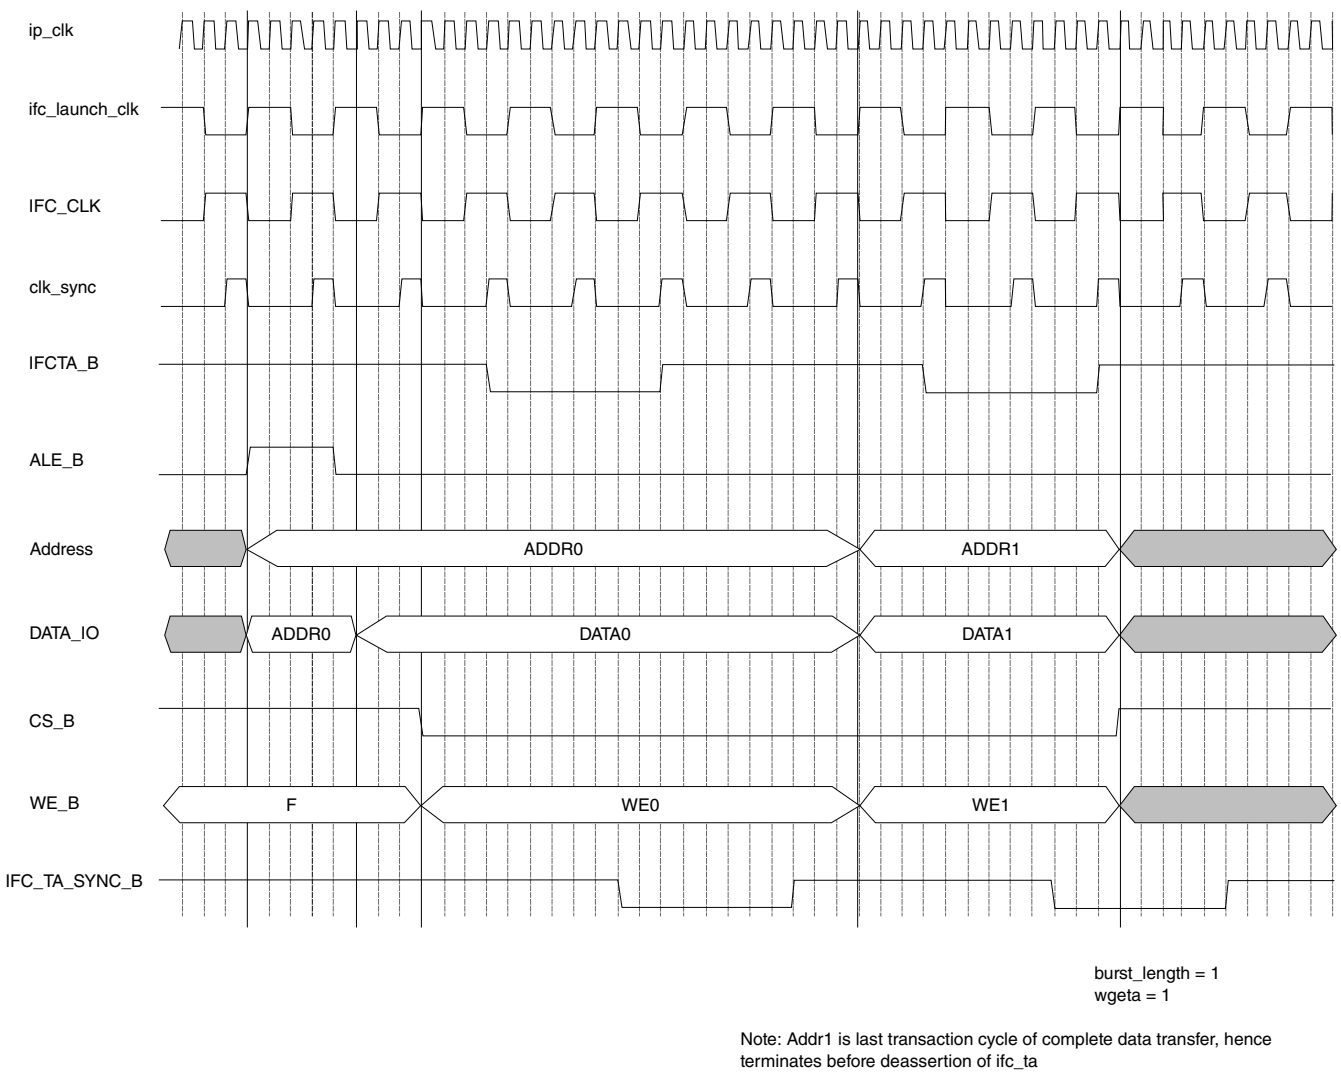

Figure 12-44. Normal GPCM program operation - acknowledgment mode

12.7.1.2 Normal GPCM read operation

In normal GPCM, the read operation depends on the register field CSOR*n*[RGETA]. The following options, through an internal counter or through an external device giving an access termination signal, are explained below.

12.7.1.2.1 Normal GPCM internal counter-based read operation

In this approach, read data from memory is sampled based on the programming of FTIM1_CSn_GPCM[TRAD] and FTIM3_CSn_GPCM[TAAD].

In non-burst mode, TRAD defines the pulse width of OE_B. The read data is sampled on rising edge of IFC_CLK just before the de-assertion of OE_B

By default, (CCR[INV_CLK_EN]=1 and CCR[CLK_DLY]=0) inverted clock of ifc_launch_clk goes out (IFC_CLK) to the external device. Because the address is launched at the rising edge of ifc_launch_clk, the setup time on an external device for the address phase is half the cycle period of IFC_CLK. The read data launched by the device will be sampled by the IFC at the next rising edge of IFC_CLK. The programming of TRAD_GPCM and TAAD_GPCM should be as follows:

- For non-burst mode TRAD value should be programmed as {(2 + n)* (CCR[CLK_DIV] + 1)}, where n defines the memory access time in terms of IFC_CLK. Memory takes n ifc_clk to output data after output enable is asserted or after new address is sampled. n can take values 0,1,2,3...
- For burst mode TRAD/TAAD programmed will be {(2 + n)* (CCR[CLK_DIV] + 1)}, where n defines the memory access time in terms of IFC_CLK. Memory takes n IFC_CLK to output data after output enable is asserted or after new address is sampled. n can take values 0,1,2,3...

The following figures explain the above-mentioned read data sampling schemes:

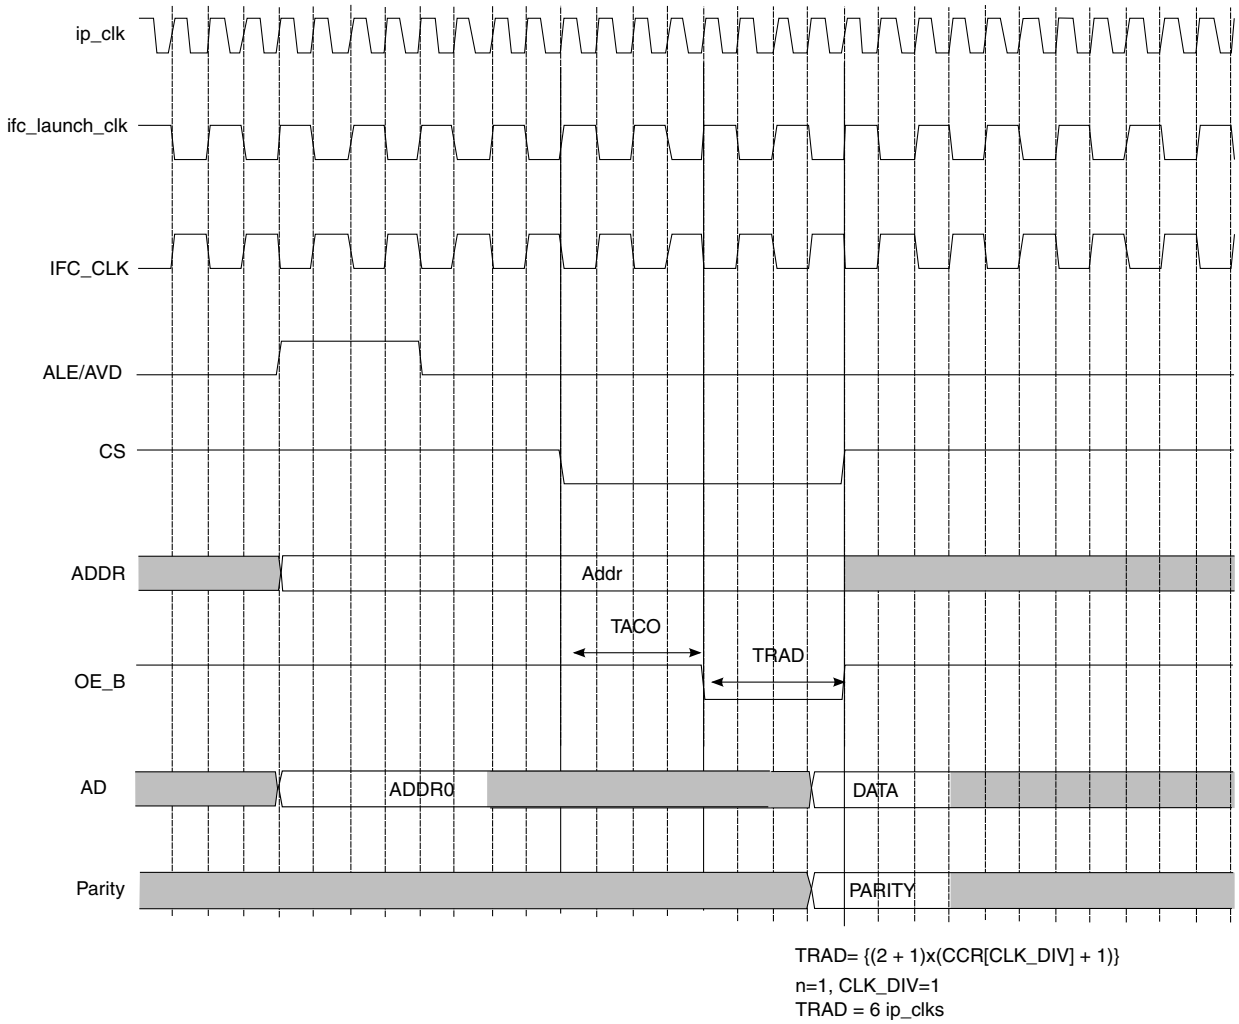

Figure 12-45. Normal GPCM read operation - non-burst mode

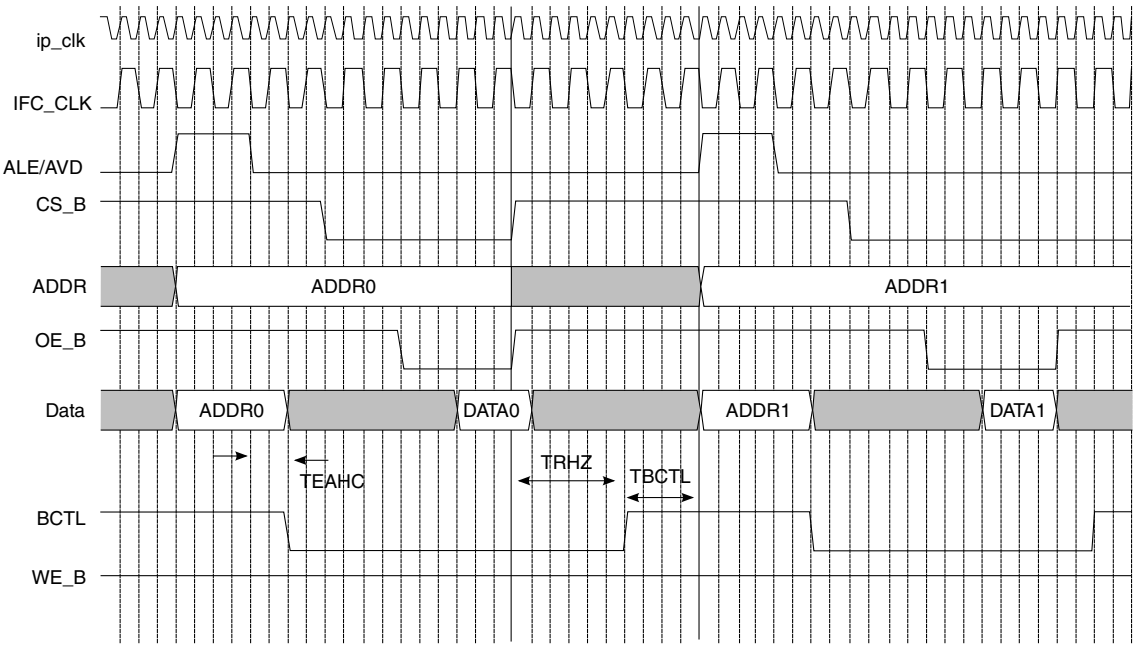

TRHZ: Extended hold time for slow memories to disable their bus drivers
TBCTL: Bus turn-around time

Figure 12-46. Normal GPCM back-to-back read operation

When RGETA is programmed to 0 and access is aborted by ifc_ta, then the current burst is terminated and new burst transaction is launched. The ongoing burst is terminated at the next rising edge of ifc_launch_clk after assertion of ifc_ta. The next burst starting address will be the last burst address + number of bytes that needed to be received in the last burst.

$Address_{n+1} = Address_n$ + (number bytes for current burst)

The next burst starts only after deassertion of ifc_ta.

An abort error is registered in the status registers and all the trasaction attributes are locked. Since ifc_ta is synchronized through asynchronous FIFO, bus termination occurs only after synchronization delay of ifc_ta signal. ifc_ta should be asserted for minimum two IFC_CLK cycles.

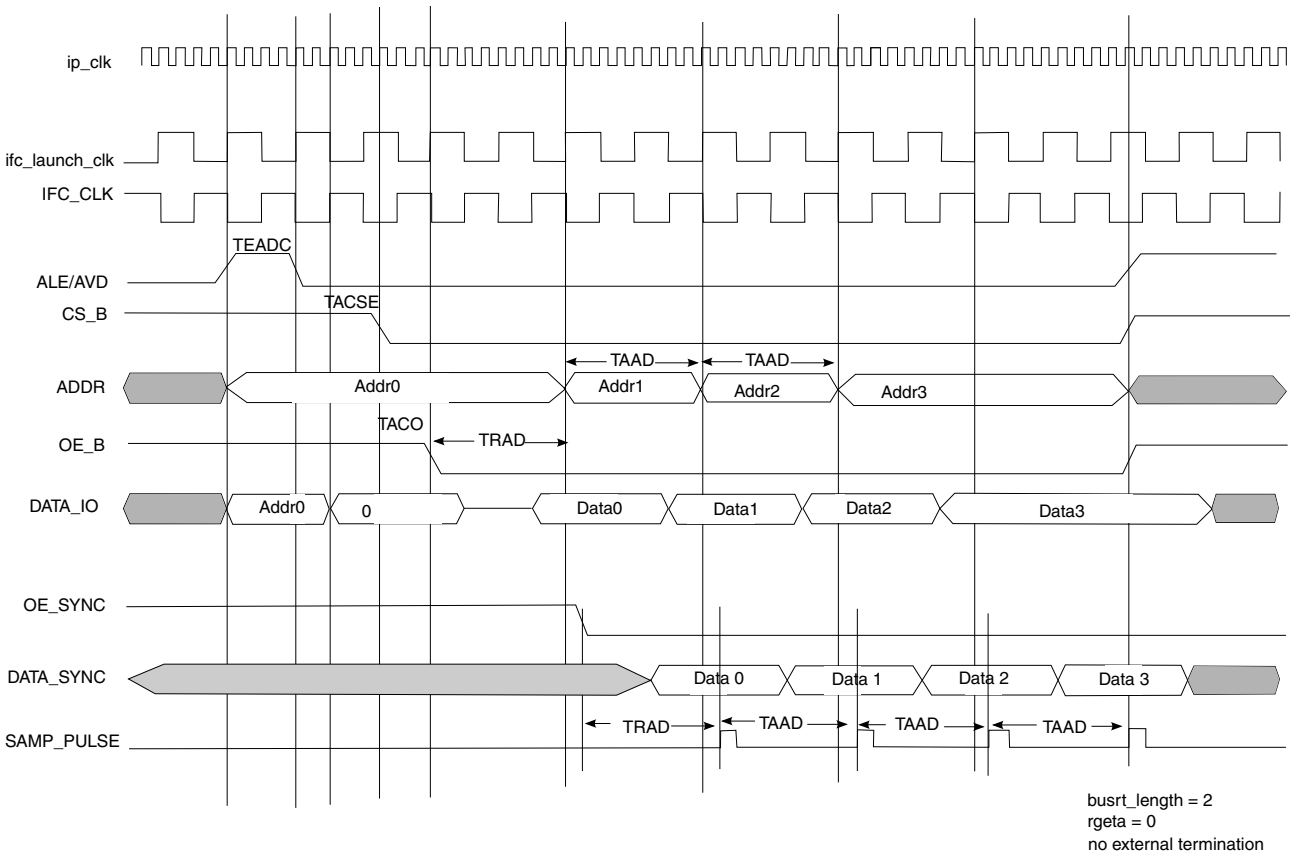

Figure 12-47. Normal GPCM read operation - burst mode

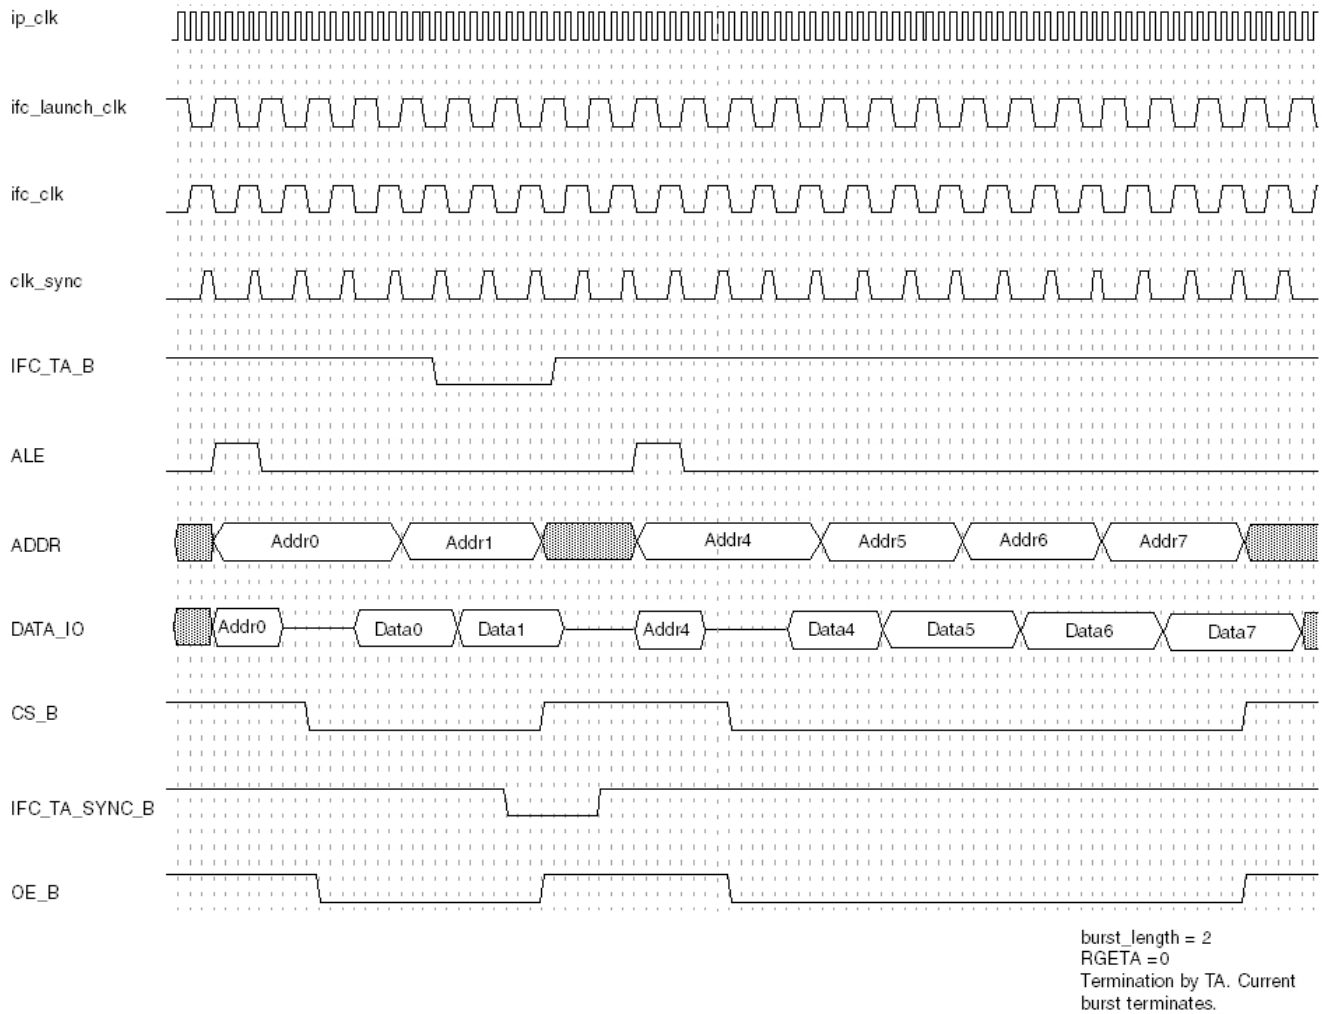

Figure 12-48. Normal GPCM read operation - transaction aborted

12.7.1.2.2 Normal GPCM external termination-based read operation

When RGETA is set to 1, each beat of the transaction waits for an external termination by IFCTA_B or timeout.

For address transfer, the next address is sent only after IFCTA_B is deasserted or after timeout. IFCTA_B is synchronized to ip_clk through the asynchronous FIFO and only after the rising edge new address beat is sent over the interface. The new address beat is sent in sync with ifc_launch_clk. The last transaction cycle does not wait for deassertion of IFCTA_B; it ends at the next rising edge of ifc_launch_clk after assertion of IFCTA_B or after timeout.

For read data sampling, the read data is sampled on the falling edge of IFCTA_B. IFCTA_B and data both are synchronized through the asynchronous FIFO.

For non-burst mode, access is terminated after IFCTA_B is asserted or timeout.

In case of a timeout, an error is registered in the GPCM status register and all transaction attributes are locked. As IFCTA_B is synchronized through the asynchronous FIFO, bus termination occurs only after a synchronization delay of the IFCTA_B signal. IFCTA_B should be asserted for at least one IFC_CLK cycle if it is synchronous (that is, meeting setup and hold time); otherwise, if asynchronous, IFCTA_B should be asserted for a minimum of two IFC_CLK cycles.

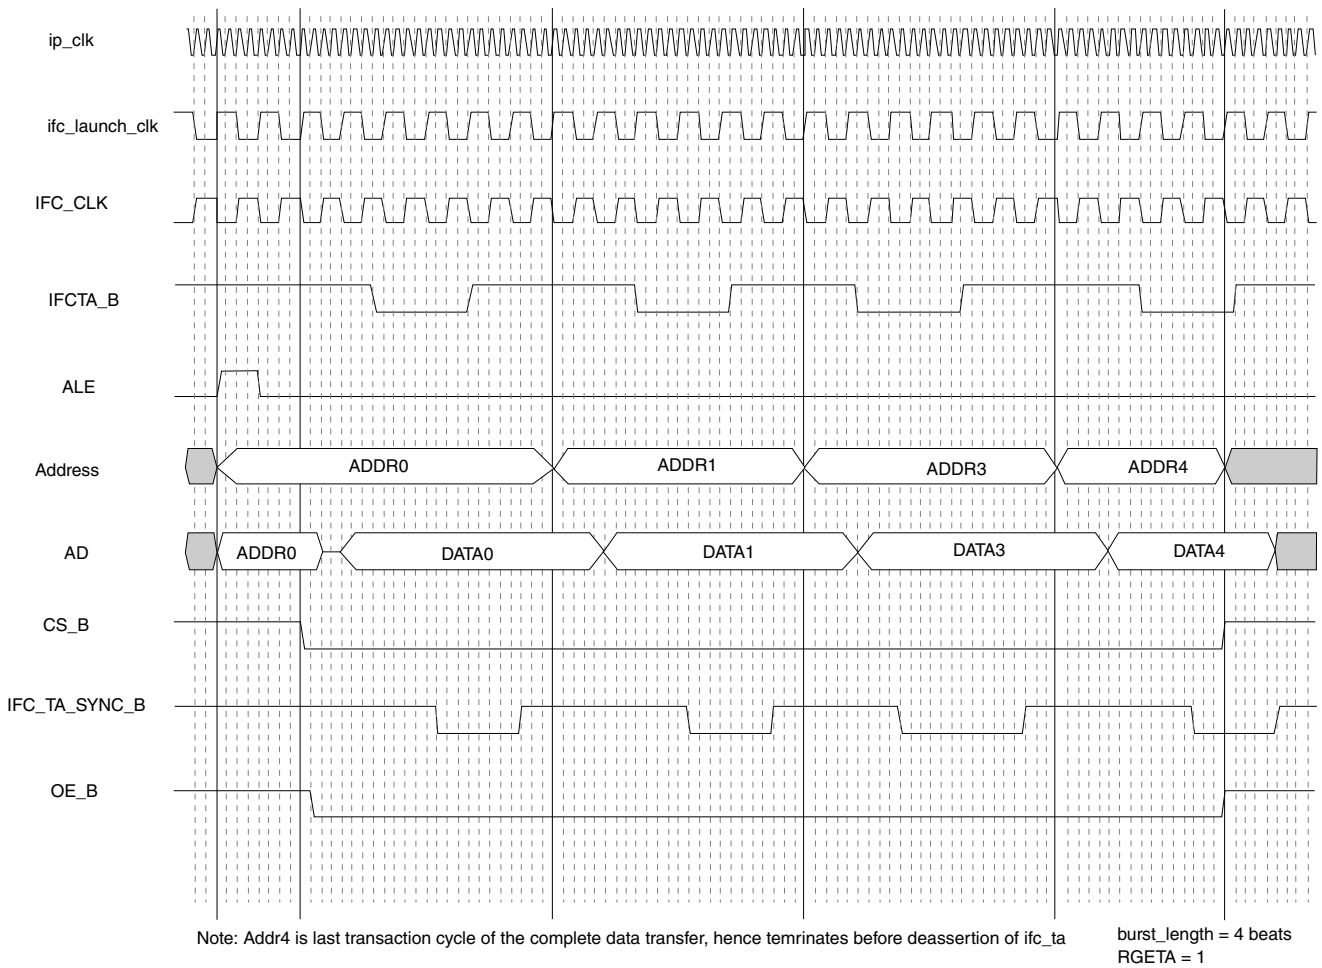

Figure 12-49. Normal GPCM read operation - acknowledgment mode

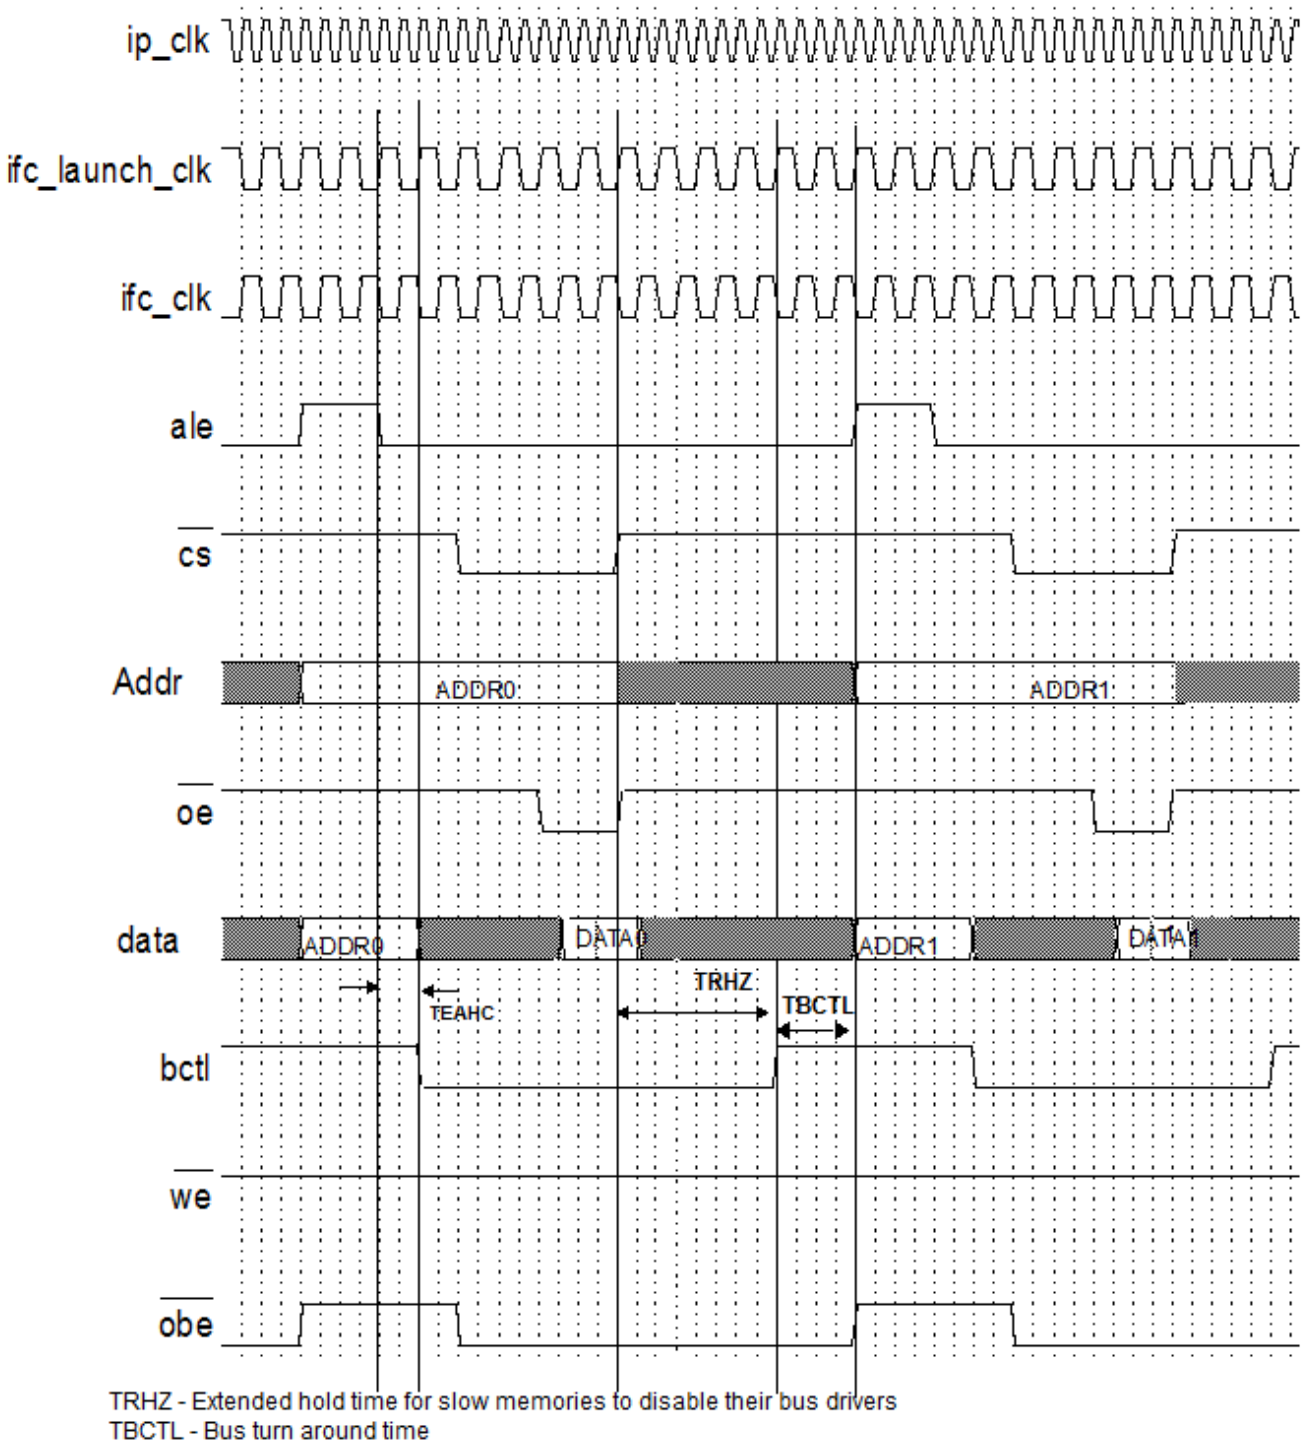

Figure 12-50. Normal GPCM back-to-back Read Operation

12.7.2 Generic ASIC mode of operation

This figure explains the interface of the IFC to a device connected through generic ASIC mode of GPCM (CSORn[GPMODE]=1).

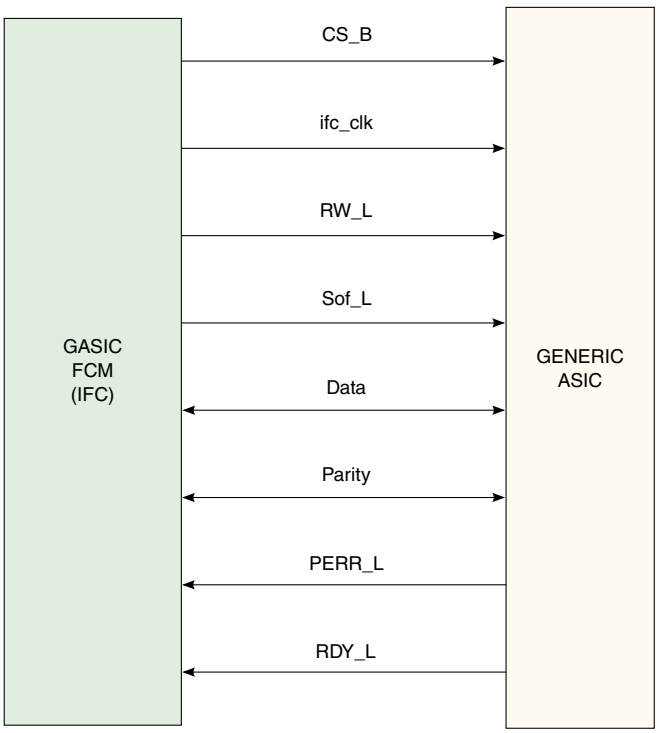

Figure 12-51. Generic ASIC interface

12.7.2.1 General ASIC program operation

Before initiating any general ASIC (GASIC) operation, the chip-select (CS_B) is asserted to select the appropriate device.

The assertion of start of frame (SOF_B) along with the low value on RW_B indicates the start of address phase for write transfer. In the case of a 32-bit device, the complete 32-bit address is driven on the AD[0:31] lines in one clock, while in the case of a 16-bit device, the upper 16 bits of address on AD[0:15] first and followed by the lower 16 bits on the next clock. After the address phase, the write data sequences are driven on AD lines based on the port size. Along with the address and write data phases, per-byte parity is driven on the parity lines. On the completion of write data phase, the host controller waits for the ready status (RDY_B) and the parity error sampling (based on CSORn[GAPERRD] time) before deasserting the chip-select to complete the transfer. In the case where the device is not asserting RDY_B before timeout (as defined in CSORn[GPTO]) occurs, the host terminates the transfer by deasserting the CS_B.

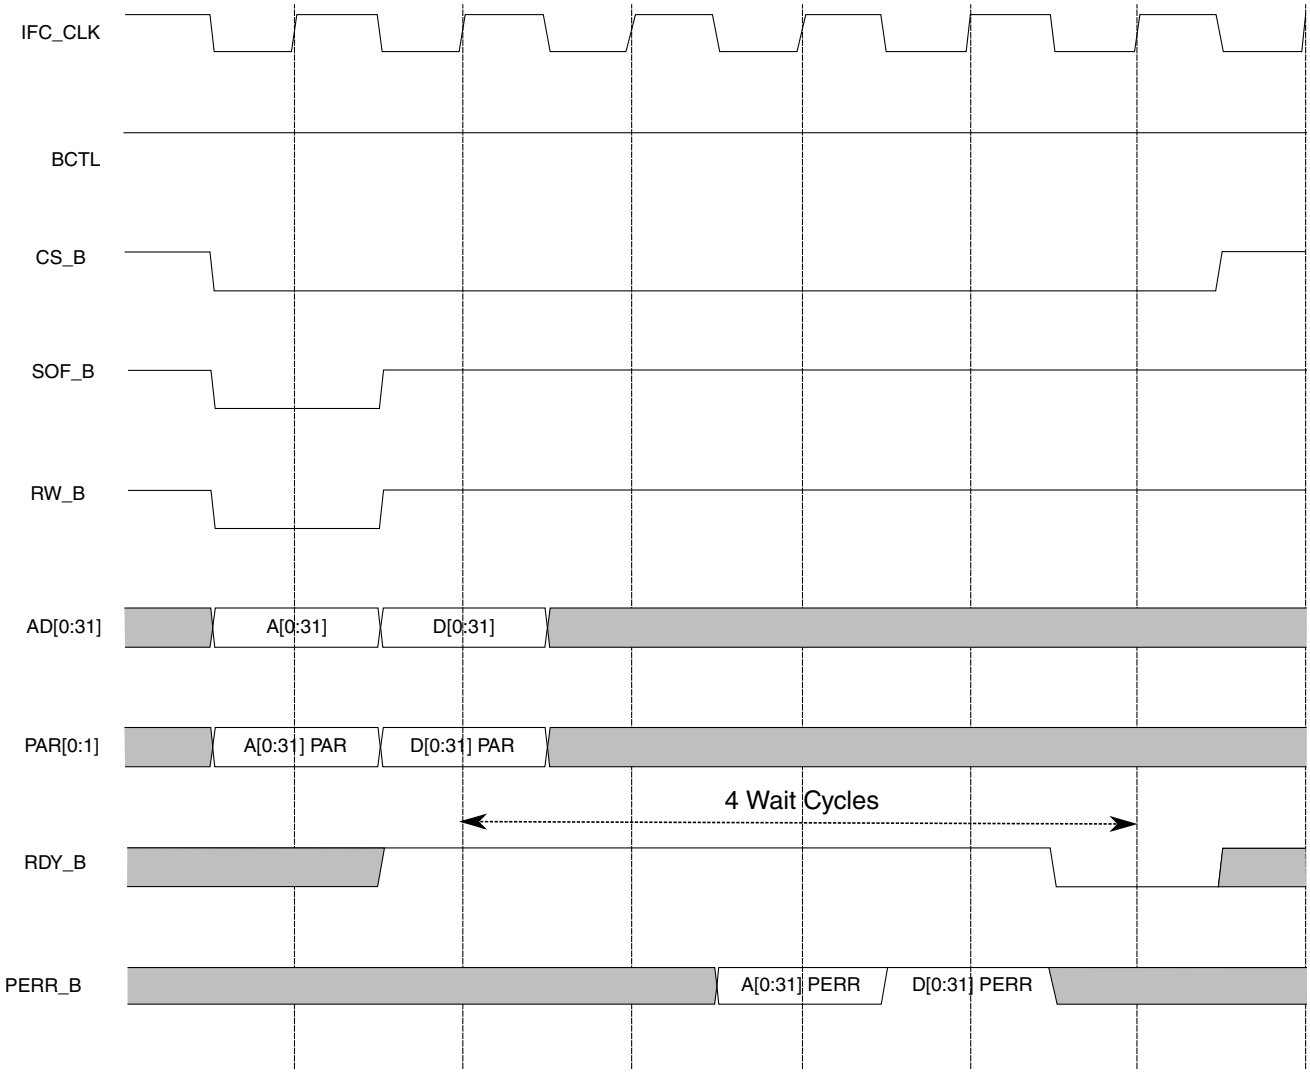

Figure 12-52. GASIC program operation with 32-bit device and 4-wait state

For program operation, wait state represents delay (in terms of IFC_CLK) between first write data beat versus RDY_B assertion time.

For read, wait state represents delay (in terms of IFC_CLK) between last address beat sent by controller and RDY_L assertion time. If RDY_L is asserted in next cycles of address sampled by GASIC device then it is termed as zero wait state.

12.7.2.2 Generic ASIC read data sampling

After selecting the general ASIC (GASIC) device, the host asserts start of frame (SOF_B) and drive high value on RW_B to indicate the start of address phase for read transfer.

The host drives the AD lines and the corresponding PAR parity lines in this phase to send the 32-bit of address to the device. After completing the address phase, the host stops driving the AD lines and waits for the assertion of ready status (RDY_B) from the device. The assertion of RDY_B indicates the start of read data phase. In case of a 32-bit device, the complete 32 bits of read data can be captured along with RDY_B assertion in 1 clock cycle, while in the case of a 16-bit device, the upper 16 bits of read data are received first while the lower 16 bits are received on the next clock cycle. After receiving the complete 32 bits of read data and sampling parity error for the address phase, the host deasserts the chip-select to end the read operation. In the case the device has not asserted RDY_B before timeout occurs, the host terminates the transfer by deasserting the CS_B.

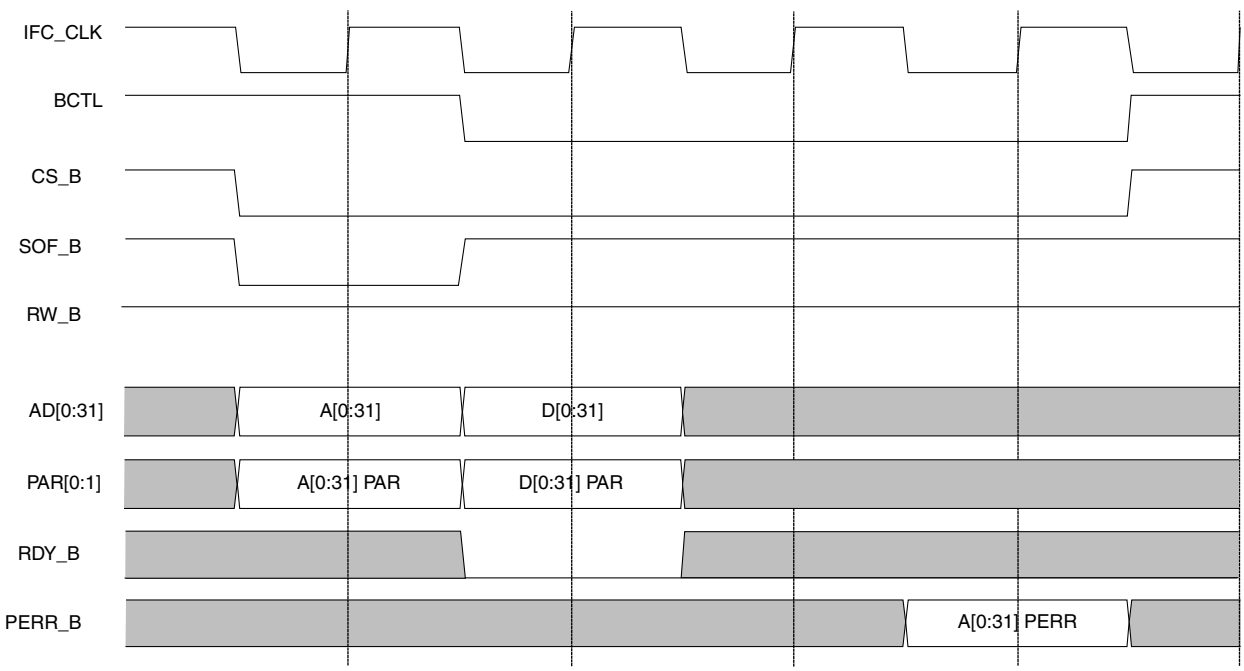

Figure 12-53. GASIC read operation with 32-bit device and zero-wait state

12.8 Clock generation module

The clock generation module generates a divided clock derived from the IFC module input clock depending on the programmed value in the CCR register.

Whenever there is a change in any clock division ratio, the clock is gated for few IFC module input clock. The clock status is reported as unstable in the CSR register.

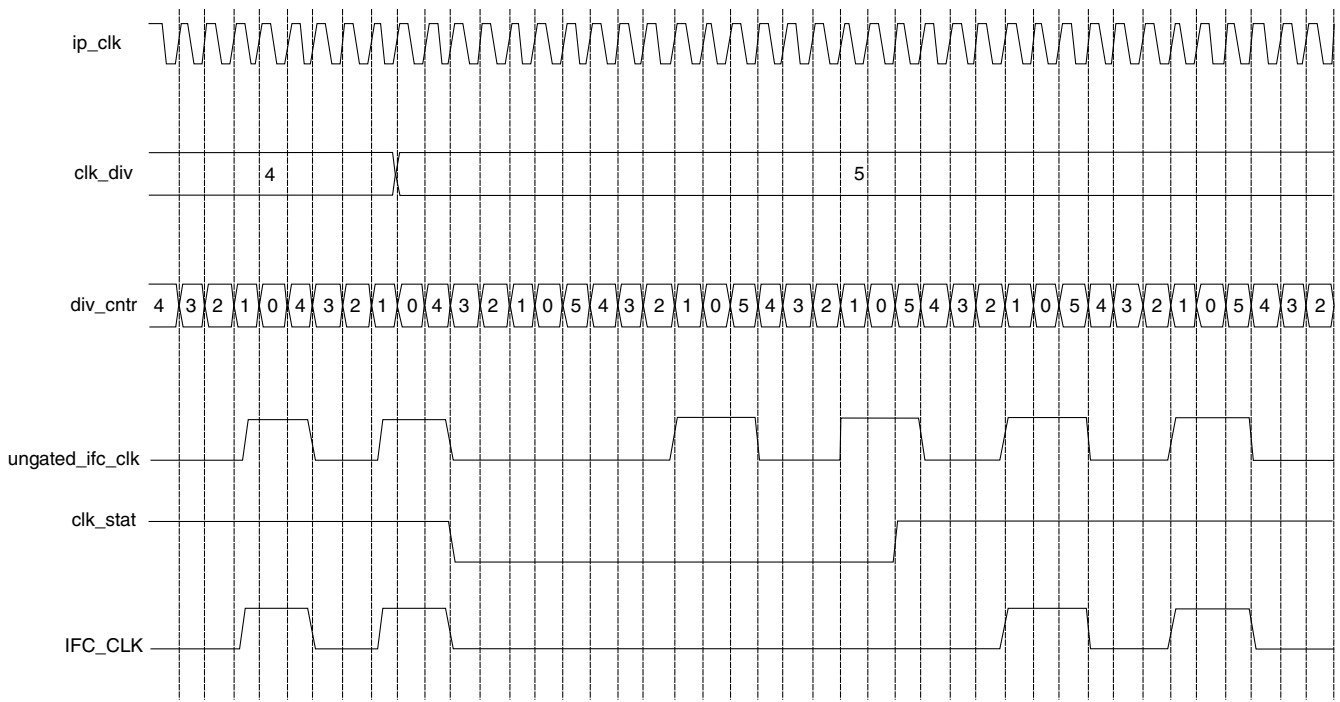

Figure 12-54. External clock generation

12.9 Initialization/Application information

The IFC can be used with separate address and data buses or with a multiplexed address/ data bus.

This section provides guidelines for interfacing peripherals in the IFC's various modes.

12.9.1 IFC flash connections

12.9.1.1 NAND flash connections

The NAND FCM provides a glueless interface to 8- or 16-bit parallel-bus NAND flash EEPROM devices.

This figure shows a simple connection between an 8-bit port size NAND flash EEPROM and the IFC. In NAND FCM mode, commands, address bytes, and data are all transferred on AD[0:7].

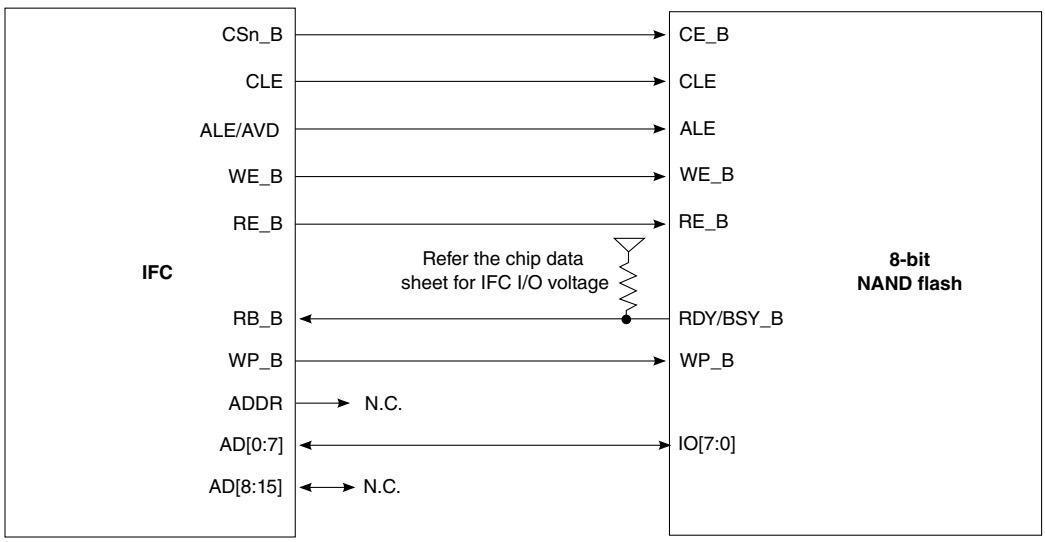

Figure 12-55. IFC to 8-bit asynchronous NAND device interface

This figure shows connection of a 16-bit NAND flash to IFC. Commands and address bytes appear on AD[8:15].

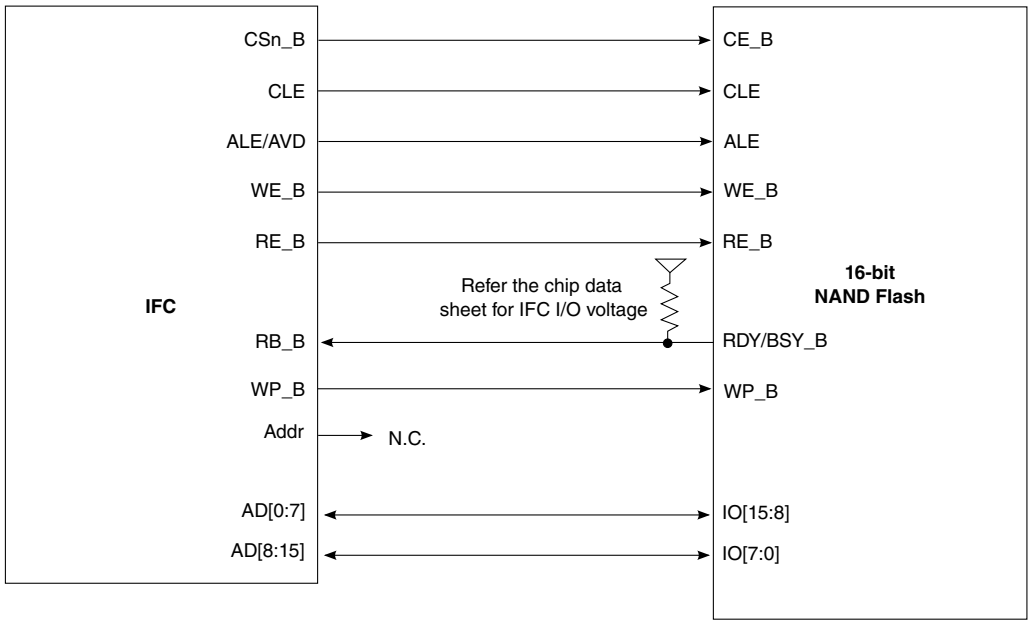

Figure 12-56. IFC to 16-bit asynchronous NAND flash device interface

12.9.1.2 NOR flash connections

For 32-bit devices, ADDR[30:31] are irrelevant, because these address bits are implicit in the byte lanes that carry data. Similarly, for 16-bit devices, ADDR[30] is used and ADDR[31] is irrelevant; however, for 8-bit devices, ADDR[30:31] are necessary.

If the bus width is 4 bytes, then ADDR[23:24] are don't cares and would not be connected. Likewise, if the bus size is 2 bytes wide, then ADDR[24] is a don't care and would not be connected.

This figure shows the IFC-to-NOR device interface.

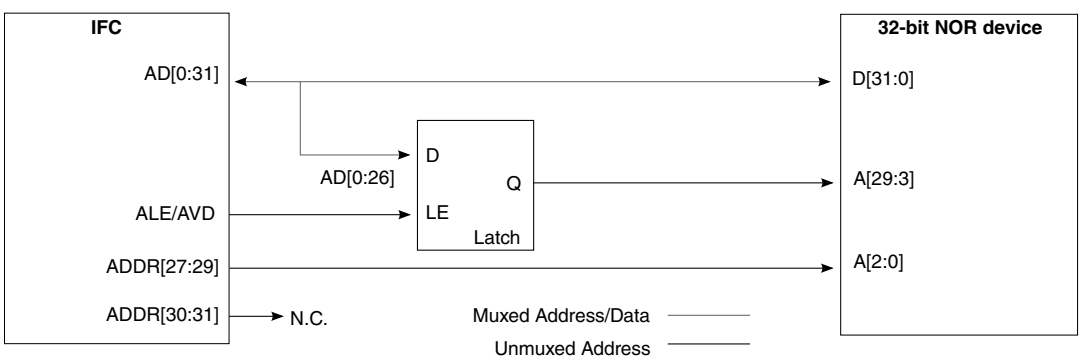

Figure 12-57. IFC to 32-bit NOR device interface

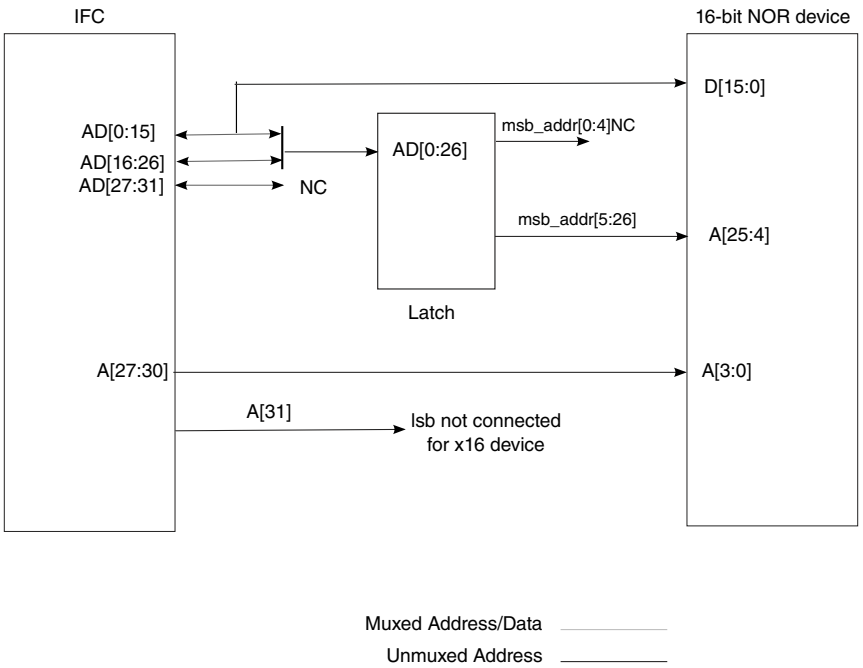

Figure 12-58. IFC to 16-bit NOR device interface

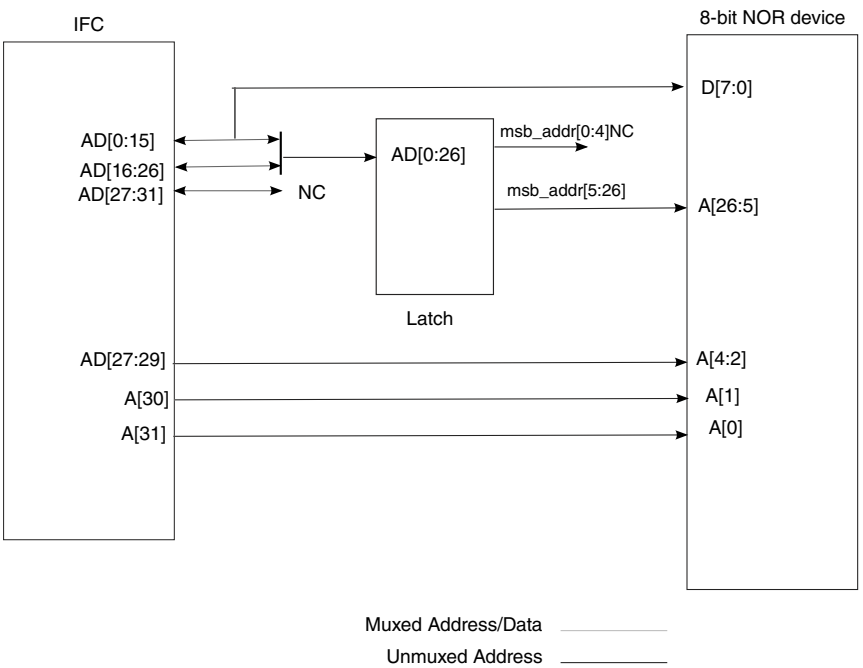

Figure 12-59. IFC to 8-bit NOR device interface

12.9.2 Bus turnaround

Because the IFC uses multiplexed address and data, special consideration is given to avoid bus contention at bus turnaround.

The following cases must be examined:

- Address phase after previous read
- Read-data phase after address phase
- Read-modify-write cycle for parity-protected memory banks

The bus does not change direction for the following cases, so no special attention is required:

- Continued burst after the first beat
- Write-data phase after address phase
- Address phase after previous write

12.9.2.1 Address phase after previous read

During a read cycle, the memory/peripheral drives the bus and the bus transceiver drives AD.

After the data has been sampled, the output drivers of the external device must be disabled, which can take some time.

After the previous cycle ends, BCTL goes high and changes the direction of the bus transceiver. The IFC then inserts a bus turnaround time (that is, TBCTL) to avoid contention. The external device has now already placed its data signals in high impedance and no bus contention occurs.

12.9.2.2 Read-data phase after address phase

During the address phase, AD actively drives the address and BCTL is high, driving the bus transceivers in the same direction as during a write.

After the end of the address phase, BCTL goes low and changes the direction of the bus transceiver.

12.9.2.3 Read-modify-write cycle for parity protected memory banks

Principally, a read-modify-write cycle is a read cycle immediately followed by a write cycle. Because the write cycle has a new address phase in any case, this essentially is the same as an address phase after a previous read.

12.9.3 Interfacing to different port sizes

The IFC supports 8-, 16-, and 32-bit data port sizes.

However, the IFC requires that the portion of the data bus used for a transfer to or from a particular port size be fixed. A 32-bit port must reside on AD[0:31], a 16-bit port must reside on AD[0:15], and an 8-bit port on AD[0:7]. This figure shows the device connections on the data bus.

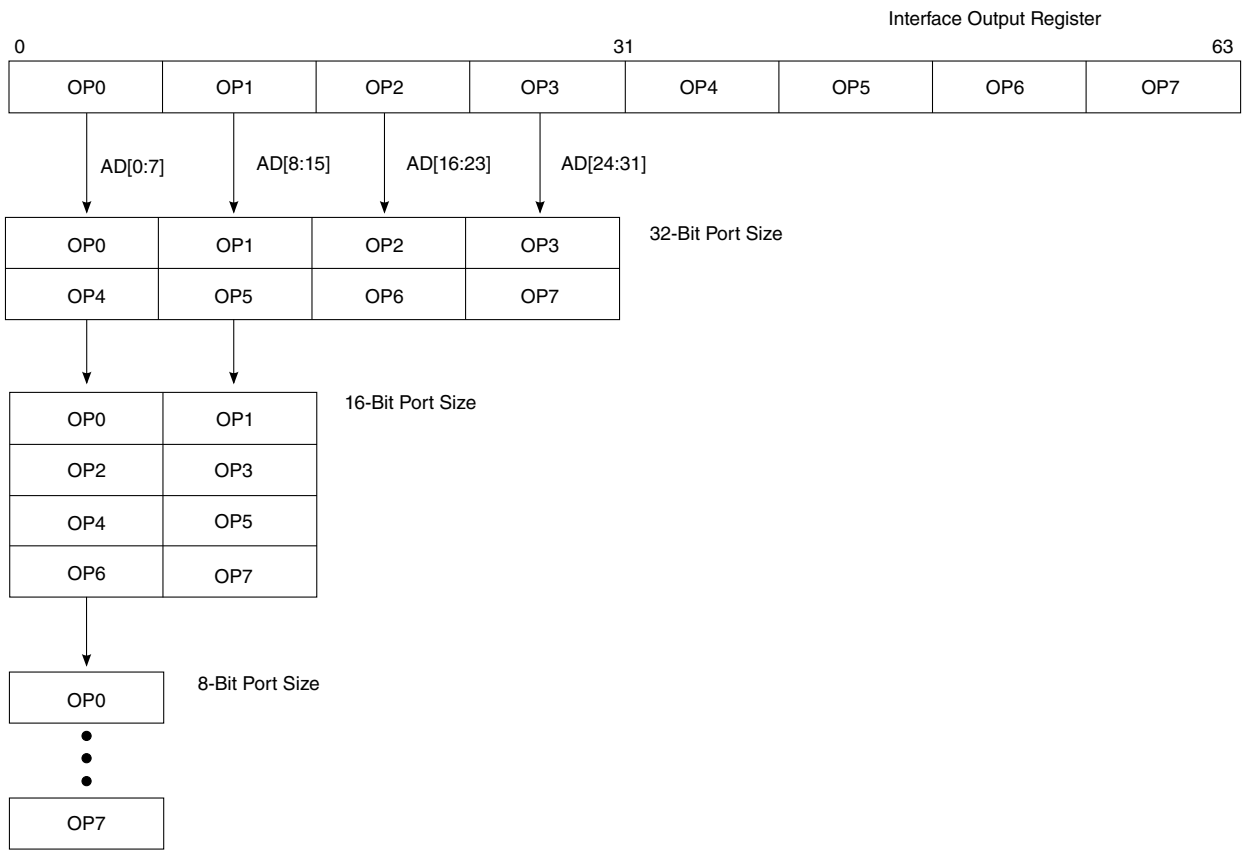

Figure 12-60. Interface to different port-size devices

12.9.4 Command sequence examples for NAND flash EEPROM

To program the IFC and FCM for executing NAND flash command sequences, obtain command codes and pause states from the relevant NAND flash device datasheet and program into FCM configuration registers.

This section describes some common sequences for multi-gigabit NAND flash EEPROMs; however, details should be verified against manufacturer's specific programming data.

Throughout these examples, it is assumed that one or more banks of the IFC have been configured under FCM control with base address, port size, ECC mode, and timing parameters configured in accordance with the device's data sheet .

12.9.4.1 NAND flash soft reset command sequence example

An example of configuring FCM to execute a soft reset command to a 2 KB-page NAND flash is shown in this table.

This sequence does not require the use of the shared FCM buffer RAM. At the conclusion of the sequence, IFC issues a command complete interrupt if interrupts are enabled.

Table 12-12. FCM register settings for soft reset

Register	Initial contents	Description
NAND_FCR0	FF00_0000h	CMD0 = FFh = reset command; other commands unused
ROW0	-	Unused
COL0	-	Unused
NAND_BC	-	Unused
NAND_FSR	-	Unused
NAND_FIR0, NAND_FIR1, NAND_FIR2	2400_0000h, 0000_0000h, 0000_0000h	OP0 = CMD0 = command 0; OP1-OP14 = NOOP

12.9.4.2 NAND flash read status command sequence example

An example of configuring FCM to execute a status read command to 2 KB-page NAND flash is shown in this table.

This sequence does not require the use of the shared FCM buffer RAM, but reads the NAND flash status into NAND_FSR.

At the conclusion of the sequence, the IFC issues a command complete interrupt if interrupts are enabled.

Table 12-13. FCM register settings for status read

Register	Initial contents	Description
NAND_FCR0	7000_0000h	CMD0 = 70h = read status command; other commands unused
ROW0	-	Unused
COL0	-	Unused
NAND_BC	-	Unused
NAND_FSR	-	Status returned in RS0
NAND_FIR0, NAND_FIR1, NAND_FIR2	25C0_0000h, 0000_0000h, 0000_0000h	OP0 = CMD0 = command 0; OP1 = RDSTAT = read status to NAND_FSR; OP2-OP14 = NOOP

12.9.4.3 NAND flash read identification command sequence example

An example of configuring FCM to execute a status ID command to 2 KB-page NAND flash is shown in this table.

This sequence uses the shared FCM buffer RAM to receive the bytes of ID during the sequence.

At the conclusion of the sequence, IFC issues a command complete interrupt if interrupts are enabled.

Table 12-14. FCM register settings for ID read

Register	Initial contents	Description
NAND_FCR0	9000_0000h	CMD0 = 90h Read ID command; other commands unused
ROW3	Row address (0000_0020h)	Locates the block and the page within that block to be accessed
COL0	0000_0000h	Locates the byte to be accessed within a given page MS = 0
NAND_BC	0000_0004h	BC = 4 to read the ONFI Signature (for ONFI devices)
NAND_FSR	-	Unused
NAND_FIR0, NAND_FIR1, NAND_FIR2	2608_4000h, 0000_0000h, 0000_0000h	OP0 = CMD0 = command 0; OP1 = UA = Send row address programmed in row address register 3. Use SRAM buffer 0 to store the read ID bytes; OP2 = RB = Read BC bytes of data into the SRAM buffer 0; OP3-OP14 = NOOP

The above sequence uses opcode UA to send the address stored in row address register 3. This is done so that the data transfer, that is, the read data is stored in buffer 0 of the internal SRAM. Thus, the UA could also be used for operations, such as read page parameter, get feature, set feature, read unique ID always using buffer 0 of the internal SRAM.

12.9.4.4 NAND flash page read command sequence example

An example of configuring FCM to execute a random page read command to 2-Kbytes page NAND flash is shown in the table below.

This sequence reads an entire page (main and spare region) into the shared FCM buffer RAM, checking ECC (if enabled) as it proceeds.

At the conclusion of the sequence, IFC will issue a command complete interrupt if interrupts are enabled. Once the sequence has completed, the shared buffer (buffer 1 for page index 5) and transfer error registers are valid.

Table 12-15. FCM register settings for page read

Register	Initial contents	Description
NAND_FCR0	0030_0000h	CMD0 = 00h = random read address entry; CMD1 = 30h = read page
ROW0	row address (for example, 0000_0005h locates page5 in block0)	Locates the block and the page within that block to be accessed
COL0	0000_0000h	Locates the byte to be accessed within a given page MS = 0
NAND_BC	0000_0000h	BC = 0 to read entire 2112-byte page
NAND_FSR	-	unused
NAND_FIR0, NAND_FIR1,NAND_FIR2	2411_4A68h, 0000_0000h, 0000_0000h	OP0 = CMD0 = command 0; OP1 = CA0 = column address; OP2 = RA0 = page address; OP3 = CMD1 = command 1; OP4 = RBCD = read BC bytes of data into FCM buffer; OP5 - OP14 = NOOP

12.9.4.5 NAND flash program command sequence example

An example of configuring FCM to execute a program command to 2 KB-page NAND flash is shown in this table.

This sequence writes an entire page (main and spare region) from the shared FCM buffer RAM, generating ECC (if enabled) as it proceeds.

The shared buffer (buffer 1 for page index 5) must be initialized by software prior to starting the sequence. At the conclusion of the sequence, the IFC issues a command complete interrupt if interrupts are enabled. The status of the programming operation is returned in NAND_FSR.

Note that operations specified by OP5 and OP6 (status read) should never be skipped while programming a NAND flash device, because it may happen that a new command is issued to the NAND flash device even when the device has not yet finished processing the previous request. This may result in unpredictable behavior.

Table 12-16. FCM register settings for page program

Register	Initial contents	Description
NAND_FCR0	8070_1000h	CMD0 = 80h = page address and data entry; CMD1 = 70h = read status CMD2 = 10h = program page;
ROW0	Row address (for example, 0000_0005h locates page5 in block0)	Locates the block and the page within that block to be accessed
COL0	0000_0000h	Locates the byte to be accessed within a given page MS = 0
NAND_BC	0000_0000h	BC = 0 to read entire 2112-byte page
NAND_FSR	-	Returns with AS0 holding program status
NAND_FIR0, NAND_FIR1, NAND_FIR2	2411_592Ch, 49C0_0000h, 0000_0000h	OP0 = CMD0 = command 0; OP1 = CA0 = column address; OP2 = RA0 = page address; OP3 = WBCD = write BC bytes of data from buffer; OP4 = CMD2 = command 2; OP5 = CW1 = wait on flash ready and issue command 1; OP6 = RDSTAT = read erase status into NAND_FSR; OP7-OP14 = NOOP

12.9.4.6 Read status command during busy period of program/erase operation

During program and erase operation, the device permits the user to read status during its busy period.

To achieve this, use the sequence of commands in this table.

Table 12-17. FCM register settings for read status during program busy period

Register	Initial contents	Description
NAND_FCR0	8070_1000h	CMD0 = 80h = page address and data entry; CMD1 = 0x70 = read status CMD2 = 10h = program page;
ROW0	row address	Locates the block and the page within that block to be accessed

Table continues on the next page...

Table 12-17. FCM register settings for read status during program busy period (continued)

Register	Initial contents	Description
	(for example, 0000_0005h locates page5 in block0)	
COL0	0000_0000h	Locates the byte to be accessed within a given page MS = 0
NAND_BC	0000_0000h	BC = 0 to read entire 2112-byte page
NAND_FSR	-	Returns with AS0 holding program status
NAND_FIR0, NAND_FIR1, NAND_FIR2	2411_592Ch, 49C00_000h, 00000_000h	OP0 = CMD0 = command 0; OP1 = CA0 = column address; OP2 = RA0 = page address; OP3 = WBCD = write BC bytes of data from buffer; OP4 = CMD2 = command 2; OP5 = NWAIT = program NCFGR[NUM_WAIT] for tWB time. OP6 = CMD1 = command 1; OP7 = RDSTAT = read erase status into NAND_FSR; OP8–OP14 = NOOP

In this sequence, use opcode (NWAIT, CMD1) instead of CW1 to issue a read status during the device-busy phase. This is different from the sequence NAND flash program command sequence example, where a read status is issued after the device becomes ready.

12.9.4.7 Valid opcode transitions in the IFC

This table describes the valid opcode transitions.

Ensure that the FIR sequence is programmed using only valid opcode transitions.

Table 12-18. Supported opcode transitions (in FIR)

Current opcode	Next opcode supported *n*=0-7, *m*=0-3								
CMD*n*	CA*m*/ RA*m*	CMD*n*	UA	RBCD/ BTRD/ SBRD/ RDSTAT/ RB_B	CW*n*	WFR	NWAIT	NOOP	
CA*m*	CA*m*/ RA*m*	CMD*n*	UA	RDSTAT/ RB	CW*n*	WFR	NWAIT	NOOP	
RA*m*	RA*m*	CMD*n*	UA	WBCD	RDSTAT/RB	CW*n*	WFR	NWAIT	NOOP

Table continues on the next page...

Table 12-18. Supported opcode transitions (in FIR) (continued)

Current opcode	Next opcode supported *n*=0-7, *m*=0-3

Chapter 13
I2C Modules

13.1 I²C Overview

This chapter describes the dual inter-integrated circuit (I^2C) bus modules implemented on this device and covers the following topics:

- Introduction to I^2C
- I^2C Signal Descriptions
- I2C Controller Memory Map
- I^2C Functional Description
- I^2C Initialization/Application Information

13.2 Introduction to I²C

This section presents the following topics:

- Definition: I^2C Module
- Advantages of the I^2C Bus
- I^2C Module Block Diagram
- I^2C Features Summary
- I^2C Modes of Operation
- Definition: I^2C Conditions

13.2.1 Definition: I²C Module

The I^2C module is a functional unit that provides a two-wire-serial data (SDA) and serial clock (SCL)-bidirectional serial bus that provides a simple efficient method of data exchange between this device and other devices, such as microcontrollers, EEPROMs, real-time clock devices, A/D converters, and LCDs.

13.2.2 Advantages of the I²C Bus

The two-wire I²C bus minimizes interconnections between devices.

The synchronous, multiple-master I²C bus allows the connection of additional devices to the bus for expansion and system development. The bus includes collision detection and arbitration that prevent data corruption if two or more masters attempt to control the bus simultaneously.

13.2.3 I²C Module Block Diagram

I²C module block diagram is shown below:

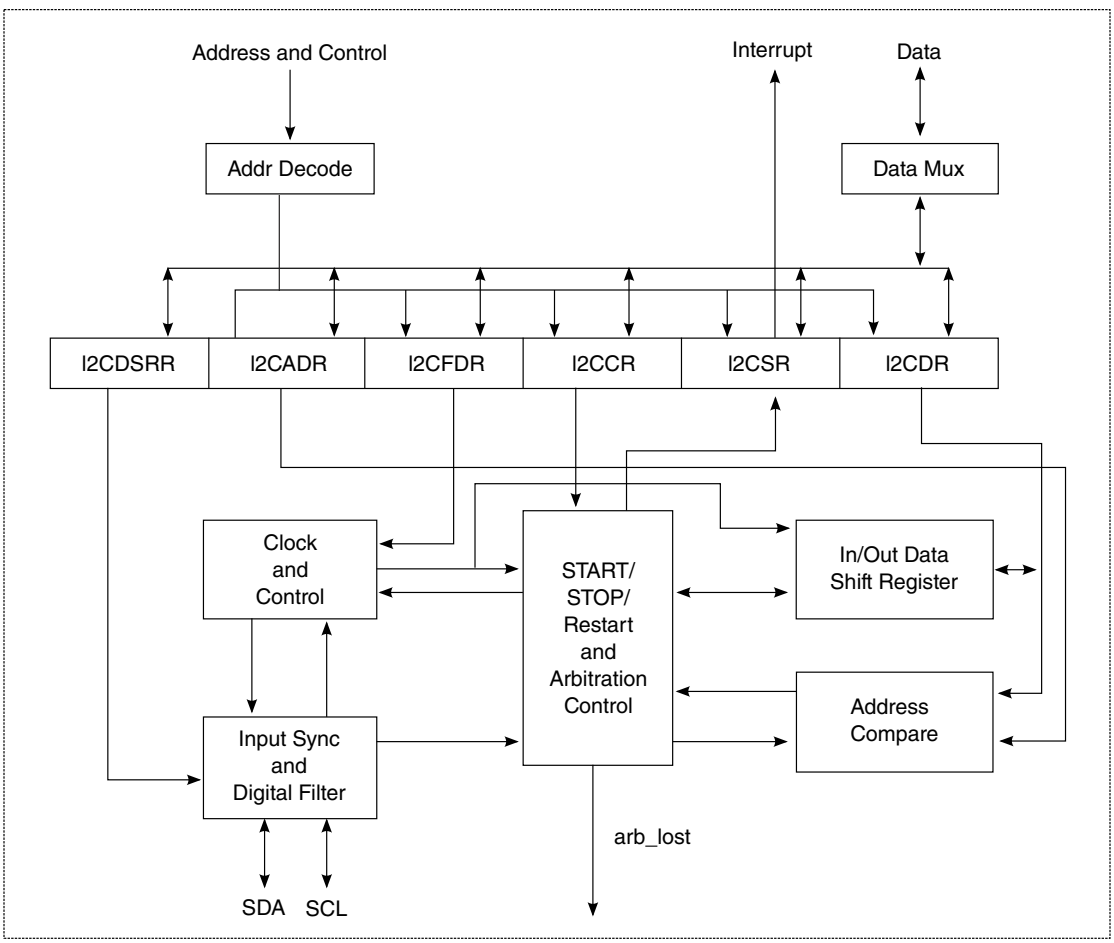

Figure 13-1. I²C Module Block Diagram

13.2.4 I²C Features Summary

The I²C module includes the following features:

- Acknowledge bit generation and detection
- Arbitration-lost interrupt with automatic mode switching from master to slave
- Bus busy detection
- Calling-address identification interrupt
- Multiple-master operation
- On-chip filtering for spikes on the bus
- Software-programmable clock frequency
- Software-selectable acknowledge bit
- START and STOP signal generation and detection
- Two-wire interface

13.2.5 I²C Modes of Operation

The I²C modules can operate in one of several modes, as shown in the following table.

Table 13-1. I²C Module Modes of Operation

Mode	Description	Important Notes
Master mode	The I²C module is the driver of the SDA line.	• Do not use the I²C module's slave address as a calling address. • The I²C module cannot be a master and a slave simultaneously.
Slave mode	The I²C module is not the driver of the SDA line.	• Enable the I²C module before a START condition from a non-I²C master is detected. • By default the I²C module performs as a slave receiver.
Interrupt-driven byte-to-byte data transfer mode	When successful slave addressing is achieved (and the I²C module deasserts SCL), the data transfer can proceed on a byte-to-byte basis in the direction specified by the R/W bit sent by the calling master.	Follow each byte of data by an acknowledge bit, which is signaled from the receiving device.

13.2.6 Definition: I²C Conditions

Describes I²C conditions:

Table 13-2. I²C Conditions

Condition	Description
START	A condition that denotes the beginning of a new data transfer and awakens all slaves. Each data transfer contains several bytes of data.
Repeated START	A START condition that is generated without a STOP condition to terminate the previous transfer.
STOP	A condition generated by the master to terminate a transfer and free the bus.

13.3 I²C Signal Descriptions

This section presents the following topics:

- Signal Overview
- I²C Detailed Signal Descriptions

13.3.1 Signal Overview

The I²C module uses the Serial Data (SDA) and Serial Clock (SCL) signals as a communication interconnect with other devices.

The signal patterns driven on the SDA signal represent address, data, or read/write information at different stages of the protocol.

All devices connected to the SDA and SCL signals must have open-drain or open-collector outputs. The logical AND function is performed on both signals with external pull-up resistors. For the electrical characteristics of these signals, see the chip data sheet .

13.3.2 I²C Detailed Signal Descriptions

The SDA and SCL signals are described in the following table.

Table 13-3. I²C Module-Detailed Signal Descriptions

Signal	I/O	Description	
IIC*n*_SCL	I/O	Serial Clock. Performs as an input when the device is programmed as an I²C slave. SCL also performs as an output when the device is programmed as an I²C master. **Idle State**: High	
	O	When the I²C module is a master, it drives SCL along with SDA when transmitting. As a slave, the I²C module drives SCL low for data pacing. As output for the bidirectional serial clock, SCL operates as described below.	
		State Meaning	Asserted/Negated - SCL is driven along with SDA as the clock for the data.
	I	When the I²C module is idle or is acting as a slave, SCL is an input by default. The I²C module uses SCL to synchronize incoming data on SDA.The bus is assumed to be busy when SCL is detected low. As input for the bidirectional serial clock, SCL operates as described below.	
		State Meaning	Asserted/Negated - The I²C module uses the SCL signal to synchronize incoming data on SDA. The bus is assumed to be busy when SCL is detected low.
IIC*n*_SDA	I/O	Serial Data. Performs as an input when the device is in a receiving mode. SDA also performs as an output signal when the device is transmitting (either as an I²C master or slave). **Idle State**: High	
	O	When the I²C module is writing as a master or slave, it drives data on SDA synchronous to SCL. As output for the bidirectional serial data, SDA operates as described below.	
		State Meaning	Asserted/Negated - Data is driven.
	I	When the I²C module is idle or is in a receiving mode, SDA is an input by default. The unit receives data from other I²C devices on SDA. The bus is assumed to be busy when SDA is detected low. As input for the bidirectional serial data, SDA operates as described below.	
		State Meaning	Asserted/Negated - SDA is used to receive data from other devices. The bus is assumed to be busy when SDA is detected low.

13.4 I2C Controller Memory Map

The I²C module registers and their offsets are described in this section, as well as register access and register figure conventions. This section also contains important notes about the location, byte order, and read/write accesses of registers.

- Register Location: Locate all I²C registers in a cache-inhibited page.

- Byte Order: The I^2C registers are shown in big-endian format. For a system that is in little-endian mode, the software must swap the bytes appropriately. Byte swapping is necessary because the I^2C registers are byte registers.
- Read/Write Accesses: To guarantee in-order execution, execute a synchronizing assembly instruction after each I^2C register read/write access.
- Writes to Reserved Fields: Reserved bits must be written with the value that they returned when read. Program the register by reading its value, modifying the appropriate fields, and writing back the value.

This section is organized as follows:

- I2C Controller Memory Map
- I2C address register (I2C_I2CADR)
- I2C frequency divider register (I2C_I2CFDR)
- I2C control register (I2C_I2CCR)
- I2C status register (I2C_I2CSR)
- I2C data register (I2C_I2CDR)
- I2C digital filter sampling rate register (I2C_I2CDFSRR)

The following table lists the I^2C registers in offset order and provides links to the complete register descriptions.

I2C memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
11_8000	I2C address register (I2C1_I2CADR)	8	R/W	00h	13.4.1/763
11_8004	I2C frequency divider register (I2C1_I2CFDR)	8	R/W	00h	13.4.2/763
11_8008	I2C control register (I2C1_I2CCR)	8	R/W	00h	13.4.3/765
11_800C	I2C status register (I2C1_I2CSR)	8	R/W	81h	13.4.4/767
11_8010	I2C data register (I2C1_I2CDR)	8	R/W	00h	13.4.5/769
11_8014	I2C digital filter sampling rate register (I2C1_I2CDFSRR)	8	R/W	10h	13.4.6/769
11_8100	I2C address register (I2C2_I2CADR)	8	R/W	00h	13.4.1/763
11_8104	I2C frequency divider register (I2C2_I2CFDR)	8	R/W	00h	13.4.2/763
11_8108	I2C control register (I2C2_I2CCR)	8	R/W	00h	13.4.3/765
11_810C	I2C status register (I2C2_I2CSR)	8	R/W	81h	13.4.4/767
11_8110	I2C data register (I2C2_I2CDR)	8	R/W	00h	13.4.5/769
11_8114	I2C digital filter sampling rate register (I2C2_I2CDFSRR)	8	R/W	10h	13.4.6/769
11_9000	I2C address register (I2C3_I2CADR)	8	R/W	00h	13.4.1/763
11_9004	I2C frequency divider register (I2C3_I2CFDR)	8	R/W	00h	13.4.2/763
11_9008	I2C control register (I2C3_I2CCR)	8	R/W	00h	13.4.3/765
11_900C	I2C status register (I2C3_I2CSR)	8	R/W	81h	13.4.4/767
11_9010	I2C data register (I2C3_I2CDR)	8	R/W	00h	13.4.5/769
11_9014	I2C digital filter sampling rate register (I2C3_I2CDFSRR)	8	R/W	10h	13.4.6/769

I2C memory map (continued)

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
11_9100	I2C address register (I2C4_I2CADR)	8	R/W	00h	13.4.1/763
11_9104	I2C frequency divider register (I2C4_I2CFDR)	8	R/W	00h	13.4.2/763
11_9108	I2C control register (I2C4_I2CCR)	8	R/W	00h	13.4.3/765
11_910C	I2C status register (I2C4_I2CSR)	8	R/W	81h	13.4.4/767
11_9110	I2C data register (I2C4_I2CDR)	8	R/W	00h	13.4.5/769
11_9114	I2C digital filter sampling rate register (I2C4_I2CDFSRR)	8	R/W	10h	13.4.6/769

13.4.1 I2C address register (I2Cx_I2CADR)

The I^2C address register (I2CADR) specifies the address to which the I^2C module responds if the I^2C is addressed as a slave. This is not the address sent on the bus during the address-calling cycle when the I^2C module is in master mode.

Address: Base address + 0h offset

Bit	0	1	2	3	4	5	6	7
Read Write	ADDR							Reserved
Reset	0	0	0	0	0	0	0	0

I2Cx_I2CADR field descriptions

Field	Description
0–6 ADDR	Slave address. The ADDR field specifies the slave address to which the I^2C module responds if it is addressed as a slave. If the I^2C is in slave mode and a transaction's calling address matches I2CADR[ADDR], the module will set I2CSR[MIF], signaling a pending interrupt. (For more information about I2CSR[MIF], see I2C status register (I2C_I2CSR).)
7 -	This field is reserved. Reserved

13.4.2 I2C frequency divider register (I2Cx_I2CFDR)

The I^2C frequency divider register (I2CFDR), shown in the following figure, specifies the ratio used to prescale the clock for selecting a specific bit rate.

For additional guidance about the proper use of I2CFDR and I2CDFSRR on Power Architecture® integrated host/communications processors, refer to the application note AN2919, *Determining the I^2C Frequency Divider Ratio for SCL.*

NOTE

Writing to the Reserved Field: While writing to the reserved field, always write back the field's original value, as described in the note in the Programmable Registers section.

The I2CFDR fields and FDR field settings for clock divider values are listed in the following table.

Address: Base address + 4h offset

Bit	0	1	2	3	4	5	6	7
Read Write	Reserved				FDR			
Reset	0	0	0	0	0	0	0	0

I2Cx_I2CFDR field descriptions

Field	Description
0–1 -	This field is reserved. Reserved
2–7 FDR	Frequency divider ratio. Specifies the ratio used to prescale the clock for bit rate selection. The serial bit clock frequency of the SCL is equal to one half the platform clock divided by the designated divider. However, the frequency divider value can be changed at any point in a program. The serial bit clock frequency divider selections are described in the following list: **FDR Divider (Decimal)** 0x00 384 0x01 416 0x02 480 0x03 576 0x04 640 0x05 704 0x06 832 0x07 1024 0x08 1152 0x09 1280 0x0A 1536 0x0B 1920 0x0C 2304 0x0D 2560 0x0E 3072 0x0F 3840 0x10 4608 0x11 5120 0x12 6144 0x13 7680 0x14 9216 0x15 10240 0x16 12288 0x17 15360 0x18 18432

Table continues on the next page...

I2Cx_I2CFDR field descriptions (continued)

Field	Description
	0x19 20480 0x1A 24576 0x1B 30720 0x1C 36864 0x1D 40960 0x1E 49152 0x1F 61440 0x20 256 0x21 288 0x22 320 0x23 352 0x24 384 0x25 448 0x26 512 0x27 576 0x28 640 0x29 768 0x2A 896 0x2B 1024 0x2C 1280 0x2D 1536 0x2E 1792 0x2F 2048 0x30 2560 0x31 3072 0x32 3584 0x33 4096 0x34 5120 0x35 6144 0x36 7168 0x37 8192 0x38 10240 0x39 12288 0x3A 14336 0x3B 16384 0x3C 20480 0x3D 24576 0x3E 28672 0x3F 32768

13.4.3 I2C control register (I2Cx_I2CCR)

The I^2C control register (I2CCR) contains fields for controlling several actions, modes, messages, conditions, and capabilities.

NOTE

Writing to the Reserved Field: While writing to the reserved field, always write back the field's original value, as described in the note in the Programmable Registers section.

.

Address: Base address + 8h offset

Bit	0	1	2	3	4	5	6	7
Read	MEN	MIEN	MSTA	MTX	TXAK		Reserved	BCST
Write						RSTA		
Reset	0	0	0	0	0	0	0	0

I2Cx_I2CCR field descriptions

Field	Description
0 MEN	Module enable. Controls the software reset of the I^2C module. 0 The module is reset and disabled. The module is held in reset, but the registers can still be accessed. 1 The I^2C module is enabled. MEN must be set before any other control register fields have any effect. All I^2C registers for slave receive or master START can be initialized before setting this field, however.
1 MIEN	Module interrupt enable. Enables the interrupt to be reported to the interrupt controller and/or (ultimately) the CPU. 0 Interrupt reporting from the I^2C module is disabled. If any pending interrupt conditions exist, they are not cleared. 1 Interrupt reporting from the I^2C module is enabled. If an interrupt condition is detected and I2CSR[MIF] is also set, the interrupt is reported.(For more information about I2CSR fields, see I2C status register (I2C_I2CSR).)
2 MSTA	Master/Slave Mode START. 0 If MSTA is changed from 1 to 0, a STOP condition is generated and the I^2C mode changes from master to slave. MSTA is cleared without generating a STOP condition when the master loses arbitration. 1 If MSTA is changed from 0 to 1, a START condition is generated on the bus and master mode is selected for the I^2C.
3 MTX	Transmit/Receive Mode Select. Specifies the direction of master and slave transfers. If the I^2C module is configured as a slave, the software should set MTX to match I2CSR[SRW]. If the I^2C module is in master mode, MTX should be set according to the type of transfer required. For address cycles, therefore, this field is always high (has a value of 1). MTX is cleared if the master loses arbitration. 0 Receive mode is selected. 1 Transmit mode is selected.
4 TXAK	Transfer Acknowledge. Specifies the value driven onto the SDA line during acknowledge cycles for both master and slave receivers. The TXAK value applies only if the I^2C module is configured as a receiver, not as a transmitter. The TXAK setting does not apply to address cycles. When the device is addressed as a slave, an acknowledge is always sent. 0 An acknowledge signal (low value on the SDA) is sent out to the bus at the ninth clock after receiving 1 byte of data. 1 No acknowledge signal (high value on the SDA) is sent.

Table continues on the next page...

I2Cx_I2CCR field descriptions (continued)

Field	Description
5 RSTA	Repeated START. Specifies whether to generate a repeated START condition. Setting RSTA always generates a repeated START condition on the bus and provides the device with the current bus master. The RSTA field is not readable; an attempt to read RSTA returns a 0. 0 No START condition is generated. 1 A repeated START condition is generated.
6 -	This field is reserved. Reserved
7 BCST	Broadcast. 0 The broadcast accept capability is disabled. 1 The I^{2}C is enabled to accept broadcast messages at address 0.

13.4.4 I2C status register (I2Cx_I2CSR)

The I^{2}C status register (I2CSR) is read-only with the exception of the MIF and MAL fields, which can be cleared by software.

Address: Base address + Ch offset

Bit	0	1	2	3	4	5	6	7
Read	MCF	MAAS	MBB	MAL	BCSTM	SRW	MIF	RXAK
Write								
Reset	1	0	0	0	0	0	0	1

I2Cx_I2CSR field descriptions

Field	Description
0 MCF	Data Transfer. When one byte of data is transferred, MCF is cleared. MCF is set by the falling edge of the ninth clock of a byte transfer. 0 A byte transfer is in progress. MCF is cleared when I2CDR is read in receive mode or written in transmit mode. (For more information about I2CDR, see I2C data register (I2C_I2CDR).) 1 The byte transfer is completed.
1 MAAS	Addressed as a slave. MAAS is set if the module is acting as a slave and has detected that the I2CADR address matches with the transaction's calling address. The processor is interrupted if I2CCR[MIEN] is set. Next, the processor must check the SRW value and set I2CCR[MTX] accordingly. Any write to I2CCR automatically clears MAAS. For more information, see I2C address register (I2C_I2CADR) (I2CADR fields) and I2C control register (I2C_I2CCR) (I2CCR fields). 0 Not addressed as a slave. 1 Addressed as a slave.
2 MBB	Bus Busy. Indicates the status of the bus. When a START condition is detected, MBB is set. If a STOP condition is detected, it is cleared.

Table continues on the next page...

I2Cx_I2CSR field descriptions (continued)

Field	Description
	0 The I^2C bus is idle. 1 The I^2C bus is busy.
3 MAL	Arbitration Lost. MAL is automatically set (value of 1) if arbitration is lost. Note that the device does not automatically retry a failed transfer attempt. 0 Arbitration is not lost. Can only be cleared by software. 1 Arbitration is lost.
4 BCSTM	Broadcast Match. The broadcast address is always all zeros. BCSTM can be set only if I2CCR[BCST] is set to enable it. (For more information about I2CCR[BCST], see I2C control register (I2C_I2CCR).) 0 There has not been a broadcast match. 1 The calling address matches with the broadcast address instead of the programmed slave address. BCSTM is also set if the I^2C drives an address of all zeros and broadcast mode is enabled.
5 SRW	Slave Read/Write. If MAAS is set, SRW indicates the value of the R/W command bit of the calling address, which is sent from the master. By checking SRW, the processor can select slave transmit/receive mode according to the master's command. 0 Slave receive mode is selected, with the master writing to the slave. 1 Slave transmit mode is selected, with the master reading from the slave. SRW is valid only if both of the following conditions are met: • A complete transfer occurred and no other transfers have been initiated. • The I^2C module is configured as a slave and has an address match.
6 MIF	Module Interrupt. MIF is set if an interrupt is detected. An interrupt is reported if I2CCR[MIEN] is set. The interrupts for I^2C1 and I^2C2 are combined into one interrupt, which is sourced by the dual I^2C module 1; similarly, the interrupts for I^2C3 and I^2C4 are combined into one interrupt, which is sourced by the dual I^2C module 2.(For more information about I2CCR fields, see I2C control register (I2C_I2CCR). 0 No interrupt is detected. MIF can be cleared only by software. 1 An interrupt is detected. MIF is set when one of the following events occurs: • One byte of data is transferred (set at the falling edge of the ninth clock). • The I2CADR value matches with the calling address in Slave Receive mode. • Arbitration is lost.
7 RXAK	Received Acknowledge. The value of SDA during the reception of a bus cycle's acknowledge bit. If RXAK = 0, it indicates that an acknowledge signal has been received after the 8 bits of data have been transmitted on the bus. If RXAK = 1, it means no acknowledge signal has been detected at the ninth clock. 0 An acknowledge signal has been received. 1 No acknowledge signal has been received.

13.4.5 I2C data register (I2Cx_I2CDR)

I2CDR specifies the calling address and data to be transmitted (if the I^2C is in master or slave transmit mode) or allows the I^2C module to receive the next byte of data on the I^2C module (if the I^2C is in master or slave receive mode).

Address: Base address + 10h offset

Bit	0	1	2	3	4	5	6	7
Read Write	DATA							
Reset	0	0	0	0	0	0	0	0

I2Cx_I2CDR field descriptions

Field	Description
0–7 DATA	Specifies data to be transmitted or allows receipt of the next data byte on the I^2C module, depending on the I^2C mode: • Transmit mode: Data transmission is initiated when data is written to I2CDR. For master transmit mode, the first byte of data written to I2CDR is used for the address transfer and is follows the format described in Transactions. When bytes are written to I2CDR in transmit mode, they cannot be verified by reading them back. • Receive mode: Reading I2CDR allows the I^2C module to receive the next byte of data on the I^2C interface (in addition to reading the contents of I2CDR). In all cases, the most significant bit is sent first. I2CCR[MTX] must be set appropriately for the desired behavior. For example, if I2CCR[MTX] is set for transmit mode (1) instead of receive mode (0), reading I2CDR does not initiate receipt of the next data byte. (For more information about I2CCR[MTX], see I2C control register (I2C_I2CCR).) For both master receive and slave receive modes, the very first read is always a dummy read.

13.4.6 I2C digital filter sampling rate register (I2Cx_I2CDFSRR)

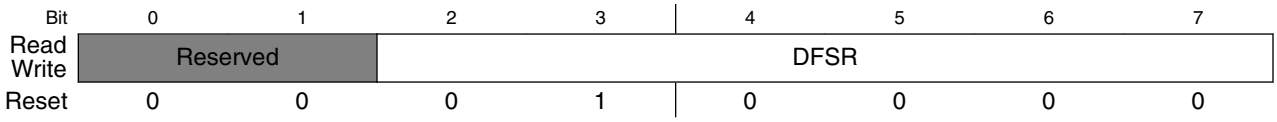
The digital filter sampling rate register (I2CDFSRR) specifies the sample rate for filtering out signal noise.

For additional guidance about the proper use of I2CFDR and I2CDFSRR on Power Architecture® integrated host/communications processors, refer to the application note AN2919, *Determining the I^2C Frequency Divider Ratio for SCL.*

NOTE

Writing to the Reserved Field: While writing to the reserved field, always write back the field's original value, as described in the note in the Programmable Registers section.

Address: Base address + 14h offset



I2Cx_I2CDFSRR field descriptions

Field	Description
0–1 -	This field is reserved. Reserved
2–7 DFSR	Digital Filter Sampling Rate. Specifies the sample rate for the program to use in filtering out signal noise. This rate is used to prescale the frequency the digital filter uses to take samples from the I^2C bus. The resulting sampling rate is calculated by dividing one half the platform frequency by the non-zero value of the DFSR. If I2CDFSRR = 0, the I^2C bus sample points to the reset divisor.

13.5 I^2C Functional Description

This section presents the following topics:

- Notes About Module Operation
- Transactions
- Protocol Implementation Details
- Bus Arbitration
- Clock Behavior
- Filtering of SCL and SDA Lines

13.5.1 Notes About Module Operation

Lists I^2C module operation:

- The I^2C module always performs as a slave receiver by default, unless explicitly programmed to be a master or slave transmitter.
- When the I^2C module is acting as a master, it must not try to call its own slave address.

13.5.2 Transactions

This section covers the following topics:

- Protocol Overview
- Definitions

- I2C Calling Address Requirements
- High-Level Protocol Steps
- START Condition
- Slave Address Transmission
- General Call (Broadcast) Addressing
- Data Transmission
- STOP Condition
- Repeated START Condition

13.5.2.1 Protocol Overview

The following figure shows the behavior of SCL and SDA during a typical I2C transaction.

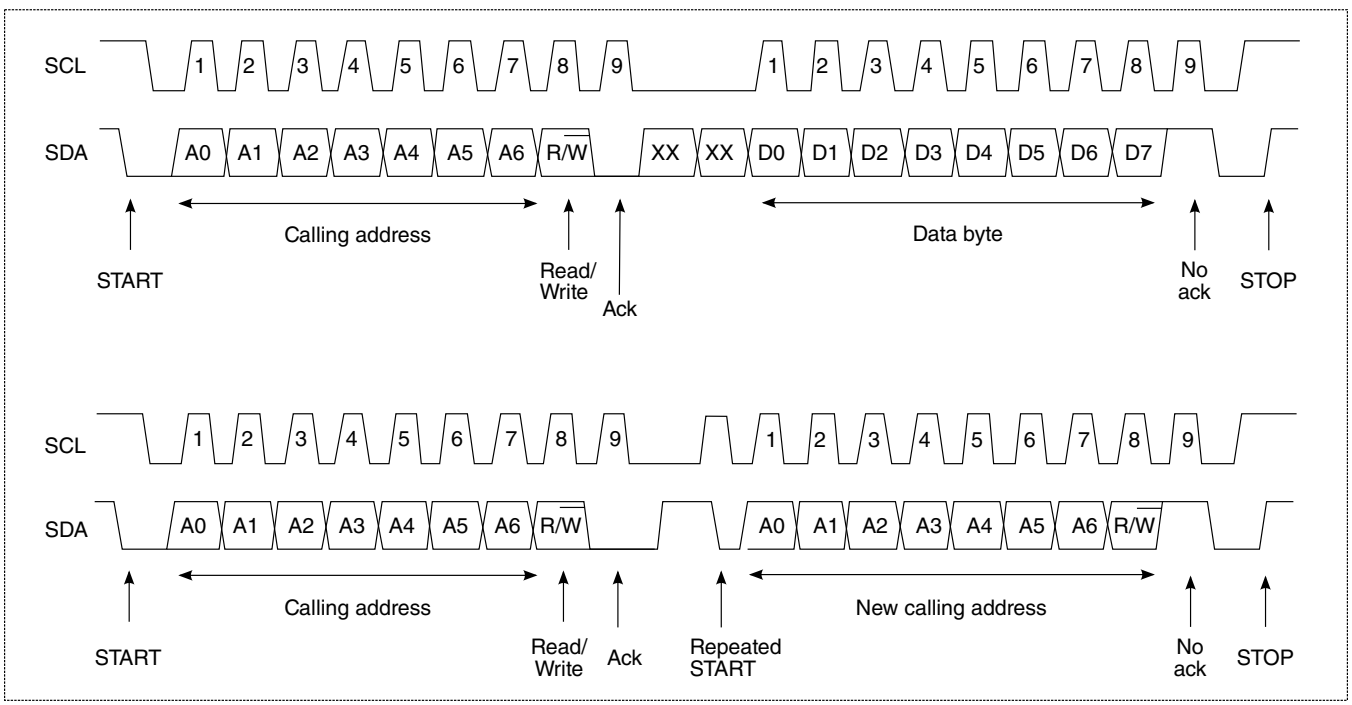


Figure 13-2. I2C Transaction Protocol

13.5.2.2 Definitions

This section defines several important terms presented in Figure 13-2.

Table 13-4. I²C Definitions

Term	Definition
START	A START condition, as defined in Definition: I²C Conditions
STOP	A STOP condition, as defined in Definition: I²C Conditions
Calling (slave) address	A seven-bit address used to identify a slave on the I²C bus. The requirements for specifying this address are presented in I²C Calling Address Requirements.
Read/write (R/W_B)	A bit that specifies the direction of the data transfer to the slave as follows: • 0 = The data is being transferred from the master to the slave ("write") • 1 = The data is being transferred from the slave to the master ("read")
Acknowledge	A bit that specifies the acknowledgement of a calling address, indicated by pulling SDA low.

13.5.2.3 I²C Calling Address Requirements

The calling addresses of the devices used on an I²C network are subject to the following requirements:

- Each slave must have a unique calling address.
- A master must not transmit a calling address that is the same as its own slave address.

13.5.2.4 High-Level Protocol Steps

The I²C protocol conceptually supports two types of transfers, which are illustrated in Figure 13-2. The significant steps in these transfers are presented in the following table.

Details of each of these steps are presented in subsequent sections.

Table 13-5. I²C High-Level Protocol Steps

Standard Transfer	Repeated START Transfer
1. START condition	1. START condition
2. Slave target or general call address transmission	2. Slave target or general call address transmission
3. Data transfer	3. Data transfer
4. STOP condition	4. Repeated START condition
5. (repeat Steps 1-4)	5. (repeat Steps 2-4 as needed)
	6. STOP condition.
	7. (repeat Steps 1-7)

13.5.2.5 START Condition

A master on the I^2C bus initiates a data transfer by sending a START condition on the I^2C bus when the bus is not engaged (both SDA and SCL are high).

On this device, the START condition is sent by setting I2CCR[MSTA]. (For more information about I2CCR[MSTA], see I2C control register (I2C_I2CCR).)

13.5.2.6 Slave Address Transmission

The master transmits the slave address immediately after the START condition (see START Condition). The process of slave address transmission is presented in Table 13-6.

Table 13-6. Slave Address Transmission Process

Step	Action
1	The master transmits the seven-bit slave address.
2	The master transmits the R/W_B bit.
3	Each slave examines the transmitted address and compares it to its own. If the addresses match, the slave device returns the acknowledge bit on the ninth SCL clock cycle.
4	The master waits for the acknowledge bit and determines the next step as follows: • The acknowledge bit is set: The master must generate a STOP condition or a repeated START condition. • The acknowledge bit is cleared: The master must wait for SCL to return to logic zero.

13.5.2.7 General Call (Broadcast) Addressing

The master may also initiate a general call (broadcast) command by transmitting a slave address of 0x00. In this case, the second byte of the broadcast message is the master address.

This device will not check the R/W_B bit in a broadcast address. Because the second byte is automatically acknowledged by hardware, the receiver device software must verify that the broadcast message is intended for itself by reading the second byte of the message. If the master address is for another receiver device and the third byte is a write command, software can ignore the third byte during the broadcast. If the master address is for another receiver device and the third byte is a read command, software must write 0xFF to I2CDR with I2CCR[TXAK] = 1, so that it does not interfere with the data written from the addressed device.

This device responds to a general call (broadcast) command if I2CCR[BCST] is set.

13.5.2.8 Data Transmission

A data transfer session has the following characteristics:

- Can transmit one or more bytes of data.
- Awakens all slaves.
- Proceeds on a byte-by-byte basis in the direction specified by the R/W_B bit sent by the calling master.

The transmitted data is subject to the following requirements:

- Each data byte must consist of 8 bits.
- Data bits can be changed only while SCL is low and must be held stable while SCL is high.
- One data bit is transmitted during one SCL clock pulse.
- The most significant bit (msb) must be transmitted first.
- Each data byte must be followed by an acknowledge bit on the ninth SCL clock pulse.

If the slave receiver does not acknowledge the master, the SDA line must be left high by the slave. The master can then generate a stop condition to abort the data transfer or a START condition (repeated START) to begin a new calling.

If the master receiver does not acknowledge the slave transmitter after a byte of transmission, the slave interprets that the end-of-data has been reached. Then the slave releases the SDA line for the master to generate a STOP or a START condition.

13.5.2.9 STOP Condition

A master on the I^2C bus can terminate a data transfer by sending a STOP condition. It can do so even if the slave has sent an acknowledge bit. In this case, the slave must release the I^2C bus.

On this device, the STOP condition is sent by clearing I2CCR[MSTA]. (For more information about I2CCR[MSTA], see I2C control register (I2C_I2CCR).)

A master is not required to send a STOP condition at the end of every transfer. For more information, see Repeated START Condition.

13.5.2.10 Repeated START Condition

The I^2C protocol also supports a repeated START condition, which can be generated without a preceding STOP condition. A master device can use this condition to communicate with another slave or with the same slave in a different mode without releasing the bus.

This condition is illustrated in the second timing diagram of Figure 13-2.

13.5.3 Protocol Implementation Details

This section provides details of how aspects of the I^2C protocol are implemented in this device. The following sections are included:

- Transaction Monitoring
- Control Transfer

13.5.3.1 Transaction Monitoring

The different conditions of the I^2C data transactions (see Transactions) are monitored as follows:

- START conditions are detected when SDA falls while SCL is high.
- STOP conditions are detected when SDA rises while SCL is high.
- Data transfers in progress are canceled when a STOP condition is detected or if there is a slave address mismatch. Cancellation of data transactions resets the clock module.
- The bus is detected to be busy upon the detection of a START condition, and idle upon the detection of a STOP condition.

13.5.3.2 Control Transfer

The I^2C module contains logic that controls the output to the serial data (SDA) and serial clock (SCL) lines of the I^2C.

The SCL output is driven low as determined by the internal clock generated in the clock module. The SDA output can only change at the midpoint of a low cycle of the SCL, unless it is performing a START, STOP, or repeated START condition. Otherwise, the SDA output is held constant.

Table 13-7 presents the behavior of the SCL and SDA signals under the various protocol conditions.

Table 13-7. SDA and SCL Signal Behavior

Mode	Conditions When SDA Is Driven Low	Conditions When SCL Corresponds to the Internal SCL Signal
Master	Data bit (transmission)	Bus owner
	Acknowledge bit (receive)	Lost arbitration
	START condition	START condition
	STOP condition	STOP condition
	Repeated START condition	Repeated START condition begin
		Repeated START condition end
Slave	Acknowledging address match	Address cycle
	Data bit (transmit)	Transmit cycle
	Acknowledge bit (receive)	Acknowledge cycle

13.5.4 Bus Arbitration

This section covers the following topics related to bus arbitration:

- Bus Arbitration Overview
- Loss of Arbitration
- Module Startup During a Data Transfer

13.5.4.1 Bus Arbitration Overview

If two or more masters simultaneously try to control the bus, each master's clock synchronization procedure (including the I^2C module) determines the bus clock.

The low part of the period is equal to the longest clock low period and the high part of the period is equal to the shortest one among the masters.

13.5.4.2 Loss of Arbitration

A bus master loses arbitration if it transmits a logic 1 on SDA while another master transmits a logic 0. In this case, the losing master performs the following tasks:

1. Switches to slave-receive mode.

2. Stops driving the SDA line without generating a STOP condition.
3. Sets I2CSR[MAL] to indicate the loss of arbitration.
4. Services the transaction if it is directed to itself.

13.5.4.3 Module Startup During a Data Transfer

Table 13-8 presents the behavior of the I^2C module if it is enabled in the middle of an ongoing byte transfer.

Table 13-8. Module Behavior at Startup During a Data Transfer

Mode	Behavior
Slave	The I^2C module ignores the current transfer on the bus and starts operating whenever a subsequent START condition is detected.
Master	The I^2C module cannot tell whether the bus is busy; therefore, if a START condition is initiated, the current bus cycle can be corrupted. This ultimately results in the current bus master of the I^2C bus losing arbitration, after which bus operations return to normal.

13.5.5 Clock Behavior

This section covers the following topics of SCL synchronization:

- SCL Synchronization
- Clock Stretching
- Handshaking

13.5.5.1 SCL Synchronization

Due to the wired-AND logic on the SCL line, a high-to-low transition on the SCL line affects all devices connected on the bus.

The devices begin counting their low period when the master drives the SCL line low. After a device has driven SCL low, it holds the SCL line low until the clock high state is reached. However, the change of low-to-high in a device clock may not change the state of the SCL line if another device is still within its low period. Therefore, the synchronized clock signal, SCL, is held low by the device with the longest low period. Devices with shorter low periods enter a high wait state during this time. When all devices concerned have counted off their low period, the synchronized SCL line is

released and pulled high. Then there is no difference between the devices' clocks and the state of the SCL line, and all the devices begin counting their high periods. The first device to complete its high period pulls the SCL line low again.

13.5.5.2 Clock Stretching

Slaves can use the clock synchronization mechanism to slow down the transfer bit rate.

After the master has driven the SCL line low, the slave can drive SCL low for the required period and then release it. If the slave SCL low period is greater than the master SCL low period, then the resulting SCL bus signal low period is stretched.

13.5.5.3 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfer.

Slave devices can hold SCL low after completion of a 1-byte transfer (9 bits). In such cases, the mechanism halts the bus clock and forces the master clock into wait states until the slave releases the SCL line.

13.5.6 Filtering of SCL and SDA Lines

This section covers the following topics:

- Filtering of SCL and SDA Lines-Overview
- Sample Rate Control

13.5.6.1 Filtering of SCL and SDA Lines-Overview

The SCL and SDA inputs are filtered to eliminate noise.

Three consecutive samples of the SCL and SDA lines are compared to a pre-determined sampling rate. If they are all high, the output of the filter is high. If they are all low, the output is low. If they are any combination of highs and lows, the output is whatever the value of the line was in the previous clock cycle.

13.5.6.2 Sample Rate Control

The sampling rate is controlled by the value stored in I2CDFSRR (as described in I2C digital filter sampling rate register (I2C_I2CDFSRR)). The duration of the sampling cycle is controlled by a down counter. This allows a software write to I2CDFSRR to control the filtered sampling rate.

13.6 I²C Initialization/Application Information

This section discusses the following topics related to I²C initialization and application:

- Recommended Interrupt Service Flow
- General Programming Guidelines (for Both Master and Slave Mode)
- Programming Guidelines Specific to Master Mode
- Programming Guidelines Specific to Slave Mode

13.6.1 Recommended Interrupt Service Flow

Figure 13-3shows a flowchart for the recommended I²C interrupt service routine.

Deviation from the flowchart may result in unpredictable I²C bus behavior. Although the flowchart does not explicitly show the synchronization after every I2C register access, it is recommended that a synchronizing instruction follow each I²C register read or write to guarantee in-order instruction execution.

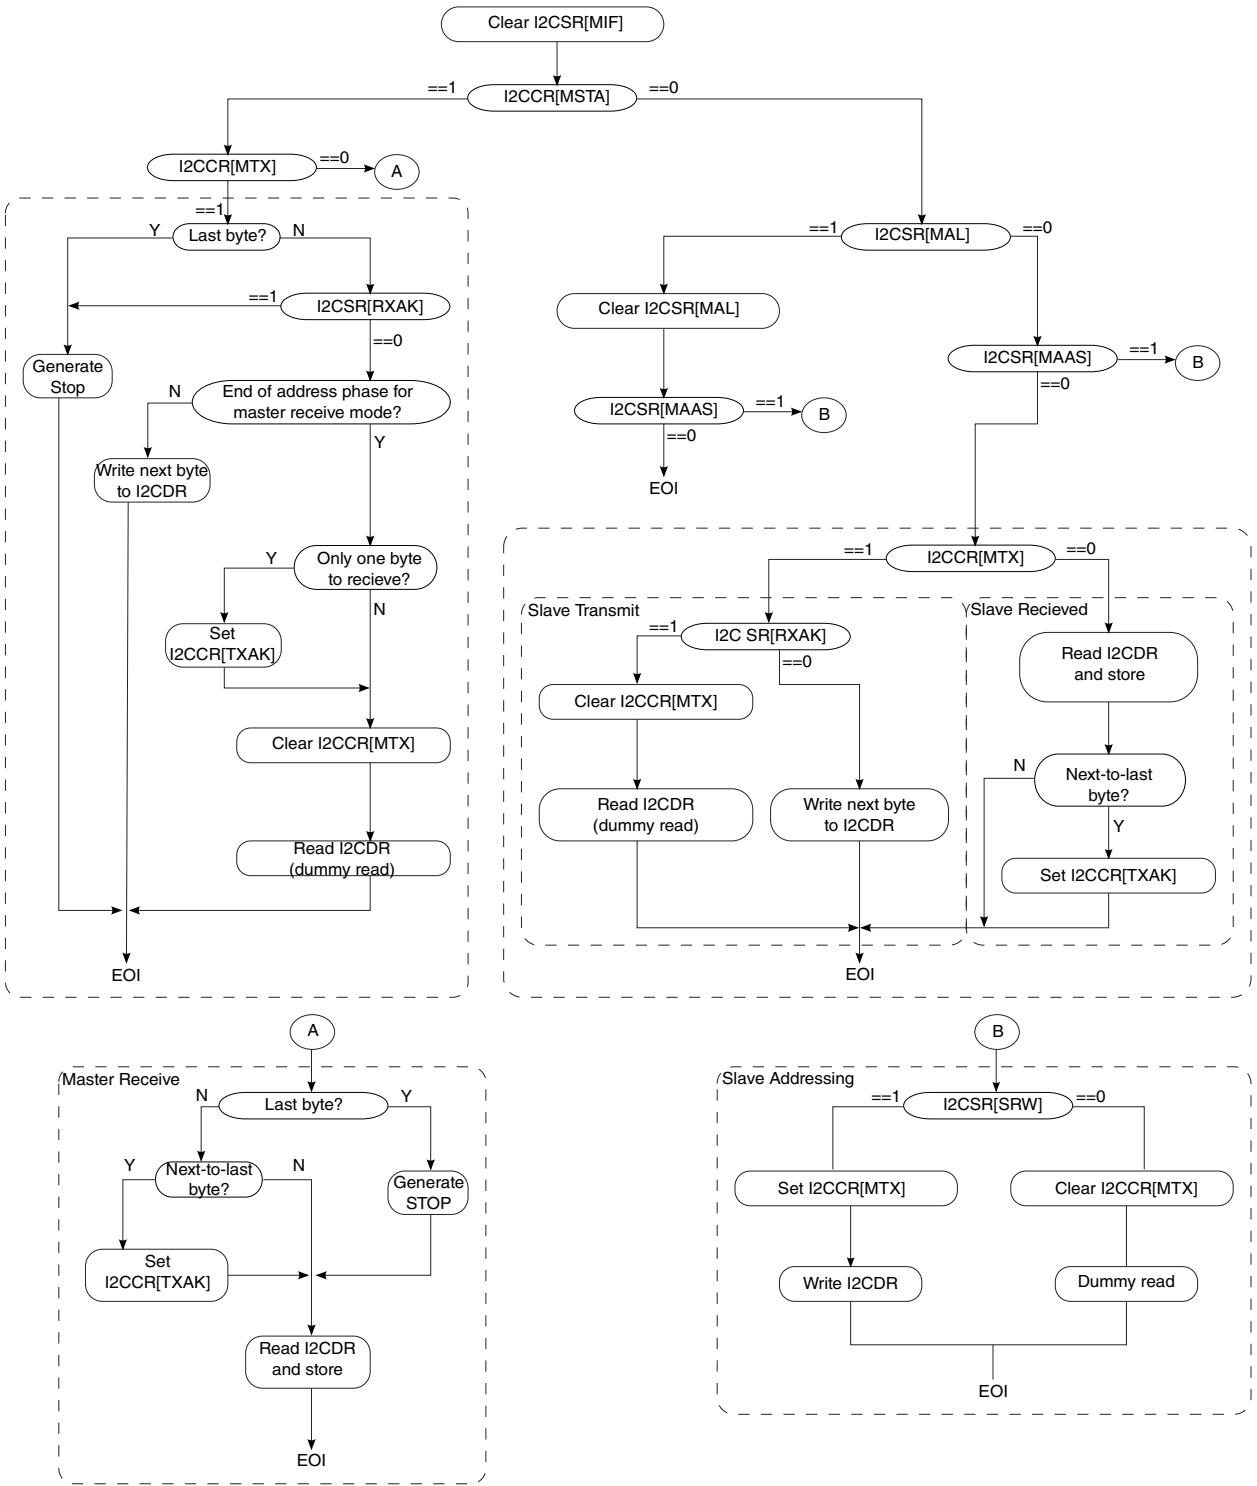

Figure 13-3. Recommended I²C Interrupt Service Routine Flowchart

13.6.2 General Programming Guidelines (for Both Master and Slave Mode)

This section provides programming guidelines recommended for the I^2C module in both master and slave mode. It describes the following procedures and processes:

- Initializing the Module
- Software Response After a Transfer
- Generating SCL when SDA is Low

NOTE

Illegal or irregular bus activity: The I^2C module does not guarantee its recovery from all illegal I^2C bus activity. Additionally, a malfunctioning device may hold the bus captive. A good programming practice is for software to rely on a watchdog timer to help recover from I^2C bus hangs. The recovery routine should also handle the case when the status bits returned after an interrupt are not consistent with what was expected due to illegal I^2C bus protocol behavior.

13.6.2.1 Initializing the Module

The following sequence initializes the I^2C unit:

1. Program I2CFDR[FDR] with the appropriate ratio for the desired SCL frequency. (For more information about the I2CFDR[FDR], see I2C frequency divider register (I2C_I2CFDR).)
2. Update I2CADR to define the slave address for this device. (For more information about I2CADR fields, see I2C address register (I2C_I2CADR).)
3. Modify I2CCR to select master/slave mode, transmit/receive mode, and interrupt-enable or disable; set I2CCR[MEN] to enable the I^2C module. (For more information about I2CCR fields, see I2C control register (I2C_I2CCR).)

13.6.2.2 Software Response After a Transfer

Transmission or reception of a byte automatically sets the data transferring bit (I2CSR[MCF]), which indicates that one byte has been transferred.

If the interrupt function is enabled during the initialization sequence (I2CCR[MIEN] is set), the I^2C interrupt bit (I2CSR[MIF]) is also set and an interrupt is generated to the PIC. In the interrupt handler, software must take the following steps:

1. Clear I2CSR[MIF].
2. Read the contents of the I^2C data register (I2CDR) in receive mode or write to I2CDR in transmit mode. Note that this access to I2CDR causes I2CSR[MCF] to be cleared automatically. See Recommended Interrupt Service Flow.

Note the programming guidelines for the following conditions:

- An interrupt at the end of the address cycle-When an interrupt occurs at the end of the address cycle, the master remains in transmit mode. If master receive mode is required, I2CCR[MTX] must be toggled at this stage. See Figure 13-3.
- Monitoring I2CSR[MIF] when the interrupt function is disabled-If the interrupt function is disabled, software can service the I2CDR in the main program by monitoring I2CSR[MIF]. In this case, I2CSR[MIF] must be polled rather than I2CSR[MCF] because MCF behaves differently when arbitration is lost. Note that interrupt or other bus conditions may be detected before the I^2C signals have time to settle. Thus, when polling I2CSR[MIF] (or any other I2CSR bits), software delays may be needed in order to give the I^2C signals sufficient time to settle.
- Slave-mode addressing-During slave-mode addressing, when I2CSR[MAAS] is set, I2CSR[SRW] should be read to determine the direction of the subsequent transfer, and I2CCR[MTX] should be programmed accordingly.
- Slave-mode data transfers-For slave-mode data transfers (MAAS is cleared), I2CSR[SRW] is not valid, and I2CCR[MTX] must be read to determine the direction of the current transfer. See Figure 13-3 for more details.

13.6.2.3 Generating SCL when SDA is Low

When a system reset does not cause all I^2C devices to be reset, it is sometimes necessary to force the I^2C module to become the I^2C bus master out of reset and drive SCL (even though SDA may already be driven, which indicates the bus is busy). Thus, SDA can be driven low by another I^2C device while this I^2C module is coming out of reset and will stay low indefinitely.

The following procedure can be used to force this I^2C module to generate SCL so that the device driving SDA can finish its transaction:

1. Disable the I^2C module (I2CCR[MEN] = 0) and change to master mode (I2CCR[MSTA] = 1) by programming the value 0x20 into I2CCR.

2. Re-enable the I^2C module (I2CCR[MEN] = 1) by programming the value 0xA0 into I2CCR.
3. Read I2CDR.
4. Return the I^2C module to slave mode (I2CCR[MSTA] = 0) by programming the value 0x80 into I2CCR.

13.6.3 Programming Guidelines Specific to Master Mode

This section includes the following programming guidelines specific to master mode:

- Generating START
- Generating STOP
- Generating Repeated START
- Loss of Arbitration and Forcing Slave Mode

13.6.3.1 Generating START

After initialization, the following sequence can be used to generate START:

1. If the device is connected to a multimaster I^2C system, test the state of I2CSR[MBB] to check whether the serial bus is available (I2CSR[MBB] = 0) before switching to master mode.
2. Select master mode (set I2CCR[MSTA]) to transmit serial data and select transmit mode (set I2CCR[MTX]) for the address cycle.
3. Write the slave address being called into I2CDR. The data written to I2CDR[0-6] comprises the slave calling address. I2CCR[MTX] indicates the direction of transfer (transmit/receive) required from the slave.

NOTE

The scenario above assumes that the I^2C interrupt bit (I2CSR[MIF]) is cleared. If MIF is set at any time, an I^2C interrupt is generated (if interrupt reporting is enabled with I2CCR[MIEN] =1).

NOTE

The interrupts for I^2C1 and I^2C2 are combined into a single interrupt to the PIC; similarly, interrupts for I^2C3 and I^2C4 are combined into a single interrupt to the PIC.

13.6.3.2 Generating STOP

A data transfer ends with a STOP condition generated by the master device.

A master transmitter generates a STOP condition after all the data has been transmitted. When the I^2C module is acting as the master transmitter, and all the data has been transmitted (that is, after last byte to be transmitted has been written to I2CDR), software clears I2CCR[MSTA] to generate a STOP condition.

When the I^2C module is acting as the master receiver, the master indicates the termination of the transfer by not acknowledging the final byte and by generating a STOP condition. For a multiple byte transfer before reading the next-to-last byte in I2CDR, software sets I2CCR[TXAK], then software reads the next-to-last byte in I2CDR, which causes the master receiver to not acknowledge the next transfer and to automatically generate a STOP at the conclusion of the next transfer. For single-byte transfers, at the conclusion of the address phase, software should set I2CCR[TXAK] and clear I2CCR[MTX], and then perform a dummy read to I2CDR. Prior to subsequent I^2C transactions, software should clear I2CCR[TXAK]. This can be performed when setting up the I2CCR for the next transfer.

13.6.3.3 Generating Repeated START

At the end of a data transfer, if the master wants to continue communicating on the bus, it can generate another START condition followed by another slave address without first generating a STOP condition. This is accomplished by setting I2CCR[RSTA].

13.6.3.4 Loss of Arbitration and Forcing Slave Mode

When a master loses arbitration, the following conditions all occur:

- I2CSR[MAL] is set.
- I2CCR[MSTA] is cleared (changing the master to slave mode).
- An interrupt occurs (if enabled) at the falling edge of the ninth clock of this transfer.

Thus, the slave interrupt service routine should first test I2CSR[MAL] and software should clear it if it is set.

13.6.4 Programming Guidelines Specific to Slave Mode

This section includes the following programming guidelines specific to slave mode:

- Slave Mode Interrupt Service Routine
- Acknowledge Receipt During Transmission

13.6.4.1 Slave Mode Interrupt Service Routine

In the slave interrupt service routine, the slave should be tested as follows to determine whether a calling of its own address has been received:

If I2CSR[MAAS] is set, software should set the transmit/receive mode select bit (I2CCR[MTX]) according to the R/W command bit (I2CSR[SRW]). Writing to I2CCR clears MAAS automatically. MAAS is read as set only in the interrupt handler at the end of that address cycle in which an address match occurred; interrupts resulting from subsequent data transfers clear MAAS.

A data transfer can then be initiated by writing to I2CDR for slave transmits or dummy reading from I2CDR in slave-receive mode. The slave drives SCL low between byte transfers. SCL is released when the I2CDR is accessed in the required mode. See Figure 13-3.

13.6.4.2 Acknowledge Receipt During Transmission

In the slave transmitter routine, the received acknowledge bit (I2CSR[RXAK]) must be checked before the next byte of data is sent:

- If I2CSR[RXAK] is cleared, the master has acknowledged the previous data transfer and the next byte of data may be transmitted.
- If I2CSR[RXAK] is set, the master is signaling an end-of-data by not acknowledging the previous data transfer. Software running on the slave transmitter must do the following:
  a. Clear I2CCR[MTX] to switch the slave from transmitter to receiver mode.
  b. Perform a dummy read of I2CDR, which releases SCL so the master can generate a STOP condition.

In the slave receiver routine, the receiver transmit acknowledge bit (I2CCR[TXAK]) must be set after the next-to-last byte of data from I2CDR is read.

See Recommended Interrupt Service Flow.

Chapter 14
Enhanced Serial Peripheral Interface

14.1 Introduction

The enhanced serial peripheral interface (eSPI) allows the device to exchange data with peripheral devices such as EEPROMs, real-time clocks, A/D converters, and ISDN devices.

The eSPI is a full-duplex, synchronous, character-oriented channel that supports a simple interface (receive, transmit, clock and chip selects). The eSPI consists of transmitter and receiver sections, an independent baud-rate generator, and a control unit. The transmitter and receiver sections use the same clock, which is derived from the eSPI baud rate generator in master mode. During an eSPI transfer, data is sent and received simultaneously.

The eSPI receiver and transmitter each have a FIFO of 32 bytes, as shown below. When the eSPI is disabled in the eSPI mode register (SPMODE[EN] = 0), it consumes little power.

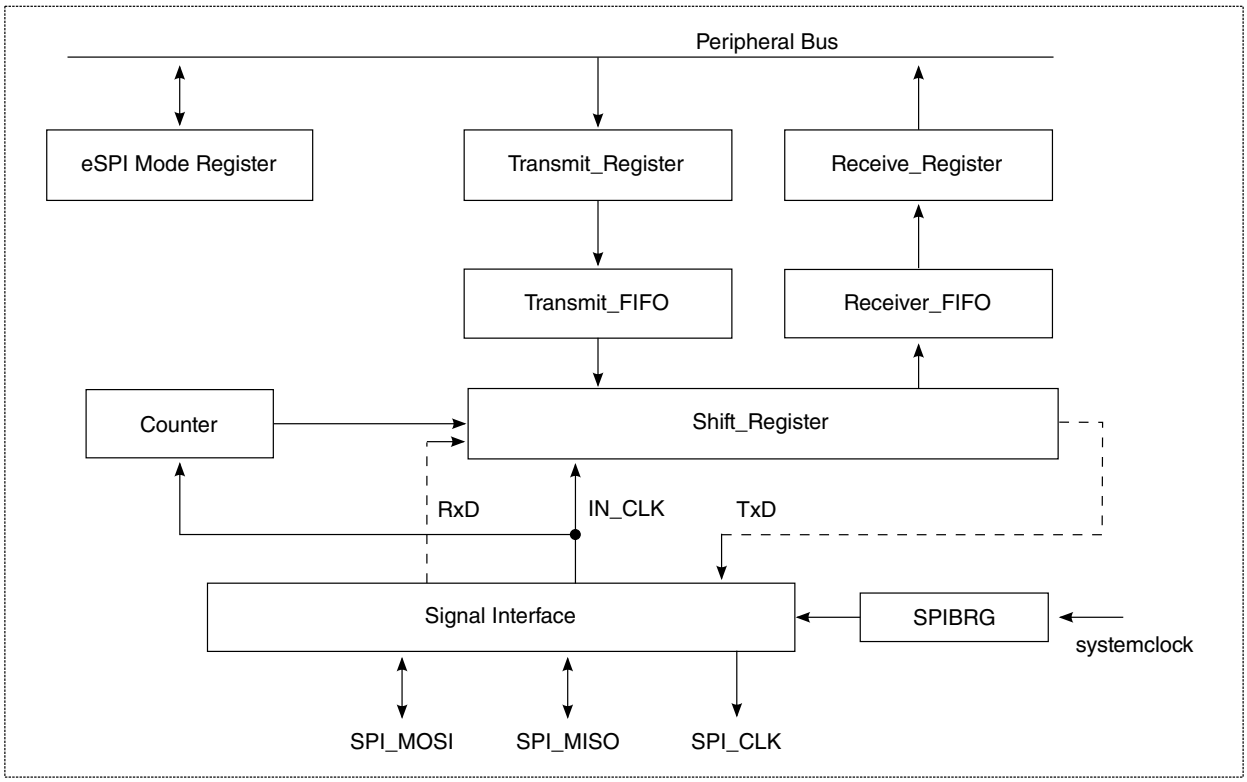

Figure 14-1. eSPI block diagram

14.1.1 Features

The major features of the eSPI are listed as follows:

- Interface contains SPI_MOSI, SPI_MISO, SPI_CLK, and 4 chip selects
- Supports eSPI master
- Supports RapidS^{TM} full clock cycle operation
- Full-duplex or half-duplex master operation
- Supports Winbond dual output read
- Command in transaction level-easier for accessing eSPI devices
- Works with a range from 4-bit to 16-bit data characters
- Supports back-to-back character transmission and reception
- Supports reverse data mode for 8/16 bits data characters
- Supports single-master environment
- Maximum clock rate possible is (platform clock rate/2)
- Independent programmable baud rate generator
- Programmable clock phase and polarity.
- Supports four different configurations per chip select
- Local loopback capability for testing

14.1.2 eSPI transmission and reception process

As the eSPI is a character-oriented communication unit, the core is responsible for packing and unpacking the receive and transmit frames.

A frame consists of all of the characters transmitted or received during a completed eSPI transmission session, from the first character written to the eSPI transmit FIFO access register (SPITF) register to the last character transmitted with the total number as indicated in the command written to the eSPI command register (ESPI_SPCOM).

The core receives data by reading the eSPI receive FIFO access register (SPIRF) when the RNE ("not empty") bit in the eSPI event register (SPIE) is set.

The core transmits data by writing it into the SPITF register. After the core writes the final character to SPITF it waits for DON bit in the SPIE register to be set indicating frame was fully transmitted. It might then write a new command to SPCOM register.

The eSPI sets the TNF ("not full") bit in SPIE register whenever its transmit FIFO is not full.

The eSPI core handshake protocol can be implemented by using a polling or interrupt mechanism. When using a polling mechanism, the core reads the SPIE in a predefined frequency and acts according to the value of the SPIE bits. The polling frequency depends on the eSPI serial channel frequency. When using the interrupt mechanism, setting either the TNF (not full) or RNE (not empty) bits of the SPIE causes an interrupt to the core. The core then reads the SPIE and acts appropriately.

14.1.3 Modes of operation

The eSPI can be programmed to work in a single master environment. This section describes eSPI master operation in a single-master configuration.

In master mode, the eSPI sends a message to the slave peripheral, which sends back a simultaneous reply. A single master with multiple slaves uses up to four chip select signals to selectively enable slaves, as shown below.

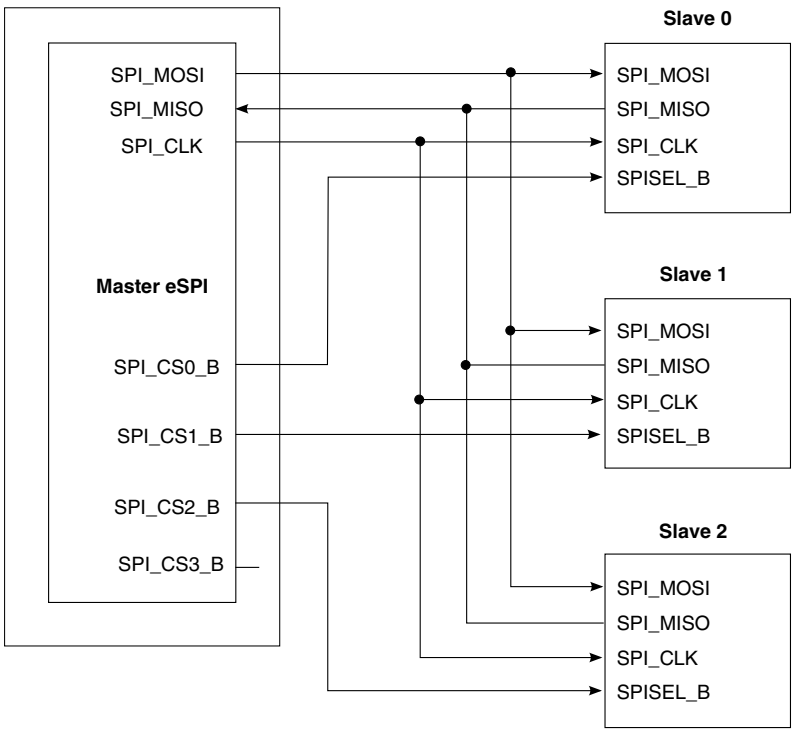

Figure 14-2. Single-master/multi-slave configuration

To start exchanging data, the core writes the data to be sent into the SPITF register. The eSPI then generates programmable clock pulses on SPI_CLK for each character. It shifts Tx data out on the "eSPI master-out slave-in" (SPI_MOSI) and Rx data in on the eSPI "master-in slave-out" (SPI_MISO) simultaneously. During the transmission process the core is responsible for supplying the data whenever the eSPI requests it to ensure smooth operation.

The maximum sustained data rate that the eSPI supports depends on the software latency. However, the eSPI can transfer a single character at very high rates— a maximum (up to system clock / 2) specified by the device data sheet (where system clock is defined as platform clock divided by 2). Gaps might be inserted between multiple frames.

14.2 External signal descriptions

The eSPI interface consists of transmit, receive, clock and chip selects.

The following table provides an overview of eSPI signal properties.

Table 14-1. Signal properties

Name	Function
SPI_MISO	Master input slave output
SPI_MOSI	Master output slave input or second master input slave output for Winbond dual output read.
SPI_CLK	Output serial clock connected to the other SPI_CLK.
SPI_CS_B [0:3]	eSPI slave select outputs

14.2.1 eSPI detailed signal descriptions

Table 14-2. ESPI detailed signal descriptions

Signal	I/O	Description	
SPI_MISO	I	Master input slave output	
		State meaning	Asserted-The data that has been received from the eSPI is high Negated-The data that has been received from the eSPI is low
		Timing	Assertion-According to the SPI_CLK assertion/negation/in the middle of phase (depends on the SPMODEx configuration register) Negation-According to the SPI_CLK assertion/negation/in the middle of phase (depends on the SPMODEx configuration register)
SPI_MOSI	I/O	Master output slave input or second master input slave output for Winbond dual output read	
		State meaning	Asserted-The data that has been transmitted from/to the eSPI is high Negated-The data that has been transmitted from/to the eSPI is low
		Timing	Assertion-According to the SPI_CLK assertion/negation/in the middle of phase (depends on the SPMODEx configuration register). Negation-According to the SPI_CLK assertion/negation/in the middle of phase (depends on the SPMODEx configuration register).
SPI_CLK	O	Serial clock out	
		State meaning	Assertion/negation-According to SPMODEx[PM,DIV16] register rate configuration
		Timing	Assertion/negation-During frame reception/transmission
SPI_CS_B [0:3]	O	eSPI slave select outputs	
		State meaning	Asserted- Slave 0, 1, 2, 3 is selected and master controls transmission/reception Negated-idle state
		Timing	Assertion-A predefined time before frame starts, during frame transmission/reception, a predefined time after frame ends Negation-When master is idle or controls another slave

The eSPI can be configured as a master in single master environment. The master eSPI generates the transfer clock SPI_CLK using the eSPI baud rate generator (BRG). The eSPI BRG takes as its input the platform clock divided by two.

SPI_CLK is a gated clock, active only during data transfers. Four combinations of SPI_CLK phase and polarity can be configured with the clock invert SPMODEx[CIx] and clock phase SPMODEx[CPx] register bits.

The eSPI master-in slave-out SPI_MISO signal acts as an input for master devices and as an output for slave devices. Conversely, the master-out slave-in SPI_MOSI signal is an output for master devices and an input for slave devices. However, it also acts as a second input for master devices and as a second output for slave devices when using Winbond dual output read.

SPI_CLK is the clock output signal that shifts received data in from SPI_MISO and transmitted data out to SPI_MOSI. eSPI masters must output a slave select signal to enable eSPI slave devices.

14.3 Enhanced serial peripheral interface (eSPI) memory map

The table below shows the memory mapped registers of the eSPI and their offsets. It lists the offset, name, and a cross-reference to the complete description of each register. Note that the full register address comprises CCSRBAR together with the SPI block base address and offset listed in the table below.

ESPI memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
11_0000	eSPI mode register (ESPI_SPMODE)	32	R/W	See section	14.3.1/793
11_0004	eSPI event register (ESPI_SPIE)	32	R/W	0020_0000h	14.3.2/795
11_0008	eSPI mask register (ESPI_SPIM)	32	R/W	0000_0000h	14.3.3/797
11_000C	eSPI command register (ESPI_SPCOM)	32	W	0000_0000h	14.3.4/799
11_0010	eSPI transmit FIFO access register (ESPI_SPITF)	32	W	0000_0000h	14.3.5/801
11_0014	eSPI receive FIFO access register (ESPI_SPIRF)	32	R	0000_0000h	14.3.6/803
11_0020	eSPI CS0 mode register (ESPI_SPMODE0)	32	R/W	0010_0000h	14.3.7/804
11_0024	eSPI CS1 mode register (ESPI_SPMODE1)	32	R/W	0010_0000h	14.3.8/806
11_0028	eSPI CS2 mode register (ESPI_SPMODE2)	32	R/W	0010_0000h	14.3.9/808
11_002C	eSPI CS3 mode register (ESPI_SPMODE3)	32	R/W	0010_0000h	14.3.10/ 810

14.3.1 eSPI mode register (ESPI_SPMODE)

The eSPI mode register (SPMODE) controls eSPI general operation mode.

Address: 11_0000h base + 0h offset = 11_0000h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

ESPI_SPMODE field descriptions

Field	Description
0 EN	Enable eSPI. Any bits in SPMODE must not change when EN is set. 0 The eSPI is disabled. The eSPI is in a idle state and consumes minimal power. The eSPI BRG is not functioning and the input clock is disabled. 1 The eSPI is enabled.
1 LOOP	Loop mode. Enables local loopback operation. 0 Normal operation. 1 Loopback mode. Used to test the eSPI controller internal functionality, the transmitter output is internally connected to the receiver input. The receiver and transmitter operate normally, except that received data is ignored.
2–12 -	This field is reserved. Reserved
13–15 HO_ADJ	Default setting for this bit is 011. 000 Output data is delayed by an extra 1 platform clock cycles 001 Output data is delayed by an extra 2 platform clock cycles 010 Output data is delayed by an extra 3 platform clock cycles 011 Output data is delayed by an extra 4 platform clock cycles 100 Output data is delayed by an extra 5 platform clock cycles 101 Output data is delayed by an extra 6 platform clock cycles 110 Output data is delayed by an extra 7 platform clock cycles 111 Output data is delayed by an extra 8 platform clock cycles

Table continues on the next page...

ESPI_SPMODE field descriptions (continued)

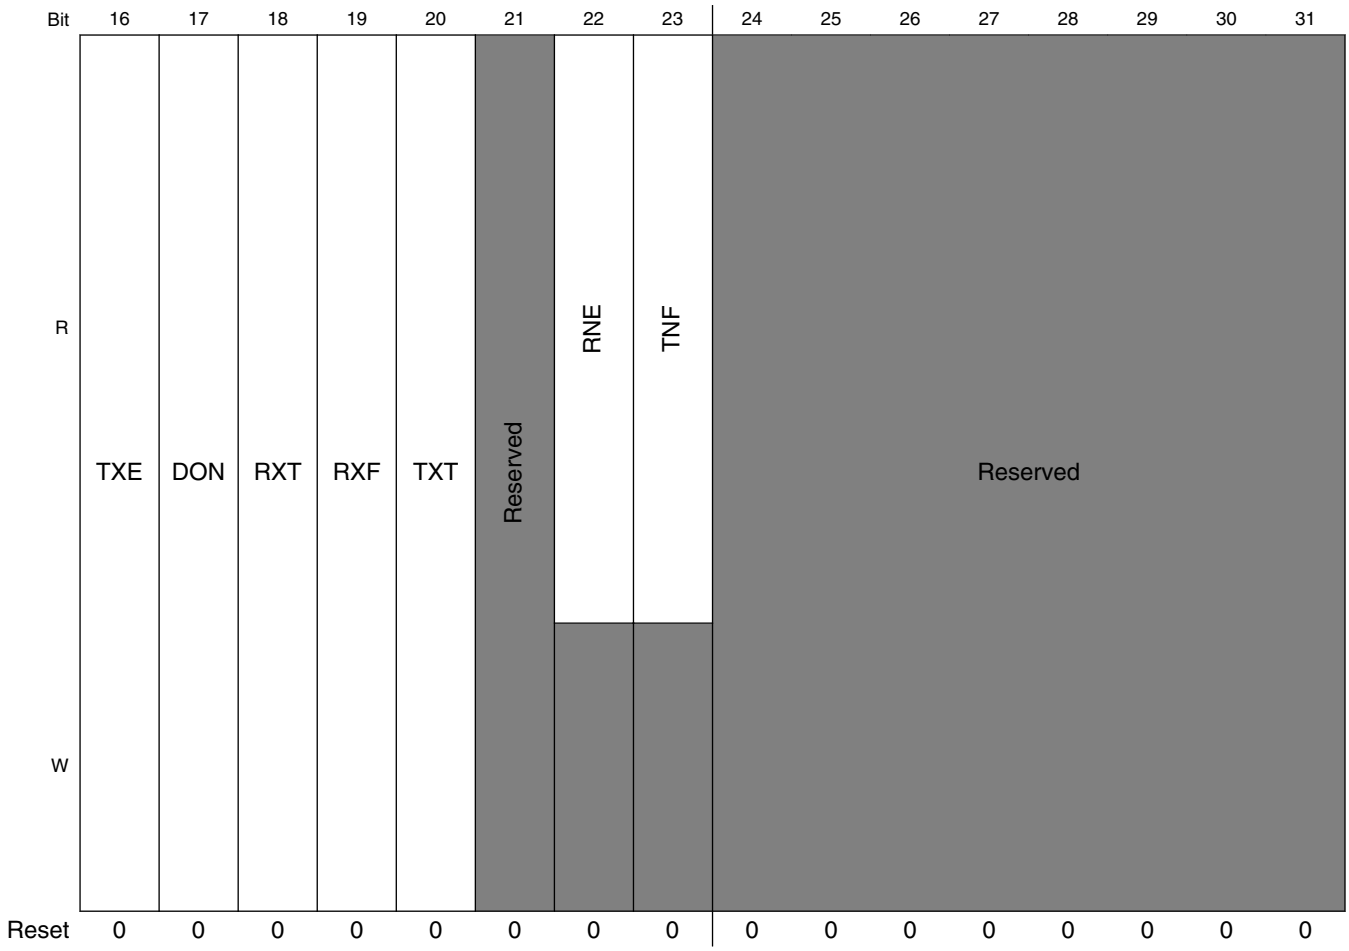
Field	Description
16–17 -	This field is reserved. Reserved
18–23 TXTHR	Tx FIFO threshold-if Tx FIFO has less than TXTHR bytes, an interrupt can be issued to the core. Valid values: 0-31
24–26 -	This field is reserved. Reserved
27–31 RXTHR	Rx FIFO threshold-if Rx FIFO has more than RXTHR bytes, an interrupt can be issued to the core. Valid values: 0-31

14.3.2 eSPI event register (ESPI_SPIE)

The eSPI event register (SPIE) generates interrupts and reports events recognized by the eSPI. When an event is recognized, the eSPI sets the corresponding SPIE bit. Clear SPIE bits by writing a 1-writing 0 has no effect. Setting a bit in the eSPI mask register (SPIM) enables interrupt and clearing a bit masks the corresponding interrupt. Unmasked SPIE bits must be cleared before the core clears internal interrupt requests. Bits RNE and TNF are status bits. Fields RXCNT and TXCNT hold Rx and Tx FIFOS' statuses. They are not cleared as a result of writing to SPIE.

Address: 11_0000h base + 4h offset = 11_0004h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	Reserved		RXCNT						Reserved		TXCNT					
W																
Reset	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0



ESPI_SPIE field descriptions

Field	Description
0–1 -	This field is reserved. Reserved, should be cleared.
2–7 RXCNT	The current number of full Rx FIFO bytes **NOTE:** For character lengths of 9 to 16 bits-each character occupies 2 bytes in Rx/Tx FIFO.
8–9 -	This field is reserved. Reserved, should be cleared.
10–15 TXCNT	The current number of free Tx FIFO bytes **NOTE:** For character lengths of 9 to 16 bits-each character occupies 2 bytes in Rx/Tx FIFO
16 TXE	Tx FIFO is empty
17 DON	Last character was transmitted. The last character was transmitted and a new command can be written for the next frame
18 RXT	Rx FIFO has more than RXTHR bytes, that is, at least RXTHR + 1 bytes
19 RXF	Rx FIFO is full

Table continues on the next page...

ESPI_SPIE field descriptions (continued)

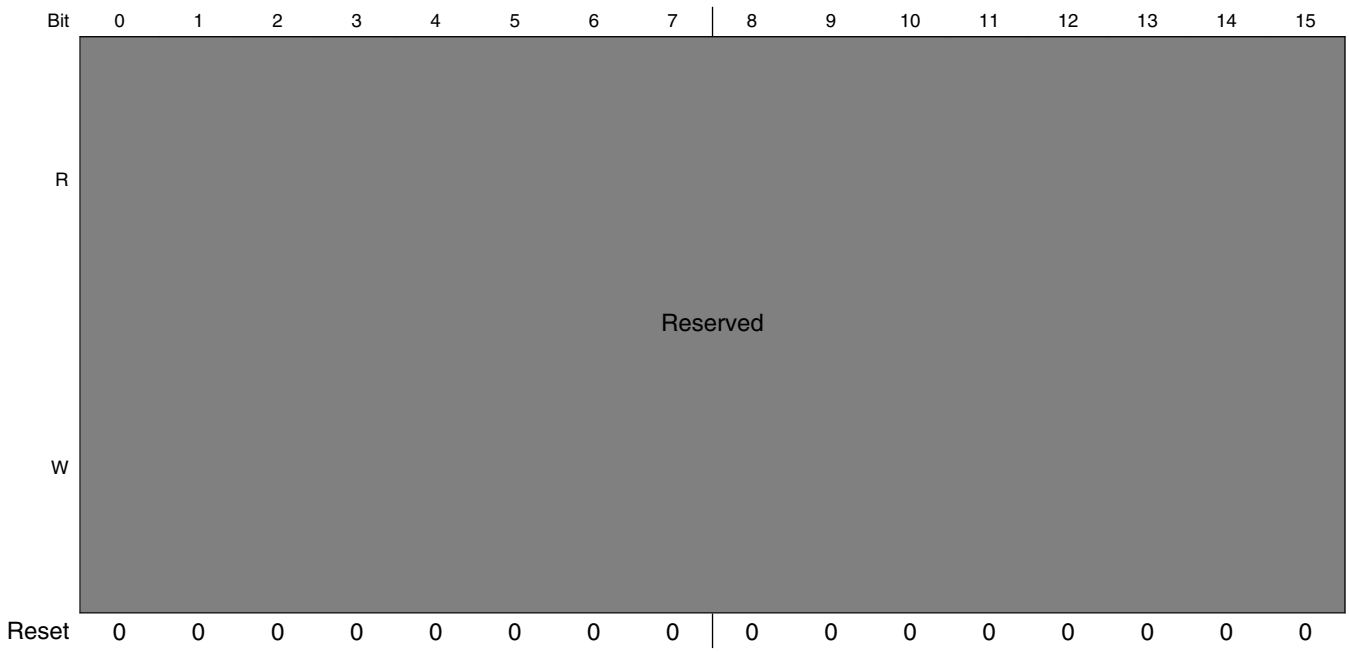
Field	Description
20 TXT	Tx FIFO has less than TXTHR bytes, that is, at most TXTHR - 1 bytes
21 -	This field is reserved. Reserved, should be cleared.
22 RNE	Not empty. Indicates that the Rx FIFO register contains a received character. 0 The Rx FIFO is empty 1 The Rx FIFO has a received character. The core can read the content of Rx FIFO through SPIRF.
23 TNF	Tx FIFO not full. 0 The transmitter FIFO is full. 1 The transmitter FIFO is not full.
24–31 -	This field is reserved. Reserved, should be cleared.

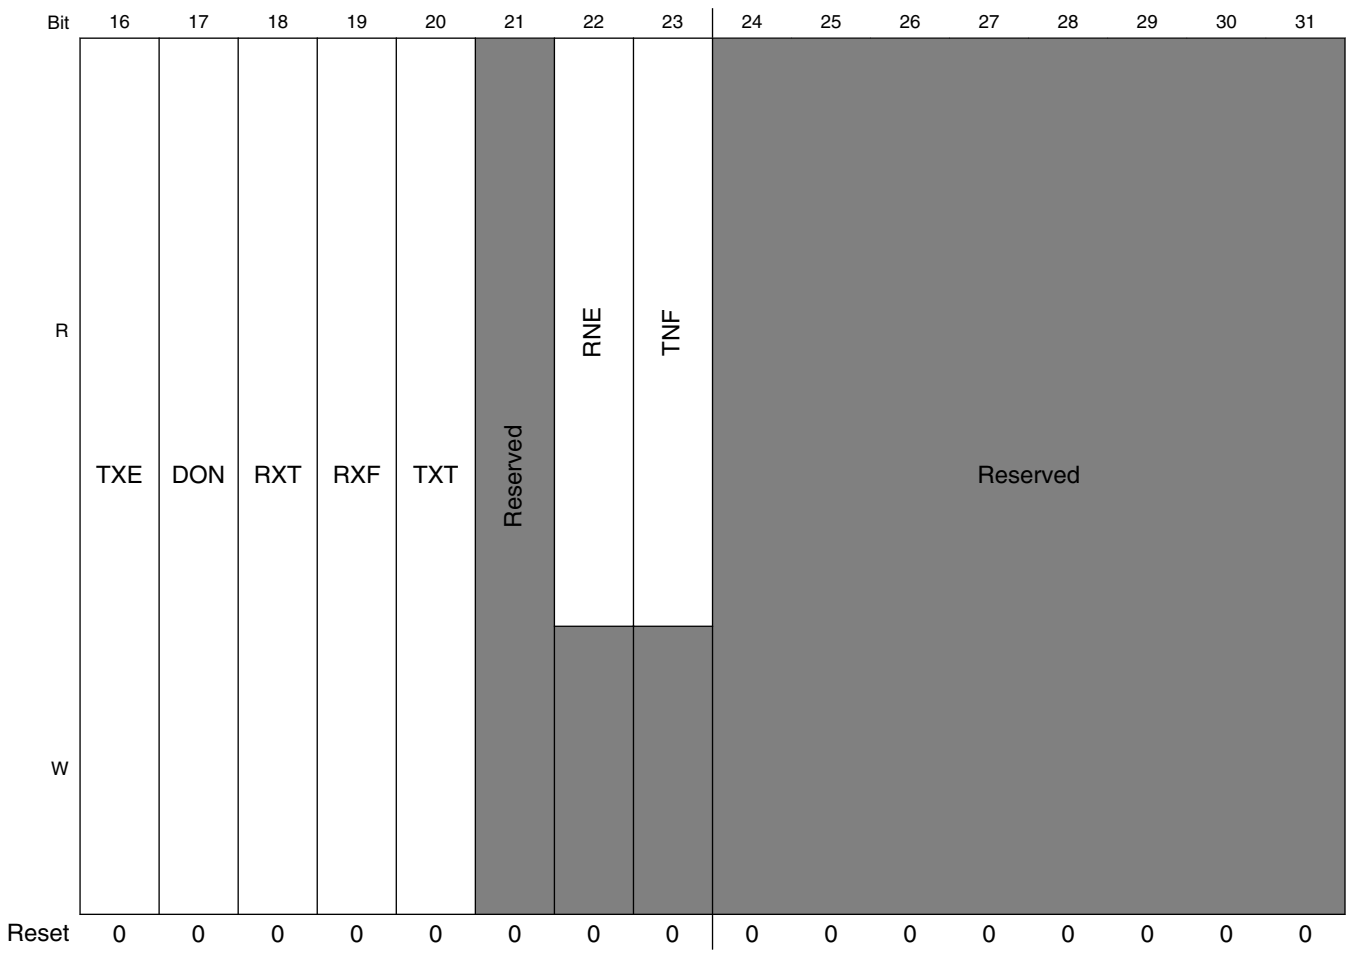
14.3.3 eSPI mask register (ESPI_SPIM)

The eSPI mask register (SPIM) enables/masks interrupts for events recognized by the eSPI. When an event is recognized, the eSPI sets the corresponding SPIE bit. Setting a bit in the eSPI mask register (SPIM) enables and clearing a bit masks the corresponding interrupt. Unmasked SPIE bits must be cleared before the core clears internal interrupt requests.

Bits RNE and TNF in SPIM are status bits. They are not cleared as a result of writing to SPIM.

Address: 11_0000h base + 8h offset = 11_0008h





ESPI_SPIM field descriptions

Field	Description
0–15 -	This field is reserved. Reserved, should be cleared.
16 TXE	Tx FIFO empty interrupt mask 0 TXE event will not cause eSPI Interrupt 1 TXE event will cause eSPI Interrupt
17 DON	Last character transmitted mask 0 DON event will not cause eSPI Interrupt 1 DON event will cause eSPI Interrupt
18 RXT	Rx threshold interrupt mask 0 RXT event will not cause eSPI Interrupt 1 RXT event will cause eSPI Interrupt
19 RXF	Rx FIFO full interrupt mask 0 RXF event will not cause eSPI Interrupt 1 RXF event will cause eSPI Interrupt
20 TXT	Tx threshold interrupt mask 0 TXT event will not cause eSPI Interrupt 1 TXT event will cause eSPI Interrupt
21 -	This field is reserved. Reserved, should be cleared.
22 RNE	Rx not empty interrupt mask 0 Not Empty event will not cause eSPI Interrupt 1 Not Empty event will cause eSPI Interrupt
23 TNF	Tx not full interrupt mask 0 Not full event will not cause eSPI Interrupt 1 Not full event will cause eSPI Interrupt
24–31 -	This field is reserved. Reserved, should be cleared.

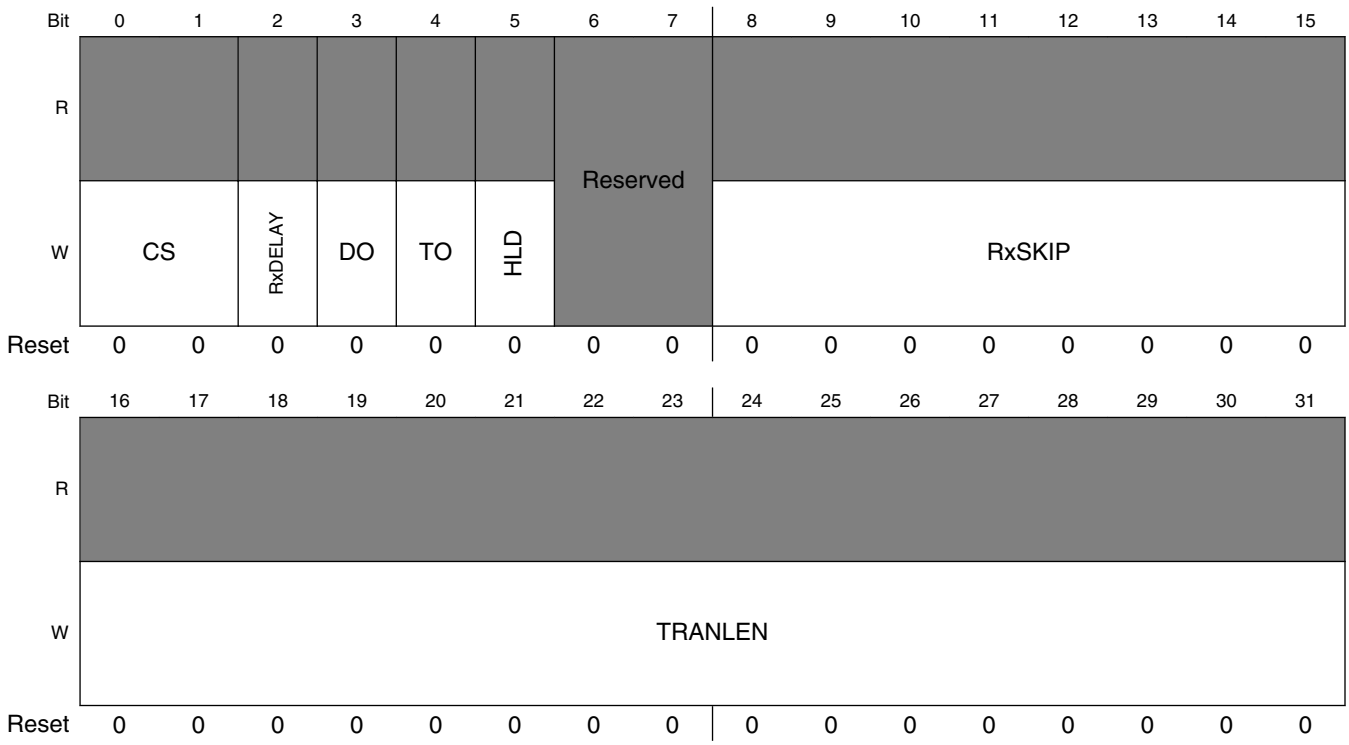
14.3.4 eSPI command register (ESPI_SPCOM)

The eSPI command register (SPCOM) is used by the host to supply information on the new frame.

After SPCOM has been written to initiate the first transaction after startup, commands can be executed only after SPIE[DON] is set. Otherwise they are ignored.

A transaction can be full duplex (regular eSPI) or half duplex. Half duplex can be used for example for write accesses to a flash (only transmit) or for a read access from a flash (first part is transmit without receive, while the second part is receive without transmit).

Address: 11_0000h base + Ch offset = 11_000Ch



ESPI_SPCOM field descriptions

Field	Description
0–1 CS	Chip select-chip select for which transaction is destined 00 SPI_CS0_B 01 SPI_CS1_B 10 SPI_CS2_B 11 SPI_CS3_B
2 RxDELAY	RxDelay 0 Normal eSPI operation 1 Rx data should be sampled a bit later than regular eSPI (used for full cycle operation such as with Atmel RapidS devices)
3 DO	This mode is useful only for character lengths of 4,6,8. DO and RapidS should not be set simultaneously. 0 Normal eSPI operation 1 Winbond dual output read-when eSPI master reads data 2 data bits are available (on MISO and MOSI)
4 TO	Transmit only 1 No reception is done for the frame (useful for write transactions) 0 Normal operation
5 HLD	HLD 0 Normal operation 1 Mask first generated SPI_CLK. Should be used only for RapidS mode0

Table continues on the next page...

ESPI_SPCOM field descriptions (continued)

Field	Description
6–7 -	This field is reserved. Reserved, should be cleared.
8–15 RxSKIP	If (RXSKIP ≠ 0)-Number of characters skipped for reception from frame start. Non-zero values of RxSKIP force the eSPI to half-duplex mode, and therefore this causes TRANLEN-RxSKIP characters to be skipped for transmission. RXSKIP is useful for reads of SPI flash memories where the first valid read data is received several characters after the transmission begins (after the eSPI has transmitted an instruction opcode and address). **NOTE:** If TO = 1, RxSKIP must be set to 0. **NOTE:** If RXSKIP = 0 and TO = 0, the eSPI changes to full duplex mode.
16–31 TRANLEN	Transaction length - (number of characters in the frame - 1)

14.3.5 eSPI transmit FIFO access register (ESPI_SPITF)

The 32-bit write-only eSPI transmit FIFO access register (SPITF) holds the characters to be written to the transmit FIFO. The number of bits in each character is specified by SPMODEx[LENx]. Each time SPIE[TNF] is set, the core can write more data to the SPITF register, if there is no error indication in the SPIE.

For character lengths of 4 to 8 bits, SPITF contains up to 4 characters (unless end of frame). The lsbs are in bits 7, 15, 23, and 31 of SPITF.

For character lengths of 9 to 16 bits, SPITF contains up to 2 characters (unless end of frame). For 16 bits with SPMODEx[REVx] = 1, the lsb is in bits 15 and 31 of SPITF. For other options, lsbs are in bits 7 and 23 while msbs are in bits (23-LENx) and (39-LENx) of SPITF.

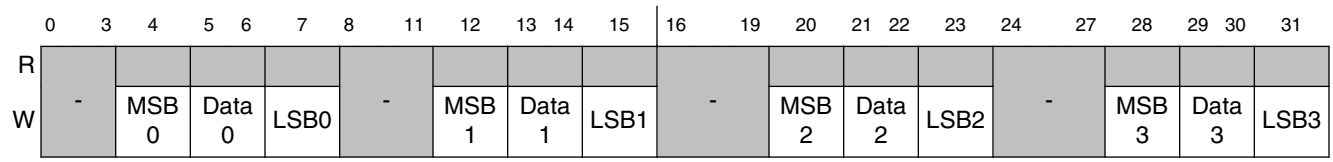
For example: REV = 0, LEN = 10 (0xA), SPITF[0-15] = 0xFB05-bitstream is: (lsb first) 11011111101 (msb last).

NOTE

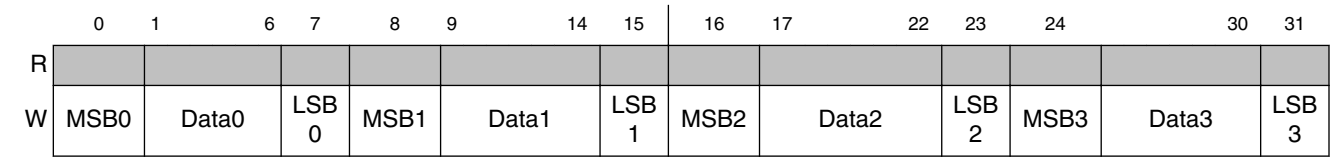
The user must write N bytes of SPITF ($1 \leq N \leq 4$) that do not exceed the number of free bytes in the transmit FIFO. It is valid for the user to write only 1 or 2 bytes of SPITF (at offset 0x010) if the user wishes to write fewer characters than the maximum supported by SPITF for the particular character length in use.

The following figures show examples of the contents of SPITF with various parameters set.

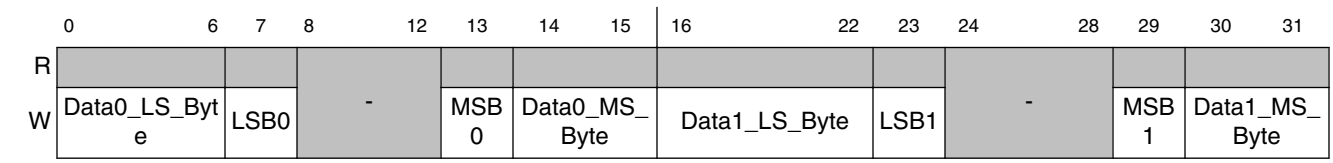
SPITF Example - SPMODEx[REVx]=0, SPMODEx[LENx]=3, LSB Sent First:



SPITF Example - SPMODEx[REVx]=x, SPMODEx[LENx]=7:



SPITF Example - SPMODEx[REVx]=0, SPMODEx[LENx]=10, LSB Sent First:



SPITF Example - SPMODEx[REVx]=1, SPMODEx[LENx]=15, MSB Sent First:

ESPI_SPITF field descriptions

Field	Description
0–31 DATA	Varies as parameters set

14.3.6 eSPI receive FIFO access register (ESPI_SPIRF)

The 32-bit read-only eSPI receive data register (SPIRF) is used to hold characters read from the receive FIFO. Each time SPIE[RNE] is set, the core can read the SPIRF register.

For character lengths of 4 to 8 bits, SPIRF contains up to 4 characters. The msbs are in bits 0, 8, 16, and 24. For character lengths of 9 to 16 bits, SPIRF contains up to 2 characters. The msbs are in bits 0 and 16. SPMODEx[REVx] does not affect the msb or lsb bit positions when reading the SPIRF register.

The user must read N bytes of SPIRF ($1 \le N \le 4$) that do not exceed the amount of data in the receive FIFO. The user can read less bytes than the amount of data in the receive FIFO. For example, a 1-byte read of SPIRF when configured for 8-bit characters with 4 characters of data in the receive FIFO results in the 3 unread characters shuffling down to the lower 24 bits of SPIRF in preparation for the following SPIRF read.

SPIRF Example - SPMODEx[LENx]=3

	0	1 2	3	4 7	8	9 10	11	12 15	16	17 18	19	20 23	24	25 26	27	28 31

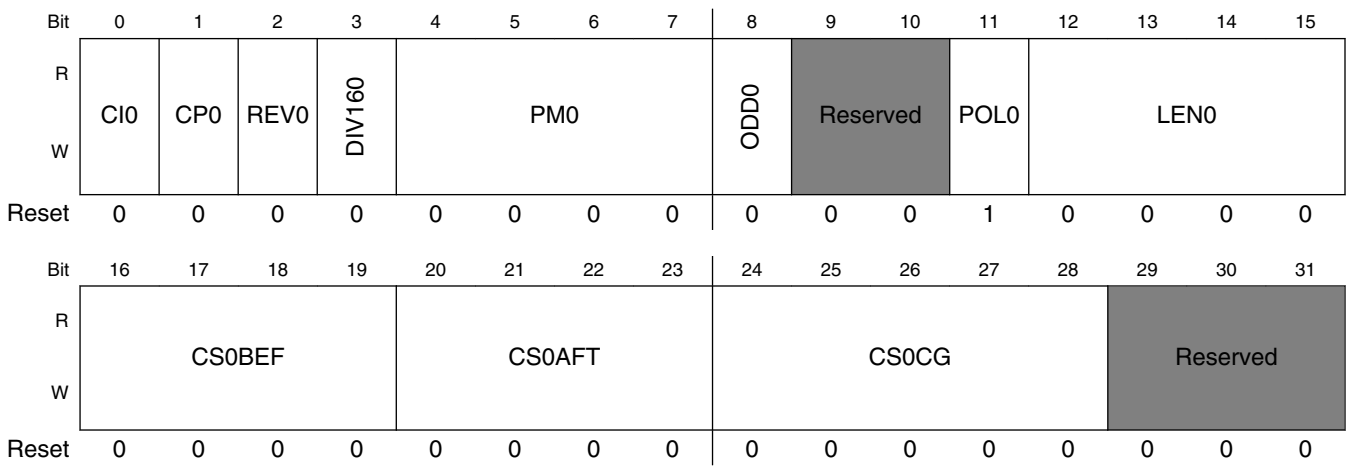
0–31 DATA	Varies as parameters set

14.3.7 eSPI CS0 mode register (ESPI_SPMODE0)

The eSPI CS0 mode register (SPMODE0) controls eSPI master operation with chip select 0.

Address: 11_0000h base + 20h offset = 11_0020h



ESPI_SPMODE0 field descriptions

Field	Description
0 CI0	Clock invert. Inverts eSPI clock polarity. See Figure 14-3 and Figure 14-4 for more information 0 The inactive state of SPI_CLK is low. 1 The inactive state of SPI_CLK is high.
1 CP0	Clock phase. Selects the transfer format. See Figure 14-3 and Figure 14-4 for more information. 0 SPI_CLK starts toggling at the middle of the data transfer. 1 SPI_CLK starts toggling at the beginning of the data transfer.
2 REV0	Reverse data mode. Determines the receive and transmit character bit order. 0 lsb of the character sent and received first 1 msb of the character sent and received first-for 8/16 bits data character only
3 DIV160	Divide by 16. Selects the clock source for the eSPI baud rate generator (eSPI BRG) when configured as an eSPI master. **NOTE:** System clock as used here is defined to be platform clock divided by 2.

Table continues on the next page...

ESPI_SPMODE0 field descriptions (continued)

Field	Description
	0 System clock is the input to the eSPI BRG. 1 System clock/16 is the input to the eSPI BRG.
4–7 PM0	Prescale modulus select. Specifies the divide ratio of the prescale divider in the eSPI clock generator. The eSPI baud rate generator clock source (either system clock or system clock divided by 16, depending on DIV16 bit) is divided by 2 x ([PM] + 1), a range from 2 to 32. For example, if the prescale modulus is set to PM=0x0011 and DIV16 is set, the SPI_CLK/system clock rate will be 16 x (2 x (0x0011 + 1)) = 128 **NOTE:** System clock as used here is defined to be platform clock divided by 2
8 ODD0	ODD0 0 Even division - 2 x (PM + 1) x (15 x DIV16 + 1) - 50% duty cycle 1 Odd division - (2 x PM + 1) x (15 x DIV16 + 1) (except for PM = 0 where it divides by 2 x (7 x DIV16 + 1)); duty cycle is (PM + 1) ÷ (2 x PM + 1) for DIV16 = 0; duty cycle is 50% for DIV16 = 1.
9–10 -	This field is reserved. Reserved
11 POL0	CS0 Polarity. 1 Asserted Low, Negated High 0 Asserted High, Negated Low.
12–15 LEN0	Character length in bits per character. Supports a range from 1-bit to 16-bit data characters.
16–19 CS0BEF	CS assertion time in bits before frame start (that is, before clock toggles) Example: CS0BEF = 0010 inserts 2 bits time gap between CS0 assertion to clock toggle
20–23 CS0AFT	CS assertion time in bits after frame end (that is, after clock finishes toggling) Example: CS0AFT = 0010 inserts 2 bits time gap between clock stop to CS0 negation
24–28 CS0CG	Clock gap insert gaps between transmitted frames according to this size (during this time, chip select is negated). Chip select is negated minimum time of 1 bit time. Example: CS0CG = 00101 inserts 5 + 1 = 6 bits time gap between every two consecutive frames
29–31 -	This field is reserved. Reserved

14.3.8 eSPI CS1 mode register (ESPI_SPMODE1)

The eSPI CS1 mode register (SPMODE1) controls eSPI master operation with chip select 1.

Address: 11_0000h base + 24h offset = 11_0024h

ESPI_SPMODE1 field descriptions

Field	Description
0 CI1	Clock invert. Inverts eSPI clock polarity. See Figure 14-3 and Figure 14-4 for more information 0 The inactive state of SPI_CLK is low. 1 The inactive state of SPI_CLK is high.
1 CP1	Clock phase. Selects the transfer format. See Figure 14-3 and Figure 14-4 for more information. 0 SPI_CLK starts toggling at the middle of the data transfer. 1 SPI_CLK starts toggling at the beginning of the data transfer.
2 REV1	Reverse data mode. Determines the receive and transmit character bit order. 0 lsb of the character sent and received first 1 msb of the character sent and received first-for 8/16 bits data character only
3 DIV161	Divide by 16. Selects the clock source for the eSPI baud rate generator (eSPI BRG) when configured as an eSPI master. **NOTE:** System clock as used here is defined to be platform clock divided by 2. 0 System clock is the input to the eSPI BRG. 1 System clock/16 is the input to the eSPI BRG.
4–7 PM1	Prescale modulus select. Specifies the divide ratio of the prescale divider in the eSPI clock generator. The eSPI baud rate generator clock source (either system clock or system clock divided by 16, depending on DIV16 bit) is divided by 2 x ([PM] + 1), a range from 2 to 32. For example, if the prescale modulus is set to PM = 0x0011 and DIV16 is set, the SPI_CLK/system clock rate will be 16 x (2 x (0x0011 + 1)) = 128 **NOTE:** System clock as used here is defined to be platform clock divided by 2.

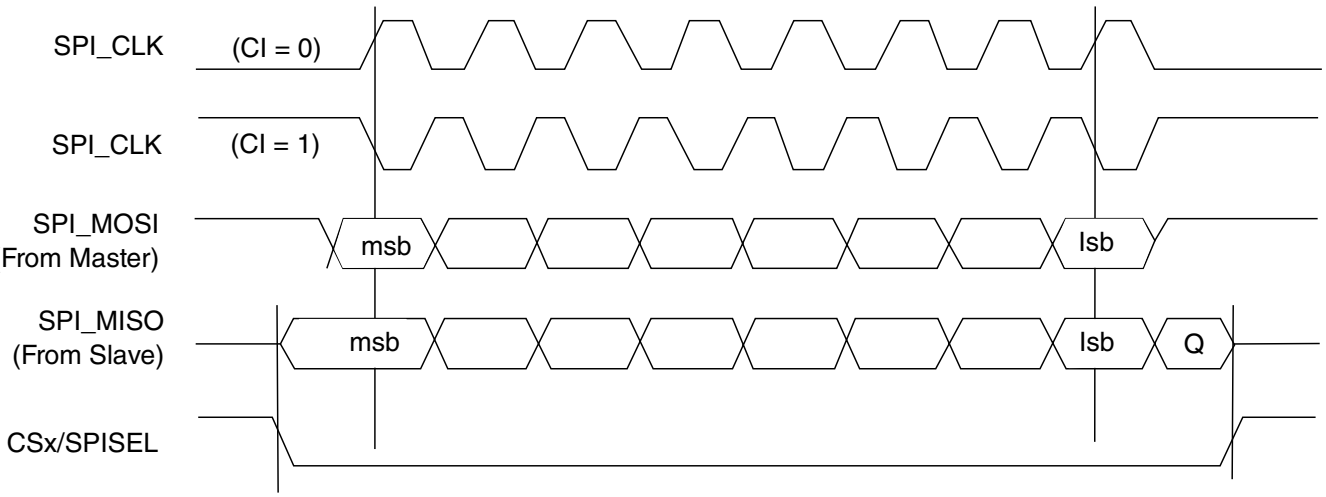
14.4 eSPI transfer formats

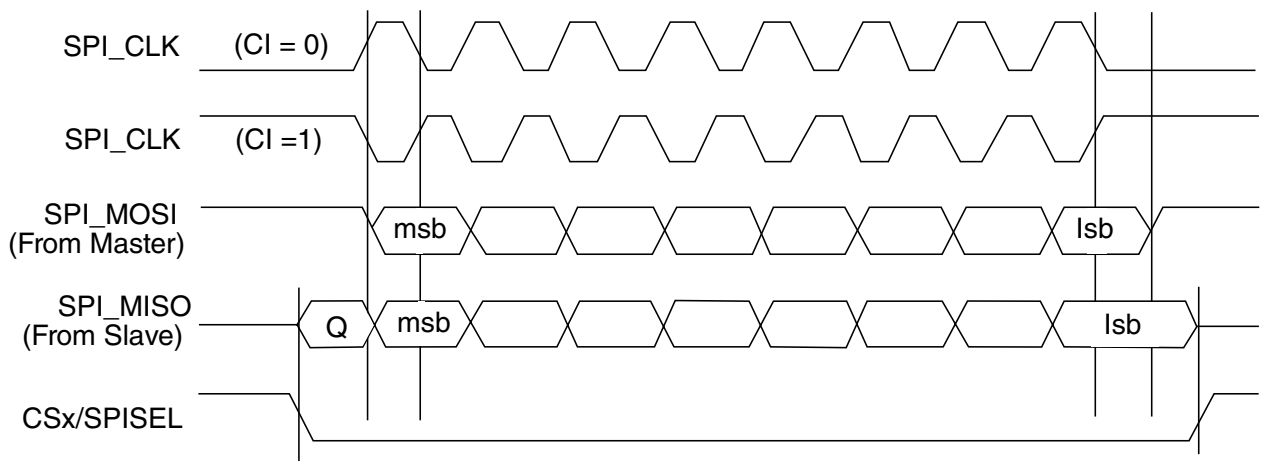
Figure below shows the eSPI transfer format in which SPI_CLK starts toggling in the middle of the transfer (SPMODEx[CPx] = 0).



NOTE: Q = Undefined Signal.

Figure 14-3. eSPI transfer format with SPMODEx[CPx] = 0

Figure below shows the eSPI transfer format in which SPI_CLK starts toggling at the beginning of the transfer (SPMODEx[CPx] = 1).



NOTE: Q = Undefined Signal.

Figure 14-4. eSPI transfer format with SPMODEx[CPx] = 1

14.5 CI and CP values for various eSPI devices

1. Regular devices-eSPI mode0-CI = CP = 0
2. Regular devices-eSPI mode3-CI = CP = 1

   For Winbond devices DO should also be set for dual output read command.
3. RapidS mode0-CI = 0, CP = 1, HLD = 1
4. RapidS mode3-CI = 1, CP = 0

14.6 eSPI programming examples

This section provides eSPI programming examples for 24-bit address memory and 16-bit address memory.

14.6.1 24-bit address example

The following sequence initializes the eSPI to read 36 bytes from 24-bit address memory, start address = 0x00_0040:

1. Configure a parallel I/O signal to operate as the eSPI CS0 output signal.
2. Write 0xFFFF_FFFF to SPIE to clear any previous events. Configure SPIM to enable all desired eSPI interrupts.
3. Configure SPMODE = 0x8000_100F to enable normal operation, eSPI enabled.
4. Configure SPMODE1 = 0x2417_1108-REV1 = 1, PM1 = 4 (divide eSPI input clock by 10), LEN1 = 7, POL1 = 1, CS1BEF = CS1AFT = CS1CG = 1.
5. Configure SPITF = 0x0300_0040-0x03 is read opcode while 0x00_0040 is the 24-bit start address.
6. Configure SPCOM = 0x0004_0027 so 4 bytes are skipped (1 for opcode and 3 for 24-bit address), TRANLEN = 36 + 4 - 1 = 39 = 27h.

14.6.2 16-bit address example

The following sequence initializes the eSPI to read 36 bytes from 16-bit address memory, start address = 0x0040:

1. Configure a parallel I/O signal to operate as the eSPI CS0 output signal.
2. Write 0xFFFF_FFFF to SPIE to clear any previous events. Configure SPIM to enable all desired eSPI interrupts.
3. Configure SPMODE = 0x8000_100F to enable normal operation, eSPI enabled.
4. Configure SPMODE1 = 0x2417_1108-REV1 = 1, PM1 = 4 (divide eSPI input clock by 10), LEN1 = 7, POL1 = 1, CS1BEF = CS1AFT = CS1CG = 1.
5. Configure SPITF = 0x0300_40xx (xx is don't care)-0x03 is read opcode while 0x0040 is the 16-bit start address.
6. Configure SPCOM = 0x0003_0026 so 3 bytes are skipped (1 for opcode and 2 for 16-bit address), TRANLEN = 36 + 3 - 1 = 38 = 26h.

Chapter 15
Enhanced Secured Digital Host Controller (eSDHC)

15.1 Overview

The enhanced secured digital host controller (eSDHC) provides interface between the host system and the SD/SDIO/MMC cards, as depicted in the figure below.

The eSDHC acts as a bridge, passing host bus transactions to the SD/SDIO/MMC cards by sending commands and performing data accesses to/from the cards.

It handles the SD/SDIO/MMC protocols at the transmission level.

Different types of cards supported by the eSDHC are described below:

- MultiMediaCard (MMC)

  MMC is a universal low-cost data storage and communication medium designed to cover a wide area of applications, including mobile video and gaming, which are available from either pre-loaded MMC cards or downloadable from cellular phones, WLAN, or other wireless networks. Old MMC cards are based on a seven-pin serial bus with a single data pin, while the new high-speed MMC communication is based on advanced 11-pin serial bus designed to operate in a low voltage range.

- Secure digital (SD) card

  The secure digital (SD) card is an evolution over the old MMC technology. It is specifically designed to meet the security, capacity, performance, and environmental requirements inherent in the emerging audio and video consumer electronic devices. The physical form factor, pin assignments, and data transfer protocol are forward-compatible with the old MMC.

- SDIO

  Under the SD protocol, the SD cards can be categorized as a memory card, I/O card, or combo card. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI standard. The I/O card provides high-speed

data I/O with low power consumption for mobile electronic devices. The combo card has both memory and I/O functions. For the sake of simplicity, the following figure does not show cards with reduced sizes.

The eSDHC acts as a bridge, passing host bus transactions to MMC/SD/SDIO cards by sending commands and performing data accesses to or from the cards. It handles the MMC/SD/SDIO protocol at the transmission level. The figure below shows connection of the eSDHC.

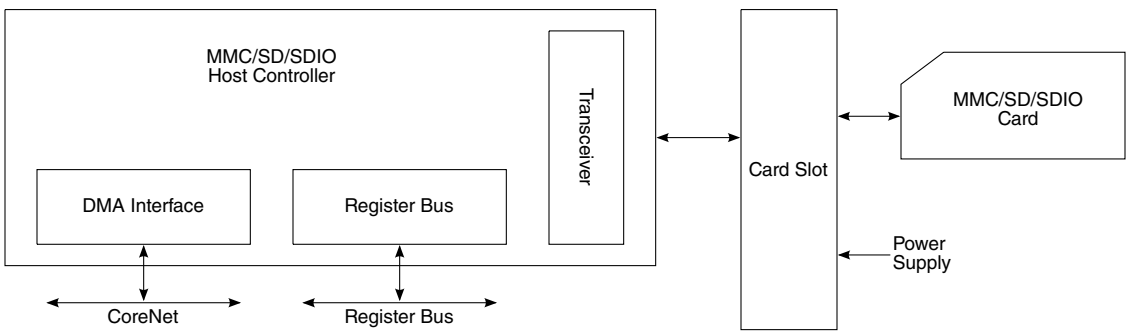


Figure 15-1. System connection of the eSDHC

The figure below is a high-level block diagram of eSDHC.

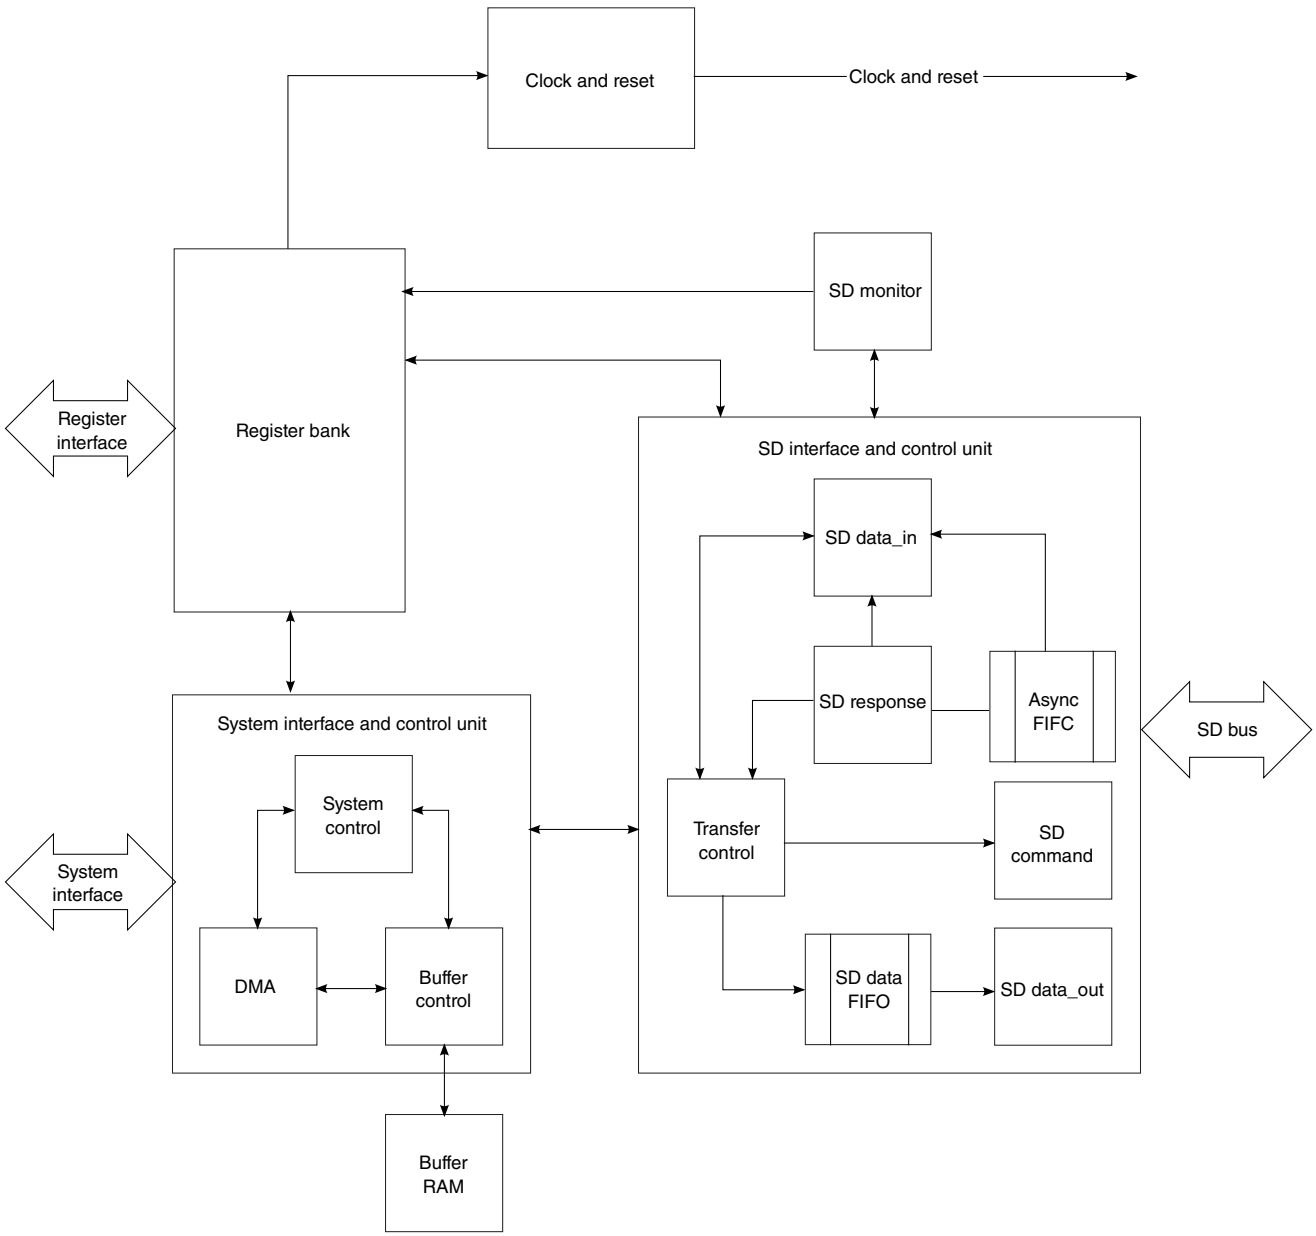

Figure 15-2. Enhanced secure digital host controller block diagram

15.1.1 eSDHC features summary

The features of the eSDHC module include the following:

- Conforms to the SD Host controller standard specification version 2.0, including test event register support
- Compatible with the MMC system specification version 4.2
- Compatible with the SD memory card specification version 2.0, and supports the high capacity SD memory card

- Compatible with the SDIO card specification version 2.0
- Designed to work with SD memory, SDIO, SD combo, MMC, and their variants, such as mini and micro.
- Card bus clock frequency up to 52 MHz
- MMCHC (MMC high capacity) support
- Supports 1- or 4-bit SD and SDIO modes, 1- or 4- or 8-bit MMC modes
- Supports single-block and multi-block read, and write data transfer
- Supports block sizes of 1-2048 bytes
- Supports the mechanical write protect detection. In the case where write protect is enabled, the host will not initiate any write data command to the card
- Supports card detection from SDHC_CD_B
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO read wait and suspend resume operations
- Supports Auto CMD12 for multi-block transfer
- Host can initiate command that does not use data lines, while data transfer is in progress
- Allows card to interrupt the host in 1 bit and 4 bit SDIO modes, also supports interrupt period
- Embodies a configurable 128 x 32 bit FIFO for read/write data
- Supports SDMA, ADMA1, and ADMA2 capabilities
- Supports external SD bus voltage selection by register configuration
- Host will send 80 idle SD clock cycles to card, which are needed during card power-up, if bit INITA in the system control register (SYSCTL) is set

15.1.2 Modes and operations

15.1.2.1 Data transfer modes

The eSDHC can select the following modes for data transfer:

- SD 1 bit
- SD 4 bit
- MMC 1 bit
- MMC 4 bit
- MMC 8 bit
- Identification mode (up to 400 kHz)
- MMC full speed mode (up to 20 MHz)
- MMC high speed mode (up to 52 MHz)

- SD/SDIO full speed mode (up to 25 MHz)
- SD/SDIO high speed mode (up to 50 MHz)

NOTE

To know the maximum speed of the mode supported, refer chip specific datasheet.

15.2 External signals

15.2.1 External signals overview

The eSDHC has the following associated I/O signals:

- SDHC_CLK is an internally generated clock signal that drives the MMC, SDIO, or SD card.
- SDHC_CMD I/O sends commands to and receives responses from the card.
- SDHC_DAT[7:0] performs data transfers between the eSDHC and the card. If the eSDHC is desired to support a 4 bit data transfer, DAT[7:4] can also be optional and tied high.
- SDHC_CD_B and SDHC_WP are card detection and write protection signals from the socket.

15.2.2 eSDHC signal descriptions

Table 15-1. Signal properties

Name	Port	Function	Reset state	Pull up
SDHC_CLK	O	Clock for MMC/SD/SDIO card	0	N/A
SDHC_CMD	I/O	CMD line connect to card	1	Pull up
SDHC_DAT7	I/O	DAT7 line in 8-bit mode Not used in other modes	1	Pull up
SDHC_DAT6	I/O	DAT6 line in 8-bit mode Not used in other modes	1	Pull up
SDHC_DAT5	I/O	DAT5 line in 8-bit mode Not used in other modes	1	Pull up
SDHC_DAT4	I/O	DAT4 line in 8-bit mode Not used in other modes	1	Pull up

Table continues on the next page...

Table 15-1. Signal properties (continued)

Name	Port	Function	Reset state	Pull up
SDHC_DAT3	I/O	DAT3 line in 4/8-bit mode	0	Pull up. Do not use DAT3 pin as a CD pin.
SDHC_DAT2	I/O	DAT2 line or read wait in 4/8-bit mode Read wait in 1-bit mode	1	Pull up
SDHC_DAT1	I/O	DAT1 line in 4/8-bit mode Also used to detect interrupt in 1/4-bit mode	1	Pull up
SDHC_DAT0	I/O	DAT0 line in all modes Also used to detect busy state	1	Pull up
SDHC_CD_B	I	Card detection pin If not used tie high	N/A	N/A
SDHC_WP	I	Card write protect detect If not used tie low	N/A	N/A

15.3 eSDHC memory map/register definition

The table below shows the memory-mapped registers of the eSDHC module and lists the offset, name, and a cross-reference to the complete description of each register. These register only support 32-bit accesses.

eSDHC memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
11_4000	SDMA system address register (eSDHC_DSADDR)	32	R/W	0000_0000h	15.3.1/821
11_4004	Block attributes register (eSDHC_BLKATTR)	32	R/W	0000_0000h	15.3.2/822
11_4008	Command argument register (eSDHC_CMDARG)	32	R/W	0000_0000h	15.3.3/823
11_400C	Transfer type register (eSDHC_XFERTYP)	32	R/W	0000_0000h	15.3.4/824
11_4010	Command response 0 register (eSDHC_CMDRSP0)	32	R	0000_0000h	15.3.5/828
11_4014	Command response 1 register (eSDHC_CMDRSP1)	32	R	0000_0000h	15.3.6/828
11_4018	Command response 2 register (eSDHC_CMDRSP2)	32	R	0000_0000h	15.3.7/829
11_401C	Command Response 3 register (eSDHC_CMDRSP3)	32	R	0000_0000h	15.3.8/829
11_4020	Buffer data port register (eSDHC_DATPORT)	32	R/W	0000_0000h	15.3.9/831
11_4024	Present state register (eSDHC_PRSSTAT)	32	R/W	See section	15.3.10/ 832

Table continues on the next page...

eSDHC memory map (continued)

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
11_4028	Protocol control register (eSDHC_PROCTL)	32	R/W	0000_0020h	15.3.11/ 837

eSDHC_DSADDR field descriptions

Field	Description
0–31 DS_ADDR	DMA system address. This register contains the 32-bit system memory address for a single DMA (SDMA) transfer. When the eSDHC stops a DMA transfer, this register points to the system address of the next contiguous data position. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). The host driver should initialize this register before starting DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register. The eSDHC DMA does not support a virtual memory system. It only supports continuous physical memory access. This register is used with Auto CMD23 to set 32-bit block count value to the argument of CMD23 while executing Auto CMD23. If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without ADMA, the available block count value is limited by 16-bit Block Count field in Block Attributes register. 65536 blocks is the maximum value available in this case.

15.3.2 Block attributes register (eSDHC_BLKATTR)

The BLKATTR is used to configure the number of data blocks and the number of bytes in each block.

Address: 11_4000h base + 4h offset = 11_4004h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	BLKCNT																Reserved				BLKSIZE											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eSDHC_BLKATTR field descriptions

Field	Description
0–15 BLKCNT	Blocks count for current transfer. • This register is enabled when XFERTYP[BCEN] is set to 1 and is valid only for multiple block transfers. The host driver should set this register to a value between 1 and the maximum block count. The eSDHC decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred. • This register should be accessed only when no transaction is executing (that is, after transactions are stopped). During data transfer, read operations on this register may return an invalid value and write operations are ignored. • When saving transfer content as a result of a suspend command, the number of blocks yet to be transferred can be determined by reading this register. The reading of this register should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend. This is because when suspend command is sent out, eSDHC will regard the current transfer is aborted and change BLKCNT back to its original value instead of keeping the dynamical indicator of remained block count. • When restoring transfer content prior to issuing a resume command, the host driver should restore the previously saved block count. 0x0000 Stop count

Table continues on the next page...

eSDHC_BLKATTR field descriptions (continued)

Field	Description
	0x0001 1 block 0x0002 2 blocks ... 0xFFFF 65535 blocks
16–19 -	This field is reserved.
20–31 BLKSIZE	Transfer block size. This register specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations will be ignored. 0x000 No data transfer 0x001 1 byte 0x002 2 bytes 0x003 3 bytes 0x004 4 bytes ... 0x1FF 511 bytes 0x200 512 bytes ... 0x800 2048 bytes

15.3.3 Command argument register (eSDHC_CMDARG)

The CMDARG contains the SD/MMC command argument.

Address: 11_4000h base + 8h offset = 11_4008h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	CMDARG																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eSDHC_CMDARG field descriptions

Field	Description
0–31 CMDARG	Command argument. The SD/MMC command argument is specified as bits 39-8 of the command format in the SD or MMC Specification. This register is write protected when PRSSTAT[CIHB] is set.

15.3.4 Transfer type register (eSDHC_XFERTYP)

The host driver should set the XFERTYP to issue any new command. To prevent data loss, the eSDHC prevents writing to the bits, that are involved in the data transfer of this register, when data transfer is active: MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

The host driver should check PRSSTAT[CDIHB] and PRSSTAT[CIHB] before writing to this register. When PRSSTAT[CDIHB] is set, any attempt to send a command with data by writing to this register is ignored; when PRSSTAT[CIHB] is set, any write to this register is ignored.

On sending commands with data transfer, it is mandatory that the block size is non-zero. Besides, block count must also be non-zero, or indicated as single block transfer (XFERTYP[MSBSEL] is '0' when written), or block count is disabled (XFERTYP[BCEN] is '0' when written), otherwise eSDHC will ignore the sending of this command and do nothing. For write commands, with all above restrictions, it is also mandatory that the write protect switch is not active (PRSSTAT[WPS] is '1), otherwise eSDHC will also ignore the command.

If the commands with write data transfer does not receive the response in 64 clock cycles, that is, response time-out, eSDHC will regard the external device does not accept the command and will not initiate the data transfer on SD bus. In this scenario, the driver should perform error recovery and issue the command again to re-try the transfer.

It is also possible that for some reason the card responds to the read data command but eSDHC does not receive the response, and if it is a DMA (SDMA or ADMA) read operation, the external system memory is over-written by the DMA with data sent back from the card.

Table 15-2. Transfer Type Register Setting for Various Transfer Types

Multi-/Single Block Select	Block Count Enable	Block Count	Function
0	Don't Care	Don't Care	Single Transfer
1	0	Don't Care	Infinite Transfer
1	1	Positive Number	Multiple Transfer
1	1	Zero	No Data Transfer

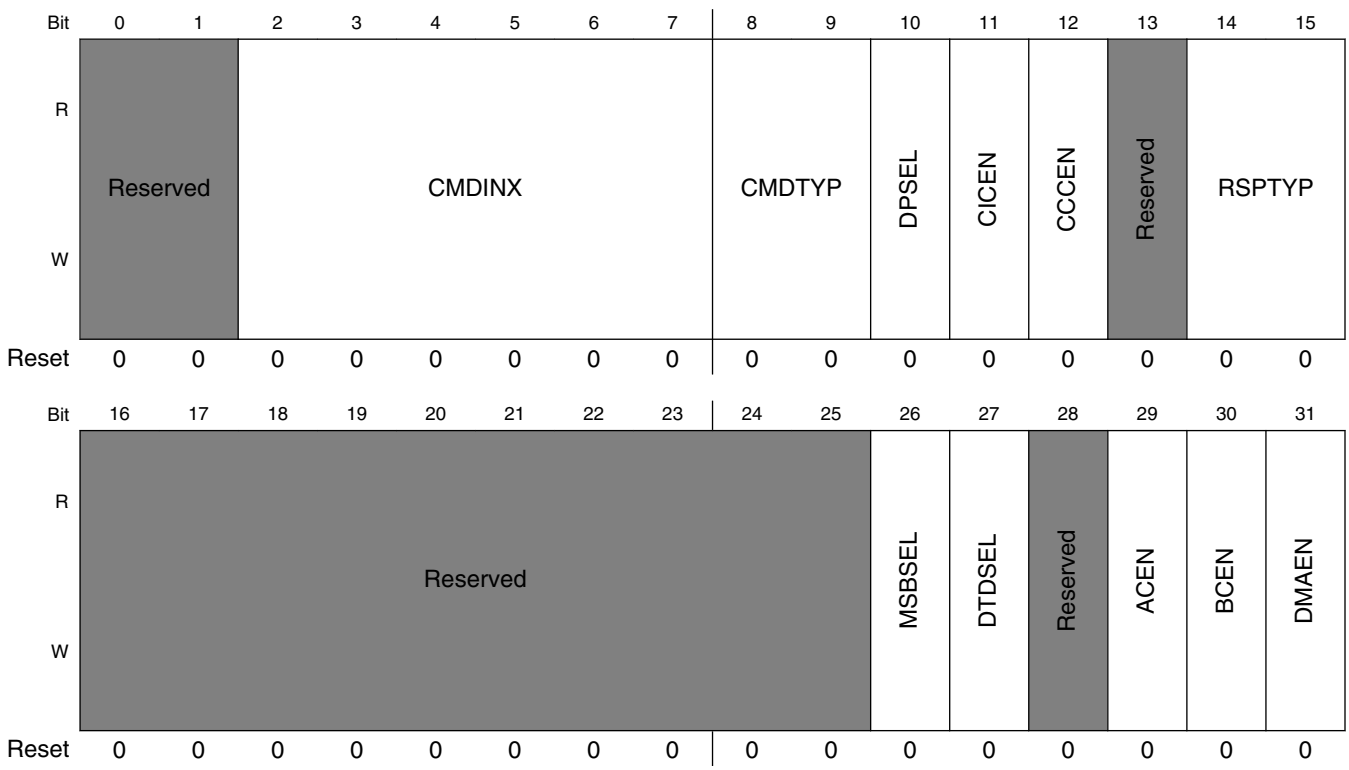
The table below shows the relationship between the command index check enable and the command CRC check enable, in regards to the response type bits as well as the name of the response type.

Table 15-3. Relationship Between Parameters and the Name of the Response Type

Response type	Index Check Enable	CRC Check Enable	Name of Response Type
00	0	0	No Response
01	0	1	R2
10	0	0	R3, R4
10	1	1	R1, R5, R6, R7
11	1	1	R1b, R5b

- In the SDIO Specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO Specification. But R5b is defined in this specification to specify that the eSDHC checks the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command should be used with R5b.
- The CRC field for R3 and R4 is expected to be all 1 bits. The CRC check should be disabled for these response types.

Address: 11_4000h base + Ch offset = 11_400Ch



eSDHC_XFERTYP field descriptions

Field	Description
0–1 -	This field is reserved.

Table continues on the next page...

eSDHC_XFERTYP field descriptions (continued)

Field	Description
2–7 CMDINX	Command index. These bits should be set to the command number that is specified in bits 45-40 of the command format in the SD Memory Card Physical Layer Specification and SDIO Card Specification .
8–9 CMDTYP	Command Type. There are three types of special commands: suspend, resume, and abort. These bits should be set to 00b for all other commands. • Suspend command: If the suspend command succeeds, the eSDHC should assume that the card bus has been released and that it is possible to issue the next command which uses the DAT line. Since eSDHC does not monitor the content of command response, it does not know if the suspend command succeeded or not. It is the host driver's responsibility to check the status of the suspend command and send another command marked as Suspend to inform the eSDHC that a suspend command was successfully issued. Refer to Suspend resume for more details. After the start bit of command is sent, the eSDHC de-asserts read wait for read transactions and stops checking busy for write transactions. In 4-bit mode, the interrupt cycle starts. If the suspend command fails, the eSDHC will maintain its current state, and the host driver should restart the transfer by setting PROCTL[CREQ]. • Resume command: The host driver re-starts the data transfer by restoring the registers saved before sending the suspend command and then sends the resume command. • Abort command: If this command is set when executing a read transfer, the eSDHC will stop write to the buffer after end bit of abort command is sent. If this command is set when executing a write transfer, the eSDHC will stop driving the DAT line. After issuing the abort command, the host driver should issue a software reset (abort transaction). 00 Normal other commands 11 Abort CMD12, CMD52 for writing I/O abort in CCCR
10 DPSEL	Data present select. This bit is set to 1 to indicate that data is present and should be transferred using the DAT line. It is set to 0 for the following: • Commands using only the CMD line (for example, CMD52) • Commands with no data transfer, but using the busy signal on DAT[0] line (R1b or R5b, for example, CMD38) **NOTE:** In resume command, this bit should be set, and other bits in this register should be set the same as when the transfer was initially launched. When the write protect switch is on (that is, PRSSTAT[WPS] is active as '0'), any command with a write operation will be ignored. That is to say, when this bit is set, while XFRTYP[DTDSEL] is 0, writes to the transfer type register (XFRTYP) are ignored. 0 No data present 1 Data present
11 CICEN	Command index check enable. If this bit is set to 1, the eSDHC checks the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a command index error. If this bit is set to 0, the Index field is not checked. 0 Disable 1 Enable
12 CCCEN	Command CRC check enable. If this bit is set to 1, the eSDHC should check the CRC field in the response. If an error is detected, it is reported as a command CRC error. If this bit is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response. (Refer to RSPTYP[1:0] and Table 15-3.) 0 Disable 1 Enable
13 -	This field is reserved.

Table continues on the next page...

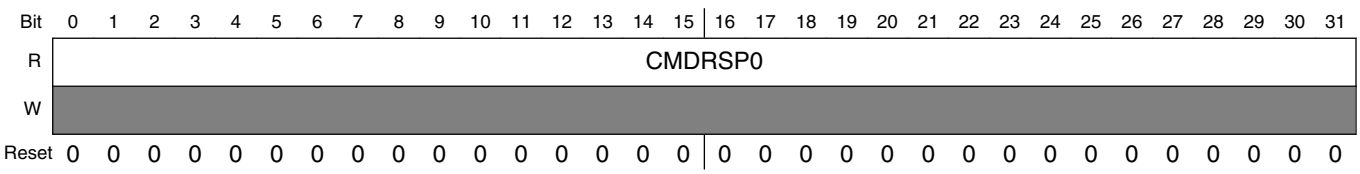
eSDHC_XFERTYP field descriptions (continued)

Field	Description
14–15 RSPTYP	Response type select. 00 No response 01 Response length 136 10 Response length 48 11 Response length 48, check busy after response
16–25 -	This field is reserved.
26 MSBSEL	Multi-/single-block select. This bit enables multiple block DAT line data transfers. For any other commands, this bit should be set to 0. If this bit is 0, it is not necessary to set the block count register. (Refer to Table 15-2.) 0 Single block 1 Multiple blocks
27 DTDSEL	Data transfer direction select. This bit defines the direction of DAT line data transfers. The bit is set to 1 by the host driver to transfer data from the SD card to the eSDHC and is set to 0 for all other commands. 0 Write (host to card) 1 Read (card to host)
28 -	This field is reserved.
29 ACEN	Auto CMD12 enable. Multiple block transfers for memory require a CMD12 to stop the transaction. When this bit is set to 1, the eSDHC will issue a CMD12 automatically when the last block transfer has completed. The host driver should not set this bit to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File security specification do not require CMD12. In single block transfer, the eSDHC will ignore this bit whether if it is set or not. 0 Auto CMD Disable 1 Auto CMD12 Enable
30 BCEN	Block count enable. This bit is used to enable the block count register, which is only relevant for multiple block transfers. When this bit is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. If ADMA data transfer is more than 65535 blocks, this bit shall be set to 0. In this case, data transfer length is designated by Descriptor Table. 0 Disable 1 Enable
31 DMAEN	DMA enable. This bit enables DMA functionality. If this bit is set to 1, a DMA operation should begin when the host driver sets the DPSEL bit of this register. Whether the single DMA or ADMA is active depends on PROCTL[DMAS]. 0 Disable 1 Enable

15.3.5 Command response 0 register (eSDHC_CMDRSP0)

The CMDRSP0 is used to store part 0 of the response bits from the card.

Address: 11_4000h base + 10h offset = 11_4010h



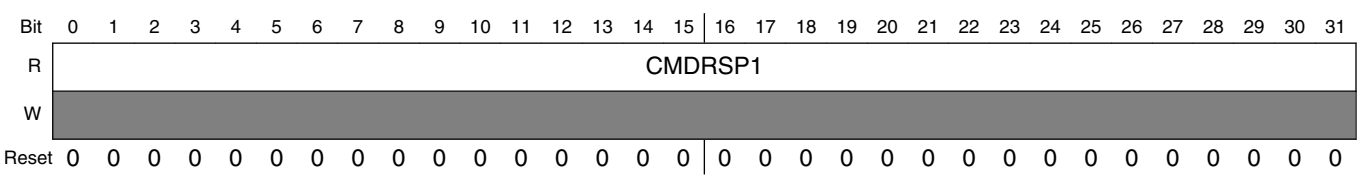
eSDHC_CMDRSP0 field descriptions

Field	Description
0–31 CMDRSP0	Command response 0. Refer to Command Response 3 register (eSDHC_CMDRSP3) for the mapping of command responses from the SD bus to this register for each response type.

15.3.6 Command response 1 register (eSDHC_CMDRSP1)

The CMDRSP1 is used to store part 1 of the response bits from the card.

Address: 11_4000h base + 14h offset = 11_4014h



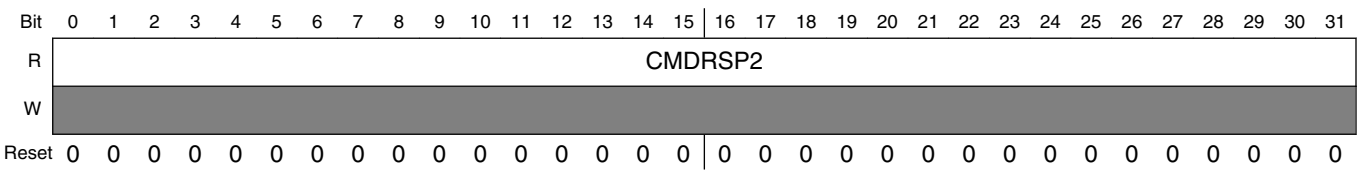
eSDHC_CMDRSP1 field descriptions

Field	Description
0–31 CMDRSP1	Command response 1. Refer to Command Response 3 register (eSDHC_CMDRSP3) for the mapping of command responses from the SD bus to this register for each response type.

15.3.7 Command response 2 register (eSDHC_CMDRSP2)

The CMDRSP2 is used to store part 2 of the response bits from the card.

Address: 11_4000h base + 18h offset = 11_4018h



eSDHC_CMDRSP2 field descriptions

Field	Description
0–31 CMDRSP2	Command response 2. Refer to Command Response 3 register (eSDHC_CMDRSP3) for the mapping of command responses from the SD bus to this register for each response type.

15.3.8 Command Response 3 register (eSDHC_CMDRSP3)

The CMDRSP3 is used to store part 3 of the response bits from the card.

Table below describes the mapping of command responses from the SD bus to command response registers for each response type. In the table, R *n* refers to a bit range within the response data as transmitted on the SD bus.

Table 15-4. Response bit definition for each response type

Response type	Meaning of response	Response field	Response register
R1,R1b (normal response)	Card Status	R[39:8]	CMDRSP0
R1b (Auto CMD12 response)	Card Status for Auto CMD12	R[39:8]	CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{CMDRSP3[8:31], CMDRSP2, CMDRSP1, CMDRSP0}
R3 (OCR register)	OCR register for memory	R[39:8]	CMDRSP0
R4 (OCR register)	OCR register for I/O	R[39:8]	CMDRSP0
R5, R5b	SDIO response	R[39:8]	CMDRSP0
R6 (Publish RCA)	New Published RCA[31:16] and card status[15:0]	R[39:9]	CMDRSP0

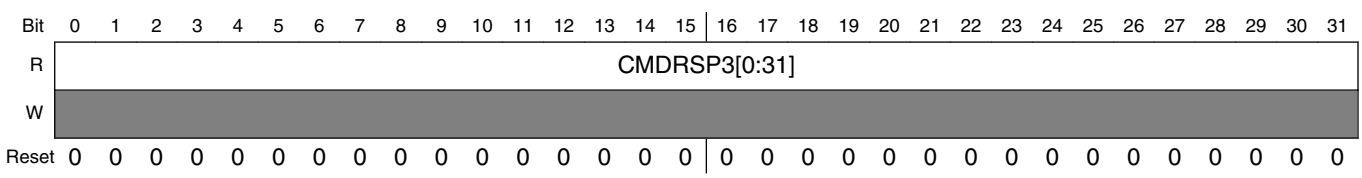
This table shows the following:

Most responses with a length of 48 (R[47:0]) have 32-bits of the response data (R[39:8]) stored in the CMDRSP0 register. Responses of type R1b (Auto CMD12 responses) have response data bits (R[39:8]) stored in the CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bits of the response data (R[127:8]) stored in the CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, the eSDHC only stores part of the response data in the command response registers (CMDRSP *n*). This enables the host driver to efficiently read 32-bits of response data in one read cycle on a 32-bit bus system. Parts of the response, the index field and the CRC, are checked by the eSDHC (as specified by the command index check enable and the command CRC check enable bits in the transfer type register, XFERTYP) and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, the eSDHC checks R[47:1], and if the response length is 136 the eSDHC checks R[119:1].

Since eSDHC may have a multiple block data transfer executing concurrently with a CMD_wo_DAT command, it stores the Auto CMD12 response in the CMDRSP3 register. The CMD_wo_DAT response is stored in CMDRSP0. This allows the eSDHC to avoid overwriting the Auto CMD12 response with the CMD_wo_DAT and vice versa. When the eSDHC modifies part of the command response registers (CMDRSP *n*), as shown in the table above, it preserves the unmodified bits.

Address: 11_4000h base + 1Ch offset = 11_401Ch



eSDHC_CMDRSP3 field descriptions

Field	Description
0–31 CMDRSP3[0:31]	Command response 3. Refer to Command Response 3 register (eSDHC_CMDRSP3) for the mapping of command responses from the SD bus to this register for each response type.

15.3.9 Buffer data port register (eSDHC_DATPORT)

The DATPORT is a 32-bit data port register used to access the internal buffer. Byte access is not allowed.

Address: 11_4000h base + 20h offset = 11_4020h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	DATCONT																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

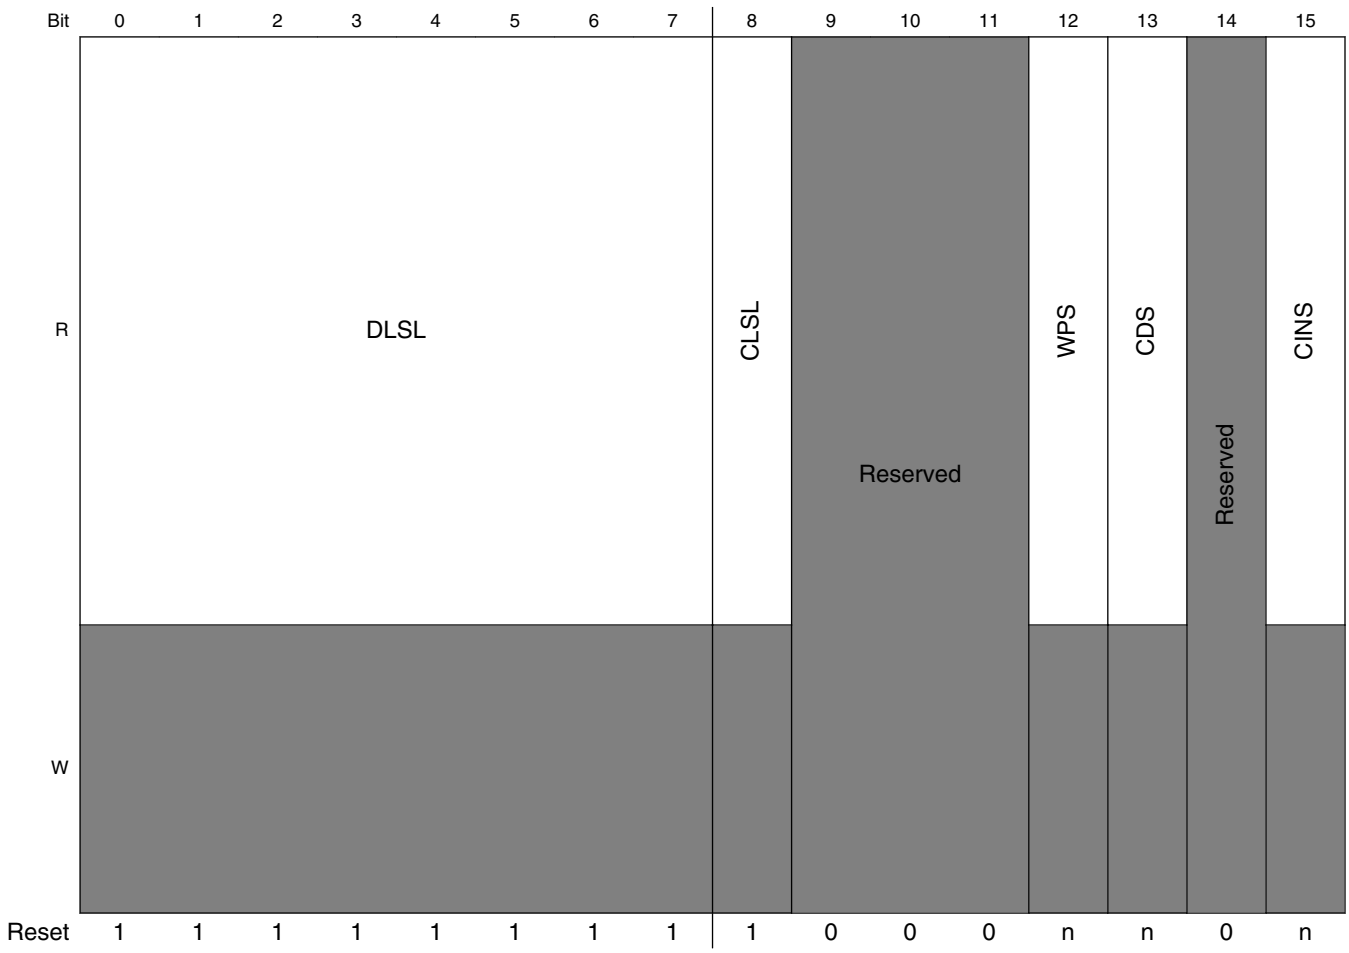
eSDHC_DATPORT field descriptions

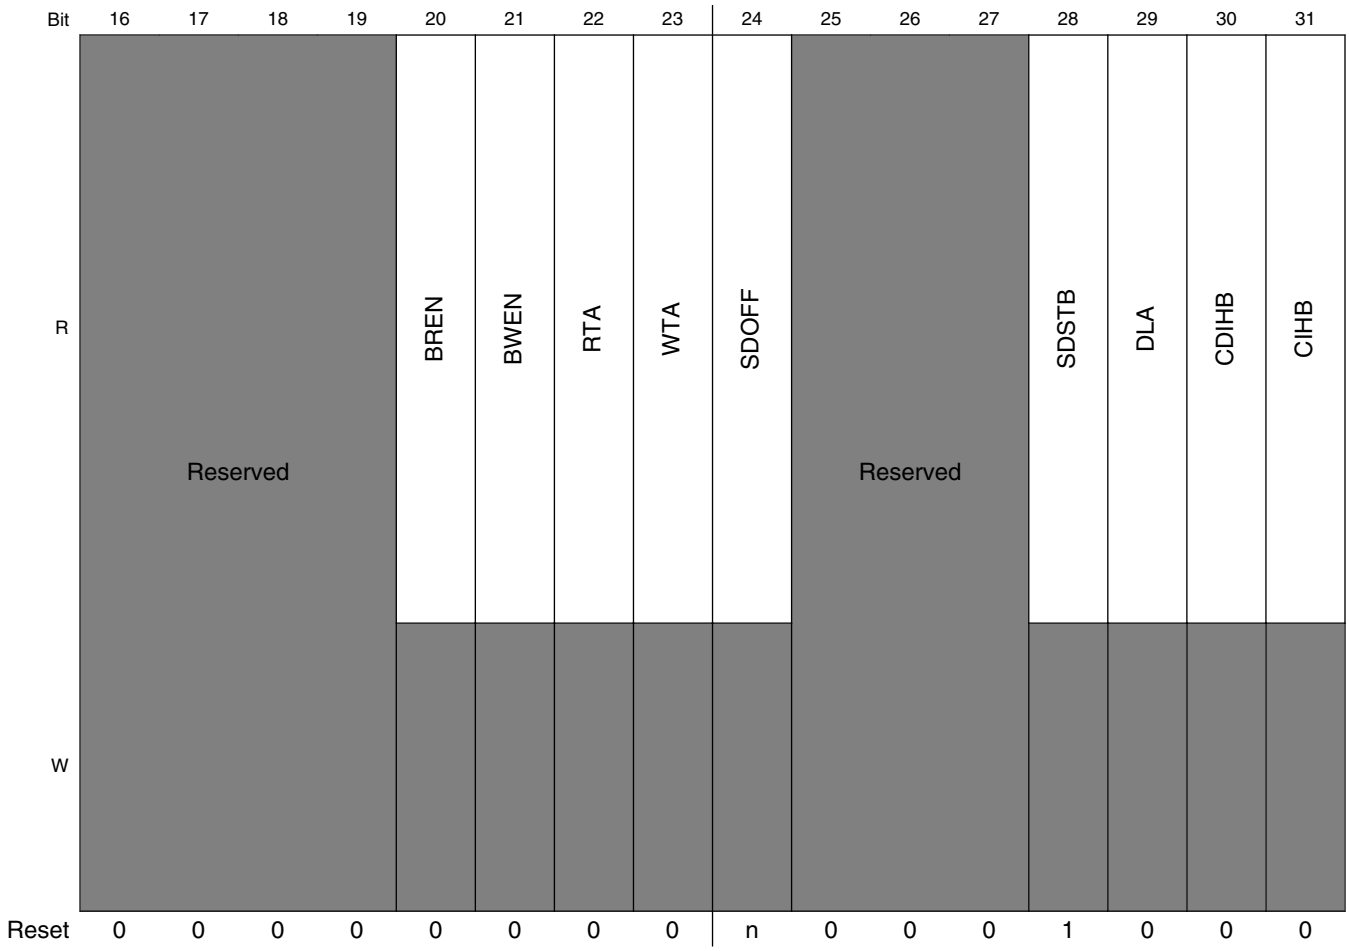
Field	Description
0–31 DATCONT	Data content. The buffer data port register is for 32-bit data access by the CPU. When the DMA is enabled, any write to this register is ignored, and any read from this register always yields zeros.

15.3.10 Present state register (eSDHC_PRSSTAT)

The host driver can get the status of the eSDHC from the PRSSTAT, which is a 32-bit, read-only register.

Address: 11_4000h base + 24h offset = 11_4024h





eSDHC_PRSSTAT field descriptions

Field	Description
0–7 DLSL	DAT[7:0] line signal level. This status is used to check the DAT line level to recover from errors, and for debugging.This is especially useful in detecting the busy signal level from DAT[0]. The reset value is effected by the external pull-up/pull-down resistors. By default, the read value of this bit field after reset is 8'b11111111 DLSL[0]: Data 0 line signal level DLSL[1]: Data 1 line signal level DLSL[2]: Data 2 line signal level DLSL[3]: Data 3 line signal level DLSL[4]: Data 4 line signal level DLSL[5]: Data 5 line signal level DLSL[6]: Data 6 line signal level DLSL[7]: Data 7 line signal level
8 CLSL	CMD line signal level. This status is used to check the CMD line level to recover from errors, and for debugging. The reset value is effected by the external pull-up/pull-down resistor, by default, the read value of this bit after reset is 1, when the command line is pulled up.
9–11 -	This field is reserved.

Table continues on the next page...

eSDHC_PRSSTAT field descriptions (continued)

Field	Description
12 WPS	Write protect state. The write protect switch is supported for memory and combo cards. This bit reflects the write protect state depending on value of SDHC_WP pin of the card socket. A software reset does not affect this bit. The reset value is effected by the external write protect switch. If the SDHC_WP pin is not used, it should be tied low, so that the reset value of this bit is high and write is enabled. 0 Write protected (SDHC_WP =1) 1 Write enabled (SDHC_WP =0)
13 CDS	Card detect state. This bit reflects the card inserted/removed state depending on value of the SDHC_CD_B pin for the card socket. Debouncing is not performed on this bit. This bit may be valid, but is not guaranteed, because of propagation delay. Use of this bit is limited to testing since it must be debounced by software. A software reset does not effect this bit. A write to the force event register (FEVT) does not affect this bit. The reset value is effected by the external card detection pin. This bit shows the value on the SDHC_CD_B pin (that is, when a card is inserted in the socket, it is 0 on the SDHC_CD_B input, and consequently the CDS reads 1.) 0 No card present (SDHC_CD_B =1) 1 Card present (SDHC_CD_B =0)
14 -	This field is reserved.
15 CINS	Card inserted. This bit indicates whether a card has been inserted. The eSDHC debounces this signal so that the host driver will not need to wait for it to stabilize. Changing from a 0 to 1 generates a card insertion interrupt in the interrupt status register (IRQSTAT). Changing from a 1 to 0 generates a card removal interrupt in the interrupt status register (IRQSTAT). A write to the force event register (FEVT) does not effect this bit. The software reset for all in the system control register (SYSCTL) does not effect this bit. A software reset does not effect this bit. 0 Power on reset or no card 1 Card inserted
16–19 -	This field is reserved.
20 BREN	Buffer read enable. This status bit is used for non-DMA read transfers. The eSDHC may implement multiple buffers to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this bit is high, valid data greater than the watermark level exist in the buffer. A change of this bit from 1 to 0 occurs when any read from the buffer is made. A change of this bit from 0 to1 occurs when there is enough valid data ready in the buffer and the buffer read ready interrupt has been generated and enabled. 0 Read disable 1 Read enable
21 BWEN	Buffer write enable. This status bit is used for non-DMA write transfers. The eSDHC can implement multiple buffers to transfer data efficiently. This read only flag indicates if space is available for write data. If this bit is 1, valid data greater than the watermark level can be written to the buffer. A change of this bit from 1 to 0 occurs when any write to the buffer is made. A change of this bit from 0 to 1 occurs when the buffer can hold valid data greater than the write watermark level and the buffer write ready interrupt is generated and enabled. 0 Write disable 1 Write enable
22 RTA	Read transfer active. This status bit is used for detecting completion of a read transfer. • This bit is set for either of the following conditions:

Table continues on the next page...

eSDHC_PRSSTAT field descriptions (continued)

Field	Description
	• After the end bit of the read command. • When read operation is restarted by writing a 1 to PROCTL[CREQ]. • This bit is cleared for either of the following conditions: • When the last data block as specified by block length is transferred to the system. • In the case of ADMA2, end of read operation is designated by descriptor table. • When all valid data blocks in the host controller have been transferred to the system and no current block transfers are being sent as a result of the stop at block gap request being set to 1. A transfer complete interrupt is generated when this bit changes to 0. 0 No valid data 1 Transferring data
23 WTA	Write transfer active. This status bit indicates a write transfer is active. If this bit is 0, it means no valid write data exists in the eSDHC. • This bit is set in either of the following cases: • After the end bit of the write command. • When write operation is restarted by writing a 1 to PROCTL[CREQ]. • This bit is cleared in either of the following cases: • After getting the CRC status of the last data block as specified by the transfer count (single and multiple). In case of ADMA2, transfer count is designated by descriptor table. • After getting the CRC status of any block where data transmission is about to be stopped by a stop at block gap request. During a write transaction, a block gap event interrupt is generated when this bit is changed to 0, as result of the stop at block gap request being set. This status is useful for the host driver in determining when to issue commands during write busy state. 0 No valid data 1 Transferring data
24 SDOFF	SD clock gated off internally. This status bit indicates that the SD clock is internally gated off, because of buffer over/under-run or read pause without read wait assertion. 0 SD clock is active 1 SD clock is gated off
25–27 -	This field is reserved.
28 SDSTB	SD clock stable. This status bit indicates that the internal card clock is stable. This bit is for the host driver to poll clock status when changing the clock frequency. It is recommended to clear SYSCTL[SDCLKEN] to remove glitch on the card clock when the frequency is changing. 0 Clock is changing frequency and not stable 1 Clock is stable
29 DLA	Data line active. This status bit indicates whether one of the DAT lines on the SD bus is in use. In the case of read transactions: • This status indicates if a read transfer is executing on the SD bus. Changes in this value from 1 to 0, between data blocks, generates a block gap event interrupt in the interrupt status register (IRQSTAT). • This bit will be set in either of the following cases: • After the end bit of the read command. • When writing a 1 to PROCTL[CREQ] to restart a read transfer. • This bit should be cleared in either of the following cases:

Table continues on the next page...

eSDHC_PRSSTAT field descriptions (continued)

Field	Description
	• When the end bit of the last data block is sent from the SD bus to the host controller. In case of ADMA2, the last block is designated by the last transfer of descriptor table. • When a read transfer is stopped at the block gap initiated by a stop at block gap request. • The eSDHC will wait at the next block gap by driving read wait at the start of the interrupt cycle. If the read wait signal is already driven (data buffer cannot receive data), the eSDHC can wait for a current block gap by continuing to drive the read wait signal. It is necessary to support read wait in order to use the suspend/resume function. This bit will remain 1 during read wait. In the case of write transactions: • This status indicates that a write transfer is executing on the SD bus. Changes in this value from 1 to 0 generate a transfer complete interrupt in the interrupt status register (IRQSTAT). • This bit will be set in either of the following cases: • After the end bit of the write command. • When writing to 1 to PROCTL[CREQ] to continue a write transfer. • This bit will be cleared in either of the following cases: • When the SD card releases write busy of the last data block. If SD card does not drive busy signal for 8 SD Clocks, the host controller should consider the card drive "Not Busy". In case of ADMA2, the last block is designated by the last transfer of descriptor table. • When the SD card releases write busy, prior to waiting for write transfer, and as a result of a stop at block gap request. In the case of command with busy pending: • Command with busy. This status indicates whether a command indicates busy (for example, erase command for memory) is executing on the SD bus. This bit is set after the end bit of the command with busy and cleared when busy is de-asserted. Changing this bit from 1 to 0 generate a transfer complete interrupt in the interrupt status register (IRQSTAT). 0 DAT line inactive 1 DAT line active
30 CDIHB	Command inhibit (DAT). This status bit is generated if either the DAT line active or the read transfer active is set to 1. If this bit is 0, it indicates the eSDHC can issue the next SD/MMC Command. Commands with busy signal belong to command inhibit (DAT) (for example, R1b, R5b type). Changing from 1 to 0 generates a transfer complete interrupt in the interrupt status register (IRQSTAT). **NOTE:** The SD host driver can save registers for a suspend transaction after this bit has changed from 1 to 0. 0 Can issue command which uses the DAT line 1 Cannot issue command which uses the DAT line
31 CIHB	Command inhibit (CMD). If this status bit is 0, it indicates that the CMD line is not in use and the eSDHC can issue a SD/MMC Command using the CMD line. This bit is set also immediately after the transfer type register (XFERTYP) is written. This bit is cleared when the command response is received. Even if the command inhibit (DAT) is set to 1, Commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a command complete interrupt in the interrupt status register (IRQSTAT). If the eSDHC cannot issue the command because of a command conflict error (Refer to command CRC error) or because of a command not issued by Auto CMD12 Error, this bit will remain 1 and the command complete is not set. The status of issuing an Auto CMD12 does not show on this bit. 0 Can issue command using only CMD line 1 Cannot issue command

15.3.11 Protocol control register (eSDHC_PROCTL)

There are three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether the eSDHC issues a suspend command or the SD card accepts the suspend command.

1. If the host driver does not issue a suspend command, the continue request should be used to restart the transfer.
2. If the host driver issues a suspend command and the SD card accepts it, a resume command should be used to restart the transfer.
3. If the host driver issues a suspend command and the SD card does not accept it, the continue request should be used to restart the transfer.

Any time a stop at block gap request stops the data transfer, the host driver should wait for a transfer complete (in the interrupt status register, IRQSTAT), before attempting to restart the transfer. When restarting the data transfer by continue request, the host driver should clear the stop at block gap request before or simultaneously.

eSDHC_PROCTL field descriptions

Field	Description
0–4 -	This field is reserved.
5 WECRM	Wakeup event enable on SD card removal. This bit enables a wakeup event, via a card removal, in the interrupt status register (IRQSTAT). FN_WUS (wake up support) in CIS of SDIO card does not effect this bit. When this bit is set, the card removal status and the eSDHC interrupt can be asserted without SDHC_CLK toggling. When the wakeup feature is not enabled, the SDHC_CLK must be active in order to assert the card removal status and the eSDHC interrupt. 0 Disable 1 Enable
6 WECINS	Wakeup event enable on SD card insertion. This bit enables a wakeup event, via a card insertion, in the interrupt status register (IRQSTAT). FN_WUS (wake up support) in CIS of the SDIO card does not affect this bit. When this bit is set, the card insertion status and the eSDHC interrupt can be asserted without SDHC_CLK toggling. When the wakeup feature is not enabled, the SDHC_CLK must be active in order to assert the card insertion status and the eSDHC interrupt. 0 Disable 1 Enable
7 WECINT	Wakeup event enable on card interrupt. This bit enables a wakeup event, via a card interrupt, in the interrupt status register (IRQSTAT). This bit can be set to 1 if FN_WUS (wake up support) in CIS of SDIO card is set to 1. When this bit is set, the card interrupt status and the eSDHC interrupt can be asserted without SDHC_CLK toggling. When the wakeup feature is not enabled, the SDHC_CLK must be active in order to assert the card interrupt status and the eSDHC interrupt. 0 Disable 1 Enable
8–11 -	This field is reserved.
12 IABG	Interrupt at block gap. This bit is valid only in 4-bit mode of the SDIO card, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SDIO card cannot signal an interrupt during a multiple block transfer, this bit should be set to 0 to avoid an inadvertent interrupt. When the host driver detects an SDIO card insertion, it should set this bit according to the CCCR of the card. 0 Disable 1 Enable
13 RWCTL	Read wait control. The read wait function is optional for SDIO cards. If the card supports read wait, set this bit to enable use of the read wait protocol to stop read data using the DAT[2] line. Otherwise the eSDHC has to stop the SD Clock to hold read data, which restricts commands generation. When the host driver detects an SDIO card insertion, it should set this bit according to the CCCR of the card. If the card does not support read wait, this bit should never be set to 1, otherwise DAT line conflicts may occur. If this bit is set to 0, stop at block gap during read operation is also supported, but the eSDHC will stop the SD clock to pause reading operation. 0 Disable read wait control, and stop SD clock at block gap when SABGREQ bit is set 1 Enable read wait control, and assert read wait without stopping SD clock at block gap when SABGREQ bit is set
14 CREQ	Continue request. This bit is used to restart a transaction, which was stopped using the stop at block gap request. To cancel stop at the block gap, set stop at block gap request to 0 and set this bit 1 to restart the transfer. The eSDHC automatically clears this bit in either of the following cases:

Table continues on the next page...

eSDHC_PROCTL field descriptions (continued)

Field	Description
	• In the case of a read transaction, the DAT line active changes from 0 to 1 as a read transaction restarts. • In the case of a write transaction, the write transfer active changes from 0 to 1 as the write transaction restarts. Therefore, it is not necessary for host driver to set this bit to 0. If stop at block gap request is set to 1, any write to this bit is ignored. 0 No effect 1 Restart
15 SABGREQ	Stop at block gap request. This bit is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the transfer complete is set to 1, indicating a transfer completion, the host driver should leave this bit set to 1. Clearing both the stop at block gap request and continue request does not cause the transaction to restart. Read wait is used to stop the read transaction at the block gap. The eSDHC will honor the stop at block gap request for write transfers, but for read transfers it requires that the SDIO card support read wait. Therefore, the host driver should not set this bit during read transfers unless the SDIO card supports read wait and has set the read wait control to 1, otherwise the eSDHC will stop the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the host driver writes data to the data port register, the host driver should set this bit after all block data is written. If this bit is set to 1, the host driver should not write data to the data port register after a block is sent. Once this bit is set, the host driver should not clear this bit before the transfer complete bit in (IRQSTAT)is set, otherwise the eSDHCs behavior is undefined. This bit effects read transfer active, write transfer active, PRSSTAT[DLA] and PRSSTAT[CDIHB]. 0 Transfer 1 Stop
16–20 -	This field is reserved.
21 VOLT_SEL	Voltage selection. Change the value of output signal SDHC_VS , to control the SD bus supply voltage for external card. There must be a control circuit out of eSDHC to change the voltage. 0 Change the SD Bus Supply voltage to high voltage range, around 3.0V 1 Change the SD bus supply voltage to low voltage range, around 1.8V
22–23 DMAS	DMA select. This field is valid while DMA (SDMA or ADMA) is enabled and selects the DMA operation. 00 Single DMA is selected 01 ADMA1 is selected 10 32-bit address ADMA2 is selected 11 Reserved
24 CDSS	Card detect signal selection. This bit selects the source for the card detection. 0 SD CD pin is selected (for normal purposes) 1 Card detection test level is selected (for test purposes)
25 CDTL	Card detect test level. This is bit is enabled while the card detection signal selection is set to 1 and it indicates card insertion. 0 Card detect test level is 0, no card inserted 1 Card detect test level is 1, card inserted
26–27 EMODE	Endian mode. The eSDHC supports little and big endian mode for transferring between buffer port register and data buffer.

Table continues on the next page...

Field	Description
0–3 -	This field is reserved.
4 INITA	Initialization active. When this bit is set, 80 SD clocks are sent to the card. After the 80 clocks are sent, this bit is self cleared. This bit is very useful during the card power-up period when 74 SD-Clocks are needed. Writing 1 to this bit when this bit is already 1 has no effect. Writing 0 to this bit at any time has no effect. When either PRSSTAT[CIHB] or PRSSTAT[CDIHB] are set, writing 1 to this bit is ignored (that is, when command line or data lines are active, write to this bit is not allowed). On the other hand, when this bit is set, that is, during intialization active period, it is allowed to issue command, and the command bit stream will appear on the CMD pad after all 80 clock cycles are done. So when this command ends, the

Table continues on the next page...

eSDHC_SYSCTL field descriptions (continued)

Field	Description
	driver can make sure the 80 clock cycles are sent out. This is very useful when the driver needs send 80 cycles to the card and does not want to wait till this bit is self cleared.

5
RSTD
	Software reset for DAT line. Only part of the data circuit is reset. DMA circuit is also reset.
	The following registers and bits are cleared by this bit:
	• Data port register
	  • Buffer is cleared and initialized
	• Present state register (PRSSTAT)
	  • Buffer read enable
	  • Buffer write enable
	  • Read transfer active
	  • Write transfer active
	  • DAT line active
	  • Command inhibit (DAT)
	• Protocol control register (PROCTL)
	  • Continue request
	  • Stop at block gap request
	• Interrupt status register (IRQSTAT)
	  • Buffer read ready
	  • Buffer write ready
	  • DMA interrupt
	  • Block gap event
	  • Transfer complete
	NOTE: This bit will be self cleared by eSDHC when Software Reset for Data is complete, so Software should poll for it to be cleared after setting it.
	0 No reset
	1 Reset

6 RSTC	Software reset for CMD line. Only part of the command circuit is reset. The following registers and bits are cleared by this bit: • PRSSTAT[CIHB] • IRQSTAT[CC] **NOTE:** This bit will be self cleared by eSDHC when Software Reset for Command is complete, so software should poll for it to be cleared after setting it. 0 No reset 1 Reset
7 RSTA	Software reset for all. This reset effects the entire host controller except for the card detection circuit. Register bits of type R, RW, RW1C are cleared. During its initialization, the host driver should set this bit to 1 to reset the eSDHC. The eSDHC should reset this bit to 0 when the capabilities registers are valid and the host driver can read them. Additional use of software reset for all does not affect the value of the capabilities registers. After this bit is set, it is recommended that the host driver reset the external card and re-initialize it. **NOTE:** The Software Reset For All in the System Control register clears Card Insertion and Card Removal bits in Interrupt Status Register. Software should issue partial reset(Reset for Command and Reset for Data) instead of Reset for All, if it wants to reset eSDHC without clearing these Interrupt Status Register bits. This bit will be self cleared by eSDHC when Software Reset for All is complete, so Software should poll for it to be cleared after setting it.

Table continues on the next page...

eSDHC_SYSCTL field descriptions (continued)

Field	Description
	0 No reset 1 Reset
8–11 -	This field is reserved.
12–15 DTOCV	Data timeout counter value. This value determines the interval by which DAT line timeouts are detected. Refer to the data timeout error bit in the Interrupt status enable register (eSDHC_IRQSTATEN) for information on factors that dictate time-out generation. Time-out clock frequency will be generated by dividing the SDCLK value by this value. The host driver can clear IRQSTATEN[DTOESEN] to prevent inadvertent time-out events. 0000 SDCLK x 2^{13} 0001 SDCLK x 2^{14} ... 1110 SDCLK x 2^{27} 1111 Reserved
16–23 SDCLKFS	SDCLK frequency select. This register is used to select the frequency of the SDCLK pin. The frequency is not programmed directly, rather this register holds the prescaler (this field) and divisor (next field) of the base clock frequency register. Setting 0x00 bypasses the frequency prescaler of the SD clock. Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of the base clock and the following divisor bits. **NOTE:** The Base clock frequency is platform_clk/2. The frequency of SDCLK is set by the following formula: Clock Frequency = (Base Clock) ÷ (prescaler x divisor) For example, if the base clock frequency is 96 MHz and the target frequency is 25 MHz, then choosing the prescaler value of 0x01 and divisor value of 0x1 will yield 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 0x08 and divisor value of 0xE yields the exact clock value of 400 kHz. The reset value of this bit field is 0x80, so if the input base clock is about 96 MHz, the default SD clock after reset is 375 kHz. The programmed SD Clock frequency shall never exceed maximum SD clock supported by the card. **NOTE:** Both DVS and SDCLKFS fields should not be programmed 0 simultaneously. Only the following settings are allowed: 0x00 Base clock 0x01 Base clock divided by 2 0x02 Base clock divided by 4 0x04 Base clock divided by 8 0x08 Base clock divided by 16 0x10 Base clock divided by 32 0x20 Base clock divided by 64 0x40 Base clock divided by 128 0x80 Base clock divided by 256
24–27 DVS	Divisor. This register is used to provide a more exact divisor to generate the desired SD clock frequency. Note the divider can even support odd divisor without deterioration of duty cycle. The settings are as following:

Table continues on the next page...

eSDHC_SYSCTL field descriptions (continued)

Field	Description
	0x0 Divisor by 1 0x1 Divisor by 2 0x2 Divisor by 3 ... 0xE Divisor by 15 0xF Divisor by 16
28 SDCLKEN	SD clock enable. the host controller should stop SDCLK when writing this bit to 0. SDCLK frequency can be changed when this bit is 0. Then, the host controller should maintain the same clock frequency until SDCLK is stopped (stop at SDCLK=0). If PRSSTAT[CINS] is cleared, this bit should be cleared by the host driver to save power.
29–31 -	This field is reserved.

15.3.13 Interrupt status register (eSDHC_IRQSTAT)

An interrupt is generated when the normal interrupt signal enable is enabled and at least one of the status bits is set to 1. For most bits, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. For card interrupt, before writing 1 to clear, it is required that the card stops asserting the interrupt, meaning that when the card driver services the interrupt condition, otherwise the CINT bit will be asserted again

Table 15-5. eSDHC Status for Command Timeout Error/Command Complete Bit Combinations

Command Complete	Command Timeout Error	Meaning of the Status
0	0	X
X	1	Response not received within 64 SDCLK cycles
1	0	Response received

Table 15-6. eSDHC Status for Data Timeout Error/Transfer Complete Bit Combinations

Transfer Complete	Data Timeout Error	Meaning of the Status
0	0	X
0	1	Timeout occurred during transfer
1	X	Data Transfer Complete

Table 15-7. eSDHC Status for Command CRC Error/Command Timeout Error Bit Combinations

Command CRC Error	Command Timeout Error	Meaning of the Status
0	0	No error
0	1	Response Timeout Error
1	0	Response CRC Error
1	1	CMD line conflict

Address: 11_4000h base + 30h offset = 11_4030h

eSDHC_IRQSTAT field descriptions

Field	Description
0–2 -	This field is reserved.
3 DMAE	DMA error. This bit indicates that DMA (SDMA or ADMA) transfer has failed. 0 No error 1 Error
4–5 -	This field is reserved.
6 ADMAE	ADMA error. This bit is set when the host controller detects errors during ADMA operation. The state of the ADMA at an error occurrence is saved in the ADMA error status register. 0 No error 1 Error
7 AC12E	Auto CMD12 error. Occurs when detecting that one of the bits in the Auto CMD12 error status register (AUTOC12ERR) has changed from 0 to 1. This bit is set to 1, not only when the errors in Auto CMD12 occur, but also when the Auto CMD12 is not executed due to the previous command error. 0 No error 1 Error

Table continues on the next page...

eSDHC_IRQSTAT field descriptions (continued)

Field	Description
8 -	This field is reserved.
9 DEBE	Data end bit error. Occurs either when detecting 0 at the end bit position of read data, which uses the DAT line, or at the end bit position of the CRC. 0 No error 1 Error
10 DCE	Data CRC error. Occurs when detecting a CRC error when transferring read data, which uses the DAT line, or when detecting the write CRC status having a value other than 010. 0 No error 1 Error
11 DTOE	Data timeout error. Occurs when detecting one of following time-out conditions. • Busy time-out for R1b, R5b type • Busy time-out after write CRC status • Write CRC status time-out • Read data time-out 0 No error 1 Time out
12 CIE	Command index error. Occurs if a command index error occurs in the command response. 0 No error 1 Error
13 CEBE	Command end bit error. Occurs when detecting that the end bit of a command response is 0. 0 No error 1 End bit error generated
14 CCE	Command CRC error. A command crc error is generated in two cases: • If a response is returned and the command timeout error is set to 0 (indicating no time-out), this bit is set when detecting a CRC error in the command response. • The eSDHC detects a CMD line conflict by monitoring the CMD line when a command is issued. If the eSDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then the eSDHC should abort the command (stop driving CMD line) and set this bit to 1. The command timeout error should also be set to 1 to distinguish CMD line conflict. 0 No error 1 CRC error generated
15 CTOE	Command timeout error. Occurs only if no response is returned within 64 SDCLK cycles from the end bit of the command. If the eSDHC detects a CMD line conflict, in which case a command CRC error should also be set (as shown in), this bit should be set without waiting for 64 SDCLK cycles. This is because the command will be aborted by the eSDHC. 0 No error 1 Time out
16–22 -	This field is reserved.
23 CINT	Card interrupt. Writing this bit to 1 does not clear this bit. It is cleared by resetting the SD card interrupt factor. In 1-bit mode, the host controller should detect the card interrupt without SD clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so there are some

Table continues on the next page...

eSDHC_IRQSTAT field descriptions (continued)

Field	Description
	sample delays between the interrupt signal from the SD card and the interrupt to the host system. It is necessary to define how to handle this delay. When this status has been set and the host driver needs to start this interrupt service, IRQSTATEN[CINTSEN] should be set to 0 in order to clear the card interrupt statuses latched in the eSDHC and to stop driving the interrupt signal to the host system. After completion of the card interrupt service (It should reset interrupt factors in the SD card and the interrupt signal may not be asserted), set the card interrupt status enable bit to 1 and start sampling the interrupt signal again. 0 No card interrupt 1 Generate card interrupt
24 CRM	Card removal. This status is set if the PRSSTAT[CINS] changes from 1 to 0. When the host driver writes this bit to 1 to clear this status, the status of the PRSSTAT[CINS] should be confirmed. Because the card detect state may possibly be changed when the host driver clear this bit and interrupt event may not be generated. **NOTE:** The Software Reset For All in the System Control register clears this bit. Software should issue partial reset(Reset for Command and Reset for Data) instead of Reset for All, if it wants to reset eSDHC without clearing this bit. eSDHC does not implement de-bouncing circuit on card detect pin, so Software should check Card Inserted in Present State register to confirm card insertion/removal status. 0 Card state unstable or inserted 1 Card removed
25 CINS	Card insertion. This status is set if PRSSTAT[CINS] changes from 0 to 1. When the host driver writes this bit to 1 to clear this status, the status of the PRSSTAT[CINS] should be confirmed. Because the card detect state may possibly be changed when the host driver clear this bit and interrupt event may not be generated. **NOTE:** The Software Reset For All in the System Control register clears this bit. Software should issue partial reset(Reset for Command and Reset for Data) instead of Reset for All, if it wants to reset eSDHC without clearing this bit. eSDHC does not implement de-bouncing circuit on card detect pin, so Software should check Card Inserted in Present State register to confirm card insertion/removal status. 0 Card state unstable or removed 1 Card inserted
26 BRR	Buffer read ready. This status bit is set if PRSSTAT[BREN] changes from 0 to 1. Refer to the description of the buffer read enable bit in Present state register (eSDHC_PRSSTAT) for additional information. 0 Not ready to read buffer 1 Ready to read buffer
27 BWR	Buffer write ready. This status bit is set if the PRSSTAT[BWEN] changes from 0 to 1. Refer to the description of the buffer write enable bit in Present state register (eSDHC_PRSSTAT) for additional information. 0 Not ready to write buffer 1 Ready to write buffer
28 DINT	DMA interrupt. Occurs only when the DMA finishes the data transfer successfully. Whenever errors occur during data transfer, this bit will not be set. Instead, the DMAE bit will be set. Either single DMA or ADMA finishes data transferring, this bit will be set.

Table continues on the next page...

eSDHC_IRQSTAT field descriptions (continued)

Field	Description
	0 No DMA Interrupt 1 DMA Interrupt is generated
29 BGE	Block gap event. If PROCTL[SABGREQ] is set, this bit is set when a read or write transaction is stopped at a block gap. If PROCTL[SABGREQ] is not set to 1, this bit is not set to 1. • In the case of a read transaction, this bit is set at the falling edge of the DAT Line active status (when the transaction is stopped at SD bus timing). The read wait must be supported in order to use this function. • In the case of a write transaction, this bit is set at the falling edge of write transfer active status (after getting CRC status at SD Bus timing). 0 No block gap event 1 Transaction stopped at block gap

30
TC
	Transfer complete. This bit is set when a read/write transfer and a command with busy is completed.
	• In the case of a read transaction, this bit is set at the falling edge of read transfer active status. This interrupt is generated in two cases:
	  • When a data transfer is completed as specified by data length (after the last data has been read to the host system)
	  • When data has stopped at the block gap and completed the data transfer by setting PROCTL[SABGREQ] (after valid data has been read to the host system)
	• In the case of a write transaction, this bit is set at the falling edge of the DAT line active status. This interrupt is generated in two cases:
	  • When the last data is written to the SD card as specified by data length and the busy signal released
	  • When data transfers are stopped at the block gap by settingPROCTL[SABGREQ] and data transfers completed (after valid data is written to the SD card and the busy signal released)
	• In the case of a command with busy, this bit is set when busy is de-asserted. Refer to PRSSTAT[DLA] and PRSSTAT[CDIHB].
	
	0 Transfer not complete
	1 Transfer complete

31 CC	Command complete. This bit is set when the end bit of the command response is received (except Auto CMD12). Refer to PRSSTAT[CIHB]. 0 Command not complete 1 Command complete

15.3.14 Interrupt status enable register (eSDHC_IRQSTATEN)

Setting the bits to 1 in the IRQSTATEN enables the corresponding interrupt status to be set by the specified event. If any bit is cleared, the corresponding interrupt status bit is also cleared (that is, when the bit in this register is cleared, the corresponding bit in interrupt status register, IRQSTAT, is always 0).

NOTE

- Depending on how PROCTL[IABG] is set, eSDHC may be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There

will be some delays on the card interrupt, asserted from the card, to the time the host system is informed.
- To detect a CMD line conflict, the host driver must set both IRSTAT[CTOESEN] and IRSTAT[CCESEN] to 1.

15.3.16 Auto CMD error status register (eSDHC_AUTOCERR)

When the Auto CMD12 error status bit in the AUTOC12ERR is set, the host driver checks this register to identify the kind of error indicated by the Auto CMD12. This register is valid only when the auto CMD12 error status bit is set.

Table 15-8. Relationship Between Command CRC Error and Command Timeout Error for Auto CMD12

Auto CMD12 CRC Error	Auto CMD12 Timeout Error	Type of Error
0	0	No Error
0	1	Response Timeout Error
1	0	Response CRC Error
1	1	CMD line conflict

Changes in Auto CMD12 error status register (AUTOC12ERR) can be classified in three scenarios:

1. When the eSDHC is going to issue an Auto CMD12
   - Set bit 0 to 1 if the Auto CMD12 cannot be issued due to an error in the previous command
   - Set bit 0 to 0 if the Auto CMD12 is issued
2. At the end bit of an Auto CMD12 response
   - Check errors correspond to bits 1-4
   - Set bits 1-4 corresponding to detected errors
   - Clear bits 1-4 corresponding to detected errors
3. Before reading the Auto CMD12 error status bit 7
   - Set bit 7 to 1 if there is a command that cannot be issued
   - Clear bit 7 if there is no command to issue

The timing for generating the Auto CMD12 error and writing to the command register are asynchronous. After that, bit 7 should be sampled when the driver is not writing to the command register. So it is suggested to read this register only when IRQSTAT[AC12E] is set. An Auto CMD12 error interrupt is generated when one of the error bits (0-4) is set to 1. The command not issued by Auto CMD12 Error does not generate an interrupt.

Address: 11_4000h base + 3Ch offset = 11_403Ch

15.3.19 Force event register (eSDHC_FEVT)

The FEVT is not a physically implemented register. Rather, it is an address at which the interrupt status register (IRQSTAT) can be written if the corresponding bit of the interrupt status enable register (IRQSTATEN) is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register actually sets the corresponding bit of interrupt status register (IRQSTAT). A read from this register always results in zeros.

Address: 11_4000h base + 50h offset = 11_4050h

15.3.20 ADMA error status register (eSDHC_ADMAES)

When an ADMA error interrupt occurs, the ADMA error states field in the ADMAES holds the ADMA state and the ADMA system address register (ADSADDR) holds the address around the error descriptor.

For recovering from this error, the host driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA system address register (ADSADDR) is the error descriptor address
- ST_FDS: Current location set in the ADMA system address register (ADSADDR) is the error descriptor address
- ST_CADR: This state is never set because it only increments the descriptor pointer and does not generate an ADMA error
- ST_TFR: Previous location set in the ADMA system address register (ADSADDR) is the error descriptor address

In case of a write operation, the host driver should use the ACMD22 to get the number of the written block rather than using this information, since unwritten data may exist in the host controller.

The Host controller generates the ADMA error interrupt when it detects invalid descriptor data (valid=0) in the ST_FDS state. The host driver can distinguish this error by reading the valid bit of the error descriptor.

Table 15-9. ADMA Error State Coding

D30-D31	ADMA Error State (When Error Has Occurred)	Contents of ADMA System Address Register
00	IDLE (idle)	Current descriptor address on which ADMA error occured
01	FETCH_DESC (fetch descriptor)	Current descriptor address on which ADMA error occured
10	DATA_XFER (data transfer)	Current descriptor address on which ADMA error occured
11	WAIT_STOP (Wait for ADMA to stop)	Current descriptor address on which ADMA error occured

Address: 11_4000h base + 54h offset = 11_4054h

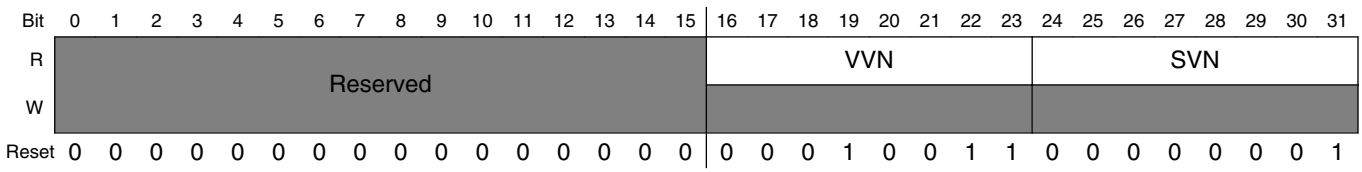
eSDHC_ADSADDR field descriptions

Field	Description
0–31 ADS_ADDR	ADMA system address. This register holds 32-bit address of executing command of the descriptor table. At the start of ADMA, the host driver should set start address of the descriptor table. The ADMA increments this register address, which points to next line, when every fetching a descriptor line. When the ADMA error interrupt is generated, this register should hold valid descriptor address depending on the ADMA state. The host driver should program descriptor table on 32-bit boundary and set 32-bit boundary address to this register. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). The host driver should initialize this register before starting an ADMA transaction.

15.3.22 Host controller version register (eSDHC_HOSTVER)

The HOSTVER contains the vendor host controller version information. All bits are read only and will read the same as the power-reset value.

Address: 11_4000h base + FCh offset = 11_40FCh



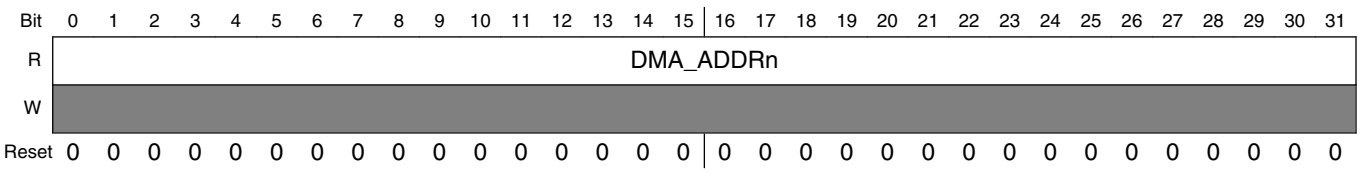
eSDHC_HOSTVER field descriptions

Field	Description
0–15 -	This field is reserved.
16–23 VVN	Vendor version number. These status bits are reserved for the vendor version number. The host driver should not use this status. Patterns not shown are reserved. 0x00 eSDHC Version 1.0 0x10 eSDHC Version 2.0 0x11 eSDHC Version 2.1 0x12 eSDHC Version 2.2 0x13 eSDHC Version 2.3
24–31 SVN	Specification version number. These status bits indicate the host controller specification version. Patterns not shown are reserved. 0x00 SD Host Specification Version 1.0 0x01 SD Host Specification Version 2.0, supports test event register , and ADMA

15.3.23 DMA error address register (eSDHC_DMAERRADDR)

The DMAERRADDR contains the address of the transaction on which DMA error occured.

Address: 11_4000h base + 104h offset = 11_4104h



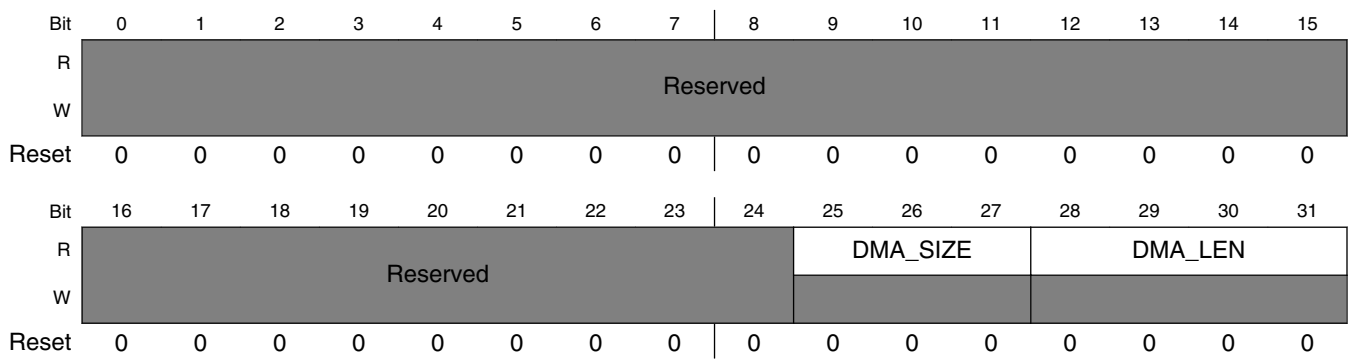
eSDHC_DMAERRADDR field descriptions

Field	Description
0–31 DMA_ADDRn	DMA error address. This field contains the system address of the transaction on which DMA error occured.

15.3.24 DMA error attribute register (eSDHC_DMAERRATTR)

The DMAERRATTR contains attributes of the transaction on which DMA error occured.

Address: 11_4000h base + 10Ch offset = 11_410Ch



eSDHC_DMAERRATTR field descriptions

Field	Description
0–24 -	This field is reserved.
25–27 DMA_SIZE	System bus burst size. This field contains burst size of the transaction on which DMA error occured.

Table continues on the next page...

eSDHC_DMAERRATTR field descriptions (continued)

Field	Description
28–31 DMA_LEN	System bus burst length. This field contains burst length of the transaction on which DMA error occured.

15.3.25 eSDHC control register (eSDHC_ESDHCCTL)

This register contains fields for controlling DMA transfers.

Address: 11_4000h base + 40Ch offset = 11_440Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	Reserved												Reserved			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R W	Reserved			RD_PRFTCH_BLKCNT					PAD_DIS	SNOOP	Reserved		WR_ BUF	RD_ SAFE	Reserved	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

eSDHC_ESDHCCTL field descriptions

Field	Description
0–11 -	This field is reserved.
12–18 -	This field is reserved.
19–23 RD_PRFTCH_ BLKCNT	Read prefetch block count. For DMA read (SD write), this field specifies the maximum number of SD blocks that the host can prefetch from the system memory. It can have following values: 00000 No prefetch 00001 1 SD block prefetch 00010 2 SD block prefetch ... 11111 31 SD block prefetch
24 PAD_DIS	Pad disable. Padding disable control for DMA transaction with non-word (4-bytes) aligned block size. For more details refer to Data buffer and block size. 0 DMA will pad data at the end each block transfer. 1 DMA will not pad data at the end of each block transfer.

Table continues on the next page...

eSDHC_ESDHCCTL field descriptions (continued)

Field	Description
25 SNOOP	Snoop attribute. Snoop enable for DMA transaction. 0 DMA transactions are not snooped by the CPU data cache. 1 DMA transactions are snooped by the CPU data cache.
26–27 -	This field is reserved.
28 WR_BUF	Write bufferable. DMA always initiate write transaction on System bus corresponding to last in every SD block as non-bufferable. This bit specifies whether all non-last write transactions will be bufferable or not. 0 Non-last write transactions are not bufferable. 1 Non-last write transactions are bufferable.
29 RD_SAFE	Read safe. This bit should be set only if the target of read dma operation is a well behaved memory which is not affected by the read operation and will return the same data if read again from the same location. This means that unaligned reading operation can be rounded up to enable more efficient read operations. 0 It is not safe to read more bytes that were intended. 1 It is safe to read more bytes that were intended.
30–31 -	This field is reserved.

15.4 Functional description

The eSDHC block is partitioned in five major sub-blocks as shown in Figure 15-2.

- SD interface and control unit

  This block interfaces with the SD bus. It is mainly responsible for controlling the SD bus operation and transferring data from Data Buffer and SD bus. It also interacts with System Interface and Control Unit.

- System interface and control unit

  This block interfaces with the system interfaces (that is, the system bus in DMA mode and register bus in CPU polling mode) and transfers the card data from the data buffer and system.

- Register bank

  This block interfaces with register bus and contains all the registers. It controls the overall operation of eSDHC and also provides status through various registers.

- Clock and reset

This block generates divided clock for SD interface and provides appropriate reset to all the blocks.

- SD monitor

  This block monitors the SD bus and provides status to register banks, such as card interrupt, write protect and card detect.

15.4.1 System interface and control unit (SysICU)

The SysICU block is further partitioned into three major sub-blocks:

- System control block

  This sub-block receives data transfer request from the register bank, controls data transfer for whole transaction and generates control signals for DMA and buffer control operation on per block basis.

- Buffer control block

  This sub-block handles buffer port register access in CPU polling mode and contains the buffer FIFO to store transfer data. It controls the data transfer per-block basis in the CPU polling mode.

- DMA block

  This sub-block generates DMA transactions on system bus to transfer the data between system memory and data buffer.

The following sections provide a brief functional description of the major system blocks, including the data buffer, DMA system interface, register bank as well as IP bus interface, dual-port memory wrapper, data/command controller, clock and reset manager, and clock generator.

15.4.1.1 Data buffer

The eSDHC uses one configurable data buffer, so that data can be transferred between the system/register bus and SD card in an optimized manner to maximize throughput between the two clock domains. See the figure below for illustration of the buffer scheme.

The buffer is used as temporary storage for data being transferred between the host system and the card.

The watermark levels for read and write are both configurable, and can be any number from 1-128 words for CPU polling mode. The burst lengths for read and write are also configurable, and can be any number from 1-16 for DMA mode.

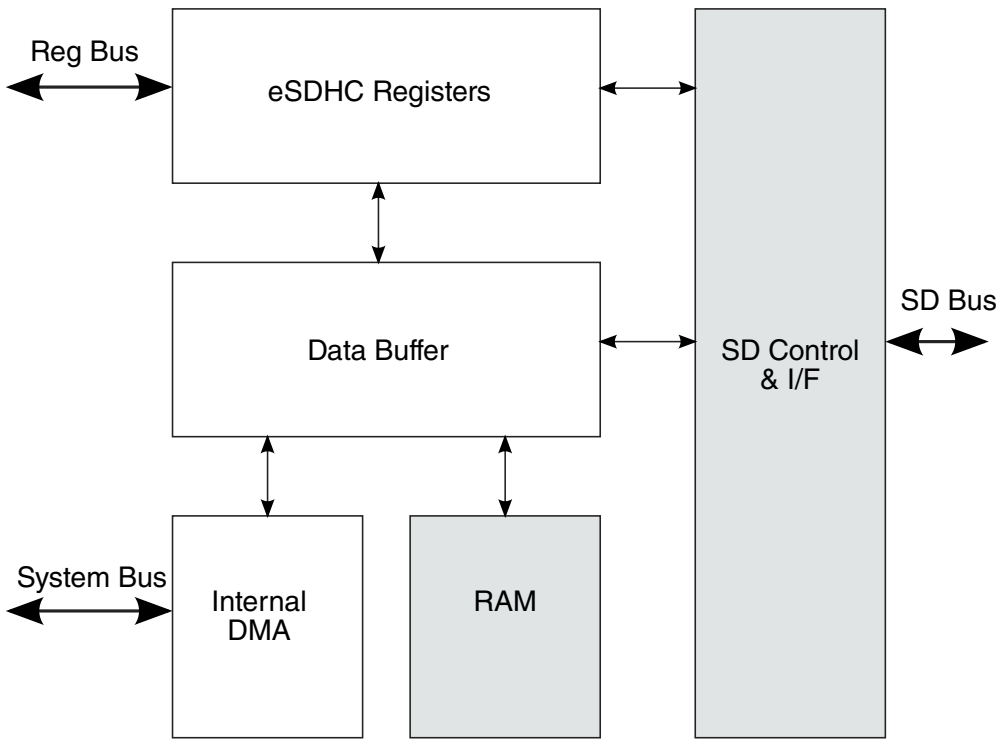

Figure 15-3. eSDHC buffer scheme

There are two transfer modes to access the data buffer:

- CPU polling mode

  Data is transferred over register bus. For a host read operation, when the number of words received in the buffer meets or exceeds the RD_WML watermark value, then by monitoring (polling or interrupt) the BRR bit the host driver can read the buffer data port register (DATPORT) to fetch the amount of words set in the RD_WML register from the buffer. For block size integral multiple of watermark level value set in watermark level register (WML), driver must access buffer data port register (DATPORT) exactly the same number of times as the watermark level. However, if the block size is not the times of the watermark level value, the software must access exactly the remained number of words at the end of each block. For example, for read operation, if the RD_WML is 4, indicating the watermark level is 16 bytes,

block size is 40 bytes, and the block count is 2, then the access times to Data Buffer Port Register for the burst sequence in the whole transfer process must be 4, 4, 2(for first block); 4, 4, 2(for second block). The write operation is similar.

- DMA mode (includes simple and advanced DMA accesses)

  Data is transferred over system bus. DMA interrupt is generated after all the data is transferred to/from the buffer.

15.4.1.1.1 Write operation sequence

There are two ways to write data into the buffer when the user transfers data to the card:

- By processor core polling through IRQSTAT[BWR] (interrupt or polling)
- By using the DMA

When the DMA is not used, (CPU polling mode, that is, the XFERTYP[DMAEN] is not set when the command is sent), and when the amount of buffer space exceeds the value set in the WR_WML register, PRSSTAT[BWR] is set. The buffer write ready interrupt is generated if it is enabled by software.

When DMA is used, the eSDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the eSDHC aborts the data transfer and abandons the current block. If the current data transfer is in multi block mode, the eSDHC does not automatically send CMD12, even though the XFERTYP[AC12EN] is set. The host driver needs to send CMD12 in this scenario. It is recommended that a Software Reset for Data be applied before the transfer is re-started after error recovery.

15.4.1.1.2 Read operation sequence

There are two ways to read data from the buffer when the user transfers data to the card:

- By processor core polling through IRQSTAT[BRR] (interrupt or polling)
- By using the DMA

When DMA is not used (CPU polling mode, that is, the XFERTYP[DMAEN] is not set when the command is sent), and when the amount of data exceeds the value set in the RD_WML register, that is available and ready for system fetching data, PRSSTAT[BRR] is set. The buffer read ready interrupt will be generated if it is enabled by software.

When DMA is used, the eSDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the eSDHC will abort the data transfer and abandon the current

block. If the current data transfer is in multi block mode, the eSDHC will not automatically send CMD12, even though the XFERTYP[AC12EN] is set. The host driver should send CMD12 in this scenario. It is recommended that a software reset for data be applied before the transfer is re-started after error recovery.

15.4.1.1.3 Data buffer and block size

In eSDHC, the data buffer can hold up to 128 words (32-bit).

The watermark levels for both write and read can be configured for CPU polling mode. The watermark level can be from one word to a maximum of 128 words. For both DMA read and write, the burst length can be configured from one to a maximum of 16. The host driver may configure watermark level and burst length value according to the system situation and requirement in the watermark level register (WML).

During a multi-block data transfer, the block length may be set to any value between 1 and 2048 bytes inclusive that satisfies the requirements of the external card. The only restriction to it can be from the external card, which may not support that large a block or partial access to block (which is not an integer times of 512 bytes).

For CPU polling mode, when block size not a multiple of four; that is, not word aligned, eSDHC requires stuff bytes at the end of each block, as defined in the host specification. For example, if the block size is 5 bytes and there are two blocks to write, there must be two register bus writes to buffer data port register (DATPORT) for each block; and for each block, the ending non-word aligned bytes should be stuffed in buffer data port register (DATPORT) write to make it word aligned. For this example, 3 bytes should be stuffed. eSDHC will transfer only the required number of bytes to the card and ignore the stuff bytes as shown in the figure below. Read operation is similar.

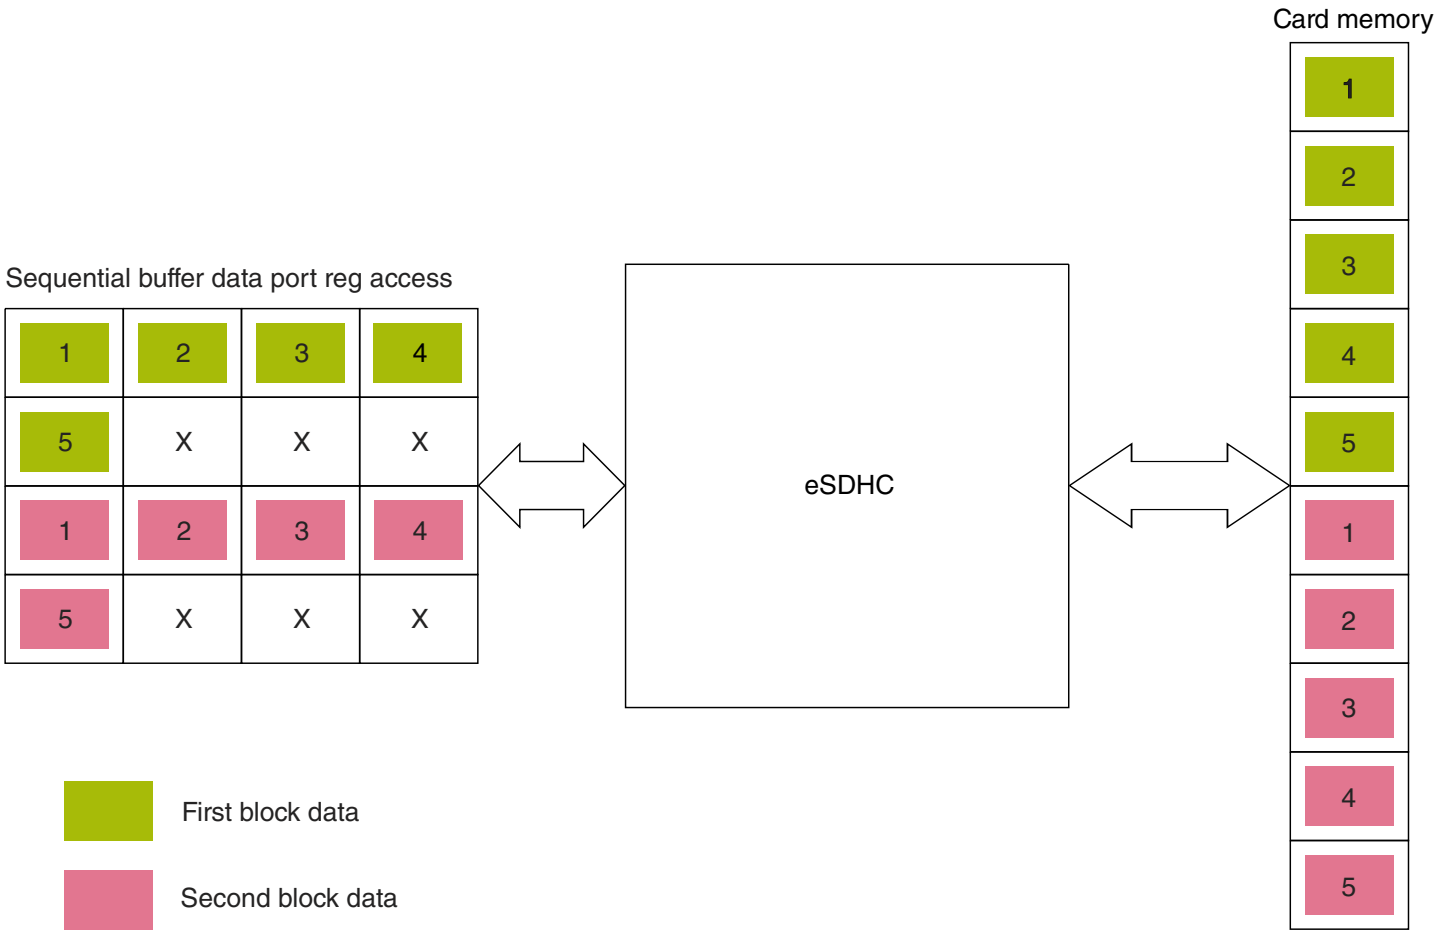

Figure 15-4. Byte stuffing for CPU polling mode

For DMA mode, when block size not a multiple of four; that is, not word aligned, eSDHC requires stuff bytes depending on the PAD_DIS field programmed in DMA Control register. The data transfer with byte stuffing enabled (when DMACTL[PAD_DIS]=0) is shown in Figure 15-5. And, data transfer with byte stuffing disabled (when DMACTL[PAD_DIS]=1) is shown in Figure 15-6. Transfer with byte stuffing disabled eliminates the software overhead of byte stuffing. Driver may program DMA Control register accordingly.

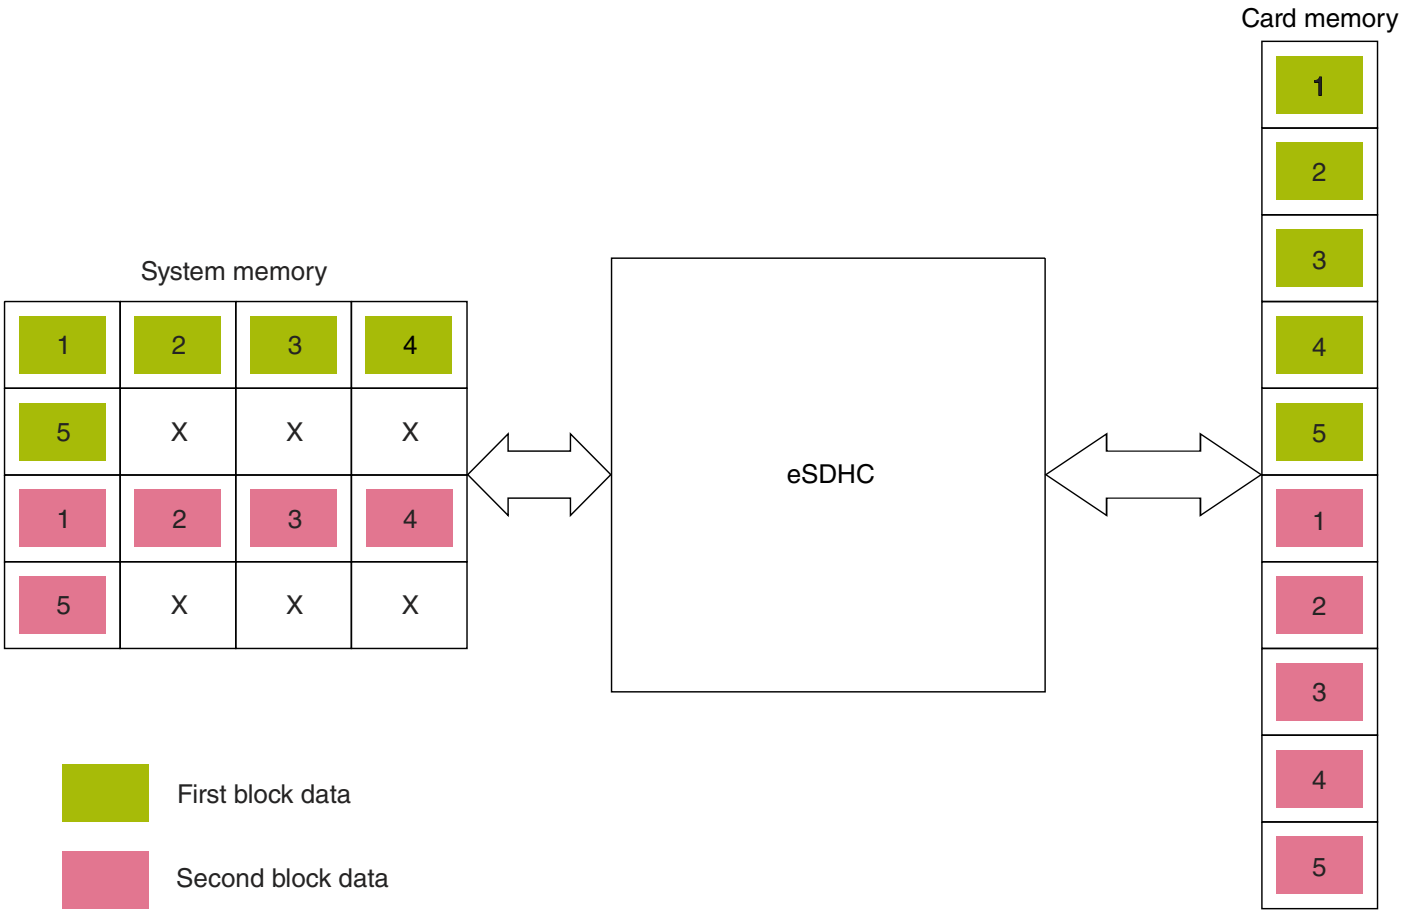

Figure 15-5. Byte stuffing for DMA mode when DMACTL[PAD_DIS]=0

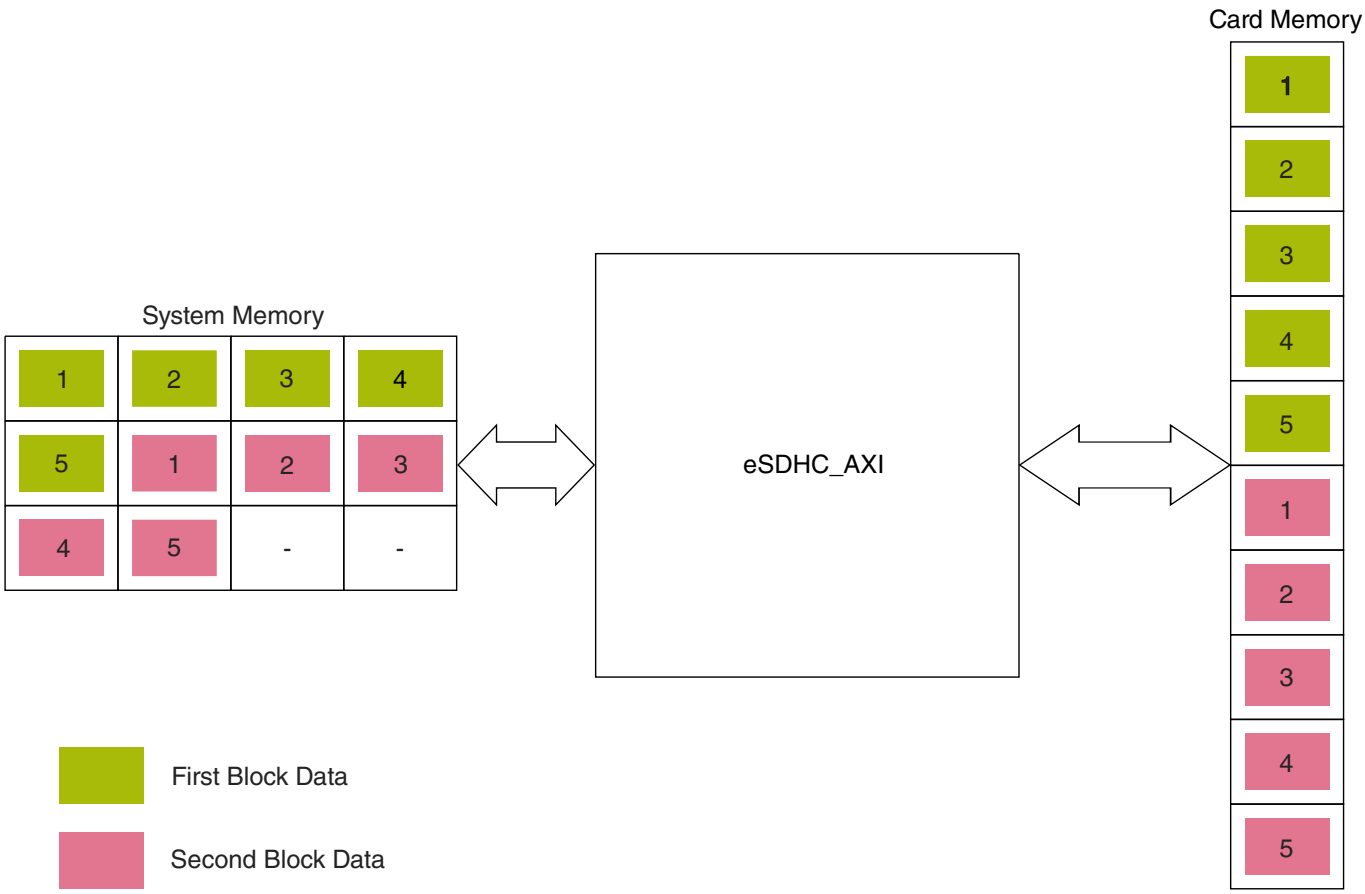

Figure 15-6. No byte stuffing for DMA mode when DMACTL[PAD_DIS]=1

15.4.1.1.4 Dividing large data transfer

This SDIO command CMD53 definition, limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in block size units. If the total data length cannot be divided evenly into a multiple of the block size, then based on the function and the card design, there are two ways to transfer the data. First option is for the host driver to split the transaction. The remainder of the block size data is then transferred by using a single block command at the end. Second option is to add dummy data in the last block to fill the block size provided the card manages the removal of the dummy data.

Figure below shows an example which explains the dividing of large data transfers. In this figure, assume a kind of WLAN SDIO card that only supports block size up to 64 bytes. Although the eSDHC supports a block size of up to 2048 bytes, the SDIO can only accept a block size less than 64 bytes. Thus, the data must be divided (see example below).

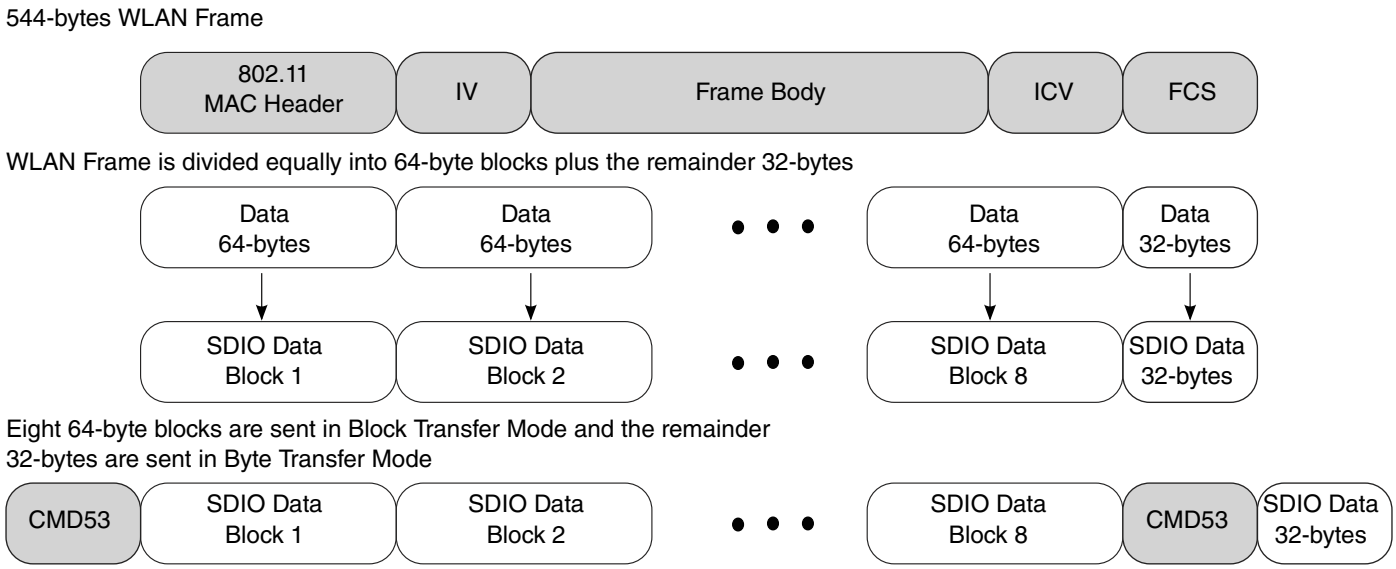

Figure 15-7. Example for dividing large data transfers

15.4.1.1.5 Byte order (endianness) of buffer data port register

For CPU polling mode, sequential and contiguous access is necessary to ensure the pointer address value is correct. Random or skipped access is not possible.

The byte order of buffer data port register (DATPORT), by reset is little endian mode. The data buffer is always little endian. The data is swapped inside the buffer, according to the endian mode configured by software in PROCTL[EMODE].

In little endian mode, the data is transferred between data buffer and buffer data port register (DATPORT) without any swapping. In big endian mode, the data between data buffer and buffer data port register (DATPORT) is byte-swapped as shown in the figure given below. For an SD write operation, byte order is swapped after data is fetched from the buffer port register and sent to data buffer. For a host read operation, byte order is swapped after the data is read from data buffer and sent to buffer port register.

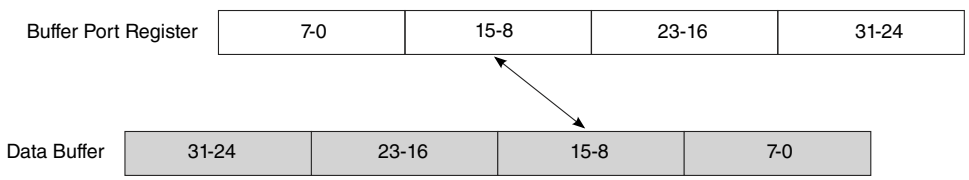

Figure 15-8. Data swap between buffer data port register and data buffer in big endian mode

15.4.1.2 DMA system interface

The DMA implements a DMA engine and the system master.

The eSDHC supports both SDMA and ADMA (ADMA1 and ADMA2). Figure below illustrates the DMA system interface block.

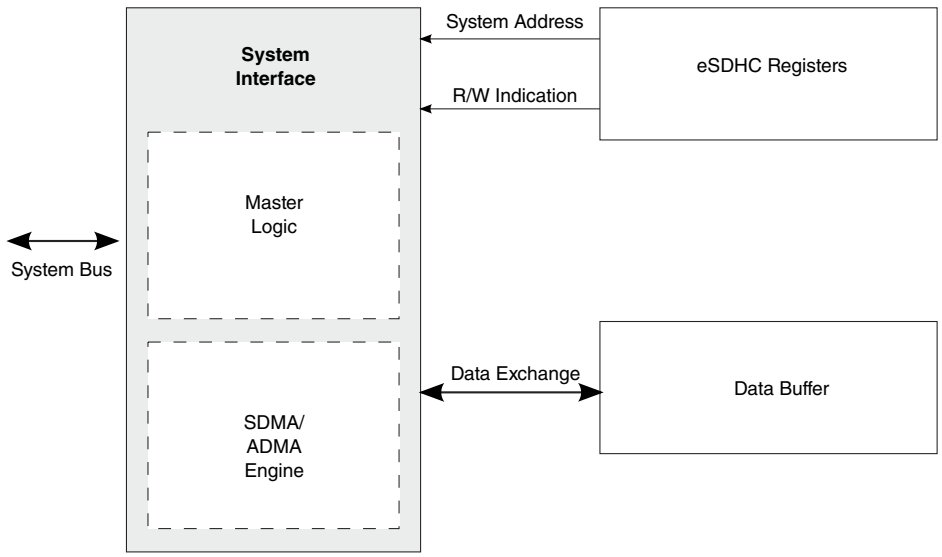

Figure 15-9. DMA system interface block

15.4.1.2.1 DMA burst length

The actual burst length on system bus depends on the shortest of following factors:

- Burst length configured in the burst length field of the watermark level register (WML)
- Block size boundary
- Data boundary configured in the current descriptor (if the ADMA is active)

15.4.1.2.2 System master interface

The System DMA engine can at times fail during data transfer.

When this error occurs:

- The DMA engine stops the transfer and goes to the error state.
- The internal data buffer stops accepting incoming data.
- The IRQSTAT[DMAE] is set to inform the driver.

Once the DMAE interrupt is received, the software sends a CMD12 to abort the current transfer and read the DMAERRADDR[DMA_ADDR] bits to get the starting address of the corrupted block. For error recovery, the software issues a data reset and re-starts the transfer from this address to recover the corrupted block.

15.4.1.3 Single DMA (SDMA)

SDMA is single operation DMA, that is, data is transferred for single operation only (unlike ADMA which has chained descriptor table) from the starting address programmed in SDMA system address register (DSADDR) for entire data transfer size (block count x block size) as programmed in the block attributes register (BLKATTR) if XFERTYP[BCEN] is set.

15.4.1.3.1 SDMA error

SDMA will stop whenever an error is encountered on the system bus.

DMA error address register latches the transaction address on which the error occured.

15.4.1.4 Advanced DMA (ADMA)

Advanced DMA (ADMA) is a new DMA transfer algorithm, which is defined in the SD Host Controller Standard.

For single DMA, the data can be transferred for single operation only. The ADMA defines the programmable descriptor table in the system memory. The host driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. Higher speed DMA transfers are realized because the host MCU intervention is not needed during long DMA based data transfers.

The host controller has two types of ADMA: ADMA1 and ADMA2. ADMA1 can support data transfer of 4KB aligned data in system memory. ADMA2 improves the restriction so that data of any location and any size can be transferred in system memory. Their formats of descriptor table are different.

ADMA can recognize all kinds of descriptors defined in SD Host Controller Standard and if 'End' flag is detected in the descriptor, ADMA stops after this descriptor is processed.

eSDHC supports ADMA1 and ADMA2 with 32-bit addressing .

15.4.1.4.1 ADMA concept and descriptor format

ADMA1 includes the following descriptors:

- Valid/invalid descriptor
- Nop descriptor
- Set data length and address descriptor
- Link descriptor
- Interrupt flag and End flag in descriptor

ADMA2 includes the following descriptors:

- Valid/Invalid descriptor
- Nop descriptor
- Rsv descriptor
- Set data length and address descriptor
- Link descriptor
- Interrupt flag and End flag in descriptor

Figure 15-10 explains the ADMA1 descriptor table format.

Figure 15-12 explains the ADMA2 descriptor table format. ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the 'Valid' flag of descriptor is 0, it will ignore the high 32-bit. Address field should be set on word aligned (lower 2-bit is always set to 0). Data length is in byte unit.

ADMA starts read/write operation after it reaches the Tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last set type descriptor before Tran type descriptor. Every Tran type triggers a transfer, and the transfer data length is extracted from the most recent Set type descriptor. If there is no set type descriptor after the previous Trans descriptor, the data length is the value for previous transfer, or 4 Kbyte if no set descriptor is ever met.

For ADMA2, Tran type descriptor contains both data length and transfer data address. Thus, only a Tran type descriptor can start a data transfer.

Address/Page Field		Address/Page Field		Attribute Field					
31	12	11	6	5	4	3	2	1	0
Addressor Data Length		000000		Act2	Act1	0	Int	End	Valid

Act2	Act1	Symbol	Comment	31-28	27-12
0	0	NOP	No Operation	Do not care	
0	1	Set	Set Data Length	0000	Data Length
1	0	Tran	Transfer Data	Data Address	
1	1	Link	Link Descriptor	Descriptor Address	

Valid	Valid=1 indicates this line of descriptor is effective. If Valid=0, generate ADMA error interrupt and stop ADMA.
End	End=1 indicates current descriptor is the ending descriptor.
Int	Int=1 generates DMA Interrupt when this descriptor is processed.

Figure 15-10. Format of the 32-bit address ADMA1 descriptor table

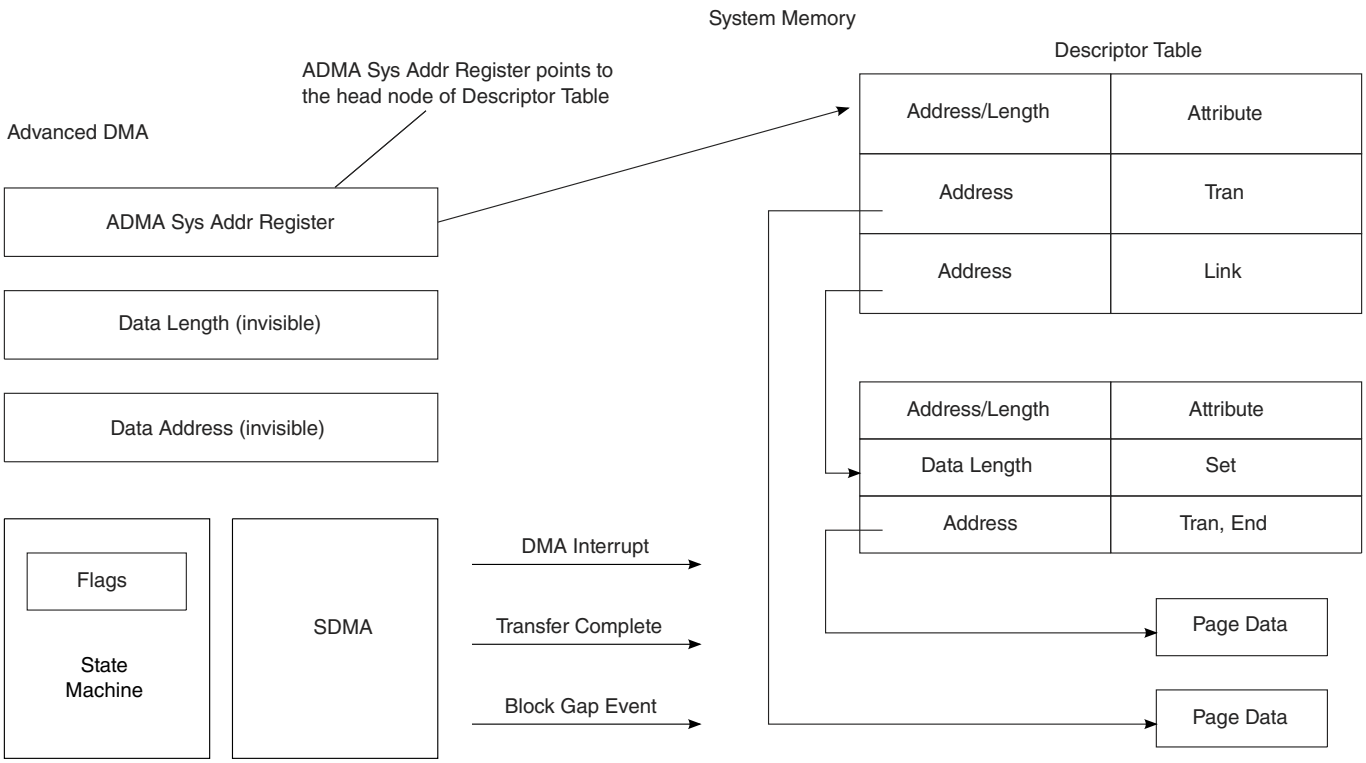

Figure 15-11. Concept and access method of ADMA1 descriptor table

Address Field		Length		Reserved		Attribute Field					
63	32	31	16	15	6	5	4	3	2	1	0
32-bit Address		16-bit Length		0000000000		Act2	Act1	0	Int	End	Valid

Act2	Act1	Symbol	Comment	Operation
0	0	NOP	No Operation	Do not care
0	1	Rsv	Reserved	Same as NOP. Read this line and go to next one
1	0	Tran	Transfer Data	Transfer data with address and length set in this descriptor line
1	1	Link	Link Descriptor	Link to another descriptor

Valid	Valid=1 indicates this line of descriptor is effective. If Valid=0, generate ADMA error interrupt and stop ADMA.
End	End=1 indicates current descriptor is the ending descriptor.
Int	Int=1 generates DMA Interrupt when this descriptor is processed.

Figure 15-12. Format of the 32-bit address ADMA2 descriptor table

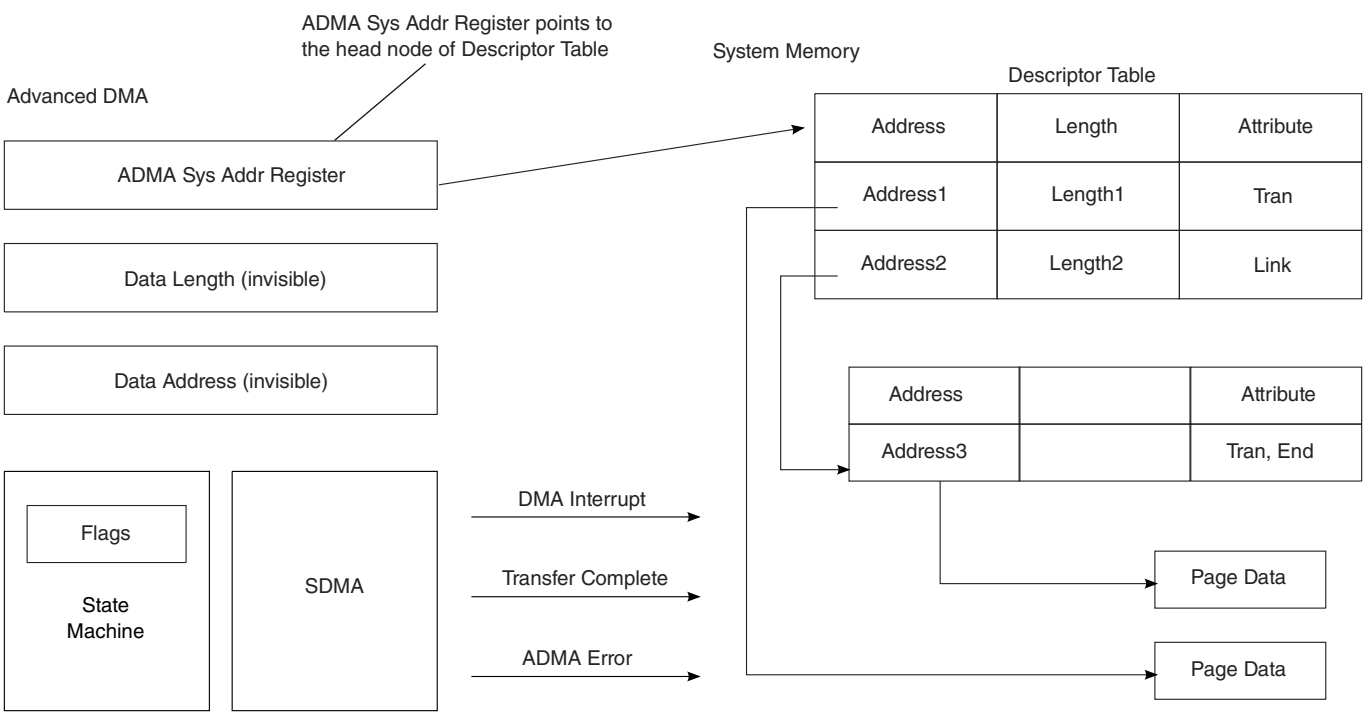

Figure 15-13. Concept and access method of ADMA2 descriptor table

15.4.1.4.2 ADMA interrupt

If the 'interrupt' flag of descriptor is set, ADMA will generate an interrupt, IRQSTAT[DINT] whenever the data transfer for the particular descriptor line is completed.

15.4.1.4.3 ADMA error

The ADMA stops whenever any of the following error is encountered:

- Fetching descriptor error
- System response error
- Data length mismatch error

ADMA descriptor error is generated when it fails to detect 'Valid' flag in the descriptor. If ADMA descriptor error occurs, the interrupt is not generated even if the 'Interrupt' flag of this descriptor is set.

When the BLKCNTEN bit is set, the data transfer length set in buffer must be equal to the whole data transfer length set in the descriptor nodes, otherwise data length mismatch error is generated.

If the BLKCNTEN bit is not set, the whole data transfer length set in descriptor should be times of block length, otherwise, when all data set in the descriptor nodes are done, the data length mismatch error will occur.

The DMA error address register (DMAERRADDR) latches the transaction address on which the error occured. The ADMA system address register (ADSADDR) latches the current descriptor line address which encountered the error.

15.4.2 SD interface and control unit (SDICU)

This block is partitioned into fivemajor sub-blocks as shown in Figure 15-2.

- Transfer control block: This sub-block receives command request from the register bank and overall controls other SDICU sub-blocks for SD bus operation on transaction level.
- SD command block: This sub-block controls the SD CMD line for sending command out. It receives the command request from Transfer Control block and sends it on SD CMD line.
- SD response block: This sub-block monitors the SD CMD line for receiving response and detecting line errors. It sends the command and response status to transfer control for transaction operation.

- SD data out block: This sub-block controls the SD DAT lines for sending out the block write data from the SD data out FIFO.
- SD data in block: This sub-block monitors the SD DAT line for detecting read and write data block end and busy period end for transfer control module. It also detects data line error and card interrupt.

15.4.2.1 Command CRC

See the figure below for an illustration of the structure for the command CRC shift register.

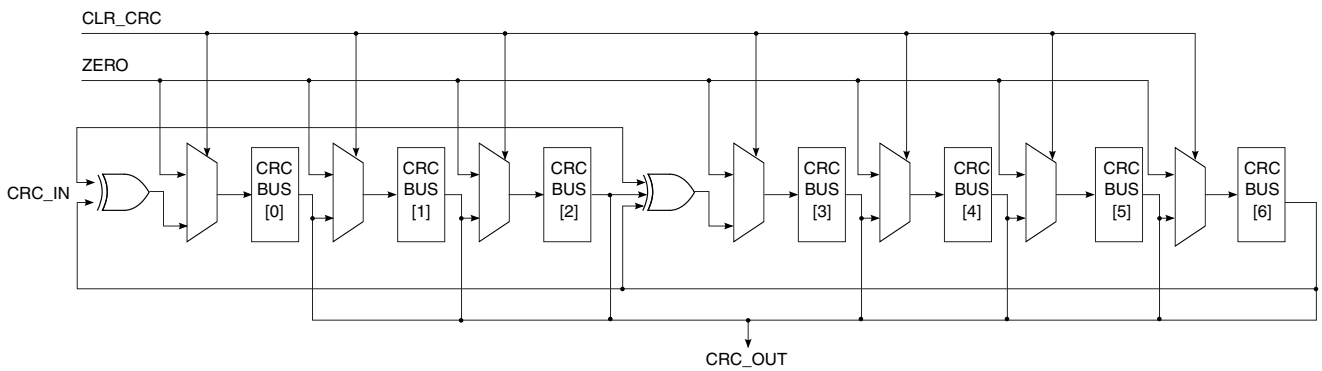

Figure 15-14. Command CRC shift register

The CRC polynomials for the CMD are as follows:

```
Generator polynomial: G(x) = x^7 + x^3 + 1
M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0
CRC[6:0] = Remainder [(M(x) * x^7) / G(x)]
```

15.4.2.2 Data CRC

The CRC polynomials for the DAT are as follows:

```
Generator polynomial: G(x) = x^16 + x^12 + x^5 +1
M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0
CRC[15:0] = Remainder [(M(x) * x^16) / G(x)]
```

15.4.3 Register bank

This block interfaces with register bus and it contains all the registers. It controls the overall operation of eSDHC and also provides status through various registers.

Register accesses is actually on the register bank. See the figure below for the block diagram.

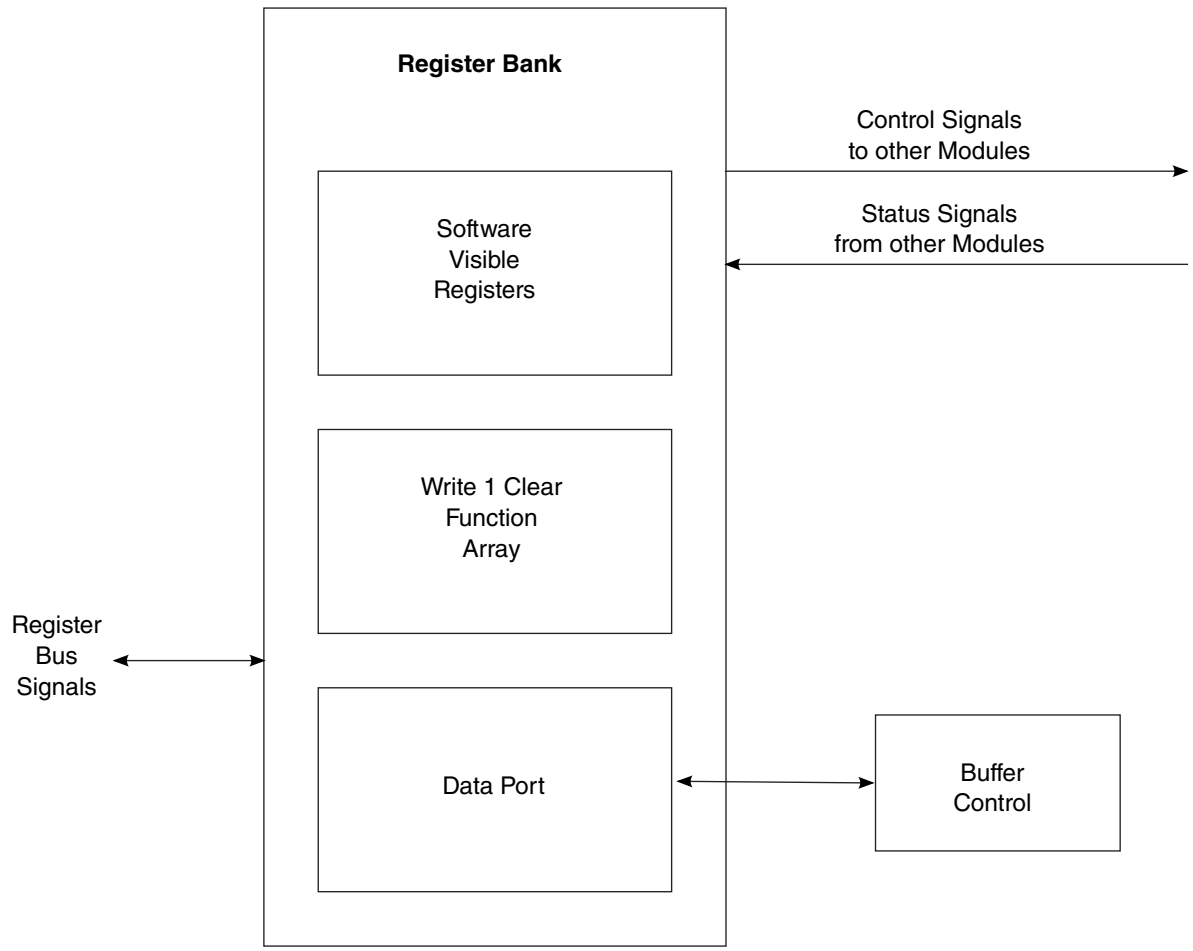

Figure 15-15. Register bank diagram

Partial access is not allowed on any register; that is, it should be 32-bit access only.

15.4.4 Clock and reset module

Clock and reset module generates divided clock for SD interface and provides appropriate reset to other modules.

There are four kinds of reset signals within eSDHC:

- Hardware reset
- Software reset for all
- Software reset for the data part
- Software reset for the command part

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules.

If the internal data buffer is in danger, and the SD clock must be gated off to avoid buffer over/under-run, this module asserts the gate of the output SD clock to shut the clock off. After the buffer danger has recovered, and when the system access of the buffer catches up, the clock gate of this module opens and the SD clock becomes active again.

15.4.4.1 Clock generator

The clock generator generates the SDHC_CLK by source clock in two stages.

The figure below illustrates the structure of the divider. The term "Base" represents the frequency of the source clock.

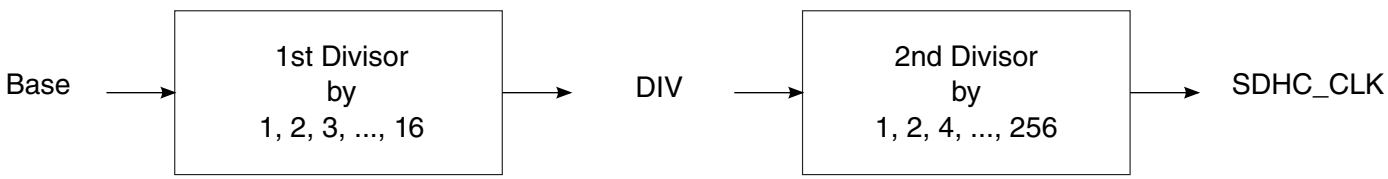

Figure 15-16. Two stages of the clock divider

The first stage outputs an intermediate clock (DIV), which can be Base, Base/2, Base/3, ..., or Base/16.

The second stage is a prescaler, and outputs the actual clock (SDHC_CLK). This clock is the driving clock for sub modules SD Command and SD Data Out in SD Interface and Control Unit (refer to Figure 15-2) to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage, can be DIV, DIV/2, DIV/4,..., or DIV/256. Thus, the highest frequency of the SDHC_CLK is Base, and the next highest is Base/2, while the lowest frequency is Base/4096.

The figure below illustrates the sequence for changing the SD clock frequency.

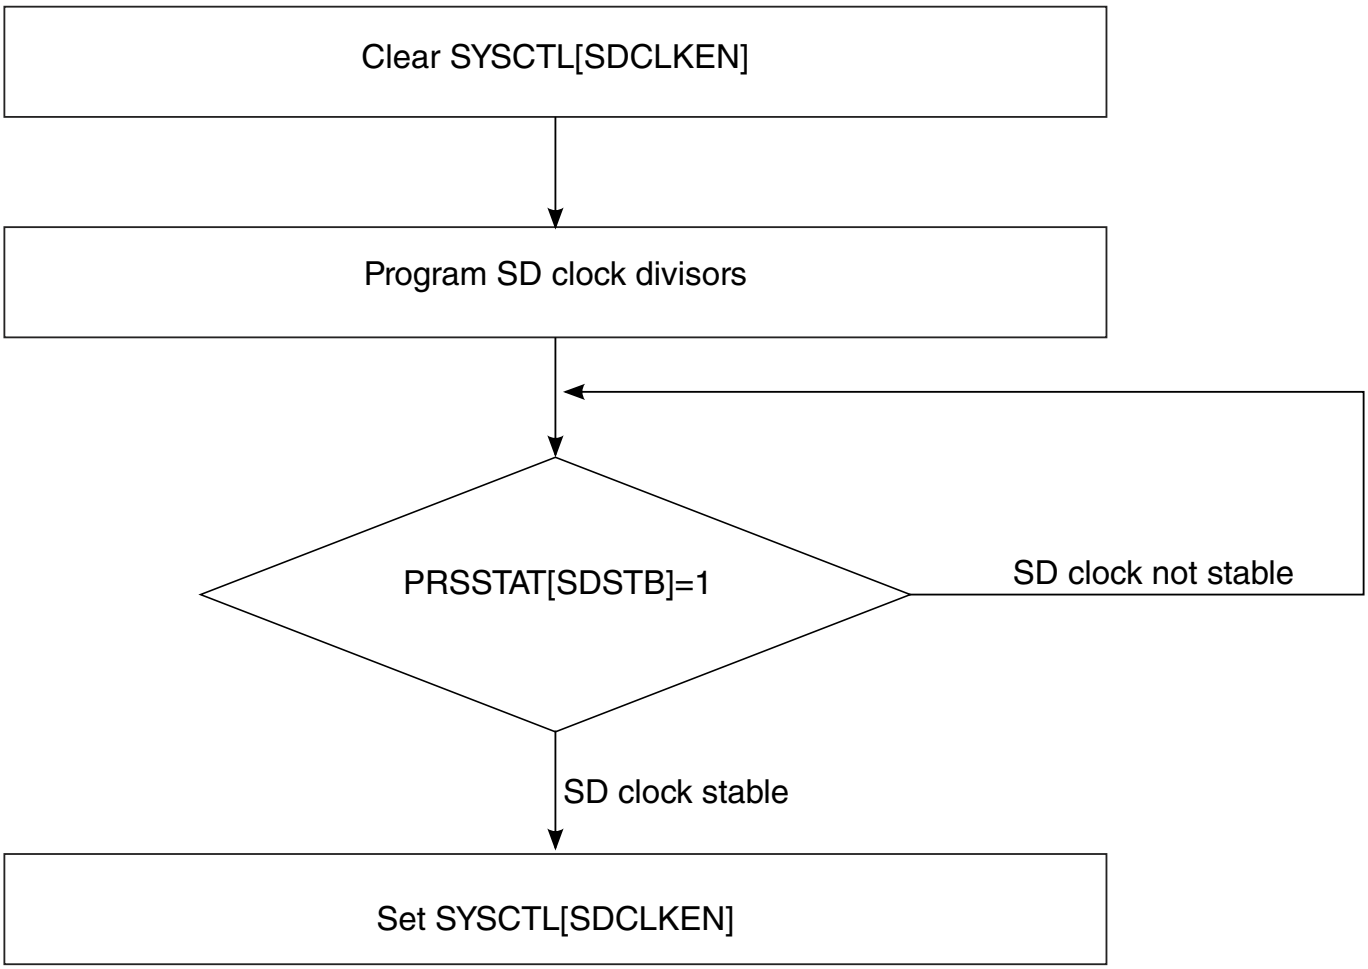

Figure 15-17. SD clock frequency change sequence

15.4.5 SD monitor

The module detects the CD_B (card detection) as well as the DAT3 signal. The transceiver reports the card insertion state according to the CD_B state, the signal level on the DAT3 signal.

NOTE

Do not use DAT3 pin as a CD pin.

The module detects the WP (write protect) signal. With the information of the WP state, the register bank ignores the command, accompanied by a write operation, when the WP switch is on.

15.4.5.1 SDIO card interrupt

15.4.5.1.1 Interrupts in 1-bit mode

In this case the DAT[1] pin is dedicated to providing the interrupt function.

An interrupt is asserted by pulling the DAT[1] low from the SDIO card, until the interrupt service is finished to clear the interrupt.

15.4.5.1.2 Interrupt in 4-bit mode

Since the interrupt and DAT[1] share pin 8 in 4-bit mode, an interrupt is sent by the card and recognized by the host only during a specific time.

This is known as the interrupt period. eSDHC only samples the level on pin 8 during the interrupt period. At all other times, the host ignores the level on pin 8, and treats it as the data signal. The definition of the interrupt period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the interrupt period becomes active two clock cycles after the completion of a data packet. This interrupt period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in 4-bit mode, there is only a limited period of time that the Interrupt Period can be active due to the limited period of data line availability between the multiple blocks of data. This requires a more strict definition of the Interrupt Period. For this case, the interrupt period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DAT[1] line is held low for one clock cycle with the last clock cycle pulling DAT[1] high. On completion of the interrupt period, the card releases the DAT[1] line into the high Z state. eSDHC samples DAT[1] during the interrupt period when the PROCTL[IABG] is set.

Refer to SDIO card specification v2.0 for further information about the SDIO card interrupt.

15.4.5.1.3 Card interrupt handling

When the CINTIEN bit in the interrupt signal enable register is set to 0, the eSDHC clears the interrupt request to the host system.

The host driver should clear this bit before servicing the SDIO interrupt and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

In 1-bit mode, eSDHC detects the SDIO interrupt with or without the SD clock (to support wakeup). In 4-bit mode, the interrupt signal is sampled during the interrupt period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the host system interrupt controller. When the SDIO status is set, and the host driver needs to service this interrupt, so the SDIO bit in the interrupt control register of SDIO card is cleared. This is required to clear the SDIO interrupt status latched in the eSDHC and to stop driving the interrupt signal to the system interrupt controller. The host driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO interrupt enable bit is set to 1, and the eSDHC starts sampling the interrupt signal again.

The figure below illustrates the SDIO card interrupt scheme and sequences of software and hardware events that take place during a card interrupt handling procedure.

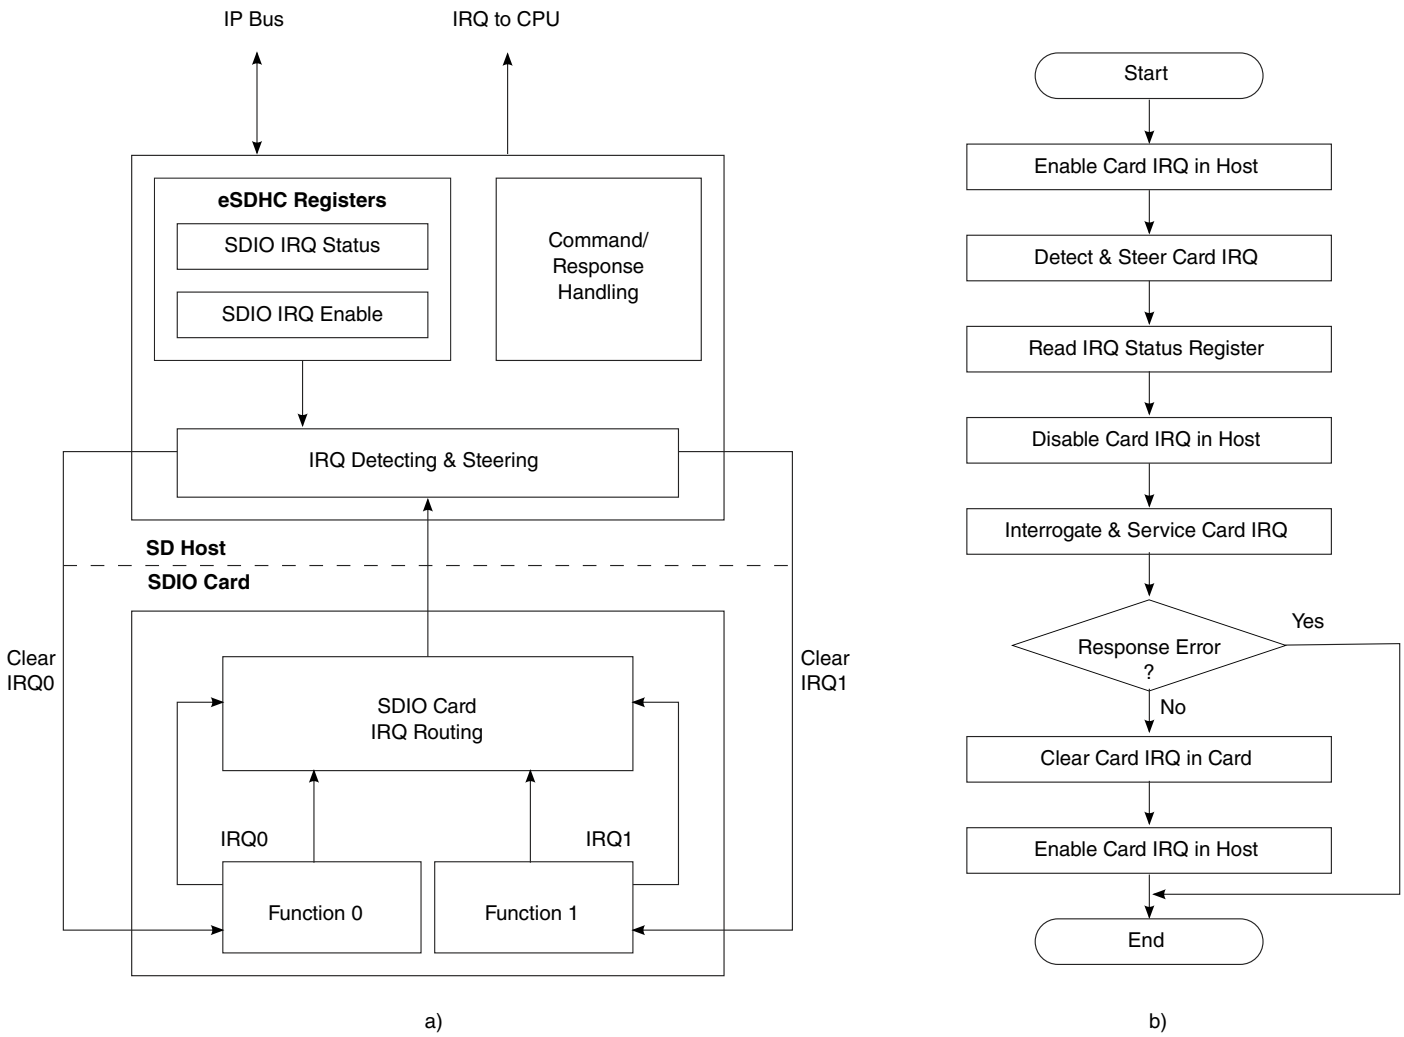

Figure 15-18. Card interrupt scheme and card interrupt detection and handling procedure

15.4.5.2 Card insertion and removal detection

When the DAT[3] pin is not used for card detection (for example, it is implemented in GPIO), the CD pin must be connected for card detection. Whether DAT[3] is configured for card detection or not, the CD pin is always a reference for card detection. Whether the DAT[3] pin or the CD pin is used to detect card insertion, the eSDHC sends an interrupt (if enabled) to inform the host system that a card is inserted.

15.4.5.3 Power management and wake up events

If no operation is expected to happen between eSDHC and the card through the SD bus, the user can completely disable the IP in the chip-level clock control module to save power.

When the user needs to use the eSDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to the eSDHC are disabled, for instance, when the system is in low power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The eSDHC can generate these interrupt even when there are no clocks enabled. The three interrupts which can be used as wake up events are:

- Card removal interrupt
- Card insertion interrupt
- Interrupt from SDIO card

The eSDHC offers a power management feature. By clearing the clock enabled bits in the system control register (SYSCTL), the clocks are gated in the low position to the eSDHC. For maximum power saving, the user can disable all the clocks to the eSDHC when there is no operation in progress.

These three wake up events (or wakeup interrupts) can also be used to wake up the system from low-power modes.

NOTE

To make the interrupt a wakeup event, when all the clocks to the eSDHC are disabled or when the whole system is in low power mode, the corresponding wakeup enabled bit needs to be set. Refer to Protocol control register (eSDHC_PROCTL) for more information.

15.4.5.3.1 Setting wake up events

For eSDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters sleep mode.

Before the software disables the host clock, it should ensure that all of the following conditions are met:

- No read or write transfer is active
- Data and command lines are not active
- No interrupts are pending
- Internal data buffer is empty

15.5 Initialization/application of eSDHC

All communication between the system and the cards are controlled by the host.

The host sends commands of two types: Broadcast and Addressed (point-to-point).

Broadcast commands are intended for all cards, such as "GO_IDLE_STATE", "SEND_OP_COND", "ALL_SEND_CID" and so on. In Broadcast mode, all cards are in the open-drain mode to avoid bus contention. Refer to Commands for MMC/SD/SDIO for the commands of bc and bcr categories.

After the Broadcast command CMD3 is issued, the cards enter standby mode. Addressed type commands are used from this point. In this mode, the CMD/DAT I/O pads will turn to push-pull mode, to have the driving capability for maximum frequency operation. Refer to Commands for MMC/SD/SDIO, for the commands of ac and adtc categories.

15.5.1 Command send and response receive basic operation

Assuming the data type WORD is an unsigned 32-bit integer, the below flow is a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)
{
WORD wCmd; // 32-bit integer to make up the data to write into transfer type register
(XFERTYP),
it is recommended to implement in a bit-field manner
wCmd = (<cmd_index> & 0x3f) >> 24; // set the first 8 bits as '00'+<cmd_index>
set CMDTYP, DPSEL, CICEN, CCCEN, RSTTYP, DTDSEL accorind to the command index;
if (DMA is used) wCmd |= 0x1;
if (multi-block transfer) {
          set MSBSEL bit;
          if (finite block number) {
                    set BCEN bit;
                    if (auto12 command is to use) set AC12EN bit;
```

```
          }
}
write_reg(CMDARG, <cmd_arg>); // configure the command argument
write_reg(XFERTYP, wCmd); // set transfer type register (XFERTYP) as wCmd value to issue the
command
}
wait_for_response(cmd_index)
{
while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
read IRQ Status register and check if any error bits about Command are set
if (any error bits are set) report error;
write 1 to clear CC bit and all Command Error bits;
}
```

For the sake of simplicity, the function wait_for_response is implemented here using polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. By doing this, make sure the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and go to the Standby State, no response to the Host when CMD2 is sent. The host driver should deal with 'fake' errors like this with caution.

15.5.2 Card identification mode

When a card is inserted to the socket or the card was reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the relative card address (RCA) or set the RCA for the MMC cards.

All data communications in the card identification mode use the command line (CMD) only.

15.5.2.1 Card detect

Figure below illustrates a flow diagram showing the detection of MMC, SDIO, and SD cards using the eSDHC.

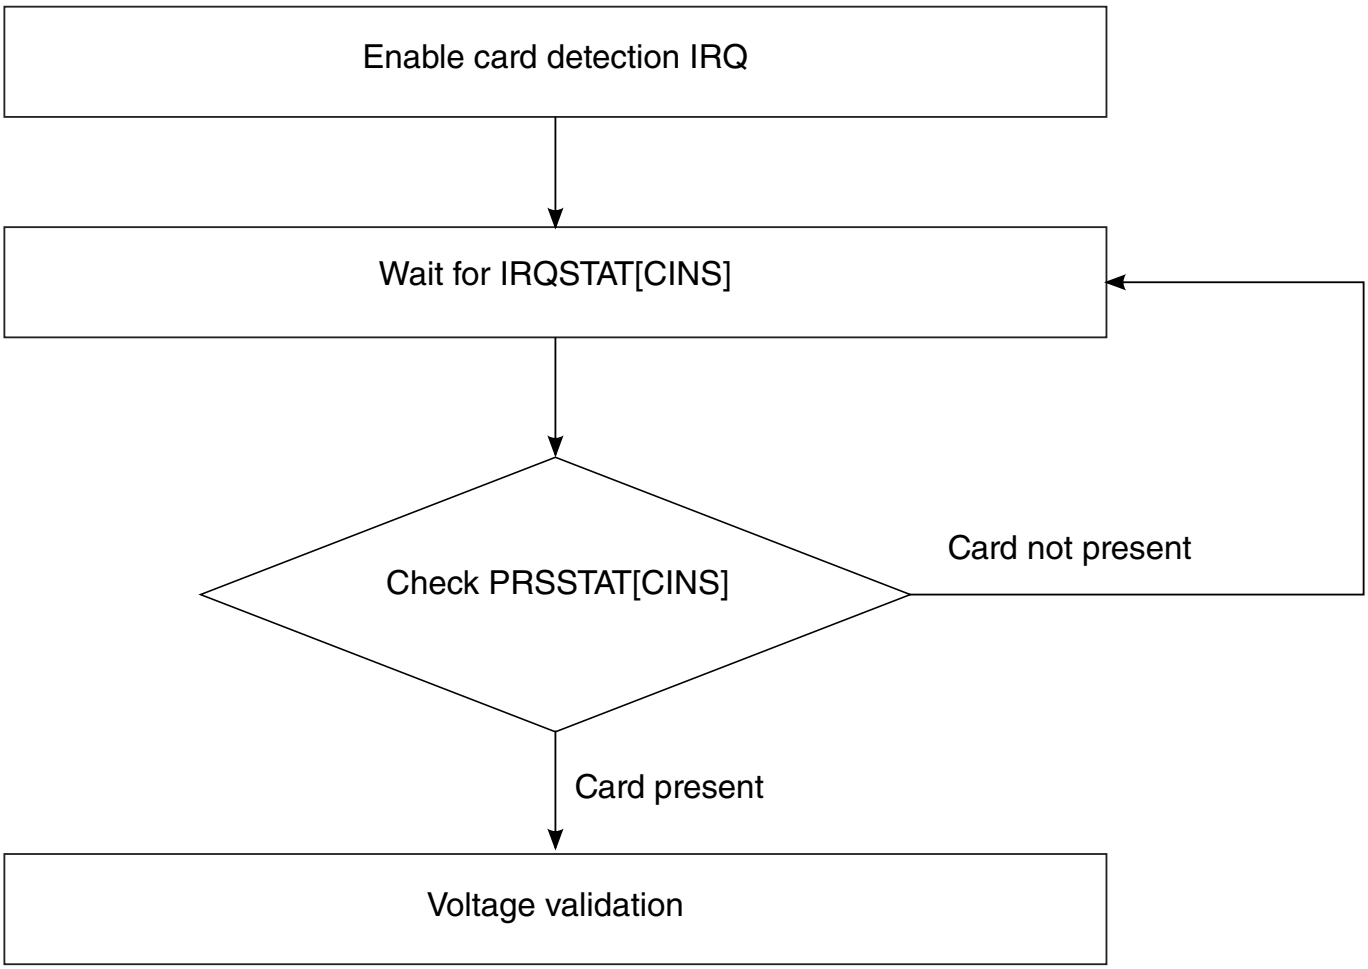

Figure 15-19. Flow diagram for card detection

The card detect sequence is as follows:

1. Set the IRQSTAT[CINSIEN] bit and IRQSIGEN[CINSIEN] bit to enable card detection interrupt.
2. When an interrupt from the eSDHC is received in IRQSTAT[CINS], check PRSSTAT[CINS] to confirm if it was caused by card insertion.

15.5.2.2 Reset

The host consists of three types of resets:

- Hardware reset (card and host) which is driven by POR (power on reset).

- Software reset (Host Only) is proceed by the write operation on SYSCTL[RSTD], SYSCTL[RSTC], or SYSCTL[RSTA] bits to reset the data part, command part, or all parts of the host controller, respectively.
- Card reset (card only). The command, "Go_Idle_State" (CMD0), is the software reset command for all types of MMC cards and SD memory cards. This command sets each card into the idle state regardless of the current card state. For an SD I/O Card, CMD52 is used to write an I/O reset in the CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. Figure below illustrates the software flow to reset both the eSDHC and the card.

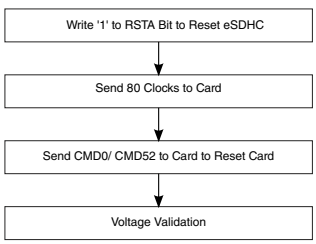

Figure 15-20. Flow chart for reset of the eSDHC and SD I/O card

```
software_reset()
{
set_bit(SYSCTRL, RSTA); // software reset the Host
set DTOCV and SDCLKFS bit fields to get the SDHC_CLK of frequency around 400 KHz
configure IO pad to set the power voltage of external card to around 3.0V
poll bits CIHB and CDIHB bits of PRSSTAT to wait both bits are cleared
set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0
or send_command(CMD_IO_RW_DIRECT, <other parameters>);
}
```

15.5.2.3 Voltage validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification.

However, the supported minimum and maximum values for Vdd are defined in the operation conditions register (OCR) and may not cover the whole range. Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer Vdd conditions. This means, if the host and card have non-common Vdd ranges, the card will not be able to complete the identification cycle, nor will it be able to send CSD data.

Therefore, a special command Send_Op_Cont (CMD1 for MMC), SD_Send_Op_Cont (ACMD41 for SD Memory) and IO_Send_Op_Cont (CMD5 for SD I/O) is used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards which do not match the Vdd range(s) desired by the host. This is accomplished by the host sending the desired Vdd voltage window as the operand of this command. Cards that cannot perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive State. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the inactive state. This query should be used if the host is able to select a common voltage range or if a notification should be sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```
voltage_validation(voltage_range_arguement)
{
label the card as UNKNOWN;

send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO
operation voltage, command argument is zero

if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
          if (0 < number of IO functions) {
                    label the card as SDIO;
                    IORDY = 0;
                    while (!(IORDY in IO OCR response)) { // set voltage range for each IO
function
                              send_command(IO_SEND_OP_COND, <voltage range>, <other
parameter>);
                              wait_for_response(IO_SEND_OP_COND);
                    } // end of while ...
          } // end of if (0 < ...
          if (memory part is present inside SDIO card) Label the card as SDCombo; // this is
an
SD-Combo card
} // end of if (RESP_TIMEOUT ...
if (the card is labelled as SDIO card) return; // card type is identified and voltage range
is
set, so exit the function;
send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application specific
CMD
prefix
if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
          send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage
range
for memory part or SD card
          wait_for_response(SD_APP_OP_COND); // voltage range is set
          if (card type is UNKNOWN) label the card as SD;
          return; //
} // end of if (no error ...
else if (errors other than time-out occur) { // command/response pair is corrupted
          deal with it by program specific manner;
} // of else if (response time-out
else { // CMD55 is refuse, it must be MMC card
          if (card is already labelled as SDCombo) { // change label
                    re-label the card as SDIO;
                    ignore the error or report it;
                    return; // card is identified as SDIO card
          } // of if (card is ...
          send_command(SEND_OP_COND, <voltage range>, <...>);
          if (RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted,
```

```
either
                    label the card as UNKNOWN;
                    return;
          } // of if (RESP_TIMEOUT ...
          else label the card as MMC;
} // of else
}
```

15.5.2.4 Card registry

Card registry for the MMC and SD/SDIO/SD combo cards are different.

For the SD card, the identification process starts at a clock rate lower than 400 KHz and the power voltage higher than 2.7 V (as defined by the card specification). At this time, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host will request the card to send their valid operation conditions. The response to ACMD41 is the operation condition register of the card. The same command should be send to all of the new cards in the system. Incompatible cards are put into the inactive state. The host then issues the command, All_Send_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified (in the ready state), send their CID number as the response. After the CID is sent by the card, the card goes into the identification state.

The host then issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA will be used to address the card for future data transfer operations. Once the RCA is received, the card changes its state to the standby state. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in system.

For MMC operation, the host starts the card identification process in open-drain mode with the identification clock rate lower than 400 KHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line allow parallel card operation during card identification. After the bus is activated the host will request the cards to send their valid operation conditions (CMD1). The response to CMD1 is the "wired OR" operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive State. The host then issues the broadcast command All_Send_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards (the cards in Ready State) simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop

sending their CID immediately and must wait for the next identification cycle. Since the CID is unique for each card, only one card can be successfully send its full CID to the host. This card then goes into the Identification State. Thereafter, the host issues Set_Relative_Addr (CMD3) to assign to the card a relative card address (RCA). Once the RCA is received the card state changes to the Stand-by State, and the card does not react in further identification cycles, and its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

```
card_registry()
{
do { // decide RCA for each card until response time-out
          if(card is labelled as SDCombo or SDIO) { // for SDIO card like device
                    send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to
publish its
RCA
                    retrieve RCA from response;
          } // end if (card is labelled as SDCombo ...
          else if (card is labelled as SD) { // for SD card
                    send_command(ALL_SEND_CID, <...>);
                    if (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
                    send_command(SET_RELATIVE_ADDR, <...>);
                    retrieve RCA from response;
          } // else if (card is labelled as SD ...
          else if (card is labelled as MMC) {
                    send_command(ALL_SEND_CID, <...>);
                    rca = 0x1; // arbitrarily set RCA, 1 here for example
                    send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper
16
bits
          } // end of else if (card is labelled as MMC ...
} while (response is not time-out);
}
```

15.5.3 Card access

This section describes access to the card.

15.5.3.1 Block write

15.5.3.1.1 Normal write

During a block write (CMD24 - 27), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host.

If the CRC fails, the card should indicate the failure on the DAT line. The transferred data will be discarded and not written, and all further transmitted blocks (in multiple block write mode) will be ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation is also aborted if the host tries to write over a write protected area.

For MMC and SD cards, programming of the CID and CSD registers do not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card will report an error and not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card will begin writing and hold the DAT line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO cards at any time, and the card will respond with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby State and release the DAT line without interrupting the write operation. When re-selecting the card, it will reactivate the busy indication by pulling DAT to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card using DMA mode is as follows:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:
   a. For SD/MMC cards, use SET_BLOCKLEN (CMD16)
   b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O block size bit field in the CCCR register (for function 0) or FBR register (for functions 1-7)
3. Set the eSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the eSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the eSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or some other error that occurred during the auto12 command sending and response receiving.

The software flow to write to a card using CPU Polling mode is as follows:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:
   a. For SD/MMC cards, use SET_BLOCKLEN (CMD16)
   b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1-7)
3. Set the eSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the eSDHC number block register (NOB), nob is 5 (for instance).
5. Issue the command with data transfer. The AC12EN bit should also be set.
6. Wait for IRQSTAT[BWR] interrupt to be set.
7. Write to Buffer port register for no. of times programmed in WML[WR_WML] considering restriction mentioned in Software polling procedure.
8. Clear IRQSTAT[BWR].
9. Repeat 6-8 steps for rest of the data transfer.
10. Wait for the Transfer Complete interrupt.
11. Check the status bit to see if a write CRC error occurred, or some other error that occurred during the auto12 command sending and response receiving.

15.5.3.1.2 Write with pause

The write operation can be paused during the transfer.

Instead of stopping the SDHC_CLK at any time to pause all the operations, which is also inaccessible to the host driver, the driver can set the PROCTL[SABGREQ] to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DAT0 line is not required to de-assert to release the busy state, no suspend command is needed.

Like in the flow described in Normal write, the write with pause is shown with the same kind of write operation:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
   a. For SD/MMC, use SET_BLOCKLEN (CMD16)
   b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O block size bit field in the CCCR register (for function 0) or FBR register (for functions 1-7)
3. Set the eSDHC block length register to be the same as the block length set for the card in Step 2.

4. Set the eSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the eSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Set the SABGREQ bit.
7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the Transfer Complete interrupt.
12. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of BLKATTR[BLKCNT]. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The driver should read the value of BLKCNT after the transfer is paused and the transfer complete interrupt is received.

It is also possible the last block has begun when the stop at block gap request is sent to the buffer. In this case, the next block gap is actually the end of the transfer. These types of requests are ignored and the driver should treat this as a non-pause transfer and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the host system is not stopped, and the transfer is active until the data buffer is full. Because of this (if not needed), it is recommended to avoid using the suspend command for the SDIO card. This is because, when such a command is sent, the eSDHC thinks that the system will switch to another function on the SDIO card, and flush the data buffer. The eSDHC takes the resume command as a normal command with data transfer, and it is left for the driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, XFERTYP[MSBSEL] and XFERTYP[BCEN] are set as well as XFERTYP[AC12EN]. However, the eSDHC will automatically send a CMD12 to mark the end of the multi-block transfer.

15.5.3.2 Block read

15.5.3.2.1 Normal read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification.

A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the transfer state. For multi-blocks read, data blocks will be continuously transferred until a stop command is issued.

The software flow to read from a card using DMA mode is as follows:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
   a. For SD/MMC, use SET_BLOCKLEN (CMD16)
   b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O block size bit field in the CCCR register (for function 0) or FBR register (for functions 1-7)
3. Set the eSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the eSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer read ready interrupt, configure the DMA settings and enable the eSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or some other error, occurred during the auto12 command sending and response receiving.

The software flow to read from a card using CPU polling mode is as follows:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
   a. For SD/MMC, use SET_BLOCKLEN (CMD16)
   b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O block size bit field in the CCCR register (for function 0) or FBR register (for functions 1-7)
3. Set the eSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the eSDHC number block register (NOB), nob is 5 (for instance).
5. Issue the command with data transfer. The AC12EN bit should also be set.
6. Wait for IRQSTAT[BRR] interrupt to be set.
7. Read from Buffer port register for number of times programmed in WML[RD_WML] considering restriction mentioned in Software polling procedure.
8. Clear IRQSTAT[BRR].
9. Repeat 6-8 steps for rest of the data transfer.
10. Wait for the Transfer Complete interrupt.
11. Check the status bit to see if a read CRC error occurred, or some other error, occurred during the auto12 command sending and response receiving.

15.5.3.2.2 Read with pause

The read operation is not generally able to pause. Only the SDIO card (and SDCombo card working under I/O mode) supporting the read wait feature can pause during the read operation.

If the SDIO card support read wait (SRW bit in CCCR register is 1), the driver can set the PROCTL[SABGREQ] to pause the transfer between the data blocks. Before setting the SABGREQ bit, make sure the PROCTL[RWCTL] is set, otherwise the eSDHC will not assert the read wait signal during the block gap and data corruption occurs. It is recommended to set the RWCTL bit once the read wait capability of the SDIO card is recognized.

Like in the flow described in Normal read, the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm the card supports read wait.
2. Set the RWCTL bit.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
   a. For SD/MMC, use SET_BLOCKLEN (CMD16)
   b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O block size bit field in the CCCR register (for function 0) or FBR register (for functions 1-7)
5. Set the eSDHC block length register to be the same as the block length set for the card in Step 2.
6. Set the eSDHC number block register (NOB), nob is 5 (for instance).
7. Disable the buffer read ready interrupt, configure the DMA setting and enable the eSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
8. Set the SABGREQ bit.
9. Wait for the transfer complete interrupt.
10. Clear the SABGREQ bit.
11. Check the status bit to see if read CRC error occurred.
12. Set the CREQ bit to continue the read operation.
13. Wait for the transfer complete interrupt.
14. Check the status bit to see if a read CRC error occurred, or some other error, occurred during the auto12 command sending and response receiving.

Like the write operation, it is possible to meet the ending block of the transfer when paused. In this case, the eSDHC will ignore the stop at block gap request and treat it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause will be transferred to the Host System. Even if the Suspend Command is sent or not, the internal data buffer is not flushed.

If the Suspend Command is sent and the transfer is later resumed by means of a Resume Command, the eSDHC takes the command as a normal one accompanied with data transfer. It is left for the driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, XFERTYP[MSBSEL] and XFERTYP[BCEN] are set, as well as XFERTYP[AC12EN]. However, the eSDHC will automatically send the CMD12 to mark the end of multi-block transfer.

15.5.3.3 Suspend resume

The eSDHC supports the suspend resume operations of SDIO cards, although slightly different than the suggested implementation of suspend in the SDIO card specification.

15.5.3.3.1 Suspend

After setting the SABGREQ bit, the host driver may send a Suspend command to switch to another function of the SDIO card. The eSDHC does not monitor the content of the response, so it doesn't know if the Suspend command succeeded or not.

Accordingly, it doesn't de-assert Read Wait for read pause. To solve this problem, the driver should not mark the Suspend command as a "Suspend", (that is, setting the CMDTYP bits to 01). Instead, the driver should send this command as if it were a normal command, and only when the command succeeds, and the BS bit is set in the response, can the driver send another command marked as "Suspend" to inform the eSDHC that the current transfer is suspended. As shown in the following sequence for Suspend operation:

1. Set the SABREQ bit to pause the current data transfer at block gap.
2. Save the context registers in the system memory for later use, including the SDMA system address register (DSADDR) for DMA operation, and the block attributes register (BLKATTR).
3. After the BGE bit is set, send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.
4. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the driver strategy.
5. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so the eSDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, the eSDHC stops driving DAT2 and goes to the idle state.

6. Begin operation for another function on the SDIO card.

15.5.3.3.2 Resume

To resume the data transfer, a resume command should be issued:

1. To resume the suspended function, restore the context register with the saved value in step #5 of the suspend operation above.
2. Send the resume command. In the transfer type register (XFERTYP), all bit fields are set to the value as if this were another ordinary data transfer, instead of a transfer resume (except the CMDTYP is set to 2'b10).
3. If the resume command has responded, the data transfer will be resumed.

15.5.3.4 ADMA usage

To use the ADMA in a data transfer, the host driver must prepare the correct descriptor chain prior to sending the read/write command.

To accomplish this:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4 Kbyte address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1-3.
4. Repeat steps 1-3 until all descriptors are created.
5. In the last descriptor, set the end flag to 1 and make sure the total length of all descriptors match the product of the block size and block number configured in the block attributes register (BLKATTR).
6. Set the ADMA system address register (ADSADDR) to the address of the first descriptor and set PROCTL[DMAS] to 01 to select the ADMA.
7. Issue a write or read command with XFERTYP[DMAEN] set.

Steps 1-5 are independent of step 6, so step 6 can finish before steps 1-5. Regarding the descriptor configuration, it is recommended not to use the link descriptor as it requires extra system memory access.

15.5.3.5 Transfer error

15.5.3.5.1 CRC transfer error

It is possible at the end of a block transfer, that a write CRC status error or read CRC error occurs.

For this type of error the latest block received should be discarded.

This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one. For a multi-block transfer, the host driver should issue a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the AC12EN and BCEND bits are set, the eSDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 will be sent by the eSDHC. In this case, the driver should re-send or re-obtain the last block with a single block transfer.

15.5.3.5.2 DMA transfer error

During the data transfer with internal single DMA, if the DMA engine encounters some error on the System bus, the DMA operation is aborted and DMA error interrupt is sent to the host system.

When acknowledged by such an interrupt, the driver should calculate the start address of data block in which the error occurs. The start address can be calculated by:

Read the DMA error address register (DMAERRADDR). Taking the block size and the start address intially preogrammed in SDMA Adress register, it is straight forward to obtain the start address of the corrupted block.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and re-start the transfer from the corrupted block to recover from the error.

15.5.3.5.3 ADMA transfer error

There are three kinds of possible ADMA errors; The System transfer, invalid descriptor, and data-length mismatch errors.

Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set. For acknowledging the status, the host driver should recover the error as shown below and re-transfer from the place of interruption.

1. System transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the

data part and re-transfer the block that was corrupted, or the next block if no block is corrupted.
2. Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and re-create the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
3. Data-length mismatch error: It is similar to recover from this error. The host driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain, and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

15.5.3.5.4 Auto CMD12 error

After the last block of the multi block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, the eSDHC automatically sends a CMD12 to the card to stop the transfer.

When errors with this command occur, it is recommended to the driver to deal with the situations in the following manner:

1. Auto CMD12 response time-out. It is not certain whether the command is accepted by the card or not. The driver should clear the Auto CMD12 error status bits and re-send the CMD12 until it is accepted by the card.
2. Auto CMD12 response CRC error. Since card responds to the CMD12, the card will abort the transfer. The driver may ignore the error and clear the error status bit.
3. Auto CMD12 conflict error or not sent. The command is not sent, so the driver should send a CMD12 manually.

15.5.3.6 Card interrupt

The external cards can inform the host controller by means of some special signals. For the SDIO card, it can be the low level on the DAT[1] line during some special period.

The eSDHC only monitors the DAT[1] line and supports the SDIO interrupt.

When the SDIO interrupt is captured by the eSDHC, and the Host System is informed by the eSDHC asserting the eSDHC interrupt line, the interrupt service from the host driver is called.

As the interrupt factor is controlled by the external card, the interrupt from the SDIO card must be served before the CINT bit is cleared by written 1. Refer to Card interrupt handling for the card interrupt handling flow.

15.5.4 Switch function

MMC cards transferring data at bus widths other than 1-bit is a new feature added to the MMC spec.

The high speed timing mode for all card devices, was also recently defined in various card specifications. To enable these new features, a "switch" command should be issued by the host driver.

For SDIO cards, the high speed mode is enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed. For SD cards, the high speed mode is queried and enabled by a CMD6 (with the mnemonic symbol as SWITCH_FUNC). For MMC cards, the high speed mode is queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The 4-bit and 8-bit bus width of the MMC is also enabled by the SWITCH command, but with a different argument.

These new functions can also be disabled by a software reset. For SDIO cards, it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following flowcharts do not show current capability check, which is recommended in the function switch process.

15.5.4.1 Query, enable and disable SDIO high speed mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report the SDIO card does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is
cleared;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of the desired value below 25MHz;
```

```
(data transactions like normal peers)
}
```

15.5.4.2 Query, enable and disable SD high speed mode

```
enable_sd_high_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFF1 and read 64 bytes of data accompanying the R1 response;
wait data transfer done bit is set;
check if the bit 401 of received 512 bit is set;
if (bit 401 is '0') report the SD card does not support high speed mode and return;
send CMD6, with argument 0x80FFFFF1 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sd_high_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

15.5.4.3 Query, enable and disable MMC high speed mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support high speed mode and
return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this MMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report MMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into eSDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

15.5.4.4 Set MMC bus width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and
return;
send CMD6 with argument 0x3B70x00; (8-bit, x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}
```

15.5.5 ADMA operation

15.5.5.1 ADMA1 operation

```
Set_adma1_descriptor
{
if (to start data transfer) {
// Make sure the address is 4KB align.
Set 'Set' type descriptor;
{
Set Act bits to 01;
Set [31:12] bits data length (byte unit);
}
Set 'Tran' type descriptor;
{
Set Act bits to 10;
Set [31:12] bits address (4KB align);
}
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to 11;
Set [31:12] bits the next descriptor address (4KB align);
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set End bit to 1;
}
if (to generate interrupt for this descriptor) {
Set Int bit to 1;
}
Set Valid bit to 1;
}
```

15.5.5.2 ADMA2 operation

```
Set_adma2_descriptor
{
if (to start data transfer) {
// Make sure the address is 32-bit boundary (lower 2-bit are always '00').
Set higher 32-bit of descriptor for this data transfer initial address;
Set [31:16] bits data length (byte unit);
```

```
Set Act bits to '10';
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to '11';
// Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
Set higher 32-bit of descriptor for the next descriptor address;
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set 'End' bit '1';
}
if (to generate interrupt for this descriptor) {
Set 'Int' bit '1';
}
Set the 'Valid' bit to '1';
}
```

15.6 Commands for MMC/SD/SDIO

See the table below for the list of commands for the MMC/SD/SDIO cards.

Refer the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the MultiMediaCard:

- Broadcast commands (bc), no response
- Broadcast commands with response (bcr), response from all cards simultaneously
- Addressed (point-to-point) commands (ac), no data transfer on the DAT
- Addressed (point-to-point) data transfer commands (adtc)

The access bits for the EXT_CSD access modes are shown in Table 15-11.

Table 15-10. Commands for MMC/SD/SDIO cards

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all MMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all MMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.
CMD3[1]	ac	[31:16] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/ SEND_RELATIVE_ADDR	Assigns relative address to the card.
CMD4	bc	[31:16] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards.

Table continues on the next page...

Table 15-10. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD6[2]	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 - 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer "SD Physical Specification V1.1" for more details.
CMD6[3]	ac	[31:26] Set to 0 [25:24] Access [23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer "The MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.
CMD7	ac	[31:16] RCA [15:0] stuff bits	R1b	SELECT/ DESELECT_CARD	Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.
CMD8[4]	bcr	[31:12] reserved bits [11:8] supply voltage (VHS) [7:0] check pattern	R7	SEND_IF_COND	Sends SD memory card interface condition, which includes host supply voltage information and asks the card whether card supports voltage. Reserved bits shall be set to 0.
CMD8[5]	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:16] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:16] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.
CMD11	Reserved				
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission.
CMD13	ac	[31:16] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				

Table continues on the next page...

Table 15-10. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD15	ac	[31:16] RCA [15:0] stuff bits	-	GO_INACTIVE_STATE	Sets the card to inactive state in order to protect the card stack against communication breakdowns.
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19-CMD22	Reserved				
CMD23	ac	[31:16] set to 0 [15:0] block count	R1	SET_BLOCKCOUNT	Defines the number of blocks which are going to be transferred in the immediately succeeding multiple block read or write command. If the argument is all 0s, the subsequent read/write operations are openended.
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command should be issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	ERASE_WR_BLK_START	Sets the address of the first write block to be erased in SD card.

Table continues on the next page...

Table 15-10. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group in MMC card.
CMD33	ac	[31:0] data address	R1	ERASE_WR_BLK_END	Sets the address of the last write block of the continuous range to be erased in SD card.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase in MMC card.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection in MMC card.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase in MMC card.
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase in MMC card.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection in MMC card.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.
CMD39	ac	[31:0] RCA [15] register write flag [14:8] register address [7:0] register data	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the MMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode in MMC cards.
CMD41	Reserved				
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43-51	Reserved				
CMD52	ac	As per SDIO spec CMD52 format	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	As per SDIO spec CMD53 format	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				

Table continues on the next page...

Table 15-10. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather that a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57-63	Reserved				
ACMD6	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.
ACMD13[6]	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD Memory Card status.
ACMD18[6]	adtc	[31:0] stuff bits	R1	SECURE_READ_MULTI_BLOCK	Protected Area Access Command: Reads continuously transfer data blocks from protected area of SD memory card. Refer Security Specification Version 2.00 for more details.
ACMD22[6]	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.
ACMD23[6]	ac	[31:0] stuff bits	R1	SET_WR_BLK_ERASE_COUNT	In SD cards, set the number of write blocks to be pre-erased before writing (to be used for faster multiple block write command) Default value is 1 (one write block).
ACMD25[6]	adtc	[31:0] stuff bits	R1	SECURE_WRITE_MULTI_BLOCK	Protected Area Access Command: Writes continuously transfer data blocks to protected area of SD memory card. Refer Security Specification Version 2.00 for more details.
ACMD26[6]	adtc	[31:0] stuff bits	R1	SECURE_WRITE_MKB	System Area Access Command: Overwrite the existing media key block (MKB) on the system area of SD Memory Card with new MKB. This command is used in dynamic update MKB scheme. Refer Security Specification Version 2.00 for more details.
ACMD38[6]	ac	[31:0] stuff bits	R1b	SECURE_ERASE	Protected Area Access Command: Erase a specified region of the Protected Area of SD Memory Card. Refer Security Specification Version 2.00 for more details.

Table continues on the next page...

Table 15-10. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
ACMD41[6]	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.
ACMD42[6]	ac	[31:1] stuff bits [0] set_cd	R1	SET_CLR_CARD_DETECT	Connect [1]/Disconnect [0] the 50KΩ pull-up resistor on CD/DAT3 of SD card.
ACMD43[6]	adtc	[31:24]Unit_Count: [23:16] MKB_ID: [15:0]Unit_Offset:	R1	GET_MKB	Reads Media Key Block from the System Area of SD Memory Card. -Unit_Count specifies the Number of units to read. (Here, a unit=512 byte (fixed).) - MKB_ID specifies the application unique number. - Unit_Offset specifies the start address(offset) to read. Refer Security Specification Version 2.00 for more details.
ACMD44[6]	adtc	[31:0] stuff bits	R1	GET_MID	Reads Media ID from the system area of SD memory card. Refer Security Specification Version 2.00 for more details.
ACMD45[6]	adtc	[31:0] stuff bits	R1	SET_CER_RN1	AKE Command: Writes random number RN1 as challenge1 in AKE process. Refer Security Specification Version 2.00 for more details.
ACMD46[6]	adtc	[31:0] stuff bits	R1	GET_CER_RN2	AKE Command: Reads random number RN2 as challenge2 in AKE process. Refer security specification version 2.00 for more details.
ACMD47[6]	adtc	[31:0] stuff bits	R1	SET_CER_RES2	AKE Command: Writes RES2 as response2 to RN2 in AKE process Refer Security Specification Version 2.00 for more details.
ACMD48[6]	adtc	[31:0] stuff bits	R1	GET_CER_RES1	AKE Command: Reads RES1 as response1 to RN1 in AKE process. Refer Security Specification Version 2.00 for more details.
ACMD49[6]	ac	[31:0] stuff bits	R1b	CHANGE_SECURE_AREA	Protected Area Access Command: Change size of the protected area. Refer Security Specification Version 2.00 for more details.

Table continues on the next page...

Table 15-10. Commands for MMC/SD/SDIO cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
ACMD51[6]	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD configuration register (SCR).

1. CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed MMC cards and high speed SD cards. Command SWITCH_FUNC is for high speed SD cards.
3. Command SWITCH is for high speed MMC cards. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in Table 2.
4. CMD8 for SD stands for SEND_IF_COND.
5. CMD8 for MMC stands for SEND_EXT_CSD.
6. ACMDs should be preceded with the APP_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).

Table 15-11. EXT_CSD access modes

Bits	Access name	Operation
00	Command set	The command set is changed according to the Cmd set field of the argument.
01	Set Bits	The bits in the pointed byte are set, according to the 1 bit in the Value field.
10	Clear bits	The bits in the pointed byte are cleared, according to the 1 bit in the Value field.
11	Write Byte	The Value field is written into the pointed byte.

15.7 Software restrictions

This section covers software restrictions.

15.7.1 Software polling procedure

For polling read or write, once the software begins a buffer read or write, it must access the buffer data port register (DATPORT) exactly the number of times as watermark level value set in the watermark level register (WML).

However, if the block size is not same as of the value in watermark level register (read and write respectively), the software must access exactly the remaining number of words at the end of each block. For example, for read operations, if the RD_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block count is 2, then the access times to data buffer port register for the burst sequence in the whole transfer process must be 4, 4, 2 (for first block); 4, 4, 2 (for second block).

15.7.2 Suspend operation

In order to suspend the data transfer, the software must inform eSDHC that the suspend command is successfully accepted.

To achieve this, after the suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (CMDTYP bits set as "01") to inform eSDHC that the transfer is suspended.

If software needs to resume the suspended transfer, it should read the value in BLKCNT register to save the remained number of blocks before sending the normal command marked as suspend, otherwise on sending such "suspend" command, eSDHC will regard the current transfer a aborted and change the BLKCNT register to its original value, instead of keeping the remaining number of blocks.

15.7.3 Data port access

Data port does not support parallel access.

For example, during an external DMA access, it is not allowed to write any data to the data port by CPU; or during a CPU read operation, it is also prohibited to write any data to the data port, by either CPU or external DMA. Otherwise, the data would be corrupted inside the eSDHC buffer.

15.7.4 Multi-block read

For pre-defined multi-block read operation, that is, the number of blocks to read has been defined by previous CMD23 for MMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or SD security read commands, or whatever multi-block read without abort command at card side; soft reset for data(SYSCTL[RSTD]) is required after the transfer is complete to drive the internal state machine to idle mode.

15.7.5 ADMA address

For ADMA1/ADMA2 operation, the ADMA system address register (ADSADDR) and address defined in the address field of the descriptor table should be 4-byte aligned.

15.7.6 Allowed operations after stop at block gap

Only one of these operations is allowed after stop at block gap event:

- Continue data transfer by setting SYSCTL[CREQ]
- Issue suspend command
- Abort data transfer by issued abort command

No other command can be issued until one of the operations listed above is performed.

15.7.7 SDIO card interrupt during soft reset

The host driver should disable SDIO card interrupts in IRQSTAT[CINT] before issuing soft reset for data or all (generally used for error recovery) in the system control register (SYSCTL), and enable it after error recovery sequence has been completed.

15.7.8 Soft reset for data not allowed when SD clock is disabled

Soft reset for data and CMD (SYSCTL[RSTD]/SYSCTL[RSTC]) should not be issued when SD clock is disabled; that is, when SYSCTL[SDCLKEN] is cleared.

Instead, the host driver may issue soft reset for all (SYSCTL[RSTA]).

15.7.9 Data transfer with Auto CMD12 Enable

When Auto CMD12 is enabled for data transfer, it generates IRQSTAT[TC] for data transfer completion but does not generate TC for Auto CMD12(command with busy).

Host Driver needs make sure that card has reached to “trans“ state before issuing any new data command. CMD13(SEND_STATUS) could be sent to check the card status.

15.7.10 Buffer Data port register should not be read when in DMA mode or buffer is empty

The Buffer Data port register (DATPORT) should not be read when XFERTYP[DMAEN] bit is set or data buffer is empty. Otherwise, it can hang the system.

Chapter 16
Universal Serial Bus Interface

16.1 Overview

This chapter describes the universal serial bus (USB) interface of the chip.

The USB interface implements many industry standards. However, it is beyond the scope of this document to document the intricacies of these standards. Instead, it is left to the reader to refer to the governing specifications.

The following documents are available from the USB Implementers Forum web page at *http://www.usb.org/developers/docs/*.

- *Universal Serial Bus Revision 2.0 Specification*

The following documents are available from the Intel USB Specifications web page at *http://www.intel.com/technology/usb/spec.htm*.

- *Enhanced Host Controller Interface (EHCI) Specification for Universal Serial Bus, Revision 1.0*
- *USB 2.0 Transceiver Macrocell Interface (UTMI) Specification, Version 1.05*

The device implements a dual-role (DR) USB module. This module may be connected to an external port. Collectively the module and external port are called the USB interface.

The USB DR module is a USB 2.0-compliant serial interface engine for implementing a USB interface. The registers and data structures are based on the *Enhanced Host Controller Interface Specification for Universal Serial Bus* (EHCI) from Intel Corporation. Each DR module is either a device or host controller.

The DR module supports the required signaling for USB transceiver macrocell interface (UTMI) and transceivers (PHYs). The PHY interfacing to the UTMI is an internal PHY.

The USB interface is shown in the figure below.

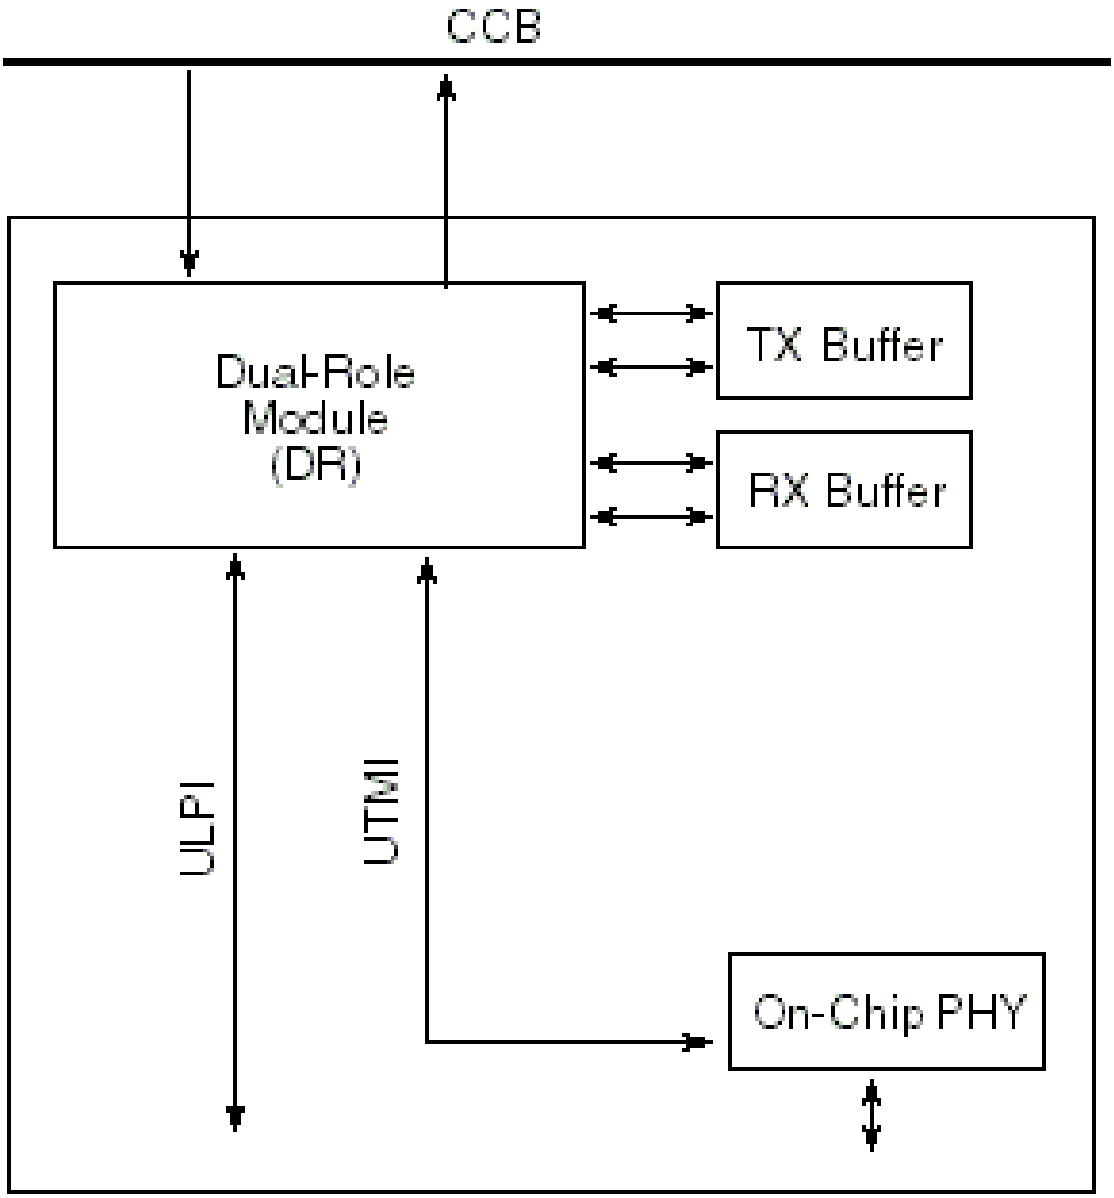

Figure 16-1. USB interface block diagram

16.1.1 USB features summary

The USBDR module includes the following features:

- Complies with *USB Specification Rev 2.0*
- Supports operation as a standalone USB host controller
  - Supports enhanced host controller interface (EHCI)
- Supports high-speed (480 Mbps), full-speed (12 Mbps), and low-speed (1.5 Mbps) operation. Low speed is only supported in host mode
- Supports on-chip, USB-2.0, full-speed/high-speed PHY with UTMI

- Supports operation as a standalone USB device
  - Supports one upstream facing port
  - Supports six bidirectional USB Endpoints
- Host and device support

16.1.2 Modes of operation

The USB DR module operates in two modes:

- Host (HS/FS/LS)
- Device (HS/FS/LS)

NOTE

Only high-speed and full-speed operations are supported in device mode.

16.2 USB External Signals

This section contains detailed descriptions of all the USB controller signals.

The table below describes the signals, indicating which interface supports each signal.

Table 16-1. USB External Signals

Signal	I/O	Description
USB*n*_UDP	I/O	On-chip PHY-USB Data Plus
USB*n*_UDM	I/O	On-chip PHY-USB Data Minus
USB*n*_VBUS_CLMP	I	On-chip PHY-VBUS_CLMP
USB*n*_UID	I	On-chip PHY-USB ID Detect
USB*n*_DRVVBUS	O	On-chip PHY-DRVVBUS is used to enable (asserted) or disable (negated) power on devices that support port power switching.
USB*n*_PWRFAULT	I	On-chip PHY-Power fault. PWRFAULT is used to indicate when a Vbus fault has occurred.
USB_CLKIN	I	USB_CLKIN is the clock input for the USB PHYs

16.2.1 UTMI

UTMI (USB transceiver macrocell interface) was developed to specify a standard interface between USB 2.0 controllers and USB 2.0 PHY's.

This interface is made available to support applications that may use a UTMI-compliant PHY. UTMI+ extensions are not supported by the USB DR module.

16.2.2 PHY clocks

The USB_CLKIN input is the clock from the external to the controller UTMI interface.

NOTE

A write to registers in the USB controller memory map may cause the system to hang if PORTSC[PHCD]=0.

16.3 USB memory map/register definition

This section provides the memory map and detailed descriptions of all USB interface registers.

The following sections provide details about the registers in the USB memory map.

NOTE

Memory may be viewed from either a big-endian or little-endian byte ordering perspective depending on the processor configuration. In big-endian mode, the most-significant byte of word 0 is located at address 0 and the least-significant byte of word 0 is located at address 3. In little-endian mode, the least-significant byte of word 0 is located at address 0 and the most-significant byte of word 0 is located at address 3. Within registers, bits are numbered within a word starting with bit 31 as the most-significant bit. By convention, USB registers use little-endian byte ordering. In the USB DR module, these are the registers from offsets 0x00 to 0x1FF. The registers associated with the internal system interface (0x400 and above) use big-endian byte ordering.

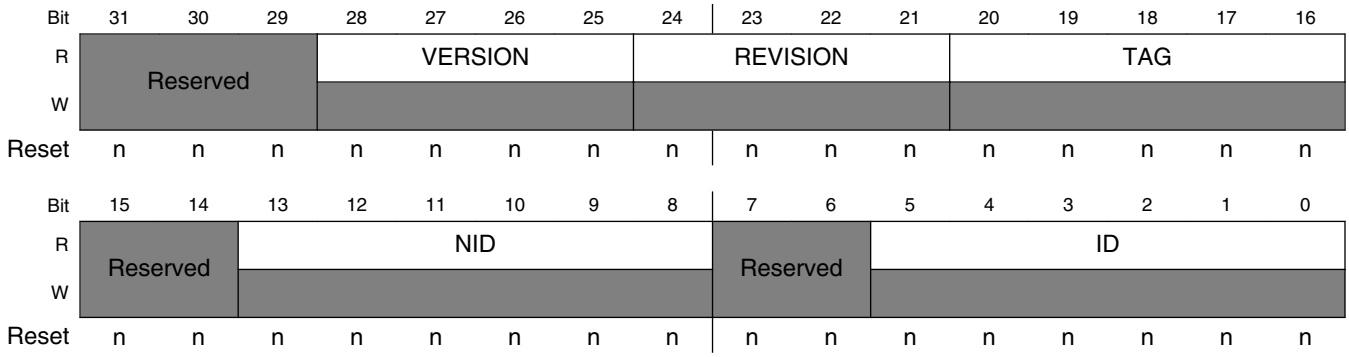
16.3.1 Identification register (USB*x*_USB_ID)

The identification register is used to declare the slave interface presence and include table of the hardware configuration parameters. It is not defined by the EHCI specification.

The ID register provides a simple way to determine if the USB DR module is provided in the system. The ID register identifies the USB DR and its revision (0000_0000).

Address: Base address + 0h offset



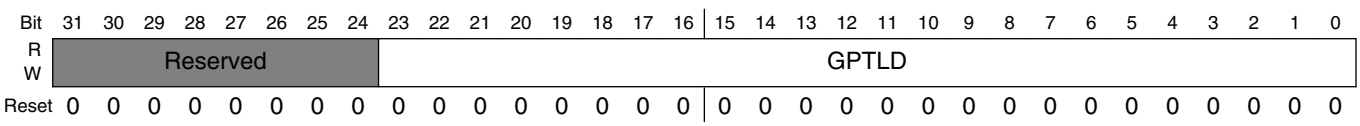
USB*x*_USB_ID field descriptions

Field	Description
31–29 -	This field is reserved. Reserved
28–25 VERSION	Identifies the version of the module.
24–21 REVISION	Identifies the revision number of the module.
20–16 TAG	Identifies the tag of the USB core.
15–14 -	This field is reserved. Reserved
13–8 NID	Ones complement version of ID bit.
7–6 -	This field is reserved. Reserved
ID	Configuration number. This number is set to 0x05 and indicates that the peripheral is the USB_DR.

16.3.2 General purpose timer load n (USB*x*_GPTIMER*n*LD)

Host/device controller drivers can measure time related activities using these timer registers. These registers are not part of standard EHCI controller.

Address: Base address + 80h offset + (8d × i), where i=0d to 1d



USB*x*_GPTIMER*n*LD field descriptions

Field	Description
31–24 -	This field is reserved. Reserved

Table continues on the next page...

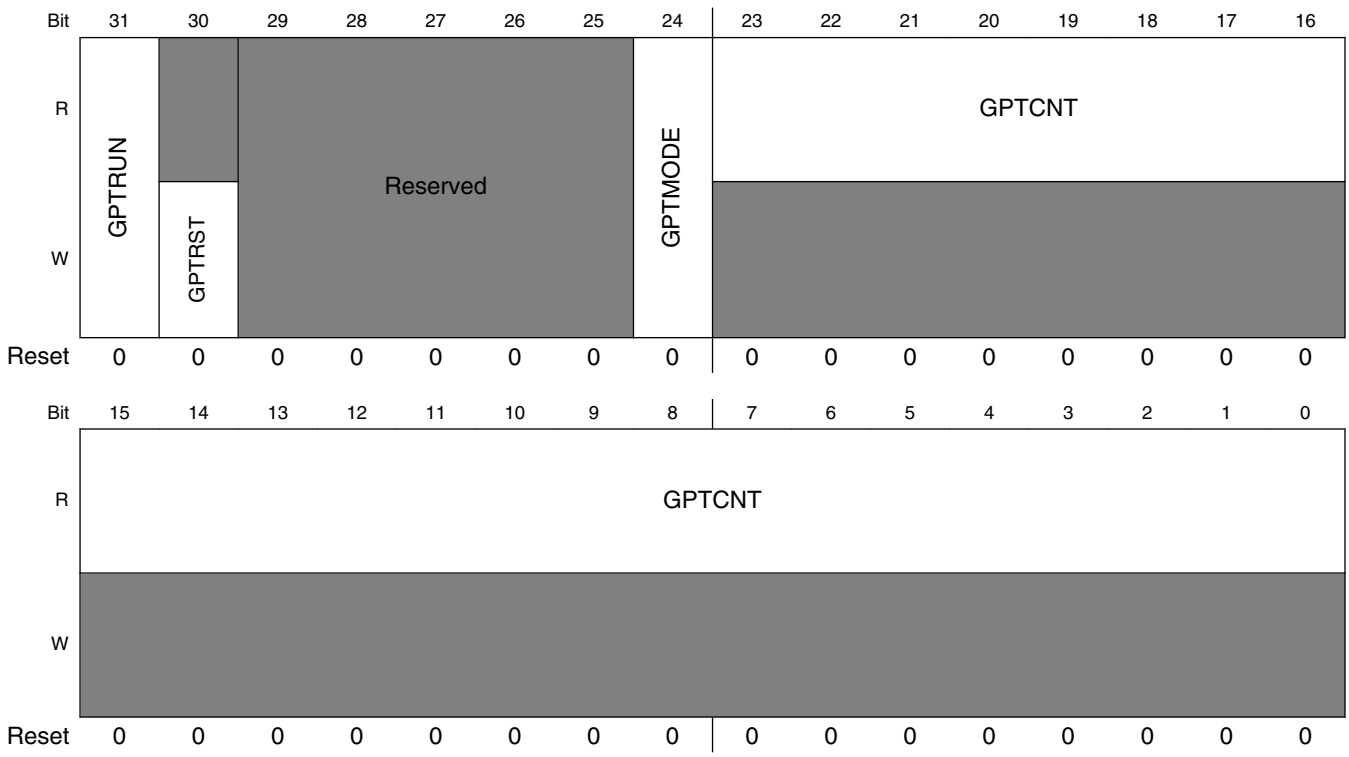
USBx_GPTIMERnLD field descriptions (continued)

Field	Description
GPTLD	**General Purpose Timer Load Value** . This field is the value loaded into the GPTCNT countdown timer on a reset action. This value represents the time in microseconds minus one for the timer duration. Note: Maximum value is 0xFFFFFF or 16.777215 seconds.

16.3.3 General purpose timer control n (USBx_GPTIMERnCTRL)

Host/device controller drivers can measure time related activities using these timer registers. These registers are not part of standard EHCI controller.

Address: Base address + 84h offset + (8d × i), where i=0d to 1d



USBx_GPTIMERnCTRL field descriptions

Field	Description
31 GPTRUN	**General Purpose Timer Run** . This bit enables the general purpose timer to run. Setting or clearing this bit does not have any effect on GPTCNT value. 0 Timer Stop 1 Timer Run
30 GPTRST	**General Purpose Timer Reset** . Writing 1 to this bit reloads GPTCNT with value in GPTLD. 0 No Action 1 Reload Counter

Table continues on the next page...

USB*x*_GPTIMER*n*CTRL field descriptions (continued)

Field	Description
29–25 -	This field is reserved. Reserved
24 GPTMODE	**General Purpose Timer Mode** . This bit selects between single timer countdown and a looped countdown. In one-shot mode, the timer counts down to zero, generates an interrupt and stops until software resets the counter. In repeat mode, the timer counts down to zero, generates an interrupt and automatically reloads the counter to begin again. 0 One-shot 1 Repeat
GPTCNT	**General Purpose Timer Counter** . Contains the value of runnig counter.

16.3.4 Capability Register Length (USBx_CAPLENGTH)

The capability registers specify the software limits, restrictions, and capabilities of the host/device controller implementation. Most of these registers are defined by the EHCI specification. Registers that are not defined by the EHCI specification are noted in their descriptions.

CAPLENGTH is used as an offset to add to the register base address to find the beginning of the operational register space, that is, the location of the USBCMD register.

Address: Base address + 100h offset

Bit	7	6	5	4	3	2	1	0
Read	CAPLENGTH							
Write								
Reset	0	1	0	0	0	0	0	0

USB*x*_CAPLENGTH field descriptions

Field	Description
CAPLENGTH	Capability registers length. It indicates which offset to add to the register base address at the beginning of the operational register. Value is 0x40.

16.3.5 Host Controller Interface Version Number (USBx_HCIVERSION)

HCIVERSION contains a BCD encoding of the EHCI revision number supported by this host controller. The most-significant byte of the register represents major revision and the least-significant byte is minor revision.

Address: Base address + 102h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	HCIVERSION															
Write																
Reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

USBx_HCIVERSION field descriptions

Field	Description
HCIVERSION	EHCI revision number. Value is 0x0100 indicating version 1.0.

16.3.6 Host Controller Structural Parameters (USBx_HCSPARAMS)

HCSPARAMS contains structural parameters such as the number of downstream ports.

Address: Base address + 104h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved				N_TT				N_PTT				Reserved			PI
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	N_CC				N_PCC				Reserved			PPC	N_PORTS			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1

USBx_HCSPARAMS field descriptions

Field	Description
31–28 -	This field is reserved. Reserved, should be cleared.

Table continues on the next page...

USBx_HCSPARAMS field descriptions (continued)

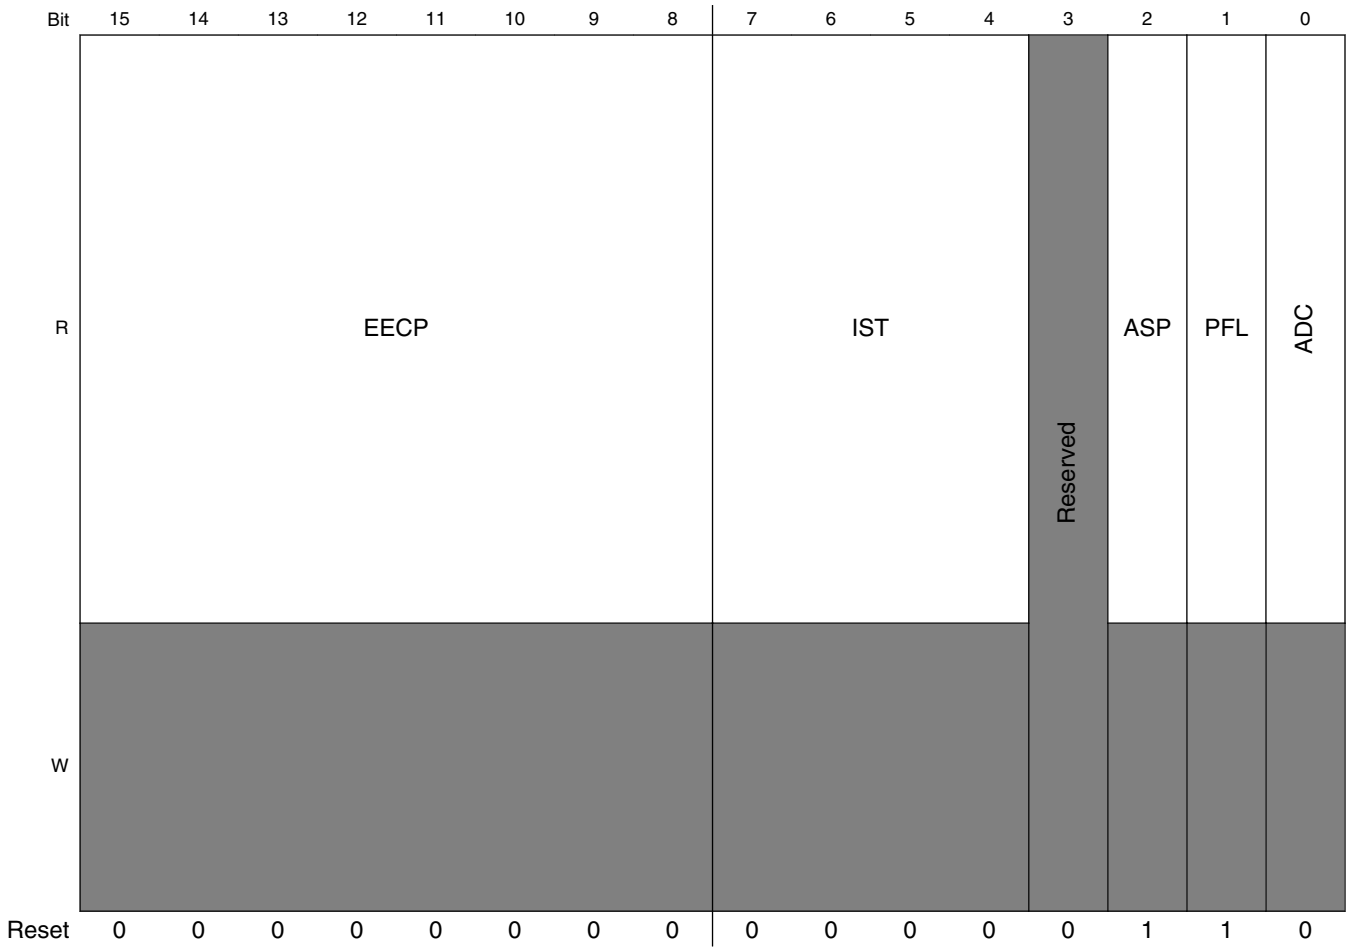
Field	Description
27–24 N_TT	Number of transaction translators. This is a non-EHCI field. This field indicates the number of embedded transaction translators associated the module. Always 1. See Embedded transaction translator function .
23–20 N_PTT	Ports per transaction translator. This is a non-EHCI field. The number of ports assigned to each transaction translator. This is equal to N_PORTS.
19–17 -	This field is reserved. Reserved, should be cleared.
16 PI	Port indicators. Indicates whether the ports support port indicator control. Always 1. 1 The port status and control registers include a R/W field for controlling the state of the port indicator.
15–12 N_CC	Number of companion controllers associated with the DR controller. Always 0.
11–8 N_PCC	Number ports per CC. This field indicates the number of ports supported per internal companion controller. Always 0.
7–5 -	This field is reserved. Reserved, should be cleared.
4 PPC	Power port control. Indicates whether the host controller supports port power control. UTMI Mode: In UTMI mode, USBDR will control the DRVVBUS signal defined in UTMI+ specification. 0 USBDR will drive utmi DRVVBUS signal LOW. 1 USBDR will drive utmi DRVVBUS signal HIGH. The operation of Port Power bit is independent of USBDR mode (host or device / USBMODE[CM]).
N_PORTS	Number of ports. Number of physical downstream ports implemented for host applications. The value of this field determines how many port registers are addressable in the operational register. Always 1.

16.3.7 Host Controller Capability Parameters (USBx_HCCPARAMS)

HCCPARAMS identifies multiple mode control (time-base bit functionality) addressing capability.

Address: Base address + 108h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



USBx_HCCPARAMS field descriptions

Field	Description
31–16 -	This field is reserved. Reserved, should be cleared.
15–8 EECP	EHCI extended capabilities pointer. Indicates the existence of a capabilities list. A value of 0x00 indicates no extended capabilities are implemented. A non-zero value in this register indicates the offset in PCI configuration space of the first EHCI extended capability. The pointer value must be 0x40 or greater if implemented to maintain the consistency of the PCI header defined for this class of device. This field is always 0.
7–4 IST	Isochronous scheduling threshold. Indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit 7 is zero, the value of the least significant 3 bits indicates the number of microframes a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit 7 is a one, then host software assumes the host controller may cache an isochronous data structure for an entire frame. This field is always 0.
3 -	This field is reserved. Reserved, should be cleared.
2 ASP	Asynchronous schedule park capability. Indicates whether the USB DR module supports the park feature for high-speed queue heads in the asynchronous schedule. The feature can be disabled or enabled and set to a specific level by using the *asynchronous schedule park mode enable* and *asynchronous schedule park mode count* fields in the USBCMD register.

Table continues on the next page...

USBx_HCCPARAMS field descriptions (continued)

Field	Description
	This field is always 1 (park feature supported).
1 PFL	Programmable frame list flag. Indicates whether system software can specify and use a frame list length less that 1024 elements. Frame list size is configured via the USBCMD register frame list size field. The frame list must always be aligned on a 4-K page boundary. This requirement ensures that the frame list is always physically contiguous. This field is always 1.
0 ADC	64-bit addressing capability. Always 0; 64-bit addressing is not supported. 0 Data structures use 32-bit address memory pointers

16.3.8 Device Controller Interface Version Number (USBx_DCIVERSION)

This register is not defined in the EHCI specification. DCIVERSION is a two-byte register containing a BCD encoding of the device controller interface. The most-significant byte of the register represents major revision and the least-significant byte is minor revision.

Address: Base address + 120h offset

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	DCIVERSION															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

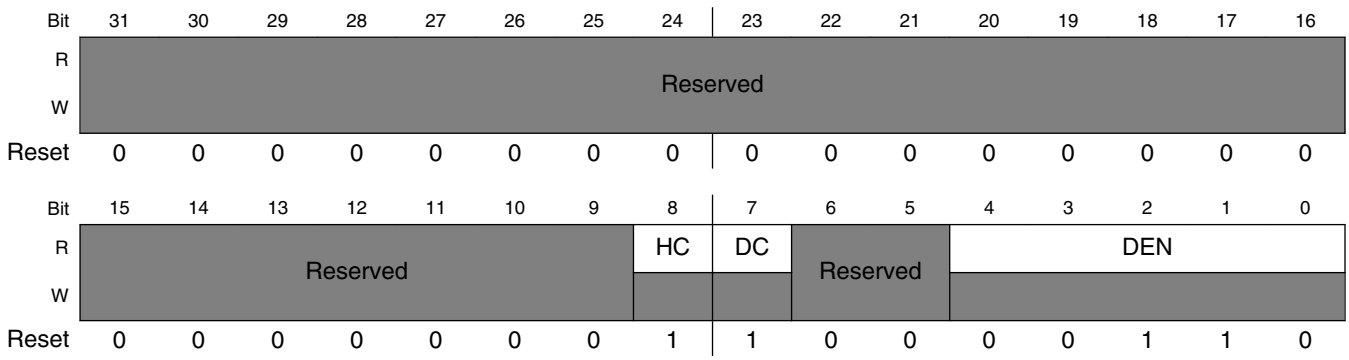
USBx_DCIVERSION field descriptions

Field	Description
DCIVERSION	Device interface revision number.

16.3.9 Device Controller Capability Parameters (USBx_DCCPARAMS)

This register is not defined in the EHCI specification. This register describes the overall host/device capability of the DR module.

Address: Base address + 124h offset



USBx_DCCPARAMS field descriptions

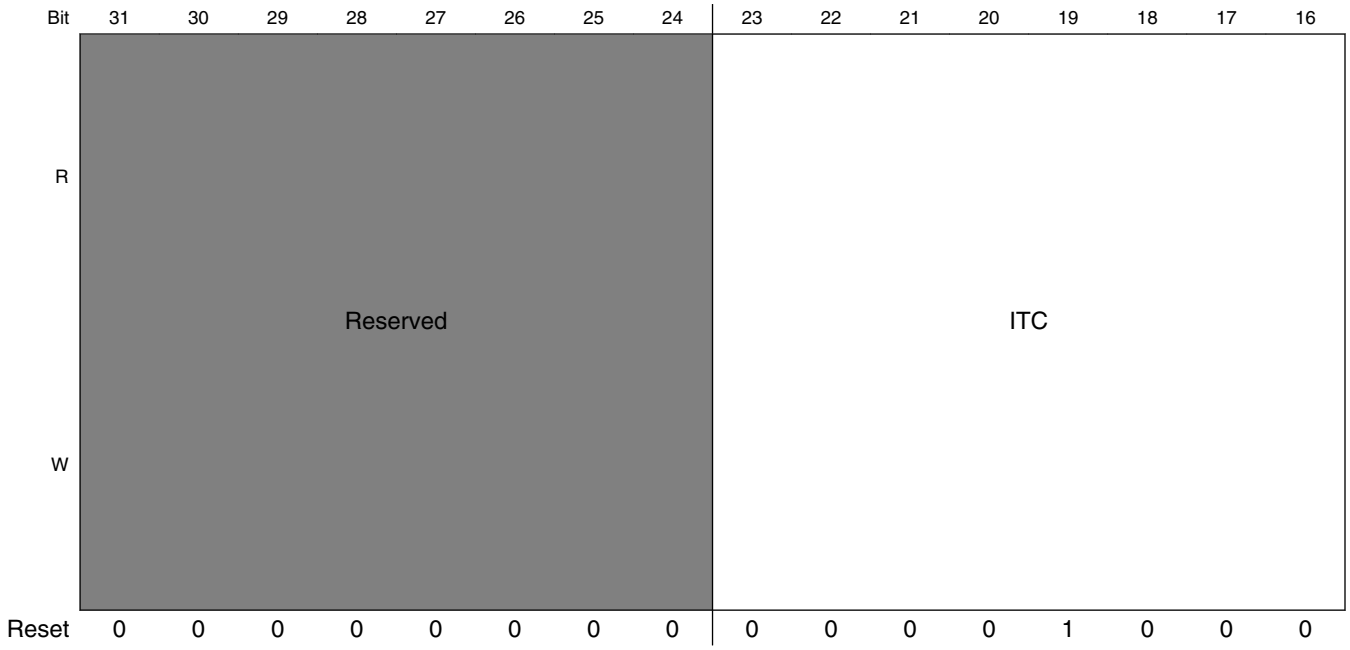
Field	Description
31–9 -	This field is reserved. Reserved, should be cleared.
8 HC	Host capable. Always 1, indicating the USB DR controller can operate as an EHCI compatible USB 2.0 host
7 DC	Device capable. Always 1, indicating the USB DR controller can operate as an USB 2.0 device. 1 Device capability. 0 No device capability (host only).
6–5 -	This field is reserved. Reserved, should be cleared.
DEN	Device endpoint number. Indicates the number of endpoints built into the device controller. Always 0x 6 .

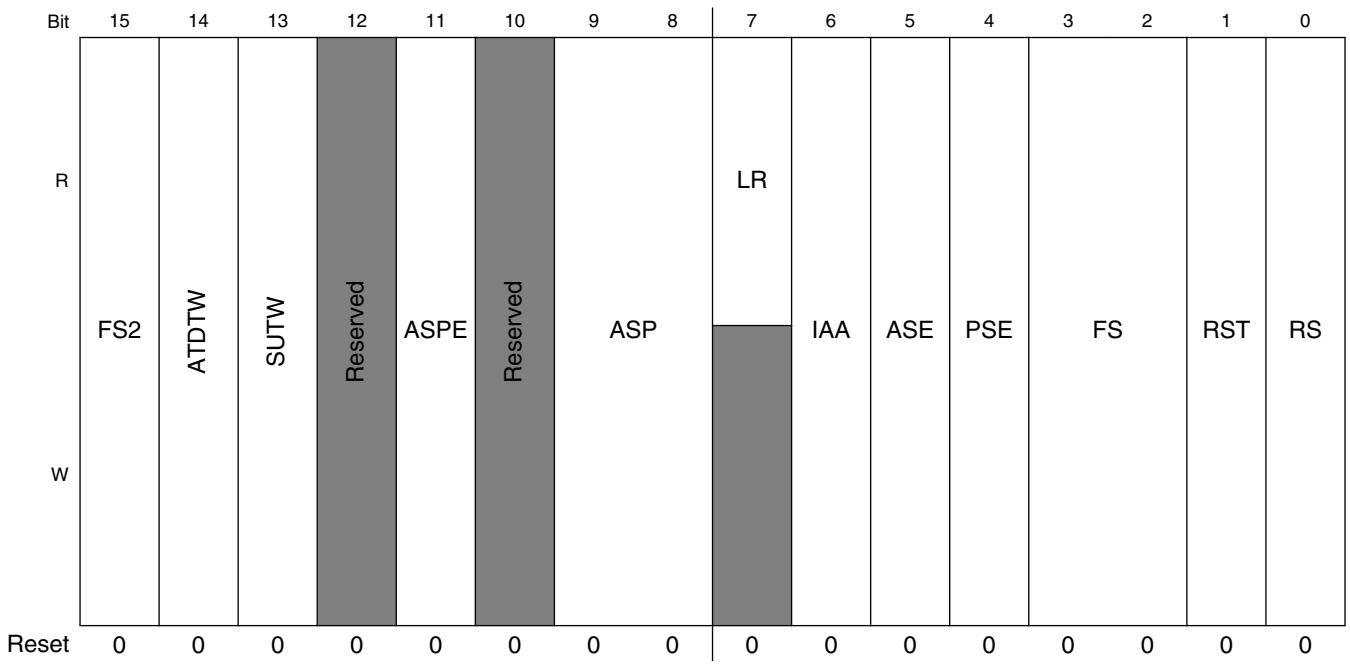
16.3.10 USB Command (USBx_USBCMD)

The operational registers are comprised of dynamic control or status registers that may be read-only, read/write, or read/write-1-to-clear. The following registers define the operational registers.

The module executes the command indicated in this register.

Address: Base address + 140h offset





USBx_USBCMD field descriptions

Field	Description
31–24 -	This field is reserved. Reserved, should be cleared.
23–16 ITC	Interrupt threshold control. The system software uses this field to set the maximum rate at which the USB DR module issues interrupts. ITC contains the maximum interrupt interval measured in microframes. Valid values are shown below. 0x00 Immediate (no threshold)

Table continues on the next page...

USBx_USBCMD field descriptions (continued)

Field	Description
	0x01 1 microframe 0x02 2 microframes 0x04 4 microframes 0x08 8microframes 0x10 16 microframes 0x20 32 microframes 0x40 40 microframes
15 FS2	See bits 3-2 below. This is a non-EHCI bit.
14 ATDTW	Add dTD TripWire. This is a non-EHCI bit. Used as a semaphore when a dTD is added to an active (primed) endpoint. This bit is set and cleared by software. This bit shall also be cleared by hardware when its state machine is in hazard region where adding a dTD to a primed endpoint may go unrecognized. More information on the use of this bit is described in Device operational model .
13 SUTW	Setup tripwire. This is a non-EHCI bit. Used as a semaphore when the 8 bytes of setup data read extracted from a QH by the DCD. If the setup lockout mode is off (See USB Device Mode (USB_USBMODE)) then there exists a hazard when new setup data arrives and the DCD is copying setup from the QH for a previous setup packet. This bit is set and cleared by software and will be cleared by hardware when a hazard exists. More information on the use of this bit is described in Device operational model .
12 -	This field is reserved. Reserved, should be cleared.
11 ASPE	Asynchronous schedule park mode enable. This bit defaults to a 1 and is R/W. Software uses this bit to enable or disable park mode. 0 Disabled 1 Enabled
10 -	This field is reserved. Reserved, should be cleared.
9–8 ASP	Asynchronous schedule park mode count. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the Asynchronous schedule before continuing traversal of the Asynchronous schedule. Valid values are 0x1H to 0x3H. Software must not write a zero to this field when ASPE is set as this results in undefined behavior.
7 LR	Light host/device controller reset (OPTIONAL). Not implemented. Always 0.
6 IAA	Interrupt on async advance doorbell. Used as a doorbell by software to tell the USB DR controller to issue an interrupt the next time it advances asynchronous schedule. Software must write a 1 to this bit to ring the doorbell. When the controller has evicted all appropriate cached schedule states, it sets USBSTS[AAI]. If USBINTR[AAE] is set, the host controller asserts an interrupt at the next interrupt threshold. The controller clears this bit after it has set USBSTS[AAI]. Software should not set this bit when the asynchronous schedule is inactive. Doing so yields undefined results. This bit is only used in host mode. Setting this bit when the USB DR module is in device mode is selected results in undefined results.
5 ASE	Asynchronous schedule enable. Controls whether the controller skips processing the asynchronous schedule. Only used in host mode. 0 Do not process the asynchronous schedule 1 Use the ASYNCLISTADDR register to access the asynchronous schedule.

Table continues on the next page...

USBx_USBCMD field descriptions (continued)

Field	Description
4 PSE	Periodic schedule enable. Controls whether the controller skips processing the periodic schedule. Only used in host mode. 0 Do not process the periodic schedule. 1 Use the PERIODICLISTBASE register to access the periodic schedule.
3–2 FS	Frame list size. Together with bit 15 these bits make the FS[2:0] field. This field is read/write only if programmable frame list flag in the HCCPARAMS registers is set to 1. This field specifies the size of the frame list that controls which bits in FRINDEX should be used for the frame list current index. Only used in host mode. Note that values below 256 elements are not defined in the EHCI specification. 000 1024 elements (4096 bytes) 001 512 elements (2048 bytes) 010 256 elements (1024 bytes) 011 128 elements (512 bytes) 100 64 elements (256 bytes) 101 32 elements (128 bytes) 110 16 elements (64 bytes) 111 8 elements (32 bytes)
1 RST	Controller reset. Software uses this bit to reset the controller. This bit is cleared by the controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register. • Host Mode: When software sets this bit, the host controller resets its internal pipelines, timers, counters, state machines, and so on to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Software should not set this bit when USBSTS[HCH] is a zero. Attempting to reset an actively running host controller results in undefined behavior. • Device Mode: When software writes a one to this bit, the USB_DR resets its internal pipelines, timers, counters, state machines, and so on to their initial value. Any transaction currently in progress on USB is immediately terminated. Writing a one to this bit when the device is in the attached state is not recommended, since the effect on an attached host is undefined. In order to ensure that the device is not in an attached state before initiating a controller reset, all primed endpoints should be flushed and the USBCMD[RS] bit should be set to 0. **NOTE:** • Once set, this bit is high for 63 clock cycles of system clock and then it transitions back to 0. Software lets the previous reset complete before setting this bit again. On setting this bit, the USBDR also resets the PHY. Software ensures that PHY also comes out reset before setting this bit again. • After power on reset, the value of RST becomes 1 and it deasserts only after programming PTS field of the controller in UTMI mode.
0 RS	Run/Stop. Host mode: • When this bit is set, the controller proceeds with the execution of the schedule. The controller continues execution as long as this bit is set. When this bit is set to 0, the host controller completes the current transaction on the USB and then halts. The USBSTS[HCH] bit indicates when the USB DR controller has finished the transaction and has entered the stopped state. Software should not write a one to this field unless the controller is in the halted state (that is, USBSTS[HCH] is a one). Device mode: • Setting this bit causes the USB DR controller to enable a pull-up on D+ and initiate an attach event. This control bit is not directly connected to the pull-up enable, as the pull-up is disabled upon

Table continues on the next page...

USBx_USBCMD field descriptions (continued)

Field	Description
	transitioning into high-speed mode. Software should use this bit to prevent an attach event before the controller has been properly initialized. Clearing this bit causes a detach event. 0 Stop 1 Run

16.3.11 USB Status (USBx_USBSTS)

The USB status register indicates various states of the USB DR module and any pending interrupts. This register does not indicate status resulting from a transaction on the serial bus. Software clears certain bits in this register by writing a 1 to them (indicated by a w1c in the bit's W cell).

Address: Base address + 144h offset

USBx_USBSTS field descriptions

Field	Description
31–16 -	This field is reserved. Reserved, should be cleared.
15 AS	Asynchronous schedule status. Reports the current real status of the asynchronous schedule. The USB DR controller is not required to immediately disable or enable the asynchronous schedule when software transitions USBCMD[ASE]. When this bit and USBCMD[ASE] have the same value, the asynchronous schedule is either enabled (1) or disabled (0). Only used in host mode. 0 Disabled 1 Enabled
14 PS	Periodic schedule status. Reports the current real status of the periodic schedule. The USB DR controller is not required to immediately disable or enable the periodic schedule when software transitions USBCMD[PSE]. When this bit and USBCMD[PSE] have the same value, the periodic schedule is either enabled (1) or disabled (0). Only used in host mode. 0 Disabled 1 Enabled
13 RCL	Reclamation. Used to detect an empty asynchronous schedule. Only used by the host mode. 0 Non-empty asynchronous schedule 1 Empty asynchronous schedule

Table continues on the next page...

USBx_USBSTS field descriptions (continued)

Field	Description
12 HCH	HC halted. This bit is a zero whenever USBCMD[RS] is a one. The USB DR controller sets this bit to one after it has stopped executing because of USBCMD[RS] being cleared, either by software or by the host controller hardware (for example, internal error). Only used in host mode. 0 Running 1 Halted
11 -	This field is reserved. Reserved, should be cleared.
10 -	This field is reserved. Reserved
9 -	This field is reserved. Reserved, should be cleared.
8 SLI	DC Suspend. This is a non-EHCI bit. When a device controller enters a suspend state from an active state, this bit is set. This bit is only cleared by software by writing a 1 to it. Only used by the device controller. 0 Active 1 Suspended
7 SRI	Host mode: • This is a non-EHCI status bit. In host mode, this bit is set every 125 µs, provided the PHY clock is present and running (for example, the port is NOT suspended), and can be used by the host controller driver as a time base. Device mode: • SOF received. When the USB DR controller detects a Start Of (Micro)Frame, this bit is set. When a SOF is extremely late, the DR controller automatically sets this bit to indicate that an SOF was expected. Therefore, this bit is set roughly every 1- ms in device FS mode and every 125 µs in HS mode and is synchronized to the actual SOF that is received. Because the controller is initialized to FS before connect, this bit is set at an interval of 1 ms during the prelude to the connect and chirp. Software writes a 1 to this bit to clear it.
6 URI	USB reset received. This is a non-EHCI bit. When the USB DR controller detects a USB reset and enters the default state, this bit is set. Software can write a 1 to this bit to clear the USB reset received status bit. Only used by the device mode. 0 No reset received 1 Reset received
5 AAI	Interrupt on async advance. System software can force the controller to issue an interrupt the next time the USB DR controller advances the asynchronous schedule by writing a one to USBCMD[IAA]. This status bit indicates the assertion of that interrupt source. Only used by the host mode. 0 No async advance interrupt 1 Async advance interrupt
4 SEI	System error. This bit is set whenever an error is detected on the system bus. If USBINTR[SEE] is set, an interrupt is generated. The interrupt and status bits remain asserted until cleared by writing a 1 to this bit. Additionally, when in host mode, USBCMD[RS] is cleared, effectively disabling the USB DR controller. For the USB DR controller in device mode, an interrupt is generated, but no other action is taken. 0 Normal operation 1 Error

Table continues on the next page...

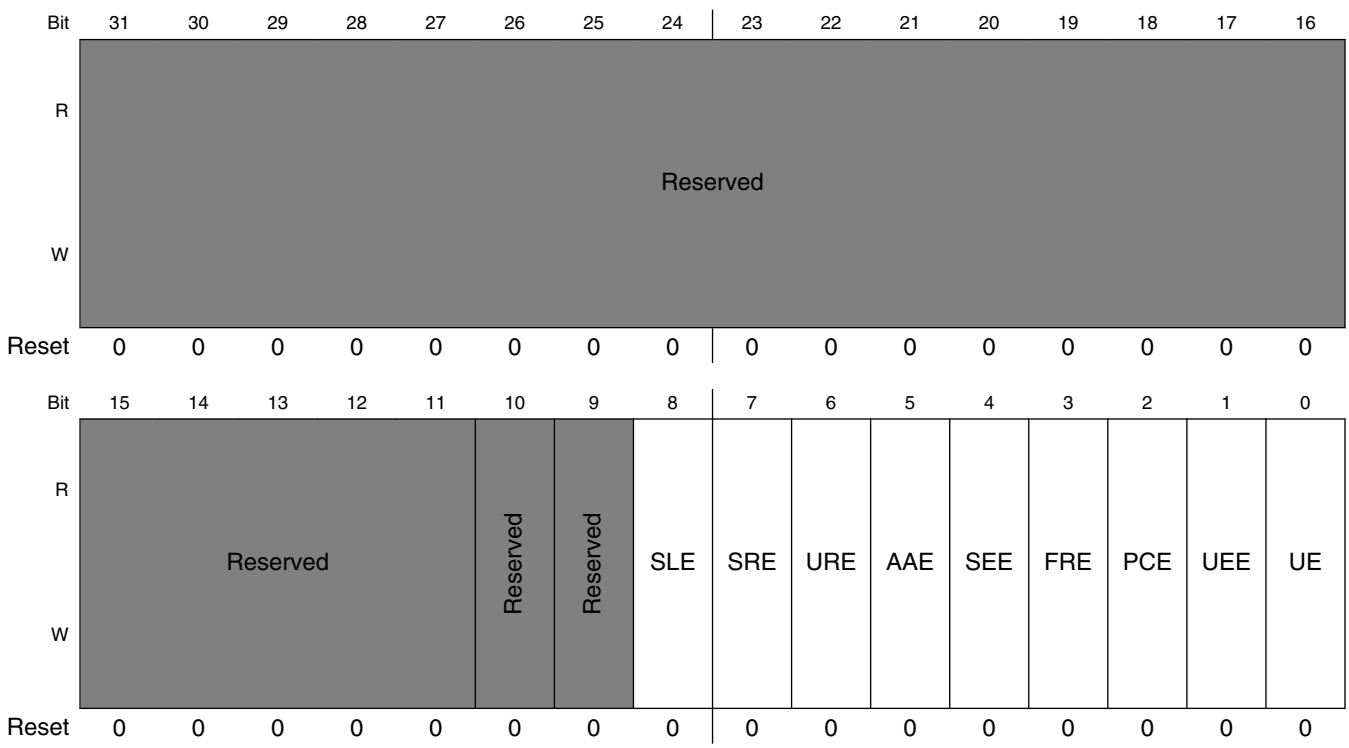
USBx_USBSTS field descriptions (continued)

Field	Description
3 FRI	Frame list rollover. The controller sets this bit to a one when the frame list index rolls over from its maximum value to zero. The exact value at which the rollover occurs depends on the frame list size. For example, if the frame list size (as programmed in USBCMD[FS]) is 1024, FRINDEX rolls over every time FRINDEX [13] toggles. Similarly, if the size is 512, the USB DR controller sets this bit to a one every time FRINDEX [12] toggles. Only used by the host mode.
2 PCI	Port change detect. Host mode: • The controller sets this bit when a connect status occurs on any port, a port enable/disable change occurs, an over current change occurs, or PORTSC[FPR] is set as the result of a J-K transition on the suspended port. Device mode: • The USB DR controller sets this bit when it enters the full or high-speed operational state. When the port controller exits the full or high-speed operation states due to reset or suspend events, the notification mechanisms are USBSTS[URI] and USBSTS[SLI], respectively. The controller also sets this bit when the VBUS de-asserts (occurs when the host disables port power or the device has been disconnected from the bus). This bit is not EHCI compatible.
1 UEI	USB error interrupt (USBERRINT). When completion of a USB transaction results in an error condition, this bit is set by the controller. This bit is set along with the UI, if the TD on which the error interrupt occurred also had its interrupt on complete (IOC) bit set. See Section 4.15.1 in EHCI for a complete list of host error interrupt conditions. Also see Table 16-64 in this chapter for more information on device error matrix. For the USB DR controller in device mode, only resume signaling is detected, all others are ignored. 0 No error 1 Error detected
0 UI	USB interrupt (USBINT). This bit is set by the controller when the cause of an interrupt is a completion of a USB transaction where the transfer descriptor (TD) has an interrupt on complete (IOC) bit set. This bit is also set by the controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes.

16.3.12 USB Interrupt Enable (USBx_USBINTR)

The interrupts to software are enabled with the USB interrupt enable register. An interrupt is generated when a bit is set and the corresponding interrupt is active. The USB status register (USBSTS) still shows interrupt sources even if they are disabled by the USBINTR register, allowing polling of interrupt events by the software.

Address: Base address + 148h offset



USBx_USBINTR field descriptions

Field	Description
31–11 -	This field is reserved. Reserved, should be cleared.
10 -	This field is reserved. Reserved
9 -	This field is reserved. Reserved, should be cleared.
8 SLE	Sleep enable. This is a non-EHCI bit. When this bit is a one, and USBSTS[SLI] transitions, the USB DR controller issues an interrupt. The interrupt is acknowledged by software writing a one to USBSTS[SLI]. Only used in device mode. 0 Disable 1 Enable

Table continues on the next page...

USBx_USBINTR field descriptions (continued)

Field	Description
7 SRE	SOF received enable. This is a non-EHCI bit. When this bit is a one, and USBSTS[SRI] is a one, the controller issues an interrupt. The interrupt is acknowledged by software clearing USBSTS[SRI]. 0 Disable 1 Enable
6 URE	USB reset enable. This is a non-EHCI bit. When this bit is a one, and USBSTS[URI] is a one, the device controller issues an interrupt. The interrupt is acknowledged by software clearing USBSTS[URI] bit. Only used in device mode. 0 Disable 1 Enable
5 AAE	Interrupt on async advance enable. When this bit is a one, and USBSTS[AAI] is a one, the controller issues an interrupt at the next interrupt threshold. The interrupt is acknowledged by software clearing USBSTS[AAI]. Only used in host mode. 0 Disable 1 Enable
4 SEE	System error enable. When this bit is a one, and USBSTS[SEI] is a one, the controller issues an interrupt. The interrupt is acknowledged by software clearing USBSTS[SEI]. 0 Disable 1 Enable
3 FRE	Frame list rollover enable. When this bit is a one, and USBSTS[FRI] is a one, the controller issues an interrupt. The interrupt is acknowledged by software clearing USBSTS[FRI]. Only used by the host mode. 0 Disable 1 Enable
2 PCE	Port change detect enable. When this bit is a one, and USBSTS[PCI] is a one, the controller issues an interrupt. The interrupt is acknowledged by software clearing USBSTS[PCI]. 0 Disable 1 Enable
1 UEE	USB error interrupt enable. When this bit is a one, and USBSTS[UEI] is a one, the controller issues an interrupt at the next interrupt threshold. The interrupt is acknowledged by software clearing USBSTS[UEI]. 0 Disable 1 Enable
0 UE	USB interrupt enable. When this bit is a one, and USBSTS[UI] is a one, the DR controller issues an interrupt at the next interrupt threshold. The interrupt is acknowledged by software clearing USBSTS[UI]. 0 Disable 1 Enable

16.3.13 USB Frame Index (USBx_FRINDEX)

In host mode, the frame index register is used by the controller to index the periodic frame list. The register updates every 125 microseconds (once each microframe). Bits N-3 are used to select a particular entry in the periodic frame list during periodic schedule execution. The number of bits used for the index depends on the size of the frame list as set by system software in USBCMD[FS].

This register must be written as a DWord. Byte writes produce-undefined results. This register cannot be written unless the USB DR controller is in the Halted state as indicated by the USBSTS[HCH]. A write to this register while USBCMD[RS] is set produces undefined results. Writes to this register also affect the SOF value.

In device mode, this register is read-only and the USB DR controller updates the FRINDEX[13-3] register from the frame number indicated by the SOF marker. Whenever a SOF is received by the USB bus, FRINDEX[13-3] is checked against the SOF marker. If FRINDEX[13-3] is different from the SOF marker, FRINDEX[13-3] is set to the SOF value and FRINDEX[2-0] is cleared (that is, SOF for 1 ms frame). If FRINDEX[13-3] is equal to the SOF value, FRINDEX[2-0] is incremented (that is, SOF for 125-µsec microframe).

The table below illustrates values of N based on the value of the Frame List Size in the USBCMD register, when used in host mode.

Table 16-2. FRINDEX N Values

USBCMD[FS]	Frame List Size	FRINDEX N value
000	1024 elements (4096 bytes)	12
001	512 elements (2048 bytes)	11
010	256 elements (1024 bytes)	10
011	128 elements (512 bytes)	9
100	64 elements (256 bytes)	8
101	32 elements (128 bytes)	7
110	16 elements (64 bytes)	6
111	8 elements (32 bytes)	5

Address: Base address + 14Ch offset

USBx_FRINDEX field descriptions

Field	Description
31–14 -	This field is reserved. Reserved, should be cleared.
FRINDEX	Frame index. The value in this register increments at the end of each time frame (for example, microframe). Bits N-3 are used for the Frame List current index. This means that each location of the frame list is accessed 8 times (frames or microframes) before moving to the next index. In device mode, the value is the current frame number of the last frame transmitted. It is not used as an index. In either mode, bits 2-0 indicate the current microframe.

16.3.14 Periodic Frame List Base Address [host mode] (USBx_PERIODICLISTBASE)

This register contains the beginning address of the periodic frame list in the system memory. The host controller driver loads this register prior to starting the schedule execution by the controller. The memory structure referenced by this physical memory pointer is assumed to be 4 KB aligned. The contents of this register are combined with the frame index register (FRINDEX) to enable the controller to step through the periodic frame list in sequence.

This register is shared between the host and device mode functions. In host mode, it is the PERIODICLISTBASE register; in device mode, it is the DEVICEADDR register. See USB Device Address [device mode] (USB_DEVICEADDR) , for more information.

Address: Base address + 154h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	PERBASE																Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBx_PERIODICLISTBASE field descriptions

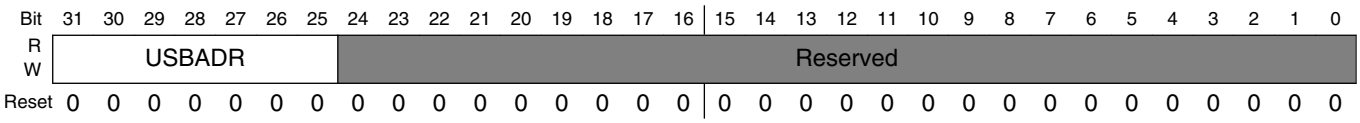
Field	Description
31–12 PERBASE	Base address. Correspond to memory address signal [31:12]. Only used in the host mode.
-	This field is reserved. Reserved, should be cleared.

16.3.15 USB Device Address [device mode] (USBx_DEVICEADDR)

The device address register is not defined in the EHCI specification. In device mode, the upper seven bits of this register represent the device address. After any controller reset or a USB reset, the device address is set to the default address (0). The default address will match all incoming addresses. Software reprograms the address after receiving a SET_ADDRESS descriptor.

This register is shared between the host and device mode functions. In device mode, it is the DEVICEADDR register; in host mode, it is the PERIODICLISTBASE register. See Periodic Frame List Base Address [host mode] (USB_PERIODICLISTBASE) , for more information.

Address: Base address + 154h offset



USBx_DEVICEADDR field descriptions

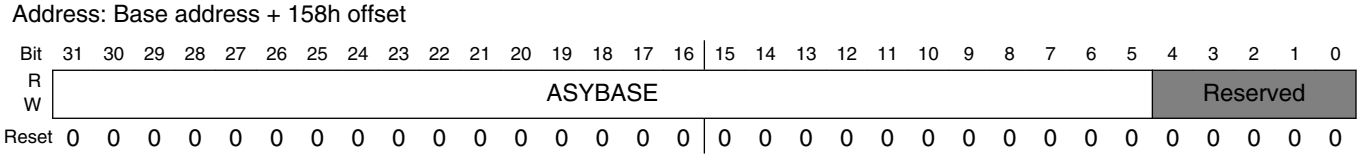
Field	Description
31–25 USBADR	Device address. This field corresponds to the USB device address.
-	This field is reserved. Reserved, should be cleared.

16.3.16 Next Asynchronous List Addr [host mode] (USBx_ASYNCLISTADDR)

This 32-bit register contains the address of the next asynchronous queue head to be executed by the host. Bits 4-0 of this register cannot be modified by the system software and always return zeros when read.

Note that this register is shared between the host and device mode functions. In host mode, it is the ASYNCLISTADDR register; in device mode, it is the ENDPOINTLISTADDR register. See Address at Endpoint List [device mode] (USB_ENDPOINTLISTADDR) , for more information.

Address: Base address + 158h offset



USBx_ASYNCLISTADDR field descriptions

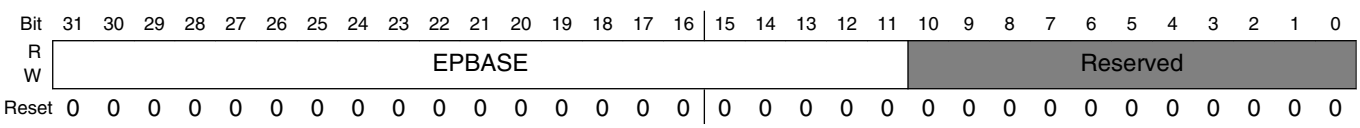
Field	Description
31–5 ASYBASE	Link pointer low (LPL). These bits correspond to memory address signals [31:5]. This field may only reference a queue head (QH). Only used by the host controller.
-	This field is reserved. Reserved, should be cleared.

16.3.17 Address at Endpoint List [device mode] (USBx_ENDPOINTLISTADDR)

The endpoint list address register is not defined in the EHCI specification. In device mode, this register contains the address of the top of the endpoint list in system memory. Bits 10-0 of this register cannot be modified by the system software and always return zeros when read. The memory structure referenced by this physical memory pointer is assumed to be 64-bytes. The queue head is actually a 48-byte structure, but must be aligned on 64-byte boundary. However, the ENDPOINTLISTADDR[EPBASE] has a granularity of 2 KB, so in practice the queue head should be 2 KB aligned.

This register is shared between the host and device mode functions. In device mode, it is the ENDPOINTLISTADDR register; in host mode, it is the ASYNCLISTADDR register. See Next Asynchronous List Addr [host mode] (USB_ASYNCLISTADDR) , for more information.

Address: Base address + 158h offset



USBx_ENDPOINTLISTADDR field descriptions

Field	Description
31–11 EPBASE	Endpoint list address. Address of the top of the endpoint list.
-	This field is reserved. Reserved, should be cleared.

16.3.18 Master Interface Data Burst Size (USBx_BURSTSIZE)

The master interface data burst size register is not defined in the EHCI specification. This register is used to control and dynamically change the burst size used during data movement on the initiator (master) interface.

Address: Base address + 160h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved																TXPBURST								RXPBURST							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0	0

USBx_BURSTSIZE field descriptions

Field	Description
31–16 -	This field is reserved. Reserved, should be cleared.
15–8 TXPBURST	Programable TX burst length. This register represents the maximum length of a burst in 32-bit words while moving data from system memory to the USB bus. Must not be set to greater that 16.
RXPBURST	Programable RX burst length. This register represents the maximum length of a burst in 32-bit words while moving data from the USB bus to system memory. Must not be set to greater than 16.

16.3.19 Transmit FIFO Tuning Controls (USBx_TXFILLTUNING)

The transmit FIFO tuning controls register is not defined in the EHCI specification. This register is used to control and dynamically change the burst size used during data movement on device DMA transfers. It is only used in host mode.

The fields in this register control performance tuning associated with how the USB DR module posts data to the TX latency FIFO before moving the data onto the USB bus. The specific areas of performance include how much data to post into the FIFO and an estimate for how long that operation should take in the target system.

Definitions:

T_0 = Standard packet overhead

T_1 = Time to send data payload

T_s = Total Packet Flight Time (send-only) packet ($Ts = T_0 + T_1$)

T_{ff} = Time to fetch packet into TX FIFO up to specified level.

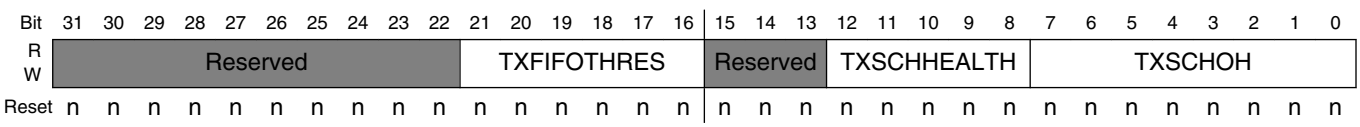
T_p = Total Packet Time (fetch and send) packet ($T_p = T_{ff} + T_s$)

Upon discovery of a transmit (OUT/SETUP) packet in the data structures, host controller checks to ensure T_p remains before the end of the [micro]frame. If so it proceeds to pre-fill the TX FIFO. If at any time during the pre-fill operation the time remaining the [micro]frame is < T_s then the packet attempt ceases and the packet is tried at a later time. Although this is not an error condition and the module eventually recovers, a mark is made in the scheduler health counter to note the occurrence of a back-off event. When a back-off event is detected, the partial packet fetched may need to be discarded from the latency buffer to make room for periodic traffic that will begin after the next SOF. Too many back-off events can waste bandwidth and power on the system bus and thus should be minimized (not necessarily eliminated). Back-offs can be minimized with use of the TSCHHEALTH (T_{ff}) parameter described below.

NOTE

This register cannot be written before the controller is programmed to the host mode. The register read 0x0000_0000 before the controller is configured to the host mode.

Address: Base address + 164h offset



USBx_TXFILLTUNING field descriptions

Field	Description
31–22 -	This field is reserved. Reserved, should be cleared.
21–16 TXFIFOTHRES	FIFO burst threshold. Control the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The minimum value is 2 and this value should be a low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if USBMODE[SDIS] (stream disable bit) is set. When USBMODE[SDIS] is set, the host controller behaves as if TXFIFOTHRES is set to the maximum value.
15–13 -	This field is reserved. Reserved, should be cleared.
12–8 TXSCHHEALTH	Scheduler health counter. Increment when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register clears the counter and this counter stops counting after reaching the maximum of 31.
TXSCHOH	Scheduler overhead. These bits add an additional fixed offset to the schedule time estimator described above as T_{ff}. As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a highly utilized bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization.

Table continues on the next page...

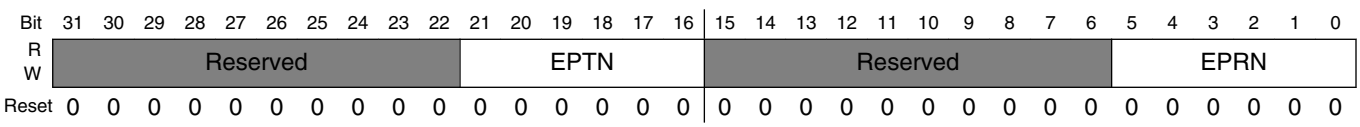
USBx_TXFILLTUNING field descriptions (continued)

Field	Description
	• The time unit represented in this register is 1.267µs when a device is connected in high-speed mode. • The time unit represented in this register is 6.333µs when a device is connected in low-/full-speed mode. For most applications, TXSCHOH can be set to 4 or less. A good value to begin with is: TXFIFOTHRES x (16 x 4 bytes-per-word) ÷ (40 x TimeUnit), always rounded to the next higher integer. TimeUnit is either 1.267 or 6.333 as noted earlier in this description. If this value of TXSCHOH results in a TXSCHHEALTH count of 0 per second, try lowering the value by 1 if optimizing performance is desired. If TXSCHHEALTH exceeds 10 per second, try raising the value by 1. If streaming mode is disabled via the USBMODE register, treat TXFIFOTHRES as the maximum value for purposes of the TXSCHOH calculation.

16.3.20 Endpoint NAK Indicaton Register (USBx_ENDPTNAK)

This register is only used in device mode.

Address: Base address + 178h offset



USBx_ENDPTNAK field descriptions

Field	Description
31–22 -	This field is reserved. Reserved.
21–16 EPTN	**TX Endpoint NAK** . Each TX endpoint has one bit in this field. This bit is set when controller sends a NAK handshake on a received IN token for the corresponding endpoint. EPTN[5] - Endpoint #5 ... EPTN[1] - Endpoint #1 EPTN[0] - Endpoint #0 Only used in device mode.
15–6 -	This field is reserved. Reserved.
EPRN	**RX Endpoint NAK** . Each RX endpoint has one bit in this field. This bit is set when controller sends a NAK handshake on a received OUT or PING token for the corresponding endpoint. EPRN[5] - Endpoint #5 ... EPRN[1] - Endpoint #1 EPRN[0] - Endpoint #0 Only used in device mode.

16.3.21 Endpoint NAK Indication Enable Register (USB*x*_ENDPTNAKEN)

This register is only used in device mode.

Address: Base address + 17Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

USB*x*_CONFIGFLAG field descriptions

Field	Description
31–1 -	This field is reserved. Reserved.
0 CF	Configure flag. Always 1. Indicating all port routings default to this host.

16.3.23 Port Status/Control (USB*x*_PORTSC)

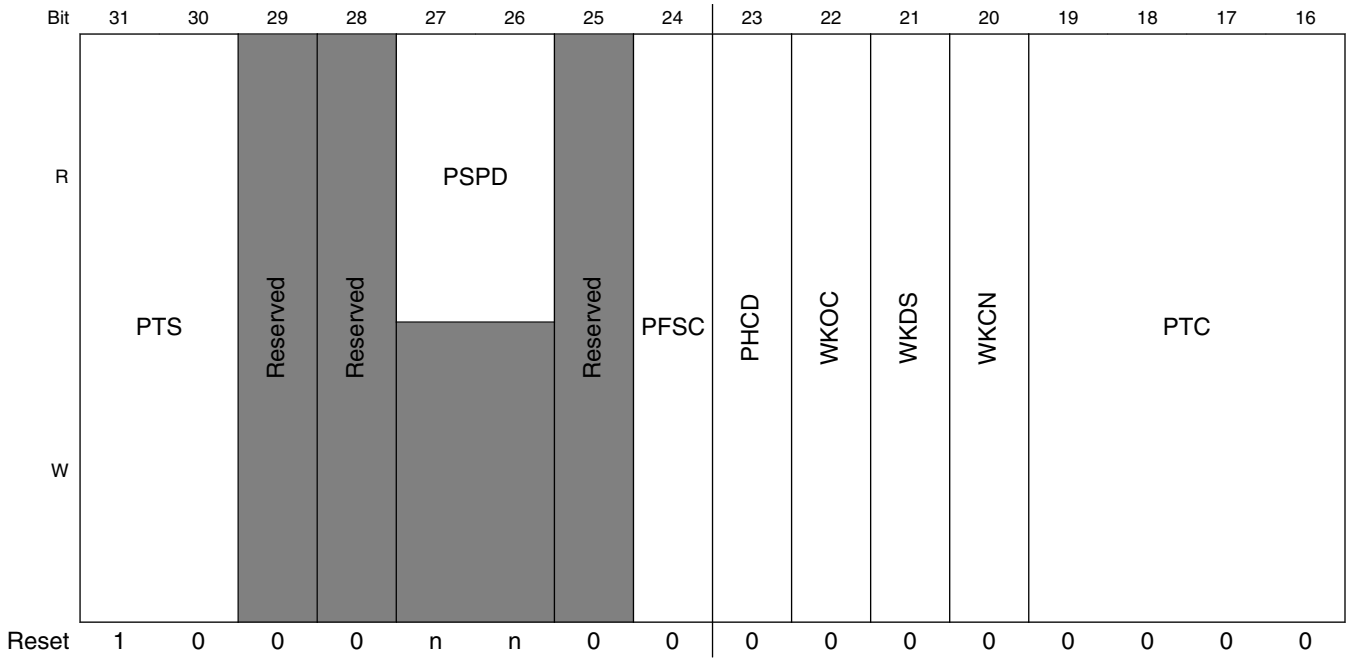
The port status and control (PORTSC) register is only reset when power is initially applied or in response to a controller reset. The initial conditions of a port are:

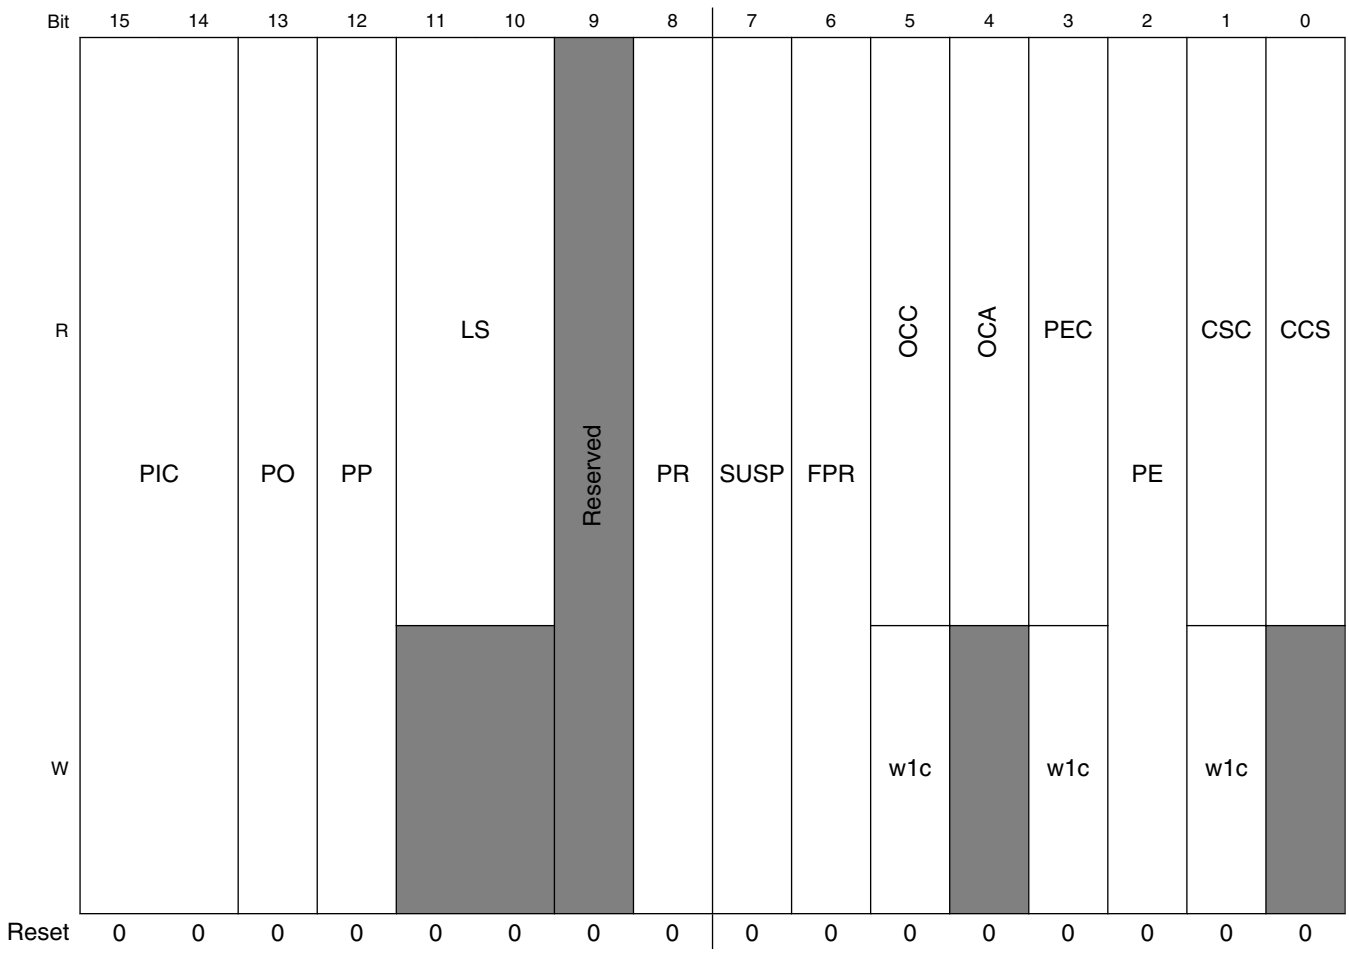
- No device connected
- Port disabled

If the port has port power control, this state remains until software applies power to the port by setting port power to one.

In device mode, the USB DR controller does not support power control. Port control in device mode is only used for status port reset, suspend, and current connect status. It is also used to initiate test mode or force signaling and allows software to put the PHY into low power suspend mode and disable the PHY clock.

Address: Base address + 184h offset





USBx_PORTSC field descriptions

Field	Description
31–30 PTS	Port transceiver select. This register bit is used to control which parallel transceiver interface is selected. This bit is not defined in the EHCI specification. 00 UTMI parallel interface 01 Reserved, should be cleared 10 Reserved 11 Reserved
29 -	This field is reserved. Reserved, should be cleared
28 -	This field is reserved. Reserved, should be cleared
27–26 PSPD	Port speed. This read-only register field indicates the speed at which the port is operating. This bit is not defined in the EHCI specification. 00 Full-speed 01 Low-speed 10 High-speed 11 Undefined
25 -	This field is reserved. Reserved, should be cleared
24 PFSC	Port force full-speed connect. Used to disable the chirp sequence that allows the port to identify itself as a HS port. This is useful for testing FS configurations with a HS host, hub or device. This bit is not defined in the EHCI specification. This bit is for debugging purposes. 0 Allow the port to identify itself as high speed. 1 Force the port to only connect at full speed.
23 PHCD	PHY low power suspend. This bit is not defined in the EHCI specification. Host mode: • The PHY can be put into low power suspend - when the downstream device has been put into suspend mode or when no downstream device is connected. Low power suspend is completely under the control of software. Device mode: • The PHY can be put into low power suspend - when the device is not running (USBCMD[RS] = 0b) or suspend signaling is detected on the USB. Low power suspend is cleared automatically when the resume signaling has been detected or when forcing port resume. Reading this bit indicates the status of the PHY. **NOTE:** If there is no clock connected to the USB*n* _CLK signals, PHCD must be set and the following registers should not be written: DEVICE_ADDR/PERIODICLISTBASE, PORTSC, ENDPTCTRL0, ENDPTCTRL1, ENDPTCTRL2 , ENDPTCTRL3, ENDPTCTRL4, ENDPTCTRL5 . 0 Normal PHY operation. 1 Signal the PHY to enter low power suspend mode
22 WKOC	Wake on over-current enable. Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events.

Table continues on the next page...

USBx_PORTSC field descriptions (continued)

Field	Description
	This field is zero if Port Power (PP) is zero. This bit is used only in Host mode and used by an external power control circuit.
21 WKDS	Wake on disconnect enable. Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. This field is zero if Port Power(PP) is zero or in device mode. This bit is used only in Host mode and used by an external power control circuit.
20 WKCN	Wake on connect enable. Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. This field is zero if Port Power(PP) is zero or in device mode. This bit is used only in Host mode and used by an external power control circuit.
19–16 PTC	Port test control. Any other value than zero indicates that the port is operating in test mode. Refer to Chapter 7 of the USB Specification Revision 2.0 [3] for details on each test mode. 0000 Not Enabled 0001 J_STATE 0010 K_STATE 0011 SEQ_NAK 0100 Packet 0101 FORCE_ENABLE 0110-1111 Reserved, should be cleared
15–14 PIC	Port indicator control. Control the link indicator signals. These signals are valid for host mode only. This field is output from the controller for use by an external LED driving circuit. 00 Off 01 Amber 10 Green 11 Undefined
13 PO	Port owner. Unconditionally goes to a 0 when the configured bit in the CONFIGFLAG register makes a 0 to 1 transition. This bit unconditionally goes to 1 whenever the Configured bit is zero. System software uses this field to release ownership of the port to a selected module (in the event that the attached device is not a high-speed device). Software writes a one to this bit when the attached device is not a high-speed device. A one in this bit means that an internal companion controller owns and controls the port. Port owner hand-off is not implemented in this design, therefore this bit is always 0.
12 PP	Port power. Represents the current setting of the switch (0=off, 1=on). When power is not available on a port (that is, PP equals a 0), the port is non-functional and will not report attaches, detaches, and so on. When an over-current condition is detected on a powered port, the PP bit in each affected port is transitioned by the host controller driver from a one to a zero (removing power from the port). This feature is implemented in the host controller (PPC = 1). In a device-only implementation port power control is not necessary, thus PPC and PP = 0. UTMI mode: In UTMI mode, USBDR controls the DRVVBUS signal defined in UTMI+ specification. 0 USBDR drives UTMI DRVVBUS signal LOW. 1 USBDR drives UTMI DRVVBUS signal HIGH.

Table continues on the next page...

USBx_PORTSC field descriptions (continued)

Field	Description
11–10 LS	Line status. Reflect the current logical levels of the USB D+ (bit 11) and D- (bit 10) signal lines. The use of line status by the host controller driver is not necessary (unlike EHCI), because the connection of FS and LS is managed by hardware. 00 SE0 10 J-state 01 K-state 11 Undefined
9 -	This field is reserved. Reserved, should be cleared
8 PR	Port reset. Host mode: • When software writes a one to this bit the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver. Device mode: • This bit is a read only status bit. Device reset from the USB bus is also indicated in the USBSTS register. This field is zero if Port Power(PP) is zero. 1 Port is in reset. 0 Port is not in reset.
7 SUSP	Suspend. Host mode: • The port enabled bit (PE) and suspend (SUSP) bit define the port states as follows: 0x Disable 10 Enable 11 Suspend • When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. • The module unconditionally sets this bit to zero when software clears the FPR bit. A write of zero to this bit is ignored by the host controller. If host software sets this bit to a one when the port is not enabled (that is, port enabled bit is a zero) the results are undefined. • This field is zero if Port Power (PP) is zero in host mode. Device mode: 1 Port in suspend state. 0 Port not in suspend state. Default. In device mode this bit is a read-only status bit.
6 FPR	Force port resume. This bit is not-EHCI compatible.

Table continues on the next page...

USBx_PORTSC field descriptions (continued)

Field	Description
	• Software sets this bit to one to drive resume signaling. The controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one a J-to-K transition is detected, USBSTS[PCI] (port change detect) is also set. This bit will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver. • Note that when the controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit will remain a one until the port has switched to the high-speed idle. Writing a zero has no affect because the port controller will time the resume operation and clear this bit when the port control state switches to HS or FS idle. • This field is zero if Port Power (PP) is zero in host mode. Device mode: • After the device has been in Suspend State for 5 ms or more, software can set this bit to one to drive resume signaling before clearing. The USB DR controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit is cleared when the device returns to normal operation. Also, when this bit transitions to a one because a J-to-K transition detected, USBSTS[PCI] is also set. 1 Resume detected/driven on port. 0 No resume (K-state) detected/driven on port.
5 OCC	Over-current change. This bit gets set when there is a change to over-current active. Software clears this bit by writing a one to this bit position. Host mode: • The user can provide over-current detection to the USB *n*_PWRFAULT signal for this condition. Device mode: • This bit must always be 0. 1 Over current detect. 0 No over current.
4 OCA	Over-current active. This bit will automatically transition from one to zero when the over-current condition is removed. Host mode: • The user can provide over-current detection to the USB *n* _PWRFAULT signal for this condition. Device mode: • This bit must always be 0. **NOTE:** Whenever over-current condition occurs, the correct operation of controller is not guaranteed even if over-current condition goes away. Software should reset the controller by writing in USBCMD[RST] bit and repeat the host controller initialization steps again before expecting the controller to behave properly. 1 Port currently in over-current condition. 0 Port not in over-current condition.
3 PEC	Port enable/disable change.

Table continues on the next page...

USBx_PORTSC field descriptions (continued)

Field	Description
	For the root hub, this bit gets set only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it. In device mode: • The device port is always enabled. (This bit is zero.) This field is zero if Port Power(PP) is zero. 1 Port disabled. 0 No change.
2 PE	Port enabled/disabled. Host mode: • Ports can only be enabled by the controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host and bus events. • When the port is disabled, (0) downstream propagation of data is blocked except for reset. • This field is zero if Port Power(PP) is zero in host mode. Device mode: • The device port is always enabled. (This bit is one.)
1 CSC	Connect change status. Host mode: • This bit indicates a change has occurred in the port's Current Connect Status. the controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware is 'setting' an already-set bit (that is, the bit will remain set). Software clears this bit by writing a one to it. 1 Connect Status has changed. 0 No change. • This field is zero if Port Power(PP) is zero. Device mode: • This bit is undefined.
0 CCS	Current Connect Status. Host Mode: 1 Device is present on port 0 No device is present This value reflects the current state of the port, and may not correspond directly to the event that caused the Connect Status Change bit to be set. This field is zero if Port Power(PP) is zero in host mode. Device Mode: 1 Attached 0 Not attached

Table continues on the next page...

USBx_PORTSC field descriptions (continued)

Field	Description
	A one indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the PSPD bits in this register. A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to USBCMD[RS] (run bit). It does not state the device being disconnected or suspended. A value of zero also occurs if vbus de-asserts either when the host disables port power or the device has been disconnected from the bus.

16.3.24 USB Device Mode (USBx_USBMODE)

The USB mode register is not defined in the EHCI specification. This register controls the operating mode of the module.

Address: Base address + 1A8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

USBx_USBMODE field descriptions

Field	Description
31–17 -	This field is reserved. Reserved
16 ALP	Auto Low Power.

Table continues on the next page...

USBx_USBMODE field descriptions (continued)

Field	Description
	When the software enables this bit, the PHY is put in low power when in suspend (PORTSC[SUSP] is enabled) even if PORTSC[PHCD] is not set.
15 -	This field is reserved. Reserved
14–12 TXHSD	Tx to Tx HS Delay. This bit controls the value of TX to TX HS interpacket delay by changing the internal delay count. The value of the global TX to TX interpacket delay depends on this internal counter and on the intrinsic PHY TX end delay and TX start delay values. The TX to TX interpacket gap must be within the interval [88,192] bit times. 88 = Controller internal delay – Tx End Delay + Tx Start Delay = 192 (HS bit times) The values of the internal controller counter in terms of PHY clock cycles are shown below. These values depend on the width of the PHY interface (8 or 16 bit). Value---Delay(8-bit, 60MHz)---Delay(16-bit, 30MHz) 000---10---5 001---11---5 010---12---6 011---13---6 100---14---7 101---15---7 110---16---8 111---17---8
11–5 -	This field is reserved. Reserved
4 SDIS	Stream disable In host mode, setting this bit ensures that overruns/underruns of the latency FIFO are eliminated for low bandwidth systems where the RX and TX buffers are sufficient to contain the entire packet. Enabling stream disable also has the effect of ensuring the TX latency is filled to capacity or a complete packet is stored in FIFO before the packet is launched onto the USB. Note that time duration to pre-fill the FIFO becomes significant when stream disable is active. See Transmit FIFO Tuning Controls (USB_TXFILLTUNING) to characterize the adjustments needed for the scheduler when using this feature. Also note that in systems with high system bus utilization, setting this bit will ensure no overruns or underruns during operation, at the expense of link utilization. For those who desire optimal link performance, SDIS can be left clear, and the rules used under the description of the TXFILLTUNING register to limit underruns/overruns. In device mode, setting this bit disables double priming on both RX and TX for low bandwidth systems. This mode ensures that when the RX and TX buffers are sufficient to contain an entire packet that the standard double buffering scheme is disabled to prevent overruns/underruns in bandwidth limited systems. Note that in high-speed mode, all packets received are responded to with a NYET handshake when stream disable is active. 1 Active. 0 Inactive.

Table continues on the next page...

USBx_USBMODE field descriptions (continued)

Field	Description
3 SLOM	Setup lockout mode. In device mode, this bit controls behavior of the setup lock mechanism. See Control endpoint operation model . 1 Setup lockouts off. DCD requires use of setup data buffer tripwire in USBCMD (SUTW). 0 Setup lockouts on
2 -	This field is reserved. Reserved, should be cleared.
CM	Controller mode This register can only be written once after reset. If it is necessary to switch modes, software must reset the controller by writing to USBCMD[RST] before reprogramming this register. Defaults to the idle state and needs to be initialized to the desired operating mode after reset. 00 Idle (default). 01 Reserved, should be cleared. 10 Device controller . 11 Host controller .

16.3.25 Endpoint Setup Status (USBx_ENDPTSETUPSTAT)

The endpoint setup status register is not defined in the EHCI specification. This register contains the endpoint setup status. It is only used in device mode.

Address: Base address + 1ACh offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																											w1c					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBx_ENDPTSETUPSTAT field descriptions

Field	Description
31–6 -	This field is reserved. Reserved, should be cleared.
ENDPTSETUPSTAT	Setup endpoint status. For every setup transaction that is received, a corresponding bit in this register is set. Software must clear or acknowledge the setup transfer by writing a one to a respective bit after it has read the setup data from queue head. The response to a setup packet as in the order of operations and total response time is crucial to limit bus time outs while the setup lockout mechanism is engaged. This register is only used in device mode.

16.3.26 Endpoint Initialization (USBx_ENDPOINTPRIME)

The endpoint initialization register is not defined in the EHCI specification. This register is used to initialize endpoints. It is only used in device mode.

Address: Base address + 1B0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved										PETB						Reserved										PERB					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

USBx_ENDPOINTPRIME field descriptions

Field	Description
31–22 -	This field is reserved. Reserved, should be cleared.
21–16 PETB	Prime endpoint transmit buffer. For each endpoint a corresponding bit is used to request that a buffer prepared for a transmit operation in order to respond to a USB IN/INTERRUPT transaction. Software should write a one to the corresponding bit when posting a new transfer descriptor to an endpoint. Hardware will automatically use this bit to begin parsing for a new transfer descriptor from the queue head and prepare a transmit buffer. Hardware will clear this bit when the associated endpoint(s) is (are) successfully primed. PETB[5] (bit 21 of the register) corresponds to endpoint 5. Note that these bits are momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated.
15–6 -	This field is reserved. Reserved, should be cleared.
PERB	Prime endpoint receive buffer. For each endpoint, a corresponding bit is used to request a buffer prepare for a receive operation in order to respond to a USB OUT transaction. Software should write a one to the corresponding bit whenever posting a new transfer descriptor to an endpoint. Hardware will automatically use this bit to begin parsing for a new transfer descriptor from the queue head and prepare a receive buffer. Hardware will clear this bit when the associated endpoint(s) is (are) successfully primed. PERB[5] corresponds to endpoint 5. Note that these bits are momentarily set by hardware during hardware re-priming operations when a dTD is retired, and the dQH is updated.

16.3.27 Endpoint Flush (USBx_ENDPTFLUSH)

The endpoint flush register is not defined in the EHCI specification. This register is only used in device mode.

Address: Base address + 1B4h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved										FETB						Reserved										FERB					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

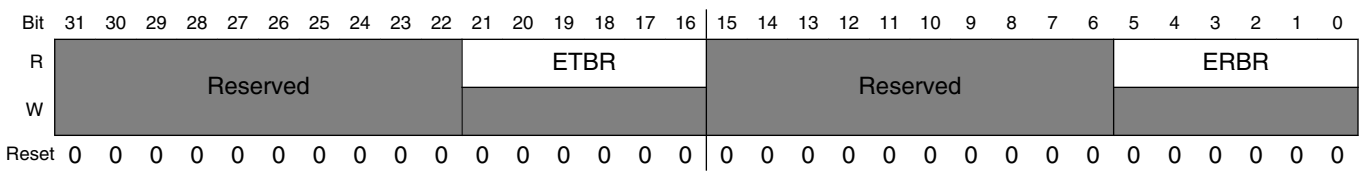
USBx_ENDPTFLUSH field descriptions

Field	Description
31–22 -	This field is reserved. Reserved, should be cleared.
21–16 FETB	Flush endpoint transmit buffer. Writing a one to a bit(s) in this register will cause the associated endpoint(s) to clear any primed buffers. If a packet is in progress for one of the associated endpoints, then that transfer will continue until completion. Hardware will clear this register after the endpoint flush operation is successful. FETB[5] (bit 21 of the register) corresponds to endpoint 5.
15–6 -	This field is reserved. Reserved, should be cleared.
FERB	Flush endpoint receive buffer. Writing a one to a bit(s) will cause the associated endpoint(s) to clear any primed buffers. If a packet is in progress for one of the associated endpoints, then that transfer will continue until completion. Hardware will clear this register after the endpoint flush operation is successful. FERB[5] corresponds to endpoint 5.

16.3.28 Endpoint Status (USBx_ENDPTSTATUS)

The endpoint status register is not defined in the EHCI specification. This register is only used in device mode.

Address: Base address + 1B8h offset



USBx_ENDPTSTATUS field descriptions

Field	Description
31–22 -	This field is reserved. Reserved, should be cleared
21–16 ETBR	Endpoint transmit buffer ready. One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. ETBR[5] (bit 21 of the register) corresponds to endpoint 5. Note that these bits are momentarily cleared by hardware during hardware endpoint re-priming operations when a dTD is retired, and the dQH is updated.
15–6 -	This field is reserved. Reserved, should be cleared
ERBR	Endpoint receive buffer ready. One bit for each endpoint indicates status of the respective endpoint buffer. This bit is set by the hardware as a response to receiving a command from a corresponding bit in the ENDPTPRIME register. There will always be a delay between setting a bit in the ENDPTPRIME register and endpoint indicating ready. This delay time varies based upon the current USB traffic and the number

Table continues on the next page...

USBx_ENDPTSTATUS field descriptions (continued)

Field	Description
	of bits set in the ENDPTPRIME register. Buffer ready is cleared by USB reset, by the USB DMA system, or through the ENDPTFLUSH register. ERBR[5] corresponds to endpoint 5. Note that these bits are momentarily cleared by hardware during hardware endpoint re-priming operations when a dTD is retired, and the dQH is updated.

16.3.29 Endpoint Complete (USBx_ENDPTCOMPLETE)

The endpoint complete register is not defined in the EHCI specification. This register is only used in device mode.

Address: Base address + 1BCh offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved										ETCE						Reserved										ERCE					
W											w1c																w1c					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

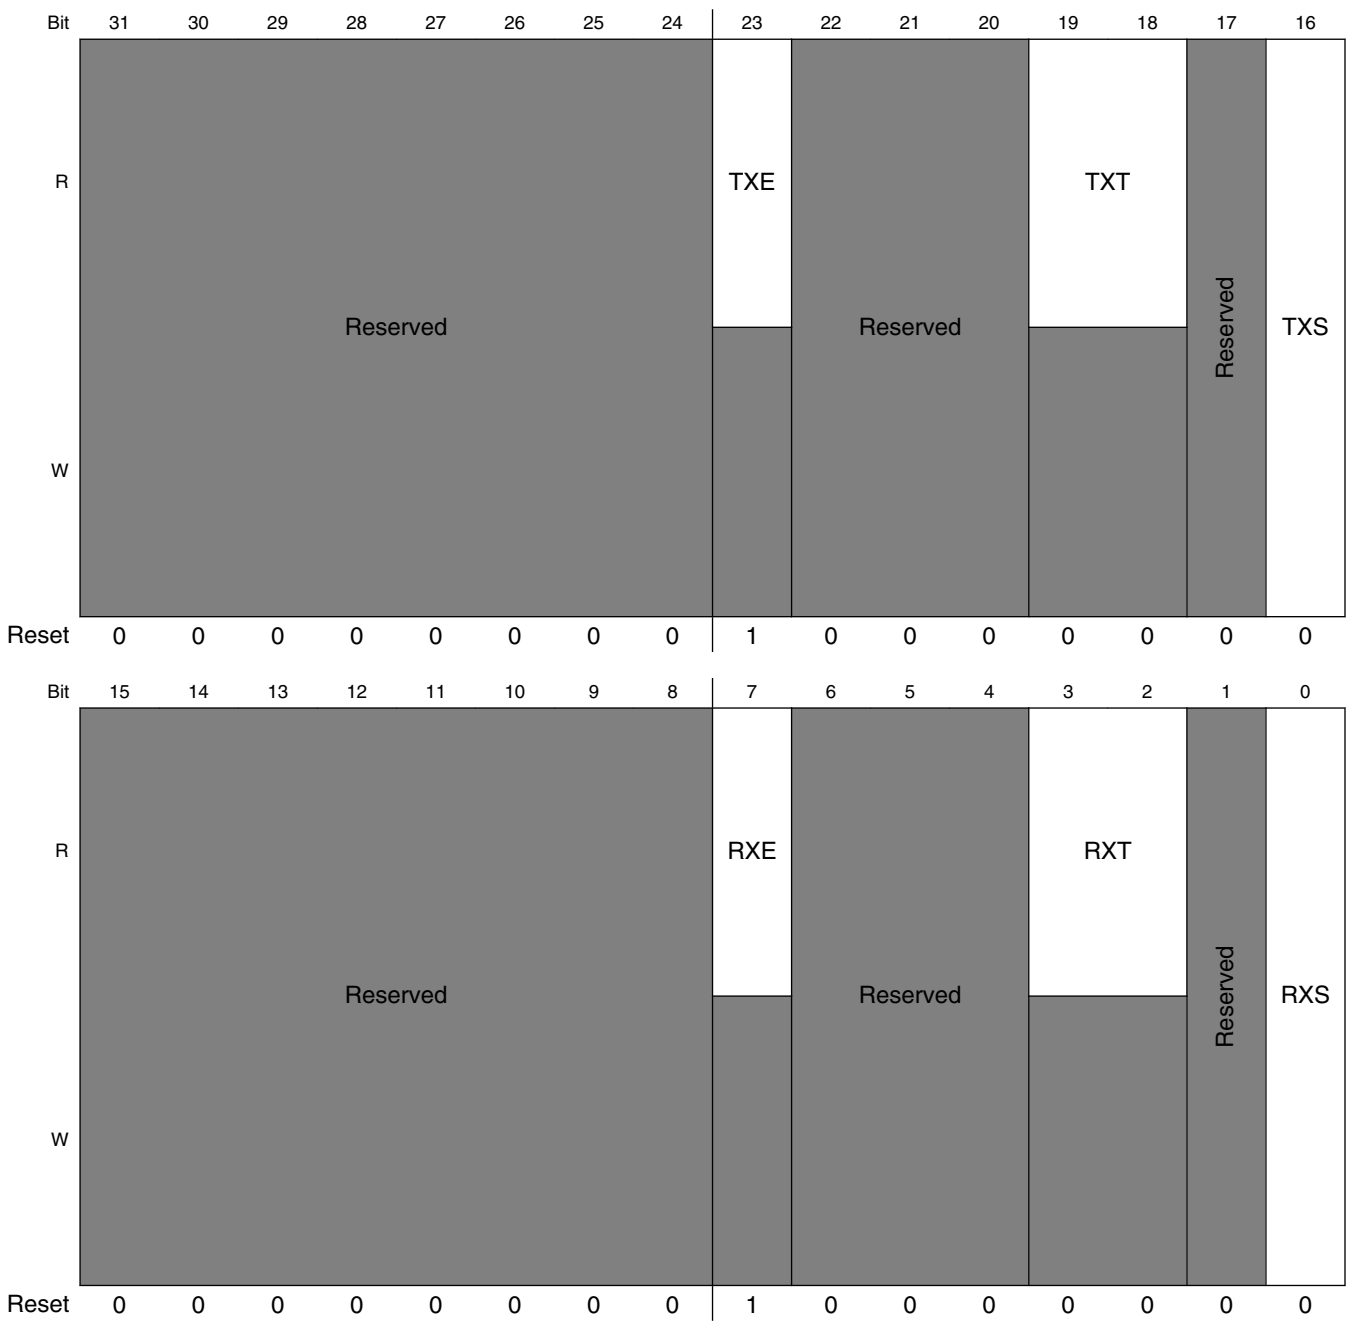
USBx_ENDPTCOMPLETE field descriptions

Field	Description
31–22 -	This field is reserved. Reserved, should be cleared
21–16 ETCE	Endpoint transmit complete event. Each bit indicates a transmit event (IN/INTERRUPT) occurred and software should read the corresponding endpoint queue to determine the endpoint status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit is set simultaneously with the USBINT. Writing a one will clear the corresponding bit in this register. ETCE[5] (bit 21 of the register) corresponds to endpoint 5.
15–6 -	This field is reserved. Reserved, should be cleared
ERCE	Endpoint receive complete event. Each bit indicates a received event (OUT/SETUP) occurred and software should read the corresponding endpoint queue to determine the transfer status. If the corresponding IOC bit is set in the Transfer Descriptor, then this bit is set simultaneously with the USBINT. Writing a one will clear the corresponding bit in this register. ERCE[5] corresponds to endpoint 5.

16.3.30 Endpoint Control 0 (USBx_ENDPTCTRL0)

Endpoint control register 0 is not defined in the EHCI specification. Every device will implement endpoint 0 as a control endpoint.

Address: Base address + 1C0h offset



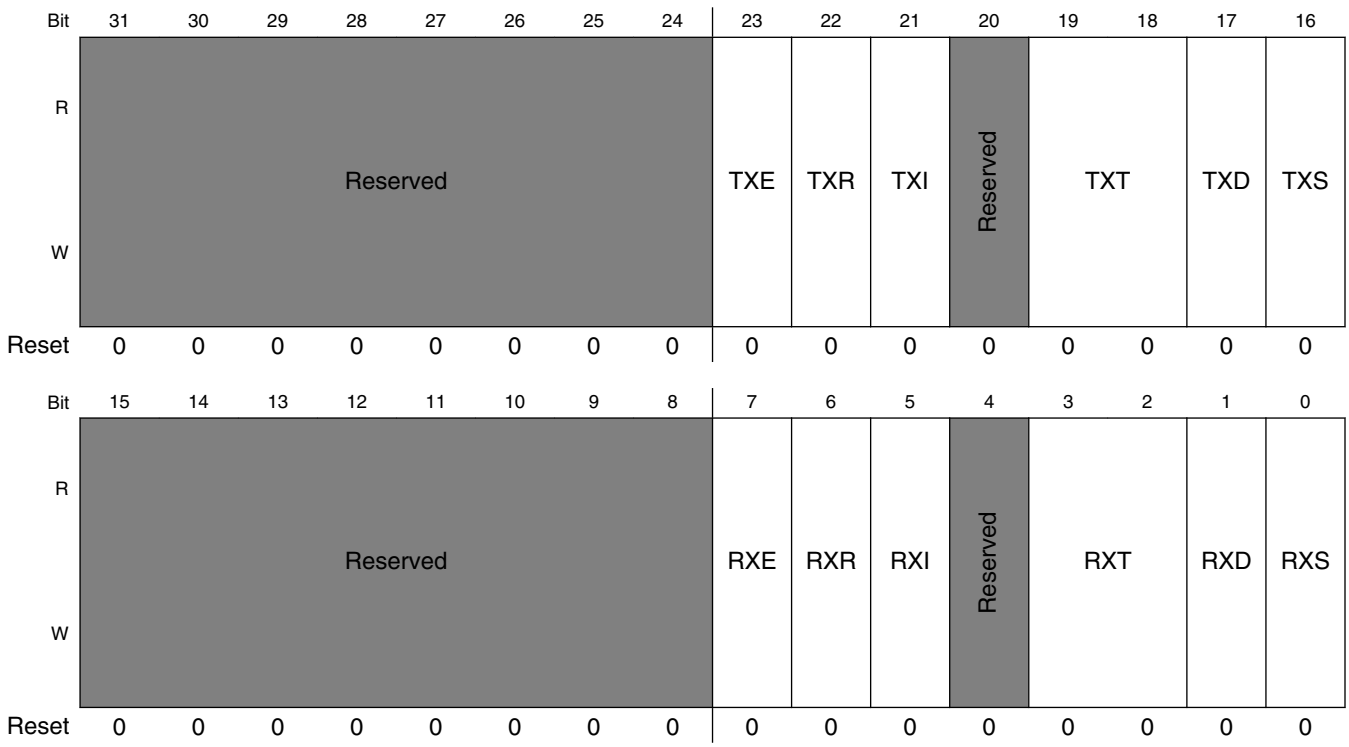
USBx_ENDPTCTRL0 field descriptions

Field	Description
31–24 -	This field is reserved. Reserved, should be cleared.
23 TXE	TX endpoint enable. Endpoint zero is always enabled. 0 Disable 1 Enable
22–20 -	This field is reserved. Reserved, should be cleared.
19–18 TXT	TX endpoint type. Endpoint zero is always a control endpoint (00).
17 -	This field is reserved. Reserved, should be cleared.
16 TXS	TX endpoint stall. Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It will continue returning STALL until the bit is cleared by software or it will automatically be cleared upon receipt of a new SETUP request. 1 Endpoint stalled 0 Endpoint OK
15–8 -	This field is reserved. Reserved, should be cleared.
7 RXE	RX endpoint enable. Endpoint zero is always enabled. 0 Disabled 1 Enabled
6–4 -	This field is reserved. Reserved, should be cleared.
3–2 RXT	RX endpoint type. Endpoint zero is always a control endpoint (00).
1 -	This field is reserved. Reserved, should be cleared.
0 RXS	RX endpoint stall Software can write a one to this bit to force the endpoint to return a STALL handshake to the host. It will continue returning STALL until the bit is cleared by software or it will automatically be cleared upon receipt of a new SETUP request. 1 Endpoint stalled 0 Endpoint OK

16.3.31 Endpoint Control n (USB*x*_ENDPTCTRL*n*)

The endpoint control *n* registers are not defined in the EHCI specification. There is an ENDPTCTRL *n* register of each endpoint in a device.

Address: Base address + 1C4h offset + (4d × i), where i=0d to 4d



USB*x*_ENDPTCTRL*n* field descriptions

Field	Description
31–24 -	This field is reserved. Reserved, should be cleared
23 TXE	TX endpoint enable 0 Disabled 1 Enabled
22 TXR	TX data toggle reset. Whenever a configuration event is received for this endpoint, software must write a one to this bit in order to synchronize the data PID's between the Host and device.
21 TXI	TX data toggle inhibit. Used only for test and should always be written as zero. Writing a one to this bit will cause this endpoint to ignore the data toggle sequence and always transmit DATA0 for a data packet. 0 PID sequencing enabled 1 PID sequencing disabled
20 -	This field is reserved. Reserved, should be cleared

Table continues on the next page...

USB*x*_ENDPTCTRL*n* field descriptions (continued)

Field	Description
19–18 TXT	TX endpoint type **NOTE:** When only one endpoint (RX or TX, but not both) of an endpoint pair is used, the unused endpoint should be configured as a bulk type endpoint. 00 Control 01 Isochronous 10 Bulk 11 Interrupt
17 TXD	TX endpoint data source. This bit should always be written as 0, which selects the dual port memory/DMA engine as the source.
16 TXS	TX endpoint stall. This bit is set automatically upon receipt of a SETUP request if this endpoint is not configured as a control endpoint. It is cleared automatically upon receipt of a SETUP request if this endpoint is configured as a control endpoint. Software can write a one to this bit to force the endpoint to return a STALL handshake to the host. It will continue to returning STALL until this bit is either cleared by software or automatically cleared as above. 0 Endpoint OK 1 Endpoint stalled
15–8 -	This field is reserved. Reserved, should be cleared
7 RXE	RX endpoint enable 0 Disabled 1 Enabled
6 RXR	RX data toggle reset. Whenever a configuration event is received for this endpoint, software must write a one to this bit in order to synchronize the data PID's between the Host and device.
5 RXI	RX data toggle inhibit. This bit is only used for test and should always be written as zero. Writing a one to this bit will cause this endpoint to ignore the data toggle sequence and always accept data packets regardless of their data PID. 1 PID sequencing enabled 0 PID sequencing disabled
4 -	This field is reserved. Reserved, should be cleared
3–2 RXT	RX endpoint type. **NOTE:** When only one endpoint (RX or TX, but not both) of an endpoint pair is used, the unused endpoint should be configured as a bulk type endpoint. 00 Control 01 Isochronous 10 Bulk 11 Interrupt
1 RXD	RX endpoint data sink. This bit should always be written as 0, which selects the dual port memory/DMA engine as the sink.
0 RXS	RX endpoint stall. This bit is set automatically upon receipt of a SETUP request if this endpoint is not configured as a control endpoint. It is cleared automatically upon receipt a SETUP request if this endpoint is configured as a control endpoint,

Table continues on the next page...

USBx_ENDPTCTRLn field descriptions (continued)

Field	Description
	Software can write a one to this bit to force the endpoint to return a STALL handshake to the host. It will continue to returning STALL until this bit is either cleared by software or automatically cleared as above, 1 Endpoint stalled 0 Endpoint OK

16.3.32 Snoop n (USBx_SNOOPn)

These registers use big-endian byte ordering and are not defined in the EHCI specification. The SNOOP1 and SNOOP2 registers provide snooping control and address range selection function. Transactions that hit a snooping window will generate cache coherent transactions on the internal system bus. When the five lower bits (SNOOP *n* [27-31]) are equal to 00000, snooping is always disabled on the system bus for all DMA transfers. When SNOOP *n* [27-31] is 01011 through 11110, the twenty upper bits (SNOOP *n* [0-19]) provide the starting base address for which transactions are snooped. These twenty bits are compared to the twenty upper bits of the address provided by the DMA block of the USB controller. When a match occurs, the five lower bits are decoded as shown below. This provides a snooping region of 4 KB to 2 GB within each starting base address that is programmed by the core. The SNOOP *n* [20-26] are not used.

Address: Base address + 400h offset + (4d × i), where i=0d to 1d

16.3.33 Age Count Threshold (USB*x*_AGE_CNT_THRESH)

Note that this register uses big-endian byte ordering and is not defined in the EHCI specification. The age count threshold (AGE_CNT_THRESH) register provides the aging counter threshold value used to determine the priority state of the USB controller's internal system interface. The threshold value is in units of platform clock cycles. This register should be written during system initialization or during normal system operation when the system bus interface is idle. It can be read at any time.

If the aging counter is less than the AGE_CNT_THRESH value, default (low) priority is chosen. If the aging counter is greater than or equal to the AGE_CNT_THRESH value >and USB_PRI_CTRL[PRI_LVL] = 1, an elevated priority is chosen.

The aging counter begins to count from zero when a bus access is requested. It increments every bus cycle until the bus transaction completes. At the completion of a bus transaction, the counter is synchronously reset to zero. If there are any outstanding bus requests, the aging counter will then begin counting immediately.

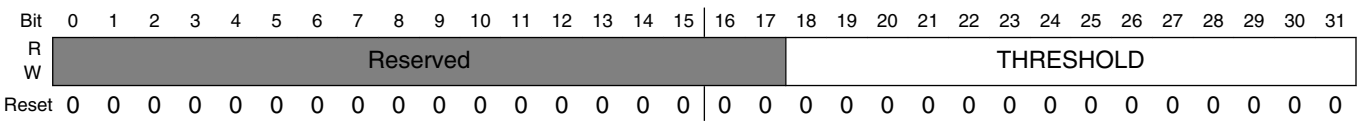
The AGE_CNT_THRESH is compared against the value of the aging counter during each clock cycle of the current transaction. If AGE_CNT_THRESH is equal to zero, an elevated priority is always chosen. If the aging counter is less than the AGE_CNT_THRESH value, default (low) priority is selected. If the aging counter is greater than or equal to the AGE_CNT_THRESH value and USB_PRI_CTRL[PRI_LVL] = 1, an elevated priority is chosen.

The setting of AGE_CNT_THRESH is highly dependent on both the mix of other controllers operating on the system bus as well as the kind of traffic moving through the USB controller. A recommended approach is first to try leaving the aging mechanism disabled and see if the USB meets performance requirements. If USB performance does not meet application requirements, try the following setting :

- Set AGE_CNT_THRESH to 80.

Raising AGE_CNT_THRESH benefits the other controllers on the system bus by reducing the frequency that this USB controller raises its priority to the arbiter.

Address: Base address + 408h offset



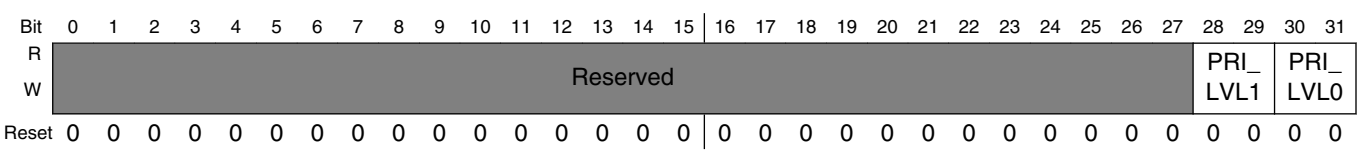
USBx_AGE_CNT_THRESH field descriptions

Field	Description
0–17 -	This field is reserved. Reserved, should be cleared
18–31 THRESHOLD	Aging counter threshold value.

16.3.34 Priority Control (USBx_PRI_CTRL)

This register uses big-endian byte ordering and is not defined in the EHCI specification. The priority control (PRI_CTRL) register sets the priority level for each of two priority states. The priority state is determined by the value programmed in the AGE_CNT_THRESH register and the number of platform cycles that a particular transaction takes to complete .

Address: Base address + 40Ch offset



USBx_PRI_CTRL field descriptions

Field	Description
0–27 -	This field is reserved. Reserved, should be cleared

Table continues on the next page...

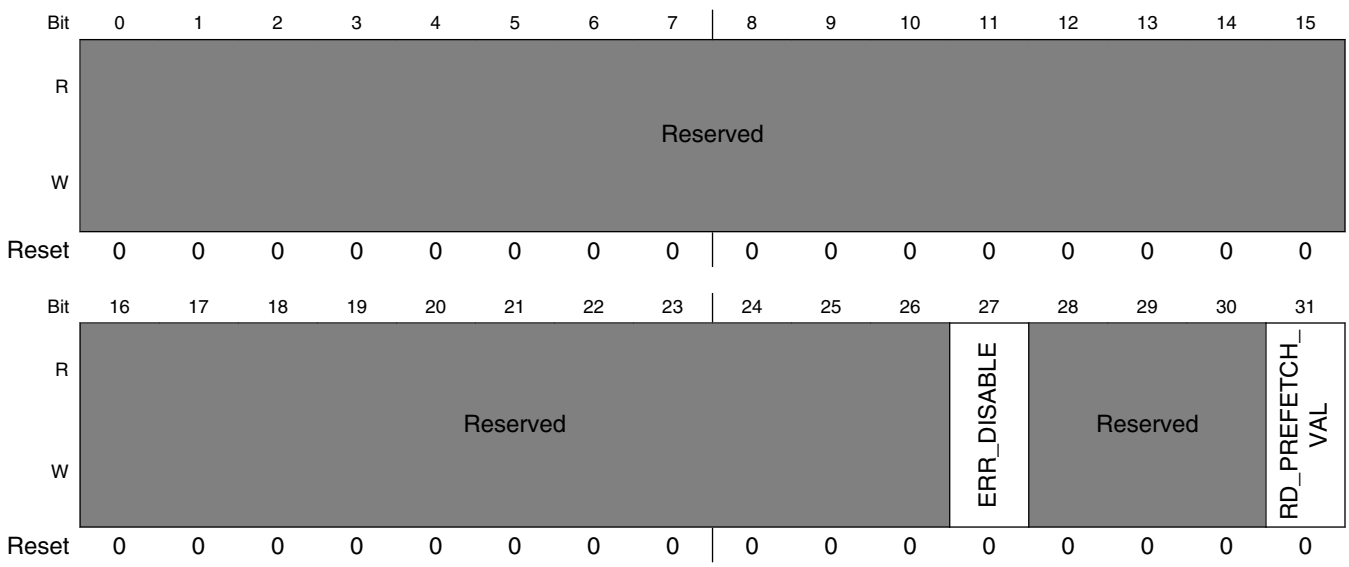
USBx_PRI_CTRL field descriptions (continued)

Field	Description
28–29 PRI_LVL1	Priority level for priority state 1. The highest priority is 2'h3 and the lowest priority is 2'b0.
30–31 PRI_LVL0	Priority level for priority state 0. The highest priority is 2'h3 and the lowest priority is 2'b0.

16.3.35 System Interface Control (USBx_SI_CTRL)

This register uses big-endian byte ordering and is not defined in the EHCI specification. The system interface control register (SI_CTRL) controls various functions pertaining to the internal system interface.

Address: Base address + 410h offset



USBx_SI_CTRL field descriptions

Field	Description
0–26 -	This field is reserved. Reserved, should be cleared
27 ERR_DISABLE	When this bit is set, it causes the controller to ignore system bus errors. If cleared the controller responds according to the values set in USBSTS[SEI] and USBINT[SEE]. 0 enable 1 disable
28–30 -	This field is reserved. Reserved, should be cleared

Table continues on the next page...

USBx_SI_CTRL field descriptions (continued)

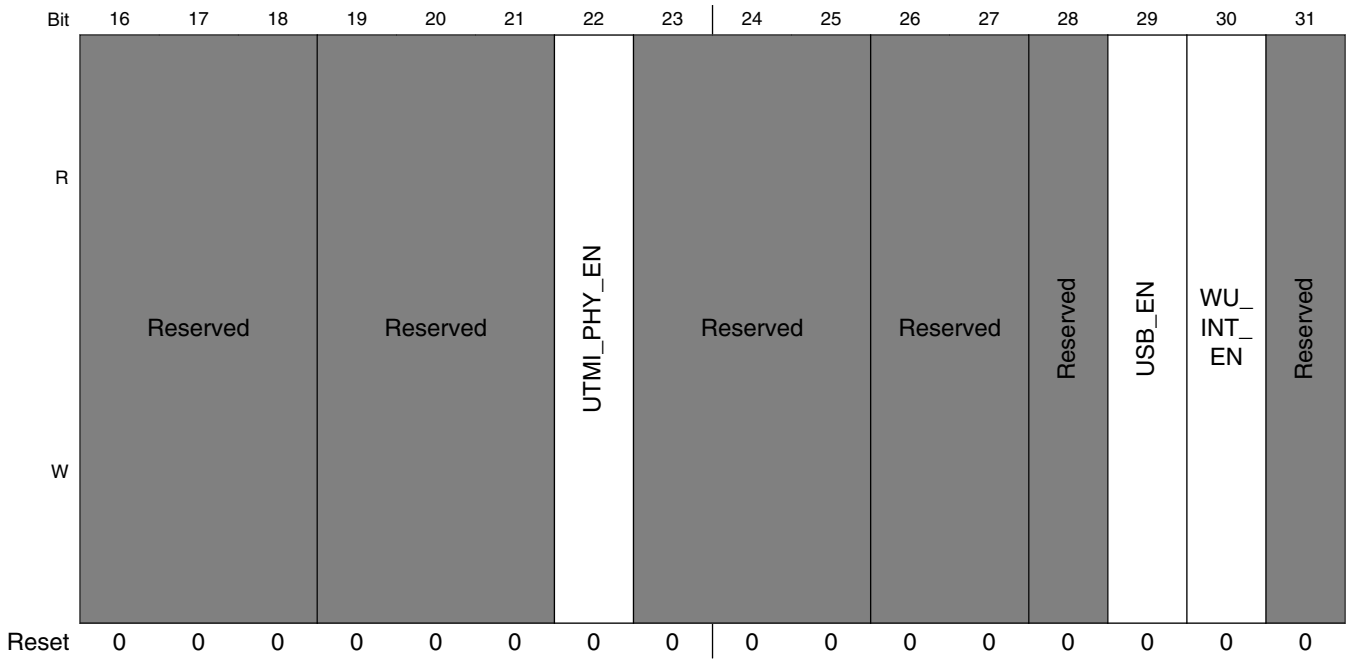
Field	Description
31 RD_ PREFETCH_VAL	Selects whether 32 bytes or 64 bytes are fetched during burst read transactions at the system interface. When this input is ZERO, 64 bytes are fetched, and when it is ONE, 32 bytes are fetched. **NOTE:** 32 byte fetch mode is not supported, this value must be set to 0. 0 64-byte fetch 1 32-byte fetch

16.3.36 Control (USB*x*_CONTROL)

This register uses big-endian byte ordering and is not defined in the EHCI specification. The USB general purpose (CONTROL) register contains the general-purpose IP control register outputs.

Address: Base address + 500h offset

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	Reserved														PHY_CLK_VALID	WU_INT
W															w1c	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



USBx_CONTROL field descriptions

Field	Description
0–13 -	This field is reserved.
14 PHY_CLK_ VALID	Indicates whether the PHY clock is valid (read only). When in UTMI mode, this bit reflects the value of the UTMI PHY Clk Valid signal. **NOTE:** Once the PHY is placed in low power suspend mode, software needs to poll for the PHY_CLK_VALID bit to be asserted in the USB_CONTROL register before making the configuration space transactions. Except waking up of PHY, no other configuration space transaction should be issued. 0 USB PHY clock is not valid 1 USB PHY clock is valid
15 WU_INT	Reflects the state of the wake up interrupt. The wake up interrupt signal is asserted when a wake-up event occurs while in a low-power suspend state. If WU_INT_EN is set, this WU_INT signal generates an interrupt to the system to indicate wake up servicing is required. WU_INT will remain set until the USB controller is exited from the low power by clearing the PORTSC[PHCD] bit. 0 Normal operation or Low Power mode waiting for wakeup event 1 Low power wakeup event has occurred
16–18 -	This field is reserved.
19–21 -	This field is reserved.
22 UTMI_PHY_EN	Enable the UTMI PHY. The UTMI PHY is reset when placed in the disable mode. 0 UTMI PHY disabled 1 UTMI PHY enabled
23–25 -	This field is reserved.

Table continues on the next page...

USBx_CONTROL field descriptions (continued)

Field	Description
26–27 -	This field is reserved.
28 -	This field is reserved.
29 USB_EN	UTMI mode: This bit is used to enable the USB interface. It must be set before setting RS bit in USB CMD register. 1 Enable 0 Disable ULPI mode: In safe mode, all USB interface signals are put into input mode or driven inactive, except for SUSPEND_STP, which is driven high. Also, the input signal DIR is forced to appear high to the controller. This prevents any start-up problems that otherwise could occur if the PHY and the controller take significantly different times to complete power-on reset. 1 Normal operation 0 Safe mode
30 WU_INT_EN	This bit is used to mask/unmask the system wakeup interrupt signal **NOTE:** PORTSC[PHCD] bit must be set for the system wakeup interrupt generation. 0 System wakeup interrupt disabled 1 System wakeup interrupt enabled
31 -	This field is reserved. Reserved

Field	Description
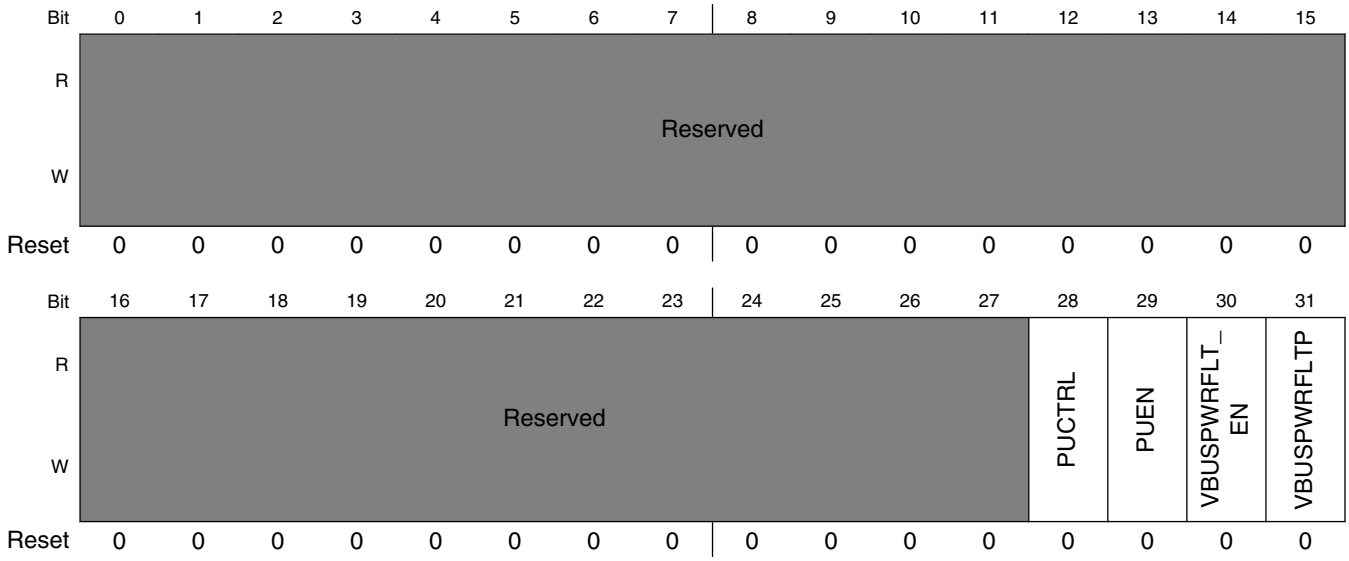
0–23 -	This field is reserved.
24–27 PUPDCTRL	Pullup/Pulldown Control 0x7 If this bit is set to high, the internal pulldown resistor value is increased by 50% from 9.2K to 13.8K. The internal pulldown is gated by the USBPnDRVVBUSCFG[PDEN] bit. 0x6 If this bit is set to high, the internal pullup resistor value is increased by 50% from 9.2K to 13.8K. The internal pullup is gated by the USBPnDRVVBUSCFG[PUEN] bit. 0x5 If this bit is set to high, the buffer drive low output strength is increased by 5% (fall time decreases by 5%). 0x4 If this bit is set to high, the buffer drive high output strength is increased by 5% (rise time decreases by 5%).
28 PDEN	DRVVBUS internal pulldown resistor enable. The pulldown enable mechanism is independent of DRVVBUS_EN.
29 PUEN	DRVVBUS internal pullup resistor enable. The pullup enable mechanism is independent of DRVVBUS_EN.
30 DRVVBUS_EN	Enable Drvvbus Pad. This bit controls the output buffer on DRVVBUS pad. 0 Buffer output is tristated 1 Buffer output is driven according to the DRVVBUS polarity bit (DRVVBUSP).
31 DRVVBUSP	DRVVBUS Polarity 0 Active high (DRVVBUS signal from USB controller will be passed on to DRVVBUS pad) 1 Active low (DRVVBUS signal from USB controller will be inverted and then passed on to DRVVBUS pad)

16.4.4 PHY PWRFLT configuration register (USB_PHY_PWRFLTCFG_PHY*n*)

This register controls the USBPnVBUSPWRFLT IO pins.

Address: 21_4000h base + Ch offset + (124d × i), where i=0d to 1d

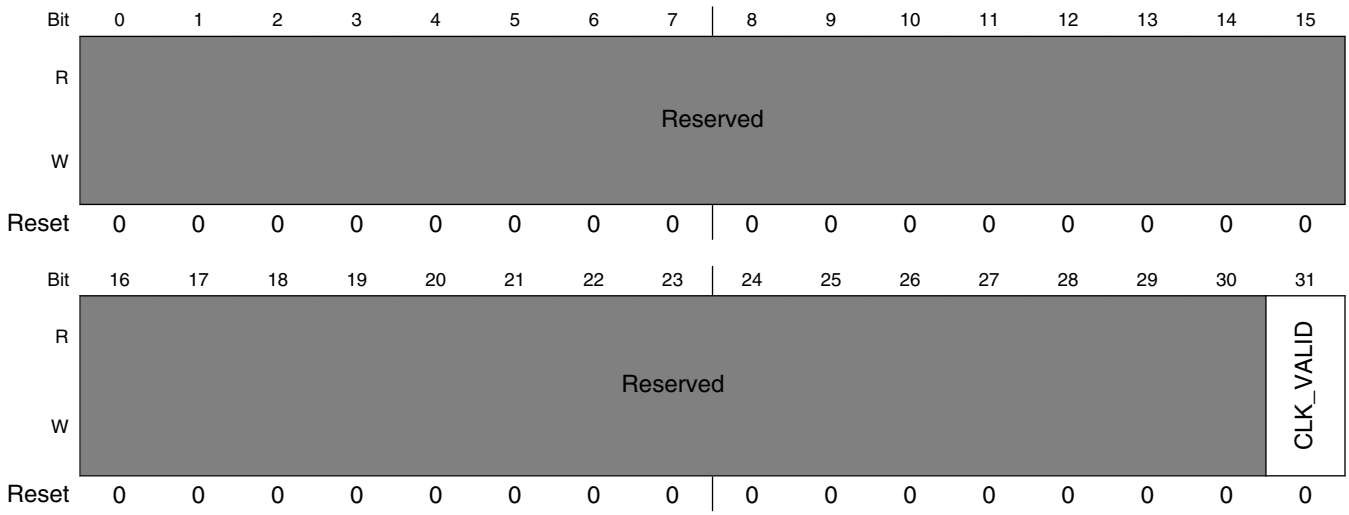


USB_PHY_PWRFLTCFG_PHY*n* field descriptions

Field	Description
0–27 -	This field is reserved.
28 PUCTRL	Pullup Control. If this bit is set, the internal resistor pullup value is increased by 50% from 9.2K to 13.8K. The internal pullup is gated by USBPnPWRFLTCFG[PUEN] bit.
29 PUEN	VBUSPWRFLT internal resistor pullup enable
30 VBUSPWRFLT_EN	VBUSPWRFLT receiver output enable 0 VBUSPWRFLT receiver output to USB controller is driven to de-asserted state (0/1 for active high/low polarity set through VBUSPWRFLTP bit 0/1). 1 VBUSPWRFLT receiver output to USB controller follows VBUSPWRFLT (receiver input).
31 VBUSPWRFLTP	VBUS power fault polarity 0 Active high (PWRFLT signal from pad will be passed on to USB controller) 1 Active low (PWRFLT signal from pad will be inverted and then passed on to USB controller)

16.4.5 PHY status register (USB_PHY_STS_PHY*n*)

Address: 21_4000h base + 10h offset + (124d × i), where i=0d to 1d



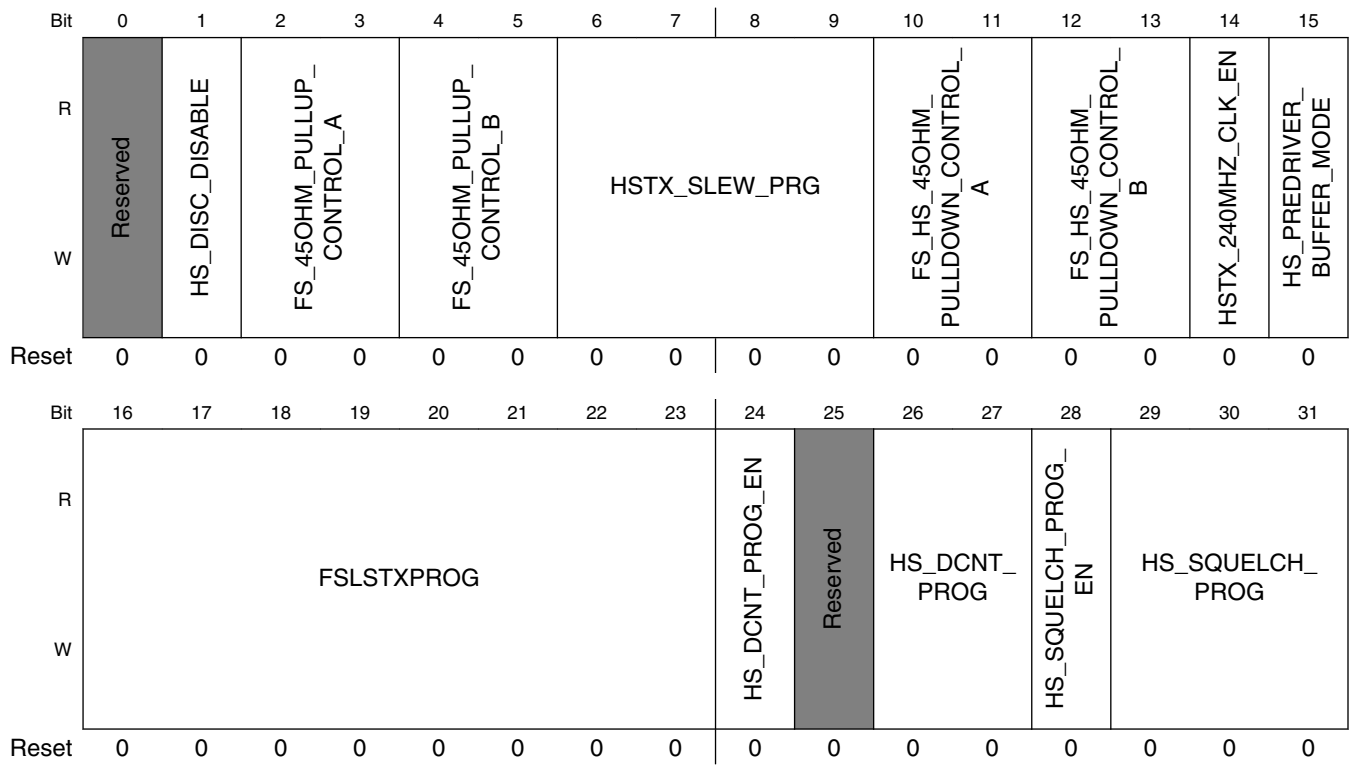
USB_PHY_STS_PHY*n* field descriptions

Field	Description
0–30 -	This field is reserved.
31 CLK_VALID	USBPHY Clock Valid 0 Clock not valid 1 Clock valid, indicates the PLL is locked and the clock is available

16.4.6 PHY transceiver program register (USB_PHY_XCVRPRG_PHY*n*)

This register is used to program the transmitter characteristics for high speed, full speed, and low speed. It can also program the detection thresholds for high speed squelch and disconnect receiver.

Address: 21_4000h base + 40h offset + (124d × i), where i=0d to 1d



USB_PHY_XCVRPRG_PHY*n* field descriptions

Field	Description
0 -	This field is reserved.
1 HS_DISC_DISABLE	When this bit is set to high, output of high speed disconnect detector is disabled. This bit is used for debug purpose or in host applications, such as on board HUB/flash drive, where disconnect sampling is not needed.
2–3 FS_45OHM_PULLUP_CONTROL_A	This bit impacts the 45ohm pullup impedance of full speed/high speed driver. This bit can be used to fix any full speed eye or impedance issues. The effect of this bit gets multiplied with impedance set by the USBPnXCVRPRG[FS_45ohm_pullup_control_B] bit. 00 Default resistance 01 Decrease resistance by 12.5%

Table continues on the next page...

USB_PHY_XCVRPRG_PHY*n* field descriptions (continued)

Field	Description
	10 Increase resistance by 12.5% 11 Increase resistance by 25%
4–5 FS_45OHM_ PULLUP_ CONTROL_B	This bit impacts the 45ohm pullup impedance of full speed/high speed driver. This bit can be used to fix any full speed eye or impedance issues. The effect of this bit gets multiplied with impedance set by the USBPnXCVRPRG[FS_45ohm_pullup_control_A] bit. 00 Default resistance 01 Decrease resistance by 13.7% 10-11 Increase resistance by 17.6%
6–9 HSTX_SLEW_ PRG	This bit alters the slew rate of internal predriver of high speed transmitter. The external observable slew characteristic of high speed transmitter may vary differently; however direction of change should be similar. This bit can be used to adjust HS eye diagram rise/fall issues. 25 This bit must be high during HS BIST test. This bit enables the HSTX bias current. 24 Increase slew rate of HSTX internal predriver output by 25% 23 Decrease slew rate of HSTX internal predriver output by 50% 22 Increase slew rate of HSTX internal predriver output by 25%
10–11 FS_HS_45OHM_ PULLDOWN_ CONTROL_A	This bit impacts the 45ohm pulldown impedance of full speed/high speed driver. This bit can be used to fix any full/high speed eye or impedance issues. The effect of this bit gets multiplied with impedance set by the USBPnXCVRPRG[FS_HS_45ohm_pulldown_control_B] bit. 00 Default resistance 01 Decrease resistance by 12.5% 10 Increase resistance by 12.5% 11 Increase resistance by 25%
12–13 FS_HS_45OHM_ PULLDOWN_ CONTROL_B	This bit impacts the 45ohm pulldown impedance of full speed/high speed driver. This bit can be used to fix any full/high speed eye or impedance issues. The effect of this bit gets multiplied with impedance set by the USBPnXCVRPRG[FS_HS_45ohm_pulldown_control_A] bit. 00 Default resistance 01 Decrease resistance by 9% 10-11 Increase resistance by 10%
14 HSTX_240MHZ_ CLK_EN	Drive 240 MHz Clock signalling on UDP/UDM Lines
15 HS_ PREDRIVER_ BUFFER_MODE	When this bit is set to high, the internal HSTX predriver operates in buffer mode with no current controlled slew rate. This is expected to result in fast rise/fall time on HSTX output. Also, the HSTX_SLEW_PRG bit has no effect when this bit is set to high.
16–23 FSLSTXPROG	Bit- Function 0x15 Increases both the rise and fall time at DP/DM by approx 25% 0x14 Decreases both the rise and fall time at DP/DM by approx 25% 0x13 Delays the falling edge of DP/DM by approx 150 psec. This can be used to adjust DP/DM crossover characteristics without impacting rise fall time. 0x12 Delays the rising edge of DP/DM by approx 150 psec. This can be used to adjust DP/DM crossover characteristics without impacting rise fall time. 0x11 Increases the fall time of DP/DM by approx 25% 0x10 Decreases the fall time of DP/DM by approx 20%

Table continues on the next page...

USB_PHY_XCVRPRG_PHY*n* field descriptions (continued)

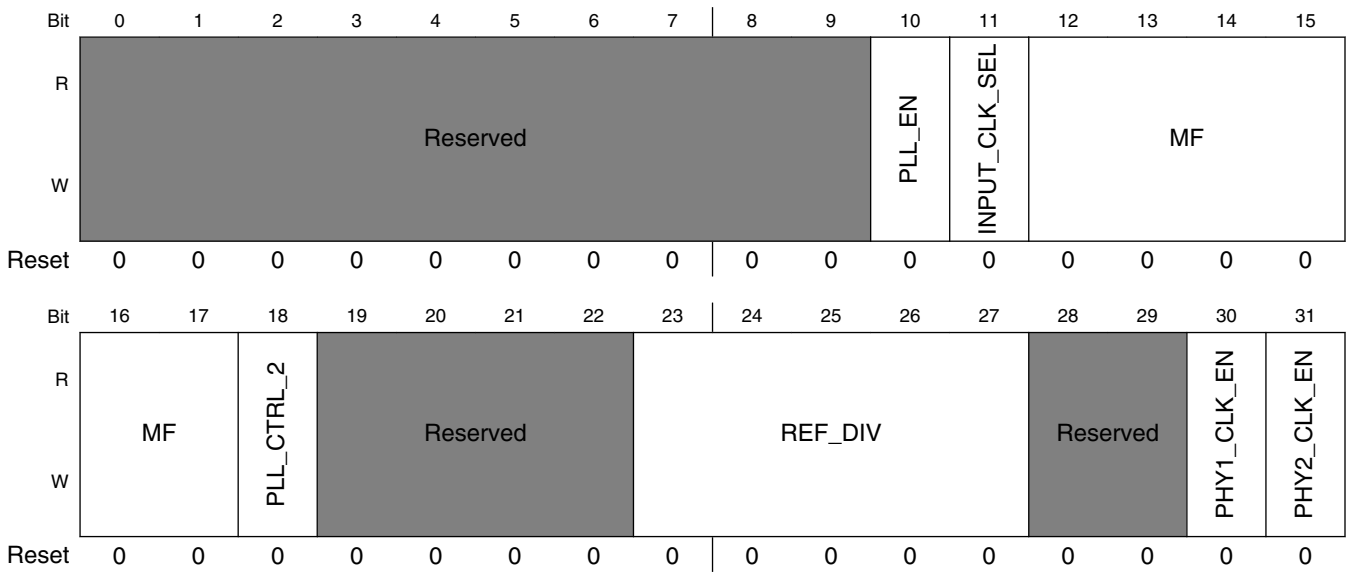
0–1 -	This field is reserved.
2–16 PLL_CTRL_0	PLL Control 0. Internal control bit for PLL.
17–31 PLL_CTRL_1	PLL Control 1. Internal control bit for PLL.

16.4.9 PHY PLL program register 2 (USB_PHY_PLLPRG2)

This register is used to program USBPHY PLL for various input clock frequency ranges.

Address: 21_4000h base + 64h offset = 21_4064h



USB_PHY_PLLPRG2 field descriptions

Field	Description
0–9 -	This field is reserved.
10 PLL_EN	Enable PLL block of USBPHY. Enable for PLL must be done after programming values are applied. This requires two writes to USB registers. 0 PLL Disabled, All clocks are off. 1 PLL Enabled
11 INPUT_CLK_SEL	Input clock source select for PLL 0 Reference clock from chip input pad is selected (typically 24 MHz input clock from pad) 1 Internal clock from chip is selected
12–17 MF	Multiplication factor for PLL internal reference clock
18 PLL_CTRL_2	PLL Control 2. Internal control bit for PLL.
19–22 -	This field is reserved.
23–27 REF_DIV	PLL input reference clock divider. The bit supplies usbphy with a input clock of upto 200 Mhz which can be divided down to pll input range of 20 to 40 Mhz.
28–29 -	This field is reserved.

Field	Description
30 PHY1_CLK_EN	Enable clock for PHY1
31 PHY2_CLK_EN	Enable clock for PHY2

16.5 Functional description

The USB DR module can be broken down into functional sub-blocks, which are described below.

16.5.1 System interface

The system interface block contains all the control and status registers that allow a processor to interface to the USB DR module.

These registers allow the processor to control the configuration of the module, ascertain the capabilities of the module, and control the module's operation. It also has registers to control snoopability and priority of the DMA interface.

16.5.2 DMA engine

The module contains a local DMA engine.

The DMA engine interfaces internally to the system memory bus. It is responsible for moving all of the data to be transferred over the USB between the module and buffers in system memory.

Like the system interface block, the DMA engine block uses a simple synchronous bus signaling protocol that eases connections to a number of different standard buses.

The DMA controller must access both control information and packet data from system memory. The control information is contained in link list-based queue structures. The DMA controller has state machines that are able to parse data structures defined in the EHCI specification. In host mode, the data structures are EHCI compliant and represent queues of transfers to be performed by the host controller, including the split-transaction requests that allow an EHCI controller to direct packets to FS and LS devices. In device

mode, the data structures are designed to be similar to those in the EHCI specification and are used to allow device responses to be queued for each of the active pipes in the device.

16.5.3 FIFO RAM controller

The FIFO RAM controller is used for context information and to control FIFOs between the protocol engine and the DMA controller.

These FIFOs decouple the system processor/memory bus requests from the extremely tight timing required by USB.

The use of the FIFO buffers differs between host and device mode operation. In host mode, a single data channel is maintained in each direction through the buffer memory. In device mode, multiple FIFO channels are maintained for each of the active Endpoints in the system.

In host mode, the USB DR module uses a 512-byte Tx buffer and a 512-byte Rx buffer. Device operation uses a single 512-byte Rx buffer and a 512-byte Tx buffer for each Endpoint. The 512-byte buffers allow the module to buffer a complete HS bulk packet.

16.5.4 PHY interface

The UTMI interface connects internally to an on-chip PHY. The USB DR module interfaces to any UTMI-compatible PHY.

The primary function of the port controller block is to isolate the rest of the module from the transceiver, and to move all of the transceiver signaling into the primary clock domain of the module.

This allows the module to run synchronously with the system processor and its associated resources.

Due to pincount limitations the module only supports certain combinations of PHY interfaces and USB functionality. Refer to the table below for more information.

Table 16-3. Supported PHY interfaces

PHY	Function
UTMI	Host/Device

16.6 Host data structures

This section defines the interface data structures used to communicate control, status, and data between HCD (software) and the Enhanced Host Controller (hardware).

The data structure definitions in this section support a 32-bit memory buffer address space. The interface consists of a periodic schedule, periodic frame list, asynchronous schedule, isochronous transaction descriptors, split-transaction isochronous transfer descriptors, queue heads, and queue element transfer descriptors.

The periodic frame list is the root of all periodic (isochronous and interrupt transfer type) support for the host controller interface. The asynchronous list is the root for all the bulk and control transfer type support. Isochronous data streams are managed using isochronous transaction descriptors. Isochronous split-transaction data streams are managed with split-transaction isochronous transfer descriptors. All interrupt, control, and bulk data streams are managed with queue heads and queue element transfer descriptors. These data structures are optimized to reduce the total memory footprint of the schedule and to reduce (on average) the number of memory accesses needed to execute a USB transaction.

NOTE

Software must ensure that no interface data structure reachable by the EHCI host controller spans a 4K-page boundary.

The data structures defined in this section are (from the host controller's perspective) a mix of read-only and read/writable fields. The host controller must preserve the read-only fields on all data structure writes.

16.6.1 Periodic frame list

The figure below shows the organization of the periodic schedule. This schedule is for all periodic transfers (isochronous and interrupt).

The periodic schedule is referenced from the operational registers space using the PERIODICLISTBASE address register and the FRINDEX register. The periodic schedule is based on an array of pointers called the periodic frame list. The PERIODICLISTBASE address register is combined with the FRINDEX register to produce a memory pointer into the frame list. The periodic frame list implements a sliding window of work over time.

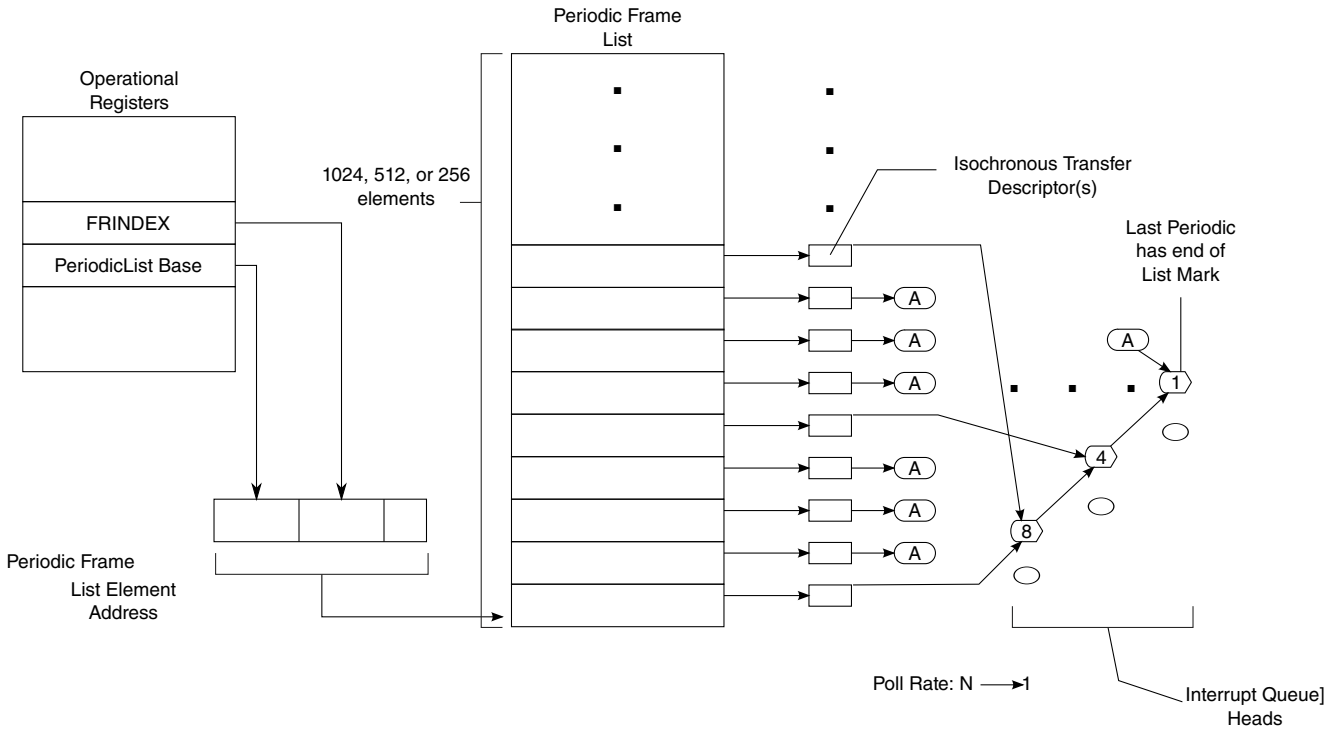

Figure 16-2. Periodic schedule organization

The periodic frame list is a 4K-page aligned array of Frame List Link pointers. The length of the frame list is programmable. The programmability of the periodic frame list is exported to system software through the HCCPARAMS register. The length can be selected by system software as one of 8, 16, 32, 64, 128, 256, 512 or 1024 elements. Programming the size (that is, the number of elements) is accomplished by system software writing the appropriate value into Frame List Size field in the USBCMD register.

Frame list link pointers direct the host controller to the first work item in the frame's periodic schedule for the current microframe. The link pointers are aligned on DWord boundaries within the frame list. The table below shows the format for the frame list link pointer.

Table 16-4. Frame list link pointer format

31																										5	4	3	2	1	0
Frame List Link Pointer																											00		Typ			T

Frame list link pointers always reference memory objects that are 32-byte aligned. The referenced object may be an isochronous transfer descriptor for high-speed devices, a split-transaction isochronous transfer descriptor (for full-speed isochronous Endpoints),

or a queue head (used to support high-, full- and low-speed interrupt). System software should not place non-periodic schedule items into the periodic schedule. The least-significant bits in a frame list pointer are used to key the host controller in as to the type of object the pointer is referencing.

The least-significant bit is the T bit (bit 0). When this bit is set, the host controller never uses the value of the frame list pointer as a physical memory pointer. The Typ field indicates the exact type of data structure being referenced by this pointer. The value encodings for the Typ field are given in the table below.

Table 16-5. Typ field encodings

Typ	Description
00	Isochronous transfer descriptor
01	Queue head
10	Split transaction isochronous transfer descriptor
11	Frame span traversal node

16.6.2 Asynchronous list queue head pointer

The asynchronous transfer list (based at the ASYNCLISTADDR register) is where all the control and bulk transfers are managed.

Host controllers use this list only when it reaches the end of the periodic list, the periodic list is disabled, or the periodic list is empty. The figure below shows the asynchronous schedule organization.

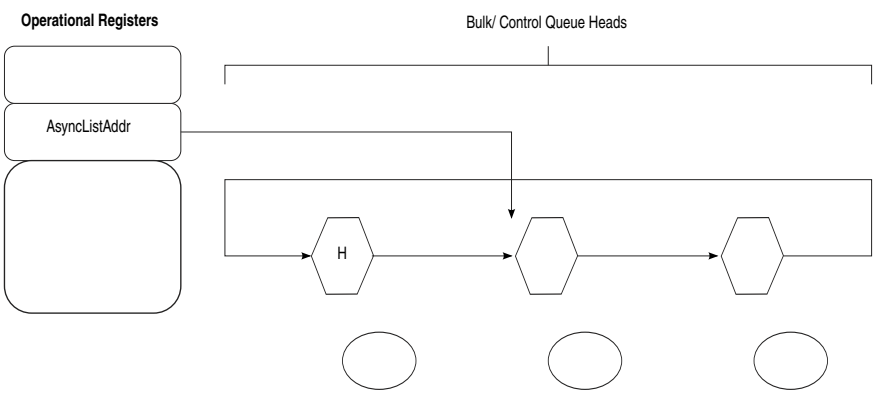

Figure 16-3. Asynchronous schedule organization

The asynchronous list is a simple circular list of queue heads. The ASYNCLISTADDR register is simply a pointer to the next queue head. This implements a pure round-robin service for all queue heads linked into the asynchronous list.

16.6.3 Isochronous (high-speed) transfer descriptor (iTD)

The table below shows the format of an isochronous transfer descriptor.

This structure is used only for high-speed isochronous Endpoints.

All other transfer types should use queue structures. Isochronous TDs must be aligned on a 32-byte boundary.

Table 16-6. Isochronous transaction descriptor (iTD)

1. Host controller read/write; all others read-only.
2. These fields may be modified by the host controller if the I/O field indicates an OUT.

16.6.3.1 Next link pointer-iTD

The first DWord of an iTD is a pointer to the next schedule data structure, as shown in the table below.

Table 16-7. Next schedule element pointer

Bits	Name	Description
31-5	Link Pointer	Correspond to memory address signals [31:5], respectively. This field points to another isochronous transaction descriptor (iTD/siTD) or queue head (QH).
4-3	-	Reserved, should be cleared. These bits are reserved and their value has no effect on operation. Software should initialize this field to zero.
2-1	Typ	Indicates to the host controller whether the item referenced is an iTD, siTD or a QH. This allows the host controller to perform the proper type of processing on the item after it is fetched. Value encodings are: 00 iTD (isochronous transfer descriptor) 01 QH (queue head) 10 siTD (split transaction isochronous transfer descriptor) 11 FSTN (frame span traversal node)
0	T	Terminate 1 Link Pointer field is not valid. 0 Link Pointer field is valid.

16.6.3.2 iTD transaction status and control list

DWords 1-8 constitute eight slots of transaction control and status.

Each transaction description includes the following:

- Status results field
- Transaction length (bytes to send for OUT transactions and bytes received for IN transactions).
- Buffer offset. The PG and Transaction *n* Offset fields are used with the buffer pointer list to construct the starting buffer address for the transaction.

The host controller uses the information in each transaction description, plus the Endpoint information contained in the first three DWords of the buffer page pointer list, to execute a transaction on the USB.

The table below shows the iTD transaction status and control fields.

Table 16-8. iTD transaction status and control

Bits	Name	Description
31-28	Status	Records the status of the transaction executed by the host controller for this slot. This field is a bit vector with the following encoding: 31 Active. Set by software to enable the execution of an isochronous transaction by the host controller. When the transaction associated with this descriptor is completed, the host controller clears this bit indicating that a transaction for this element should not be executed when it is next encountered in the schedule. 30 Data buffer error. Set by the host controller during status update to indicate that the host controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (underrun). If an overrun condition occurs, no action is necessary. 29 Babble detected. Set by the host controller during status update when" babble" is detected during the transaction generated by this descriptor. 28 Transaction error (XactErr). Set by the host controller during status update in the case where the host did not receive a valid response from the device (Time-out, CRC, Bad PID, and so on). This bit may only be set for isochronous IN transactions.
27-16	Transaction *n* Length	For an OUT, this field is the number of data bytes the host controller will send during the transaction. The host controller is not required to update this field to reflect the actual number of bytes transferred during the transfer. For an IN, the initial value of the Endpoint to deliver. During the status update, the host controller writes back the field is the number of bytes the host expects the number of bytes successfully received. The value in this register is the actual byte count (for example, 0 zero length data, 1 one byte, 2 two bytes, and so on). The maximum value this field may contain is 0xC00 (3072).
15	ioc	Interrupt on complete. If this bit is set, it specifies that when this transaction completes, the host controller should issue an interrupt at the next interrupt threshold.
14-12	PG	These bits are set by software to indicate which of the buffer page pointers the offset field in this slot should be concatenated to produce the starting memory address for this transaction. The valid range of values for this field is 0 to 6.
11-0	Transaction *n* Offset	This field is a value that is an offset, expressed in bytes, from the beginning of a buffer. This field is concatenated onto the buffer page pointer indicated in the adjacent PG field to produce the starting buffer address for this transaction.

16.6.3.3 iTD buffer page pointer list (plus)

DWords 9-15 of an isochronous transaction descriptor are nominally page pointers (4K aligned) to the data buffer for this transfer descriptor.

This data structure requires the associated data buffer to be contiguous (relative to virtual memory), but allows the physical memory pages to be non-contiguous. Seven page pointers are provided to support the expression of eight isochronous transfers. The seven pointers allow for 3 (transactions) x 1024 (maximum packet size) x 8 (transaction records) = 24 576 bytes to be moved with this data structure, regardless of the alignment offset of the first page.

Since each pointer is a 4 K-aligned page pointer, the least-significant 12 bits in several of the page pointers are used for other purposes.

The following tables describe buffer pointer page *n*.

Table 16-9. Buffer pointer page 0 (Plus)

Bits	Name	Description
31-12	Buffer pointer (Page 0)	A 4K-aligned pointer to physical memory. Corresponds to memory address bits 31-12.
11-8	EndPt	Selects the particular Endpoint number on the device serving as the data source or sink.
7	-	Reserved, should be cleared. Reserved for future use and should be initialized by software to zero.
6-0	Device Address	This field selects the specific device serving as the data source or sink.

Table 16-10. iTD buffer pointer page 1 (plus)

Bits	Name	Description
31-12	Buffer Pointer (Page 1)	This is a 4K aligned pointer to physical memory. Corresponds to memory address bits 31-12.
11	I/O	Direction (I/O). This field encodes whether the high-speed transaction should use an IN or OUT PID. 0 OUT 1 IN
10-0	Maximum Packet Size	This directly corresponds to the maximum packet size of the associated Endpoint (wMaxPacketSize). This field is used for high-bandwidth Endpoints where more than one transaction is issued per transaction description (for example, per microframe). This field is used with the Multi field to support high-bandwidth pipes. This field is also used for all IN transfers to detect packet babble. Software should not set a value larger than 1024 (0x400). Any value larger yields undefined results.

Table 16-11. Buffer pointer page 2 (plus)

Bits	Name	Description
31-12	Buffer pointer (page 2)	This is a 4K-aligned pointer to physical memory. Corresponds to memory address bits 31-12.
11-2	-	Reserved, should be cleared. This bit reserved for future use and should be cleared.
1-0	Mult	Indicates to the host controller the number of transactions that should be executed per transaction description (for example, per microframe). 00 Reserved, should be cleared. A zero in this field yields undefined results. 01 One transaction to be issued for this Endpoint per microframe 10 Two transactions to be issued for this Endpoint per microframe 11 Three transactions to be issued for this Endpoint per microframe

Table 16-12. Buffer pointer page 3-6

Bits	Name	Description
31-12	Buffer Pointer	This is a 4K aligned pointer to physical memory. Corresponds to memory address bits 31-12.
11-0	-	Reserved, should be cleared. These bits reserved for future use and should be cleared.

16.6.4 Split transaction isochronous transfer descriptor (siTD)

All full-speed isochronous transfers through the internal transaction translator are managed using the siTD data structure.

This data structure satisfies the operational requirements for managing the split transaction protocol.

The table below shows the split-transaction isochronous transfer descriptor (siTD).

Table 16-13. Split-transaction isochronous transaction descriptor (siTD)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	offset

1. Host controller read/write; all others read-only.

16.6.4.1 Next link pointer-siTD

DWord0 of a siTD is a pointer to the next schedule data structure.

The table below describes the next link pointer fields.

Table 16-14. Next link pointer

Bits	Name	Description
31-5	Next Link Pointer	This field contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4-3	-	Reserved, should be cleared. These bits must be written as zeros.
2-1	Typ	Indicates to the host controller whether the item referenced is an iTD/siTD or a QH. This allows the host controller to perform the proper type of processing on the item after it is fetched. Value encodings are: 00 iTD (isochronous transfer descriptor) 01 QH (queue head) 10 siTD (split transaction isochronous transfer descriptor 11 FSTN (frame span traversal node)
0	T	Terminate.

Table 16-14. Next link pointer

Bits	Name	Description
		0 Link pointer is valid. 1 Link pointer field is not valid.

16.6.4.2 siTD Endpoint capabilities/characteristics

DWords 1 and 2 specify static information about the full-speed Endpoint, the addressing of the parent Companion Controller, and microframe scheduling control.

The table below describes the Endpoint and transaction translator characteristics.

Table 16-15. Endpoint and transaction translator characteristics

Bits	Name	Description
31	I/O	Direction (I/O). This field encodes whether the full-speed transaction should be an IN or OUT. 0 OUT 1 IN
30-24	Port Number	This field is the port number of the recipient transaction translator.
23	-	Reserved, should be cleared. Bit reserved and should be cleared.
22-16	Hub Address	This field holds the device address of the companion controllers' hub.
15-12	-	Reserved, should be cleared. Field reserved and should be cleared.
11-8	EndPt	Endpoint Number. Selects the particular Endpoint number on the device serving as the data source or sink.
7	-	Reserved, should be cleared. Bit is reserved for future use. It should be cleared.
6-0	Device Address	Selects the specific device serving as the data source or sink.

The table below describes the microframe schedule control.

Table 16-16. Microframe schedule control

Bits	Name	Description
31-16	-	Reserved, should be cleared. This field reserved for future use. It should be cleared.
15-8	µFrame C-mask	Split completion mask. This field (along with the Active and SplitX- state fields in the status byte) is used to determine during which microframes the host controller should execute complete-split transactions. When the criteria for using this field is met, an all-zeros value has undefined behavior. The host controller uses the value of the three low-order bits of the FRINDEX register to index into this bit field. If the FRINDEX register value indexes to a position where the µFrame C-Mask field is a one, this siTD is a candidate for transaction execution. There may be more than one bit in this mask set.
7-0	µFrame S-mask	Split start mask. This field (along with the Active and SplitX-state fields in the Status byte) is used to determine during which microframes the host controller should execute start-split transactions. The host controller uses the value of the three low-order bits of the FRINDEX register to index into

Table 16-16. Microframe schedule control

Bits	Name	Description
		this bit field. If the FRINDEX register value indexes to a position where the µFrame S-mask field is a one, then this siTD is a candidate for transaction execution. An all zeros value in this field, in combination with existing periodic frame list has undefined results.

16.6.4.3 siTD transfer state

DWords 3-6 manage the state of the transfer, as described in the table below.

Table 16-17. siTD transfer status and control

Bits	Name	Description	
31	ioc	Interrupt on complete 0 Do not interrupt when transaction is complete. 1 Do interrupt when transaction is complete. When the host controller determines that the split transaction has completed it will assert a hardware interrupt at the next interrupt threshold.	
30	P	Page select. Indicates which data page pointer should be concatenated with the CurrentOffset field to construct a data buffer pointer 0 Selects Page 0 pointer 1 Selects Page 1 pointer The host controller is not required to write this field back when the siTD is retired (Active bit transitioned from a one to a zero).	
29-26	-	Reserved, should be cleared. This field reserved for future use and should be cleared.	
25-16	Total Bytes to Transfer	This field is initialized by software to the total number of bytes expected in this transfer. Maximum value is 1023 (3FFh)	
15-8	µFrame C-prog-mask	Split complete progress mask. This field is used by the host controller to record which split-completes have been executed.	
7-0	Status	This field records the status of the transaction executed by the host controller for this slot. This field is a bit vector with the following encoding:	
		Status Bits	**Definition**
		7	Active. Set by software to enable the execution of an isochronous split transaction by the host controller.
		6	ERR. Set by the host controller when an ERR response is received from the companion controller.
		5	Data buffer error. Set by the host controller during status update to indicate that the host controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). In the case of an under run, the host controller will transmit an incorrect CRC (thus invalidating the data at the Endpoint). If an overrun condition occurs, no action is necessary.
		4	Babble detected. Set by the host controller during status update when" babble" is detected during the transaction generated by this descriptor.

Table continues on the next page...

Table 16-17. siTD transfer status and control (continued)

Bits	Name	Description	
		3	Transaction error (XactErr). Set by the host controller during status update in the case where the host did not receive a valid response from the device (Time-out, CRC, Bad PID, and so on). This bit will only be set for IN transactions.
		2	Missed microframe. The host controller detected that a host-induced hold- off caused the host controller to miss a required complete-split transaction.
		1	Split transaction state (SplitXstate). The bit encodings are: 0 Do start split. This value directs the host controller to issue a Start split transaction to the Endpoint when a match is encountered in the S-mask. 1 Do complete split. This value directs the host controller to issue a Complete split transaction to the Endpoint when a match is encountered in the C-mask.
		0	Reserved, should be cleared. Bit reserved for future use and should be cleared.

16.6.4.4 siTD buffer pointer list (plus)

DWords 4 and 5 are the data buffer page pointers for the transfer.

This structure supports one physical page cross. The most-significant 20 bits of each DWord in this section are the 4K (page) aligned buffer pointers. The least-significant 12 bits of each DWord are used as additional transfer state.

The table below describes the siTD buffer pointer page 0.

Table 16-18. siTD buffer pointer page 0 (plus)

Bits	Name	Description
31-12	Buffer Pointer (Page 0)	Bits 31-12 are 4K page-aligned, physical memory addresses. These bits correspond to physical address bits 31-12 respectively. The field P specifies the current active pointer
11-0	Current Offset	The 12 least-significant bits of the Page 0 pointer is the current byte offset for the current page pointer (as selected with the page indicator bit (P field)). The host controller is not required to write this field back when the siTD is retired (Active bit transitioned from a one to a zero).

The table below describes the siTD buffer pointer page 1.

Table 16-19. siTD buffer pointer page 1 (plus)

Bits	Name	Description
31-12	Buffer Pointer (Page 1)	Bits 31-12 are 4K page-aligned, physical memory addresses. These bits correspond to physical address bits 31-12 respectively. The field P specifies the current active pointer
11-5	-	Reserved, should be cleared.
4-3	TP	Transaction position. This field is used with T-count to determine whether to send all, first, middle, or last with each outbound transaction payload. System software must initialize this field with the appropriate starting value. The host controller must correctly manage this state during the lifetime of the transfer. The bit encodings are:

Table continues on the next page...

Table 16-19. siTD buffer pointer page 1 (plus) (continued)

Bits	Name	Description
		00 All. The entire full-speed transaction data payload is in this transaction (that is, less than or equal to 188 bytes). 01 Begin. This is the first data payload for a full-speed transaction that is greater than 188 bytes. 10 Mid. This is the middle payload for a full-speed OUT transaction that is larger than 188 bytes. 11 End. This is the last payload for a full-speed OUT transaction that was larger than 188 bytes.
2-0	T-Count	Transaction count. Software initializes this field with the number of OUT start-splits this transfer requires. Any value larger than 6 is undefined.

16.6.4.5 siTD back link pointer

DWord 6 of a siTD is simply another schedule link pointer.

This pointer is always zero, or references a siTD. This pointer cannot reference any other schedule data structure.

The table below describes the siTD back link pointer.

Table 16-20. siTD back link pointer

Bits	Name	Description
31-5	Back Pointer	A physical memory pointer to an siTD
4-1	-	Reserved, should be cleared. This field is reserved for future use. It should be cleared.
0	T	Terminate 0 siTD Back Pointer field is valid 1 siTD Back Pointer field is not valid

16.6.5 Queue element transfer descriptor (qTD)

This data structure is only used with a queue head.

This data structure is used for one or more USB transactions. This data structure is used to transfer up to 20,480 (5 x 4096) bytes. The structure contains two structure pointers used for queue advancement, a DWord of transfer state, and a five-element array of data buffer pointers. This structure is 32 bytes (or one 32-byte cache line). This data structure must be physically contiguous.

The buffer associated with this transfer must be virtually contiguous. The buffer may start on any byte boundary. A separate buffer pointer list element must be used for each physical page in the buffer, regardless of whether the buffer is physically contiguous.

Host controller updates (host controller writes) to stand-alone qTDs only occur during transfer retirement. References in the following bit field definitions of updates to the qTD are to the qTD portion of a queue head.

The table below shows the queue element transfer descriptors.

Table 16-21. Queue element transfer descriptor (qTD)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	offset

1. Host controller read/write; all others read-only.

Queue element transfer descriptors must be aligned on 32-byte boundaries.

16.6.5.1 Next qTD pointer

The first DWord of an element transfer descriptor is a pointer to another transfer element descriptor.

The table below describes the qTD next element transfer pointer.

Table 16-22. qTD next element transfer pointer (DWord 0)

Bits	Name	Description
31-5	Next qTD Pointer	This field contains the physical memory address of the next qTD to be processed and corresponds to memory address signals [31:5], respectively.
4-1	-	Reserved, should be cleared. These bits are reserved and their value has no effect on operation.
0	T	Terminate. Indicates to the host controller that there are no more valid entries in the queue. 0 Pointer is valid (points to a valid transfer element descriptor) 1 Pointer is invalid

16.6.5.2 Alternate next qTD pointer

The second DWord of a queue element transfer descriptor is used to support hardware-only advance of the data stream to the next client buffer on short packet.

To be more explicit the host controller always uses this pointer when the current qTD is retired due to short packet. The table below describes the alternate qTD next element transfer pointer.

Table 16-23. qTD alternate next element transfer pointer (DWord 1)

Bits	Name	Description
31-5	Alternate next qTD pointer	This field contains the physical memory address of the next qTD to be processed in the event that the current qTD execution encounters a short packet (for an IN transaction). The field corresponds to memory address signals [31:5], respectively.
4-1	-	Reserved, should be cleared. These bits are reserved and their value has no effect on operation.
0	T	Terminate. Indicates to the host controller that there are no more valid entries in the queue. 0 Pointer is valid (points to a valid transfer element descriptor) 1 Pointer is invalid

16.6.5.3 qTD token

The third DWord of a queue element transfer descriptor contains most of the information the host controller requires to execute a USB transaction (the remaining Endpoint-addressing information is specified in the queue head).

Note that some of the field descriptions in the table below reference fields are defined in the queue head. See Queue head, for more information on these fields.

Table 16-24. qTD token (DWord 2)

Bits	Name	Description
31	dt	Data toggle. This is the data toggle sequence bit. The use of this bit depends on the setting of the Data Toggle Control bit in the queue head.
30-16	Total bytes to transfer	Total bytes to transfer. This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction, only on the successful completion of the transaction. The maximum value software may store in this field is 5 x 4K (0x5000). This is the maximum number of bytes 5 page pointers can access. If the value of this field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the host controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for OUT transfers that total bytes to transfer be an even multiple of QH[Maximum Packet Length]. If software builds such a transfer descriptor for an OUT transfer, the last transaction will always be less than QH[Maximum Packet Length]. Although it is possible to create a transfer up to 20K this assumes the page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K. Therefore, the maximum recommended transfer is 16K (0x4000).
15	ioc	Interrupt on complete. If this bit is set, the host controller should issue an interrupt at the next interrupt threshold when this qTD is completed.
14-12	C_Page	Current range. This field is used as an index into the qTD buffer pointer list. Valid values are in the range 0x0 to 0x4. The host controller is not required to write this field back when the qTD is retired.

Table continues on the next page...

Table 16-24. qTD token (DWord 2) (continued)

<table>
<tr><th>Bits</th><th>Name</th><th colspan="2">Description</th></tr>
<tr><td>11-10</td><td>Cerr</td><td colspan="2">Error counter. 2-bit down counter that keeps track of the number of consecutive errors detected while executing this qTD. If this field is programmed with a non-zero value during setup, the host controller decrements the count and writes it back to the qTD if the transaction fails. If the counter counts from one to zero, the host controller marks the qTD inactive, sets the Halted bit to a one, and error status bit for the error that caused Cerr to decrement to zero. An interrupt is generated if USBINTR[UEE] is set. If the host controller driver (HCD) software programs this field to zero during setup, the host controller will not count errors for this qTD and there is no limit on the retries of this qTD. Note that write-backs of intermediate execution state are to the queue head overlay area, not the qTD.</td></tr>
<tr><td></td><td></td><td>Error</td><td>Decrement Counter</td></tr>
<tr><td></td><td></td><td>Transaction Error</td><td>Yes</td></tr>
<tr><td></td><td></td><td>Data Buffer Error</td><td>No. Data buffer errors are host problems. They don't count against the device's retries. Note that software must not program Cerr to a value of zero when the EPS field is programmed with a value indicating a full- or low-speed device. This combination could result in undefined behavior.</td></tr>
<tr><td></td><td></td><td>Stalled</td><td>No. Detection of babble or stall automatically halts the queue head. Thus, count is not decremented</td></tr>
<tr><td></td><td></td><td>Babble Detected</td><td>No. Detection of babble or stall automatically halts the queue head. Thus, count is not decremented</td></tr>
<tr><td></td><td></td><td>No Error</td><td>No. If the EPS field indicates a HS device or the queue head is in the asynchronous schedule (and PIDCode indicates an IN or OUT) and a bus transaction completes and the host controller does not detect a transaction error, then the host controller should reset Cerr to extend the total number of errors for this transaction. For example, Cerr should be reset with maximum value (0b11) on each successful completion of a transaction. The host controller must never reset this field if the value at the start of the transaction is 0b00.</td></tr>
<tr><td>9-8</td><td>PID Code</td><td colspan="2">This field is an encoding of the token, which should be used for transactions associated with this transfer descriptor. Encodings are:
00 OUT Token generates token (E1H)
01 IN Token generates token (69H)
10 SETUP Token generates token (2DH) (undefined if Endpoint is an Interrupt transfer type, for example. µFrame S-mask field in the queue head is non-zero.)
11 Reserved, should be cleared</td></tr>
<tr><td>7-0</td><td>Status</td><td colspan="2">This field is used by the host controller to communicate individual command execution states back to the host controller driver (HCD) software. This field contains the status of the last transaction performed on this qTD. The bit encodings are:</td></tr>
<tr><td></td><td></td><td>Bits</td><td>Status Field Description</td></tr>
<tr><td></td><td></td><td>7</td><td>Active. Set by software to enable the execution of transactions by the host controller.</td></tr>
<tr><td></td><td></td><td>6</td><td>Halted. Set by the host controller during status updates to indicate that a serious error has occurred at the device/Endpoint addressed by this qTD. This can be caused by babble, the error counter counting down to zero, or reception of the STALL handshake from the device during a transaction. Any time that a transaction results in the Halted bit being set, the Active bit is also cleared.</td></tr>
</table>

Table continues on the next page...

Table 16-24. qTD token (DWord 2) (continued)

Bits	Name	Description	
		5	Data buffer error. Set by the host controller during status update to indicate that the host controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, the host controller will force a time-out condition on the USB, invalidating the transaction at the source. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
		4	Babble detected. Set by the host controller during status update when babble is detected during the transaction. In addition to setting this bit, the host controller also sets the Halted bit to a one. Since babble is considered a fatal error for the transfer, setting the Halted bit to a one insures that no more transactions occur because of this descriptor.
		3	Transaction error (XactErr). Set by the host controller during status update in the case where the host did not receive a valid response from the device (time-out, CRC, bad PID). If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
		2	Missed microframe. This bit is ignored unless the QH[EPS] field indicates a full- or low-speed Endpoint and the queue head is in the periodic list. This bit is set when the host controller detected that a host-induced hold-off caused the host controller to miss a required complete-split transaction. If the host controller sets this bit to a one, then it remains a one for the duration of the transfer.
		1	Split transaction state (SplitXstate). This bit is ignored by the host controller unless the QH[EPS] field indicates a full- or low-speed Endpoint. When a full- or low-speed device, the host controller uses this bit to track the state of the split- transaction. The functional requirements of the host controller for managing this state bit and the split transaction protocol depends on whether the Endpoint is in the periodic or asynchronous schedule. The bit encodings are: 0 Do start split. This value directs the host controller to issue a start split transaction to the Endpoint. 1 Do complete split. This value directs the host controller to issue a Complete split transaction to the Endpoint.
		0	Ping state (P)/ERR. If the QH[EPS] field indicates a high-speed device and the PID Code indicates an OUT Endpoint, then this is the state bit for the Ping protocol. The bit encodings are: 0 Do OUT. This value directs the host controller to issue an OUT PID to the Endpoint. 1 Do Ping. This value directs the host controller to issue a PING PID to the Endpoint. If the QH[EPS] field does not indicate a high-speed device, then this field is used as an error indicator bit. It is set by the host controller whenever a periodic split-transaction receives an ERR handshake.

16.6.5.4 qTD buffer page pointer list

The last five DWords of a queue element transfer descriptor make up an array of physical memory address pointers.

These pointers reference the individual pages of a data buffer.

System software initializes the Current Offset field to the starting offset into the current page, where current page is selected with the value in the C_Page field.

The table below describes the qTD buffer pointer.

Table 16-25. qTD buffer pointer

Bits	Name	Description
31-12	Buffer pointer (page *n*)	Each element in the list is a 4K page aligned physical memory address. The lower 12 bits in each pointer are reserved (except for the first one), as each memory pointer must reference the start of a 4K page. The field C_Page specifies the current active pointer. When the transfer element descriptor is fetched, the starting buffer address is selected using C_Page (similar to an array index to select an array element). If a transaction spans a 4K buffer boundary, the host controller must detect the page-span boundary in the data stream, increment C_Page and advance to the next buffer pointer in the list, and conclude the transaction via the new buffer pointer.
11-0	Current offset (Page 0)/ - (pages 1-4)	Reserved in all pointers except the first one (that is, page 0). The host controller should ignore all reserved bits. For the page 0 current offset interpretation, this field is the byte offset into the current page (as selected by C_Page). The host controller is not required to write this field back when the qTD is retired. Software should ensure the reserved fields are initialized to zeros.

16.6.6 Queue head

The table below shows the queue head structure.

Table 16-26. Queue head layout

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	offset

Table continues on the next page...

Table 16-26. Queue head layout (continued)

Buffer Pointer (Page 4)[2]	0000_0000_0000	0x2C[3]

1. Offsets 0x00 through 0x07 contain the static Endpoint state.
2. Host controller read/write; all others read-only.
3. Offsets 0x10 through 0x2F contain the transfer overlay.
4. Offsets 0x10 through 0x27 contain the transfer results.

16.6.6.1 Queue head horizontal link pointer

The first DWord of a queue head contains a link pointer to the next data object to be processed after any required processing in this queue has been completed, as well as the control bits defined below.

This pointer may reference a queue head or one of the isochronous transfer descriptors. It must not reference a queue element transfer descriptor.

The table below describes the queue head.

Table 16-27. Queue head DWord 0

Bits	Name	Description
31-5	QHLP	Queue head horizontal link pointer. This field contains the address of the next data object to be processed in the horizontal list and corresponds to memory address signals [31:5], respectively.
4-3	-	Reserved, should be cleared. These bits must be written as zeros.
2-1	Typ	Indicates to the hardware whether the item referenced by the link pointer is an iTD, siTD or a QH. This allows the host controller to perform the proper type of processing on the item after it is fetched. 00 iTD (isochronous transfer descriptor) 01 QH (queue head) 10 siTD (split transaction isochronous transfer descriptor) 11 FSTN (frame span traversal node)
0	T	Terminate. 1 Last QH (pointer is invalid). 0 Pointer is valid. If the queue head is in the context of the periodic list, a one bit in this field indicates to the host controller that this is the end of the periodic list. This bit is ignored by the host controller when the queue head is in the asynchronous schedule. Software must ensure that queue heads reachable by the host controller always have valid horizontal link pointers.

16.6.6.2 Endpoint capabilities/characteristics

The second and third DWords of a queue head specify static information about the Endpoint.

This information does not change over the lifetime of the Endpoint. There are three types of information in this region:

- Endpoint characteristics. These are the USB Endpoint characteristics, which include addressing, maximum packet size, and Endpoint speed.
- Endpoint capabilities. These are adjustable parameters of the Endpoint. They affect how the Endpoint data stream is managed by the host controller.
- Split transaction characteristics. This data structure manages full- and low-speed data streams for bulk, control, and interrupt with split transactions to USB 2.0 Hub transaction translator. Additional fields exist for addressing the hub and scheduling the protocol transactions (for periodic).

The host controller must not modify the bits in this region.

The following tables describe the Endpoint characteristics.

Table 16-28. Endpoint characteristics: Queue head DWord 1

Bits	Name	Description
31-28	RL	Nak count reload. This field contains a value, which is used by the host controller to reload the Nak Counter field.
27	C	Control Endpoint flag. If the QH[EPS] field indicates the Endpoint is not a high-speed device, and the Endpoint is a control Endpoint, then software must set this bit to a one. Otherwise, it should always set this bit to a zero.
26-16	Maximum packet length	This directly corresponds to the maximum packet size of the associated Endpoint (wMaxPacketSize). The maximum value this field may contain is 0x400 (1024).
15	H	Head of reclamation list flag. This bit is set by system software to mark a queue head as being the head of the reclamation list.
14	dtc	Data toggle control (DTC). Specifies where the host controller should get the initial data toggle on an overlay transition. 0 Ignore DT bit from incoming qTD. Host controller preserves DT bit in the queue head. 1 Initial data toggle comes from incoming qTD DT bit. Host controller replaces DT bit in the queue head from the DT bit in the qTD.
13-12	EPS	Endpoint speed. This is the speed of the associated Endpoint. 00 Full-speed (12 Mbps) 01 Low-speed (1.5 Mbps) 10 High-speed (480 Mbps) 11 Reserved, should be cleared This field must not be modified by the host controller.
11-8	EndPt	Endpoint number. Selects the particular Endpoint number on the device serving as the data source or sink.
7	I	Inactivate on next transaction. This bit is used by system software to request that the host controller set the Active bit to zero. This field is only valid when the queue head is in the periodic schedule and the EPS field indicates a full- or low-speed Endpoint. Setting this bit when the queue head is in the asynchronous schedule or the EPS field indicates a high-speed device yields undefined results.
6-0	Device address	Selects the specific device serving as the data source or sink.

Table 16-29. Endpoint capabilities: Queue head DWord 2

Bits	Name	Description
31-30	Mult	High-bandwidth pipe multiplier. This field is a multiplier used to key the host controller as the number of successive packets the host controller may submit to the Endpoint in the current execution. The host controller makes the simplifying assumption that software properly initializes this field (regardless of location of queue head in the schedules or other run time parameters). 00 Reserved, should be cleared. A zero in this field yields undefined results. 01 One transaction to be issued for this Endpoint per microframe 10 Two transactions to be issued for this Endpoint per microframe 11 Three transactions to be issued for this Endpoint per microframe
29-23	Port number	This field is ignored by the host controller unless the EPS field indicates a full- or low-speed device. The value is the port number identifier on the USB 2.0 hub (for hub at device address Hub Addr below), below which the full- or low-speed device associated with this Endpoint is attached. This information is used in the split-transaction protocol.
22-16	Hub addr	This field is ignored by the host controller unless the EPS field indicates a full-or low-speed device. The value is the USB device address of the USB 2.0 hub below which the full- or low-speed device associated with this Endpoint is attached. This field is used in the split-transaction protocol.
15-8	µFrame C-mask	This field is ignored by the host controller unless the EPS field indicates this device is a low- or full-speed device and this queue head is in the periodic list. This field (along with the Active and SplitX-state fields) is used to determine during which microframes the host controller should execute a complete-split transaction. When the criteria for using this field are met, a zero value in this field has undefined behavior. This field is used by the host controller to match against the three low-order bits of the FRINDEX register. If the FRINDEX register bits decode to a position where the µFrame C- mask field is a one, then this queue head is a candidate for transaction execution. There may be more than one bit in this mask set.
7-0	µFrame S-mask	Interrupt schedule mask. This field is used for all Endpoint speeds. Software should set this field to a zero when the queue head is on the asynchronous schedule. A non-zero value in this field indicates an interrupt Endpoint. The host controller uses the value of the three low-order bits of the FRINDEX register as an index into a bit position in this bit vector. If the µFrame S-mask field has a one at the indexed bit position then this queue head is a candidate for transaction execution. If the EPS field indicates the Endpoint is a high-speed Endpoint, then the transaction executed is determined by the PID_Code field contained in the execution area. This field is also used to support split transaction types: Interrupt (IN/OUT). This condition is true when this field is non-zero and the EPS field indicates this is either a full- or low-speed device. A zero value in this field, in combination with existing in the periodic frame list has undefined results.

16.6.6.3 Transfer overlay

The nine DWords in this area represent a transaction working space for the host controller.

The general operational model is that the host controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it follows the queue head horizontal link pointer to the next queue head. The host controller never follows the next transfer queue element or alternate queue element pointers unless it is actively attempting to advance the queue. For the duration of the

transfer, the host controller keeps the incremental status of the transfer in the overlay area. When the transfer is complete, the results are written back to the original queue element.

The DWord3 of a queue head contains a pointer to the source qTD currently associated with the overlay. The host controller uses this pointer to write back the overlay area into the source qTD after the transfer is complete.

The table below describes the current qTD link pointer.

Table 16-30. Current qTD link pointer

Bits	Name	Description
31-5	Current qTD pointer	Current element transaction descriptor link pointer. This field contains the address Of the current transaction being processed in this queue and corresponds to memory address signals [31:5], respectively.
4-0	-	Reserved, should be cleared. These bits are ignored by the host controller when using the value as an address to write data. The actual value may vary depending on the usage.

The DWords 4-11 of a queue head are the transaction overlay area. This area has the same base structure as a queue element transfer descriptor. The queue head utilizes the reserved fields of the page pointers to implement tracking the state of split transactions.

This area is characterized as an overlay because when the queue is advanced to the next queue element, the source queue element is merged onto this area. This area serves an execution cache for the transfer.

The table below describes the host-controller rules for bits in overlay.

Table 16-31. Host-controller rules for bits in overlay (DWords 5, 6, 8, and 9)

DWord	QH Offset	Bits	Name	Description
5	0x14	4-1	NakCnt	Nak counter-RW. This field is a counter the host controller decrements whenever a transaction for the Endpoint associated with this queue head results in a Nak or Nyet response. This counter is reloaded from RL before a transaction is executed during the first pass of the reclamation list (relative to an Asynchronous List Restart condition). It is also loaded from RL during an overlay.
6	0x18	31	dt	Data toggle. The Data toggle control controls whether the host controller preserves this bit when an overlay operation is performed.
6	0x18	15	ioc	Interrupt on complete. The ioc control bit is always inherited from the source qTD when the overlay operation is performed.
6	0x18	11-10	Cerr	Error counter. Copied from the qTD during the overlay and written back during queue advancement.
6	0x18	0	Status[0]	Ping state (P)/ERR. If the EPS field indicates a high-speed Endpoint, then this field should be preserved during the overlay operation.
8	0x20	7-0	C-prog-mask	Split-transaction complete-split progress. Initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.

Table continues on the next page...

Table 16-31. Host-controller rules for bits in overlay (DWords 5, 6, 8, and 9) (continued)

DWord	QH Offset	Bits	Name	Description
9	0x24	11-5	S-bytes	Software must ensure that the S-bytes field in a qTD is zero before activating the qTD. Keeps track of the number of bytes sent or received during an IN or OUT split transaction.
9	0x24	4-0	FrameTag	Split-transaction frame tag. Initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.

16.6.7 Periodic frame span traversal node (FSTN)

The periodic frame span traversal node (FSTN) data structure, shown in the table below, is to be used only for managing full- and low-speed transactions that span a host-frame boundary.

Software must not use an FSTN in the asynchronous schedule. An FSTN in the asynchronous schedule results in undefined behavior.

Table 16-32. Frame span traversal node structure

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	offset
Normal path link pointer																											-		Typ		T	0x00
Back path link pointer																											-		Typ		T	0x04

NOTE

The host controller performs only read operations to the FSTN data structure.

16.6.7.1 FSTN normal path pointer

The first DWord of an FSTN contains a link pointer to the next schedule object.

This object can be of any valid periodic schedule data type. The table below describes the FSTN normal path pointer.

Table 16-33. FSTN normal path pointer

Bits	Name	Description
31-5	NPLP	Normal path link pointer. Contains the address of the next data object to be processed in the periodic list and corresponds to memory address signals [31:5], respectively.
4-3	-	Reserved, should be cleared. These bits must be written as 0s.

Table continues on the next page...

Table 16-33. FSTN normal path pointer (continued)

Bits	Name	Description
2-1	Typ	Indicates to the host controller whether the item referenced is a iTD/siTD, QH, or FSTN. This allows the host controller to perform the proper type of processing on the item after it is fetched. 00 iTD (isochronous transfer descriptor) 01 QH (queue head) 10 siTD (split transaction isochronous transfer descriptor) 11 FSTN (frame span traversal node)
0	T	Terminate. 0 Link pointer is valid. 1 Link pointer field is not valid.

16.6.7.2 FSTN back path link pointer

The second DWord of an FSTN node contains a link pointer to a queue head.

If the T-bit in this pointer is a zero, then this FSTN is a Save-Place indicator. Its Typ field must be set by software to indicate the target data structure is a queue head. If the T-bit in this pointer is set, then this FSTN is the Restore indicator. When the T-bit is a one, the host controller ignores the Typ field.

The table below describes the FSTN back path link pointer.

Table 16-34. FSTN back path link pointer

Bits	Name	Description
31-5	BPLP	Back path link pointer. Contains the address of a queue head. This field corresponds to memory address signals [31:5], respectively.
4-3	-	Reserved, should be cleared. These bits must be written as 0s.
2-1	Typ	Software must ensure this field is set to indicate the target data structure is a Queue Head (01). Any other value in this field yields undefined results.
0	T	Terminate. 0 Link pointer is valid (that is, the host controller may use bits 31-5 as a valid memory address). This value also indicates that this FSTN is a Save-Place indicator. 1 Link pointer field is not valid (that is, the host controller must not use bits 31-5 as a valid memory address). This value also indicates that this FSTN is a Restore indicator.

16.7 Host operations

The general operational model for the USB DR module in host mode is defined by the Enhanced Host Controller Interface (EHCI) Specification. The EHCI specification describes the register-level interface for a host controller for the USB Revision 2.0. It includes a description of the hardware/software interface between system software and host controller hardware. Information concerning the initialization of the USB module is included in the following section; however, the full details of the EHCI specification are beyond the scope of this document.

16.7.1 Host controller initialization

After initial power-on or host controller reset (hardware or through USBCMD[RST]), all of the operational registers are at their default values.

To configure the internal UTMI PHY, the following initialization sequence is required:

1. After power-on reset, the UTMI PHY will be in disabled state and the PLL will be held reset.
3. Set the USB_CONTROL[UTMI_PHY_EN] to enable the UTMI PHY and release the PLL.
4. Wait (approx 10ms) for PHY clock to become valid. This can be determined by polling the CONTROL[PHY_CLK_VALID] status bit.

Once the PHY clock is valid the user can proceed to the host controller initialization phase.

In order to initialize the USB DR module, software should perform the following steps:

1. Set the controller mode to host mode. Optionally set USBMODE[SDIS] (streaming disable)

NOTE

Transitioning from device mode to host mode requires a host controller reset before modifying USBMODE.

2. Program the PTS field of the PORTSC register if using a non-ULPI PHY.
3. Set CONTROL[USB_EN].
4. Write the appropriate value to the USBINTR register to enable the appropriate interrupts.

5. Write the base address of the periodic frame list to the PERIODICLIST BASE register. If there are no work items in the periodic schedule, all elements of the periodic frame list should have their T-Bits set.
6. Write the USBCMD register to set the desired interrupt threshold, frame list size (if applicable) and turn on the controller by setting the RS bit.

At this point, the USB DR module is up and running and the port registers begin reporting device connects. System software can enumerate a port through the reset process (where the port is in the enabled state). At this point, the port is active with SOFs occurring down the enabled high-speed ports, but the schedules have not yet been enabled. The EHCI host controller will not transmit SOFs to enabled Full- or Low-speed ports.

In order to communicate with devices via the asynchronous schedule, system software must write the ASYNDLISTADDR register with the address of a control or bulk queue head. Software must then enable the asynchronous schedule by writing a one to USBCMD[ASE]. In order to communicate with devices via the periodic schedule, system software must enable the periodic schedule by writing a one to USBCMD[PSE]. Note that the schedules can be turned on before the first port is reset (and enabled).

Any time the USBCMD register is written, system software must ensure the appropriate bits are preserved, depending on the intended operation.

16.7.2 Power port

The HCSPARAMS[PPC] bit indicates whether the USB 2.0 host controller has port power control.

When the PPC bit is set, the host controller supports port power switches. Each available switch has an output enable. PPE is controlled based on the state of the combination bits-PPC bit, EHCI Configured (CF)-bit and individual Port Power (PP) bit. The Configured Flag and Port Power Control bits are always 1'b1 in Host Mode. The PPE always follows the state of Port Power (PP) bit that is, if PP is 0, PPE will be 0 and if PP is 1, PPE will be 1.

16.7.3 Reporting over-current

Host ports by definition are power providers on USB.

Whether the ports are considered high- or low-powered is a platform implementation issue. The EHCI PORTSC register has an over-current status and over-current change bit. The functionality of these bits is specified in the USB Specification Revision 2.0.

The over current detection and limiting logic resides outside the DR logic. The over-current condition effects the following bits in the PORTSC register on the EHCI port:

- Over-current active bit (OCA) is set. When the over-current condition goes away, the OCA will transition from a one to a zero.
- Over-current change bit (OCC) is set. On every transition of OCA, the controller will set OCC to a one. Software sets OCC to a zero by writing a one to this bit.
- Port enabled/disabled bit (PE) is cleared. When this change bit gets set, USBSTS[PCI] (the port change detect bit) is set.
- Port power (PP) bit may optionally be cleared. There is no requirement in USB that a power provider shut off power in an over current condition. It is sufficient to limit the current and leave power applied. When OCC transitions from a zero to a one, the controller also sets USBSTS[PCI] to a one. In addition, if the Port Change Interrupt Enable bit, USBINTR[PCE], is a one, the controller issues an interrupt to the system. Refer to Table 16-35 for summary of behavior for over-current detection when the controller is halted (suspended from a device component point of view).

16.7.4 Suspend/resume

The host controller provides an equivalent suspend and resume model as that defined for individual ports in a USB 2.0 hub.

Control mechanisms are provided to allow system software to suspend and resume individual ports. The mechanisms allow the individual ports to be resumed completely through software initiation. Other control mechanisms are provided to parameterize the host controller's response (or sensitivity) to external resume events. In this discussion, host-initiated, or software-initiated resumes are called Resume Events/Actions; bus-initiated resume events are called wake-up events. The classes of wakeup events are:

- Remote-wakeup enabled device asserts resume signaling. In similar kind to USB 2.0 hubs, when in host mode the host controller responds to explicit device resume signaling and wake up the system (if necessary).
- Port connect and disconnect and over-current events. Sensitivity to these events can be turned on or off by using the port control bits in the PORTSC register.

Selective suspend is a feature supported by the PORTSC register. It is used to place specific ports into a suspend mode. This feature is used as a functional component for implementing the appropriate power management policy implemented in a particular operating system. When system software intends to suspend the bus, it should suspend the enabled port, then shut off the controller by setting the USBCMD[RS] to a zero.

When a wake event occurs the system will resume operation and system software must set the RS bit to a one and resume the suspended port.

16.7.4.1 Port suspend/resume

System software places the USB into suspend mode by writing a one into the appropriate PORTSC Suspend bit.

Software must only set the Suspend bit when the port is in the enabled state (Port Enabled bit is a one).

The host controller may evaluate the Suspend bit immediately or wait until a microframe or frame boundary occurs. If evaluated immediately, the port is not suspended until the current transaction (if one is executing) completes. Therefore, there may be several microframes of activity on the port until the host controller evaluates the Suspend bit. The host controller must evaluate the Suspend bit at least every frame boundary.

System software can initiate a resume on the suspended port by writing a one to PORTSC[FPR]. Software should not attempt to resume a port unless the port reports that it is in the suspended state. If system software sets PORTSC[FPR] when the port is not in the suspended state, the resulting behavior is undefined. In order to assure proper USB device operation, software must wait for at least 10 milliseconds after a port indicates that it is suspended (Suspend bit is a one) before initiating a port resume through PORTSC[FPR]. When PORTSC[FPR] is set, the host controller sends resume signaling down the port. System software times the duration of the resume (nominally 20 milliseconds) then clears PORTSC[FPR]. When the host controller receives the write to transition PORTSC[FPR] to zero, it completes the resume sequence as defined in the USB specification, and clears both PORTSC[FPR] and PORTSC[SUSP]. Software-initiated port resumes do not affect the port change detect bit (USBSTS[PCI]) nor do they cause an interrupt if USBINTR[PCE] (port change interrupt enable) is a one. When a wake event occurs on a suspended port, the resume signaling is detected by the port and the resume is reflected downstream within 100 μsec. The port's PORTSC[FPR] bit is set and USBSTS[PCI] is set. If USBINTR[PCE] is a one, the host controller issues a hardware interrupt.

System software observes the resume event on the port, delays a port resume time (nominally 20 milliseconds), then terminates the resume sequence by clearing PORTSC[FPR] in the port. The host controller receives the write of zero to PORTSC[FPR], terminates the resume sequence and clears PORTSC[FPR] and PORTSC[SUSP]. Software can determine that the port is enabled (not suspended) by sampling the PORTSC register and observing that the SUSP and FPR bits are zero. Software must ensure that the host controller is running (that is, USBSTS[HCH] is a zero), before terminating a resume by clearing the port's PORTSC[FPR] bit. If HCH is a one when PORTSC[FPR] is cleared, then SOFs will not occur down the enabled port and the device will return to suspend mode in a maximum of 10 milliseconds.

The table below summarizes the wake-up events. Whenever a resume event is detected, USBSTS[PCI] is set. If USBINTR[PCE] (port change interrupt enable) is a one, the host controller also generates an interrupt on the resume event. Software acknowledges the resume event interrupt by clearing the USBSTS[PCI].

Table 16-35. Behavior during wake-up events

Port status and signaling type	Signaled port response	Device state	
		D0	Not D0
Port disabled, resume K-State received	No effect	N/A	N/A
Port suspended, Resume K-State received	Resume reflected downstream on signaled port. PORTSC[FPR] is set. USBSTS[PCI] is set.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's PORTSC[WKDS], is set. A disconnect is detected.	Depending on the initial port state, the PORTSC Connect (CCS) and Enable (PE) status bits are cleared, and the Connect Change status bit (CSC) is set. USBSTS[PCI] is set.	[1], [2]	[2]
Port is enabled, disabled or suspended, and the port's PORTSC[WKDS], is cleared. A disconnect is detected.	Depending on the initial port state, the PORTSC Connect (CCS) and Enable (PE) status bits are cleared, and the Connect Change status bit (CSC) is set. USBSTS[PCI] is set.	[1], [3]	[3]
Port is not connected and the port's PORTSC[WKCN] bit is a one. A connect is detected.	PORTSC Connect Status (CCS) and Connect Status Change (CSC) bits are set. USBSTS[PCI] is set.	[1], [2]	[2]
Port is not connected and the port's PORTSC[WKCN] bit is a zero. A connect is detected.	PORTSC Connect Status (CCS) and Connect Status Change (CSC) bits are set. USBSTS[PCI] is set.	[1], [3]	[3]
Port is connected and the port's PORTSC[WKOC] bit is a one. An over-current condition occurs.	PORTSC Over-current Active (OCA), Over-current Change (OCC) bits are set. If Port Enable/Disable bit (PE) is a one, it is cleared. USBSTS[PCI] is set	[1], [2]	[2]
Port is connected and the port's PORTSC[WKOC] bit is a zero. An over-current condition occurs.	PORTSC Over-current Active (OCA), Over-current Change (OCC) bits are set. If Port Enable/Disable bit (PE) is a one, it is cleared. USBSTS[PCI] is set.	[1], [3]	[3]

[1] Hardware interrupt issued if USBINTR[PCE] (port change interrupt enable) is set.

[2] PME# asserted if enabled (Note: PME Status must always be set).

[3] PME# not asserted.

16.7.5 Schedule traversal rules

The host controller executes transactions for devices using a simple, shared-memory schedule.

The schedule is comprised of a few data structures, organized into two distinct lists. The data structures are designed to provide the maximum flexibility required by USB, minimize memory traffic and hardware/software complexity.

System software maintains two schedules for the host controller: a periodic schedule and an asynchronous schedule. The root of the periodic schedule is the USB_PERIODICLISTBASE register. The PERIODICLISTBASE register is the physical memory base address of the periodic frame list. The periodic frame list is an array of physical memory pointers. The objects referenced from the frame list must be valid schedule data structures as defined in Host data structures. In each microframe, if the periodic schedule is enabled (see Periodic schedule) then the host controller must execute from the periodic schedule before executing from the asynchronous schedule. It will only execute from the asynchronous schedule after it encounters the end of the periodic schedule. The host controller traverses the periodic schedule by constructing an array offset reference from the PERIODICLISTBASE and the FRINDEX registers (see the figure below). It fetches the element and begins traversing the graph of linked schedule data structures.

The end of the periodic schedule is identified by a next link pointer of a schedule data structure having its T-bit set. When the host controller encounters a T-Bit set during a horizontal traversal of the periodic list, it interprets this as an End-Of-Periodic-List mark. This causes the host controller to cease working on the periodic schedule and transitions immediately to traversing the asynchronous schedule. Once this transition is made, the host controller executes from the asynchronous schedule until the end of the microframe.

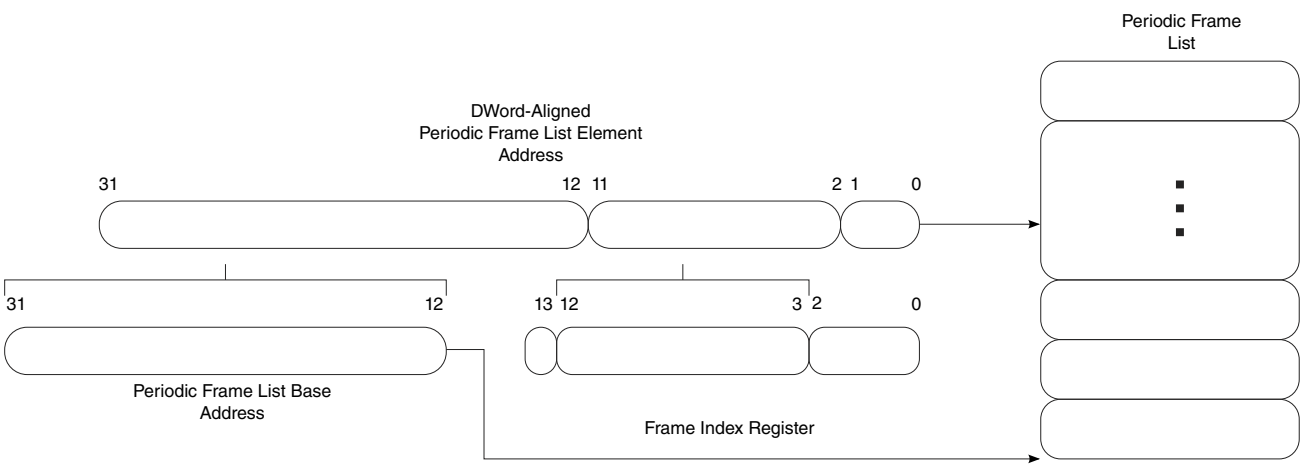

Figure 16-4. Derivation of pointer into frame list array

When the host controller determines that it is time to execute from the asynchronous list, it uses the operational register ASYNCLISTADDR to access the asynchronous schedule, as shown in the figure below.

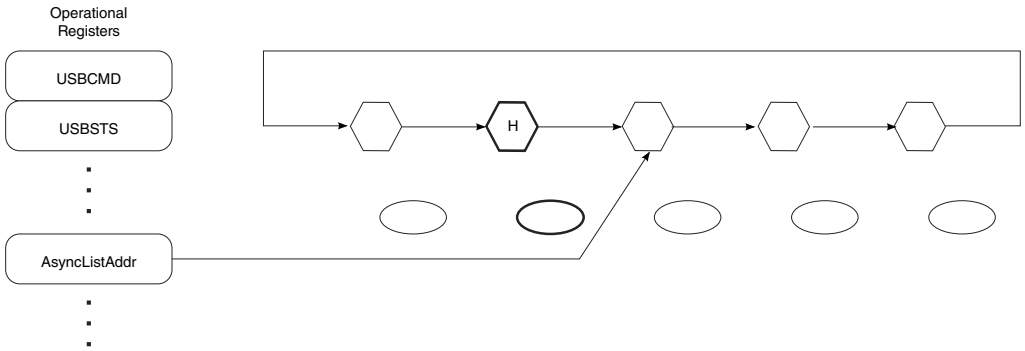

Figure 16-5. General format of asynchronous schedule list

The ASYNCLISTADDR register contains a physical memory pointer to the next queue head. When the host controller makes a transition to executing the asynchronous schedule, it begins by reading the queue head referenced by the ASYNCLISTADDR register. Software must set queue head horizontal pointer T-bits to a zero for queue heads in the asynchronous schedule.

16.7.6 Periodic schedule frame boundaries vs. bus frame boundaries

The USB Specification Revision 2.0 requires that the frame boundaries (SOF frame number changes) of the high-speed bus and the full- and low-speed bus(es) below USB 2.0 hubs be strictly aligned.

Super-imposed on this requirement is that USB 2.0 hubs manage full- and low-speed transactions via a microframe pipeline (see start- (SS) and complete- (CS) splits illustrated in the figure below). A simple, direct projection of the frame boundary model into the host controller interface schedule architecture creates tension (complexity for both hardware and software) between the frame boundaries and the scheduling mechanisms required to service the full- and low-speed transaction translator periodic pipelines.

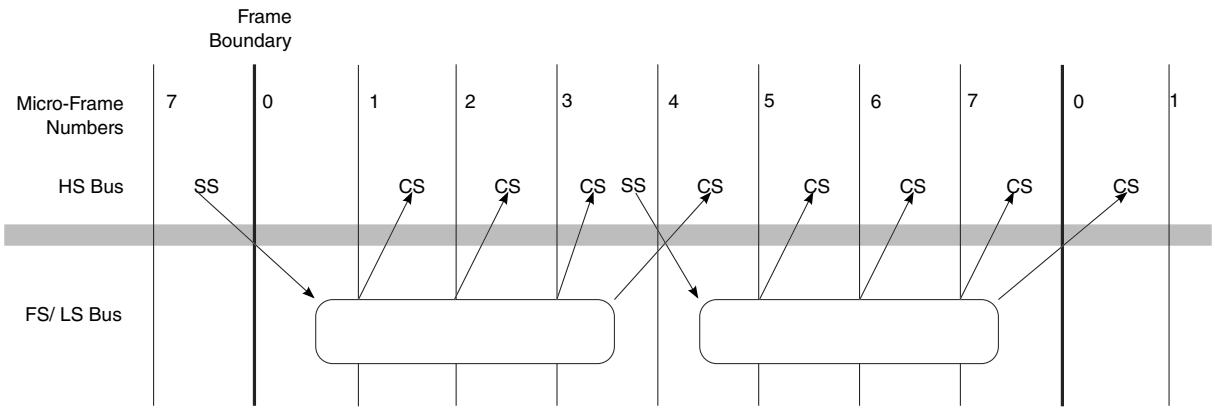

Figure 16-6. Frame boundary relationship between HS bus and FS/LS bus

The simple projection, as the figure above illustrates, introduces frame-boundary wrap conditions for scheduling on both the beginning and end of a frame. In order to reduce the complexity for hardware and software, the host controller is required to implement a one microframe phase shift for its view of frame boundaries. The phase shift eliminates the beginning of frame and frame-wrap scheduling boundary conditions.

The implementation of this phase shift requires that the host controller use one register value for accessing the periodic frame list and another value for the frame number value included in the SOF token. These two values are separate, but tightly coupled. The periodic frame list is accessed via the Frame List Index Register (FRINDEX). Bits FRINDEX[2-0], represent the microframe number. The SOF value is coupled to the value of FRINDEX[13-3]. Both FRINDEX[13-3] and the SOF value are incremented based on FRINDEX[2-0]. It is required that the SOF value be delayed from the FRINDEX value by one microframe. The one microframe delay yields a host controller periodic schedule and bus frame boundary relationship as illustrated in the figure below. This adjustment allows software to trivially schedule the periodic start and complete-split transactions for full-and low-speed periodic Endpoints, using the natural alignment of the periodic schedule interface.

The figure below illustrates how periodic schedule data structures relate to schedule frame boundaries and bus frame boundaries. To aid the presentation, two terms are defined. The host controller's view of the 1-millisecond boundaries is called H-Frames. The high-speed bus's view of the 1-millisecond boundaries is called B-Frames.

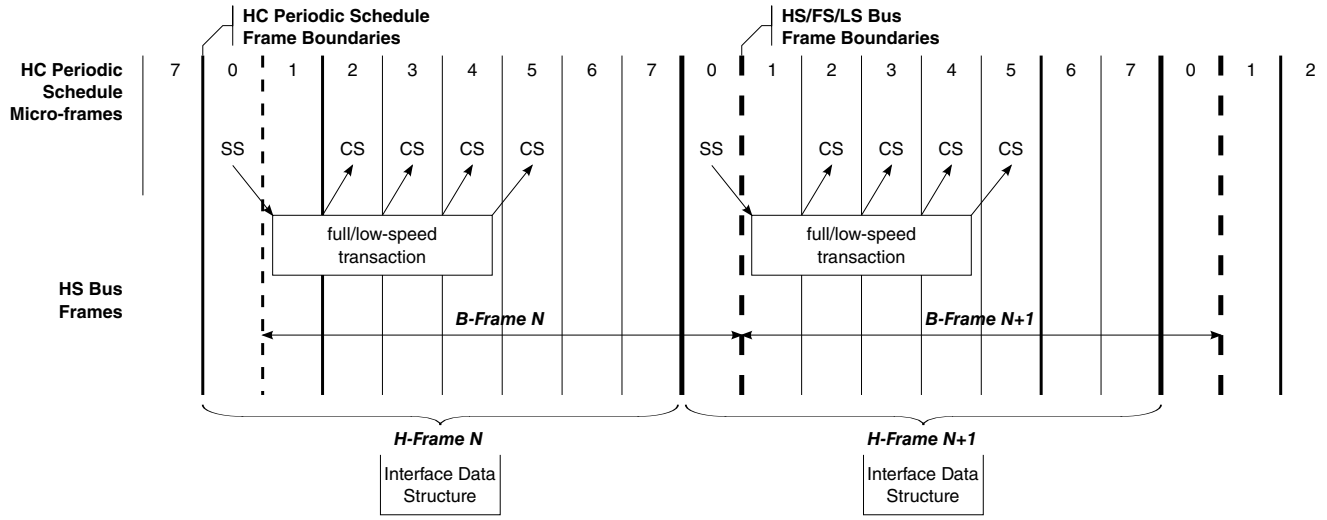

Figure 16-7. Relationship of periodic schedule frame boundaries to bus frame boundaries

H-Frame boundaries for the host controller correspond to increments of FRINDEX[13-3]. Microframe numbers for the H-Frame are tracked by FRINDEX[2-0]. B-Frame boundaries are visible on the high-speed bus via changes in the SOF token's frame number. Microframe numbers on the high-speed bus are only derived from the SOF token's frame number (that is, the high-speed bus will see eight SOFs with the same frame number value). H-Frames and B-Frames have the fixed relationship (that is, B-Frames lag H-Frames by one microframe time) illustrated in the figure above. The host controller's periodic schedule is naturally aligned to H-Frames. Software schedules transactions for full- and low-speed periodic Endpoints relative the H-Frames. The result is these transactions execute on the high-speed bus at exactly the right time for the USB 2.0 hub periodic pipeline. As described in USB_FRINDEX, the SOF Value can be implemented as a shadow register (in this example, called SOFV), which lags the FRINDEX register bits [13-3] by one microframe count. The table below illustrates the required relationship between the value of FRINDEX and the value of SOFV. This lag behavior can be accomplished by incrementing FRINDEX[13-3] based on carry-out on the 7 to 0 increment of FRINDEX[2-0] and incrementing SOFV based on the transition of 0 to 1 of FRINDEX[2-0].

Software is allowed to write to FRINDEX. USB_FRINDEX provides the requirements that software should adhere when writing a new value in FRINDEX.

Table 16-36. Operation of FRINDEX and SOFV (SOF value register)

Current			Next		
FRINDEX[13-3]	SOFV	FRINDEX[2-0]	FRINDEX[13-3]	SOFV	FRINDEX[2-0]
N	N	111	N+1	N	000

Table continues on the next page...

Table 16-36. Operation of FRINDEX and SOFV (SOF value register) (continued)

Current			Next		
FRINDEX[13-3]	SOFV	FRINDEX[2-0]	FRINDEX[13-3]	SOFV	FRINDEX[2-0]
N+1	N	000	N+1	N+1	001
N+1	N+1	001	N+1	N+1	010
N+1	N+1	010	N+1	N+1	011
N+1	N+1	011	N+1	N+1	100
N+1	N+1	100	N+1	N+1	101
N+1	N+1	101	N+1	N+1	110
N+1	N+1	110	N+1	N+1	111

16.7.7 Periodic schedule

The periodic schedule traversal is enabled or disabled through USBCMD[PSE] (periodic schedule enable).

If USBCMD[PSE] is cleared, then the host controller simply does not try to access the periodic frame list via the PERIODICLISTBASE register. Likewise, when USBCMD[PSE] is a one, then the host controller does use the PERIODICLISTBASE register to traverse the periodic schedule. The host controller will not react to modifications to USBCMD[PSE] immediately. In order to eliminate conflicts with split transactions, the host controller evaluates USBCMD[PSE] only when FRINDEX[2-0] is zero. System software must not disable the periodic schedule if the schedule contains an active split transaction work item that spans the 0b000 microframe. These work items must be removed from the schedule before USBCMD[PSE] is cleared. USBSTS[PS] (periodic schedule status) indicates status of the periodic schedule. System software enables (or disables) the periodic schedule by setting (or clearing) USBCMD[PSE]. Software then can poll USBSTS[PS] to determine when the periodic schedule has made the desired transition. Software must not modify USBCMD[PSE] unless the value of USBCMD[PSE] equals that of USBSTS[PS].

The periodic schedule is used to manage all isochronous and interrupt transfer streams. The base of the periodic schedule is the periodic frame list. Software links schedule data structures to the periodic frame list to produce a graph of scheduled data structures. The graph represents an appropriate sequence of transactions on the USB. The figure below illustrates isochronous transfers (using iTDs and siTDs) with a period of one are linked directly to the periodic frame list. Interrupt transfers (are managed with queue heads) and isochronous streams with periods other than one are linked following the period-one iTD/

siTDs. Interrupt queue heads are linked into the frame list ordered by poll rate. Longer poll rates are linked first (for example, closest to the periodic frame list), followed by shorter poll rates, with queue heads with a poll rate of one, on the very end.

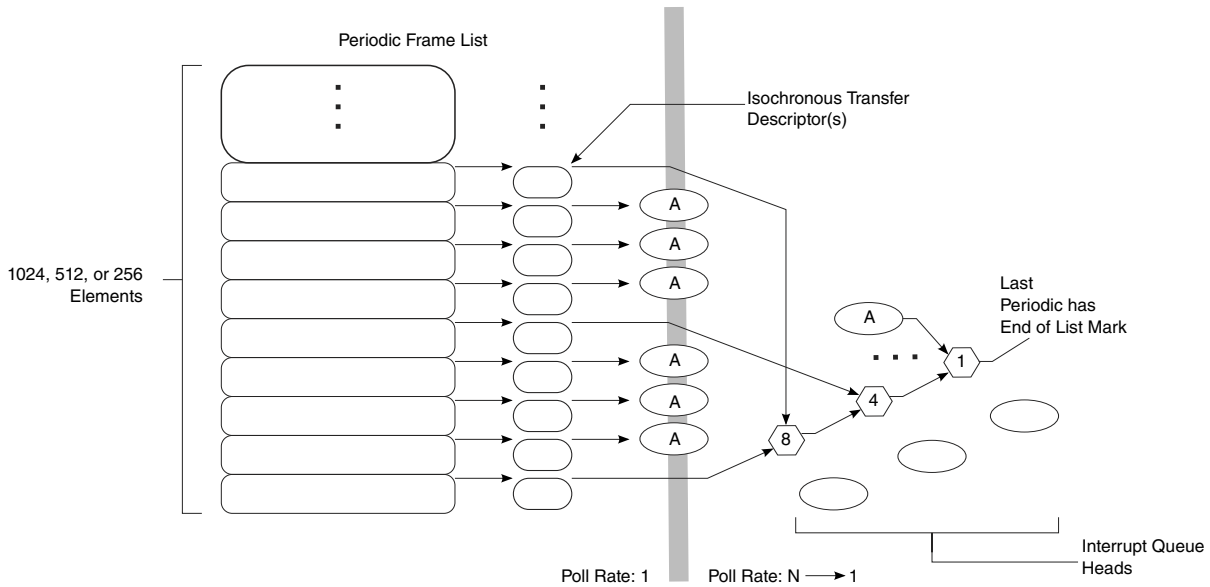

Figure 16-8. Example periodic schedule

16.7.8 Managing isochronous transfers using iTDs

The structure of an iTD is presented in isochronous (high-speed) transfer descriptor (iTD).

There are four distinct sections to an iTD:

- Next link pointer
  - This is the first field.
  - This field is for schedule linkage purposes only.
- Transaction description array
  - This is an eight-element array.
  - Each element represents control and status information for one microframe's worth of transactions for a single high-speed isochronous Endpoint.
- Buffer page pointer array
  - This is a 7-element array of physical memory pointers to data buffers.
  - These are 4K aligned pointers to physical memory.
- Endpoint capabilities

- This area utilizes the unused low-order 12 bits of the buffer page pointer array.
- Its fields are used across all transactions executed for this iTD, including Endpoint addressing, transfer direction, maximum packet size and high-bandwidth multiplier.

16.7.8.1 Host controller operational model for iTDs

The host controller uses FRINDEX register bits 12-3 to index into the periodic frame list.

This means that the host controller visits each frame list element eight consecutive times before incrementing to the next periodic frame list element. Each iTD contains eight transaction descriptions, which map directly to FRINDEX register bits 2-0. Each iTD can span 8 microframes worth of transactions. When the host controller fetches an iTD, it uses FRINDEX register bits 2-0 to index into the transaction description array. When the first iTD in the periodic list is traversed after periodic schedule is enabled, the value of FRINDEX[2:0] may be other than 0, so the first transaction issued by the controller may be any of the eight available active transactions. If the active bit in the Status field of the indexed transaction description is cleared, the host controller ignores the iTD and follows the Next pointer to the next schedule data structure.

When the indexed active bit is a one the host controller continues to parse the iTD. It stores the indexed transaction description and the general Endpoint information (device address, Endpoint number, maximum packet size, and so on). It also uses the Page Select (PG) field to index the buffer pointer array, storing the selected buffer pointer and the next sequential buffer pointer. For example, if PG field is a 0, then the host controller will store Page 0 and Page 1.

The host controller constructs a physical data buffer address by concatenating the current buffer pointer (as selected using the current transaction description's PG field) and the transaction description's Transaction Offset field. The host controller uses the Endpoint addressing information and I/O-bit to execute a transaction to the appropriate Endpoint. When the transaction is complete, the host controller clears the active bit and writes back any additional status information to the Status field in the currently selected transaction description.

The data buffer associated with the iTD must be virtually contiguous memory. Seven page pointers are provided to support eight high-bandwidth transactions regardless of the starting packet's offset alignment into the first page. A starting buffer pointer (physical memory address) is constructed by concatenating the page pointer (example: page 0 pointer) selected by the active transaction descriptions' PG (example value: 0b00) field with the transaction offset field. As the transaction moves data, the host controller must detect when an increment of the current buffer pointer will cross a page boundary. When

this occurs the host controller simply replaces the current buffer pointer's page portion with the next page pointer (example: page 1 pointer) and continues to move data. The size of each bus transaction is determined by the value in the Maximum Packet Size field. An iTD supports high-bandwidth pipes via the Mult (multiplier) field. When the Mult field is 1, 2, or 3, the host controller executes the specified number of Maximum Packet sized bus transactions for the Endpoint in the current microframe. In other words, the Mult field represents a transaction count for the Endpoint in the current microframe. If the Mult field is zero, the operation of the host controller is undefined. The transfer description is used to service all transactions indicated by the Mult field.

For OUT transfers, the value of the Transaction *n* Length field represents the total bytes to be sent during the microframe. The Mult field must be set by software to be consistent with Transaction *n* Length and Maximum Packet Size. The host controller will send the bytes in Maximum Packet Sized portions. After each transaction, the host controller decrements it's local copy of Transaction *n* Length by Maximum Packet Size. The number of bytes the host controller sends is always Maximum Packet Size or Transaction *n* Length, whichever is less. The host controller advances the transfer state in the transfer description, updates the appropriate record in the iTD and moves to the next schedule data structure. The maximum sized transaction supported is 3 x 1024 bytes.

For IN transfers, the host controller issues Mult transactions. It is assumed that software has properly initialized the iTD to accommodate all possible data. During each IN transaction, the host controller must use Maximum Packet Size to detect packet babble errors. The host controller keeps the sum of bytes received in the Transaction *n* Length field.

After all transactions for the Endpoint have completed for the microframe, Transaction *n* Length contains the total bytes received. The following actions can occur:

- If the final value of Transaction *n* Length is less than the value of Maximum Packet Size, less data was received than was allowed for from the associated Endpoint. This short packet condition does not set USBSTS[UI] (USB interrupt). The host controller does not detect this condition.
- If the device sends more than Transaction *n* Length or Maximum Packet Size bytes (whichever is less), the host controller sets the Babble Detected bit and clears the Active bit. Note, that the host controller does not update the iTD field Transaction *n* Length in this error scenario.
- If the Mult field is greater than one, the host controller automatically executes the value of Mult transactions. The host controller does not execute all Mult transactions in the following cases:

- The Endpoint is an OUT and Transaction *n* Length goes to zero before all the Mult transactions have executed (ran out of data).
- The Endpoint is an IN and the Endpoint delivers a short packet, or an error occurs on a transaction before Mult transactions have been executed.

The end of microframe may occur before all of the transaction opportunities have been executed. When this happens, the transfer state of the transfer description is advanced to reflect the progress that was made; the result is written back to the iTD; and the host controller proceeds to processing the next microframe.

16.7.8.2 Software operational model for iTDs

A client buffer request to an isochronous Endpoint may span 1 to N microframes.

When N is larger than one, system software may have to use multiple iTDs to read or write data with the buffer (if N is larger than eight, it must use more than one iTD).

The figure below illustrates the simple model of how a client buffer is mapped by system software to the periodic schedule (that is, the periodic frame list and a set of iTDs).

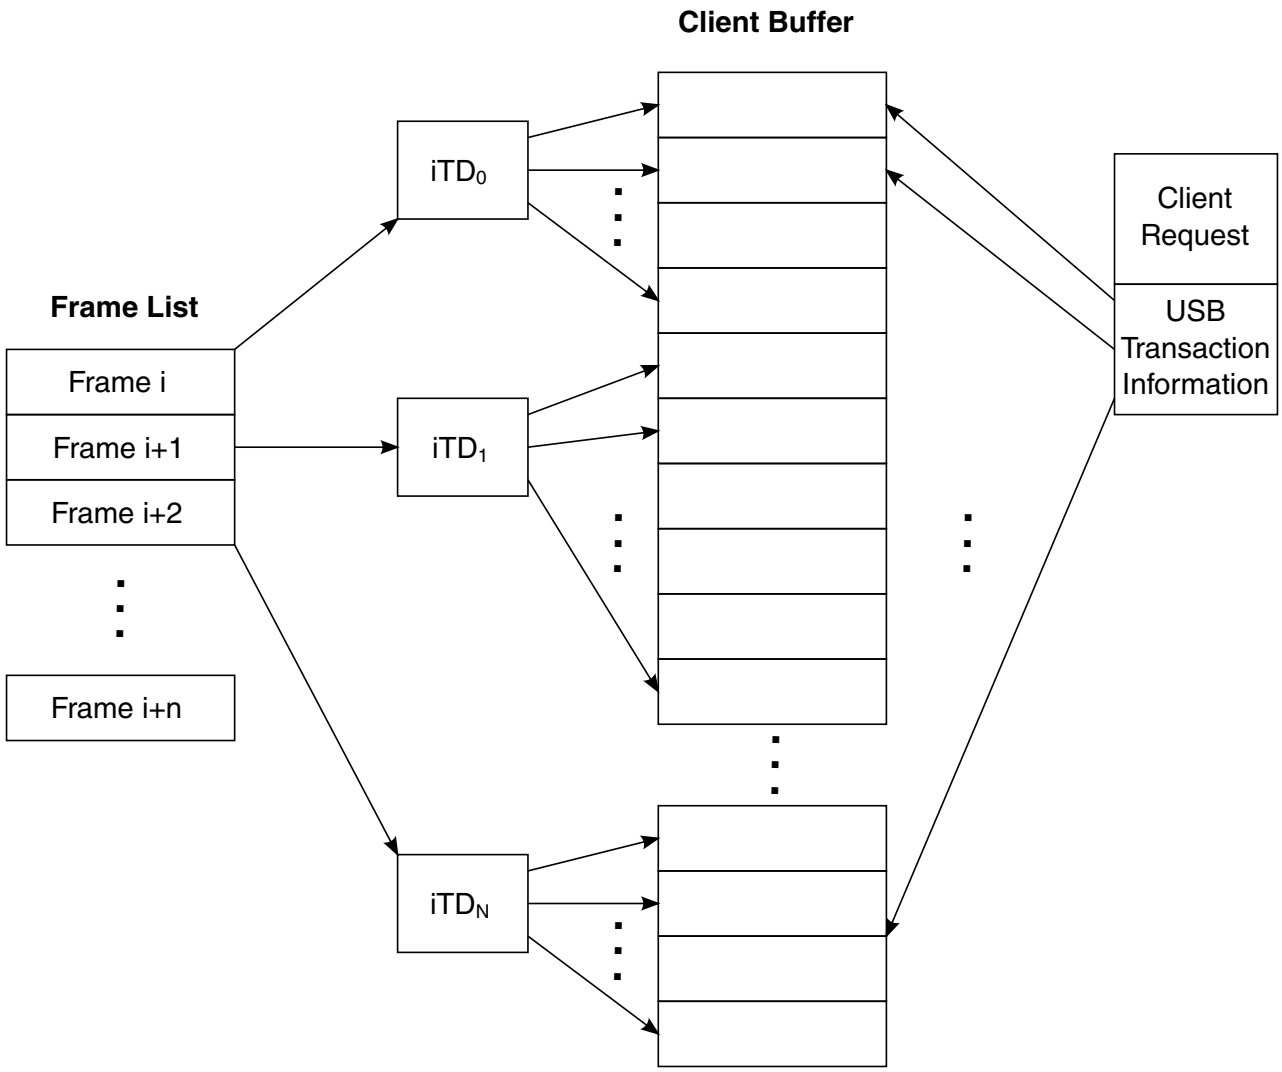

Figure 16-9. Example Association of iTDs to Client Request Buffer

On the right is the client description of its request. The description includes a buffer base address plus additional annotations to identify which portions of the buffer should be used with each bus transaction. In the middle is the iTD data structures used by the system software to service the client request. Each iTD can be initialized to service up to 24 transactions, organized into eight groups of up to three transactions each. Each group maps to one microframe's worth of transactions. The EHCI controller does not provide per transaction results within a microframe. It treats the per microframe transactions as a single logical transfer.

On the left is the host controller's frame list. System software establishes references from the appropriate locations in the frame list to each of the appropriate iTDs. If the buffer is large, system software can use a small set of iTDs to service the entire buffer. System software can activate the transaction description records (contained in each iTD) in any pattern required for the particular data stream.

As noted above, the client request includes a pointer to the base of the buffer and offsets into the buffer to annotate which buffer sections are to be used on each bus transaction that occurs on this Endpoint. System software must initialize each transaction description in an iTD to ensure it uses the correct portion of the client buffer. For example, for each transaction description, the PG field is set to index the correct physical buffer page pointer and the Transaction Offset field is set relative to the correct buffer pointer page (for example, the same one referenced by the PG field). When the host controller executes a transaction it selects a transaction description record based on FRINDEX[2-0]. It then uses the current Page Buffer Pointer (as selected by the PG field) and concatenates to the transaction offset field. The result is a starting buffer address for the transaction. As the host controller moves data for the transaction, it must watch for a page wrap condition and properly advance to the next available Page Buffer Pointer. System software must not use the Page 6 buffer pointer in a transaction description where the length of the transfer will wrap a page boundary. Doing so yields undefined behavior. The host controller hardware is not required to alias the page selector to page zero. USB 2.0 isochronous Endpoints can specify a period greater than one. Software can achieve the appropriate scheduling by linking iTDs into the appropriate frames (relative to the frame list) and by setting appropriate transaction description elements active bits to a one.

16.7.8.2.1 Periodic scheduling threshold

The isochronous scheduling threshold field in the HCCPARAMS capability register is an indicator to system software as to how the host controller pre-fetches and effectively caches schedule data structures.

It is used by system software when adding isochronous work items to the periodic schedule. The value of this field indicates to system software the minimum distance it can update isochronous data (relative to the current location of the host controller execution in the periodic list) and still have the host controller process them.

The iTD and siTD data structures each describe 8 microframes worth of transactions. The host controller is allowed to cache one (or more) of these data structures in order to reduce memory traffic. There are three basic caching models that account for the fact the isochronous data structures span 8 microframes. The three caching models are: no caching, microframe caching and frame caching.

When software is adding new isochronous transactions to the schedule, it always performs a read of the FRINDEX register to determine the current frame and microframe the host controller is currently executing. Of course, there is no information about where in the microframe the host controller is, so a constant uncertainty factor of one microframe has to be assumed. Combining the knowledge of where the host controller is executing with the knowledge of the caching model allows the definition of simple algorithms for how closely software can reliably work to the executing host controller.

No caching is indicated with a value of zero in the isochronous scheduling threshold field. The host controller may pre-fetch data structures during a periodic schedule traversal (per microframe) but will always dump any accumulated schedule state at the end of the microframe. At the appropriate time relative to the beginning of every microframe, the host controller always begins schedule traversal from the frame list. Software can use the value of the FRINDEX register (plus the constant 1 uncertainty-factor) to determine the approximate position of the executing host controller. When no caching is selected, software can add an isochronous transaction as near as 2 microframes in front of the current executing position of the host controller.

Frame caching is indicated with a non-zero value in bit [7] of the isochronous scheduling threshold field. In the frame-caching model, system software assumes that the host controller caches one (or more) isochronous data structures for an entire frame (8 microframes). Software uses the value of the FRINDEX register (plus the constant 1 uncertainty) to determine the current microframe/frame (assume modulo 8 arithmetic in adding the constant 1 to the microframe number). For any current frame N, if the current microframe is 0 to 6, then software can safely add isochronous transactions to Frame N + 1. If the current microframe is 7, then software can add isochronous transactions to Frame N + 2.

Microframe caching is indicated with a non-zero value in the least-significant 3 bits of the isochronous scheduling threshold field. System software assumes the host controller caches one or more periodic data structures for the number of microframes indicated in theisochronous scheduling threshold field. For example, if the count value were 2, then the host controller keeps a window of two microframes worth of state (current microframe, plus the next) on chip. On each microframe boundary, the host controller releases the current microframe state and begins accumulating the next microframe state.

16.7.9 Asynchronous schedule

The asynchronous schedule traversal is enabled or disabled through USBCMD[ASE] (asynchronous schedule enable).

If USBCMD[ASE] is cleared, then the host controller simply does not try to access the asynchronous schedule via the ASYNCLISTADDR register. Likewise, if USBCMD[ASE] is set, the host controller does use the ASYNCLISTADDR register to traverse the asynchronous schedule. Modifications to USBCMD[ASE] are not necessarily immediate. Rather the new value of the bit will only be taken into consideration the next time the host controller needs to use the value of the ASYNCLISTADDR register to get the next queue head.

USBSTS[AS] indicates status of the asynchronous schedule. System software enables (or disables) the asynchronous schedule by writing a one (or zero) to USBCMD[ASE]. Software then can poll USBSTS[AS] to determine when the asynchronous schedule has made the desired transition. Software must not modify USBCMD[ASE] unless the value of USBCMD[ASE] equals that of the USBSTS[AS] (asynchronous schedule status).

The asynchronous schedule is used to manage all Control and Bulk transfers. Control and Bulk transfers are managed using queue head data structures. The asynchronous schedule is based at the ASYNCLISTADDR register. The default value of the ASYNCLISTADDR register after reset is undefined and the schedule is disabled when USBCMD[ASE] is cleared.

Software may only write this register with defined results when the schedule is disabled, for example, USBCMD[ASE] and the USBSTS[AS] are cleared. System software enables execution from the asynchronous schedule by writing a valid memory address (of a queue head) into this register. Then software enables the asynchronous schedule by setting USBCMD[ASE]. The asynchronous schedule is actually enabled when USBSTS[AS] is set.

When the host controller begins servicing the asynchronous schedule, it begins by using the value of the ASYNCLISTADDR register. It reads the first referenced data structure and begins executing transactions and traversing the linked list as appropriate. When the host controller completes processing the asynchronous schedule, it retains the value of the last accessed queue head's horizontal pointer in the ASYNCLISTADDR register. Next time the asynchronous schedule is accessed, this is the first data structure that is serviced. This provides round-robin fairness for processing the asynchronous schedule.

A host controller completes processing the asynchronous schedule when one of the following events occurs:

- The end of a microframe occurs.
- The host controller detects an empty list condition
- The schedule has been disabled through USBCMD[ASE].

The queue heads in the asynchronous list are linked into a simple circular list as shown in Figure 16-5. Queue head data structures are the only valid data structures that may be linked into the asynchronous schedule. An isochronous transfer descriptor (iTD or siTD) in the asynchronous schedule yields undefined results.

The maximum packet size field in a queue head is sized to accommodate the use of this data structure for all non-isochronous transfer types. The USB Specification, Revision 2.0 specifies the maximum packet sizes for all transfer types and transfer speeds. System software should always parameterize the queue head data structures according to the core specification requirements.

16.7.9.1 Adding queue heads to asynchronous schedule

This is a software requirement section. There are two independent events for adding queue heads to the asynchronous schedule.

The first is the initial activation of the asynchronous list. The second is inserting a new queue head into an activated asynchronous list.

Activation of the list is simple. System software writes the physical memory address of a queue head into the ASYNCLISTADDR register, then enables the list by setting USBCMD[ASE] to a one.

When inserting a queue head into an active list, software must ensure that the schedule is always coherent from the host controllers' point of view. This means that the system software must ensure that all queue head pointer fields are valid. For example qTD pointers have T-Bits set or reference valid qTDs and the Horizontal Pointer references a valid queue head data structure. The following algorithm represents the functional requirements:

```
InsertQueueHead (pQHeadCurrent, pQueueHeadNew)
--

-- Requirement: all inputs must be properly initialized.

--

-- pQHeadCurrent is a pointer to a queue head that is

-- already in the active list

-- pQHeadNew is a pointer to the queue head to be added

--

-- This algorithm links a new queue head into a existing

-- list

--

pQueueHeadNew.HorizontalPointer = pQueueHeadCurrent.HorizontalPointer

pQueueHeadCurrent.HorizontalPointer = physicalAddressOf(pQueueHeadNew)
End InsertQueueHead
```

16.7.9.2 Removing queue heads from asynchronous schedule

This is a software requirement section.

There are two independent events for removing queue heads from the asynchronous schedule.

The first is shutting down (deactivating) the asynchronous list. The second is extracting a single queue head from an activated list. Software deactivates the asynchronous schedule by setting USBCMD[ASE] to a zero. Software can determine when the list is idle when USBSTS[AS] is cleared. The normal mode of operation is that software removes queue heads from the asynchronous schedule without shutting it down. Software must not remove an active queue head from the schedule. Software should first deactivate all active qTDs, wait for the queue head to go inactive, and then remove the queue head from the asynchronous list. Software removes a queue head from the asynchronous list using the following algorithm. Software merely must ensure all of the link pointers reachable by the host controller are kept consistent.

```
UnlinkQueueHead (pQHeadPrevious, pQueueHeadToUnlink, pQHeadNext)
--
-- Requirement: all inputs must be properly initialized.
--
-- pQHeadPrevious is a pointer to a queue head that
-- references the queue head to remove
-- pQHeadToUnlink is a pointer to the queue head to be
-- removed
-- pQheadNext is a pointer to a queue head still in the
-- schedule. Software provides this pointer with the
-- following strict rules:
-- if the host software is one queue head, then
-- pQHeadNext must be the same as
-- QueueheadToUnlink.HorizontalPointer. If the host
-- software is unlinking a consecutive series of
-- queue heads, QHeadNext must be set by software to
-- the queue head remaining in the schedule.
--
-- This algorithm unlinks a queue head from a circular list
--
pQueueHeadPrevious.HorizontalPointer = pQueueHeadToUnlink.HorizontalPointer

pQueueHeadToUnlink.HorizontalPointer = pQHeadNext
End UnlinkQueueHead
```

If software removes the queue head with the H-bit set, it must select another queue head still linked into the schedule and set it's H-bit. This should be completed before removing the queue head. The requirement is that software keep one queue head in the asynchronous schedule, with it's H-bit set. At the point software has removed one or more queue heads from the asynchronous schedule, it is unknown whether the host

controller has a cached pointer to them. Similarly, it is unknown how long the host controller might retain the cached information, as it is implementation dependent and may be affected by the actual dynamics of the schedule load. Therefore, once software has removed a queue head from the asynchronous list, it must retain the coherency of the queue head (link pointers). It cannot disturb the removed queue heads until it knows that the host controller does not have a local copy of a pointer to any of the removed data structures.

The method software uses to determine when it is safe to modify a removed queue head is to handshake with the host controller. The handshake mechanism allows software to remove items from the asynchronous schedule, then execute a simple, lightweight handshake that is used by software as a key that it can free (or reuse) the memory associated the data structures it has removed from the asynchronous schedule.

The handshake is implemented with three bits in the host controller. The first bit is a command bit (USBCMD[IAA]-interrupt on async advance doorbell) that allows software to inform the host controller that something has been removed from it's asynchronous schedule. The second bit is a status bit (USBSTS[AAI]-interrupt on async advance) that the host controller sets after it has released all on-chip state that may potentially reference one of the data structures just removed. When the host controller sets this status bit, it also clears the command bit. The third bit is an interrupt enable (USBINTR[AAE]-interrupt on async advance enable) that is matched with the status bit. If the status bit is set and the interrupt enable bit is set, then the host controller asserts a hardware interrupt.

The figure below illustrates a general example where consecutive queue heads (B and C) are unlinked from the schedule using the algorithm above. Before the unlink operation, the host controller has a copy of queue head A.

The unlink algorithm requires that as software unlinks each queue head, the unlinked queue head is loaded with the address of a queue head that will remain in the asynchronous schedule.

When the host controller observes that doorbell bit being set, it makes a note of the local reachable schedule information. In this example, the local reachable schedule information includes both queue heads (A & B). It is sufficient that the host controller can set the status bit (and clear the doorbell bit) as soon as it has traversed beyond current reachable schedule information (that is, traversed beyond queue head (B) in this example).

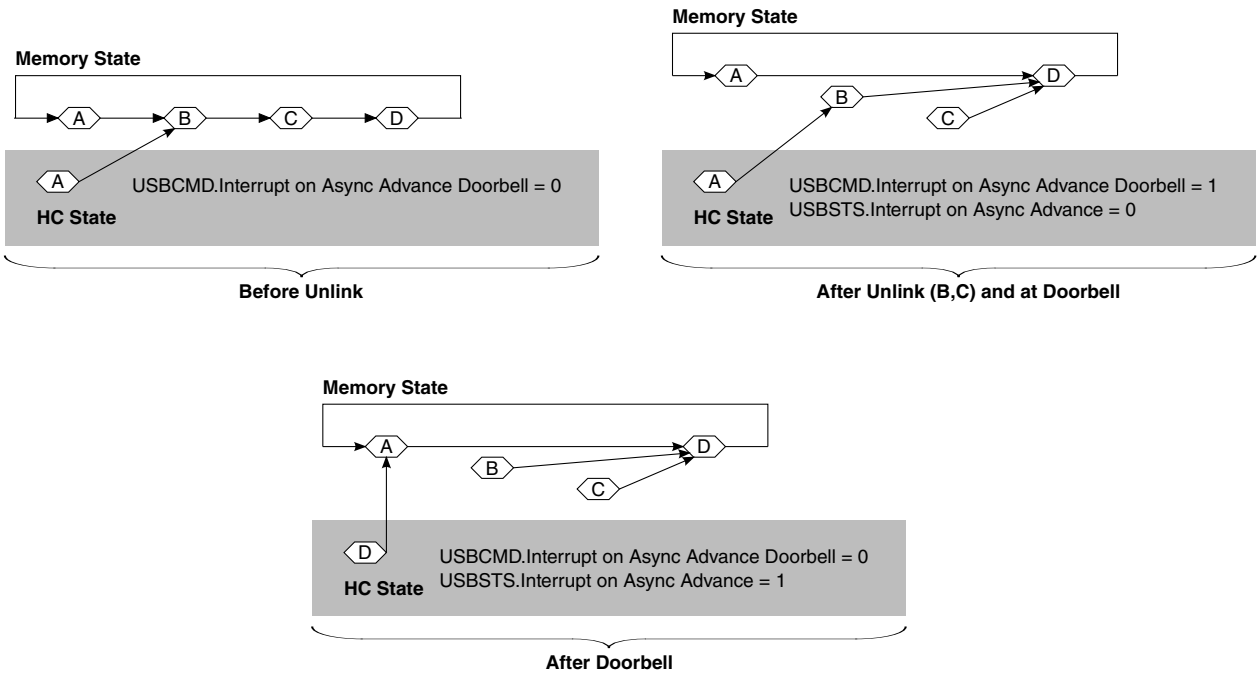

Figure 16-10. Generic queue head unlink scenario

Alternatively, a host controller implementation is allowed to traverse the entire asynchronous schedule list (for example, observed the head of the queue (twice)) before setting USBSTS[AAI].

Software may re-use the memory associated with the removed queue heads after it observes USBSTS[AAI] is set, following assertion of the doorbell. Software should acknowledge the interrupt on async advance status as indicated in the USBSTS register, before using the doorbell handshake again

16.7.9.3 Empty asynchronous schedule detection

EHCI uses two bits to detect when the asynchronous schedule is empty.

The queue head data structure (see Table 16-26) defines an H-bit in the queue head, which allows software to mark a queue head as being the head of the reclaim list. Host controller also keeps a 1-bit flag in the USBSTS register (Reclamation) that is cleared when the host controller observes a queue head with the H-bit set. The reclamation flag in the status register is set when any USB transaction from the asynchronous schedule is executed (or whenever the asynchronous schedule starts, see Asynchronous schedule traversal: Start event.

If the controller ever encounters an H-bit of one and a Reclamation bit of zero, the controller simply stops traversal of the asynchronous schedule.

The figure below shows an example illustrating the H-bit in a schedule.

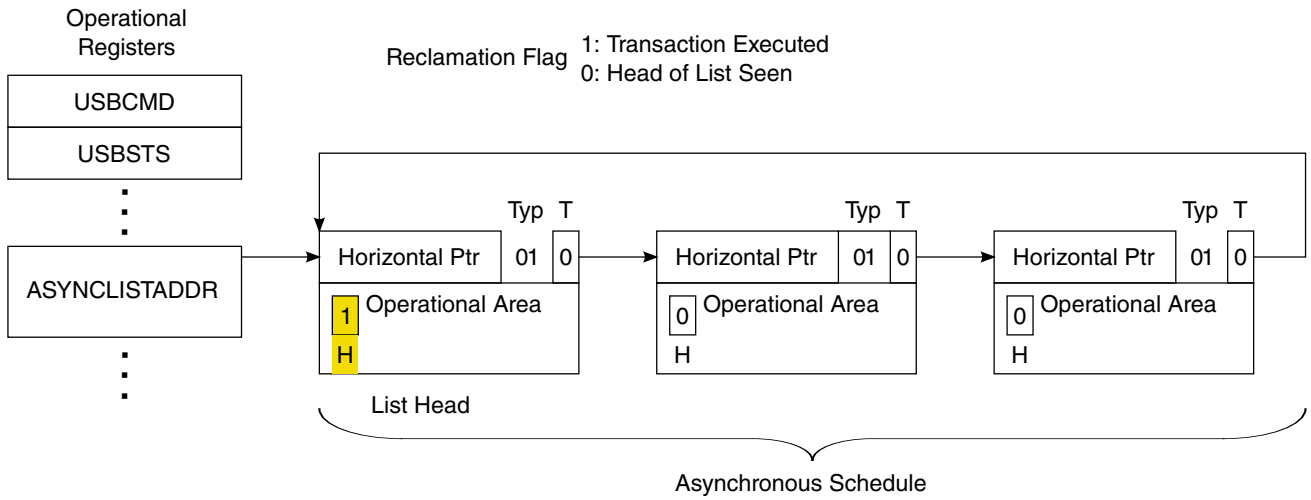

Figure 16-11. Asynchronous schedule list with annotation to mark head of list

16.7.9.4 Asynchronous schedule traversal: Start event

Once the host controller has idled itself using the empty schedule detection, it naturally activates and begins processing from the Periodic Schedule at the beginning of each microframe.

In addition, it may have idled itself early in a microframe. When this occurs (idles early in the microframe) the host controller must occasionally reactivate during the microframe and traverse the asynchronous schedule to determine whether any progress can be made. Asynchronous schedule Start Events are defined to be:

- Whenever the host controller transitions from the periodic schedule to the asynchronous schedule. If the periodic schedule is disabled and the asynchronous schedule is enabled, then the beginning of the microframe is equivalent to the transition from the periodic schedule, or
- The asynchronous schedule traversal restarts from a sleeping state.

16.7.9.5 Reclamation status bit (USBSTS Register)

The operation of the empty asynchronous schedule detection feature depends on the proper management of the Reclamation bit (RCL) in the USBSTS register.

The host controller tests for an empty schedule just after it fetches a new queue head while traversing the asynchronous schedule. The host controller sets USBSTS[RCL] whenever an asynchronous schedule traversal Start Event occurs. USBSTS[RCL] is also set whenever the host controller executes a transaction while traversing the asynchronous schedule.The host controller clears USBSTS[RCL] whenever it finds a queue head with its H-bit set. Software should only set a queue head's H-bit if the queue head is in the asynchronous schedule. If software sets the H-bit in an interrupt queue head, the resulting behavior is undefined. The host controller may clear USBSTS[RCL] when executing from the periodic schedule.

16.7.10 Managing control/bulk/interrupt transfers via queue heads

This section presents an overview of how the host controller interacts with queuing data structures.

Queue heads use the Queue Element Transfer Descriptor (qTD) structure defined in Queue element transfer descriptor (qTD).

One queue head is used to manage the data stream for one Endpoint. The queue head structure contains static Endpoint characteristics and capabilities. It also contains a working area from where individual bus transactions for an Endpoint are executed. Each qTD represents one or more bus transactions, which is defined in the context of the EHCI specification as a transfer.

The general processing model for the host controller's use of a queue head is simple:

- Read a queue head,
- Execute a transaction from the overlay area,
- Write back the results of the transaction to the overlay area
- Move to the next queue head.

If the host controller encounters errors during a transaction, the host controller will set one of the error reporting bits in the queue head's Status field. The Status field accumulates all errors encountered during the execution of a qTD (that is, the error bits in the queue head Status field are sticky until the transfer (qTD) has completed). This state is always written back to the source qTD when the transfer is complete. On transfer (for example, buffer or halt conditions) boundaries, the host controller must auto-advance (without software intervention) to the next qTD. Additionally, the hardware must be able to halt the queue so no additional bus transactions will occur for the Endpoint and the host controller will not advance the queue.

16.7.10.1 Buffer pointer list use for data streaming with qTDs

A qTD has an array of buffer pointers, which is used to reference the data buffer for a transfer.

The EHCI specification requires that the buffer associated with the transfer be virtually contiguous. This means that if the buffer spans more than one physical page, it must obey the following rules:

- The first portion of the buffer must begin at some offset in a page and extend through the end of the page.
- The remaining buffer cannot be allocated in small chunks scattered around memory. For each 4K chunk beyond the first page, each buffer portion matches to a full 4K page. The final portion, which may only be large enough to occupy a portion of a page, must start at the top of the page and be contiguous within that page.

The figure below illustrates these requirements.

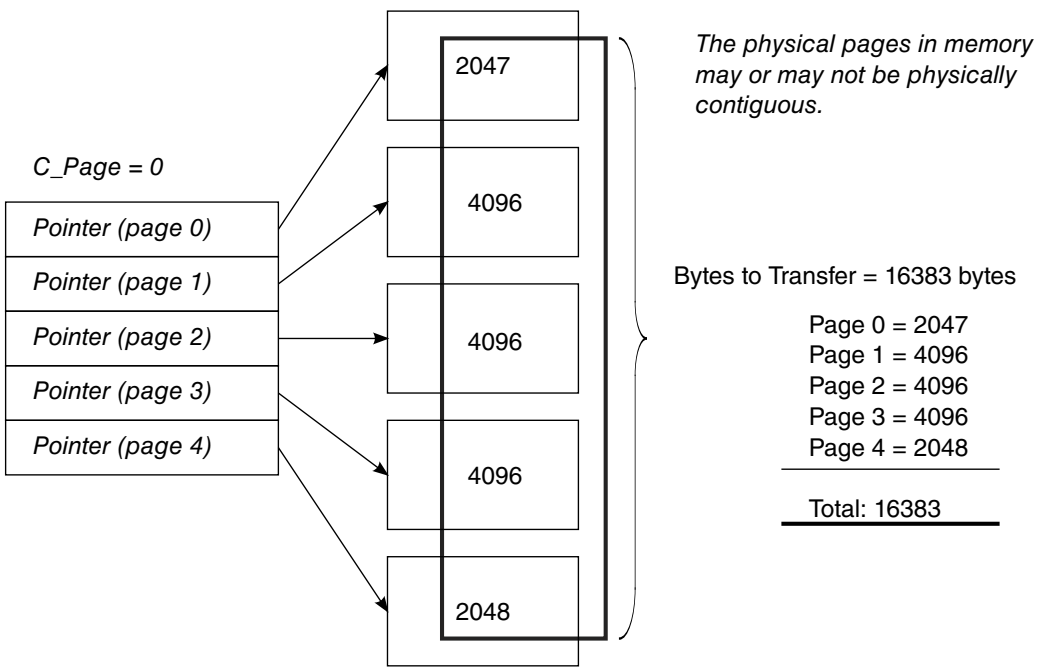

Figure 16-12. Example mapping of qTD buffer pointers to buffer pages

The buffer pointer list in the qTD is long enough to support a maximum transfer size of 20K bytes. This case occurs when all five buffer pointers are used and the first offset is zero. A qTD handles a 16Kbyte buffer with any starting buffer alignment.

The host controller uses the C_Page field as an index value to determine which buffer pointer in the list should be used to start the current transaction. The host controller uses a different buffer pointer for each physical page of the buffer. This is always true, even if the buffer is physically contiguous.

The host controller must detect when the current transaction spans a page boundary and automatically move to the next available buffer pointer in the page pointer list. The next available pointer is reached by incrementing C_Page and pulling the next page pointer from the list. Software must ensure there are sufficient buffer pointers to move the amount of data specified in the Bytes to Transfer field.

The figure above illustrates a nominal example of how System software would initialize the buffer pointers list and the C_Page field for a transfer size of 16383 bytes. C_Page is cleared. The upper 20-bits of Page 0 references the start of the physical page. Current Offset (the lower 12-bits of queue head Dword 7) holds the offset in the page for example, 2049 (for example, 4096-2047). The remaining page pointers are set to reference the beginning of each subsequent 4K page.

For the first transaction on the qTD (assuming a 512-byte transaction), the host controller uses the first buffer pointer (page 0 because C_Page is cleared) and concatenates the Current Offset field. The 512 bytes are moved during the transaction, the Current Offset and Total Bytes to Transfer are adjusted by 512 and written back to the queue head working area.

During the 4th transaction, the host controller needs 511 bytes in page 0 and one byte in page 1. The host controller will increment C_Page (to 1) and use the page 1 pointer to move the final byte of the transaction. After the 4th transaction, the active page pointer is the page 1 pointer and Current Offset has rolled to one, and both are written back to the overlay area. The transactions continue for the rest of the buffer, with the host controller automatically moving to the next page pointer (that is, C_Page) when necessary. There are three conditions for how the host controller handles C_Page.

- The current transaction does not span a page boundary. The value of C_Page is not adjusted by the host controller.
- The current transaction does span a page boundary. The host controller must detect the page cross condition and advance to the next buffer while streaming data to/from the USB.
- The current transaction completes on a page boundary (that is, the last byte moved for the current transaction is the last byte in the page for the current page pointer). The host controller must increment C_Page before writing back status for the transaction.

Note that the only valid adjustment the host controller may make to C_Page is to increment by one.

16.7.10.2 Adding interrupt queue heads to the periodic schedule

The link path(s) from the periodic frame list to a queue head establishes in which frames a transaction can be executed for the queue head.

Queue heads are linked into the periodic schedule so they are polled at the appropriate rate. System software sets a bit in a queue head's S-Mask to indicate which microframe within a 1 millisecond period a transaction should be executed for the queue head. Software must ensure that all queue heads in the periodic schedule have S-Mask set to a non-zero value. An S-mask with a zero value in the context of the periodic schedule yields undefined results.

If the desired poll rate is greater than one frame, system software can use a combination of queue head linking and S-Mask values to spread interrupts of equal poll rates through the schedule so that the periodic bandwidth is allocated and managed in the most efficient manner possible. Some examples are illustrated in the table below.

Table 16-37. Example periodic reference patterns for interrupt transfers

Frame # reference sequence	Description
0, 2, 4, 6, 8, ... S-Mask = 0x01	A queue head for the bInterval of 2 milliseconds (16 microframes) is linked into the periodic schedule so that it is reachable from the periodic frame list locations indicated in the previous column. In addition, the S-Mask field in the queue head is set to 0x01, indicating that the transaction for the Endpoint should be executed on the bus during microframe 0 of the frame.
0, 2, 4, 6, 8, ... S-Mask = 0x02	Another example of a queue head with a bInterval of 2 milliseconds is linked into the periodic frame list at exactly the same interval as the previous example. However, the S-Mask is set to 0x02 indicating that the transaction for the Endpoint should be executed on the bus during microframe 1 of the frame.

16.7.10.3 Managing transfer complete interrupts from queue heads

The host controller sets an interrupt to be signaled at the next interrupt threshold when the completed transfer (qTD) has an Interrupt on Complete (IOC) bit set, or whenever a transfer (qTD) completes with a short packet.

If system software needs multiple qTDs to complete a client request (that is, like a control transfer) the intermediate qTDs do not require interrupts. System software may only need a single interrupt to notify it that the complete buffer has been transferred. System software may set IOC's to occur more frequently. A motivation for this may be that it wants early notification so that interface data structures can be re-used in a timely manner.

16.7.11 Ping control

USB 2.0 defines an addition to the protocol for high-speed devices called Ping.

Ping is required for all USB 2.0 High-speed bulk and control Endpoints. Ping is not allowed for a split-transaction stream. This extension to the protocol eliminates the bad side-effects of Naking OUT Endpoints. The Status field has a Ping State bit, which the host controller uses to determine the next actual PID it will use in the next transaction to the Endpoint (see Table 16-24). The Ping State bit is only managed by the host controller for queue heads that meet all of the following criteria:

- The queue head is not an interrupt
- The EPS field equals High-Speed
- The PIDCode field equals OUT

The table below illustrates the state transition table for the host controller's responsibility for maintaining the PING protocol. Refer to Chapter 8 in the *USB Specification, Revision 2.0* for detailed description on the Ping protocol.

Table 16-38. Ping control state transition table

	Event		
Current	**Host**	**Device**	**Next**
Do Ping	PING	Nak	Do Ping
Do Ping	PING	Ack	Do OUT
Do Ping	PING	XactErr[1]	Do Ping
Do Ping	PING	Stall	N/C[2]
Do OUT	OUT	Nak	Do Ping
Do OUT	OUT	Nyet	Do Ping[3]
Do OUT	OUT	Ack	Do OUT
Do OUT	OUT	XactErr[1]	Do Ping
Do OUT	OUT	Stall	N/C[2]

1. Transaction Error (XactErr) is any time the host misses the handshake.
2. No transition change required for the Ping State bit. The Stall handshake results in the Endpoint being halted (for example, Active cleared and Halt set). Software intervention is required to restart queue.
3. A Nyet response to an OUT means that the device has accepted the data, but cannot receive any more at this time. Host must advance the transfer state and additionally, transition the Ping State bit to Do Ping.

The Ping State bit is described in Table 16-24. The defined ping protocol allows the host to be imprecise on the initialization of the ping protocol (that is, start in Do OUT when there is uncertainty about the space in the device). The host controller manages the Ping State bit. System software sets the initial value in the queue head when it initializes a

queue head. The host controller preserves the Ping State bit across all queue advancements. This means that when a new qTD is written into the queue head overlay area, the previous value of the Ping State bit is preserved.

NOTE

For high-speed bulk and control Endpoints, a host controller queries the high-speed device Endpoint with a special ping token to determine whether the device has sufficient space for the next OUT transaction. The mechanism avoids using bus time to send data until the host controller knows that the Endpoint has space for the data. If a timeout occurs after the data phase of an OUT transaction, the host controller fails to enter the ping state and instead retries the OUT token again.

The Ping flow control for the high-speed devices does not work under this condition. Therefore, some USB bandwidth could be wasted. However, NAK response to PING token or timeout is expected to be an unusual occurrence. A high-speed bulk/ control Endpoint must specify its maximum NAK rate in its Endpoint descriptor. The Endpoint is allowed to NAK at most one time each micro-frame period.

16.7.12 Split transactions

USB 2.0 defines extensions to the bus protocol for managing USB 1.x data streams through USB 2.0 hubs. This section describes how the host controller uses the interface data structures to manage data streams with full- and low-speed devices, connected below a USB 2.0 hub, utilizing the split transaction protocol. Refer to the USB 2.0 Specification for the complete definition of the split transaction protocol.

Full- and low-speed devices are enumerated identically as high-speed devices, but the transactions to the full- and low-speed Endpoints use the split-transaction protocol on the high-speed bus.

The split transaction protocol is an encapsulation of (or wrapper around) the full- or low-speed transaction. The high-speed wrapper portion of the protocol is addressed to the USB 2.0 hub and transaction translator below which the full- or low-speed device is attached.

EHCI uses dedicated data structures for managing full-speed isochronous data streams. Control, Bulk and Interrupt are managed using the queuing data structures. The interface data structures need to be programmed with the device address and the transaction

translator number of the USB 2.0 hub operating as the low-/full-speed host controller for this link. The following sections describe the details of how the host controller processes and manages the split transaction protocol.

16.7.12.1 Split transactions for asynchronous transfers

A queue head in the asynchronous schedule with an EPS field indicating a full-or low-speed device indicates to the host controller that it must use split transactions to stream data for this queue head.

All full-speed bulk and full-, low-speed control are managed via queue heads in the asynchronous schedule.

Software must initialize the queue head with the appropriate device address and port number for the transaction translator that is serving as the full-/low-speed host controller for the links connecting the Endpoint. Software must also initialize the split transaction state bit (SplitXState) to Do-Start-Split. Finally, if the Endpoint is a control Endpoint, then system software must set the Control Transfer Type (C) bit in the queue head to a one. If this is not a control transfer type Endpoint, the C bit must be initialized by software to be a zero. This information is used by the host controller to properly set the Endpoint Type (ET) field in the split transaction bus token. When the C bit is a zero, the split transaction token's ET field is set to indicate a bulk Endpoint. When the C bit is a one, the split transaction token's ET field is set to indicate a control Endpoint. Refer to Chapter 8 of *USB Specification, Revision 2.0* for details.

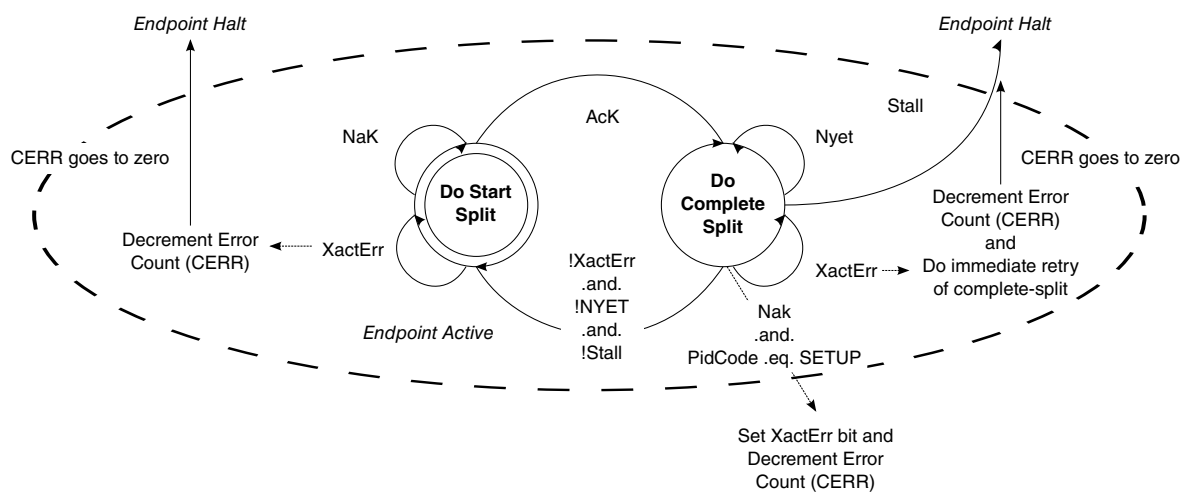

Figure 16-13. Host controller asynchronous schedule split-transaction state machine

16.7.12.1.1 Asynchronous-do-start-split

Do-start-split is the state which software must initialize a full- or low-speed asynchronous queue head.

This state is entered from the Do-Complete-Split state only after a complete-split transaction receives a valid response from the transaction translator that is not a Nyet handshake.

For queue heads in this state, the host controller executes a start-split transaction to the transaction translator. If the bus transaction completes without an error and PID Code indicates an IN or OUT transaction, then the host controller reloads the error counter (Cerr). If it is a successful bus transaction and the PID Code indicates a SETUP, the host controller will not reload the error counter. If the transaction translator responds with a Nak, the queue head is left in this state, and the host controller proceeds to the next queue head in the asynchronous schedule.

If the host controller times out the transaction (no response, or bad response) the host controller decrements Cerr and proceeds to the next queue head in the asynchronous schedule.

16.7.12.1.2 Asynchronous-do-complete-split

This state is entered from the Do-Start-Split state only after a start-split transaction receives an Ack handshake from the transaction translator.

For queue heads in this state, the host controller executes a complete-split transaction to the transaction translator. If the transaction translator responds with a Nyet handshake, the queue head is left in this state, the error counter is reset and the host controller proceeds to the next queue head in the asynchronous schedule. When a Nyet handshake is received for a bus transaction where the queue head's PID Code indicates an IN or OUT, the host controller reloads the error counter (Cerr). When a Nyet handshake is received for a complete-split bus transaction where the queue head's PID Code indicates a SETUP, the host controller must not adjust the value of Cerr.

Independent of PID Code, the following responses have the indicated effects:

- Transaction Error (XactErr). Timeout/data CRC failure. The error counter (Cerr) is decremented by one and the complete split transaction is immediately retried (if possible). If there is not enough time in the microframe to execute the retry, the host controller ensures that the next time the host controller begins executing from the Asynchronous schedule, it must begin executing from this queue head. If another start-split (for some other Endpoint) is sent to the transaction translator before the complete-split is really completed, the transaction translator could dump the results (which were never delivered to the host). This is why the core specification states the

retries must be immediate. When the host controller returns to the asynchronous schedule in the next microframe, the first transaction from the schedule will be the retry for this Endpoint. If Cerr went to zero, the host controller halts the queue.

- NAK. The target Endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced and the state is exited. If the PID Code is a SETUP, then the Nak response is a protocol error. The XactErr status bit is set and the Cerr field is decremented.
- STALL. The target Endpoint responded with a STALL handshake. The host controller sets the halt bit in the status byte, retires the qTD but does not attempt to advance the queue.

If the PID Code indicates an IN, then any of following response is expected:

- DATA0/1. On reception of data, the host controller ensures the PID matches the expected data toggle and checks CRC. If the packet is good, the host controller advances the state of the transfer (for example, moves the data pointer by the number of bytes received, decrements the BytesToTransfer field by the number of bytes received, and toggles the dt bit). The host controller then exits this state. The response and advancement of transfer may trigger other processing events, such as retirement of the qTD and advancement of the queue.

  If the data sequence PID does not match the expected, the data is ignored, the transfer state is not advanced and this state is exited.

If the PID Code indicates an OUT/SETUP, then any of following response is expected:

- ACK. The target Endpoint accepted the data, so the host controller must advance the state of the transfer. The current offset field is incremented by maximum packet length or bytes to transfer, whichever is less. The bytes to transfer field is decremented by the same amount and the data toggle bit (dt) is toggled. The host controller then exits this state.

  Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue.

16.7.12.2 Split transaction interrupt

Split-transaction interrupt-IN/OUT Endpoints are managed using the same data structures used for high-speed interrupt Endpoints.

They both co-exist in the periodic schedule. Queue heads/qTDs offer the set of features required for reliable data delivery, which is characteristic to interrupt transfer types. The split-transaction protocol is managed completely within this defined functional transfer

framework. For example, for a high-speed Endpoint, the host controller will visit a queue head, execute a high-speed transaction (if criteria are met) and advance the transfer state (or not) depending on the results of the entire transaction. For low- and full-speed Endpoints, the details of the execution phase are different (that is, takes more than one bus transaction to complete), but the remainder of the operational framework is intact.

16.7.12.2.1 Split transaction scheduling mechanisms for interrupt

Full- and low-speed interrupt queue heads have an EPS field indicating full- or low-speed and have a non-zero S-mask field.

The host controller can detect this combination of parameters and assume the Endpoint is a periodic Endpoint. Low- and full-speed interrupt queue heads require the use of the split transaction protocol. The host controller sets the Endpoint Type (ET) field in the split token to indicate the transaction is an interrupt. These transactions are managed through a transaction translator's periodic pipeline. Software should not set these fields to indicate the queue head is an interrupt unless the queue head is used in the periodic schedule.

System software manages the per/transaction translator periodic pipeline by budgeting and scheduling exactly during which microframes the start-splits and complete-splits for each Endpoint will occur. The characteristics of the transaction translator are such that the high-speed transaction protocol must execute during explicit microframes, or the data or response information in the pipeline is lost. The figure below illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule and queue head data structure. The S and C_n labels indicate microframes where software can schedule start-splits and complete splits (respectively).

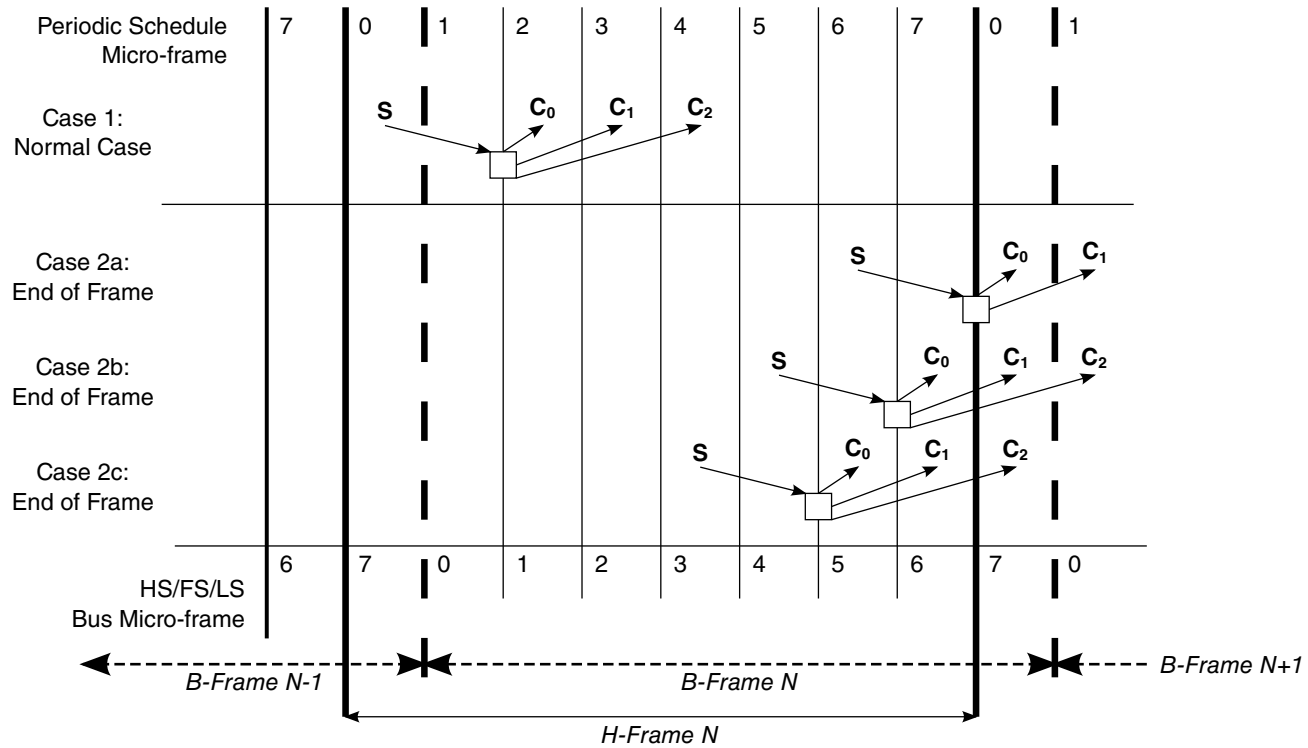

Figure 16-14. Split transaction, interrupt scheduling boundary conditions

The scheduling cases are:

- Case 1: The normal scheduling case is where the entire split transaction is completely bounded by a frame (H-Frame in this case).
- Case 2a through Case 2c: The USB 2.0 hub pipeline rules states clearly, when and how many complete-splits must be scheduled to account for earliest to latest execution on the full/low-speed link. The complete-splits may span the H-Frame boundary when the start-split is in microframe 4 or later. When this occurs, the H-Frame to B-Frame alignment requires that the queue head be reachable from consecutive periodic frame list locations. System software cannot build an efficient schedule that satisfies this requirement unless it uses FSTNs.

The figure below illustrates the general layout of the periodic schedule.

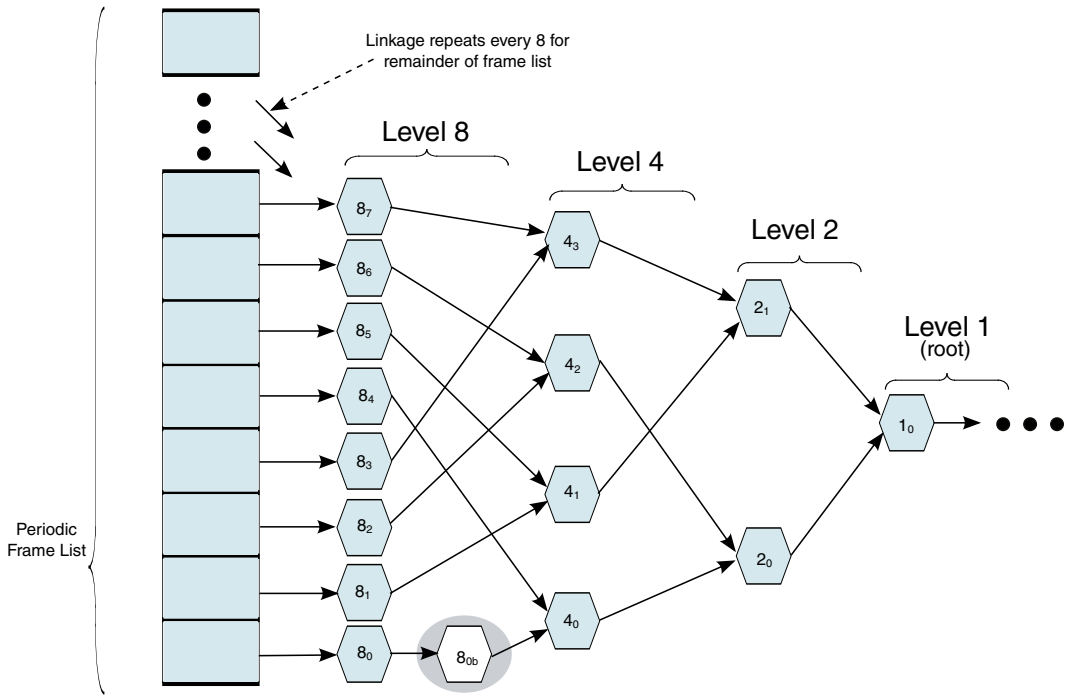

Figure 16-15. General structure of EHCI periodic schedule utilizing interrupt spreading

The periodic frame list is effectively the leaf level a binary tree, which is always traversed leaf to root. Each level in the tree corresponds to a 2^N poll rate. Software can efficiently manage periodic bandwidth on the USB by spreading interrupt queue heads that have the same poll rate requirement across all the available paths from the frame list. For example, system software can schedule eight poll rate 8 queue heads and account for them once in the high-speed bus bandwidth allocation.

When an Endpoint is allocated an execution footprint that spans a frame boundary, the queue head for the Endpoint must be reachable from consecutive locations in the frame list. An example would be if 8_{0b} were such an Endpoint. Without additional support on the interface, to get 8_{0b} reachable at the correct time, software would have to link 8_1 to 8_{0b}. It would then have to move 4_1 and everything linked after into the same path as 4_0. This upsets the integrity of the binary tree and disallows the use of the spreading technique.

FSTN data structures are used to preserve the integrity of the binary-tree structure and enable the use of the spreading technique. Periodic frame span traversal node (FSTN), defines the hardware and software operational model requirements for using FSTNs.

The following queue head fields are initialized by system software to instruct the host controller when to execute portions of the split-transaction protocol.

- SplitXState. This is a single bit residing in the Status field of a queue head (Table 16-24). This bit is used to track the current state of the split transaction.

- Frame S-mask. This is a bit-field where-in system software sets a bit corresponding to the microframe (within an H-Frame) that the host controller should execute a start-split transaction. This is always qualified by the value of the SplitXState bit in the Status field of the queue head. For example, referring to Figure 16-14, case one, the S-mask would have a value of 0b0000_0001 indicating that if the queue head is traversed by the host controller, and the SplitXState indicates Do_Start, and the current microframe as indicated by FRINDEX[2-0] is 0, then execute a start-split transaction.
- Frame C-mask. This is a bit-field where system software sets one or more bits corresponding to the microframes (within an H-Frame) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the SplitXState bit in the Status field of the queue head. For example, referring to Figure 16-14, case one, the C-mask would have a value of 0b0001_1100 indicating that if the queue head is traversed by the host controller, and the SplitXState indicates Do_Complete, and the current microframe as indicated by FRINDEX[2-0] is 2, 3, or 4, then execute a complete-split transaction. It is software's responsibility to ensure that the translation between H-Frames and B-Frames is correctly performed when setting bits in S-mask and C-mask.

16.7.12.2.2 Host controller operational model for FSTNs

The FSTN data structure is used to manage Low/Full-speed interrupt queue heads that need to be reached from consecutive frame list locations (that is, boundary cases 2a through 2c).

An FSTN is essentially a back pointer, similar in intent to the back pointer field in the siTD data structure.

This feature provides software a simple primitive to save a schedule position, redirect the host controller to traverse the necessary queue heads in the previous frame, then restore the original schedule position and complete normal traversal.

There are four components to the use of FSTNs:

- FSTN data structure, defined in Periodic frame span traversal node (FSTN).
- A Save Place indicator; this is always an FSTN with its Back Path Link Pointer[T] bit cleared.
- A Restore indicator; this is always an FSTN with its Back Path Link Pointer[T] bit set.
- Host controller FSTN traversal rules.

When the host controller encounters an FSTN during microframes 2 through 7 it simply follows the node's Normal Path Link Pointer to access the next schedule data structure. Note that the FSTN's Normal Path Link Pointer[T] bit may set, which the host controller must interpret as the end of periodic list mark.

When the host controller encounters a Save-Place FSTN in microframes 0 or 1, it saves the value of the Normal Path Link Pointer and sets an internal flag indicating that it is executing in Recovery Path mode. Recovery Path mode modifies the host controller's rules for how it traverses the schedule and limits which data structures are considered for execution of bus transactions. The host controller continues executing in Recovery Path mode until it encounters a Restore FSTN or it determines that it has reached the end of the microframe.

The rules for schedule traversal and limited execution while in Recovery Path mode are:

- Always follow the Normal Path Link Pointer when it encounters an FSTN that is a Save-Place indicator. The host controller must not recursively follow Save-Place FSTNs. Therefore, while executing in Recovery Path mode, it must never follow an FSTN's Back Path Link Pointer.
- Do not process an siTD or iTD data structure; simply follow its Next Link Pointer.
- Do not process a QH (Queue Head) whose EPS field indicates a high-speed device; simply follow its Horizontal Link Pointer.
- When a QH's EPS field indicates a Full/Low-speed device, the host controller only considers it for execution if its SplitXState is DoComplete (note: this applies whether the PID Code indicates an IN or an OUT). Refer to the *EHCI Specification* for a complete list of additional conditions that must be met in general for the host controller to issue a bus transaction. Note that the host controller must not execute a Start-split transaction while executing in Recovery Path mode. Refer to the *EHCI Specification* for special handling when in Recovery Path mode.
- Stop traversing the recovery path when it encounters an FSTN that is a Restore indicator. The host controller unconditionally uses the saved value of the Save-Place FSTN's Normal Path Link Pointer when returning to the normal path traversal. The host controller must clear the context of executing a Recovery Path when it restores schedule traversal to the Save-Place FSTN's Normal Path Link Pointer.

  If the host controller determines that there is not enough time left in the microframe to complete processing of the periodic schedule, it abandons traversal of the recovery path, and clears the context of executing a recovery path. The result is that at the start of the next consecutive microframe, the host controller starts traversal at the frame list.

An example traversal of a periodic schedule that includes FSTNs is illustrated in the figure below.

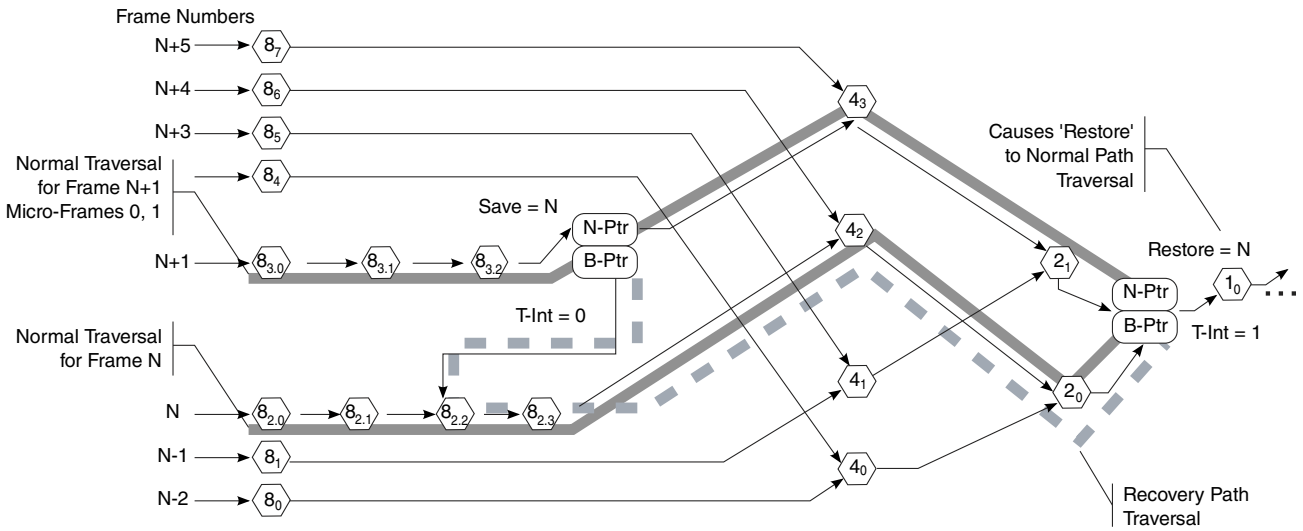

Figure 16-16. Example host controller traversal of recovery path via FSTNs

In frame N (microframes 0-7), for this example, the host controller traverses all of the schedule data structures utilizing the Normal Path Link Pointers in any FSTNs it encounters. This is because the host controller has not yet encountered a Save-Place FSTN so it is not executing in Recovery Path mode. When it encounters the Restore FSTN, (Restore-N), during microframes 0 and 1, it uses Restore-N. Normal Path Link Pointer to traverse to the next data structure (that is, normal schedule traversal). This is because the host controller must use a Restore FSTN's Normal Path Link Pointer when not executing in a Recovery-Path mode. The nodes traversed during frame N include: {$8_{2.0}$, $8_{2.1}$, $8_{2.2}$, $8_{2.3}$, 4_2, 2_0, Restore-N, 1_0 ...}.

In frame N+1 (microframes 0 and 1), when the host controller encounters Save-Path FSTN (Save-N), it observes that Save-N.Back Path Link Pointer.T-bit is zero (definition of a Save-Path indicator). The host controller saves the value of Save-N. Normal Path Link Pointer and follows Save-N.Back Path Link Pointer. At the same time, it sets an internal flag indicating that it is now in Recovery Path mode (the recovery path is annotated in the figure above with a large dashed line). The host controller continues traversing data structures on the recovery path and executing only those bus transactions as noted above, on the recovery path until it reaches Restore FSTN (Restore-N). Restore-N.Back Path Link Pointer.T-bit is set (definition of a Restore indicator), so the host controller exits Recovery Path mode by clearing the internal Recovery Path mode flag and commences (restores) schedule traversal using the saved value of the Save-Place FSTN's Normal Path Link Pointer (for example, Save-N.Normal Path Link Pointer). The nodes traversed during these microframes include: {$8_{3.0}$, $8_{3.1}$, $8_{3.2}$, Save-A, $8_{2.2}$, $8_{2.3}$, 4_2, 2_0, Restore-N, 4_3, 2_1, Restore-N, 10 ...}.

In frame N+1 (microframes 2-7), when the host controller encounters Save-Path FSTN Save-N, it unconditionally follows Save-N.Normal Path Link Pointer. The nodes traversed during these microframes include: {$8_{3.0}$, $8_{3.1}$, $8_{3.2}$, Save-A, 4_3, 2_1, Restore-N, 1_0 ...}.

16.7.12.2.3 Software operational model for FSTNs

Software must create a consistent, coherent schedule for the host controller to traverse.

When using FSTNs, system software must adhere to the following rules:

- Each Save-Place indicator requires a matching Restore indicator.

  The Save-Place indicator is an FSTN with a valid Back Path Link Pointer and T-bit equal to zero. Note that Back Path Link Pointer[Typ] field must be set to indicate the referenced data structure is a queue head. The Restore indicator is an FSTN with its Back Path Link Pointer[T] bit set.

  A Restore FSTN may be matched to one or more Save-Place FSTNs. For example, if the schedule includes a poll-rate 1 level, then system software only needs to place a Restore FSTN at the beginning of this list in order to match all possible Save-Place FSTNs.

- If the schedule does not have elements linked at a poll-rate level of one, and one or more Save-Place FSTNs are used, then System Software must ensure the Restore FSTN's Normal Path Link Pointer's T-bit is set, as this is used to mark the end of the periodic list.
- When the schedule does have elements linked at a poll rate level of one, a Restore FSTN must be the first data structure on the poll rate one list. All traversal paths from the frame list converge on the poll-rate one list. System software must ensure that Recovery Path mode is exited before the host controller is allowed to traverse the poll rate level one list.
- A Save-Place FSTN's Back Path Link Pointer must reference a queue head data structure. The referenced queue head must be reachable from the previous frame list location. In other words, if the Save-Place FSTN is reachable from frame list offset N, then the FSTN's Back Path Link Pointer must reference a queue head that is reachable from frame list offset N-1.

Software should make the schedule as efficient as possible. What this means in this context is that software should have no more than one Save-Place FSTN reachable in any single frame. Note there are times when two (or more, depending on the implementation) could exist as full-/low-speed footprints change with bandwidth adjustments. This could

occur, for example when a bandwidth rebalance causes system software to move the Save-Place FSTN from one poll rate level to another. During the transition, software must preserve the integrity of the previous schedule until the new schedule is in place.

16.7.12.2.4 Tracking split transaction progress for interrupt transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where data is lost.

For interrupt-IN transfers, data is lost when it makes it into the USB 2.0 hub, but the USB 2.0 host system is unable to get it from the USB 2.0 hub and into the system before it expires from the transaction translator pipeline. When a lost data condition is detected, the queue is halted, thus signaling system software to recover from the error. A data-loss condition exists whenever a start-split is issued, accepted and successfully executed by the USB 2.0 hub, but the complete-splits get unrecoverable errors on the high-speed link, or the complete-splits do not occur at the correct times. One reason complete-splits might not occur at the right time would be due to host-induced system hold-offs that cause the host controller to miss bus transactions because it cannot get timely access to the schedule in system memory.

The same condition can occur for an interrupt-OUT, but the result is not an Endpoint halt condition, but rather effects only the progress of the transfer. The queue head has the following fields to track the progress of each split transaction. These fields are used to keep incremental state about which (and when) portions have been executed.

- C-prog-mask. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the transaction translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. C-prog-mask is a simple bit-vector that the host controller sets one of the C-prog-mask bits for each complete-split executed. The bit position is determined by the microframe number in which the complete-split was executed. The host controller always checks C-prog-mask before executing a complete-split transaction. If the previous complete-splits have not been executed then it means one (or more) have been skipped and data has potentially been lost.
- FrameTag. This field is used by the host controller during the complete-split portion of the split transaction to tag the queue head with the frame number (H-Frame number) when the next complete split must be executed.
- S-bytes. This field can be used to store the number of data payload bytes sent during the start-split (if the transaction was an OUT). The S-bytes field must be used to accumulate the data payload bytes received during the complete-splits (for an IN).

16.7.12.2.5 Split transaction execution state machine for interrupt

In the following section, all references to microframe are in the context of a microframe within an H-Frame.

As with asynchronous full- and low-speed endpoints, a split-transaction state machine is used to manage the split transaction sequence. Aside from the fields defined in the queue head for scheduling and tracking the split transaction, the host controller calculates one internal mechanism that is also used to manage the split transaction. The internal calculated mechanism is:

- cMicroFrameBit. This is a single-bit encoding of the current microframe number. It is an eight-bit value calculated by the host controller at the beginning of every microframe. It is calculated from the three least significant bits of the FRINDEX register (that is, cMicroFrameBit = (1 shifted-left(FRINDEX[2-0]))). The cMicroFrameBit has at most one bit asserted, which always corresponds to the current microframe number. For example, if the current microframe is 0, then cMicroFrameBit will equal 0b0000_0001.

  The variable cMicroFrameBit is used to compare against the S-mask and C-mask fields to determine whether the queue head is marked for a start- or complete-split transaction for the current microframe.

The figure below illustrates how a complete interrupt split transaction is managed. There are two phases to each split transaction. The first is a single start-split transaction, which occurs when the SplitXState is at Do_Start and the single bit in cMicroFrameBit has a corresponding bit active in QH[S-mask]. The transaction translator does not acknowledge the receipt of the periodic start-split, so the host controller unconditionally transitions the state to Do_Complete. Due to the available jitter in the transaction translator pipeline, there is more than one complete-split transaction scheduled by software for the Do_Complete state. This translates simply to the fact that there are multiple bits set in the QH[C-mask] field.

The host controller keeps the queue head in the Do_Complete state until the split transaction is complete (see definition below), or an error condition triggers the three-strikes-rule (for example, after the host tries the same transaction three times, and each encounters an error, the host controller stops retrying the bus transaction and halts the endpoint, thus requiring system software to detect the condition and perform system-dependent recovery).

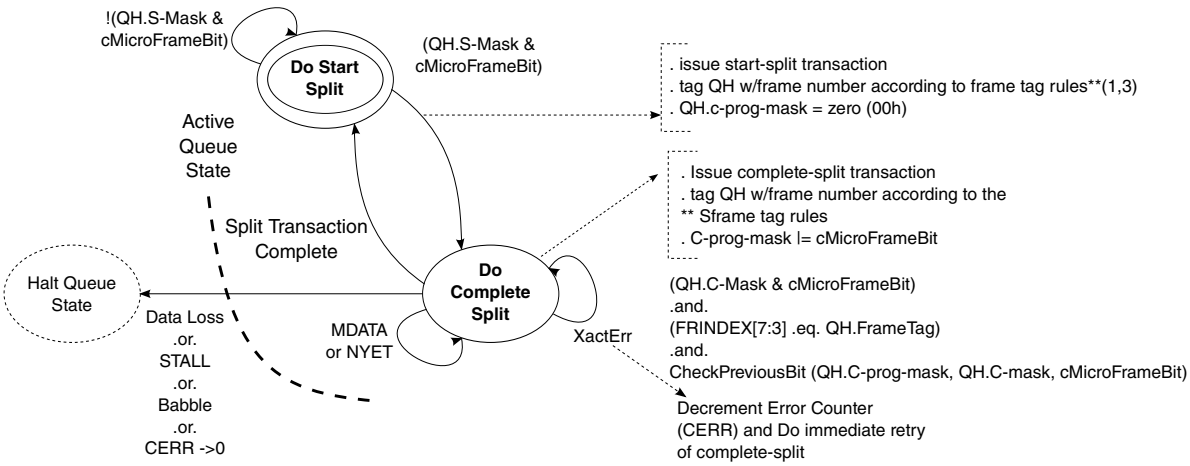

Figure 16-17. Split transaction state machine for interrupt

16.7.12.2.6 Periodic interrupt-do-start-split

This is the state when software must initialize a full- or low-speed interrupt queue head StartXState bit. This state is entered from the Do_Complete Split state only after the split transaction is complete.

This occurs when one of the following events occur: The transaction translator responds to a complete-split transaction with one of the following:

- NAK. A NAK response is a propagation of the full- or low-speed endpoint's NAK response.
- ACK. An ACK response is a propagation of the full- or low-speed endpoint's ACK response. Only occurs on an OUT endpoint.
- DATA 0/1. Only occurs for INs. Indicates that this is the last of the data from the endpoint for this split transaction.
- ERR. The transaction on the low-/full-speed link below the transaction translator had a failure (for example, timeout, bad CRC, and so on).
- NYET (and Last). The host controller issued the last complete-split and the transaction translator responded with a NYET handshake. This means that the start-split was not correctly received by the transaction translator, so it never executed a transaction to the full- or low-speed endpoint, see Periodic interrupt-do-complete-split , for the definition of 'Last'.

Each time the host controller visits a queue head in this state (once within the execute transaction state), bit-wise ANDs QH[S-mask] with cMicroFrameBit to determine whether to execute a start-split. If the result is non-zero, then the host controller issues a start-split transaction. If the PID Code field indicates an IN transaction, the host controller must zero-out the QH[S-bytes] field. After the split-transaction has been executed, the host controller sets up state in the queue head to track the progress of the

complete-split phase of the split transaction. Specifically, it records the expected frame number into QH[FrameTag] field, sets C-prog-mask to zero (0x00), and exits this state. Note that the host controller must not adjust the value of Cerr as a result of completion of a start-split transaction.

16.7.12.2.7 Periodic interrupt-do-complete-split

This state is entered unconditionally from the Do-Start-Split state after a start-split transaction is executed on the bus.

Each time the host controller visits a queue head in this state (once within the execute transaction state), it checks to determine whether a complete-split transaction should be executed now.

There are four tests to determine whether a complete-split transaction should be executed.

- Test A. cMicroFrameBit is bit-wise ANDed with QH[C-mask] field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this microframe.
- Test B. QH[FrameTag] is compared with the current contents of FRINDEX[7-3]. An equal indicates a match.
- Test C. The complete-split progress bit vector is checked to determine whether the previous bit is set, indicating that the previous complete-split was appropriately executed. An example algorithm for this test is provided below:

```
Algorithm Boolean CheckPreviousBit(QH.C-prog-mask, QH.C-mask, cMicroFrameBit)

Begin

-- Return values:

-- TRUE - no error

-- FALSE - error

--

Boolean rvalue = TRUE;

previousBit = cMicroframeBit logical-rotate-right(1)

-- Bit-wise anding previousBit with C-mask indicates

-- whether there was an intent

-- to send a complete split in the previous microframe. So,

-- if the

-- 'previous bit' is set in C-mask, check C-prog-mask to

-- make sure it

-- happened.

If (previousBit bitAND QH.C-mask)then
```

```
If not(previousBit bitAND QH.C-prog-mask) then
          rvalue = FALSE;
     End if
End If
-- If the C-prog-mask already has a one in this bit position,
-- then an aliasing
-- error has occurred. It will probably get caught by the
-- FrameTag Test, but
-- at any rate it is an error condition that as detectable here
-- should not allow
-- a transaction to be executed.
If (cMicroFrameBit bitAND QH.C-prog-mask) then
rvalue = FALSE;
End if
return (rvalue)
End Algorithm
```

- Test D. Check to see if a start-split should be executed in this microframe. Note this is the same test performed in the Do Start Split state. Whenever it evaluates to TRUE and the controller is NOT processing in the context of a Recovery Path mode, it means a start-split should occur in this microframe. Test D and Test A evaluating to TRUE at the same time is a system software error. Behavior is undefined.

If (Test A and B and C and not(D)) then the host controller will execute a complete-split transaction. When the host controller commits to executing the complete-split transaction, it updates QH[C-prog-mask] by bit-ORing with cMicroFrameBit. On completion of the complete-split transaction, the host controller records the result of the transaction in the queue head and sets QH[FrameTag] to the expected H-Frame number. The effect to the state of the queue head and thus the state of the transfer depends on the response by the transaction translator to the complete-split transaction. The following responses have the effects (note that any responses that result in decrementing of the Cerr will result in the queue head being halted by the host controller if the result of the decrement is zero):

- NYET (and Last)

  On each NYET response, the host controller checks to determine whether this is the last complete-split for this split transaction. Last is defined in this context as the condition where all of the scheduled complete-splits have been executed. If it is the last complete-split (with a NYET response), then the transfer state of the queue head is not advanced (never received any data) and this state exited. The transaction

translator must have responded to all the complete-splits with NYETs, meaning that the start-split issued by the host controller was not received. The start-split should be retried at the next poll period.

The test for whether this is the Last complete split can be performed by XOR QH[C-mask] with QH[C-prog-mask]. If the result is all zeros then all complete-splits have been executed. When this condition occurs, the XactErr status bit is set and the Cerr field is decremented.

- NYET (and not Last)

  See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for C-prog-mask and FrameTag) and stay in this state. The host controller must not adjust Cerr on this response.

- Transaction Error (XactErr). Timeout, data CRC failure, and so on

  The Cerr field is decremented and the XactErr bit in the Status field is set. The complete split transaction is immediately retried (if Cerr is non-zero). If there is not enough time in the microframe to complete the retry and the endpoint is an IN, or Cerr is decremented to a zero from a one, the queue is halted. If there is not enough time in the microframe to complete the retry and the endpoint is an OUT and Cerr is not zero, then this state is exited (that is, return to Do Start Split). This results in a retry of the entire OUT split transaction, at the next poll period. Refer to Chapter 11 Hubs (specifically the section on full- and low-speed interrupts) in the *USB Specification Revision 2.0* for detailed requirements on why these errors must be immediately retried.

- ACK

  This can only occur if the target endpoint is an OUT. The target endpoint ACK'd the data and this response is a propagation of the endpoint ACK up to the host controller. The host controller must advance the state of the transfer. The Current Offset field is incremented by Maximum Packet Length or Bytes to Transfer, whichever is less. The field Bytes To Transfer is decremented by the same amount. And the data toggle bit (dt) is toggled. The host controller will then exit this state for this queue head. The host controller must reload Cerr with maximum value on this response. Advancing the transfer state may cause other process events such as retirement of the qTD and advancement of the queue.

- MDATA

This response will only occur for an IN endpoint. The transaction translator responded with zero or more bytes of data and an MDATA PID. The incremental number of bytes received is accumulated in QH[S-bytes]. The host controller must not adjust Cerr on this response.

- DATA0/1

  This response may only occur for an IN endpoint. The number of bytes received is added to the accumulated byte count in QH[S-bytes]. The state of the transfer is advanced by the result and the host controller exits this state for this queue head.

  Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue.

  If the data sequence PID does not match the expected, the entirety of the data received in this split transaction is ignored, the transfer state is not advanced and this state is exited.

- NAK

  The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced, and this state is exited. The host controller must reload Cerr with maximum value on this response.

- ERR

  There was an error during the full- or low-speed transaction. The ERR status bit is set, Cerr is decremented, the state of the transfer is not advanced, and this state is exited.

- STALL

  The queue is halted (an exit condition of the Execute Transaction state). The status field bits: Active bit is cleared and the Halted bit is set and the qTD is retired. Responses which are not enumerated in the list or which are received out of sequence are illegal and may result in undefined host controller behavior. The other possible combinations of tests A, B, C, and D may indicate that data or response was lost. The table below lists the possible combinations and the appropriate action.

Table 16-39. Interrupt IN/OUT do complete split state execution criteria

Condition	Action	Description
not(A) not(D)	Ignore QHD	Neither a start nor complete-split is scheduled for the current microframe. Host controller should continue walking the schedule.

Table continues on the next page...

Table 16-39. Interrupt IN/OUT do complete split state execution criteria (continued)

Condition	Action	Description
A not(C)	If PIDCode = IN Halt QHDIf PIDCode = OUT Retry start-split	Progress bit check failed. These means a complete-split has been missed. There is the possibility of lost data. If PID Code is an IN, then the queue head must be halted. If PID Code is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect Cerr. In either case, set the Missed Microframe bit in the status field to a one.
A not(B) C	If PIDCode = IN Halt QHD If PIDCode = OUT Retry start-split	QH.FrameTag test failed. This means that exactly one or more H-Frames have been skipped. This means complete-splits and have missed. There is the possibility of lost data. If PID Code is an IN, then the queue head must be halted. If PID Code is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect Cerr. In either case, set the Missed Microframe bit in the status field to a one.
A B C not(D)	Execute complete-split	This is the non-error case where the host controller executes a complete-split transaction.
D	If PIDCode = IN Halt QHDIf PIDCode = OUT Retry start-split	This is a degenerate case where the start-split was issued, but all of the complete-splits were skipped and all possible intervening opportunities to detect the missed data failed to fire. If PID Code is an IN, then the Queue head must be halted. If PID Code is an OUT, then the transfer state is not advanced and the state exited (for example, start-split is retried). This is a host-induced error and does not effect Cerr. In either case, set the Missed Microframe bit in the status field to a one. Note that when executing in the context of a Recovery Path mode, the host controller is allowed to process the queue head and take the actions indicated above, or it may wait until the queue head is visited in the normal processing mode. Regardless, the host controller must not execute a start-split in the context of a executing in a Recovery Path mode.

16.7.12.2.8 Managing the QH[FrameTag] field

The QH[FrameTag] field in a queue head is completely managed by the host controller.

The rules for setting QH[FrameTag] are simple:

- Rule 1: If transitioning from Do Start Split to Do Complete Split and the current value of FRINDEX[2-0] is 6, QH[FrameTag] is set to FRINDEX[7-3] + 1. This accommodates split transactions whose start-split and complete-splits are in different H-Frames (case 2a, see Figure 16-14).
- Rule 2: If the current value of FRINDEX[2-0] is 7, QH[FrameTag] is set to FRINDEX[7-3] + 1. This accommodates staying in Do Complete Split for cases 2a, 2b, and 2c in Figure 16-14.
- Rule 3: If transitioning from Do_Start Split to Do Complete Split and the current value of FRINDEX[2-0] is not 6, or currently in Do Complete Split and the current value of (FRINDEX[2-0]) is not 7, FrameTag is set to FRINDEX[7-3]. This accommodates all other cases in Figure 16-14.

16.7.12.2.9 Rebalancing the periodic schedule

System software must occasionally adjust a periodic queue head's S-mask and C-mask fields during operation.

This need occurs when adjustments to the periodic schedule create a new bandwidth budget and one or more queue head's are assigned new execution footprints (that is, new S-mask and C-mask values).

It is imperative that system software must not update these masks to new values in the midst of a split transaction. In order to avoid any race conditions with the update, the host controller provides a simple assist to system software. System software sets the Inactivate-on-next-Transaction (I) bit to signal the host controller that it intends to update the S-mask and C-mask on this queue head. System software then waits for the host controller to observe the I-bit is set and transitions the Active bit to a zero. The rules for how and when the host controller clears the Active bit are:

- If the Active bit is cleared, no action is taken. The host controller does not attempt to advance the queue when the I-bit is set.
- If the Active bit is set and the SplitXState is DoStart (regardless of the value of S-mask), the host controller simply clears the Active bit. The host controller is not required to write the transfer state back to the current qTD. Note that if the S-mask indicates that a start-split is scheduled for the current microframe, the host controller must not issue the start-split bus transaction; it must clear the Active bit.

System software must save transfer state before setting the I-bit. This is required so that it can correctly determine what transfer progress (if any) occurred after the I-bit was set and the host controller executed it's final bus-transaction and cleared the Active bit.

After system software has updated the S-mask and C-mask, it must then reactivate the queue head. Since the Active bit and the I-bit cannot be updated with the same write, system software needs to use the following algorithm to coherently re-activate a queue head that has been stopped using the I-bit.

1. Set the Halted bit, then
2. Clear the I-bit, then
3. Set the Active bit and clear the Halted bit in the same write.

Setting the Halted bit inhibits the host controller from attempting to advance the queue between the time the I-bit is cleared and the Active bit is set.

16.7.12.3 Split transaction isochronous

Full-speed isochronous transfers are managed using the split-transaction protocol through a USB 2.0 transaction translator in a USB 2.0 hub.

The host controller utilizes siTD data structure to support the special requirements of isochronous split-transactions. This data structure uses the scheduling model of isochronous TDs (see Managing isochronous transfers using iTDs, for the operational model of iTDs) with the contiguous data feature provided by queue heads. This simple arrangement allows a single isochronous scheduling model and adds the additional feature that all data received from the endpoint (per split transaction) must land into a contiguous buffer.

16.7.12.3.1 Split transaction scheduling mechanisms for isochronous

Full-speed isochronous transactions are managed through a transaction translator's periodic pipeline.

As with full- and low-speed interrupt, system software manages each transaction translator's periodic pipeline by budgeting and scheduling exactly during which microframes the start-splits and complete-splits for each full-speed isochronous endpoint occur. The requirements described in Split transaction scheduling mechanisms for interrupt , apply.

Figure 16-18 illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule. The S_n and C_n labels indicate microframes where software can schedule start- and complete-splits (respectively). The H-Frame boundaries are marked with a large, solid bold vertical line. The B-Frame boundaries are marked with a large, bold, dashed line.The figure below illustrates the relationship of an siTD to the H-Frame.

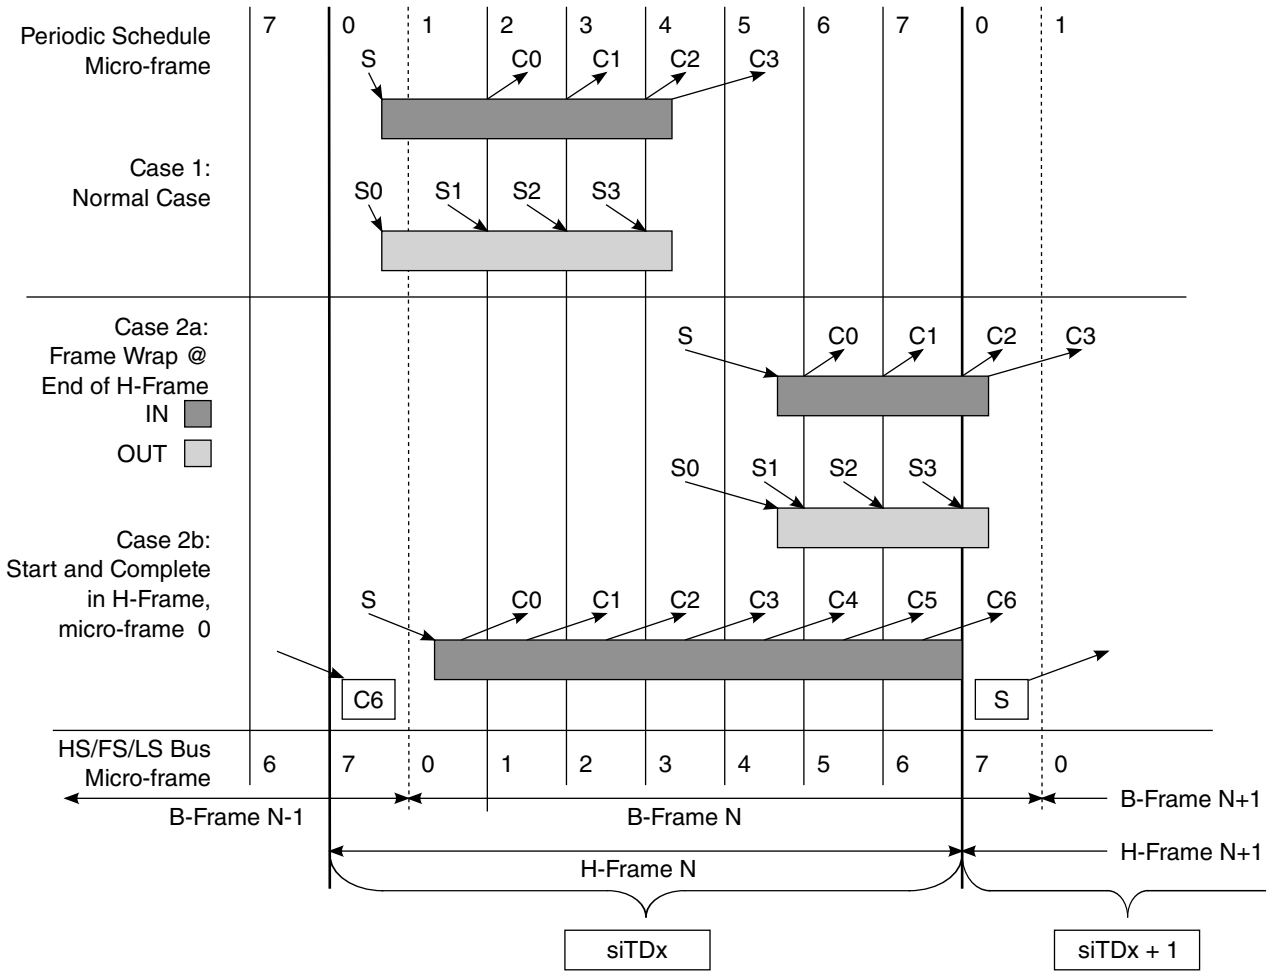

Figure 16-18. Split transaction, isochronous scheduling boundary conditions

When the endpoint is an isochronous OUT, there are only start-splits, and no complete-splits. When the endpoint is an isochronous IN, there is at most one start-split and one to N complete-splits. The scheduling boundary cases are:

- Case 1: The entire split transaction is completely bounded by an H-Frame. For example, the start-splits and complete-splits are all scheduled to occur in the same H-Frame.
- Case 2a: This boundary case is where one or more (at most two) complete-splits of a split transaction IN are scheduled across an H-Frame boundary. This can only occur when the split transaction has the possibility of moving data in B-Frame, microframes 6 or 7 (H-Frame microframe 7 or 0). When an H-Frame boundary wrap condition occurs, the scheduling of the split transaction spans more than one location in the periodic list.(for example, it takes two siTDs in adjacent periodic frame list locations to fully describe the scheduling for the split transaction).

Although the scheduling of the split transaction may take two data structures, all of the complete-splits for each full-speed IN isochronous transaction must use only one data pointer. For this reason, siTDs contain a back pointer.

Software must never schedule full-speed isochronous OUTs across an H-Frame boundary.

- Case 2b: This case can only occur for a very large isochronous IN. It is the only allowed scenario where a start-split and complete-split for the same endpoint can occur in the same microframe. Software must enforce this rule by scheduling the large transaction first. Large is defined to be anything larger than 579 byte maximum packet size.

A subset of the same mechanisms employed by full- and low-speed interrupt queue heads are employed in siTDs to schedule and track the portions of isochronous split transactions. The following fields are initialized by system software to instruct the host controller when to execute portions of the split transaction protocol:

- SplitXState

  This is a single bit residing in the Status field of an siTD (see Table 16-17). This bit is used to track the current state of the split transaction. The rules for managing this bit are described in Split transaction execution state machine for isochronous .

- Frame S-mask

  This is a bit-field wherein system software sets a bit corresponding to the microframe (within an H-Frame) that the host controller should execute a start-split transaction. This is always qualified by the value of the SplitXState bit. For example, referring to the IN example in Figure 16-18, case 1, the S-mask would have a value of 0b0000_0001 indicating that if the siTD is traversed by the host controller, and the SplitXState indicates Do Start Split, and the current microframe as indicated by FRINDEX[2-0] is 0, then execute a start-split transaction.

- Frame C-mask

  This is a bit-field where system software sets one or more bits corresponding to the microframes (within an H-Frame) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the SplitXState bit. For example, referring to the IN example in Figure 16-18, case 1, the C-mask would have a value of 0b 0011_1100 indicating that if the siTD is traversed by the host controller, and the SplitXState indicates Do Complete Split, and the current microframe as indicated by FRINDEX[2-0] is 2, 3, 4, or 5, then execute a complete-split transaction.

- Back Pointer

This field in a siTD is used to complete an IN split-transaction using the previous H-Frame's siTD. This is only used when the scheduling of the complete-splits span an H-Frame boundary.

There exists a one-to-one relationship between a high-speed isochronous split transaction (including all start- and complete-splits) and one full-speed isochronous transaction. An siTD contains (amongst other things) buffer state and split transaction scheduling information. An siTD's buffer state always maps to one full-speed isochronous data payload. This means that for any full-speed transaction payload, a single siTD's data buffer must be used. This rule applies to both IN an OUTs. An siTD's scheduling information usually also maps to one high-speed isochronous split transaction. The exception to this rule is the H-Frame boundary wrap cases mentioned above.

The siTD data structure describes at most, one frame's worth of high-speed transactions and that description is strictly bounded within a frame boundary. The figure below illustrates some examples. On the top are examples of the full-speed transaction footprints for the boundary scheduling cases described above. In the middle are time-frame references for both the B-Frames (HS/FS/LS Bus) and the H-Frames. On the bottom is illustrated the relationship between the scope of an siTD description and the time references. Each H-Frame corresponds to a single location in the periodic frame list. The implication is that each siTD is reachable from a single periodic frame list location at a time.

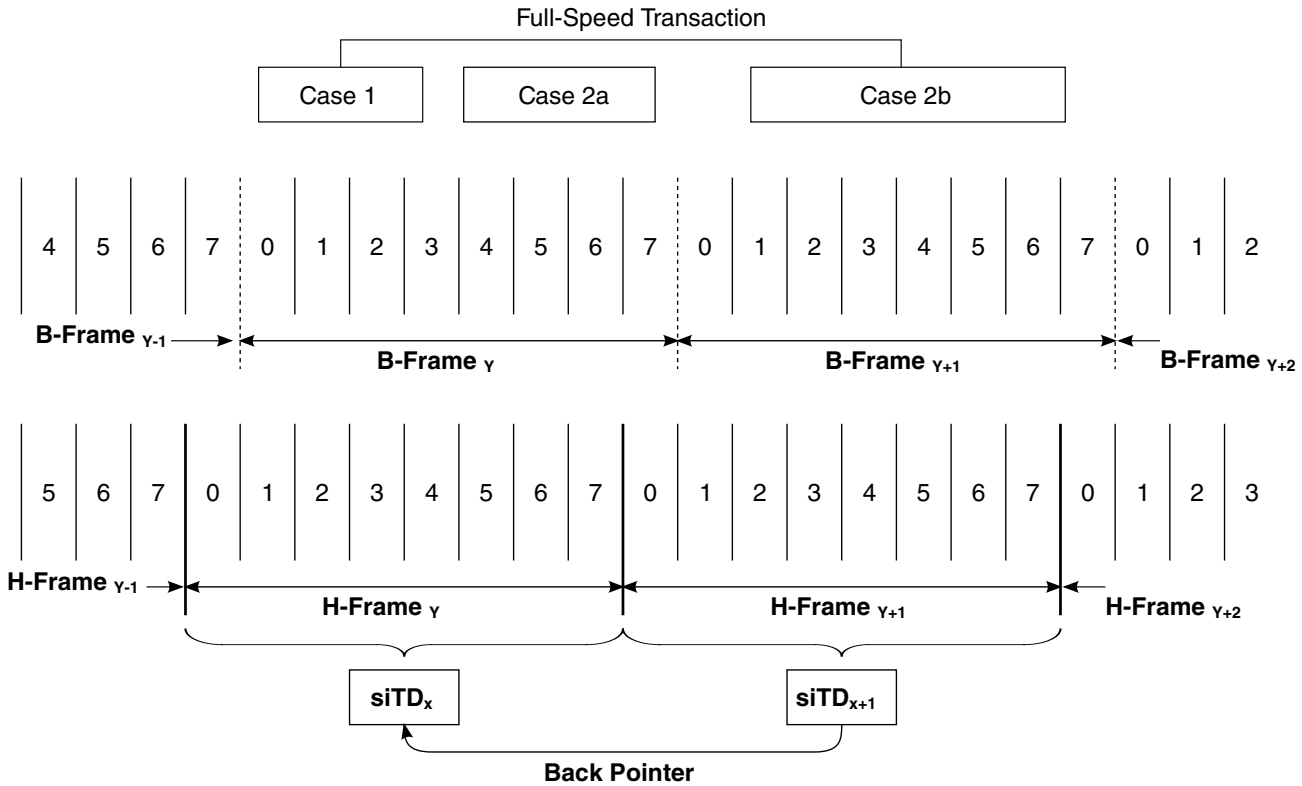

Figure 16-19. siTD scheduling boundary examples

Each case is described below:

- Case 1: One siTD is sufficient to describe and complete the isochronous split transaction because the whole isochronous split transaction is tightly contained within a single H-Frame.
- Case 2a, 2b: Although both INs and OUTs can have these footprints, OUTs always take only one siTD to schedule. However, INs (for these boundary cases) require two siTDs to complete the scheduling of the isochronous split transaction. siTDX is used to always issue the start-split and the first N complete-splits. The full-speed transaction (for these cases) can deliver data on the full-speed bus segment during microframe 7 of H-Frame$_{Y+1}$, or microframe 0 of H-Frame$_{Y+2}$. The complete splits are scheduled using siTD$_{X+2}$ (not shown). The complete-splits to extract this data must use the buffer pointer from siTD$_{X+1}$. The only way for the host controller to reach siTD$_{X+1}$ from H-Frame$_{Y+2}$ is to use siTD$_{X+2}$'s back pointer.

Software must apply the following rules when calculating the schedule and linking the schedule data structures into the periodic schedule:

- Software must ensure that an isochronous split-transaction is started so that it will complete before the end of the B-Frame.
- Software must ensure that for a single full-speed isochronous endpoint, there is never a start-split and complete-split in H-Frame, microframe 1. This is mandated as a rule so that case 2a and case 2b can be discriminated. According to the core USB specification, the long isochronous transaction illustrated in Case 2b, could be scheduled so that the start-split was in microframe 1 of H-Frame N and the last complete-split would need to occur in microframe 1 of H-Frame N+1. However, it is impossible to discriminate between cases 2a and case 2b, which has significant impact on the complexity of the host controller.

16.7.12.3.2 Tracking split transaction progress for isochronous transfers

Isochronous endpoints do not employ the concept of a halt on error, however the host controller does identify and report per-packet errors observed in the data stream.

This includes schedule traversal problems (skipped microframes), timeouts and corrupted data received.

In similar kind to interrupt split-transactions, the portions of the split transaction protocol must execute in the microframes they are scheduled. The queue head data structure used to manage full- and low-speed interrupt has several mechanisms for tracking when portions of a transaction have occurred. Isochronous transfers use siTDs for their transfers and the data structures are only reachable using the schedule in the exact microframe in which they are required (so all the mechanism employed for tracking in queue heads is not required for siTDs). Software has the option of reusing siTD several times in the complete periodic schedule. However, it must ensure that the results of split transaction N are consumed and the siTD re-initialized (activated) before the host controller gets back to the siTD (in a future microframe).

Split-transaction isochronous OUTs utilize a low-level protocol to indicate which portions of the split transaction data have arrived. Control over the low-level protocol is exposed in an siTD using the fields Transaction Position (TP) and Transaction Count (T-count). If the entire data payload for the OUT split transaction is larger than 188 bytes, there will be more than one start-split transaction, each of which require proper annotation. If host hold-offs occur, then the sequence of annotations received from the host will not be complete, which is detected and handled by the transaction translator. See Split transaction scheduling mechanisms for isochronous , for a description on how these fields are used during a sequence of start-split transactions.

The fields siTD[T-Count] and siTD[TP] are used by the host controller to drive and sequence the transaction position annotations. It is the responsibility of system software to properly initialize these fields in each siTD. Once the budget for a split-transaction

isochronous endpoint is established, S-mask, T-Count, and TP initialization values for all the siTD associated with the endpoint are constant. They remain constant until the budget for the endpoint is recalculated by software and the periodic schedule adjusted.

For IN-endpoints, the transaction translator simply annotates the response data packets with enough information to allow the host controller to identify the last data. As with split transaction Interrupt, it is the host controller's responsibility to detect when it has missed an opportunity to execute a complete-split. The following field in the siTD is used to track and detect errors in the execution of a split transaction for an IN isochronous endpoint.

- C-prog-mask. This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the transaction translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. C-prog-mask is a simple bit-vector that the host controller sets a bit for each complete-split executed. The bit position is determined by the microframe (FRINDEX[2-0]) number in which the complete-split was executed. The host controller always checks C-prog-mask before executing a complete-split transaction. If the previous complete-splits have not been executed, then it means one (or more) have been skipped and data has potentially been lost. System software is required to initialize this field to zero before setting an siTD's Active bit to a one.

If a transaction translator returns with the final data before all of the complete-splits have been executed, the state of the transfer is advanced so that the remaining complete-splits are not executed. It is important to note that an IN siTD is retired based solely on the responses from the transaction translator to the complete-split transactions. This means, for example, that it is possible for a transaction translator to respond to a complete-split with an MDATA PID. The number of bytes in the MDATA's data payload could cause the siTD[Total Bytes to Transfer] field to decrement to zero. This response can occur, before all of the scheduled complete-splits have been executed. In other interface, data structures (for example, high-speed data streams through queue heads), the transition of Total Bytes to Transfer to zero signals the end of the transfer and results in clearing the Active bit. However, in this case, the result has not been delivered by the transaction translator and the host must continue with the next complete-split transaction to extract the residual transaction state. This scenario occurs because of the pipeline rules for a transaction translator. In summary, the periodic pipeline rules require that on a microframe boundary, the transaction translator holds the final two bytes received (if it has not seen an End Of Packet (EOP)) in the full-speed bus pipe stage and gives the remaining bytes to the high-speed pipeline stage. At the microframe boundary, the transaction translator could have received the entire packet (including both CRC bytes)

but not received the packet EOP. In the next microframe, the transaction translator responds with an MDATA and sends all of the data bytes (with the two CRC bytes being held in the full-speed pipeline stage). This could cause the siTD to decrement it's Total Bytes to Transfer field to zero, indicating it has received all expected data. The host must still execute one more (scheduled) complete-split transaction in order to extract the results of the full-speed transaction from the transaction translator (for example, the transaction translator may have detected a CRC failure, and this result must be forwarded to the host).

If the host experiences hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous OUT, then the protocol to the transaction translator is not consistent and the transaction translator detects and reacts to the problem. Likewise, for host hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous IN, the C-prog-mask is used by the host controller to detect errors. However, if the host experiences a hold-off that causes it to skip all of an siTD, or an siTD expires during a host hold off (for example, a hold-off occurs and the siTD is no longer reachable by the host controller in order for it to report the hold-off event), then system software must detect that the siTDs have not been processed by the host controller (for example, state not advanced) and report the appropriate error to the client driver.

16.7.12.3.3 Split transaction execution state machine for isochronous

In this section, all references to microframe are in the context of a microframe within an H-Frame.

If the active bit in the status byte is a zero, the host controller ignores the siTD and continues traversing the periodic schedule. Otherwise the host controller processes the siTD as specified below. A split transaction state machine is used to manage the split-transaction protocol sequence. The host controller uses the fields defined in Tracking split transaction progress for isochronous transfers , plus the variable cMicroFrameBit defined in Split transaction execution state machine for interrupt , to track the progress of an isochronous split transaction. The figure below illustrates the state machine for managing an siTD through an isochronous split transaction. Bold, dotted circles denote the state of the Active bit in the Status field of a siTD. The Bold, dotted arcs denote the transitions between these states. Solid circles denote the states of the split transaction state machine and the solid arcs denote the transitions between these states. Dotted arcs and boxes reference actions that take place either as a result of a transition or from being in a state.

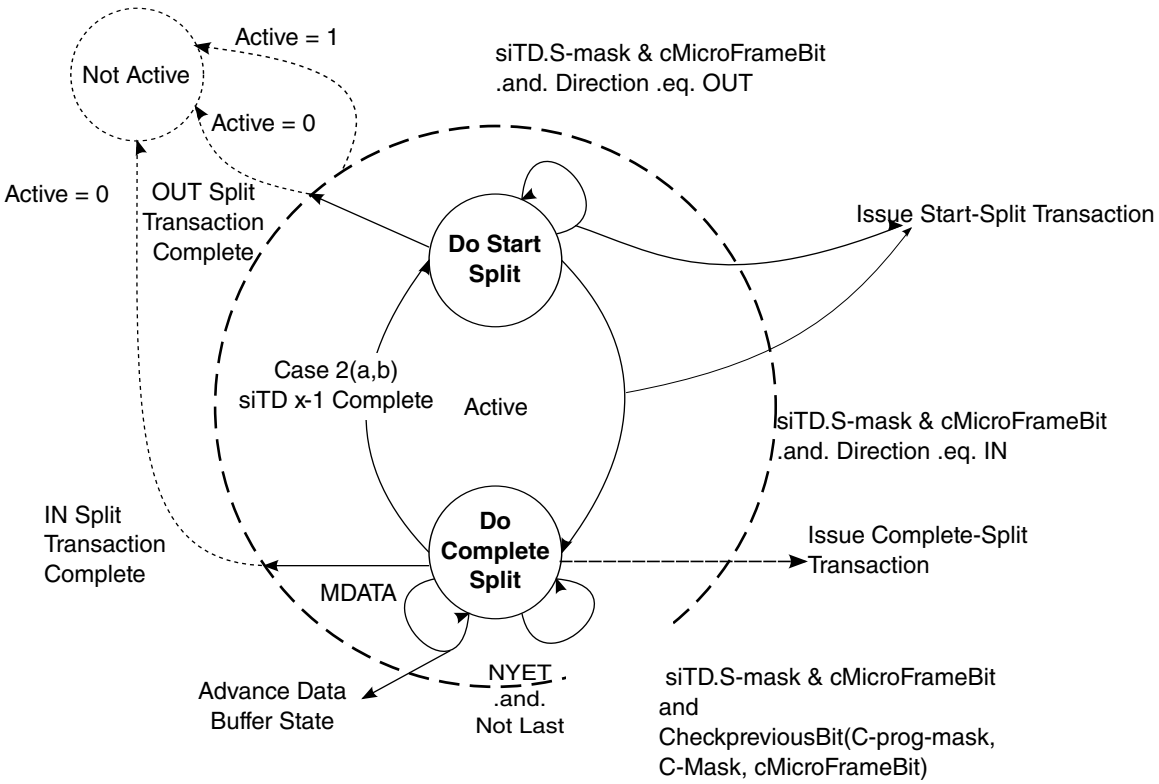

Figure 16-20. Split transaction state machine for isochronous

16.7.12.3.4 Periodic isochronous-do-start-split

Isochronous split transaction OUTs use only this state.

An siTD for a split-transaction isochronous IN is either initialized to this state, or the siTD transitions to this state from Do Complete Split when a case 2a (IN) or 2b scheduling boundary isochronous split-transaction completes.

Each time the host controller reaches an active siTD in this state, it checks the siTD[S-mask] against cMicroFrameBit. If there is a one in the appropriate position, the siTD executes a start-split transaction. By definition, the host controller cannot reach an siTD at the wrong time. If the I/O field indicates an IN, then the start-split transaction includes only the extended token plus the full-speed token. Software must initialize the siTD[Total Bytes To Transfer] field to the number of bytes expected. This is usually the maximum packet size for the full-speed endpoint. The host controller exits this state when the start-split transaction is complete.

The remainder of this section is specific to an isochronous OUT endpoint (that is, the I/O field indicates an OUT). When the host controller executes a start-split transaction for an isochronous OUT it includes a data payload in the start-split transaction. The memory buffer address for the data payload is constructed by concatenating siTD[Current Offset]

with the page pointer indicated by the page select field (siTD[P]). A zero in this field selects Page 0 and a 1 selects Page 1. During the start-split for an OUT, if the data transfer crosses a page boundary during the transaction, the host controller must detect the page cross, update the siTD[P] bit from a zero to a one, and begin using the siTD Page 1 with siTD[Current Offset] as the memory address pointer. The field siTD[TP] is used to annotate each start-split transaction with the indication of which part of the split-transaction data the current payload represents (ALL, BEGIN, MID, END). In all cases, the host controller simply uses the value in siTD[TP] to mark the start-split with the correct transaction position code.

T-count is always initialized to the number of start-splits for the current frame. TP is always initialized to the first required transaction position identifier. The scheduling boundary case (see Figure 16-19) is used to determine the initial value of TP. The initial cases are summarized in the table below.

Table 16-40. Initial conditions for OUT siTD TP and T-count fields

Case	T-Count	TP	Description
1, 2a	=1	ALL	When the OUT data payload is less than (or equal to) 188 bytes, only one start-split is required to move the data. The one start-split must be marked with an ALL.
1, 2a	!=1	BEGIN	When the OUT data payload is greater than 188 bytes more than one start-split must be used to move the data. The initial start-split must be marked with a BEGIN.

After each start-split transaction is complete, the host controller updates T-count and TP appropriately so that the next start-split is correctly annotated. The table below illustrates all of the TP and T-count transitions, which must be accomplished by the host controller.

Table 16-41. Transaction position (TP)/transaction count (T-count) transition table

TP	T-Count Next	TP Next	Description
ALL	0	N/A	Transition from ALL, to done.
BEGIN	1	END	Transition from BEGIN to END. Occurs when T-count starts at 2.
BEGIN	!=1	MID	Transition from BEGIN to MID. Occurs when T-count starts at greater than 2.
MID	!=1	MID	TP stays at MID while T-count is not equal to 1 (for example, greater than 1). This case can occur for any of the scheduling boundary cases where the T-count starts greater than 3.
MID	1	END	Transition from MID to END. This case can occur for any of the scheduling boundary cases where the T-count starts greater than 2.

The start-split transactions do not receive a handshake from the transaction translator, so the host controller always advances the transfer state in the siTD after the bus transaction is complete. To advance the transfer state the following operations take place:

- The siTD[Total Bytes To Transfer] and the siTD[Current Offset] fields are adjusted to reflect the number of bytes transferred.

- The siTD[P] (page select) bit is updated appropriately.
- The siTD[TP] and siTD[T-count] fields are updated appropriately as defined in Table 16-41.

These fields are then written back to the memory based siTD. The S-mask is fixed for the life of the current budget. As mentioned above, TP and T-count are set specifically in each siTD to reflect the data to be sent from this siTD. Therefore, regardless of the value of S-mask, the actual number of start-split transactions depends on T-count (or equivalently, Total Bytes to Transfer). The host controller must clear the Active bit when it detects that all of the schedule data has been sent to the bus. Setting the Active bit to zero depends on siTD.TP being 00 or 11, and siTD.Total Bytes decrements to 0. Software must ensure that TP, T-count and Total Bytes to Transfer are set to deliver the appropriate number of bus transactions from each siTD. An inconsistent combination yields undefined behavior.

If the host experiences hold-offs that cause the host controller to skip start-split transactions for an OUT transfer, the state of the transfer does not progress appropriately. The transaction translator observes protocol violations in the arrival of the start-splits for the OUT endpoint (that is, the transaction position annotation is incorrect as received by the transaction translator).

Example scenarios are described in Split transaction for isochronous-processing example.

The host controller can optionally track the progress of an OUT split transaction by setting appropriate bits in the siTD[C-prog-mask] as it executes each scheduled start-split. The checkPreviousBit() algorithm defined in Periodic isochronous-do complete split, can be used prior to executing each start-split to determine whether start-splits were skipped. The host controller can use this mechanism to detect missed microframes. It can then clear the siTD's Active bit and stop execution of this siTD. This saves on both memory and high-speed bus bandwidth.

16.7.12.3.5 Periodic isochronous-do complete split

This state is only used by a split-transaction isochronous IN endpoint. This state is entered unconditionally from the Do Start State after a start-split transaction is executed for an IN endpoint.

Each time the host controller visits an siTD in this state, it conducts a number of tests to determine whether it should execute a complete-split transaction. The sequence in which they are applied depends on which microframe the host controller is currently executing, which means that the tests might not be applied until after the siTD referenced from the back pointer has been fetched. The individual tests are as follows.

- Test A

cMicroFrameBit is bit-wise ANDed with the siTD[C-mask] field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this microframe. This test is always applied to a newly fetched siTD that is in this state.

- Test B

  The siTD[C-prog-mask] bit vector is checked to determine whether the previous complete splits have been executed. An example algorithm is given below (this is slightly different than the algorithm used in Periodic interrupt-do-complete-split). The sequence in which this test is applied depends on the current value of FRINDEX[2-0]. If FRINDEX[2-0] is 0 or 1, it is not applied until the back pointer has been used. Otherwise it is applied immediately.

```
Algorithm Boolean CheckPreviousBit(siTD.C-prog-mask, siTD.C-mask, cMicroFrameBit)
Begin
     Boolean rvalue = TRUE;
     previousBit = cMicroFrameBit rotate-right(1)
     -- Bit-wise anding previousBit with C-mask indicates whether there
     -- was an intent to send a complete split in the previous micro-
     -- frame. So, if the 'previous bit' is set in C-mask, check
     -- C-prog-mask to make sure it happened.
     if previousBit bitAND siTD.C-mask then
          if not (previousBit bitAND siTD.C-prog-mask) then

rvalue = FALSE
          End if
     End if
     Return rvalue
End Algorithm
```

If Test A is true and FRINDEX[2-0] is zero or one, this is a case 2a or 2b scheduling boundary (see Figure 16-18). See Complete-split for scheduling boundary cases 2a, 2b, for details in handling this condition.

If Test A and Test B evaluate to true, the host controller executes a complete-split transaction using the transfer state of the current siTD. When the host controller commits to executing the complete-split transaction, it updates QH[C-prog-mask] by bit-ORing with cMicroFrameBit. The transfer state is advanced based on the completion status of the complete-split transaction. To advance the transfer state of an IN siTD, the host controller must perform the following actions:

1. Decrement the number of bytes received from siTD[Total Bytes To Transfer]

2. Adjust siTD[Current Offset] by the number of bytes received
3. Adjust the siTD[P] (page select) field if the transfer caused the host controller to use the next page pointer
4. Set any appropriate bits in the siTD[Status] field, depending on the results of the transaction.

Note that if the host controller encounters a condition where siTD[Total Bytes To Transfer] is zero, and it receives more data, the host controller must not write the additional data to memory. The siTD[Status-Active] bit must be cleared and the siTD[Status-Babble Detected] bit must be set. The fields siTD[Total Bytes To Transfer], siTD[Current Offset], and siTD[P] are not required to be updated as a result of this transaction attempt.

The host controller accepts (assuming good data packet CRC and sufficient room in the buffer as indicated by the value of siTD[Total Bytes To Transfer]) MDATA and DATA0/1 data payloads up to and including 192 bytes. The host controller may optionally clear siTD[Status-Active] and set siTD[Status-Babble Detected] when it receives MDATA or DATA0/1 with a data payload of more than 192 bytes. The following responses have the noted effects:

- ERR

  The full-speed transaction completed with a time-out or bad CRC and this is a reflection of that error to the host. The host controller sets the ERR bit in the siTD[Status] field and clears the Active bit.

- Transaction Error (XactErr)

  The complete-split transaction encounters a Timeout, CRC16 failure, and so on. The siTD[Status] field XactErr field is set and the complete-split transaction must be retried immediately. The host controller must use an internal error counter to count the number of retries as a counter field is not provided in the siTD data structure. The host controller will not retry more than two times. If the host controller exhausts the retries or the end of the microframe occurs, the Active bit is cleared.

- DATAx (0 or 1)

  This response signals that the final data for the split transaction has arrived. The transfer state of the siTD is advanced and the Active bit is cleared. If the Bytes To Transfer field has not decremented to zero (including the reception of the data payload in the DATAx response), then less data than was expected, or allowed for was actually received. This short packet event does not set the USB interrupt status bit (USBSTS[UI]) to a one. The host controller will not detect this condition.

- NYET (and Last)

On each NYET response, the host controller also checks to determine whether this is the last complete-split for this split transaction. Last was defined in Periodic interrupt-do-complete-split . If it is the last complete-split (with a NYET response), then the transfer state of the siTD is not advanced (never received any data) and the Active bit is cleared. No bits are set in the Status field because this is essentially a skipped transaction. The transaction translator must have responded to all the scheduled complete-splits with NYETs, meaning that the start-split issued by the host controller was not received. This result should be interpreted by system software as if the transaction was completely skipped. The test for whether this is the last complete split can be performed by XORing C-mask with C-prog-mask. A zero result indicates that all complete-splits have been executed.

- MDATA (and Last)

  See above description for testing for Last. This can only occur when there is an error condition. Either there has been a babble condition on the full-speed link, which delayed the completion of the full-speed transaction, or software set up the S-mask and/or C-masks incorrectly. The host controller must set the XactErr bit and clear the Active bit.

- NYET (and not Last)

  See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for C-prog-mask) and stay in this state.

- MDATA (and not Last)

  The transaction translator responds with an MDATA when it has partial data for the split transaction. For example, the full-speed transaction data payload spans from microframe X to X+1 and during microframe X, the transaction translator responds with an MDATA and the data accumulated up to the end of microframe X. The host controller advances the transfer state to reflect the number of bytes received.

If Test A succeeds, but Test B fails, it means that one or more of the complete-splits have been skipped. The host controller sets the Missed Micro-Frame status bit and clears the Active bit.

16.7.12.3.6 Complete-split for scheduling boundary cases 2a, 2b

Boundary cases 2a and 2b (INs only) (see Figure 16-18) require that the host controller use the transaction state context of the previous siTD to finish the split transaction. The table below enumerates the transaction state fields.

Table 16-42. Summary siTD split transaction state

Buffer state	Status	Execution progress
Total bytes To transfer P (page select) Current Offset TP (transaction position) T-count (transaction count)	All bits in the status field	C-prog-mask

NOTE

TP and T-count are used only for Host to Device (OUT) endpoints.

If software has budgeted the schedule of this data stream with a frame wrap case, then it must initialize the siTD[Back Pointer] field to reference a valid siTD and have the T bit in the siTD[Back Pointer] field cleared. Otherwise, software must set the T bit in siTD[Back Pointer]. The host controller's rules for interpreting when to use the siTD[Back Pointer] field are listed below. These rules apply only when the siTD's Active bit is a one and the SplitXState is Do Complete Split.

- When cMicroFrameBit is a 0x1 and the $siTD_X$[Back Pointer] T-bit is zero, or
- If cMicroFrameBit is a 0x2 and $siTD_X$[S-mask[0]] is zero

When either of these conditions apply, then the host controller must use the transaction state from $siTD_{X-1}$.

In order to access $siTD_{X-1}$, the host controller reads on-chip the siTD referenced from $siTD_X$[Back Pointer].

The host controller must save the entire state from $siTD_X$ while processing $siTD_{X-1}$. This is to accommodate for case 2b processing. The host controller must not recursively walk the list of siTD[Back Pointers].

If $siTD_{X-1}$ is active (Active bit is set and SplitXStat is Do Complete Split), then both Test A and Test B are applied as described above. If these criteria to execute a complete-split are met, the host controller executes the complete split and evaluates the results as described above. The transaction state (see Table 16-42) of $siTD_{X-1}$ is appropriately advanced based on the results and written back to memory. If the resultant state of $siTD_{X-1}$'s Active bit is a one, then the host controller returns to the context of $siTD_X$, and follows its next pointer to the next schedule item. No updates to $siTD_X$ are necessary.

If $siTD_{X-1}$ is active (Active bit is set and SplitXStat is Do Start Split), then the host controller must clear the Active bit and set the Missed Micro-Frame status bit and the resultant status is written back to memory.

If $siTD_{X-1}$'s Active bit is cleared, (because it was cleared when the host controller first visited $siTD_{X-1}$ via $siTD_X$'s back pointer, it transitioned to zero as a result of a detected error, or the results of $siTD_{X-1}$'s complete-split transaction cleared it), then the host controller returns to the context of $siTD_X$ and transitions its SplitXState to Do Start Split. The host controller then determines whether the case 2b start split boundary condition exists (that is, if cMicroframeBit is 1 and $siTD_X$[S-mask[0]] is 1). If this criterion is met the host controller immediately executes a start-split transaction and appropriately advances the transaction state of $siTD_X$, then follows $siTD_X$[Next Pointer] to the next schedule item. If the criterion is not met, the host controller simply follows $siTD_X$[Next Pointer] to the next schedule item. Note that in the case of a 2b boundary case, the split-transaction of $siTD_{X-1}$ will have its Active bit cleared when the host controller returns to the context of $siTD_X$. Also, note that software should not initialize an siTD with C-mask bits 0 and 1 set and an S-mask with bit 0 set. This scheduling combination is not supported and the behavior of the host controller is undefined.

16.7.12.3.7 Split transaction for isochronous-processing example

There is an important difference between how the hardware/software manages the isochronous split transaction state machine and how it manages the asynchronous and interrupt split transaction state machines.

The asynchronous and interrupt split transaction state machines are encapsulated within a single queue head. The progress of the data stream depends on the progress of each split transaction. In some respects, the split-transaction state machine is sequenced using the Execute Transaction queue head traversal state machine.

Isochronous is a pure time-oriented transaction/data stream. The interface data structures are optimized to efficiently describe transactions that need to occur at specific times. The isochronous split-transaction state machine must be managed across these time-oriented data structures. This means that system software must correctly describe the scheduling of split-transactions across more than one data structure.

Then the host controller must make the appropriate state transitions at the appropriate times, in the correct data structures.

For example, the table below illustrates a few frames worth of scheduling required to schedule a case 2a full-speed isochronous data stream.

Table 16-43. Example case 2a-software scheduling siTDs for an IN endpoint

$siTD_X$		Micro-frames								InitialSplitXState
#	Masks	0	1	2	3	4	5	6	7	
X	S-mask					1				Do start split
	C-mask	1	1					1	1	

Table continues on the next page...

Table 16-43. Example case 2a-software scheduling siTDs for an IN endpoint (continued)

$siTD_X$		Micro-frames								InitialSplitXState
X+1	S-mask					1				Do complete split
	C-mask	1	1					1	1	
X+2	S-mask					1				Do complete split
	C-mask	1	1					1	1	
X+3	S-mask	Repeats previous pattern								Do complete split
	C-mask									

This example shows the first three siTDs for the transaction stream. Since this is the case-2a frame-wrap case, S-masks of all siTDs for this endpoint have a value of 0x10 (a one bit in microframe 4) and C-mask value of 0xC3 (one-bits in microframes 0,1, 6 and 7). Additionally, software ensures that the Back Pointer field of each siTD references the appropriate siTD data structure (and the Back Pointer T-bits are cleared).

The initial SplitXState of the first siTD is Do Start Split. The host controller will visit the first siTD eight times during frame X. The C-mask bits in microframes 0 and 1 are ignored because the state is Do Start Split. During microframe 4, the host controller determines that it can run a start-split (and does) and changes SplitXState to Do Complete Split. During microframes 6 and 7, the host controller executes complete-splits. Notice the siTD for frame X+1 has it's SplitXState initialized to Do Complete Split. As the host controller continues to traverse the schedule during H-Frame X+1, it will visit the second siTD eight times. During microframes 0 and 1 it will detect that it must execute complete-splits.

During H-Frame X+1, microframe 0, the host controller detects that $siTD_{X+1}$'s Back Pointer[T] bit is a zero, saves the state of $siTD_{X+1}$ and fetches $siTD_X$. It executes the complete split transaction using the transaction state of $siTD_X$. If the $siTD_X$ split transaction is complete, siTD's Active bit is cleared and results written back to $siTD_X$. The host controller retains the fact that $siTD_X$ is retired and transitions the SplitXState in $siTD_{X+1}$ to Do Start Split. At this point, the host controller is prepared to execute the start-split for $siTD_{X+1}$ when it reaches microframe 4. If the split-transaction completes early (transaction-complete is defined in Periodic isochronous-do complete split), that is, before all the scheduled complete-splits have been executed, the host controller changes $siTD_X$[SplitXState] to Do Start Split early and naturally skips the remaining scheduled complete-split transactions. For this example, $siTD_{X+1}$ does not receive a DATA0 response until H-Frame X+2, microframe 1.

During H-Frame X+2, microframe 0, the host controller detects that $siTD_{X+2}$'s Back Pointer[T] bit is zero, saves the state of $siTD_{X+2}$ and fetches $siTD_{X+1}$. As described above, it executes another split transaction, receives an MDATA response, updates the

transfer state, but does not modify the Active bit. The host controller returns to the context of $siTD_{X+2}$, and traverses it's next pointer without any state change updates to $siTD_{X+2}$.

During H-Frame X+2, microframe 1, the host controller detects $siTD_{X+2}$'s S-mask[0] bit is zero, saves the state of $siTD_{X+2}$ and fetches $siTD_{X+1}$. It executes another complete-split transaction, receives a DATA0 response, updates the transfer state and clears the Active bit. It returns to the state of $siTD_{X+2}$ and changes its SplitXState to Do Start Split. At this point, the host controller is prepared to execute start-splits for $siTD_{X+2}$ when it reaches microframe 4.

16.7.13 Port test modes

EHCI host controllers implement the port test modes Test J_State, Test K_State, Test_Packet, Test Force_Enable, and Test SE0_NAK as described in the *USB Specification Revision 2.0*.

The required, port test sequence, assuming the CF-bit in the CONFIGFLAG register is set, is as follows:

1. Disable the periodic and asynchronous schedules by clearing the USBCMD[ASE] and USBCMD[PSE].
2. Place all enabled root ports into the suspended state by setting the Suspend bit in the PORTSC register (PORTSC[SUSP]).
3. Clear USBCMD[RS] (run/stop) and wait for USBSTS[HCH] to transition to a one. In Device mode, the Test Mode starts only if Run/Stop bit is set to 1. In Host mode, the Test Mode starts regardless of Run/Stop bit.
4. Set the Port Test Control field in the port under test PORTSC register to the value corresponding to the desired test mode. If the selected test is Test_Force_Enable, then USBCMD[RS] must then be transitioned back to one, in order to enable transmission of SOFs out of the port under test.
5. When the test is complete, system software must ensure the host controller is halted (HCH bit is a one) then it terminates and exits test mode by setting USBCMD[RST].

16.7.14 Interrupts

The EHCI host controller hardware provides interrupt capability based on a number of sources.

The following list describes the general groups of interrupt sources:

- Interrupts as a result of executing transactions from the schedule (success and error conditions)
- Host controller events (Port change events, and so on)
- Host controller error events

All transaction-based sources are maskable through the host controller's Interrupt Enable register (USBINTR). Additionally, individual transfer descriptors can be marked to generate an interrupt on completion. This section describes each interrupt source and the processing that occurs in response to the interrupt.

During normal operation, interrupts may be immediate or deferred until the next interrupt threshold occurs. The interrupt threshold is a tunable parameter via the interrupt threshold control field in the USBCMD register. The value of this register controls when the host controller generates an interrupt on behalf of normal transaction execution. When a transaction completes during an interrupt interval period, the interrupt signaling the completion of the transfer will not occur until the interrupt threshold occurs. For example, the default value is eight microframes. This means that the host controller will not generate interrupts any more frequently than once every eight microframes.

Host system error details effects of a host system error.

If an interrupt has been scheduled to be generated for the current interrupt threshold interval, the interrupt is not signaled until after the status for the last complete transaction in the interval has been written back to system memory. This may sometimes result in the interrupt not being signaled until the next interrupt threshold.

Initial interrupt processing is the same, regardless of the reason for the interrupt. When an interrupt is signaled by the hardware, CPU control is transferred to host controller's USB interrupt handler. The precise mechanism to accomplish the transfer is OS specific. For this discussion it is just assumed that control is received. When the interrupt handler receives control, its first action is to reads the USBSTS. It then acknowledges the interrupt by clearing all of the interrupt status bits by writing ones to these bit positions. The handler then determines whether the interrupt is due to schedule processing or some other event. After acknowledging the interrupt, the handler (via an OS-specific mechanism), schedules a deferred procedure call (DPC) which will execute later. The DPC routine processes the results of the schedule execution. The precise mechanisms used are beyond the scope of this document.

NOTE

The only method software should use for acknowledging an interrupt is by transitioning the appropriate status bits in the USBSTS register from a one to a zero.

16.7.14.1 Transfer/transaction based interrupts

These interrupt sources are associated with transfer and transaction progress. They are all dependent on the next interrupt threshold.

16.7.14.1.1 Transaction error

A transaction error is any error that caused the host controller to think that the transfer did not complete successfully.

The table below lists the events/responses that the host can observe as a result of a transaction. The effects of the error counter and interrupt status are summarized in the following paragraphs. Most of these errors set the XactErr status bit in the appropriate interface data structure.

Table 16-44. Summary of transaction errors

Event/ Result	Queue Head/qTD/iTD/siTD Side Effects		USBSTS[USBERRINT]
	Cerr	Status Field	
CRC	-1	XactErr set	1[1]
Timeout	-1	XactErr set	1[1]
Bad PID[2]	-1	XactErr set	1[1]
Babble	N/A	See Serial bus babble	1
Buffer Error	N/A	See Data buffer error	

[1] If occurs in a queue head, then USBERRINT is asserted only when Cerr counts down from a one to a zero. In addition the queue is halted.

[2] The host controller received a response from the device, but it could not recognize the PID as a valid PID.

There is a small set of protocol errors that relate only when executing a queue head and fit under the umbrella of a WRONG PID error that are significant to explicitly identify. When these errors occur, the XactErr status bit in the queue head is set and the Cerr field is decremented. When the PID Code indicates a SETUP, the following responses are protocol errors and result in XactErr bit being set and the Cerr field being decremented.

- EPS field indicates a high-speed device and it returns a Nak handshake to a SETUP.
- EPS field indicates a high-speed device and it returns a Nyet handshake to a SETUP.
- EPS field indicates a low- or full-speed device and the complete-split receives a Nak handshake.

16.7.14.1.2 Serial bus babble

When a device transmits more data on the USB than the host controller is expecting for this transaction, it is defined to be babbling.

In general, this is called a packet babble. When a device sends more data than the maximum length number of bytes, the host controller sets the babble detected bit to a one and halts the endpoint if it is using a queue head. Maximum length is defined as the minimum of total bytes to transfer and maximum packet size. The Cerr field is not decremented for a packet babble condition (only applies to queue heads).

A babble condition also exists if IN transaction is in progress at High-speed EOF2 point. This is called a frame babble. A frame babble condition is recorded into the appropriate schedule data structure. In addition, the host controller must disable the port to which the frame babble is detected.

USBSTS[UEI] (USB error interrupt) is set and if the USBINTR[UEE] (USB error interrupt enable) is set, then a hardware interrupt is signaled to the system at the next interrupt threshold. The host controller must never start an OUT transaction that babbles across a microframe EOF.

NOTE

When a host controller detects a data PID mismatch, it must either: disable the packet babble checking for the duration of the bus transaction or do packet babble checking based solely on Maximum Packet Size. The USB core specification defines the requirements on a data receiver when it receives a data PID mismatch (for example, expects a DATA0 and gets a DATA1 or visa-versa). In summary, it must ignore the received data and respond with an ACK handshake, in order to advance the transmitter's data sequence.The EHCI interface allows system software to provide buffers for a Control, Bulk or Interrupt IN endpoint that are not an even multiple of the maximum packet size specified by the device. Whenever a device misses an ACK for an IN endpoint, the host and device are out of synchronization with respect to the progress of the data transfer. The host controller may have advanced the transfer to a buffer that is less than maximum packet size. The device re-sends its maximum packet size data packet, with the original data PID, in response to the next IN token. In order to properly manage the bus protocol, the host controller must disable the packet babble check when it observes the data PID mismatch.

16.7.14.1.3 Data buffer error

This event indicates that an overrun of incoming data or a underrun of outgoing data has occurred for this transaction.

This would generally be caused by the host controller not being able to access required data buffers in memory within necessary latency requirements. These conditions are not considered transaction errors, and do not effect the error count in the queue head. When these errors do occur, the host controller records the fact the error occurred by setting the Data Buffer Error bit in the queue head, iTD or siTD.

If the data buffer error occurs on a non-isochronous IN, the host controller will not issue a handshake to the endpoint. This forces the endpoint to resend the same data (and data toggle) in response to the next IN to the endpoint.

If the data buffer error occurs on an OUT, the host controller must corrupt the end of the packet so that it cannot be interpreted by the device as a good data packet. Simply truncating the packet is not considered acceptable. An acceptable implementation option is to 1's complement the CRC bytes and send them. There are other options suggested in the transaction translator section of the *USB Specification Revision 2.0*.

NOTE

When the USB controller is in device mode and the host sends two consecutive ISO OUT transactions (for example: OUT - DATA0 - OUT - DATA1) with a short inter-packet delay between DATA0 and the second OUT (less than 200 ns), the device sees the DATA1 packet as a short-packet even if it is correctly formed. In this case, the device terminates the transfer, generating an IOC interrupt (USBSTS[UI]). Note however, that DATA0 is correctly received.

16.7.14.1.4 USB interrupt (interrupt on completion (IOC))

Transfer descriptors (iTDs, siTDs, and queue heads (qTDs)) contain a bit that can be set to cause an interrupt on their completion.

The completion of the transfer associated with that schedule item causes USBSTS[UI] (USB interrupt) to be set. In addition, if a short packet is encountered on an IN transaction associated with a queue head, then this event also causes USBINT to be set. If USBINTR[UE] (USB interrupt enable) is set, a hardware interrupt is signaled to the system at the next interrupt threshold. If the completion is because of errors, USBSTS[UEI] (USB error interrupt) is also set.

16.7.14.1.5 Short packet

Reception of a data packet that is less than the endpoint's Max Packet size during Control, Bulk or Interrupt transfers signals the completion of the transfer.

Whenever a short packet completion occurs during a queue head execution, USBSTS[UI] (USB interrupt bit) is set. If the USB interrupt enable bit is set (USBINTR[UE]), a hardware interrupt is signaled to the system at the next interrupt threshold.

16.7.14.2 Host controller event interrupts

These interrupt sources are independent of the interrupt threshold (with the one exception being the Interrupt on Async Advance.

16.7.14.2.1 Port change events

Port registers contain status and status change bits.

When the status change bits are set, the host controller sets the USBSTS[PCI]. If the port change interrupt enable bit (PCE) in the USBINTR register is set, the host controller issues a hardware interrupt. The port status change bits in PORTSC include:

- Connect change status (CSC)
- Port enable/disable change (PEC)
- Over-current change (OCC)
- Force port resume (FPR)

16.7.14.2.2 Frame list rollover

This event indicates that the host controller has wrapped the frame list.

The current programmed size of the frame list effects how often this interrupt occurs. If the frame list size is 1024, then the interrupt occurs every 1024 milliseconds, if it is 512, then it occurs every 512 milliseconds, and so on. When a frame list rollover is detected, the host controller sets the frame list rollover bit, USBSTS[FRI]. If USBINTR[FRE] is set (frame list rollover enable), the host controller issues a hardware interrupt. This interrupt is not delayed to the next interrupt threshold.

16.7.14.2.3 Interrupt on async advance

This event is used for deterministic removal of queue heads from the asynchronous schedule.

Whenever the host controller advances the on-chip context of the asynchronous schedule, it evaluates the value of USBCMD[IAA]. If it is set, it sets USBSTS[AAI]. If USBINTR[AAE] is set, the host controller issues a hardware interrupt at the next interrupt threshold. A detailed explanation of this feature is described in Removing queue heads from asynchronous schedule.

16.7.14.2.4 Host system error

The host controller is a bus master and any interaction between the host controller and the system may experience errors.

The type of host error may be catastrophic to the host controller making it impossible for the host controller to continue in a coherent fashion. Behavior for these types of errors is to halt the host controller. Host-based error must result in the following actions:

- USBCMD[RS] is cleared.
- USBSTS[SEI] and USBSTS[HCH] register are set
- If the host system error enable bit, USBINTR[SEE] is set, the host controller issues a hardware interrupt. This interrupt is not delayed to the next interrupt threshold.

The table below summarizes the required actions taken on the various host errors.

Table 16-45. Summary behavior on host system errors

Cycle type	Master abort	Target abort	Data phase parity
Frame list pointer fetch (read)	Fatal	Fatal	Fatal
siTD fetch (read)	Fatal	Fatal	Fatal
siTD status write-back (write)	Fatal	Fatal	Fatal
iTD fetch (read)	Fatal	Fatal	Fatal
iTD status write-back (write)	Fatal	Fatal	Fatal
qTD fetch (read)	Fatal	Fatal	Fatal
qHD status write-back (write)	Fatal	Fatal	Fatal
Data write	Fatal	Fatal	Fatal
Data read	Fatal	Fatal	Fatal

NOTE

After a host system error, software must reset the host controller using USBCMD[RST] before re-initializing and restarting the host controller.

16.8 Device data structures

This section defines the interface data structures used to communicate control, status, and data between device controller driver (DCD) software and the device controller. The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of device queue heads and transfer descriptors.

NOTE

Software must ensure that no interface data structure reachable by the device controller spans a 4K-page boundary.

The data structures defined in the section are (from the device controller's perspective) a mix of read-only and read/writable fields. The device controller must preserve the read-only fields on all data structure writes.

The USB DR module includes DCD software called the USB 2.0 Device API. The device API provides an easy to use Application Program Interface for developing device (peripheral) applications. The device API incorporates and abstracts for the application developer all of the elements of the program interface.

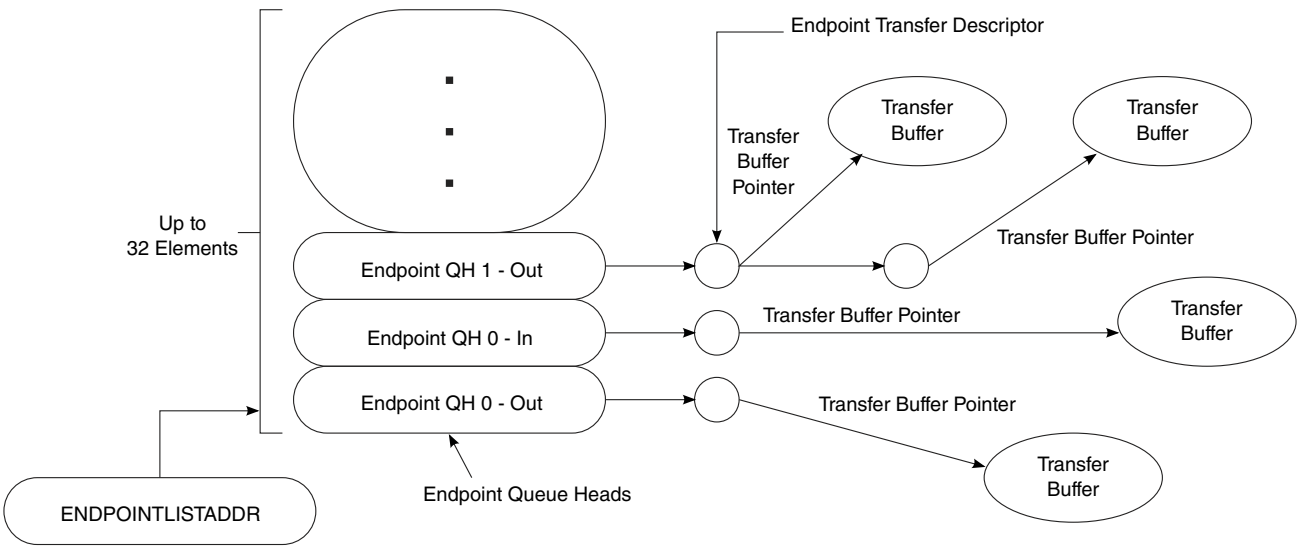

Figure 16-21. Endpoint queue head organization

16.8.1 Endpoint queue head

The device endpoint queue head (dQH) is where all transfers are managed.

The dQH is a 48-byte data structure, but must be aligned on 64-byte boundaries. During priming of an endpoint, the dTD (device transfer descriptor) is copied into the overlay area of the dQH, which starts at the nextTD pointer DWord and continues through the end of the buffer pointers DWords. After a transfer is complete, the dTD status DWord is updated in the dTD pointed to by the currentTD pointer. While a packet is in progress, the overlay area of the dQH is used as a staging area for the dTD so that the Device Controller can access needed information with little minimal latency.

The figure below shows the endpoint queue head structure.

Table 16-46. Endpoint queue head layout

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	offset

1. Device controller read/write; all others read-only.
2. Offsets 0x08 through 0x20 contain the transfer overlay.

16.8.1.1 Endpoint capabilities/characteristics

This DWord specifies static information about the Endpoint, in other words, this information does not change over the lifetime of the Endpoint.

Device controller software should not attempt to modify this information while the corresponding Endpoint is enabled.

The table below describes the Endpoint capabilities and characteristics fields.

Table 16-47. Endpoint capabilities/characteristics

Bits	Name	Description
31-30	Mult	Mult. This field is used to indicate the number of packets executed per transaction description as given by the following: 00 - Execute N Transactions as demonstrated by the USB variable length packet protocol where N is computed using the Maximum Packet Length (dQH) and the Total Bytes field (dTD) 01 Execute 1 Transaction. 10 Execute 2 Transactions. 11 Execute 3 Transactions. **NOTE:** Non-ISO Endpoints must set Mult = 00. **NOTE:** ISO Endpoints must set Mult = 01, 10, or 11 as needed.
29	zlt	Zero length termination select. This bit is used to indicate when a zero length packet is used to terminate transfers where the total transfer length is a multiple. This bit is not relevant for Isochronous transfers.

Table continues on the next page...

Table 16-47. Endpoint capabilities/characteristics (continued)

Bits	Name	Description
		0 Enable zero length packet to terminate transfers equal to a multiple of the Maximum Packet Length. (default). 1 Disable the zero length packet on transfers that are equal in length to a multiple Maximum Packet Length.
28-27	-	Reserved, should be cleared. These bit reserved for future use and should be cleared.
26-16	Maximum Packet Length	Maximum packet length. This directly corresponds to the maximum packet size of the associated Endpoint (wMaxPacketSize). The maximum value this field may contain is 0x400 (1024).
15	ios	Interrupt on setup (IOS). This bit is used on control type Endpoints to indicate if USBINT is set in response to a setup being received.
14-0	-	Reserved, should be cleared. Bits reserved for future use and should be cleared.

16.8.1.2 Transfer overlay

The seven DWords in the overlay area represent a transaction working space for the device controller.

The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it will not read the associated Endpoint.

After an Endpoint is read, the dTD is copied into this queue head overlay area by the device controller. Until a transfer is expired, software must not write the queue head overlay area or the associated transfer descriptor. When the transfer is complete, the device controller will write the results back to the original transfer descriptor and advance the queue.

See dTD for a description of the overlay fields.

16.8.1.3 Current dTD pointer

The current dTD pointer is used by the device controller to locate the transfer in progress.

This word is for USB_DR controller (hardware) use only and should not be modified by DCD software.

The table below describes the current dTD pointer fields.

Table 16-48. Current dTD pointer

Bits	Description
31-5	Current dtd. This field is a pointer to the dTD that is represented in the transfer overlay area. This field is modified by the Device Controller to next dTD pointer during endpoint priming or queue advance.
4-0	Reserved, should be cleared. Bit reserved for future use and should be cleared.

16.8.1.4 Setup buffer

The setup buffer is dedicated storage for the 8-byte data that follows a setup PID.

NOTE

Each endpoint has a TX and an RX dQH associated with it, and only the RX queue head is used for receiving setup data packets.

The table below describes the multiple mode control fields.

Table 16-49. Multiple mode control

DWord	Bits	Description
1	31-0	Setup Buffer 0. This buffer contains bytes 3 to 0 of an incoming setup buffer packet and is written by the device controller to be read by software.
2	31-0	Setup Buffer 1. This buffer contains bytes 7 to 4 of an incoming setup buffer packet and is written by the device controller to be read by software.

16.8.2 Endpoint transfer descriptor (dTD)

The dTD describes the location and quantity of data to be sent/received for given transfer to the device controller.

The DCD should not attempt to modify any field in an active dTD except the Next Link Pointer, which should only be modified as described in Managing transfers with transfer descriptors.

The figure below shows the endpoint transfer descriptor.

Table 16-50. Endpoint transfer descriptor (dTD)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	offset
Next Link Pointer																											0000				T	0x00
0	Total Bytes[1]															ioc	000			MultO		00		Status[1]								0x04

Table continues on the next page...

Table 16-50. Endpoint transfer descriptor (dTD) (continued)

Buffer Pointer (Page 0)	Current Offset[1]	0x08
Buffer Pointer (Page 1)	0 Frame Number[1]	0x0C
Buffer Pointer (Page 2)	0000_0000_0000	0x10
Buffer Pointer (Page 3)	0000_0000_0000	0x14
Buffer Pointer (Page 4)	0000_0000_0000	0x18

1. Device controller read/write; all others read-only.

The table below describes the next dTD pointer fields.

Table 16-51. Next dTD pointer

Bits	Description
31-5	Next transfer element pointer. This field contains the physical memory address of the next dTD to be processed. The field corresponds to memory address signals [31:5], respectively.
4-1	Reserved, should be cleared. Bits reserved for future use and should be cleared.
0	Terminate (T). 1=pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Device Controller that there are no more valid entries in the queue.

The table below describes the next dTD token fields.

Table 16-52. dTD token

Bits	Description
31	Reserved, should be cleared. Bit reserved for future use and should be cleared.
30-16	Total Bytes. This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction and only on the successful completion of the transaction. The maximum value software may store in the field is 5*4K(5000H). This is the maximum number of bytes 5 page pointers can access. Although it is possible to create a transfer up to 20K this assumes the 1st offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K. Therefore, the maximum recommended transfer is 16K(4000H). If the value of the field is zero when the controller fetches this transfer descriptor (and the active bit is set), the device controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for IN transfers that Total Bytes To Transfer be a multiple of Maximum Packet Length. If software builds such a transfer descriptor for an IN transfer, the last transaction will always be less that Maximum Packet Length.
15	Interrupt On Complete (IOC). This bit is used to indicate if USBINT is to be set in response to device controller being finished with this dTD.
14-12	Reserved, should be cleared. Bits reserved for future use and should be cleared.
11-10	Multiplier Override (MultO). This field can be used for transmit ISO's (that is, ISO-IN) to override the multiplier in the QH. This field must be zero for all packet types that are not transmit-ISO. Example: if QH.multiplier = 3; Maximum packet size = 8; Total bytes = 15; MultiO = 0 [default] Three packets are sent: {Data2(8); Data1(7); Data0(0)} if QH.multiplier = 3; Maximum packet size = 8; Total bytes = 15; MultiO = 2

Table continues on the next page...

Table 16-52. dTD token (continued)

Bits	Description
	Two packets are sent: {Data1(8); Data0(7)} For maximal efficiency, software should compute MultO = greatest integer of (Total Bytes/Max. Packet Size) except for the case when Total bytes = 0; then MultO should be 1. **NOTE:** Non-ISO and non-TX endpoints must set MultO = 00.
9-8	Reserved, should be cleared. Bits reserved for future use and should be cleared.
7-0	Status. This field is used by the Device Controller to communicate individual command execution states back to the Device Controller software. This field contains the status of the last transaction performed on this qTD. The bit encodings are: **Bit Status Field Description** 7 Active 6 Halted 5 Data Buffer Error 3 Transaction Error 4,2,0 Reserved, should be cleared

The following tables describe the buffer pointer page *n* fields.

Table 16-53. Buffer pointer page 0

Bits	Description
31-12	Buffer Pointer. Selects the page offset in memory for the packet buffer. Non virtual memory systems will typically set the buffer pointers to a series of incrementing integers.
11-0	Current Offset. Offset into the 4kb buffer where the packet is to begin.

Table 16-54. Buffer pointer page 1

Bits	Description
31-12	Buffer Pointer. Selects the page offset in memory for the packet buffer. Non virtual memory systems will typically set the buffer pointers to a series of incrementing integers.
11	Reserved
10-0	Frame Number. Written by the device controller to indicate the frame number in which a packet finishes. This is typically be used to correlate relative completion times of packets on an ISO endpoint.

Table 16-55. Buffer pointer pages 2-4

Bits	Description
31-12	Buffer Pointer. Selects the page offset in memory for the packet buffer. Non virtual memory systems will typically set the buffer pointers to a series of incrementing integers.
11-0	Reserved

16.9 Device operational model

The function of the device operation is to transfer a request in the memory image to and from the Universal Serial Bus. Using a set of linked list transfer descriptors, pointed to by a queue head, the device controller will perform the data transfers. The following sections explain the use of the device controller from the device controller driver (DCD) point-of-view and further describe how specific USB bus events relate to status changes in the device controller programmer's interface.

16.9.1 Device controller initialization

After hardware reset, the USB DR module is disabled until the run/stop bit (USBCMD[RS]) is set to a '1'.

In the disabled state, the pull-up on the USB D+ is not active which prevents an attach event from occurring. At a minimum, it is necessary to have the queue heads setup for endpoint zero before the device attach occurs. Shortly after the device is enabled, a USB reset will occur followed by setup packet arriving at endpoint 0. A queue head must be prepared so that the device controller can store the incoming setup packet.

To configure the internal UTMI PHY the following initialization sequence is required:

1. After power-on reset the UTMI PHY will be in disabled state and the PLL will be held reset.
3. Set the CONTROL[UTMI_PHY_EN] to enable the UTMI PHY and release the PLL.
4. Wait (approx 10 ms) for PHY clock to become valid.

Once the PHY clock is valid the user can proceed to the host controller initialization phase.

Once the PHY clock is valid the user can proceed to the device controller initialization phase.

In order to initialize a device, the software should perform the following steps:

1. Set the controller mode to device mode. Optionally set USBMODE[SDIS] (streaming disable).

NOTE

Transitioning from host mode to device mode requires a device controller reset before modifying USBMODE.

2. Program PORTSC[PTS] if using a UTMI PHY.

3. Set CONTROL[USB_EN]
4. Allocate and initialize device queue heads in system memory Minimum: Initialize device queue heads 0 Tx and 0 Rx.

NOTE

All device queue heads must be initialized for control endpoints before the endpoint is enabled. Device queue heads for non-control endpoints must be initialized before the endpoint can be used.

For information on device queue heads, refer to Device data structures.

5. Configure the ENDPOINTLISTADDR pointer.

   For additional information on ENDPOINTLISTADDR, refer to the register table.

6. Enable the microprocessor interrupt associated with the USB DR module and optionally change setting of USBCMD[ITC].

   Recommended: enable all device interrupts including: USBINT, USBERRINT, Port Change Detect, USB Reset Received, DCSuspend.

   For a list of available interrupts refer to the USBINTR and the USBSTS register tables.

7. Set USBCMD[RS] to run mode.

   After the run bit is set, a device reset will occur. The DCD must monitor the reset event and set the DEVICEADDR register, set the ENDPTCTRLx registers, and adjust the software state as described in Bus reset.

NOTE

Endpoint 0 is designed as a control endpoint only and does not need to be configured using ENDPTCTRL0 register.

It is also not necessary to initially prime Endpoint 0 because the first packet received will always be a setup packet. The contents of the first setup packet will require a response in accordance with USB device framework command set.

16.9.2 Port state and control

From a chip or system reset, the USB_DR controller enters the powered state.

A transition from the powered state to the attach state occurs when the run/stop bit (USBCMD[RS]) is set to a '1'. After receiving a reset on the bus, the port will enter the defaultFS or defaultHS state in accordance with the protocol reset described in Appendix C.2 of the *USB Specification Rev. 2.0*. The figure below depicts the state of a USB 2.0 device.

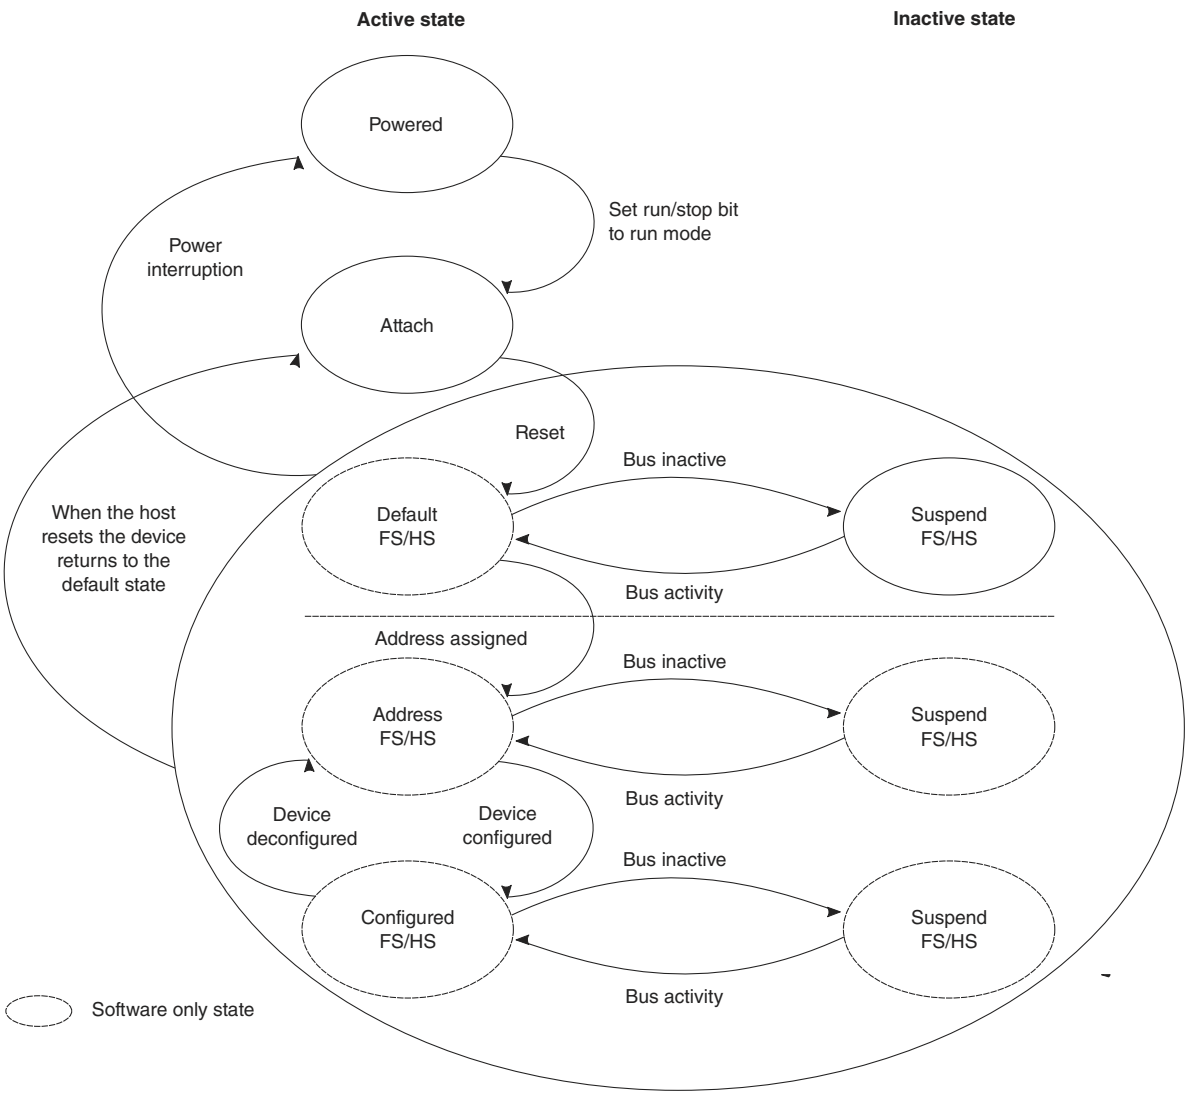

Figure 16-22. USB 2.0 device states

States Powered, Attach, DefaultFS/HS, SuspendFS/HS are implemented in the USB_DR controller and are communicated to the DCD using status bits, as shown in the table below:

Table 16-56. Device controller state information bits

Bits	Register
DCSuspend (SLI)	USBSTS

Table continues on the next page...

Table 16-56. Device controller state information bits (continued)

Bits	Register
USB Reset Received (URI)	USBSTS
Port Change Detect (PCI)	USBSTS
High-Speed Port	PORTSC

It is the responsibility of the DCD to maintain a state variable to differentiate between the defaultFS/HS state and the address/configured states. Change of state from default to address and the configured states is part of the enumeration process described in the device framework section of the USB 2.0 Specification.

As a result of entering the address state, the device address register (DEVICEADDR) must be programmed by the DCD.

Entry into the configured indicates that all endpoints to be used in the operation of the device have been properly initialized by programming the ENDPTCTRL*n* registers and initializing the associated queue heads.

16.9.2.1 Bus reset

A bus reset is used by the host to initialize downstream devices.

When a bus reset is detected, the USB_DR controller will renegotiate its attachment speed, reset the device address to 0, and notify the DCD by interrupt (assuming the USB reset interrupt enable bit, USBINTR[URE], is set). After a reset is received, all endpoints (except endpoint 0) are disabled and any primed transactions are canceled by the device controller. The concept of priming is clarified below, but the DCD must perform the following tasks when a reset is received:

1. Clear all setup token semaphores by reading the ENDPTSETUPSTAT register and writing the same value back to the ENDPTSETUPSTAT register.
2. Clear all the endpoint complete status bits by reading the ENDPTCOMPLETE register and writing the same value back to the ENDPTCOMPLETE register.
3. Cancel all primed status by waiting until all bits in the ENDPTPRIME are 0 and then writing 0xFFFF_FFFF to ENDPTFLUSH.
4. Read the reset bit in the PORTSC register (PORTSC[PR]) and make sure that it is still active.
    - A USB reset occurs for a minimum of 3 ms, and the DCD must reach this point in the reset cleanup before end of the reset occurs.
    - If it does not, a hardware reset of the device controller is recommended. A hardware reset can be performed by writing a one to the USB_DR controller reset bit in (USBCMD[RST]). Note that a hardware reset will cause the device to

detach from the bus by clearing USBCMD[RS] bit. Thus, the DCD must completely re-initialize the USB_DR controller after a hardware reset.

5. Free all allocated dTDs because they will no longer be executed by the device controller. If this is the first time the DCD is processing a USB reset event, then it is likely that no dTDs have been allocated.

At this time, the DCD may release control back to the OS because no further changes to the device controller are permitted until a Port Change Detect is indicated.

After a Port Change Detect, the device has reached the default state and the DCD can read the PORTSC to determine if the device is operating in FS or HS mode. At this time, the device controller has reached normal operating mode and DCD can begin enumeration according to the USB Chapter 9, Device Framework.

NOTE

The device DCD may use the FS/HS mode information to determine the bandwidth mode of the device.

In some applications, it may not be possible to enable one or more pipes while in FS mode. Beyond the data rate issue, there is no difference in DCD operation between FS and HS modes.

16.9.2.2 Suspend/resume

This section discusses the suspend and resume functions.

16.9.2.2.1 Suspend description

In order to conserve power, USB_DR controller automatically enters the suspended state when no bus traffic has been observed for a specified period.

When suspended, the USB_DR controller maintains any internal status, including its address and configuration. Attached devices must be prepared to suspend at any time they are powered, regardless of if they have been assigned a non-default address, are configured, or neither. Bus activity may cease due to the host entering a suspend mode of its own. In addition, a USB device shall also enter the suspended state when the hub port it is attached to is disabled.

The USB_DR controller exits suspend mode when there is bus activity. It may also request the host to exit suspend mode or selective suspend by using electrical signaling to indicate remote wake-up. The ability of a device to signal remote wake-up is optional. The USB_DR controller is capable of remote wake-up signaling. When the USB_DR controller is reset, remote wake-up signaling must be disabled.

16.9.2.2.2 Suspend operational model

The USB_DR controller moves into the suspend state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period.

After the device controller enters the suspend state, the DCD is notified by an interrupt (assuming DC Suspend Interrupt is enabled). When the USBSTS[SLI] (device controller suspend) is set, the device controller is suspended.

DCD response when the device controller is suspended is application specific and may involve switching to low power operation. Information on the bus power limits in suspend state can be found in USB 2.0 specification.

16.9.2.2.3 Resume

If the USB_DR controller is suspended, its operation is resumed when any non-idle signaling is received on its upstream facing port.

In addition, the USB_DR controller can signal the system to resume operation by forcing resume signaling to the upstream port. Resume signaling is sent upstream by writing a '1' to the PORTSC[FPR] (resume bit) while the device is in suspend state. Sending resume signal to an upstream port should cause the host to issue resume signaling and bring the suspended bus segment (one or more devices) back to the active condition.

NOTE

Before resume signaling can be used, the host must enable it by using the Set Feature command defined in device framework (Chapter 9) of the USB 2.0 Specification.

16.9.3 Managing endpoints

The USB 2.0 specification defines an endpoint, also called a device endpoint or an address endpoint as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device.

The endpoint address is specified by the combination of the endpoint number and the endpoint direction.

The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a control type data channel used for device discovery and enumeration. Other types of endpoints support by USB include bulk, interrupt, and

isochronous. Each endpoint type has specific behavior related to packet response and error handling. More detail on endpoint operation can be found in the USB 2.0 specification.

The USB_DR controller supports up to six endpoint specified numbers. The DCD can enable, disable, and configure each endpoint.

Each endpoint direction is essentially independent and can be configured with differing behavior in each direction. For example, the DCD can configure endpoint 1-IN to be a bulk endpoint and endpoint 1-OUT to be an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0, for example, is always a control endpoint and uses the pair of directions.

Each endpoint direction requires a queue head allocated in memory. If the maximum of 6 endpoint numbers, one for each endpoint direction are being used by the device controller, then 12 queue heads are required. The operation of an endpoint and use of queue heads are described later in this document.

16.9.3.1 Endpoint initialization

After hardware reset, all endpoints except endpoint zero are uninitialized and disabled.

The DCD must configure and enable each endpoint by writing to configuration bit in the ENDPTCTRL*n* register. Each 32-bit ENDPTCTRL*n* is split into an upper and lower half. The lower half of ENDPTCTRL*n* is used to configure the receive or OUT endpoint and the upper half is likewise used to configure the corresponding transmit or IN endpoint. Control endpoints must be configured the same in both the upper and lower half of the ENDPTCTRL*n* register otherwise the behavior is undefined. The table below shows how to construct a configuration word for endpoint initialization.

Table 16-57. Device controller endpoint initialization

Field	Value
Data Toggle Reset	1
Data Toggle Inhibit	0
Endpoint Type	00 Control 01 Isochronous 10 Bulk 11 Interrupt
Endpoint Stall	0

16.9.3.1.1 Stalling

There are two occasions where the USB_DR controller may need to return to the host a STALL.

The first occasion is the functional stall, which is a condition set by the DCD as described in the USB 2.0 device framework (Chapter 9). A functional stall is only used on non-control endpoints and can be enabled in the device controller by setting the endpoint stall bit in the ENDPTCTRL*n* register associated with the given endpoint and the given direction. In a functional stall condition, the device controller will continue to return STALL responses to all transactions occurring on the respective endpoint and direction until the endpoint stall bit is cleared by the DCD.

A protocol stall, unlike a function stall, is used on control endpoints is automatically cleared by the device controller at the start of a new control transaction (setup phase). When enabling a protocol stall, the DCD should enable the stall bits (both directions) as a pair. A single write to the ENDPTCTRL*n* register can ensure that both stall bits are set at the same instant.

NOTE

Any write to the ENDPTCTRL*n* register during operational mode must preserve the endpoint type field (that is, perform a read-modify-write).

The table below describes the device controller stall response matrix.

Table 16-58. Device controller stall response matrix

USB Packet	Endpoint Stall Bit.	Effect on STALL Bit.	USB Response
SETUP packet received by a non-control endpoint	N/A	None	STALL
IN/OUT/PING packet received by a non-control endpoint	'1	None	STALL
IN/OUT/PING packet received by a non-control endpoint	'0	None	ACK/NAK/NYET
SETUP packet received by a control endpoint	N/A	Cleared	ACK
IN/OUT/PING packet received by a control endpoint	'1	None	STALL
IN/OUT/PING packet received by a control endpoint	'0	None	ACK/NAK/NYET

16.9.3.2 Data toggle

Data toggle is a mechanism to maintain data coherency between host and device for any given data pipe.

For more information on data toggle, refer to the *Universal Serial Bus Revision 2.0 Specification*.

16.9.3.2.1 Data toggle reset

The DCD may reset the data toggle state bit and cause the data toggle sequence to reset in the device controller by writing a '1' to the data toggle reset bit in the ENDPTCTRL*n* register.

This should only be necessary when configuring/initializing an endpoint or returning from a STALL condition.

16.9.3.2.2 Data toggle inhibit

This feature is for test purposes only and should never be used during normal device controller operation.

Setting the data toggle Inhibit bit active ('1') causes the USB_DR controller to ignore the data toggle pattern that is normally sent and accept all incoming data packets regardless of the data toggle state.

In normal operation, the USB_DR controller checks the DATA0/DATA1 bit against the data toggle state bit to determine if the packet is valid. If Data PID does not match the data toggle state bit maintained by the device controller for that endpoint, the Data toggle is considered not valid. If the data toggle is not valid, the device controller assumes the packet was already received and discards the packet (not reporting it to the DCD). To prevent the USB_DR controller from re-sending the same packet, the device controller will respond to the error packet by acknowledging it with either an ACK or NYET response.

16.9.3.3 Device operational model for packet transfers

All transactions on the USB bus are initiated by the host and in turn, the device must respond to any request from the host within the turnaround time stated in the *Universal Serial Bus Revision 2.0 Specification*.

A USB host will send requests to the USB_DR controller in an order that cannot be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable when the endpoint number and direction is considered. For example, if endpoint 2 (transmit direction) is configured as a bulk pipe, then the host sends IN requests to that endpoint. This USB_DR controller prepares packets for each endpoint/direction in anticipation of the host request. The process of preparing the device controller to send or

receive data in response to host initiated transaction on the bus is referred to as 'priming' the endpoint. This term is used throughout the following documentation to describe the USB_DR controller operation so the DCD can be architected properly use priming. Further, note that the term 'flushing' is used to describe the action of clearing a packet that was queued for execution.

16.9.3.3.1 Priming transmit endpoints

Priming a transmit endpoint will cause the device controller to fetch the device transfer descriptor (dTD) for the transaction pointed to by the device queue head (dQH).

After the dTD is fetched, it is stored in the dQH until the device controller completes the transfer described by the dTD. Storing the dTD in the dQH allows the device controller to fetch the operating context needed to handle a request from the host without the need to follow the linked list, starting at the dQH when the host request is received.

After the device has loaded the dTD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO is split into virtual channels so that the leading data can be stored for any endpoint.

After a priming request is complete, an endpoint state of primed is indicated in the ENDPTSTATUS register. For a primed transmit endpoint, the device controller can respond to an IN request from the host and meet the stringent bus turnaround time of High Speed USB.

Since only the leading data is stored in the device controller FIFO, it is necessary for the device controller to begin filling in behind leading data after the transaction starts. The FIFO has been sized to account for the maximum latency that can be incurred by the system memory bus.

16.9.3.3.2 Priming receive endpoints

Priming receive endpoints is identical to priming of transmit endpoints from the point of view of the DCD.

At the device controller the major difference in the operational model is that there is no data movement of the leading packet data simply because the data is to be received from the host.

Note as part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the RX FIFO does not scale with the number of endpoints.

16.9.3.4 Interrupt/bulk endpoint operational model

The behaviors of the device controller for interrupt and bulk endpoints are identical.

All valid IN and OUT transactions to bulk pipes will handshake with a NAK unless the endpoint had been primed. Once the endpoint has been primed, data delivery will commence.

A dTD is retired by the device controller when the packets described in the transfer descriptor have been completed. Each dTD describes N packets to be transferred according to the USB Variable Length transfer protocol. The formula and the following tables describe how the device controller computes the number and length of the packets to be sent/received by the USB vary according to the total number of bytes and maximum packet length.

With Zero Length Termination (ZLT) = 0

N = INT(number of bytes/max. packet length) + 1

With Zero Length Termination (ZLT) = 1

N = MAXINT(number of bytes/max. packet length)

Table 16-59. Variable length transfer protocol example (ZLT = 0)

Bytes (dTD)	Max. packet length (dQH)	N	P1	P2	P3
511	256	2	256	255	-
512	256	3	256	256	0
512	512	2	512	0	-

Table 16-60. Variable length transfer protocol example (ZLT = 1)

Bytes (dTD)	Max. packet length (dQH)	N	P1	P2	P3
511	256	2	256	255	-
512	256	2	256	256	-
512	512	1	512	-	-

NOTE

The MULT field in the dQH must be set to '00' for bulk, interrupt, and control endpoints.

TX-dTD is complete when:

- All packets described dTD were successfully transmitted. *** Total bytes in dTD will equal zero when this occurs.

RX-dTD is complete when:

- All packets described in dTD were successfully received. *** Total bytes in dTD will equal zero when this occurs.
- A short packet (number of bytes < maximum packet length) was received. *** This is a successful transfer completion; DCD must check Total Bytes in dTD to determine the number of bytes that are remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received.
- A long packet was received (number of bytes > maximum packet size) OR (total bytes received > total bytes specified). *** This is an error condition. The device controller will discard the remaining packet, and set the Buffer Error bit in the dTD. In addition, the endpoint is flushed and the USBERR interrupt will become active.

On the successful completion of the packet(s) described by the dTD, the active bit in the dTD is cleared and the next pointer will be followed when the Terminate bit is clear. When the Terminate bit is set, the USB_DR controller will flush the endpoint/direction and cease operations for that endpoint/direction.

On the unsuccessful completion of a packet (see long packet above), the dQH is left pointing to the dTD that was in error. In order to recover from this error condition, the DCD must properly re-initialize the dQH by clearing the active bit and update the nextTD pointer before attempting to re-prime the endpoint.

NOTE

All packet level errors such as a missing handshake or CRC error will be retried automatically by the device controller.

There is no required interaction with the DCD for handling such errors.

16.9.3.4.1 Interrupt/bulk endpoint bus response matrix

The table below shows the interrupt/bulk endpoint bus response matrix.

Table 16-61. Interrupt/bulk endpoint bus response matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	Ignore	Ignore	Ignore	N/A	N/A
In	STALL	NAK	Transmit	BS Error[1]	N/A
Out	STALL	NAK	Receive + NYET/ACK[2]	N/A	NAK
Ping	STALL	NAK	ACK	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

1. Force Bit Stuff Error.
2. NYET/ACK-NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

   SYSERR-System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

16.9.3.5 Control endpoint operation model

This section discusses the control endpoint operation model.

16.9.3.5.1 Setup phase

All requests to a control endpoint begin with a setup phase followed by an optional data phase and a required status phase.

The USB_DR controller will always accept the setup phase unless the setup lockout is engaged.

The setup lockout will engage so that future setup packets are ignored. Lockout of setup packets ensures that while software is reading the setup packet stored in the queue head, that data is not written as it is being read potentially causing an invalid setup packet.

The setup lockout mechanism can be disabled and a tripwire type semaphore will ensure that the setup packet payload is extracted from the queue head without being corrupted by an incoming setup packet. This is the preferred behavior because ignoring repeated setup packets due to long software interrupt latency would be a compliance issue.

Setup Packet Handling

- Disable Setup Lockout by writing '1' to Setup Lockout Mode (SLOM) in USBMODE (once at initialization). Setup lockout is not necessary when using the tripwire as described below.

NOTE

Leaving the Setup Lockout Mode as '0' will result in a potential compliance issue.

- After receiving an interrupt and inspecting ENDPTSETUPSTAT to determine that a setup packet was received on a particular pipe:
  - Write '1' to clear corresponding bit ENDPTSETUPSTAT.
  - Write '1' to Setup Tripwire (SUTW) in USBCMD register.
  - Duplicate contents of dQH.SetupBuffer into local software byte array.
  - Read Setup TripWire (SUTW) in USBCMD register. (if set-continue; if cleared-goto 2)
  - Write '0' to clear Setup Tripwire (SUTW) in USBCMD register.
  - Process setup packet using local software byte array copy and execute status/ handshake phases.

NOTE

After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed and de-allocated before linking a new status and/or handshake dTD for the most recent setup packet.

16.9.3.5.2 Data phase

If the control transfer requires a data stage following the setup phase, the DCD must create a device transfer descriptor for the data phase and prime the transfer.

After priming the packet, the DCD must verify a new setup packet has not been received by reading the ENDPTSETUPSTAT register immediately verifying that the prime had completed. A prime will complete when the associated bit in the ENDPTPRIME register is zero and the associated bit in the ENDPTSTATUS register is a one. If a prime fails, that is, The ENDPTPRIME bit goes to zero and the ENDPTSTATUS bit is not set, then the prime has failed. This can only be due to improper setup of the dQH, dTD or a setup arriving during the prime operation. If a new setup packet is indicated after the ENDPTPRIME bit is cleared, then the transfer descriptor can be freed and the DCD must reinterpret the setup packet.

Should a setup arrive after the data stage is primed, the device controller will automatically clear the prime status (ENDPTSTATUS) to enforce data coherency with the setup packet.

NOTE

The MULT field in the dQH must be set to '00' for bulk, interrupt, and control endpoints.

NOTE

Error handling of data phase packets is the same as bulk packets described previously.

16.9.3.5.3 Status phase

Similar to the data phase, the DCD must create a transfer descriptor (with byte length equal zero) and prime the endpoint for the status phase.

The DCD must also perform the same checks of the ENDPTSETUPSTAT as described above in the data phase.

NOTE

The MULT field in the dQH must be set to '00' for bulk, interrupt, and control endpoints.

NOTE

Error handling of data phase packets is the same as bulk packets described previously.

16.9.3.5.4 Control endpoint bus response matrix

The table below shows the device controller response to packets on a control endpoint, according to the device controller state.

Table 16-62. Control endpoint bus response matrix

Token type	Endpoint state					Setup lockout
	Stall	Not primed	Primed	Underflow	Overflow	
Setup	ACK	ACK	ACK	N/A	SYSERR[1]	
In	STALL	NAK	Transmit	BS Error[2]	N/A	N/A
Out	STALL	NAK	Receive + NYET/ACK[3]	N/A	NAK	N/A
Ping	STALL	NAK	ACK	N/A	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore	Ignore

1. SYSERR-System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.
2. Force Bit Stuff Error.
3. NYET/ACK-NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

16.9.3.6 Isochronous endpoint operational model

Isochronous endpoints are used for real-time scheduled delivery of data and their operational model is significantly different than the host throttled Bulk, Interrupt, and Control data pipes.

Real time delivery by the USB_DR controller is accomplished by the following:

- Exactly MULT Packets per (micro)Frame are transmitted/received. Note that MULT is a two-bit field in the device Queue Head. The variable length packet protocol is not used on isochronous endpoints.
- NAK responses are not used. Instead, zero length packets and sent in response to an IN request to an unprimed endpoints. For unprimed RX endpoints, the response to an OUT transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next (micro)frame. If the ISO-dTD is still active after that frame, then the ISO-dTD is held ready until executed or canceled by the DCD.

The USB_DR controller in host mode uses the periodic frame list to schedule data exchanges to Isochronous endpoints. The operational model for device mode does not use such a data structure. Instead, the same dTD used for Control/Bulk/Interrupt endpoints is also used for isochronous endpoints. The difference is in the handling of the dTD.

The first difference between bulk and ISO-endpoints is that priming an ISO-endpoint is a delayed operation such that an endpoint will become primed only after a SOF is received. After the DCD writes the prime bit, the prime bit is cleared as usual to indicate to software that the device controller completed a priming the dTD for transfer. Internal to the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD but occurs so that the device controller can match the dTD to a specific (micro)frame.

Another difference with isochronous endpoints is that the transaction must wholly complete in a (micro)frame. Once an ISO transaction is started in a (micro)frame it will retire the corresponding dTD when MULT transactions occur or the device controller finds a fulfillment condition.

The transaction error bit set in the status field indicates a fulfillment error condition. When a fulfillment error occurs, the frame after the transfer failed to complete wholly, the device controller will force retire the ISO-dTD and move to the next ISO-dTD.

It is important to note that fulfillment errors are only caused due to partially completed packets. If no activity occurs to a primed ISO-dTD, the transaction will stay primed indefinitely. This means it is up to software discard transmit ISO-dTDs that pile up from a failure of the host to move the data.

Finally, the last difference with ISO packets is in the data level error handling. When a CRC error occurs on a received packet, the packet is not retried similar to bulk and control endpoints. Instead, the CRC is noted by setting the Transaction Error bit and the data is stored as usual for the application software to sort out.

- TX Packet Retired
  - MULT counter reaches zero.
  - Fulfillment Error [Transaction Error bit is set]
  - #Packets Occurred > 0 AND # Packets Occurred < MULT

NOTE

For TX-ISO, MULT Counter can be loaded with a lesser value in the dTD Multiplier Override field. If the Multiplier Override is zero, the MULT Counter is initialized to the Multiplier in the QH.

- RX Packet Retired:
  - MULT counter reaches zero.

- Non-MDATA Data PID is received
- Overflow Error:
- Packet received is > maximum packet length. [Buffer Error bit is set]
- Packet received exceeds total bytes allocated in dTD. [Buffer Error bit is set]
- Fulfillment Error [Transaction Error bit is set]
- # Packets Occurred > 0 AND # Packets Occurred < MULT
- CRC Error [Transaction Error bit is set]

NOTE

For ISO, when a dTD is retired, the next dTD is primed for the next frame. For continuous (micro)frame to (micro)frame operation the DCD should ensure that the dTD linked-list is out ahead of the device controller by at least two (micro)frames.

16.9.3.6.1 Isochronous pipe synchronization

When it is necessary to synchronize an isochronous data pipe to the host, the (micro)frame number (FRINDEX register) can be used as a marker.

To cause a packet transfer to occur at a specific (micro)frame number [N], the DCD should interrupt on SOF during frame N - 1. When the FRINDEX = N - 1, the DCD must write the prime bit. The USB_DR controller will prime the isochronous endpoint in (micro)frame N - 1 so that the device controller will execute delivery during (micro)frame N.

NOTE

Priming an endpoint towards the end of (micro)frame N - 1 will not guarantee delivery in (micro)frame N. The delivery may actually occur in (micro)frame N + 1 if device controller does not have enough time to complete the prime before the SOF for packet N is received.

16.9.3.6.2 Isochronous endpoint bus response matrix

The table below shows the isochronous endpoint bus response matrix.

Table 16-63. Isochronous endpoint bus response matrix

	Stall	Not Primed	Primed	Underflow	Overflow
Setup	STALL	STALL	STALL	N/A	N/A
In	NULL[1] Packet	NULL Packet	Transmit	BS Error[2]	N/A
Out	Ignore	Ignore	Receive	N/A	Drop Packet
Ping	Ignore	Ignore	Ignore	Ignore	Ignore
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

1. Zero Length Packet.
2. Force Bit Stuff Error.

16.9.4 Managing queue heads

The figure below shows the endpoint queue head diagram.

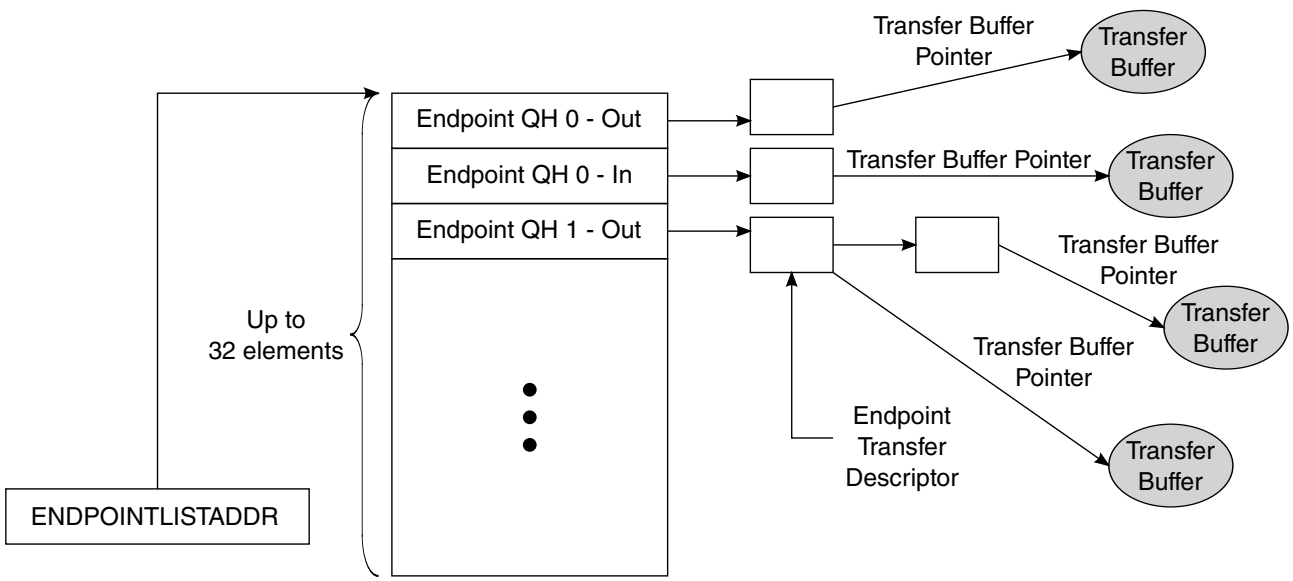

Figure 16-23. Endpoint queue head diagram

The device queue head (dQH) points to the linked list of transfer tasks, each depicted by the device Transfer Descriptor (dTD). An area of memory pointed to by ENDPOINTLISTADDR contains a group of all dQHs in a sequential list as shown in Figure 16-23. The even elements in the list of dQH's are used for receive endpoints (OUT/SETUP) and the odd elements are used for transmit endpoints (IN/INTERRUPT). Device transfer descriptors are linked head to tail starting at the queue head and ending at a terminate bit. Once the dTD has been retired, it will no longer be part of the linked list from the queue head. Therefore, software is required to track all transfer descriptors since pointers will no longer exist within the queue head once the dTD is retired (see Software link pointers).

In addition to the current and next pointers and the dTD overlay, the dQH also contains the following parameters for the associated endpoint: Multipler, Maximum Packet Length, Interrupt On Setup. The complete initialization of the dQH including these fields is demonstrated in the next section.

16.9.4.1 Queue head initialization

One pair of device queue heads must be initialized for each active endpoint.

To initialize a device queue head:

- Write the wMaxPacketSize field as required by the USB Chapter 9 or application specific protocol.
- Write the multiplier field to 0 for control, bulk, and interrupt endpoints. For ISO endpoints, set the multiplier to 1, 2, or 3 as required bandwidth an in conjunction with the USB Chapter 9 protocol. Note that in FS mode, the multiplier field can only be 1 for ISO endpoints.
- Write the next dTD Terminate bit field to '1.'
- Write the Active bit in the status field to '0.'
- Write the Halt bit in the status field to '0.'

NOTE

The DCD must only modify dQH if the associated endpoint is not primed and there are no outstanding dTDs.

16.9.4.2 Operational model for setup transfers

As discussed in Control endpoint operation model, setup transfer requires special treatment by the DCD.

A setup transfer does not use a dTD but instead stores the incoming data from a setup packet in an 8-byte buffer within the dQH.

Upon receiving notification of the setup packet, the DCD should handle the setup transfer as demonstrated here:

1. Copy setup buffer contents from dQH - RX to software buffer.
2. Acknowledge setup backup by writing a '1' to the corresponding bit in ENDPTSETUPSTAT.

NOTE

The acknowledge must occur before continuing to process the setup packet.

NOTE

After the acknowledge has occurred, the DCD must not attempt to access the setup buffer in the dQH - RX. Only the local software copy should be examined.

3. Check for pending data or status dTD's from previous control transfers and flush if any exist as discussed in Flushing/depriming an endpoint.

NOTE

It is possible for the device controller to receive setup packets before previous control transfers complete. Existing control packets in progress must be flushed and the new control packet completed.

4. Decode setup packet and prepare data phase [optional] and status phase transfer as required by the USB Chapter 9 or application specific protocol.

16.9.5 Managing transfers with transfer descriptors

This section describes software link pointers, transfer descriptors, transfer completion and the device error matrix.

16.9.5.1 Software link pointers

It is necessary for the DCD software to maintain head and tail pointers for the linked list of dTDs for each respective queue head.

This is necessary because the dQH only maintains pointers to the current working dTD and the next dTD to be executed. The operations described in next section for managing dTD will assume the DCD can use reference the head and tail of the dTD linked list.

NOTE

To conserve memory, the reserved fields at the end of the dQH can be used to store the Head and Tail pointers but it still remains the responsibility of the DCD to maintain the pointers.

The figure below shows the software link pointers.

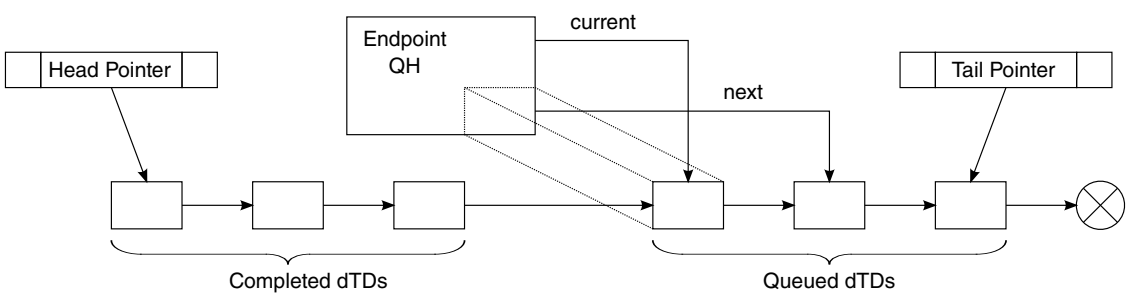

Figure 16-24. Software link pointers

16.9.5.2 Building a transfer descriptor

Before a transfer can be executed from the linked list, a dTD must be built to describe the transfer.

Use the following procedure for building dTDs.

Allocate 8-DWord dTD block of memory aligned to 8-DWord boundaries. Example: bit address 4-0 would be equal to '00000'.

Write the following fields:

1. Initialize first seven DWords to '0'.
2. Set the terminate bit to '1'.
3. Fill in total bytes with transfer size.
4. Set the interrupt on complete if desired.
5. Initialize the status field with the active bit set to '1' and all remaining status bits set to '0'.
6. Fill in buffer pointer page 0 and the current offset to point to the start of the data buffer.
7. Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointer.

16.9.5.3 Executing a transfer descriptor

To safely add a dTD, the DCD must account for the event in which the device controller reaches the end of the dTD list at the same time a new dTD is being added to the end of the list.

First, determine whether the link list is empty by checking the DCD driver to see if the pipe is empty (internal representation of linked-list should indicate if any packets are outstanding). Then follow the sequence of actions in the following list as appropriate, depending on whether the link list is empty or not empty.

Case 1: Link list is empty

1. Write dQH next pointer AND dQH terminate bit to '0' as a single DWord operation.
2. Clear active and halt bit in dQH (in case set from a previous error).
3. Prime endpoint by writing '1' to correct bit position in ENDPTPRIME.

Case 2: Link list is not empty

1. Add dTD to end of linked list.

2. Read correct prime bit in ENDPTPRIME-if '1' DONE.
3. Set ATDTW bit in USBCMD register to '1'.
4. Read correct status bit in ENDPTSTATUS. (store in tmp. variable for later).
5. Read ATDTW bit in USBCMD register.

   If '0' goto 3.

   If '1' continue to 6.

6. Write ATDTW bit in USBCMD register to '0'.
7. If status bit read in (4) is '1' DONE.
8. If status bit read in (4) is '0' then Goto Case 1: Step 1.

16.9.5.4 Transfer completion

After a dTD has been initialized and the associated endpoint primed, the device controller will execute the transfer upon the host-initiated request.

The DCD is notified with a USB interrupt if the Interrupt On Complete bit was set or alternately, the DCD can poll the endpoint complete register to find when the dTD had been executed. After a dTD has been executed, DCD can check the status bits to determine success or failure.

NOTE

Multiple dTD can be completed in a single endpoint complete notification. After clearing the notification, DCD must search the dTD linked list and retire all dTDs that have finished (Active bit cleared).

By reading the status fields of the completed dTDs, the DCD can determine if the transfers completed successfully. Success is determined with the following combination of status bits:

- Active = 0
- Halted = 0
- Transaction Error = 0
- Data Buffer Error = 0

Should any combination other than the one shown above exist, the DCD must take proper action. Transfer failure mechanisms are indicated in the Device Error Matrix.

In addition to checking the status bit the DCD must read the Transfer Bytes field to determine the actual bytes transferred. When a transfer is complete, the Total Bytes transferred is by decremented by the actual bytes transferred. For Transmit packets, a

packet is only complete after the actual bytes reaches zero, but for receive packets, the host may send fewer bytes in the transfer according the USB variable length packet protocol.

16.9.5.5 Flushing/depriming an endpoint

It is necessary for the DCD to flush to deprime one or more endpoints on a USB device reset or during a broken control transfer.

There may also be application specific requirements to stop transfers in progress. The following procedure can be used by the DCD to stop a transfer in progress:

1. Write a '1' to the corresponding bit(s) in ENDPTFLUSH.
2. Wait until all bits in ENDPTFLUSH are '0'.
3. Software note: this operation may take a large amount of time depending on the USB bus activity. It is not desirable to have this wait loop within an interrupt service routine.
4. Read ENDPTSTATUS to ensure that for all endpoints commanded to be flushed, that the corresponding bits are now '0'. If the corresponding bits are '1' after step #2 has finished, then the flush failed as described in the following:

   Explanation: In very rare cases, a packet is in progress to the particular endpoint when commanded flush using ENDPTFLUSH. A safeguard is in place to refuse the flush to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush be repeating steps 1-3 until each endpoint is successfully flushed.

16.9.5.6 Device error matrix

The table below summarizes packet errors that are not automatically handled by the USB controller.

Table 16-64. Device error matrix

Error	Direction	Packet Type	Data Buffer Error Bit	Transaction Error Bit
Overflow **	RX	Any	1	0
ISO Packet Error	RX	ISO	0	1
ISO Fulfillment Error	Both	ISO	0	1

Notice that the device controller handles all errors on Bulk/Control/Interrupt Endpoints except for a data buffer overflow. However, for ISO endpoints, errors packets are not retried and errors are tagged as indicated. The table below provides the error descriptions.

Table 16-65. Error descriptions

Overflow	Number of bytes received exceeded max. packet size or total buffer length. **NOTE:** This error also sets the Halt bit in the dQH. If there are dTDs remaining in the linked list for the endpoint, they will not be executed.
ISO Packet Error	CRC Error on received ISO packet. Contents not guaranteed to be correct.
ISO Fulfillment Error	Host failed to complete the number of packets defined in the dQH mult field within the given (micro)frame. For scheduled data delivery the DCD may need to readjust the data queue because a fulfillment error will cause Device Controller to cease data transfers on the pipe for one (micro)frame. During the dead (micro)frame, the Device Controller reports error on the pipe and primes for the following frame.

16.9.6 Servicing interrupts

The interrupt service routine must consider that there are high-frequency, low-frequency operations, and error operations and order accordingly.

16.9.6.1 High-frequency interrupts

High frequency interrupts in particular should be handed in the order shown in the table below. The most important of these is listed first because the DCD must acknowledge a setup buffer in the timeliest manner possible.

Table 16-66. Interrupt handling order

Execution order	Interrupt	Action
1a	USB Interrupt[1] ENDPTSETUPSTATUS	Copy contents of setup buffer and acknowledge setup packet (as indicated in Managing queue heads). Process setup packet according to USB 2.0 Chapter 9 or application specific protocol.
1b	USB Interrupt ENDPTCOMPLETE	Handle completion of dTD as indicated in Managing queue heads.
2	SOF Interrupt	Action as deemed necessary by application. This interrupt may not have a use in all applications.

1. It is likely that multiple interrupts to stack up on any call to the Interrupt Service Routine AND during the Interrupt Service Routine.

16.9.6.2 Low-frequency interrupts

The low frequency events include the interrupts shown in the table below.

These interrupts can be handled in any order because they do not occur often in comparison to the high-frequency interrupts.

Table 16-67. Low frequency interrupt events

Interrupt	Action
Port Change	Change software state information.
Sleep enable (Suspend)	Change software state information. Low power handling as necessary.
Reset Received	Change software state information. Abort pending transfers.

16.9.6.3 Error interrupts

Error interrupts are the least frequently occurring events. They should be placed last in the interrupt service routine.

The table below shows the error interrupt events.

Table 16-68. Error interrupt events

Interrupt	Action
USB Error Interrupt	This error is redundant because it combines USB Interrupt and an error status in the dTD. The DCD will more aptly handle packet-level errors by checking dTD status field upon receipt of USB Interrupt (w/ ENDPTCOMPLETE).
System Error	Unrecoverable error. Immediate Reset of core; free transfers buffers in progress and restart the DCD.

16.10 PHY PLL Initialization

USB PLL generates 480 MHz clock for two instances of USB transceiver inside the PHY.

Output Frequency = (Input Frequency / Ref Divider) x PLL Multiplier

where

Ref Divider = USB_PHY_PLLPRG2[REF_DIV]

PLL Multiplier = USB_PHY_PLLPRG2[MF]

USB PLL has an internal input clock division scheme as shown in the following figure. The maximum input clock range on the inputs of USB PLL is in the range of up to 200 MHz. The ref_clock_from pad is typically at external 24 MHz clock. The input clock division factor can be controlled by programming reference divider such that the pll_int_ref clock is in the range 20-40 MHz.

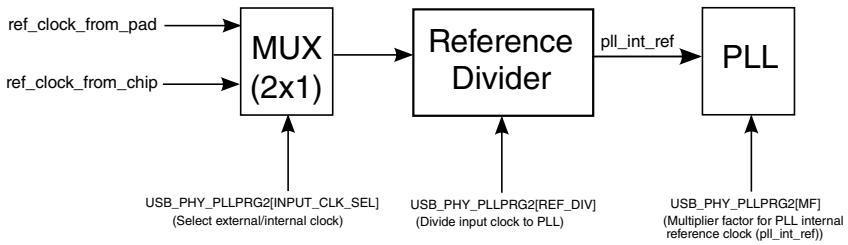

Figure 16-25. USBPHY PLL initialization

The PLL programming registers are programmed in two steps for the USBPHY PLL initialization. This allows programming values be settled before enabling PLL.

1. In the first step, the required programming values are loaded keeping PLL enable low.
2. In the second step, the PLL enable bits are also additionally enabled.

If USBCLK (24 MHz) is used as USB PHY clock, follow the steps below for the PHY PLL initialization:

1. Write USB_PHY_PLLPRG1 with 0x00000001 and USB_PHY_PLLPRG2 with 0x00052013.
   a. This ensures USB_PHY_PLLPRG2[PLL_EN]=0, keeping PLL disabled.
   b. This ensures USB_PHY_PLLPRG2[INPUT_CLK_SEL]=0, selecting external input.
   c. This ensures USB_PHY_PLLPRG2[MF]=010100, setting multiplier to 20 for PLL.
   d. This ensures USB_PHY_PLLPRG2[REF_DIV]=00001, setting reference divider to 1.
2. Read USB_PHY_PLLPRG1 and USB_PHY_PLLPRG2 registers.
3. Write USB_PHY_PLLPRG2[PLL_EN] as 1 (USB_PHY_PLLPRG2 as 0x00252013).
   a. This ensures USB_PHY_PLLPRG2[PLL_EN]=1, keeping rest of bits as in step 1
4. Set USB_PHY_PnCTRL[USBPEN].
5. Wait for USB_PHY_PnSTS[CLK_VALID] bit to go high, which ensures that USBPHY PLL is up and clock is running.

If clock derived from system clock (100 MHz only) is used as USB PHY clock, follow the steps below for the PHY PLL initialization:

1. Write USB_PHY_PLLPRG1 with 0x00000001 and USB_PHY_PLLPRG2 with 0x00162053.
   a. This ensures USB_PHY_PLLPRG2[PLL_EN]=0, keeping PLL disabled.
   b. This ensures USB_PHY_PLLPRG2[INPUT_CLK_SEL]=1, selecting internal input.
   c. This ensures USB_PHY_PLLPRG2[MF]=011000, setting multiplier to 24 for PLL.
   d. This ensures USB_PHY_PLLPRG2[REF_DIV]=00101, setting reference divider to 5. This makes PLL internal reference clock to be of 20MHz.
2. Read USB_PHY_PLLPRG1 and USB_PHY_PLLPRG2 registers.
3. Write USB_PHY_PLLPRG2[PLL_EN] as 1 (USB_PHY_PLLPRG2 as 0x00362053).
   a. This ensures USB_PHY_PLLPRG2[PLL_EN]=1, keeping rest of bits as in step 1.
4. Set USB_PHY_PnCTRL[USBPEN].
5. Wait for USB_PHY_PnSTS[CLK_VALID] bit to go high, which ensures that USBPHY PLL is up and clock is running.

16.11 Deviations from the EHCI specifications

The host mode operation of the USB DR module is nearly EHCI-compatible with few minor differences. For the most part, the module conforms to the data structures and operations described in Section 3, "Data Structures," and Section 4, "Operational Model," in the EHCI specification. The particulars of the deviations occur in the following areas:

- Embedded transaction translator-Allows direct attachment of FS and LS devices in host mode without the need for a companion controller.
- Device operation-In host mode, the device operational registers are generally disabled and thus device mode is mostly transparent when in host mode. However, there are a couple exceptions documented in the following sections.
- Embedded design interface-The module does not have a PCI interface and therefore the PCI configuration registers described in the EHCI specification are not applicable.

16.11.1 Embedded transaction translator function

The DR module supports directly connected full and low speed devices without requiring a companion controller by including the capabilities of a USB 2.0 high speed hub transaction translator.

Although there is no separate transaction translator block in the system, the transaction translator function normally associated with a high speed hub has been implemented within the DMA and Protocol engine blocks. The embedded transaction translator function is an extension to EHCI interface, but makes use of the standard data structures and operational models that exist in the EHCI specification to support full and low speed devices.

16.11.1.1 Capability registers

The following additions have been added to the capability registers to support the embedded transaction translator function:

- N_TT added to HSCPARAMS-Host Controller Structural Parameters
- N_PTT added to HSCPARAMS-Host Controller Structural Parameters

See USB_HCSPARAMS for usage information.

16.11.1.2 Operational registers

The following additions have been added to the operational registers to support the embedded TT:

- ASYNCTTSTS is a new register.
- Addition of two-bit Port Speed (PSPD) to the PORTSC register.

16.11.1.3 Discovery differences

In a standard EHCI controller design, the EHCI host controller driver detects a full speed (FS) or low speed (LS) device by noting if the port enable bit is set after the port reset operation.

The port enable will only be set in a standard EHCI controller implementation after the port reset operation and when the host and device negotiate a High-Speed connection (that is, Chirp completes successfully).

The module always sets the port enable after the port reset operation regardless of the result of the host device chirp result. The resulting port speed is indicated by the PSPD field in PORTSC. Therefore, the standard EHCI host controller driver requires an alteration to handle directly connected full- and low-speed devices or hubs. The table below summarizes the functional differences between EHCI and EHCI with embedded TT.

Table 16-69. Functional differences between EHCI and EHCI with embedded TT

Standard EHCI	EHCI with embedded transaction translator
After port enable bit is set following a connection and reset sequence, the device/hub is assumed to be HS.	After port enable bit is set following a connection and reset sequence, the device/hub speed is noted from PORTSC.
FS and LS devices are assumed to be downstream from a HS hub thus, all port-level control is performed through the Hub Class to the nearest Hub.	FS and LS device can be either downstream from a HS hub or directly attached. When the FS/LS device is downstream from a HS hub, then port-level control is done using the Hub Class through the nearest Hub. When a FS/LS device is directly attached, then port-level control is accomplished using PORTSC.
FS and LS devices are assumed to be downstream from a HS hub with HubAddr=X. [where HubAddr > 0 and HubAddr is the address of the Hub where the bus transitions from HS to FS/LS (that is, Split target hub)]	FS and LS device can be either downstream from a HS hub with HubAddr = X [HubAddr > 0] or directly attached [where HubAddr = 0 and HubAddr is the address of the Root Hub where the bus transitions from HS to FS/LS (that is, Split target hub is the root hub)]

16.11.1.4 Data structures

The same data structures used for FS/LS transactions though a HS hub are also used for transactions through the root hub.

The following list demonstrates how the hub address and endpoint speed fields should be set for directly attached FS/LS devices and hubs:

1. QH (for direct attach FS/LS)-Async. (Bulk/Control Endpoints) Periodic (Interrupt)
   - Hub Address = 0
   - Transactions to direct attached device/hub.
     - QH.EPS = Port Speed
   - Transactions to a device downstream from direct attached FS hub.
     - QH.EPS = Downstream Device Speed

NOTE

When QH.EPS = 01 (LS) and PORTSC[PSPD] = 00 (FS), a LS-pre-pid is sent before the transmitting LS traffic.

Maximum Packet Size must be less than or equal 64 or undefined behavior may result.

2. siTD (for direct attach FS)-Periodic (ISO Endpoint)
   - All FS ISO transactions:
     - Hub Address = 0
     - siTD.EPS = 00 (full speed)

     Maximum packet size must less than or equal to 1023 or undefined behavior may result.

16.11.1.5 Operational model

The operational models are well defined for the behavior of the transaction translator (see *Universal Serial Bus Revision 2.0 Specification*) and for the EHCI controller moving packets between system memory and a USB-HS hub.

Since the embedded transaction translator exists within the DR module there is no physical bus between EHCI host controller driver and the USB FS/LS bus. These sections will briefly discuss the operational model for how the EHCI and transaction translator operational models are combined without the physical bus between. The following sections assume the reader is familiar with both the EHCI and USB 2.0 transaction translator operational models.

16.11.1.5.1 Microframe pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the host (H) and the bus (B).

The embedded transaction translator shall use the same pipeline algorithms specified in the *Universal Serial Bus Revision 2.0 Specification* for a Hub-based transaction translator.

All periodic transfers always begin at B-frame 0 (after SOF) and continue until the stored periodic transfers are complete. As an example of the microframe pipeline implemented in the embedded transaction translator, all periodic transfers that are tagged in EHCI to execute in H-frame 0 will be ready to execute on the bus in B-frame 0.

NOTE

When programming the S-mask and C-masks in the EHCI data structures to schedule periodic transfers for the embedded transaction translator, the EHCI host controller driver must follow the same rules specified in EHCI for programming the

S-mask and C-mask for downstream Hub-based transaction translators.

Once periodic transfers are exhausted, any stored asynchronous transfer are moved. Asynchronous transfers are opportunistic in that they shall execute whenever possible and their operation is not tied to H-frame and B-frame boundaries with the exception that an asynchronous transfer cannot babble through the SOF (start of B-frame 0).

16.11.1.5.2 Split state machines

The start and complete split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded transaction translator.

Where a start or complete-split operation would occur by requesting the split to the HS hub, the start/complete split operation is simple an internal operation to the embedded transaction translator. The table below summarizes the conditions where handshakes are emulated from internal state instead of actual handshakes to HS split bus traffic.

Table 16-70. Emulated handshakes

Condition	Emulate TT response
Start-Split: All asynchronous buffers full	NAK
Start-Split: All periodic buffers full	ERR
Start-Split: Success for start of Async. Transaction	ACK
Start-Split: Start Periodic Transaction	No handshake (Ok)
Complete-Split: Failed to find transaction in queue	Bus Time Out
Complete-Split: Transaction in Queue is Busy	NYET
Complete-Split: Transaction in Queue is Complete	[Actual handshake from FS/LS device]

16.11.1.5.3 Asynchronous transaction scheduling and buffer management

The following *Universal Serial Bus Revision 2.0 Specification* items are implemented in the embedded transaction translator:

- USB 2.0-11.17.3
  - Sequencing is provided and a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.
- USB 2.0-11.17.4
  - Transaction tracking for 2 data pipes.
- USB 2.0-11.17.5
  - Clear_TT_Buffer capability provided

16.11.1.5.4 Periodic transaction scheduling and buffer management

The following *Universal Serial Bus Revision 2.0 Specification* items are implemented in the embedded transaction translator:

- USB 2.0-11.18.6.[1-2]
  - Abort of pending start-splits
    - EOF (and not started in microframes 6)
    - Idle for more than 4 microframes
  - Abort of pending complete-splits
    - EOF
    - Idle for more than 4 microframes

NOTE

There is no data schedule mechanism for these transactions other than the microframe pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 msec) or else undefined behavior may result.

16.11.1.5.5 Multiple transaction translators

The maximum number of embedded transaction translators that is currently supported is one as indicated by the N_TT field in the HCSPARAMS register.

See USB_HCSPARAMS for more information.

16.11.2 Device operation

The co-existence of a device operational controller within the DR module has little effect on EHCI compatibility for host operation except as noted in this section.

16.11.3 Non-zero fields the register file

Some of the reserved fields and reserved addresses in the capability registers and operational registers have use in device mode, the following must be adhered to:

- Write operations to all EHCI reserved fields (some of which are device fields in the DR module) in the operation registers should always be written to zero. This is an EHCI requirement of the device controller driver that must be adhered to.
- Read operations by the module must properly mask EHCI reserved fields (some of which are device fields in the DR module registers).

16.11.4 SOF interrupt

The SOF interrupt is a free running 125 μsec interrupt for host mode.

EHCI does not specify this interrupt, but it has been added for convenience and as a potential software time base. The free running interrupt is shared with the device-mode start-of-frame interrupt. See USB_USBSTS and USB_USBINTR for more information.

16.11.5 Embedded design

This is an Embedded USB Host Controller as defined by the EHCI specification and thus does not implement the PCI configuration registers.

16.11.5.1 Frame adjust register

Given that the optional PCI configuration registers are not included in this implementation, there is no corresponding bit level timing adjustments like those provided by the Frame Adjust register in the PCI configuration registers.

Starts of microframes are timed precisely to 125 μsec using the transceiver clock as a reference clock. That is, 60-MHz transceiver clock for 8-bit physical interfaces and full-speed serial interfaces or 30-MHz transceiver clock.

16.11.6 Miscellaneous variations from EHCI

The modules support multiple physical interfaces which can operate in different modes when the module is configured with the software programmable Physical Interface Modes.

The control bits for selecting the PHY operating mode have been added to the PORTSC register providing a capability that is not defined by the EHCI specification.

16.11.6.1 Discovery

This section discusses port reset and port speed detection.

16.11.6.1.1 Port reset

The port connect methods specified by EHCI require setting the port reset bit in the register for a duration of 10 msec.

Due to the complexity required to support the attachment of devices that are not high speed there are counter already present in the design that can count the 10 msec reset pulse to alleviate the requirement of the software to measure this duration. Therefore, the basic connection is then summarized as the following:

- [Port Change Interrupt] Port connect change occurs to notify the host controller driver that a device has attached.
- Software shall write a '1' to the reset the device.
- Software shall write a '0' to the reset the device after 10 msec.
    - This step, which is necessary in a standard EHCI design, may be omitted with this implementation. Should the EHCI host controller driver attempt to write a '0' to the reset bit while a reset is in progress the write will simple be ignored and the reset will continue until completion.
- [Port Change Interrupt] Port enable change occurs to notify the host controller that the device in now operational and at this point the port speed has been determined.

16.11.6.1.2 Port speed detection

After the port change interrupt indicates that a port is enabled, the EHCI stack should determine the port speed.

Unlike the EHCI implementation which will re-assign the port owner for any device that does not connect at High-Speed, this host controller supports direct attach of non-HS devices. Therefore, the following differences are important regarding port speed detection:

- Port owner is read-only and always reads 0.
- A 2-bit port speed indicator has been added to PORTSC to provide the current operating speed of the port to the host controller driver.
    - A 1-bit high-speed indicator has been added to PORTSC to signify that the port is in HS vs. FS/LS

Chapter 17
DUART

17.1 Overview

This chapter describes the dual universal asynchronous receiver/transmitters (DUART). It describes the functional operation, the initialization sequence, and the programming details for the DUART registers and features.

The DUART consists of two universal asynchronous receiver/transmitters (UARTs). The UARTs act independently; all references to UART refer to one of these receiver/transmitters. Each UART is clocked by the platform clock/2. The DUART programming model is compatible with the PC16552D.

The UART interface is point to point, meaning that only two UART devices are attached to the connecting signals. As shown in the figure below, each UART module consists of the following:

- Receive and transmit buffers
- Clear to send (CTS_B) input port and request to send (RTS_B) output port for data flow control
- 16-bit counter for baud rate generation
- Interrupt control logic

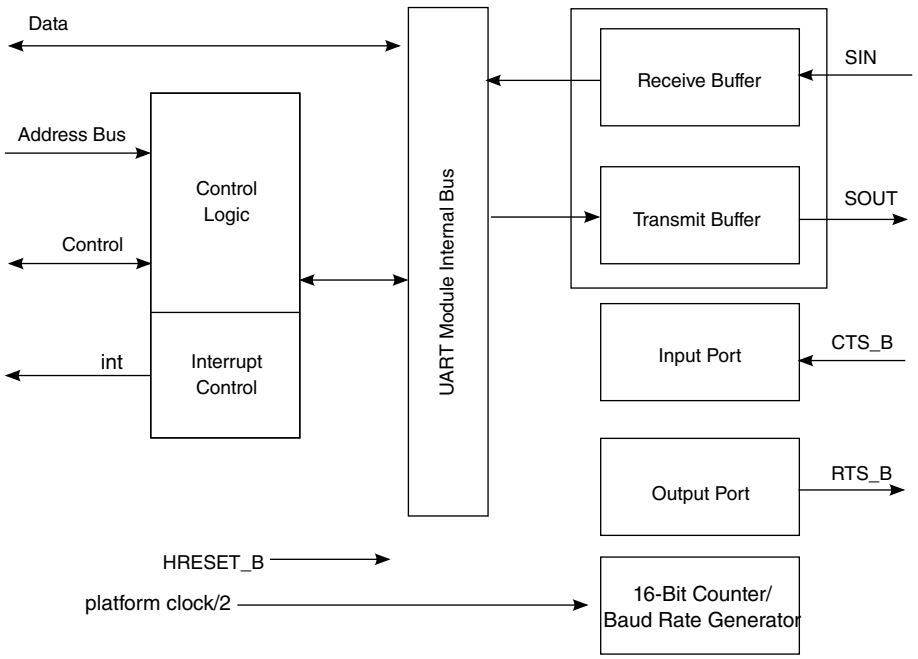

Figure 17-1. UART block diagram

17.1.1 The DUART module as implemented on the chip

This section provides details about how the DUART module is integrated into this chip.

The chip implements two DUART modules, DUART1 and DUART2. The DUART1 module contains UART1 and UART2 and the DUART2 module contains UART3 and UART4.

Table 17-1. DUART module as implemented on chip

Module name	Module base address
DUART1	0011_C000h
DUART2	0011_D000h

17.1.2 Features

The DUART includes these distinctive features:

- Full-duplex operation
- Programming model compatible with original PC16450 UART and PC16550D (improved version of PC16450 that also operates in FIFO mode)

- PC16450 register reset values
- Configurable FIFO mode for both transmitter and receiver, providing 16-byte FIFOs
- Serial data encapsulation and decapsulation with standard asynchronous communication bits (START, STOP, and parity)
- Maskable transmit, receive, line status, and modem status interrupts
- Software-programmable baud generators that divide the platform clock/2 by 1 to (2^{16} - 1) and generate a 16x clock for the transmitter and receiver engines
- Clear to send (CTS_B and ready to send (RTS_B) modem control functions
- Software-selectable serial interface data format (data length, parity, 1/1.5/2 STOP bit, baud rate)
- Line and modem status registers
- Line-break detection and generation
- Internal diagnostic support, local loopback, and break functions
- Prioritized interrupt reporting
- Overrun, parity, and framing error detection

17.1.3 Modes of operation

The communication channel provides a full-duplex asynchronous receiver and transmitter using an operating frequency derived from the one-half of the platform clock.

The transmitter accepts parallel data from a write to the transmitter holding register (UTHR). In FIFO mode, the data is placed directly into an internal transmitter shift register of the transmitter FIFO. The transmitter converts the data to a serial bit stream inserting the appropriate start, stop, and optional parity bits. Finally, it outputs a composite serial data stream on the channel transmitter serial data output signal (SOUT). The transmitter status may be polled or interrupt driven.

The receiver accepts serial data bits on the channel receiver serial data input signal (SIN), converts it to parallel format, checks for a start bit, parity (if any), stop bits, and transfers the assembled character (with start, stop, parity bits removed) from the receiver buffer (or FIFO) in response to a read of the UART's receiver buffer register (URBR). The receiver status may be polled or interrupt driven.

17.2 DUART external signal descriptions

The DUART signals are described in the table below.

NOTE

Although the actual device signal names are prepended with the UART_ prefix as shown in the table, the abbreviated signal names are often used throughout this chapter.

Table 17-2. DUART signals-detailed signal descriptions

Signal	I/O	Description	
UART*n*_SIN	I	Serial data in. Data is received on the receivers of UART*n* through the respective serial data input signal, with the least-significant bit received first. Note that UART3_SIN is not available when UART1 is configured for CTS_B mode and UART4_SIN is not available when UART2 is configured for CTS_B mode.	
		State meaning	Asserted/Negated-Represents the data being received on the UART interface.
		Timing	Assertion/Negation-An internal logic sample signal, *rxcnt*, uses the frequency of the baud-rate generator to sample the data on SIN.
UART*n*_SOUT	O	Serial data out. The serial data output signals for the UART*n* are set ('mark' condition) when the transmitter is disabled, idle, or operating in the local loopback mode. Data is shifted out on these signals, with the least significant bit transmitted first. Note that UART3_SOUT is not available when UART1 is configured for RTS_B mode and UART4_SOUT is not available when UART2 is configured for RTS_B mode.	
		State meaning	Asserted/Negated-Represents the data being transmitted on the respective UART interface.
		Timing	Assertion/Negation- An internal logic sample signal, *rxcnt*, uses the frequency of the baud-rate generator to update and drive the data on SOUT.
UART*n*_CTS_B	I	Clear to send. These active-low inputs are the clear-to-send inputs. They are connected to the respective RTS_B outputs of the other UART devices on the bus. They can be programmed to generate an interrupt on change-of-state of the signal. Note that UART1_CTS_B is not available when UART3 is configured for SIN mode and UART2_CTS_B is not available when UART4 is configured for SIN mode. **NOTE:** The DUARTs are set during reset to be in either two-pin or four-pin mode (or disabled if the GPIO functionality is selected). For two-pin mode, the CTS_B inputs are asserted internally.	
		State meaning	Asserted/Negated-Represent the clear to send condition for their respective UART.
		Timing	Assertion/Negation-Sampled at the rising edge of every input clock (platform clock/2).
UART*n*_RTS_B	O	Request to send. UART*n*_RTS_B are active-low output signals that can be programmed to be negated and asserted by either the receiver or transmitter. When connected to the clear-to-send (CTS_B) input of a transmitter, this signal can be used to control serial data flow. Note that UART1_RTS_B is not available when UART3 is configured for SOUT mode and UART2_RTS_B is not available when UART4 is configured for SOUT mode.	
		State meaning	Asserted/Negated-Represents the data being transmitted on the respective UART interface.
		Timing	Assertion/Negation-Updated and driven at the rising edge of every input clock (platform clock/2).

17.3 DUART memory map/register definition

The table below lists the DUART registers and their offsets. It lists the address, name, and a cross-reference to the complete description of each register.

NOTE

The full register address is comprised of CCSRBAR together with the block base address and offset listed in the table below.

The UARTs on the device are identical, except that the registers for each UART are located at different offsets . Throughout this chapter, the registers are described by an acronym: for example, LCR represents the line control register for each UART (see The DUART module as implemented on the chip for the number of UARTs supported on chip).

The registers in each UART interface are used for configuration, control, and status. The divisor latch access bit, ULCR[DLAB], is used to access the divisor latch least- and most-significant bit registers and the alternate function register. See UART line control register (DUART_ULCR*n*) for more information on ULCR[DLAB].

All the DUART registers are one-byte wide. Reads and writes to these registers must be byte-wide operations. The table below provides a register summary with references to the section and page that contains detailed information about each register. Undefined byte address spaces within offset 0x000-0xFFF are reserved.

DUART memory map

Offset address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
11_C500	UART receiver buffer register (DUART1_URBR1)	8	R	00h	17.3.1/1139
11_C500	UART transmitter holding register (DUART1_UTHR1)	8	W	00h	17.3.2/1140
11_C500	UART divisor least significant byte register (DUART1_UDLB1)	8	R/W	00h	17.3.3/1140
11_C501	UART divisor most significant byte register (DUART1_UDMB1)	8	R/W	00h	17.3.4/1142
11_C501	UART interrupt enable register (DUART1_UIER1)	8	R/W	00h	17.3.5/1143
11_C502	UART interrupt ID register (DUART1_UIIR1)	8	R	01h	17.3.6/1143
11_C502	UART FIFO control register (DUART1_UFCR1)	8	W	00h	17.3.7/1145
11_C502	UART alternate function register (DUART1_UAFR1)	8	R/W	00h	17.3.8/1146
11_C503	UART line control register (DUART1_ULCR1)	8	R/W	00h	17.3.9/1147

17.3.1 UART receiver buffer register (DUARTx_URBR*n*)

These registers are accessible when ULCR[DLAB] = 0.

These registers contain the data received from the transmitter on the UART buses. In FIFO mode, when read, they return the first byte received. For FIFO status information, refer to the UDSR[RXRDY] description.

Except for the case when there is an overrun, URBR returns the data in the order it was received from the transmitter. Refer to the ULSR[OE] description, UART line status register (DUART_ULSR*n*) . Note that these registers have same offset as the UTHRs.

Address: Base address + 500h offset + (256d × i), where i=0d to 1d

Bit	0	1	2	3	4	5	6	7
Read	DATA							
Write								
Reset	0	0	0	0	0	0	0	0

DUARTx_URBR*n* field descriptions

Field	Description
0–7 DATA	Data received from the transmitter on the UART bus (read only)

17.3.2 UART transmitter holding register (DUARTx_UTHR*n*)

These registers are accessible when ULCR[DLAB] = 0.

A write to these 8-bit registers causes the UART devices to transfer 5-8 data bits on the UART bus in the format set up in the ULCR (line control register). In FIFO mode, data written to UTHR is placed into the FIFO. The data written to UTHR is the data sent onto the UART bus, and the first byte written to UTHR is the first byte onto the bus. UDSR[TXRDY_B] indicates when the FIFO is full. See UART DMA status register (DUART_UDSR*n*) for more details.

Address: Base address + 500h offset + (256d × i), where i=0d to 1d

DUARTx_UTHR*n* field descriptions

Field	Description
0–7 DATA	Data that is written to UTHR (write only)

17.3.3 UART divisor least significant byte register (DUARTx_UDLB*n*)

These registers are accessible when ULCR[DLAB] = 1.

The divisor least significant byte register (UDLB) is concatenated with the divisor most significant byte register (UDMB) to create the divisor used to divide the input clock into the DUART. The output frequency of the baud generator is 16 times the baud rate; therefore the desired baud rate = platform clock/2 frequency ÷ (16 x [UDMB||UDLB]). Equivalently, [UDMB||UDLB:0b0000] = platform clock/2 frequency ÷ desired baud rate. Baud rates that can be generated by specific input clock frequencies are shown in the table below.

The following table shows examples of baud rate generation based on common input clock frequencies. Many other target baud rates are also possible.

NOTE

Because only integer values can be used as divisors, the actual baud rate differs slightly from the desired (target) baud rate; for this reason, both target and actual baud rates are given, along with the percentage of error.

Table 17-3. Baud Rate Examples

Target baud rate (Decimal)	Divisor		Platform clock/2 frequency (MHz)	Actual baud rate (Decimal)	Percent error (Decimal)
	Decimal	Hex			
9,600	1953	0x7A1	300	9600.61444	0.0064

DUARTx_UDLB*n* field descriptions

Field	Description
0–7 UDLB	Divisor least significant byte. This is concatenated with UDMB.

17.3.4 UART divisor most significant byte register (DUARTx_UDMB*n*)

These registers are accessible when ULCR[DLAB] = 1.

The divisor least significant byte register (UDLB) is concatenated with the divisor most significant byte register (UDMB) to create the divisor used to divide the input clock into the DUART. The output frequency of the baud generator is 16 times the baud rate; therefore the desired baud rate = platform clock/2 frequency ÷ (16 x [UDMB||UDLB]). Equivalently, [UDMB||UDLB:0b0000] = platform clock/2 frequency ÷ desired baud rate. Baud rates that can be generated by specific input clock frequencies are shown in UART divisor least significant byte register (DUART_UDLB*n*).

Address: Base address + 501h offset + (256d × i), where i=0d to 1d

DUARTx_UDMB*n* field descriptions

Field	Description
0–7 UDMB	Divisor most significant byte

17.3.5 UART interrupt enable register (DUARTx_UIER*n*)

These registers are accessible when ULCR[DLAB] = 0.

The UIER gives the user the ability to mask specific UART interrupts to the programmable interrupt controller (PIC).

Address: Base address + 501h offset + (256d × i), where i=0d to 1d

Bit	0	1	2	3	4	5	6	7
Read Write	Reserved				EMSI	ERLSI	ETHREI	ERDAI
Reset	0	0	0	0	0	0	0	0

DUARTx_UIER*n* field descriptions

Field	Description
0–3 -	This field is reserved. Reserved.
4 EMSI	Enable modem status interrupt. 0 Mask interrupts caused by UMSR[DCTS] being set. 1 Enable and assert interrupts when the clear-to-send bit in the UART modem status register (UMSR) changes state.
5 ERLSI	Enable receiver line status interrupt. 0 Mask interrupts when ULSR's overrun, parity error, framing error or break interrupt bits are set. 1 Enable and assert interrupts when ULSR's overrun, parity error, framing error or break interrupt bits are set.
6 ETHREI	Enable transmitter holding register empty interrupt. 0 Mask interrupt when ULSR[THRE] is set. 1 Enable and assert interrupts when ULSR[THRE] is set.
7 ERDAI	Enable received data available interrupt. 0 Mask interrupt when new receive data is available or receive data time out has occurred. 1 Enable and assert interrupts when a new data character is received from the external device and/or a time-out interrupt occurs in the FIFO mode.

17.3.6 UART interrupt ID register (DUARTx_UIIR*n*)

These registers are accessible when ULCR[DLAB] = 0.

The UIIRs indicate when an interrupt is pending from the corresponding UART and what type of interrupt is active. They also indicate if the FIFOs are enabled.

The DUART prioritizes interrupts into four levels and records these in the corresponding UIIR. The four levels of interrupt conditions in order of priority are:

1. Receiver line status
2. Received data ready/character time out
3. Transmitter holding register empty
4. Modem status

When the UIIR is read, the associated DUART serial channel freezes all interrupts and indicates the highest priority pending interrupt. While this read transaction is occurring, the associated DUART serial channel records new interrupts, but does not change the contents of UIIR until the read access is complete.

Table 17-4. UIIR IID bits summary

IID bits IID[3-0]	Priority level	Interrupt type	Interrupt description	How to reset interrupt
0b0001	-	-	-	-
0b0110	Highest	Receiver line status	Overrun error, parity error, framing error, or break interrupt	Read the line status register.
0b0100	Second	Receiver data available	Receiver data available or trigger level reached in FIFO mode	Read the receiver buffer register or interrupt is automatically reset if the number of bytes in the receiver FIFO drops below the trigger level.
0b1100	Second	Character time out	No characters have been removed from or input to the receiver FIFO during the last 4 character times and there is at least one character in the receiver FIFO during this time.	Read the receiver buffer register.
0b0010	Third	UTHR empty	Transmitter holding register is empty	Read the UIIR or write to the UTHR.
0b0000	Fourth	Modem status	CTS_B input value changed since last read of UMSR	Read the UMSR.

Address: Base address + 502h offset + (256d × i), where i=0d to 1d

Bit	0	1	2	3	4	5	6	7

DUARTx_UIIR*n* field descriptions

Field	Description
0–1 FE	FIFOs enabled. Reflects the setting of UFCR[FEN]
2–3 -	This field is reserved. Reserved
4 IID3	Interrupt ID bits identify the highest priority interrupt that is pending as indicated in the table above. IID3 is set along with IID2 only when a timeout interrupt is pending for FIFO mode.
5 IID2	Interrupt ID bits identify the highest priority interrupt that is pending as indicated in the table above.
6 IID1	Interrupt ID bits identify the highest priority interrupt that is pending as indicated in the table above.
7 IID0	IID0 indicates when an interrupt is pending. 0 The UART has an active interrupt ready to be serviced. 1 No interrupt is pending.

17.3.7 UART FIFO control register (DUARTx_UFCR*n*)

These registers are accessible when ULCR[DLAB] = 0.

The UFCR, a write-only register, is used to enable and clear the receiver and transmitter FIFOs, set a receiver FIFO trigger level to control the received data available interrupt, and select the type of DMA signaling.

When the UFCR bits are written, the FIFO enable bit must also be set or else the UFCR bits are not programmed. When changing from FIFO mode to 16450 mode (non-FIFO mode) and vice versa, data is automatically cleared from the FIFOs.

After all the bytes in the receiver FIFO are cleared, the receiver internal shift register is not cleared. Similarly, the bytes are cleared in the transmitter FIFO, but the transmitter internal shift register is not cleared. Both TFR and RFR are self-clearing bits.

Address: Base address + 502h offset + (256d × i), where i=0d to 1d

Bit	0	1	2	3	4	5	6	7
Read			Reserved					
Write	RTL				DMS	TFR	RFR	FEN
Reset	0	0	0	0	0	0	0	0

DUARTx_UFCR*n* field descriptions

Field	Description
0–1 RTL	Receiver trigger level. A received data available interrupt occurs when UIER[ERDAI] is set and the number of bytes in the receiver FIFO equals the designated interrupt trigger level as follows: 00 1 byte

Table continues on the next page...

DUARTx_UFCRn field descriptions (continued)

Field	Description
	01 4 bytes 10 8 bytes 11 14 bytes
2–3 -	This field is reserved. Reserved
4 DMS	DMA mode select. See DMA mode select for more information. 0 UDSR[RXRDY] and UDSR[TXRDY] bits are in mode 0. 1 UDSR[RXRDY] and UDSR[TXRDY] bits are in mode 1 if UFCR[FEN] = 1.
5 TFR	Transmitter FIFO reset 0 No action 1 Clears all bytes in the transmitter FIFO and resets the FIFO counter/pointer to 0
6 RFR	Receiver FIFO reset 0 No action 1 Clears all bytes in the receiver FIFO and resets the FIFO counter/pointer to 0
7 FEN	FIFO enable 0 FIFOs are disabled and cleared 1 Enables the transmitter and receiver FIFOs

17.3.8 UART alternate function register (DUARTx_UAFRn)

These registers are accessible when ULCR[DLAB] = 1.

The UAFRs give software the ability to gate off the baud clock and write to each UARTn registers simultaneously with the same write operation.

Address: Base address + 502h offset + (256d × i), where i=0d to 1d

Bit	0	1	2	3	4	5	6	7
Read Write	Reserved						BO	CW
Reset	0	0	0	0	0	0	0	0

DUARTx_UAFRn field descriptions

0–5 -	This field is reserved. Reserved
6 BO	Baud clock select 0 The baud clock is not gated off 1 The baud clock is gated off
7 CW	Concurrent write enable

Table continues on the next page...

DUARTx_UAFR*n* field descriptions (continued)

Field	Description
	0 Disables writing to each UART*n* 1 Enables concurrent writes to corresponding UART registers. A write to a register in UART*n* is also a write to the corresponding register in UART*n+1* and vice versa for each DUART where *n* refers to the number of UART controller. The user needs to ensure that the ULCR[DLAB] of each UART is in the same state before executing a concurrent write to register addresses 0x*m*00, 0x*m*01 and 0x*m*02, where *m* is the base address of the corresponding UART.

17.3.9 UART line control register (DUARTx_ULCR*n*)

These registers are accessible when ULCR[DLAB] = x.

The ULCRs specify the data format for the UART bus and set the divisor latch access bit ULCR[DLAB], which controls the ability to access the divisor latch least and most significant bit registers and the alternate function register.

After initializing the ULCR, the software should not re-write the ULCR when valid transfers on the UART bus are active. The software should not re-write the ULCR until the last STOP bit has been received and there are no new characters being transferred on the bus.

The stick parity bit, ULCR[SP], assigns a set parity value for the parity bit time slot sent on the UART bus. The set value is defined as mark parity (logic 1) or space parity (logic 0). ULCR[PEN] and ULCR[EPS] help determine the set parity value. See the table below for more information. ULCR[NSTB], defines the number of STOP bits to be sent at the end of the data transfer. The receiver only checks the first STOP bit, regardless of the number of STOP bits selected. The word length select bits (1 and 0) define the number of data bits that are transmitted or received as a serial character. The word length does not include START, parity, and STOP bits.

Table 17-5. Parity selection using ULCR[PEN], ULCR[SP], and ULCR[EPS]

PEN	SP	EPS	Parity selected
0	0	0	No parity
0	0	1	No parity
0	1	0	No parity
0	1	1	No parity
1	0	0	Odd parity
1	0	1	Even parity
1	1	0	Mark parity
1	1	1	Space parity

Reset	0	0	0	0	0	0	0	0

DUARTx_ULCR*n* field descriptions

Field	Description
0 DLAB	Divisor latch access bit 0 Access to all registers except UDLB, UAFR, and UDMB. 1 Ability to access divisor latch least and most significant byte registers and alternate function register (UAFR).
1 SB	Set break 0 Send normal UTHR data onto the serial output (SOUT) signal. 1 Force logic 0 to be on the SOUT signal. Data in the UTHR is not affected.
2 SP	Stick parity 0 Stick parity is disabled 1 If PEN = 1 and EPS = 1, space parity is selected. And if PEN = 1 and EPS = 0, mark parity is selected.
3 EPS	Even parity select. See the table above for more information. 0 If PEN = 1 and SP = 0, odd parity is selected. 1 If PEN = 1 and SP = 0, even parity is selected.
4 PEN	Parity enable 0 No parity generation and checking. 1 Generate parity bit as a transmitter, and check parity as a receiver.
5 NSTB	Number of STOP bits 0 One STOP bit is generated in the transmitted data. 1 When a 5-bit data length is selected, 1½ STOP bits are generated. When either a 6-, 7-, or 8-bit word length is selected, two STOP bits are generated.
6–7 WLS	Word length select. Number of bits that comprise the character length. The word length select values are as follows: 00 5 bits 01 6 bits 10 7 bits 11 8 bits

17.3.10 UART modem control register (DUARTx_UMCR*n*)

These registers are accessible when ULCR[DLAB] = x.

The UMCRs control the interface with the external peripheral device on the UART bus.

Address: Base address + 504h offset + (256d × i), where i=0d to 1d

Bit	0	1	2	3	4	5	6	7
Read Write	Reserved			LOOP	Reserved		RTS	Reserved
Reset	0	0	0	0	0	0	0	0

DUARTx_UMCR*n* field descriptions

Field	Description
0–2 -	This field is reserved. Reserved
3 LOOP	Local loopback mode 0 Normal operation 1 Functionally, the data written to UTHR can be read from URBR of the same UART , and UMCR[RTS] is tied to UMSR[CTS].
4–5 -	This field is reserved. Reserved
6 RTS	Ready to send 0 Negates corresponding RTS_B output. 1 Asserts corresponding RTS_B output. Informs external modem or peripheral that the UART is ready for sending/receiving data.
7 -	This field is reserved. Reserved

17.3.11 UART line status register (DUARTx_ULSR*n*)

These registers are accessible when ULCR[DLAB] = x.

The ULSRs are read-only registers that monitor the status of the data transfer on the UART buses. To isolate the status bits from the proper character received through the UART bus, software should read the ULSR and then the URBR.

Address: Base address + 505h offset + (256d × i), where i=0d to 1d

Bit	0	1	2	3	4	5	6	7
Read	RFE	TEMT	THRE	BI	FE	PE	OE	DR
Write								
Reset	0	1	1	0	0	0	0	0

DUARTx_ULSR*n* field descriptions

Field	Description
0 RFE	Receiver FIFO error 0 This bit is cleared when there are no errors in the receiver FIFO or on a read of the ULSR with no remaining receiver FIFO errors. 1 Set to one when one of the characters in the receiver FIFO encounters an error (framing, parity, or break interrupt)

Table continues on the next page...

DUARTx_ULSR*n* field descriptions (continued)

Field	Description
1 TEMT	Transmitter empty 0 Either or both the UTHR or the internal transmitter shift register has a data character. In FIFO mode, a data character is in the transmitter FIFO or the internal transmitter shift register. 1 Both the UTHR and the internal transmitter shift register are empty. In FIFO mode, both the transmitter FIFO and the internal transmitter shift register are empty.
2 THRE	Transmitter holding register empty 0 The UTHR is not empty. 1 A data character has transferred from the UTHR into the internal transmitter shift register. In FIFO mode, the transmitter FIFO contains no data character.
3 BI	Break interrupt. **NOTE:** For a single break signal, BI and DR are set multiple times, approximately once every character period. The BI and DR bits continue to be set each character period after they are cleared. This continues for the entire duration of the break signal. To accommodate this behavior, read URBR, which returns zeros and clears DR. Then delay one character period and read URBR again. Note that at the end of the break signal, a random character may be falsely detected and received in the URBR, with ULSR[DR] being set. 0 This bit is cleared when the ULSR is read or when a valid data transfer is detected (that is, STOP bit is received). 1 Received data of logic 0 for more than START bit + Data bits + Parity bit + one STOP bits length of time. A new character is not loaded until SIN returns to the mark state (logic 1) and a valid START is detected. In FIFO mode, a zero character is encountered in the FIFO (the zero character is at the top of the FIFO). In FIFO mode, only one zero character is stored.
4 FE	Framing error 0 This bit is cleared when ULSR is read or when a new character is loaded into the URBR from the receiver shift register. 1 Invalid STOP bit for receive data (only the first STOP bit is checked). In FIFO mode, this bit is set when the character that detected a framing error is encountered in the FIFO (that is the character at the top of the FIFO). An attempt to resynchronize occurs after a framing error. The UART assumes that the framing error (due to a logic 0 being read when a logic 1 (STOP) was expected) was due to a STOP bit overlapping with the next START bit, so it assumes this logic 0 sample is a true START bit and then receives the following new data.
5 PE	Parity error 0 This bit is cleared when ULSR is read or when a new character is loaded into the URBR. 1 Unexpected parity value encountered when receiving data. In FIFO mode, the character with the error is at the top of the FIFO .
6 OE	Overrun error 0 This bit is cleared when ULSR is read. 1 Before the URBR is read, the URBR was overwritten with a new character. The old character is loss. In FIFO mode, the receiver FIFO is full (regardless of the receiver FIFO trigger level setting) and a new character has been received into the internal receiver shift register. The old character was overwritten by the new character. Data in the receiver FIFO was not overwritten.
7 DR	Data ready 0 This bit is cleared when URBR is read or when all of the data in the receiver FIFO is read. 1 A character has been received in the URBR or the receiver FIFO.

17.3.12 UART modem status register (DUARTx_UMSRn)

These registers are accessible when ULCR[DLAB] = x.

The UMSRs track the status of the modem (or external peripheral device) clear to send (CTS_B) signal for the corresponding UART .

Address: Base address + 506h offset + (256d × i), where i=0d to 1d

Bit	0	1	2	3	4	5	6	7
Read	Reserved			CTS	Reserved			DCTS
Write								
Reset	0	0	0	0	0	0	0	0

DUARTx_UMSRn field descriptions

Field	Description
0–2 -	This field is reserved. Reserved.
3 CTS	Clear to send. Represents the inverted value of the CTS_B input pin from the external peripheral device. 0 Corresponding UART*n*_CTS_B is negated. 1 Corresponding UART*n*_CTS_B is asserted. The modem or peripheral device is ready for data transfers.
4–6 -	This field is reserved. Reserved.
7 DCTS	Clear to send. 0 No change on the corresponding UART*n*_CTS_B signal since the last read of UMSR[CTS]. 1 The UART*n*_CTS_B value has changed, since the last read of UMSR[CTS]. Causes an interrupt if UIER[EMSI] is set to detect this condition.

17.3.13 UART scratch register (DUARTx_USCRn)

These registers are accessible when ULCR[DLAB] = x.

The USCR registers are for debugging software or the DUART hardware. The USCRs do not affect the operation of the DUART.

Address: Base address + 507h offset + (256d × i), where i=0d to 1d

Bit	0	1	2	3	4	5	6	7
Read Write	DATA							
Reset	0	0	0	0	0	0	0	0

DUARTx_USCR*n* field descriptions

Field	Description
0–7 DATA	Data

17.3.14 UART DMA status register (DUARTx_UDSR*n*)

These registers are accessible when ULCR[DLAB] = x.

The DMA status registers (UDSRs) are read-only registers that return transmitter and receiver FIFO status. UDSRs also provide the ability to assist DMA data operations to and from the FIFOs.

Table 17-6. UDSR[TXRDY] set conditions

DMS	FEN	DMA mode	Meaning
0	0	0	TXRDY is set after the first character is loaded into the transmitter FIFO or UTHR.
0	1	0	
1	0	0	
1	1	1	TXRDY is set when the transmitter FIFO is full.

Table 17-7. UDSR[TXRDY] cleared conditions

DMS	FEN	DMA mode	Meaning
0	0	0	TXRDY is cleared when there are no characters in the transmitter FIFO or UTHR.
0	1	0	
1	0	0	
1	1	1	TXRDY is cleared when there are no characters in the transmitter FIFO or UTHR. TXRDY remains clear when the transmitter FIFO is not yet full.

Table 17-8. UDSR[RXRDY] set conditions

DMS	FEN	DMA mode	Meaning
0	0	0	RXRDY is set when there are no characters in the receiver FIFO or URBR.
0	1	0	
1	0	0	
1	1	1	RXRDY is set when the trigger level has not been reached and there has been no time out.

Table 17-9. UDSR[RXRDY] cleared conditions

DMS	FEN	DMA mode	Meaning
0	0	0	RXRDY is cleared when there is at least one character in the receiver FIFO or URBR.
0	1	0	
1	0	0	
1	1	1	RXRDY is cleared when the trigger level or a time-out has been reached. RXRDY remains cleared until the receiver FIFO is empty.

Address: Base address + 510h offset + (256d × i), where i=0d to 1d

Bit	0	1	2	3	4	5	6	7

Write								
Reset	0	0	0	0	0	0	0	1

DUART*x*_UDSR*n* field descriptions

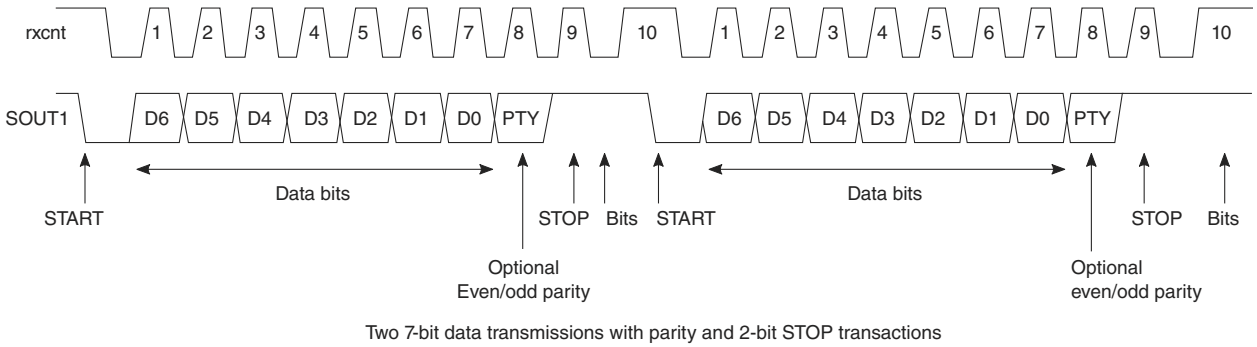
Field	Description
0–5 -	This field is reserved. Reserved.
6 TXRDY	Transmitter ready. This read-only bit reflects the status of the transmitter FIFO or the UTHR. The status depends on the DMA mode selected, which is determined by the DMS and FEN bits in the UFCR. 0 This bit is cleared, as shown in Table 17-7 . 1 This bit is set, as shown in Table 17-6 .
7 RXRDY	Receiver ready. This read-only bit reflects the status of the receiver FIFO or URBR. The status depends on the DMA mode selected, which is determined by the DMS and FEN bits in the UFCR. 0 This bit is cleared, as shown in Table 17-9 . 1 This bit is set, as shown in Table 17-8 .

17.4 Functional description

The following sections provide the function of the DUART controller.

17.4.1 Serial interface

The UART bus is a serial, full-duplex, point-to-point bus as shown in the following figure. Therefore, only two devices are attached to the same signals and there is no need for address or arbitration bus cycles.



Two 7-bit data transmissions with parity and 2-bit STOP transactions

Figure 17-2. UART bus interface transaction protocol example

A standard UART bus transfer is composed of either three or four parts:

- START bit
- Data transfer bits (least-significant bit is first data bit on the bus)
- Parity bit (optional)
- STOP bits

An internal logic sample signal, *rxcnt*, uses the frequency of the baud-rate generator to drive the bits on SOUT.

The following sections describe the four components of the serial interface, the baud-rate generator, local loopback mode, different errors, and FIFO mode.

17.4.1.1 START bit

A write to the transmitter holding register (UTHR) generates a START bit on the SOUT signal.

Figure 17-2 shows that the START bit is defined as a logic 0. The START bit denotes the beginning of a new data transfer which is limited to the bit length programmed in the UART line control register (ULCR). When the bus is idle, SOUT is high.

17.4.1.2 Data transfer

Each data transfer contains 5-8 bits of data.

The ULCR data bit length for the transmitter and receiver UART devices must agree before a transfer begins; otherwise, a parity or framing error may occur. A transfer begins when UTHR is written. At that time a START bit is generated followed by 5-8 of the data bits previously written to the UTHR. The data bits are driven from the least significant to the most significant bits. After the parity and STOP bits, a new data transfer can begin if new data is written to the UTHR.

17.4.1.3 Parity bit

The user has the option of using even, odd, no parity, or stick parity.

See UART line control register (DUART_ULCR*n*). Both the receiver and transmitter parity definition must agree before attempting to transfer data. When receiving data, a parity error can occur if an unexpected parity value is detected. See UART line status register (DUART_ULSR*n*).

17.4.1.4 STOP bit

The transmitter device ends the write transfer by generating a STOP bit.

The STOP bit is always high. The length of the STOP bit(s) can be programmed in the ULCR. Both the receiver and transmitter STOP bit length must agree before attempting to transfer data. A framing error can occur if an invalid STOP bit is detected.

17.4.2 Baud-rate generator logic

Each UART contains an independent programmable baud-rate generator, that is capable of taking the platform clock frequency/2as input and dividing the input by any divisor from 1 to 2^{16} - 1.

The baud rate is defined as the number of bits per second that can be sent over the UART bus. The formula for calculating baud rate is as follows:

Baud rate = (1/16) x ((platform clock/2) frequency ÷ divisor value)

Therefore, the output frequency of the baud-rate generator is 16 times the baud rate.

The divisor value is determined by the following two 8-bit registers to form a 16-bit binary number:

- UART divisor most significant byte register (UDMB)
- UART divisor least significant byte register (UDLB)

Upon loading either of the divisor latches, a 16-bit baud-rate counter is loaded.

The divisor latches must be loaded during initialization to ensure proper operation of the baud-rate generator. Both UART devices on the same bus must be programmed for the same baud-rate before starting a transfer.

The baud clock can be passed to the performance monitor by enabling the UAFR[BO] bit. This can be used to determine baud rate errors.

17.4.3 Local loopback mode

Local loopback mode is provided for diagnostic testing.

The data written to UTHR can be read from the receiver buffer register (URBR) of the same UART. In this mode, the modem control register UMCR[RTS] is internally tied to the modem status register UMSR[CTS]. The transmitter SOUT is set to a logic 1 and the receiver SIN is disconnected. The output of the transmitter shift register is looped back into the receiver shift register input. The CTS_B (input signal) is disconnected, RTS_B is internally connected to CTS_B, and the RTS_B (output signal) becomes inactive. In this diagnostic mode, data that is transmitted is immediately received. In local loopback mode, the transmit and receive data paths of the DUART can be verified.

NOTE

In local loopback mode, the transmit/receive interrupts are fully operational and can be controlled by the interrupt enable register (UIER).

17.4.4 Errors

The following sections describe framing, parity, and overrun errors which may occur while data is transferred on the UART bus.

Each of the error bits are usually cleared, as described below, when the line status register (ULSR) is read.

17.4.4.1 Framing error

When an invalid STOP bit is detected, a framing error occurs and ULSR[FE] is set.

Note that only the first STOP bit is checked. In FIFO mode, ULSR[FE] is set when the character at the top of the FIFO detects a framing error. An attempt to re-synchronize occurs after a framing error. The UART assumes that the framing error (due to a logic 0 being read when a logic 1 (STOP) was expected) was due to a STOP bit overlapping with the next START bit. ULSR[FE] is cleared when ULSR is read or when a new character is loaded into the URBR from the receiver shift register.

17.4.4.2 Parity error

A parity error occurs, and ULSR[PE] is set, when unexpected parity values are encountered while receiving data.

In FIFO mode, ULSR[PE] is set when the character with the error is at the top of the FIFO. ULSR[PE] is cleared when ULSR is read or when a new character is loaded into the URBR.

17.4.4.3 Overrun error

When a new (overwriting character) STOP bit is detected and the old character is lost, an overrun error occurs and ULSR[OE] is set.

In FIFO mode, ULSR[OE] is set after the receiver FIFO is full (despite the receiver FIFO trigger level setting) and a new character has been received into the internal receiver shift register. Data in the FIFO is not overwritten; only the shift register data is overwritten. Therefore, the interrupt occurs immediately. ULSR[OE] is cleared when ULSR is read.

17.4.5 FIFO mode

The UARTs use an alternate mode (FIFO mode) to relieve the processor core from excessive software overhead.

The FIFO control register (UFCR) is used to enable and clear the receiver and transmitter FIFOs and set the FIFO receiver trigger level UFCR[RTL] to control the received data available interrupt UIER[ERDAI].

The UFCR also selects the type of DMA signaling. The UDSR[RXRDY] indicates the status of the receiver FIFO. The DMA status registers (UDSR[TXRDY]) indicate when the transmitter FIFO is full. When in FIFO mode, data written to UTHR is placed into the transmitter FIFO. The first byte written to UTHR is the first byte onto the UART bus.

17.4.5.1 FIFO interrupts

In FIFO mode, the UIER[ERDAI] is set when a time-out interrupt occurs. When a receive data time-out occurs there is a maskable interrupt condition (through UIER[ERDAI]). See UART interrupt enable register (DUART_UIER*n*) for more details on interrupt enables.

The interrupt ID register (UIIR) indicates if the FIFOs are enabled. The interrupt ID3 bit UIIR[IID3] is only set for FIFO mode interrupts. The character time-out interrupt occurs when no characters have been removed from or input to the receiver FIFO during the last four character times and there is at least one character in the receiver FIFO during this time. The character time-out interrupt (controlled by UIIR[IID*n*]) is cleared when the URBR is read. See UART interrupt ID register (DUART_UIIR*n*) for more information.

The UIIR[FE] bit indicates if FIFO mode is enabled.

17.4.5.2 DMA mode select

The UDSR[RXRDY] bit reflects the status of the receiver FIFO or URBR.

In mode 0 (UFCR[DMS] is cleared), UDSR[RXRDY] is cleared when there is at least one character in the receiver FIFO or URBR and it is set when there are no more characters in the receiver FIFO or URBR. This occurs regardless of the setting of the UFCR[FEN] bit. In mode 1 (UFCR[DMS] and UFCR[FEN] are set), UDSR[RXRDY] is cleared when the trigger level or a time-out has been reached and it is set when there are no more characters in the receiver FIFO.

The UDSR[TXRDY] bit reflects the status of the transmitter FIFO or UTHR. In mode 0 (UFCR[DMS] is cleared), UDSR[TXRDY] is cleared when there are no characters in the transmitter FIFO or UTHR and it is set after the first character is loaded into the transmitter FIFO or UTHR. This occurs regardless of the setting of the UFCR[FEN] bit. In mode 1 (UFCR[DMS] and UFCR[FEN] are set), UDSR[TXRDY] is cleared when there are no characters in the transmitter FIFO or UTHR and it is set when the transmitter FIFO is full.

See UART DMA status register (DUART_UDSR*n*), for a complete description of the USDR[RXRDY] and USDR[TXRDY] bits.

NOTE

The chip does not support the DMA operation where software or an external DMA fills the inbuilt FIFO. When FIFO is full, DUART initiates the transmission.

17.4.5.3 Interrupt control logic

An interrupt is active when DUART interrupt ID register bit 7 (UIIR[IID0]), is cleared.

The interrupt enable register (UIER) is used to mask specific interrupt types. See UART interrupt enable register (DUART_UIER*n*) for more details.

When the interrupts are disabled in UIER, polling software cannot use UIIR[IID0] to determine whether the UART is ready for service. The software must monitor the appropriate bits in the line status (ULSR) and/or the modem status registers (UMSR). UIIR[IID0] can be used for polling if the interrupts are enabled in UIER.

17.5 Initialization/Application information

The following requirements must be met for DUART accesses:

- All DUART registers are 1 byte wide. Reads and writes to these registers must be byte-wide operations.

A system reset puts the DUART registers to a default state. Before the interface can transfer serial data, the following initialization steps are recommended:

1. Update the programmable interrupt controller (PIC) DUART channel interrupt vector source registers.
2. Set data attributes and control bits in the ULCR, UFCR, UAFR, UMCR, UDLB, and UDMB.
3. Set the data attributes and control bits of the external modem or peripheral device.
4. Set the interrupt enable register (UIER).
5. To start a write transfer, write to the UTHR.
6. Poll UIIR, if the interrupts generated by the DUART are masked.

Chapter 18
SerDes Module

18.1 Overview

The SerDes module implements link serialization/deserialization and PCS functions for high speed serial interfaces.

18.1.1 The SerDes module as implemented on the chip

This section provides more details about how the SerDes module is implemented on this chip.

18.1.1.1 T4240 SerDes Integration

Module	Module base address	Minimum symbol rate (Gbps)	Maximum symbol rate (Gbps)	Notes
SerDes 1	0E_A000h	1.25	10.3125	Used for networking protocols
SerDes 2	0E_B000h	1.25	10.3125	Used for networking protocols
SerDes 3	0E_C000h	1.25	10.3125	Used for non-networking protocols
SerDes 4	0E_D000h	1.25	10.3125	Used for non-networking protocols

18.1.1.2 SerDes Lane Assignments and Multiplexing

18.1.1.2.1 Configuration of Networking SerDes

- SerDes 1 Configuration:
  - Protocol(s): Selected using RCW[SRDS_PRTCL_S1]
  - PLLs: Enabled using RCW[SRDS_PLL_PD_S1]

    - PLL Reference Clock: RCW[SRDS_PLL_REF_CLK_SEL_S1]
    - rates are determined by the protocol selection
- SerDes 2 Configuration:
    - Protocol(s): Selected using RCW[SRDS_PRTCL_S2]
    - PLLs: Enabled using RCW[SRDS_PLL_PD_S2]
    - PLL Reference Clock: RCW[SRDS_PLL_REF_CLK_SEL_S2]
    - rates are determined by the protocol selection

18.1.1.2.2 Networking Protocols (SerDes 1 and SerDes 2)

The following table shows the supported networking protocol options for SerDes modules 1 and 2. The following notation conventions are used in the table:

- XAUI notation: XAUIm.n means XAUI (4 lanes @ 3.125 Gbaud)
    - "m" indicates which Frame Manager (FM1 or FM2)
    - "n" indicates which MAC on the Frame Manager
    - For example, "XAUI1.10," indicates XAUI using FM1's MAC 10.
- XFI notation (also supporting 10GBASE-KR): XFIm.n means XFI (1 lane @ 10.3125 Gbaud)
    - "m" indicates which Frame Manager (FM1 or FM2)
    - "n" indicates which MAC on the Frame Manager
    - For example, "XFI1.10," indicates XFI using FM1's MAC 10.
- HiGig notation: HiGig[2]m.n means HiGig[2] (4 lanes @ 3.125 or 3.75 Gbaud)
    - "m" indicates which Frame Manager (FM1 or FM2)
    - "n" indicates which MAC on the Frame Manager
    - [2] indicates optional selection of 16 byte headers via IF_MODE[MSG]. Please refer T4240 QorIQ Data Path Acceleration Architecture (DPAA) Reference Manual for the register description.
    - For example, "HiGig[2]1.10," indicates HiGig with either 12 or 16 byte headers using FM1's MAC 10.
    - In the table below italics means HiGig[2] (4 lanes @ 3.75 Gbps)
- SGMII notation:
    - sgm.n means SGMII (1 lane @ 1.25 Gbaud)
        - "m" indicates which Frame Manager (FM1 or FM2)
        - "n" indicates which MAC on the Frame Manager.
        - For example, "sg1.9," indicates SGMII for MAC 9 on FM1.
    - *sgm.n* that is italics, means SGMII (1 lane @ 3.125 Gbaud)
        - "m" indicates which Frame Manager (FM1 or FM2)
        - "n" indicates which MAC on the Frame Manager
        - For example, "*s1.9*" indicates SGMII for MAC 9 on FM1
- QSGMII notation: qsm.a or qsm.a means QSGMII (1 lane @ 5 Gbps)

- "m" indicates which Frame Manager (FM1 or FM2)
- "a" indicates MACs 1-4 and 'b' indicates MACs 5, 6, 9, and 10.

- RGMII Notation:
  - rm.n means RGMII (uses LVCMOS pins instead of SerDes)
    - "m" indicates which Frame Manager (FM1 or FM2)
    - "n" indicates which MAC on the Frame Manager
  - r.* = RGMII (uses LVCMOS pins instead of SerDes), which stands for one of two MACs:
    - FM1's MAC5 which is guaranteed to be available
    - FM2's MAC6 which is only available if not used by SerDes2
  - r.+ = RGMII (uses LVCMOS pins instead of SerDes), which stands for FM2's MAC6 which is only available if not used by SerDes2
- Per lane PLL mapping:
  - 1 = PLL1
  - 2 = PLL2
  - x = not applicable

18.1.1.2.2.1 SerDes 1 options

Table 18-1. SerDes 1

18.1.1.2.2.4 Networking SerDes Option Restrictions

A valid configuration for SerDes 1 and 2 is subject to the following rules:

18.1.1.2.2.4.1 Rules restricting protocol selections (networking)

The following SerDes 1 protocols (S1) are available only if one of the listed SerDes 2 protocols (S2) is selected:

- S1 = 1 is available for all entries where S2 = 1-53
- S1 = 2 is available for entries where S2 = 2-57
- S1 = 4 is available for entries where S2 = 4-57
- S1 = 27 is available for entries where S2 = 6-57
- S1 = 35 is available for entries where S2 = 6-26 or 35-57
- S1 = 37 is available for entries where S2 = 6-26 or 37-57
- S1 = 39 is available for entries where S2 = 6-26 or 39-57
- S1 = 45 is available for entries where S2 = 6-26 or 45-57
- S1 = 47 is available for entries where S2 = 6-26 or 47-57

18.1.1.2.2.4.2 Rules restricting protocol selections due to max of 25 Gbps PCD

If S2 = 55 or 57 and both XFI1.9 and XFI1.10 are used, then only the following are supported on SerDes 1:

- S1 = 27 for lanes E-H (4 SGMII @ 1.25 Gbaud)
- S1 = 35 for lanes E-F (2 SGMII @ 3.125 Gbaud)
- S1 = 37 for lane G (1 QSGMII)

If S2 = 55 and both XFI2.9 and XFI2.10 are used, then only the following is supported on the rightmost four lanes of SerDes 2:

- SGMII on lanes E-H (4 SGMII @ 1.25 Gbaud)

If S2 = 57 and both XFI2.9 and XFI2.10 are used, then only the following is supported on the rightmost four lanes of SerDes 2:

- SGMII on lanes E-F (2 SGMII @ 3.125 Gbaud)

If S2=55 and XFI2.9, XFI2.10 are used as well as s2.1 through s2.4, then only one RGMII from FM2 can be used

If S2=57 and XFI2.9, XFI2.10 are used as well as one RGMII from FM2, then a maximum of one SerDes 2 SGMII @ 3.125 Gbaud is available for use in lanes E-H

NOTE

The rate is directly proportional to the Frame manager clocking frequency which determines the availability of protocols the frame manager runs.

The rate calculated from the equation below should be less or equal 25 Gbps to avoid protocols from being unavailable:

Rate = (Frame Manager clocking frequency in MHz / 800 MHz) * 25 Gbps

For FMan clocking frequency of 733 MHz:

- If pause is acceptable, then 25 Gbps connectivity is okay with a max processing rate of 23 Gbps ≈ 733/(800)* 25 Gbps
- If pause is not acceptable, then max allowed connectivity is 23 Gbps

For FMan clocking frequency of 667 MHz:

- If pause is acceptable, then 25 Gbps connectivity is okay with a max processing rate of 21 Gbps ≈ 667/800 * 25 Gbps
- If pause is not acceptable, then max allowed connectivity is 21 Gbps

18.1.1.2.2.4.3 Rules for selection of HiGig/HiGig2 protocols

When a SerDes protocol is selected with dual HiGigs in one SerDes, both HiGigs must be configured with the same protocol (for example, both with 12 byte headers or both with 16 byte headers).

18.1.1.2.2.4.4 Rules restricting networking SerDes PLL powerdown

SerDes 1 PLL2 must be powered down using SRDS_PLL_PD_S1 when SRDS_PRTCL_S1 is any of the following values: 1, 2, 4, 27, 37, or 39

SerDes 2 PLL2 must be powered down using SRDS_PLL_PD_S2 when SRDS_PRTCL_S2 is any of the following values: 1, 2, 4, 14, 23, 27, 37, or 39

NOTE

HiGig and HiGig2 use XAUI configuration.

18.1.1.2.2.5 Rules for disabling networking SerDes PLLs when not all lanes are needed

SerDes 1: Disabling Rightmost Lanes

- If SRDS_PRTCL_S1 is 35 or 47, it is permissible to power down SerDes 1 PLL2 only if software powers down SerDes 1 lanes E-H
- If SRDS_PRTCL_S1 is 45, it is permissible to power down SerDes 1 PLL2 only if software powers down SerDes 1 lanes C-D

SerDes 2: Disabling Rightmost Lanes

- If SRDS_PRTCL_S2 is 6, 15, 24, 26, 35, 47, or 49-57, it is permissible to power down SerDes 2 PLL2 only if software powers down SerDes 2 lanes E-H
- If SRDS_PRTCL_S2 is 12 or 21, it is permissible to power down SerDes 2 PLL2 only if software powers down SerDes 2 lanes G-H
- If SRDS_PRTCL_S2 is 45, it is permissible to power down SerDes 2 PLL2 only if software powers down SerDes 2 lanes C-D

SerDes 2: Disabling Leftmost Lanes

- If SRDS_PRTCL_S2 is 6, 15, 24, 26, 35, or 55-57, it is permissible to power down SerDes 2 PLL1 only if software powers down SerDes 2 lanes A-D
- If SRDS_PRTCL_S2 is 12 or 21, it is permissible to power down SerDes 2 PLL1 only if software powers down SerDes 2 lanes A-F

18.1.1.2.2.5.1 Rules for disabling a networking SerDes module

If SerDes 1 and/or 2 is not used, then it must be disabled as described in Disabling Unused SerDes Modules.

18.1.1.2.3 Non-Networking Protocols (SerDes 3 and SerDes 4)

The following notation is used in the SerDes tables:

- PEXn (8/5/2.5) = PCIe operating up to 8, 5, or 2.5 GT/s depending on maximum rate selection and training
- PEXn (5/2.5) = PCIe operating up to 5 or 2.5 GT/s depending on maximum rate selection and training
- SRIOn (5/2.5) = SRIO operating at 5 or 2.5 Gbaud depending on rate selection
- SRIOn (3.125) = SRIO operating at 3.125 Gbaud
- Interlaken (6.25) = Interlaken operating at 6.25 Gbps
- SATAn (3/1.5) = SATA operating at 3 or 1.5 Gbps depending on rate selection
- Aurora (5/2.5) = Debug operating at 5 or 2.5 Gbps depending on rate selection
- Aurora (3.125) = Debug operating at 3.125 Gbps

18.1.1.2.3.1 SerDes 3 Options

The following table shows the supported non-networking protocol options for SerDes modules 3 and 4.

NOTE

For SRDS_PRTCL_S4 values of 5, 7, 13, or 15 where SRIO2 is supported, DMA3 is not available.

NOTE

Two PCIe Gen 3 controllers can be run at the same time with same SerDes reference clock source.

Endpoint SR-IOV is only available on PCIe controller (PCIe) 1.

In combinations of SerDes protocols with more than one PCIe capable of 8 Gbps, RCW's SRDS_DIV_PEX_S3 and SRDS_DIV_PEX_S4 must be configured so that a maximum of one PCIe controller can train up to 8 GT/s operation.

Table 18-5. SerDes 3 Options

SRDS_PRTCL_S3		SerDes 3								
Decimal	Hex	A	B	C	D	E	F	G	H	Per Lane PLL mapping
1	1	PCIe1 (5/2.5)								11111111
3[1]	3	PCIe1 (5/2.5)				PCIe2 (8/5/2.5)				11111111
5	5	PCIe1 (5/2.5)				SRIO1 (5/2.5)				11111111
7	7	PCIe1 (8/5/2.5)				SRIO1 (3.125)				11112222
10	A	Interlaken (6.25)								11111111
11	B					PCIe2 (8/5/2.5)				11112222
13	D	Interlaken (6.25)				PCIe2 (8/5/2.5)				11112222

Table continues on the next page...

Table 18-5. SerDes 3 Options (continued)

SRDS_PRTCL_S3		SerDes 3								
Decimal	Hex	A	B	C	D	E	F	G	H	Per Lane PLL mapping
15	F					SRIO1 (5/2.5)				11112222
17	11					SRIO1 (3.125)				11112222
18	12	Interlaken (6.25)				SRIO1 (5/2.5)				11112222
20	14	Interlaken (6.25)				SRIO1 (3.125)				11111111

1. This SerDes combination supports PCIe 8 GT/s which starts out with only PLL1 enabled. Since PLL2 is automatically enabled during speed switch, the system must supply a reference clock to PLL2 and SRDS_PLL_PD_S3 must be set to 2'b01. Write SRDS_PLL_REF_CLK_SEL_S3[PLL2]=100 MHz or 125MHz and supply the reference clock to PLL2 accordingly.

18.1.1.2.3.2 SerDes 4 options

Table 18-6. SerDes 4

SRDS_PRTCL_S4		SerDes 4								
Decimal	Hex	A	B	C	D	E	F	G	H	Per lane PLL mapping
1	1	PCIe3 (5/2.5)								11111111
3 [1]	3	PCIe3 (5/2.5)				PCIe4 (8/5/2.5)				11111111
5	5	PCIe3 (5/2.5)				SRIO2 (5/2.5)				11111111
7	7	PCIe3 (8/5/2.5)				SRIO2 (3.125)				11112222
9	9	PCIe3 (5/2.5)				PCIe4 (5/2.5)		SATA1 (3/1.5)	SATA2 (3/1.5)	11111122
11	B	PCIe3 (5/2.5)				Aurora (5/2.5)		SATA1 (3/1.5)	SATA2 (3/1.5)	11111122
13	D	PCIe3 (5/2.5)				Aurora (5/2.5)		SRIO2 (5/2.5)		11111111
15	F	PCIe3 (8/5/2.5)				Aurora (3.125)		SRIO2 (3.125)		11112222

1. This SerDes combination supports PCIe 8 GT/s which starts out with only PLL1 enabled. Since PLL2 is automatically enabled during speed switch, the system must supply a reference clock to PLL2 and SRDS_PLL_PD_S4 must be set to 2'b01. Write SRDS_PLL_REF_CLK_SEL_S4[PLL2]=100 MHz or 125MHz and supply the reference clock to PLL2 accordingly.

18.1.1.2.3.3 SerDes 3 Lane Assignments

The SerDes 3 lanes correspond to the SD3_TXn_P/SD3_TXn_N and SD3_RXn_P/SD3_RXn_N signals as shown in the table below. The table also shows the lane assignments for the controllers that can use SerDes 3.

Table 18-7. SerDes 3 Lane/Signal Assignments

SerDes 3 Lane	Signal	Controller Lane Assignments			
		PCI Express		SRIO1	Interlaken
		PCIe1	PCIe2		
A	SD3_TX[0]_P/SD3_TX[0]_N SD3_RX[0]_P/SD3_RX[0]_N	0			0
B	SD3_TX[1]_P/SD3_TX[1]_N SD3_RX[1]_P/SD3_RX[1]_N	1			1
C	SD3_TX[2]_P/SD3_TX[2]_N SD3_RX[2]_P/SD3_RX[2]_N	2			2
D	SD3_TX[3]_P/SD3_TX[3]_N SD3_RX[3]_P/SD3_RX[3]_N	3			3
E	SD3_TX[4]_P/SD3_TX[4]_N SD3_RX[4]_P/SD3_RX[4]_N	4	0	3	4
F	SD3_TX[5]_P/SD3_TX[5]_N SD3_RX[5]_P/SD3_RX[5]_N	5	1	2	5
G	SD3_TX[6]_P/SD3_TX[6]_N SD3_RX[6]_P/SD3_RX[6]_N	6	2	1	6
H	SD3_TX[7]_P/SD3_TX[7]_N SD3_RX[7]_P/SD3_RX[7]_N	7	3	0	7

18.1.1.2.3.4 SerDes 4 Lane Assignments

The SerDes 4 lanes correspond to the SD4_TX_Pn/SD4_TX_Nn and SD4_RX_Pn/SD4_RX_Nn signals as shown in the table below. The table also shows the lane assignments for the controllers that can use SerDes 4.

Table 18-8. SerDes 4 Lane/Signal Assignments

SerDes 4 Lane	Signal	Controller Lane Assignments					
		PCI Express		SRIO2	Aurora (Debug)	SATA1	SATA2
		PCIe3	PCIe4				
A	SD4_TX[0]_P/SD4_TX[0]_N SD4_RX[0]_P/SD4_RX[0]_N	0					
B	SD4_TX[1]_P/SD4_TX[1]_N SD4_RX[1]_P/SD4_RX[1]_N	1					
C	SD4_TX[2]_P/SD4_TX[2]_N SD4_RX[2]_P/SD4_RX[2]_N	2					
D	SD4_TX[3]_P/SD4_TX[3]_N SD4_RX[3]_P/SD4_RX[3]_N	3					
E	SD4_TX[4]_P/SD4_TX[4]_N SD4_RX[4]_P/SD4_RX[4]_N	4	0	3	1 (2-lane)		
F	SD4_TX[5]_P/SD4_TX[5]_N SD4_RX[5]_P/SD4_RX[5]_N	5	1	2	0 (2-lane)		
G	SD4_TX[6]_P/SD4_TX[6]_N SD4_RX[6]_P/SD4_RX[6]_N	6	2	1		SATA1	

Table continues on the next page...

Table 18-8. SerDes 4 Lane/Signal Assignments (continued)

SerDes 4 Lane	Signal	Controller Lane Assignments					
		PCI Express		SRIO2	Aurora (Debug)	SATA1	SATA2
		PCIe3	PCIe4				
H	SD4_TX[7]_P/SD4_TX[7]_N SD4_RX[7]_P/SD4_RX[7]_N	7	3	0			SATA2

18.1.1.2.3.5 Non-Networking SerDes Option Restrictions

A valid configuration for SerDes 3 and 4 is subject to the following rules:

18.1.1.2.3.5.1 Rules restricting protocol selections (non-networking)

- PCIe3 configured as 8 lanes (SRDS_PRTCL_S4 = 1) is only available when SRDS_PRTCL_S3 is not equal to 3, 5 or 7.
- PCIe3 and PCIe4 configured as 4 lanes (SRDS_PRTCL_S4 = 3) is only available when SRDS_PRTCL_S3 is not equal to 5 or 7.
- PCIe3 configured as 4 lanes and SRIO configured as 4 lanes, 5/2.5 (SRDS_PRTCL_S4 = 5) is only available when SRDS_PRTCL_S3 is not equal to 7.

18.1.1.2.3.5.2 Rules restricting non-networking SerDes PLL powerdown

SerDes 3 PLL2 must be powered down using SRDS_PLL_PD_S3 when SRDS_PRTCL_S3 is any of the following values:

- 1, 3, 5, 10, 20
- 3 and PCIe2 is limited to a maximum of 5 Gbps

SerDes 4 PLL2 must be powered down using SRDS_PLL_PD_S4 when SRDS_PRTCL_S4 is any of the following values:

- 1, 3, 5, 13
- 3 and PCIe4 is limited to a maximum of 5 Gbps

18.1.1.2.3.5.3 Rules for disabling a non-networking SerDes module

If SerDes 3 and/or 4 is not used, then it must be disabled as described in Disabling Unused SerDes Modules.

All lanes associated with that SerDes should also be powered down as described in the hardware specifications.

18.1.1.3 Disabling Unused SerDes Modules

SerDes 1 is disabled as follows:

- SRDS_PLL_PD_S1 = 2'b11 (both PLLs configured as powered down)
- SRDS_PLL_REF_CLK_SEL_S1 = 2'b00
- SRDS_PRTCL_S1 = 2 (no other values are permitted when both PLLs are powered down)

SerDes 2 is disabled as follows:

- SRDS_PLL_PD_S2 = 2'b11 (both PLLs configured as powered down)
- SRDS_PLL_REF_CLK_SEL_S2 = 2'b00
- SRDS_PRTCL_S2 = 2 (no other values are permitted when both PLLs are powered down)

NOTE

To disable SerDes 2 for T4160 and T4080, SRDS_PRTCL_S2 should be set to 2 even though the option SRDS_PRTCL_S2 is not supported on T4160 and T4080.

SerDes 3 is disabled as follows:

- SRDS_PLL_PD_S3 = 2'b11 (both PLLs configured as powered down)
- SRDS_PLL_REF_CLK_SEL_S3 = 2'b00
- SRDS_PRTCL_S3 = 2 (no other values are permitted when both PLLs are powered down)

SerDes 4 is disabled as follows:

- SRDS_PLL_PD_S4 = 2'b11 (both PLLs configured as powered down)
- SRDS_PLL_REF_CLK_SEL_S4 = 2'b00
- SRDS_PRTCL_S4 = 2 (no other values are permitted when both PLLs are powered down)

18.1.1.3.1 Powering Down Unused SerDes Lanes

Powering down of SerDes data lanes is only supported in software using registers in the SerDes Control Block. Also see the RCW bit definition for SRDS_PLL_PD_S1 for how lanes can be powered down based on the powering down of individual PLLs.

18.1.1.4 Reference Clocks for SerDes Protocols

Each SerDes protocol allows for a finite set of valid SerDes-related RCW fields and reference clock frequencies, as shown in Table 18-9.

Table 18-9. Valid SerDes Reference Clocks and RCW Encodings

SerDes Protocol (given lane)	Valid reference clock frequency	Valid setting as determined by SRDS_PRTCL_S*n*	Valid setting as determined by SRDS_PLL_REF_CLK_SEL_S*n*	Valid setting as determined by SRDS_DIV_[prot]_S*n*
Networking Protocols (SerDes 1 and SerDes 2)				
SGMII (1.25 Gbaud)	100 MHz	SGMII @ 1.25 Gbaud	0: 100 MHz	Don't Care
	125 MHz		1: 125 MHz	
2.5x SGMII (3.125 Gbaud)	125 MHz	SGMII @ 3.125 Gbaud	0: 125 MHz	Don't Care
	156.25 MHz		1: 156.25 MHz	
QSGMII (5.0 Gbps)	100 MHz	Any QSGMII	0: 100 MHz	Don't Care
	125 MHz		1: 125 MHz	
XAUI (3.125 Gbaud)	125 MHz	XAUI @ 3.125 Gbaud	0: 125 MHz	Don't Care
	156.25 MHz		1: 156.25 MHz	
HiGig (3.125 Gbaud)	125 MHz	HiGig @ 3.125 Gbaud	0: 125 MHz	Don't Care
	156.25 MHz		1: 156.25 MHz	
HiGig[2] (3.75 Gbaud)	125 MHz	HiGig[2] @ 3.75 Gbaud	0: 125 MHz	Don't Care
	156.25 MHz		1: 156.25 MHz	
XFI (10.3125 Gbaud) or 10GBASE-KR	156.25 Mhz	XFI @ 10.3125 Gbaud	0: 156.25 MHz	Don't Care
Non-networking Protocols (SerDes 3 and SerDes 4)				
PCI Express 2.5 GT/s (doesn't negotiate upwards)	100 MHz[1]	Any PCIe	0: 100 MHz	2'b10: 2.5 G
	125 MHz[1]		1: 125 MHz	
PCI Express 5 GT/s (can negotiate up to 5 Gbps)	100 MHz[1]	Any PCIe	0: 100 MHz	2'b01: 5.0 G
	125 MHz[1]		1: 125 MHz	
PCI Express 8 GT/s (can negotiate up to 8 Gbps)	100 MHz[1]	Any PCIe	0: 100 MHz	2'b00: 8.0 G
	125 MHz[1]		1: 125 MHz	
Serial RapidIO 2.5 Gbaud	100 MHz	SRIO @ 2.5/5 Gbaud	0: 100 MHz	1: 2.5 G
	125 MHz		1: 125 MHz	
Serial RapidIO 3.125 Gbaud	125 MHz	SRIO @ 3.125 Gbaud	0: 125 MHz	Don't Care
	156.25 MHz		1: 156.25 MHz	
Serial RapidIO 5 Gbaud	100 MHz	SRIO @ 2.5/5 Gbaud	0: 100 MHz	0: 5.0 G
	125 MHz		1: 125 MHz	
InterLaken Lookaside (6.25 Gbps)	125 Mhz	InterLaken LA @ 6.25 Gbps	0: 125 MHz	Don't Care
	156.25 Mhz		1: 156.25 MHz	
SATA (1.5 or 3 Gbps)	100 MHz	Any SATA	0: 100 MHz	Don't Care[2]
	125 MHz		1: 125 MHz	
Debug (2.5 Gbps)	100 MHz	Aurora @ 2.5/5 Gbps	0: 100 MHz	1: 2.5 G
	125 MHz		1: 125 MHz	
Debug (3.125 Gbps)	125 MHz	Aurora @ 3.125 Gbps	0: 125 MHz	0: 3.125 G
	156.25 MHz		1: 156.25 MHz	
Debug (5 Gbps)	100 MHz	Aurora @ 2.5/5 Gbps	0: 100 MHz	0: 5.0 G
	125 MHz		1: 125 MHz	

1. A spread-spectrum reference clock is permitted for PCI Express. However, if any other high speed interface such as SRIO, Interlaken, SATA, or Debug is used concurrently on the same SerDes, spread-spectrum clocking is not permitted.
2. SerDes lanes configured as SATA initially operate at 3.0 Gbps. 1.5 Gbps operation may be enabled later through the SATA IP itself. It is possible for software to set each SATA at different rates.

18.1.1.4.1 SerDes Clocking Restrictions

There is a restriction that applies to the clocking of the SerDes PLL either within same SerDes set of PLLs or other SerDes PLLs. If any two SerDes PLLs are configured for the same frequency per Table 18-9, then they must share the same input clock source.

18.1.1.5 Ethernet management interface (EMI)

This section discusses the electrical characteristics for the EMI1 and EMI2 interfaces.

Frame Manager 2's external GE MDIO configures external GE PHYs connected to EMI1 pins. Frame Manager 2's external 10GE MDIO configures external XAUI, XFI and HiGig/HiGig2 PHYs connected to EMI2 pins.

The EMI1 interface timing is compatible with IEEE Std 802.3™ clause 22 and EMI2 interface timing is compatible with IEEE Std 802.3™ clause 45. The External MDIO interfaces on FM1 are not available for use.

18.1.1.6 MDIO port mapping

The SerDes module also contains MDIO slave ports containing registers for each PCS module. Each PCS MDIO is driven by the corresponding MAC's MDIO. The following table shows the mapping of PCS MDIO Slave to MAC MDIO Master.

SerDes *n*	MAC MDIO master	PCS MDIO slave	PCS MDIO device port address	Supported DEV_ADDR (or PHY_ADDR) values	PCS MDIO register offsets per DEV_ADDR/ PHY_ADDR
2	FM2-MAC9	XFIa	XFIACR1[MDEV_PORT]	0x01, 0x03, 0x07, 0x1E	0x0000-0xFFFF
2	FM2-MAC10	XFIb	XFIBCR1[MDEV_PORT]	0x01, 0x03, 0x07, 0x1E	0x0000-0xFFFF
2	FM1-MAC9	XFIc	XFICCR1[MDEV_PORT]	0x01, 0x03, 0x07, 0x1E	0x0000-0xFFFF
2	FM1-MAC10	XFId	XFIDCR1[MDEV_PORT]	0x01, 0x03, 0x07, 0x1E	0x0000-0xFFFF
1, 2	FMn-MAC1	SGMIIa	SGMIIACR1[MDEV_PORT]	N/A	0x00-0x1F
1, 2	FMn-MAC2	SGMIIb	SGMIIBCR1[MDEV_PORT]	N/A	0x00-0x1F
1, 2	FMn-MAC3	SGMIIc	SGMIICCR1[MDEV_PORT]	N/A	0x00-0x1F
1, 2	FMn-MAC4	SGMIId	SGMIIDCR1[MDEV_PORT]	N/A	0x00-0x1F
1, 2	MAC5	SGMIIe	SGMIIECR1[MDEV_PORT]	N/A	0x00-0x1F

Table continues on the next page...

SerDes *n*	MAC MDIO master	PCS MDIO slave	PCS MDIO device port address	Supported DEV_ADDR (or PHY_ADDR) values	PCS MDIO register offsets per DEV_ADDR/ PHY_ADDR
1, 2	MAC6	SGMIIf	SGMIIFCR1[MDEV_PORT]	N/A	0x00-0x1F
1, 2	FMn-MAC9	SGMIIg	SGMIIGCR1[MDEV_PORT]	N/A	0x00-0x1F
1, 2	FMn-MAC10	SGMIIh	SGMIIHCR1[MDEV_PORT]	N/A	0x00-0x1F
1, 2	FMn-MAC1	QSGMIIa	QSGMIIACR1[MDEV_PORT]	0x0, 0x1, 0x2, 0x3	0x00-0x1F
1, 2	FMn-MAC5	QSGMIIb	QSGMIIBCR1[MDEV_PORT]	0x0, 0x1, 0x2, 0x3	0x00-0x1F

18.1.2 Features

The SerDes module includes eight data lanes and two PLLs, and supports the following protocols:

- PCI Express 3.0 (November, 2010) @ 2.5, 5, 8 GT/s
  - Note: 8 GT/s is not supported for all configurations. See The SerDes module as implemented on the chip for details on the supported configurations for PCIe gen3.
- Serial RapidIO™ 2.1 (August, 2009) @ 1.25, 2.5, 3.125, 5 Gbaud
- Aurora SP002, Revision 1.3 (June, 2004) @ 2.5, 3.125, 5 Gbit/s
- SGMII ENG-46158, Revision 1.7 (July, 2001) @ 1.25, 3.125 Gbaud
- QSGMII EDCS-540123, Revision 1.2 (September, 2007) @ 5 Gbit/s
- IEEE 802.3ae - 2002 XAUI (August, 2002) @ 3.125 Gbaud
- HiGig @3.125 Gbaud
- HiGig2 @ 3.125 Gbaud
- HiGig2 @ 3.75 Gbaud
- XFI/10GBASE-R and 10GBASE-KR @ 10.3125 Gbaud
  - IEEE 802.3-2007
  - IEEE 802.3ae-2007
  - IEEE 802.3ap-2007
  - IEEE 802.3aq-2007
  - IEEE 802.3an-2006
- Interlaken-LA Version 1.2 (October, 2008) @ 6.25 Gbit/s
- Serial ATA Revision 2.6 (February, 2007) @ 1.5, 3 Gbit/s

18.2 Modes of Operation

The SerDes supports several combinations of protocols. See The SerDes module as implemented on the chip for details on the supported configurations of lanes and frequencies.

18.3 External Signals Description

The table below lists the external signals for the SerDes.

Table 18-10. SerDes Interface Signals

Pin Name	Description	No. of Signals	I/O
SD_TX[0:7]_P	Transmit data (positive)	8	O
SD_TX[0:7]_N	Transmitter data (negative)	8	O
SD_IMP_CAL_TX	Transmit impedance calibration	1	I
SD_RX[0:7]_P	Receive data (positive)	8	I
SD_RX[0:7]_N	Receive data (negative)	8	I
SD_IMP_CAL_RX	Receive impedance calibration	1	I
SD_REF_CLK1_P	PLL1 reference clock, positive differential input	1	I
SD_REF_CLK1_N	PLL1 reference clock, negative differential input	1	I
SD_REF_CLK2_P	PLL2 reference clock, positive differential input	1	I
SD_REF_CLK2_N	PLL2 reference clock, negative differential input	1	I
