38.7.2.10 General-Purpose Interrupt Enable (GIER)

Offset

Register	Offset
GIER	110h

Function
Contains the MUB general-purpose interrupt enable fields.

Fields

Field	Function
31 GIE31	MUB General-purpose Interrupt Enable Enables general-purpose interrupt. There are 32 general-purpose interrupts (*n* = 0 to 31). When GIE*n* = 1, a general-purpose interrupt *n* request is issued to processor B when MUB GSR[GIP*n*] = 1. If GIE*n* = 0, the general-purpose interrupt request pending does not trigger the general-purpose interrupt. GIE*n* becomes 0 when MU resets. **NOTE** This field is not supported in every instance. The following table includes only supported registers.

Instance	Field supported in	Field not supported in

Specifies whether general-purpose interrupts are requested to MUA. There are 32 general-purpose interrupts (n = 0 to 31).
Writing 1 to GIRn sets MUA_GSR[GIPn]. If MUA_GIER[GIEn] = 1, a general-purpose interrupt request is triggered on processor A.
This field becomes 0 when MUA_GSR[GIPn] is cleared. This clearing informs MUB that the interrupt is accepted (cleared by software).
To ensure proper operations, verify that GIRn is 0 (no pending interrupt) before writing 1 to it.
This field becomes 0 when MU resets.
NOTE
This field is not supported in every instance. The following table includes only supported registers.

Fields

Field	Function
31 GIP31	MUB General-Purpose Interrupt Request Pending Indicates whether a general-purpose interrupt request is pending. There are 32 general-purpose interrupts (*n* = 0 to 31). GIP*n* informs MUB that MUA_GCR[GIR*n*] changed from 0 to 1. If MUB_GIER[GIE*n*] = 1, a general-purpose interrupt request is issued to processor B. GIP*n* is cleared when MU resets. After GIP*n* is cleared, if MUB_GIER[GIE*n*] = 1, the general-purpose interrupt request is cleared on the MUB side.

38.7.2.13 Transmit Control (TCR)

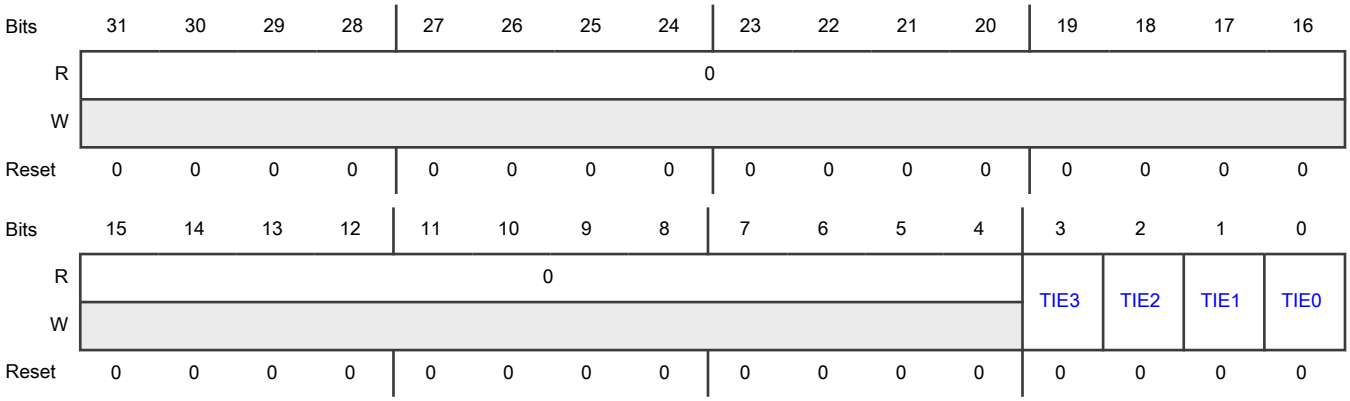
Offset

Register	Offset
TCR	120h

Function

Contains the MUB transmit interrupt enable fields.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 TIEn	MUB Transmit Interrupt Enable Enables MUB transmit interrupt *n*, where *n* = 0 to 3. If this field is 1, an MUB transmit interrupt *n* request is issued when MUB_TSR[TE*n*] is set. If this field is 0, MU ignores the value of MUB_TSR[TE*n*], and no MUB transmit interrupt *n* request is issued. 0b - Disable 1b - Enable

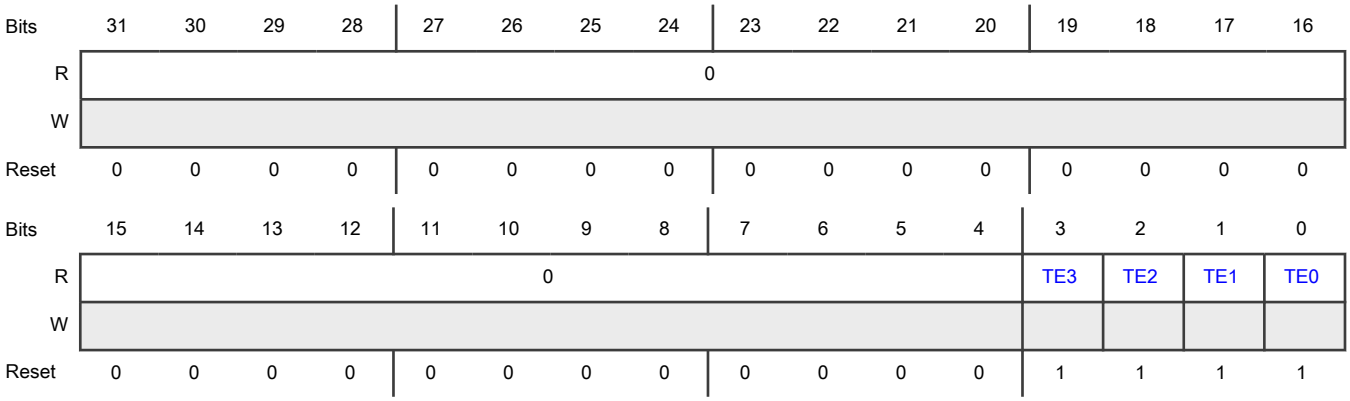
38.7.2.14 Transmit Status (TSR)

Offset

Register	Offset
TSR	124h

Function
Indicates whether the MUB transmit registers are empty.

Diagram



Fields

Field	Function
31-4 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
3-0 TEn	MUB Transmit Empty Indicates whether MUB Transmit (TR*n*) register is empty, where *n* = 0 to 3. This field becomes 1 after the MUA_RR*n* register is read on the MUA side. When TE*n* = 1, it indicates to the MUB side that the MUB_TR*n* register is ready to be written on the MUB side. If MUB_TCR[TIE*n*] = 1, a transmit *n* interrupt is issued on the MUB side. This field becomes 0 after the MUB_TR*n* register is written to on the MUB side. After this field becomes 0, if MUB_TCR[TIE*n*] = 1, the transmit *n* interrupt request is cleared on the MUB side. This field becomes 1 when MU resets. 0b - Not empty 1b - Empty

38.7.2.15 Receive Control (RCR)

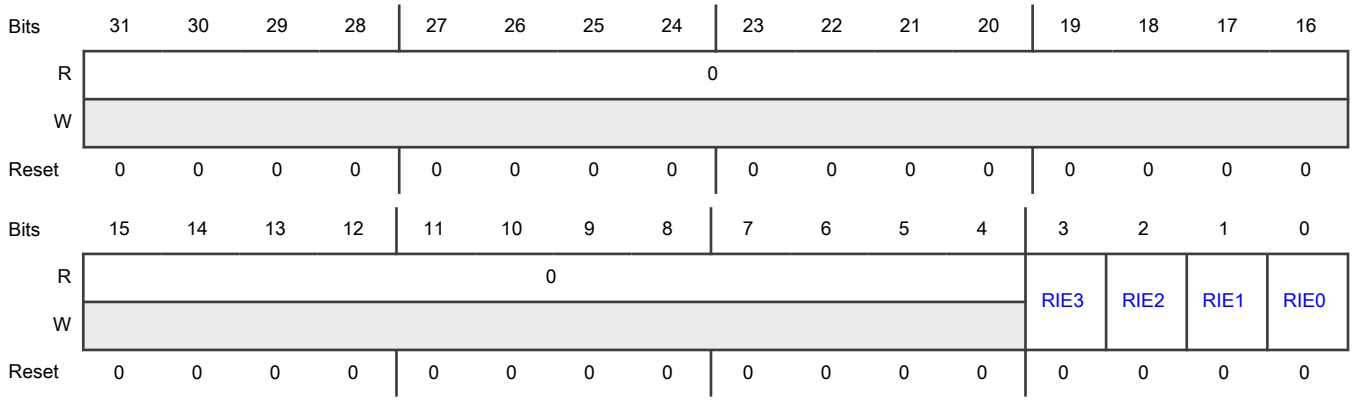
Offset

Register	Offset
RCR	128h

Function

Contains the MUB receive interrupt enables.

Diagram



Fields

Field	Function
31-4 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
3-0 RIEn	MUB Receive Interrupt Enable Enables MUB receive interrupt *n*, where *n* = 0 to 3. If this field is 1, an MUB receive interrupt *n* request is issued when MUB_RSR[RF*n*] is set. If this field is 0, MU ignores the value of MUB_RSR[RF*n*], and no MUB receive interrupt request is issued. 0b - Disable 1b - Enable

38.7.2.16 Receive Status (RSR)

Offset

Register	Offset
RSR	12Ch

Function
Indicates whether the MUB receive registers are full.

Fields

Field	Function
31-0	MUB Transmit Data

Table continues on the next page...

Field	Function
TR_DATA	Contains MUB transmit data. MUA_RR*n* reflects the data written to this register. The TR*n* and RR*n* registers are not double-buffered. Writing to MUB_TR*n* overrides the data readable in the MUA_RR*n* register. A write to the Transmit register clears MUB_TSR[TE*n*] on the transmitter side, and sets MUA_RSR[RF*n*] on the receiver side. You can write to this register only when MUB_TSR[TE*n*] = 1. Reading this register returns all zeroes.

38.7.2.18 Receive (RR0 - RR3)

Offset

Register	Offset
RR0	280h
RR1	284h
RR2	288h
RR3	28Ch

Function
Contains MUB receive data.

R	RR_DATA															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 RR_DATA	MUB Receive Data Reflects the data written to MUA TR*n*.

Table continues on the next page...

Field	Function
	Reading this register clears MUB_RSR[RF*n*] on the receiver side, and sets MUA_TSR[TE*n*] on the transmitter side. You can read this register only when MUB_RSR[RF*n*] = 1. Reading it before MUB_RSR[RF*n*] becomes 1 may result in reading incorrect data. Poll MUB_RSR[RF*n*] to confirm it is set before reading RR*n*. Writing to this register generates an error response to MUB.

Chapter 39
Power Management

39.1 Overview

The power management system monitors and controls power supplies and related resets. This chapter describes the system's interaction with other peripherals.

The power management system includes the modules listed below.

Table 198. Power management system modules and functions

Module	Function
MC_ME	Initiates entry into Low-Power mode
MC_PCU	Controls entry into and exit from Low-Power mode
PMC	Regulates and monitors power supplies of the Run and the Standby domains
MC_RGM	Ensures a clean state and correct Run domain functionality by controlling the reset sequence
FIRC, WKPU, and other chip peripherals	Controls Standby mode wake-up and operations in Run and Standby modes

39.1.1 Block diagram

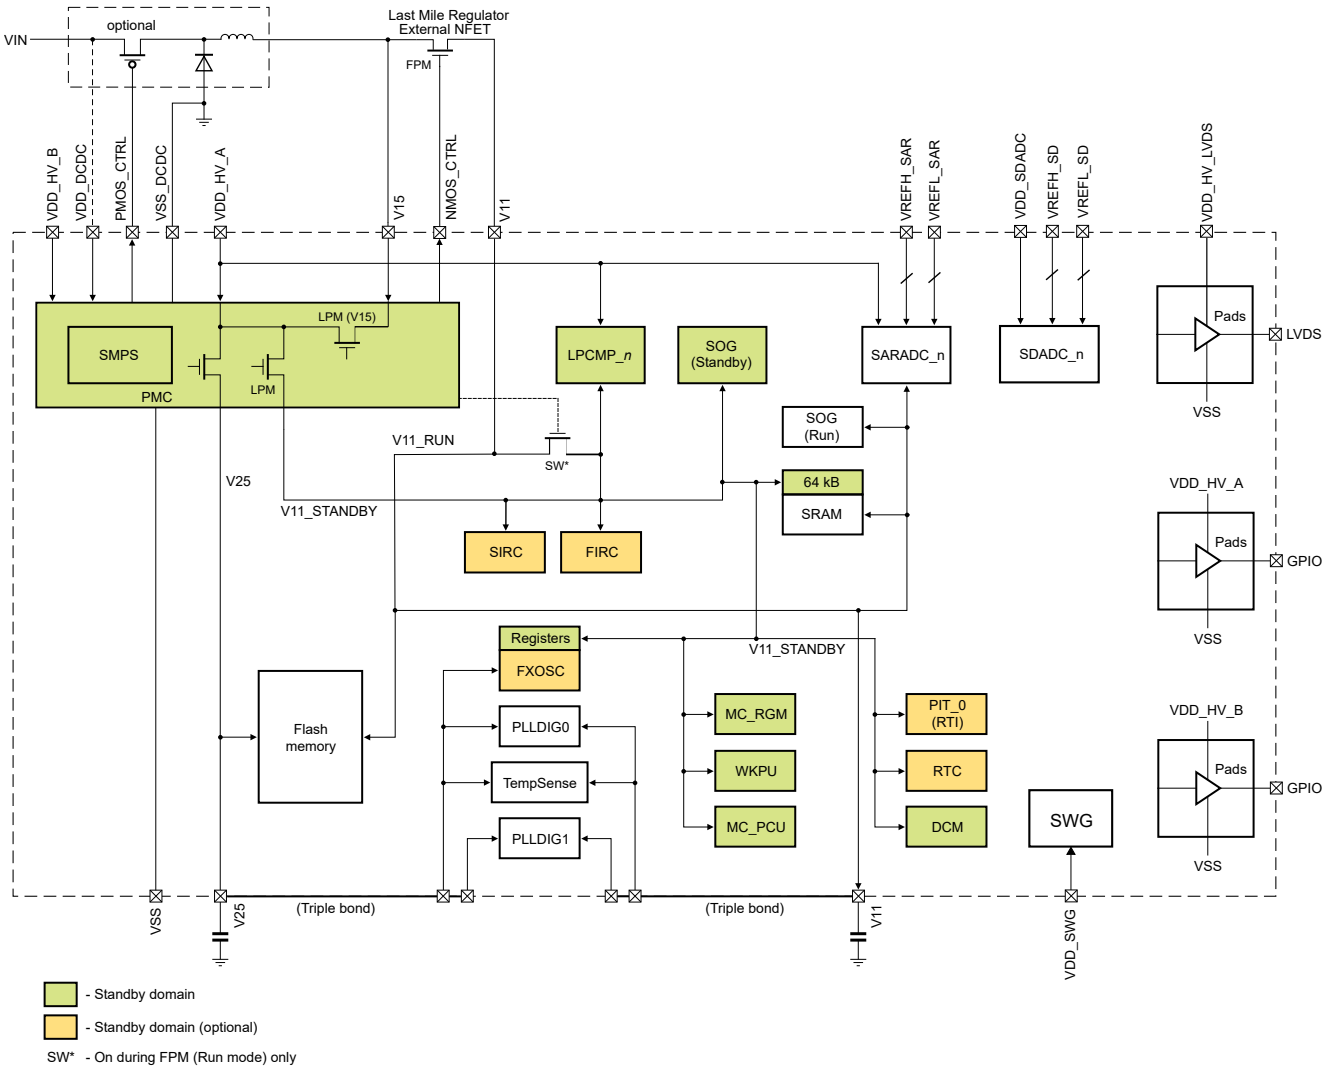

Figure 156. Block diagram

39.1.2 Features

- Supports a low-power regulator (LPM) that supplies core logic during Standby mode (V11_STANDBY)
- PMC maintains 1.4–1.5 V output voltage when using the DC-to-DC buck converter stage
- Chip controls an external NMOS transistor, and uses V15 generated from SMPS as input to generate V11 for a load current up to 1.5 A (disabled in Standby mode)
- Includes Last-mile (FPM) regulator for driving logic in Run mode.
- Supports power switches that isolate voltage islands and configure the chip in Standby mode
- Includes a linear regulator that generates a 2.5 V supply (V25) from VDD_HV_A
- Supports voltage monitors ensuring transitions to a safe state (POR) when a supply is out of the valid range
- Controls power-mode transitions through an interaction with the digital interface
- Provides a pad-keeping feature that retains the I/O configuration after exiting Standby mode

- Separates ADC reference supplies (VREFH and VREFL)

39.1.3 Operational power modes

This chip has two power modes:

- Run mode (FPM): Main operation mode with full-chip performance and a higher current consumption than Standby mode.
- Standby mode (LPM): Low-power mode of the chip in which the Run domain is switched off. Most of the cores and peripherals are off in this mode.
  - We have two option of the standby mode (configured by the DCMRWF1[PMIC_PGOOD_HNDSHK_BYP]):
    - Standalone (Only the MCU is going into the standby mode)
    - PMIC handshake (Together with the MCU, the PMIC device are going to standby mode), selected by default.

39.1.4 Regulator

The LPM regulator manages the chip in Standby mode.

39.1.5 Requirement

Separate VREFH and VREFL supplies are required for SD-ADC operation. The SD_ADC power supply is isolated at the die level and must be shorted with VDD_HV_A at PCB level.

39.1.6 External 1.5 V source

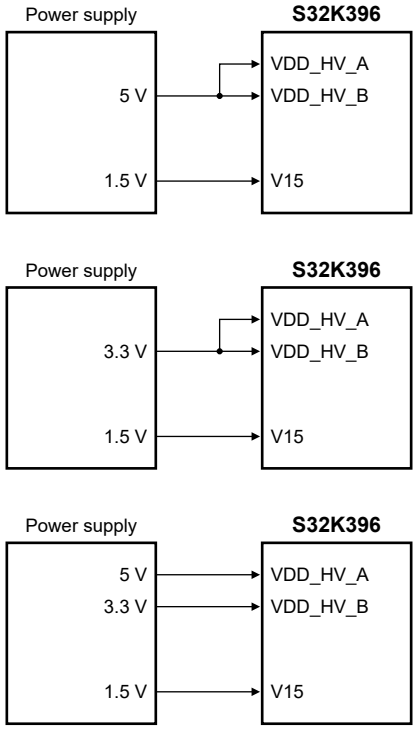

Figure 157. External 1.5 V source

39.2 Power-up sequence

Figure 158 shows the reset sequence for a power-up or Standby mode event. This sequence starts from the POR phase. For the Run domain logic, Standby mode exit operation is the same for power-up.

See the Reset Overview chapter for more information about the chip reset sequence.

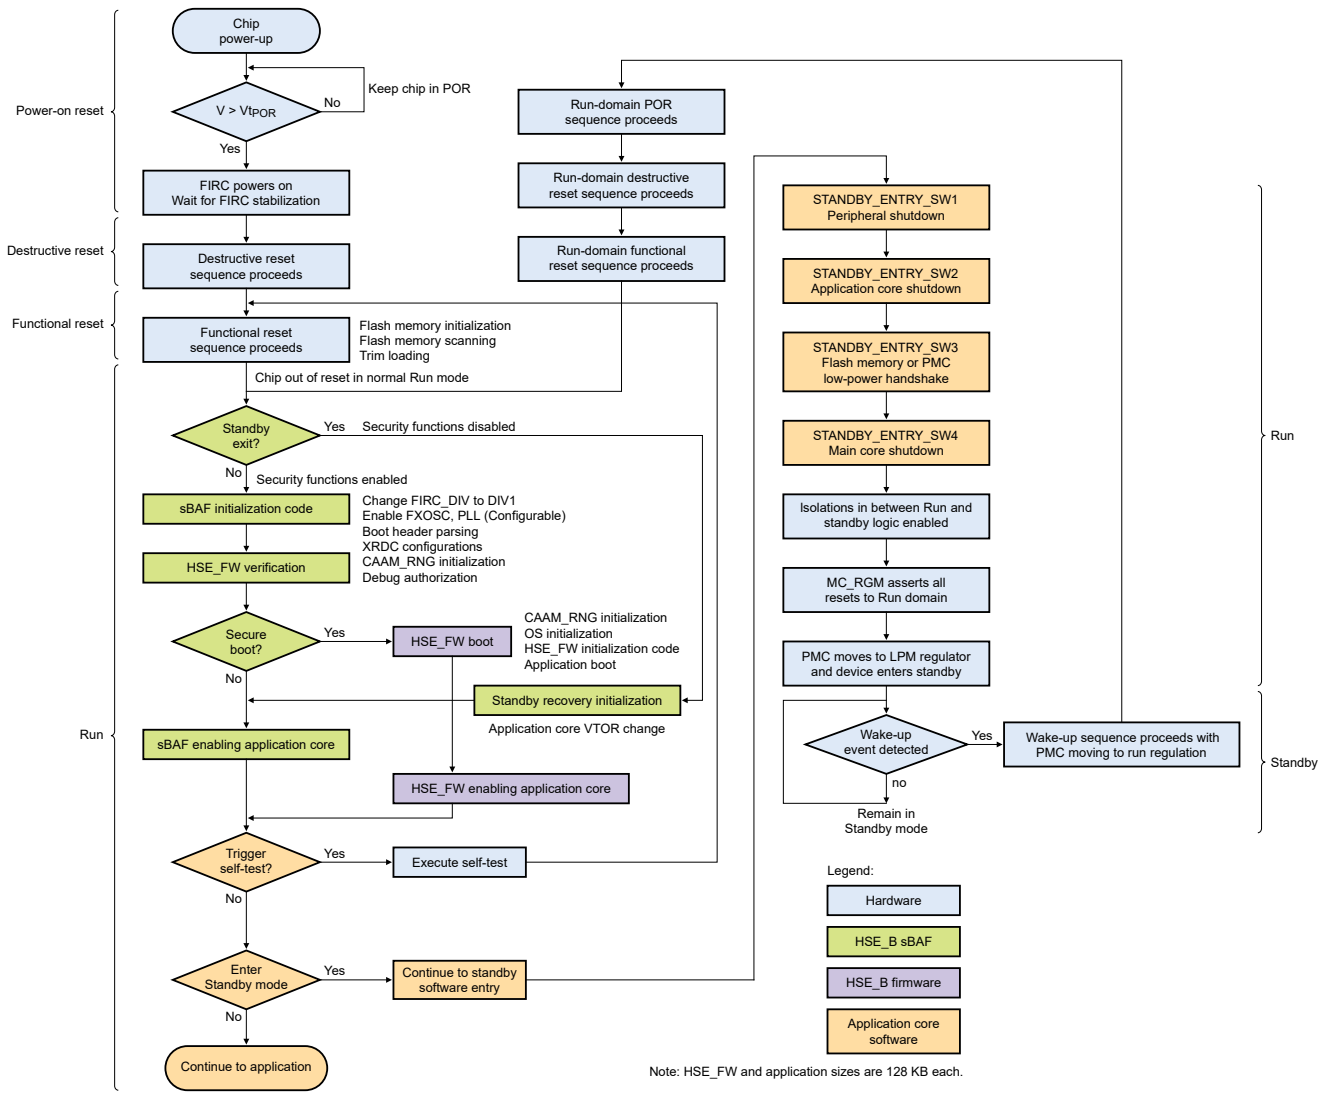

Figure 158. Power-up sequence

39.3 Supplies exposed to ADC0

- Bandgap voltage
- Chip temperature sensor
- VDD_HV_A (2.97–5.5 V) divided by two
- VDD_HV_B (2.97–5.5 V) divided by two to ensure that the supply limits are not exceeded during rising or falling
- V15 divided by two
- VDD_HV_OSC (~2.5 V)
- VDD_LV_hot (~1.1 V)
- VDD_LV_cold (~1.1 V))
- VDD_LV_OSC (~1.1 V)

- VDD_LV_PD0 (~1.1 V)
- VSS

39.4 Supplies Exposed to ADC1

- VDD1P1_PLL2 (~1.1 V)
- VDD2P5_PLL2 (~2.5 V)
- VDD33_LVDS (~3.3 V)

39.5 Standby mode entry sequence

The Standby mode entry sequence consists of three phases:

- Standby mode entry configuration phase or software Standby mode entry sequence
- Standby mode entry handshake phase or hardware Standby mode entry sequence
- Standby mode entry or PMC Standby mode entry

NOTE

The Standby mode entry sequence described in this section is the only supported sequence. Contact NXP support if you require an alternate Standby mode entry sequence.

NOTE

After triggering Standby Entry from Application, If Reset is asserted before Standby entry then reset can be issued to system, which will be visible at RESET_B pad.

39.5.1 Software Standby mode entry sequence

The Standby mode entry sequence includes chip configuration as described in the following sections.

Before entering the software Standby mode sequence, the system clock source must be changed to FIRC. This is done because PLLDIG is not available in Standby mode. In Standby mode, all clock sources can be optionally disabled (including FIRC, which results in a no-clock, low-power consumption mode). You could also use FXOSC, if enabled, when the 2.5 V supply is available by appropriate configuration of PMC.CONFIG[LPM25EN].

NOTE

You also need to configure DCMRWF1[PMIC_PGOOD_HNDSHK_BYP] bit as per your requirement.

The software Standby mode entry sequence consists of four steps:

1. SW1: Module shutdown process
2. SW2: Application core shutdown process
3. SW3: Flash memory low-power handshake
4. SW4: Main core shutdown process

The following sections describe each step. See Figure 158 for the relationship between these four steps in a flow diagram.

39.5.1.1 SW1: Module shutdown process

I/O and module configuration for Standby mode discusses the procedure to configure I/O and the chip modules for Standby mode.

The entry sequence for this mode includes module clock-disabling steps (see the "Clocking" chapter for module clock turn-on and turn-off processes). You must use MC_ME.PRTN*n*_COFB*m*_CLKEN[REQ*p*] fields to enable or disable module clocks.

39.5.1.1.1 Disabling modules

Disable modules by configuring the appropriate fields in their registers for Standby mode operation. See specific module chapters for more information.

The Standby mode entry sequence includes the module clock-disabling step, with which you can disable the modules that you do not need for Standby mode operation.

The sequence of disabling modules is shown in I/O and module configuration for Standby mode.

NOTE

- While enabling or disabling modules, you must verify that the module is disabled when you read MC_ME.PRTN*n*_COFB*m*_STAT register and the module disable field, if applicable. In there is a discrepancy, you must perform proper diagnostic steps.
- You must clear the I/O controls for the pads that you do not require in Standby mode (OBE, IBE, and so on). This avoids any unwanted pad-keeping settings. See Pad-keeping for more information on the chip pad-keeping process.
- For any standby wake source, if an interrupt occurs it must be disabled before entering Standby mode. Only the wake-up event of that source must be enabled. This action avoids any software conflict in the interrupt handling for multi-application core cases.

The MC_ME.PRTN*n*_COFB*m*_STAT register indicates the status of peripheral clock enable or disable. It may take up to three clock cycles for MC_ME.PRTN*n*_COFB*m*_STAT register to update after MC_ME.PRTN*n*_COFB*m*_CLKEN register is updated.

39.5.1.1.2 I/O and module configuration for Standby mode

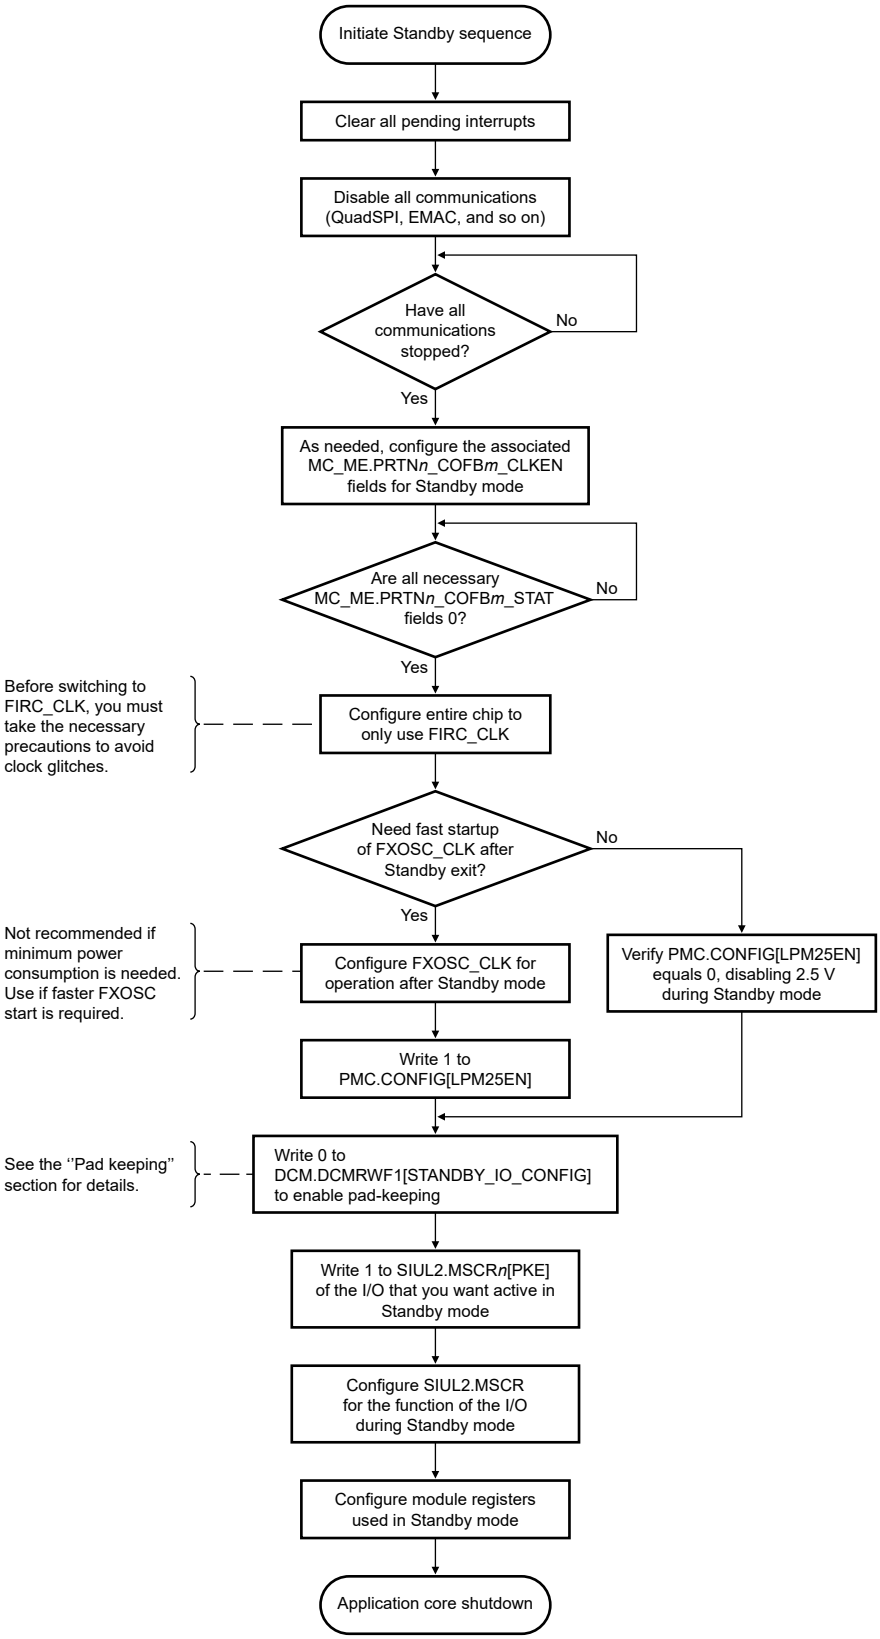

Figure 159. I/O and module configuration for Standby mode

39.5.1.2 SW2: Application core shutdown process

The application cores(s) execute a WFI (as opposed to the main core running the Standby mode entry sequence). See the section "Application core shutdown" in the MC_ME chapter for more information.

The main core configuration (programming valid core ID and enabling standby entry process) and the wake-up source configuration must also be set in SW2, so that SW4 contains only the main core WFI execution.

39.5.1.3 SW3: Flash memory low-power handshake

In this process, you execute a flash memory low-power handshake by executing the procedures indicated in Figure 160.

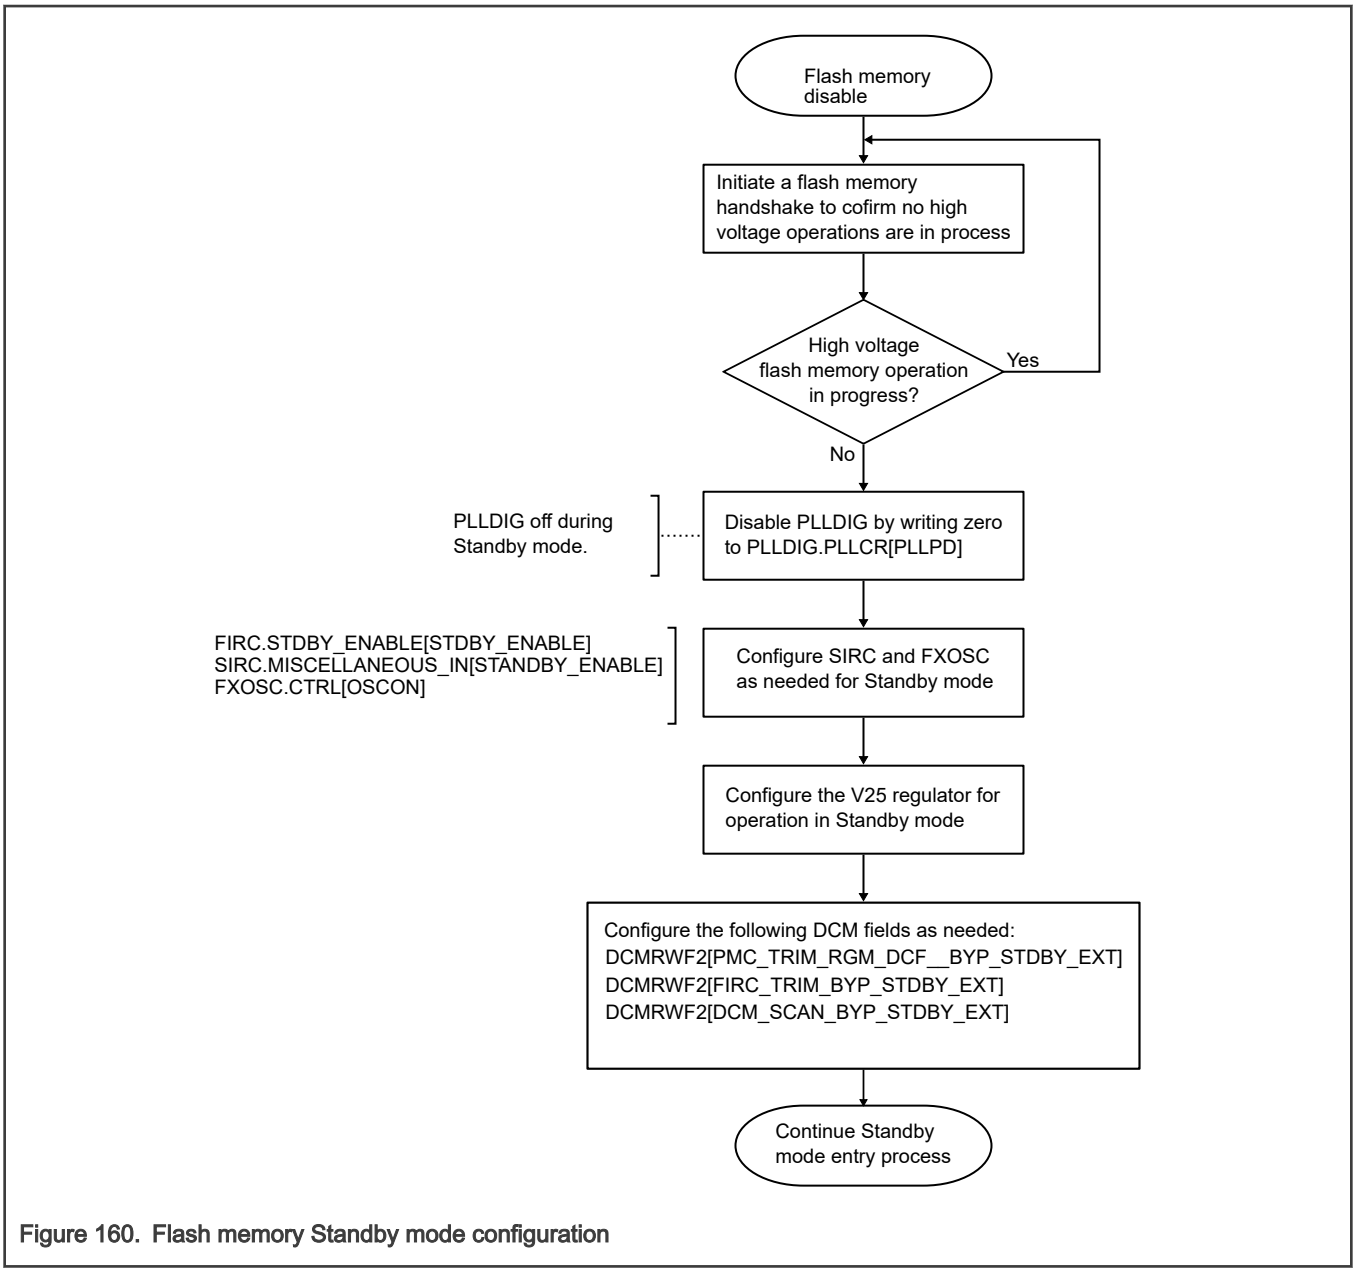

Figure 160. Flash memory Standby mode configuration

39.5.1.4 SW4: Main core shutdown process

For information on this process, see the following portions of the "Mode Entry Module (MC_ME)" chapter:

- Figure "Standby entry sequence along with main core shutdown"

- Section "Main core shutdown and Standby mode entry"

You must configure WKPU before disabling interrupts to avoid missing any events, as shown in the Standby entry sequence along with main core shutdown flowchart in the MC_ME chapter. You must program WKPU, disable interrupts, and configure MC_ME's Standby mode entry in SW1 (see SW1: Module shutdown process for more information). In SW4, you must perform only the main-core WFI execution.

39.5.2 Hardware Standby mode entry sequence

The hardware Standby mode entry sequence consists of the handshaking between MC_PCU and MC_ME occurring after Software Standby mode entry sequence completes. The FSM in MC_PCU performs these steps automatically and does not require your intervention (see Power sequence FSM in the Power Control Unit (MC_PCU) chapter for more information).

When PMIC handshake Standby mode is selected, the PGOOD, EXTWAKE, and RESET_B need to be connected to the PMIC (See PMIC Handshake with MCU for more information).

39.5.2.1 PMC Standby mode entry

The PMC Standby mode entry sequence starts after Hardware Standby mode entry sequence completes, and consists of MC_PCU automatically performing the following steps after receiving a Standby mode entry request:

1. Acknowledge the request and initiate an internal low-power process.
2. Disable the V25 regulator and the FPM LVR monitors.
3. Disable the V25 regulator (oscillator and flash memory supply) and the LPM monitor, unless it is enabled during Standby mode (see PMC.CONFIG[LPM25EN] in the "Power management controller (PMC)" chapter for more information).
4. Disable the VDD_HV_B LPM monitors.

39.6 Chip status at the end of Standby mode entry sequence

After PMC Standby mode entry completes, then the chip completes Standby mode entry as follows:

1. Configures Standby domain peripherals according to SW1 (see SW1: Module shutdown process).
2. Enables pad-keeping on pins as described in SW1 (see SW1: Module shutdown process). See Pad-keeping for other details.
3. Powers down all memory types except Standby RAM (in SRAM0).
   - The V25 regulator can remain on during Standby mode. However, for maximum power savings, it must remain off in this mode.
4. Isolates Standby and Run domains from each other:
   - Standby domain is functional.
   - Run domain is held in reset.
5. Configures the system clock (FIRC_CLK or PLL_PHI*n*_CLK, depending on their configuration) and other clock sources according to SW3 (see Figure 160 for the procedure details).

   The cores are now off and in the Standby domain.
6. Turns off the FPM regulator.
7. Waits for a wake-up event to initiate recovery from Standby mode.

39.7 Chip operation in Standby mode

This chip supports the following functionalities in Standby mode:

- STANDBY_RAM content retention during Standby mode.

- Wake-up from up to 60 digital inputs (for details, see the signals WKUP[*n*] functions of WKPU module in the IOMUX file attached to this document). The section WKPU configuration on the chip in the "Wakeup Unit (WKPU)" chapter shows mapping of the wake-up sources.
- Wake-up from up to 16 analog inputs through the Trigger mode functionality (see the signals LPCMP*n*_IN*m* functions of LPCMP*n* modules in the IOMUX file attached to this document).
- Wake-up from on-chip timers:
  - RTI (function of PIT[0])
  - SWT0
  - RTC
- Ability to configure the chip clocking modules to optionally enable or disable in Standby mode (FIRC and SIRC).

39.8 Standby mode exit

This chip supports Standby mode exit from any of these events:

- Wake-up
- Functional reset
- Destructive reset

The sources that cause chip Standby mode exit are:

- MC_RGM functional reset event
- MC_RGM destructive reset event
- WKPU wake-up events, WKPU[0]–WKPU[63] (see the WKPU chapter for more information)

After Standby mode exit, the following events occur (for more information, see "Power sequence FSM" in the MC_PCU chapter for MC_PCU FSM transitions during entry into and exit from Standby mode):

1. A wake-up event arrives.
2. If PMIC handshake is enabled (default enabled), see PMIC Handshake with MCU for additional hardware sequence.
3. FIRC begins powering up (if disabled in Standby mode).
4. PMC begins the transition process to FPM
5. MC_PCU removes the isolation between Run and Standby domains.
6. Run domain reset deasserts (asserts on Standby mode entry) and the chip undergoes a functional reset exit sequence for this domain.
7. The chip enters Run mode of operation.

39.8.1 Faster Standby mode exit

This chip supports an optional feature for the Standby mode exit sequence that bypasses:

- FIRC trimming
- PMC trimming
- DCM scanning

To use the bypass operation, write 1 to DCM.DCMRWF2[5], DCM.DCMRWF2[4], and DCM.DCMRWF2[3] respectively before Standby mode entry. This results in a considerable reduction in Standby mode exit duration. The trim values are retained across Standby mode and bypassing these values does not cause any impact.

39.9 PMIC Handshake with MCU

For interfacing with PMIC where handshake is required, MCU will follow a sequence to come out of standby. This handshake will make sure that power supply to the MCU is in proper condition.

3 GPIOs will be used to perform this handshake as shown in below figure.

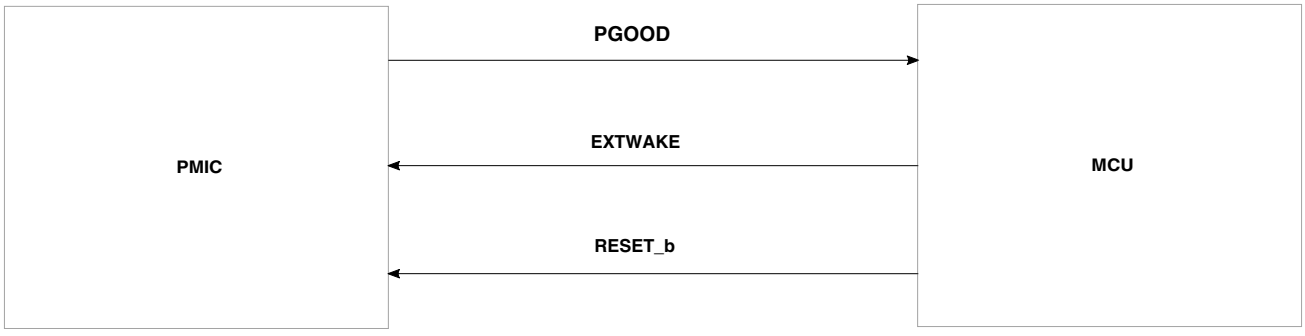

Figure 161. PMIC Handshake with MCU

MCU will assert EXTWAKE signal on receiving a wakeup request from any of the available wakeup sources. If the EXTWAKE signal is enabled via the MSCR configuration (see S32K39_and_S32K37_IOMUX file attached to this document), this wakeup will be triggered to the external PMIC and the PMIC will use it to come out of standby mode. MCU sends the reset_b signal to PMIC to reset the PMIC.

NOTE

After EXTWAKE assertion, POR WDOG is triggered. If PGOOD assertion does not arrive within the configured time, POR WDOG will issue a reset to the MCU.

PMIC will raise PGOOD signal towards MCU for indicating the MCU that it is now able to provide the supplies in proper conditions. If the PGOOD input is enabled via the corresponding IMCR configuration (see S32K39_and_S32K37_IOMUX file attached to this document) and the appropriate PGOOD polarity and enable settings are selected in the corresponding DCMRWF configuration registers (see PMIC_PGOOD_HNDSHK_BYP and PGOOD_POLARITY in Chapter 36, Device Configuration Module General-Purpose Registers (DCM_GPR)), the MCU will proceed to exit from STANDBY mode once the PGOOD input is asserted.

39.10 Chip power domain partitioning

The Standby domain includes the modules listed below. For more information, see "Peripheral reset status" in the "Reset Overview" chapter.

- FIRC
- FXOSC
- MC_RGM
- DCM
- WKPU
- PIT_0 (RTI)
- LPCMP_[0:1]
- PMC
- SIRC
- RTC
- SWT_0

- DCF clients

39.10.1 Module power status

Table 199. Module power status

PD0 contents	K396
External pin wake-ups	Minimum 77 external pin wake-ups
RTC_API	Yes
LPCMP0	Yes
LPCMP1	Yes
SWT0	Yes
WKPU	Yes
PMC	Yes
RGM	Yes
FXOSC	Yes
FIRC	Yes
SIRC	Yes
CLK	Yes
64 KB SRAM	Yes
PIT_RTI_0	Yes
DCM	Yes

SWT0 (Cortex-M7_0) resides in the Standby domain and supports a configurable hardware-based timer operation during Standby mode, depending on the configuration of SWTs.

All clock sources (except PLLDIG) are available in Standby mode. SIRC is present in the Standby domain for low-power wake-up, but can be enabled.

NOTE

This chip does not support Stop and Wait modes. The only low-power mode it supports is Standby.

39.11 Pad-keeping

Pad-keeping enables you to return to I/O Run mode configuration settings after using I/O during Standby mode. It eliminates the need for I/O reconfiguration in Run mode.

39.11.1 Pad-keeping on Run domain pins

The process of entering Standby mode ensures that the chip maintains the Run domain configuration settings. Software Standby mode entry sequence specifies that you must write 0 to DCM.DCMRWF1[STANDBY_IO_CONFIG] before configuring I/O pad-keeping. You could consider DCM.DCMRWF1[STANDBY_IO_CONFIG] field as a global enable for all pad-keeping purposes during Standby mode. If you are unable to write to this field as described, pad-keeping works as explained in this chapter, during Standby mode.

After the chip exits Standby mode, you must write 1 to DCM.DCMRWF1[STANDBY_IO_CONFIG] (see "Chip-specific register descriptions" in the DCM chapter). Writing 1 to this field disables pad-keeping and configures chip I/O according to its Run mode configuration.

39.11.2 Pad-keeping on Standby domain pins

The Standby domain pads can have pad-keeping enabled or disabled based on pad availability in Standby mode. Writing to SIUL2.MSCR*n*[PKE] configures Standby mode pad-keeping on a selected I/O.

Ensure that DCM.DCMRWF1[STANDBY_IO_CONFIG] = 0 before Standby mode entry for pad-keeping on Standby domain pads. Write 0 to the field in case its value is not 0 already.

If a pad is not required during Standby mode, then the value of the corresponding SIUL2.MSCR*n*[PKE] field must be 0.

39.11.3 Pad-keeping configuration procedure

This procedure specifies how to enable an I/O for pad-keeping:

1. Configure SIUL2.MSCR*n* to control the pad state prior to Standby mode entry (for example, by writing 0 to SIUL2.MSCR*n*[OBE], SIUL2.MSCR*n*[IBE], and SIUL2.MSCR[PUE] 3-states the corresponding I/O).
2. Configure SIUL2.MSCR*n*[PKE] as needed for an I/O pad-keeping state during Standby mode.
3. Write 0 to DCM.DCMRWF1[STANDBY_IO_CONFIG].

   The application core executes a WFI, and Standby mode sequence starts.
4. Write 1 to DCM.DCMRWF1[STANDBY_IO_CONFIG] on Standby mode exit to disable pad-keeping. This configures SIUL2 according to its previous settings.

If you write 1 to DCM.DCMRWF1[STANDBY_IO_CONFIG] before entering Standby mode, the isolation removal hardware removes pad-keeping on Standby mode exit. This action (writing 1 to DCM.DCMRWF1[STANDBY_IO_CONFIG] before Standby mode entry) is useful in case of low-power debug, because enabling pad-keeping does not allow low-power debug protocol to work properly (because the TDO pad is pad-kept). For low-power debug, you must write 1 to DCM.DCMRWF1[STANDBY_IO_CONFIG] prior to Standby mode entry.

In case of Standby mode exit by reset, the pad-keeping of the reset pin is removed when the chip is reset on Standby mode wake-up. See the "GPIO padkeeping enable" signal in Figure 163. This signal corresponds to wake-up via reset event case.

39.11.4 Pad-keeping waveforms

39.11.4.1 Pad-keeping when the chip wakes up from Standby mode via an interrupt event

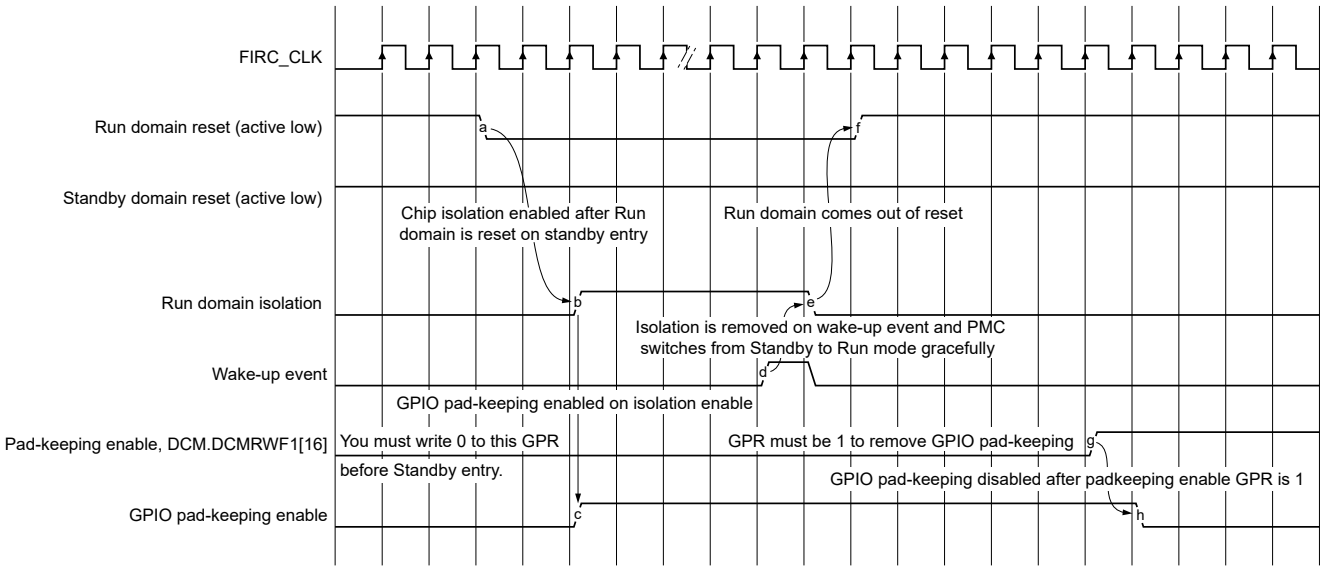

Figure 162. Pad-keeping when the chip wakes up from Standby mode via an interrupt event

39.11.4.2 Pad-keeping when the chip wakes up from Standby mode via reset

If the chip exits Standby mode through reset, the reset pad-keeping is removed when the chip resets after Standby-mode wake-up. See the figure's "GPIO padkeeping enable" waveform corresponding to wake-up via a reset event.

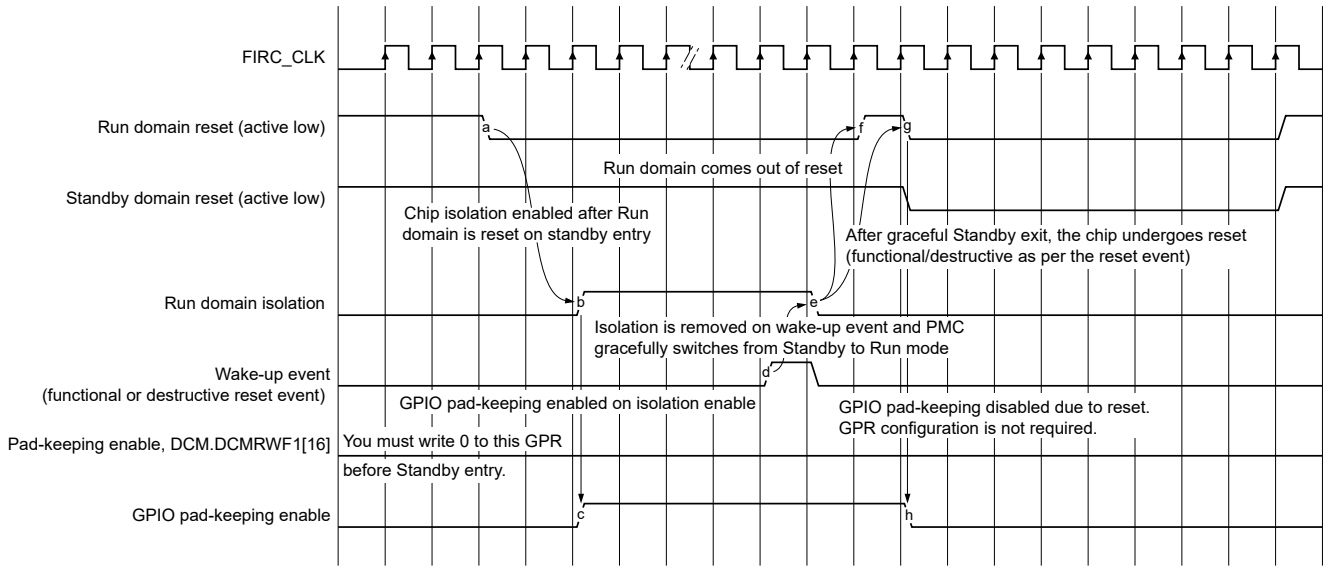

Figure 163. Pad-keeping when the chip wakes up from Standby mode via reset

39.11.5 SIUL2's fields for actively-driven pins in Standby mode

If you use a WKPU pin as a wake-up input, perform these operations:

1. Write 1 to SIUL2.MSCR*x*[IBE].
2. Program SIUL2.MSCR*x*[PUE] and SIUL2.MSCR*x*[PUS] according to the use case.
3. Write 0 to SIUL2.MSCR*x*[PKE].

For the GPIO pins that are driven to high impedance during Standby mode:

1. Write 0 to DCM.DCMRWF1[STANDBY_IO_CONFIG].
2. Write 0 to SIUL2.MSCR*x*[SSS] (GPIO mode).
3. Write 0 to SIUL2.MSCR*x*[IBE] and SIUL2.MSCR*x*[OBE].

Some of the pins are, by default, actively driven in Standby mode. If these pins retain a static value throughout the mode, program the corresponding MSCR*x*[PKE] bits individually.

This table shows the list of pins available in Standby mode along with the functions they perform.

Table 200. Active pins in Standby mode

Pin[1]	Function
GPIO_4	LPCMP0_OUT
GPIO_5	RESET_b
GPIO_8	LPCMP0_OUT/EXTWAKE
GPIO_9	LPCMP1_OUT
GPIO_10	JTAG_TDO

Table continues on the next page...

Table 200. Active pins in Standby mode (continued)

Pin[1]	Function
GPIO_22	CLKOUT_STANDBY
GPIO_25	EXTWAKE
GPIO_26	PGOOD
GPIO_69	JTAG_TDI
GPIO_84	LPCMP0_RRT
GPIO_94	LPCMP1_OUT

GPIO_128	LPCMP0_OUT
GPIO_129	LPCMP1_OUT
GPIO_138	CLKOUT_STANDBY
GPIO_143	LPCMP1_RRT
GPIO_149	EXTWAKE
GPIO_158	LPCMP1_OUT
GPIO_159	LPCMP1_RRT
GPIO_174	LPCMP0_OUT
GPIO_175	LPCMP0_RRT
GPIO_183	LPCMP0_OUT

1. See the IOMUX sheet attached to this document for details on pin configuration in different chips.

39.12 Standby mode entry

The Standby mode entry sequence includes three phases:

- SW Configurations phase
- MC_ME and PCU phase
- PMC phase

39.12.1 Software configuration phase

During the software configuration phase, software:

- Clears all pending interrupts.
- Disables all communications (for example, Ethernet).
- Switches to FIRC as the system clock.
- Disables PLL LFASTPLL and waits for clock status.
- Disables FXOSC/SIRC (if needed) and waits for clock status.
- Configures STANDBY entry.
- Programs SIUL/IOMUX and DCM to configure EXTWAKE and PGOOD functionalities (only for PMIC handshake Standby mode).
- Sends SPI command to PMIC to enter standby before going to WFI state (only for PMIC handshake Standby mode).

- Executes a WFI instruction on all running cores.

39.12.2 MC_ME and PCU phase

During the MC_ME and PCU phase, MC_ME and PCU:

- Enable FIRC.
- Deassert isolation.
- Deassert reset to PD1.

39.12.3 PMC phase

During PMC phase, after receiving an LPM request, PMC:

- Deasserts FPM ready signal.
- Starts the courtesy timer.
- When the courtesy timer expires, PMC:
  - Disables the V25 regulator.
  - Disables the HP reference blocks.
  - Disables the external NMOS.
  - Opens the PD0 switch.
  - Enables a core LPM request.
  - If selected, enables a 2.5 V LPM request.
  - Disengages FPM monitors.
  - Disables the VDD_HV_B LPM monitor, if present and deselected.
- Waits for LPM signal deassertion.

39.13 Glossary

Application core	Core in addition to the main core
FSM	Finite state machine
FPM	Full-power mode (Run mode)—uses the last-mile regulator and 1.5 V source to generate the 1.1 V core logic supply during a full-power operation (V11_RUN)
LPM	Low-power mode (Standby mode)—uses the low-power regulator to generate the 1.1 V core logic supply during low-power operation (V11_STANDBY)
LVR	Low voltage reset
Main core	Core initiating the chip Standby mode request (for example, the core corresponding to the "core index" in MC_ME's MAIN_COREID register)
Pad-keeping	Maintains I/O pad configuration during Standby mode, if enabled
V11_STANDBY	Core logic and clock sources, low-voltage supply to Standby domain
V11_RUN	Low-voltage supply to Run domain
V15	High-current input for core or logic supply from either an external BJT or from direct 1.5 V external supply
V25	Flash memory, FXOSC, and PLLDIG high-voltage supply
VDDA_ADC	ADC supply voltage

VREFH	ADC high-voltage reference supply
VREFL	ADC low-voltage reference supply
VSS	Core logic ground supply
VDD_HV_A	Main I/O voltage supply (5 V or 3.3 V)
VDD_HV_B	Other I/O domain voltage supply (5 V or 3.3 V)
VRC_CTRL	PMC voltage regulator control output using the BJT option to generate a 1.5 V supply
WFI	Wait for interrupt software instruction

Chapter 40
Power Management Controller (PMC)

40.1 Introduction

PMC is the power management controller for the S32K3 family of microcontrollers. It provides multiple power options to allow you to optimize power consumption for the level of functionality needed. It includes internal voltage regulators, POR, and the integrated low/high voltage detector system with reset (brown-out) capability. The voltage regulator requires a 3.3 V or 5 V input to generate all the required secondary supplies.

40.2 Features

- Combination of internal and external voltage regulator options, offering Run and Standby modes
- Active POR providing brown-out detect
- LVR for all system-relevant power domains
- LVD and HVD as indication for software
- Two bandgaps to enable independent supply generation and monitoring
- Two independent LVR monitors for each safety-relevant power supply domain

40.3 Modes of operation

PMC provides two basic modes of operation for voltage regulators and monitors:

- FPM, which is used on chip-level in Run modes (for high-current consumption)
- LPM, which is used on chip-level for Standby modes (for low-current consumption)

40.4 Block diagram

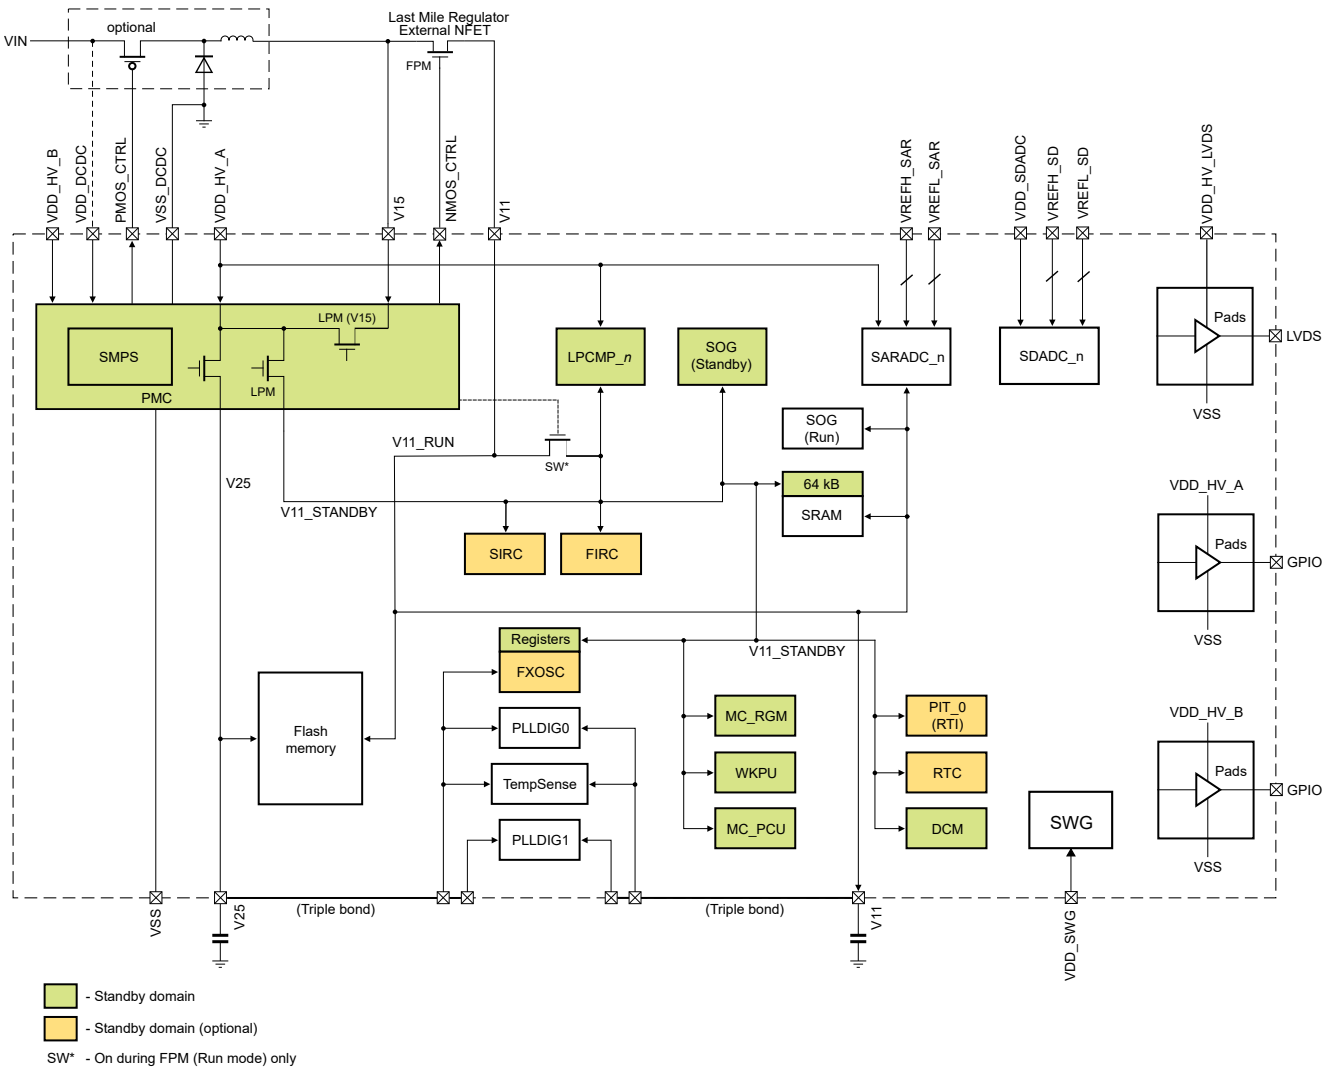

Figure 164. PMC block diagram

40.5 Signals

Table 201. Signal description

Signal	I/O	Description
VDD_HV_A	Supply input	VDD_HV_A is the primary high-voltage supply input to PMC. It is used for the PMC internal precision references. After the VDD_HV_A domain is powered up, you must keep it powered at all times of operation (FPM and LPM).
VDD_HV_B	Supply input	VDD_HV_B is the secondary high-voltage supply input that PMC supervises. After the VDD_HV_B domain is powered up, you must keep it powered at all times of operation (FPM and LPM).

Table continues on the next page...

Table 201. Signal description (continued)

Signal	I/O	Description
V25	Supply output	A fully integrated low-dropout linear voltage regulator drives this V25 power supply domain. It supplies the flash memory and (via a double bond) the clock modules.
V15	Supply input	The V15 supply is generated by the SMPS or by an external source (see Figure 164). PMC uses this pin to measure the voltage level on V15. Optionally, for SMPS, a PMC internal trickle LDO can sustain the V15 supply in LPM.
NMOS_CTRL	Output	NMOS_CTRL connects to the gate of an external NFET, which is used to regulate V15 down to V11 (core voltage). For the 1.1 V core regulator, an external NFET with low-threshold voltage (v_{th} smaller than 1.0 V) is needed, for example, Vishay SQ2310ES. Additionally 1 nF at the gate is required for stability reasons.
V11	Supply input	V11 is the core and logic supply. It is driven by the external NFET which is controlled by a linear regulator inside PMC.
VSS	Ground	VSS must be grounded. All VSS pins need to be externally connected to the same ground node.
VDD_DCDC	SMPS supply input	VDD_DCDC is the power supply domain for the SMPS gate driver. It must be shorted with the source voltage of the external power FET. An off-chip decoupling capacitor between VDD_DCDC and ground is required. See Datasheet for the recommended value. **NOTE** If SMPS (DCDC) mode is used and the PMC is in low power mode, it must be ensured that SMPS supply input VDD_DCDC is fully operational and loadable before wake-up from low power mode. Otherwise a low voltage reset might occur on wake-up.
VSS_DCDC	SMPS ground	VSS_DCDC is the power ground for the SMPS gate driver. It must be shorted with the main ground node and the ground node of the external Schottky diode.
PMOS_CTRL	PMOS control, gate drive output	PMOS_CTRL is the gate driver output for the external power FET.
VDD_SD_ADC0, VDD_SD_ADC1	Supply input (double bond)	VDD_SD_ADC is the power domain for sigma-delta ADCs. You must short on-board level to VDD_HV_A.
VDD_SWG	Supply input	VDD_SWG is the power domain for the sine wave generator (SWG). You must short on-board level to VDD_HV_A.
VDD_LVDS	Supply input	VDD_LVDS is the power domain supply pin. This is the power supply used by the 3.3 V Zipwire interface to the companion die.

40.6 Functional description

40.6.1 Reset

The POR and all LVRs are combined into one single MCU POR.

After an MCU POR event, you can determine which power domain caused the event by reading LVSC[PORF] and the relevant LVR*x* field (for example, LVSC[LVR11LPF]).

After an initial power ramp-up of the MCU, PMC writes 1 to LVSC[PORF] and all LVSC[LVR*x*] fields. The Go/Nogo fields have an arbitrary value.

NOTE

After an initial power ramp-up, you must write FFFFFFFFh to LVSC to clear all flags.

Because the flags are sticky bits, you must clear them before using them. Doing so makes it possible to track and debug the source of the problem by reading the Low Voltage Status and Control (LVSC) fields, if there is an unexpected MCU POR.

40.6.2 Interrupts

PMC includes two interrupt sources:

- HVD: Combines all HVD monitors into a single interrupt source. You enable the interrupt with CONFIG[HVDIE].
- LVD: Combines the LVD5A and LVDS monitors into a single interrupt source. You enable the interrupt with CONFIG[LVDIE].

See PMC Configuration (CONFIG) and Low Voltage Status and Control (LVSC) for details.

40.7 PMC register descriptions

40.7.1 PMC memory map

This section includes the PMC module memory map and detailed descriptions for all the registers. Registers marked "Reserved" should not be modified from their reset value by a write access.

PMC base address: 402E_8000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Low Voltage Status and Control (LVSC)	32	RW	See section
4h	PMC Configuration (CONFIG)	32	RW	0000_0081h
8h	SMPS Configuration (SMPSCONFIG)	32	RW	See section
Ch	Version ID (VERID)	32	R	0500_0001h

40.7.2 Low Voltage Status and Control (LVSC)

Offset

Register	Offset
LVSC	0h

Function

Contains status and control fields that support the low-voltage reset and LVD or HVD function. When the PMC is in LPM, the LVD or HVD systems are disabled.

For flags that are not affected by reset (POR flag, all LVR flags, all GNG flags), if a reset occurs at the same time as an attempt to clear the flags (by writing 1), the flag value is not defined appropriately. In this case, you need to clear the flag again after exit from reset.

For the GNG flags, if a GNG event occurs at the same time as the GNG flag is read, the flag value might not be defined appropriately. In this case, you need to read the flag twice and consider the value only if it both read values match.

Diagram

Fields

Field	Function
31 PORF	POR Flag Indicates that a POR event has occurred. Other reset sources have no effect. 0b - No POR event 1b - POR event
30 GNGSWGF	Go/NoGo Detect Flag On VDD_SWG Domain Indicates that the Go/NoGo sensor has detected a low voltage on the VDD_SWG domain in FPM. Other reset sources have no effect. 0b - No event 1b - NoGo event
29 GNGSDADC1F	Go/NoGo Detect Flag On VDD_SD_ADC1 Domain Indicates that the Go/NoGo sensor has detected a low voltage on the VDD_SD_ADC1 domain in FPM. Other reset sources have no effect. 0b - No event 1b - NoGo event
28	Go/NoGo Detect Flag On VDD_SD_ADC0 Domain

Table continues on the next page...

Table continued from the previous page...

Field	Function
GNGSDADC0F	Indicates that the Go/NoGo sensor has detected a low voltage on the VDD_SD_ADC0 domain in FPM. Other reset sources have no effect. 0b - No event 1b - NoGo vent
27 GNG11OSC2F	Go/NoGo Detect Flag On Second PLL Part Of V11 Domain Indicates that the Go/NoGo sensor has detected a low voltage on the V11 domain in FPM. This applies to only the part of the domain that supplies the second PLL. Other reset sources have no effect. 0b - No event 1b - NoGo event
26 GNG25OSC2F	GO/NoGo Detect Flag On Second PLL Part Of V25 Domain Indicates that the Go/NoGo sensor has detected a low voltage on the V25 domain in FPM. This applies to only the part of the domain that supplies the second PLL. Other reset sources have no effect. 0b - No event 1b - NoGo event
25 GNG11OSCF	Go/NoGo Detect Flag On Osc Part Of V11 Domain Indicates that the Go/NoGo sensor has detected a low voltage on the V11 domain in FPM. This applies to only the part of the domain that supplies the 1.1 V clocking modules (for example, PLL or IRC). Other reset sources have no effect. 0b - No event 1b - NoGo event
24 GNG25OSCF	GO/NoGo Detect Flag On Osc Part Of V25 Domain Indicates that the Go/NoGo sensor has detected a low voltage on the V25 domain in FPM. This applies to only the part of the domain that supplies the 2.5 V clocking modules (for example, PLL, XOSC, and IRC). Other reset sources have no effect. 0b - No event 1b - NoGo event
23 LVR11LPF	LVR11LP Flag On V11 Domain Indicates that an LVR event has occurred on the 1.1 V V11 power domain (FPM or LPM). Other reset sources have no effect. 0b - No event 1b - Event
22 LVR11F	LVR11 Flag On V11 Domain In FPM Indicates that an LVR event has occurred on the 1.1 V V11 power domain in the FPM. Other reset sources have no effect.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No event 1b - Event
21 LVR25LPF	LVR25LP Flag On V25 Domain Indicates that an LVR event has occurred on the V25 power domain (FPM or LPM). Other reset sources have no effect. 0b - No event 1b - Event
20 LVR25F	LVR25 Flag On V25 Domain In FPM Indicates that an LVR event has occurred on the V25 power domain in FPM. Other reset sources have no effect. 0b - No event 1b - Event
19 LVRBLPF	LVRBLP Flag On VDD_HV_B Domain Indicates that an LVR event has occurred on the VDD_HV_B power domain (FPM or LPM). Other reset sources have no effect. 0b - No event 1b - Event
18 LVRBF	LVRB Flag On VDD_HV_B Domain In FPM Indicates that an LVR event has occurred on the VDD_HV_B power domain in FPM. Other reset sources have no effect. 0b - No event 1b - Event
17 LVRALPF	LVRALP Flag On VDD_HV_A Domain Indicates that an LVR event has occurred on the VDD_HV_A power domain (FPM or LPM). Other reset sources have no effect. 0b - No event 1b - Event
16 LVRAF	LVRA Flag On VDD_HV_A Domain In FPM Indicates that an LVR event has occurred on the VDD_HV_A power domain in FPM. Other reset sources have no effect. 0b - No event 1b - Event
15	LVDS Status On VDD_LVDS Domain In FPM

Table continues on the next page...

Table continued from the previous page...

Field	Function
LVDSS	Shows the status of the low-voltage detect, LVDSS, on the VDD_LVDS power domain. This monitor indicates if the voltage is below a certain threshold. This feature is available only in FPM and is disabled in LPM. After a reset or wake-up from LPM, you must write 0 to LVDSF and check the status field LVDSS to determine if the voltage level on VDD_LVDS is sufficient. 0b - Above threshold 1b - Below threshold
14 HVD15S	HVD15 Status On V15 Domain In FPM Shows the status of the high-voltage detect, HVD15, on the V15 power domain. This feature is available only in FPM and is disabled in LPM. 0b - Below threshold or LPM 1b - Above threshold and FPM
13 —	Reserved
12 LVD5AS	LVD5A Status On VDD_HV_A Domain In FPM Shows the status of the 5 V LVD, LVD5A, on the VDD_HV_A power domain. This monitor indicates if the voltage is below a certain threshold, which is set slightly below 4.5 V (see the data sheet for the exact value). This feature is available only in FPM and is disabled in LPM. After a reset or wake-up from LPM, you must clear the LVD5AF flag and check the status field LVD5AS to determine the voltage level on the VDD_HV_A supply. 0b - Above threshold 1b - Below threshold
11 HVD11S	HVD11 Status On V11 Domain In FPM Shows the status of HVD11 on the V11 power domain. This feature is available only in FPM and is disabled in LPM. 0b - Below threshold or LPM 1b - Above threshold and FPM
10 HVD25S	HVD25 Status On V25 Domain In FPM Shows the status of the high-voltage detect, HVD25, on the V25 power domain. This feature is available only in FPM and is disabled in LPM. 0b - Below threshold or LPM 1b - Above threshold and FPM
9 HVDBS	HVDB Status On VDD_HV_B Domain In FPM Shows the status of the high-voltage detect, HVDB, on the VDD_HV_B power domain. This feature is available only in FPM and is disabled in LPM. 0b - Below threshold or LPM

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Above threshold and FPM
8 HVDAS	HVDA Status On VDD_HV_A Domain In FPM Shows the status of the high-voltage detect HVDA on the VDD_HV_A power domain. This feature is available only in FPM and is disabled in LPM. 0b - Below threshold or LPM 1b - Above threshold and FPM
7 LVDSF	LVDS Flag On VDD_LVDS Domain In FPM PMC writes 1 to this field when the LVDSS status field changes. To clear LVDSF, write 1 to it. If enabled, LVDSF causes an interrupt request. 0b - Not changed 1b - Changed
6 HVD15F	HVD15 Flag On V15 Domain In FPM PMC writes 1 to this field when the HVD15S status field changes. To clear HVD15F, write 1 to it. If enabled, HVD15F causes an interrupt request. 0b - Not changed 1b - Changed
5 —	Reserved
4 LVD5AF	LVD5A Flag On VDD_HV_A Domain In FPM PMC writes 1 to this field when the LVD5AS status field changes. To clear LVD5AF, write 1 to it. If enabled, LVD5AF causes an interrupt request. 0b - Not changed 1b - Changed
3 HVD11F	HVD11 Flag On V11 Domain In FPM PMC writes 1 to this field when the HVD11S status field changes. To clear HVD11F, write 1 to it. If enabled, HVD11F causes an interrupt request. 0b - Not changed 1b - Changed
2 HVD25F	HVD25 Flag On V25 Domain In FPM PMC writes 1 to this field when the HVD25S status field changes. To clear HVD25F, write 1 to it. If enabled, HVD25F causes an interrupt request. 0b - Not changed 1b - Changed

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 HVDBF	HVDB Flag On VDD_HV_B Domain In FPM PMC writes 1 to this field when the HVDBS status field changes. To clear HVDBF, write 1 to it. If enabled, HVDBF causes an interrupt request. 0b - Not changed 1b - Changed
0 HVDAF	HVDA Flag On VDD_HV_A Domain In FPM PMC writes 1 to this field when the HVDAS status field changes. To clear HVDAF, write 1 to it. If enabled, HVDAF causes an interrupt request. 0b - Not changed 1b - Changed

40.7.3 PMC Configuration (CONFIG)

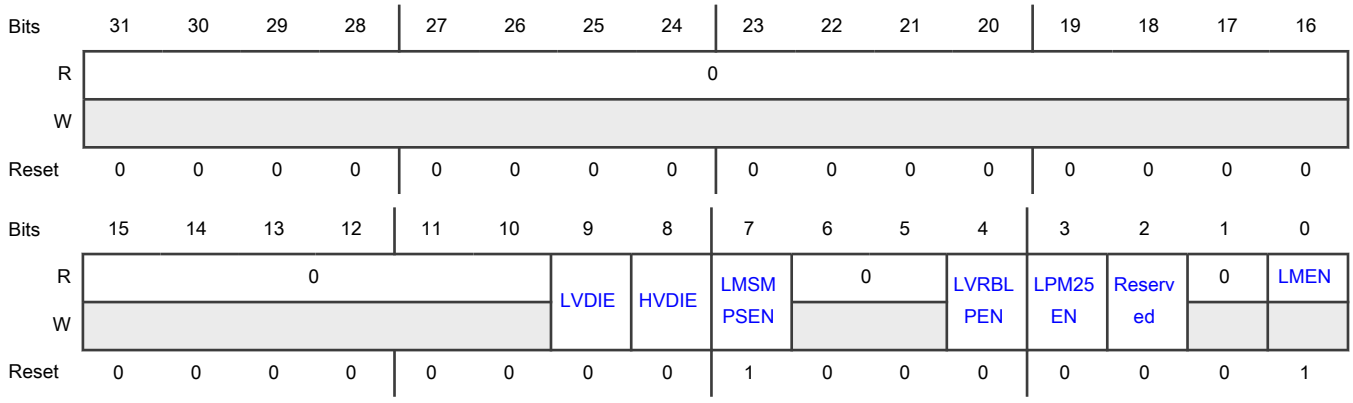
Offset

Register	Offset
CONFIG	4h

Function

Configures the various PMC options.

Diagram



Fields

Field	Function
31-10	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
9 LVDIE	Low Voltage Detect Interrupt Enable Enables hardware interrupt requests if either LVSC[LVD5AF] = 1 or LVSC[LVDSF] = 1. The LVD interrupt must be disabled before entering LPM. If enabled, there is a request for an LVD hardware interrupt. If disabled, LVD hardware interrupt is disabled (use polling). 0b - Disables 1b - Enables
8 HVDIE	HVD Interrupt Enable Enables hardware interrupt requests if any of the following fields = 1: • LVSC[HVDAF] • LVSC[HVDBF] • LVSC[HVD25F] • LVSC[HVD11F] 0b - Disables 1b - Enables
7 LMSMPSEN	V15 Switched-Mode Power Supply Enable Enables the SMPS regulator (switched-mode power supply), which regulates from VDD_DCDC down to 1.5 V on the V15 pin to supply the last mile regulator. Because LMSMPSEN = 1 after startup or reset, if SMPS is not used, you must write 0 to LMBSMPSEN after each reset to turn the feature off. When LMSMPSEN = 0, you can no longer write 1 to it until the next reset. 0b - Disables 1b - Enables
6-5 —	Reserved
4 LVRBLPEN	LVRBLP Enable During LPM Enables low-voltage reset detection (LVRBLP) on the VDD_HV_B power domain in LPM. 0b - Disables 1b - Enables
3 LPM25EN	V25 Domain Enable During LPM Enables a low-power V25 regulator and the low-voltage reset detection (LVR25LP) in LPM. In FPM, this low-power regulator is always off. 0b - Disables 1b - Enables

Table continues on the next page...

Table continued from the previous page...

Field	Function
2 —	Reserved
1 —	Reserved
0 LMEN	Last Mile Regulator Enable Enables the last mile regulator, which regulates an external 1.5 V voltage on V15 down to the core and logic supply (V11 power domain), which is typically 1.1 V. Because the last mile regulator is always enabled on this chip, LMEN always reads 1.

40.7.4 SMPS Configuration (SMPSCONFIG)

Offset

Register	Offset
SMPSCONFIG	8h

Function

Configures the various options of the switched-mode power supply (SMPS) generating V15 (1.5 V input supply to the last mile regulator).

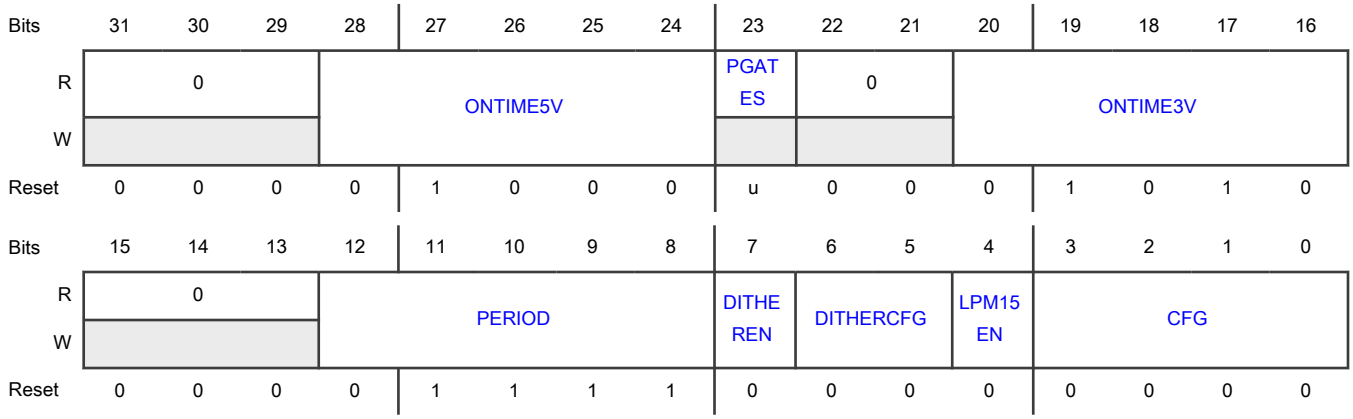
Table 202. SMPS configurations for driving the PMOS_CTRL pin

CFG[3:0]	PMOS_CTRL frequency	PMOS_CTRL duty cycle 3 V	PMOS_CTRL duty cycle 5 V
0000	470 kHz	58.8%	47.1%
0001	470 kHz	64.7%	52.9%
0010	470 kHz	52.9%	41.2%
0011	533 kHz	60%	46.7%
0100	533 kHz	66.7%	53.3%
0101	533 kHz	53.3%	40%
0110	421 kHz	57.9%	47.4%
0111	421 kHz	63.2%	52.6%
1000	421 kHz	52.6%	42.1%
1001–1110	Reserved	Reserved	Reserved
1111	8 MHz ÷ (PERIOD[4:0] + 1)	ONTIME3V[4:0] ÷ (PERIOD[4:0] + 1)	ONTIME5V[4:0] ÷ (PERIOD[4:0] + 1)

Table 203. 8 MHz IRC dither configurations

DITHERCFG[1:0]	Dither amplitude	Dither frequency
00	± 0.4 MHz	400 kHz
01	± 0.6 MHz	286 kHz
10	± 0.8 MHz	222 kHz
11	± 1 MHz	182 kHz

Diagram



Fields

Field	Function
31-29 —	Reserved
28-24 ONTIME5V	SMPS Duty Cycle For 5 V Range Determines the duty cycle of the output signal at the PMOS_CTRL pin. This duty cycle is applied when VDD_DCDC is greater than or equal to 4 V. The duty cycle is calculated as follows: Duty_pmos_ctrl = ONTIME3V[4:0] ÷ (PERIOD[4:0] + 1)
23 PGATES	PMOS_CTRL Status Reflects the status of the PMOS_CTRL pin. If = 0, note that VSS_DCDC is connected to GND. 0b - Driven to VSS_DCDC 1b - Driven to VDD_DCDC
22-21 —	Reserved
20-16 ONTIME3V	SMPS Duty Cycle For 3 V Range Determines the duty cycle of the output signal at the PMOS_CTRL pin. This duty cycle is applied when VDD_DCDC is smaller than 4 V.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The duty cycle is calculated as follows: Duty_pmos_ctrl = ONTIME3V[4:0] ÷ (PERIOD[4:0] + 1)
15-13 —	Reserved
12-8 PERIOD	SMPS Period Determines the frequency of the output signal at the PMOS_CTRL pin. The frequency is calculated as follows: Freq_pmos_ctrl = 8 MHz ÷ (PERIOD[4:0] + 1)
7 DITHEREN	IRC Dither Enable Enables dithering of the 8 MHz IRC. The amplitude and frequency of the dithering is determined by the DITHERCFG[1:0] bits. 0b - Disables 1b - Enables
6-5 DITHERCFG	IRC Dither Configuration Selects the IRC dithering amplitude and frequency. This feature spreads the frequency spectrum of driving the PMOS_CTRL pin to reduce radiated emission. To change the value: 1. Write 0 to DITHEREN. 2. Write the dither configuration (DITHERCFG[1:0]). 3. Write 1 to DITHEREN. See Table 203 for configuration options.
4 LPM15EN	V15 Domain Enable During LPM Enables V15 in LPM. This is useful for fast recovery to FPM when using the SMPS mode to generate V15. This feature is active only in LPM, and is turned off in FPM. For this purpose, there is a small LDO inside the PMC that regulates V15 to the target value during LPM. **NOTE** LPM15EN is only used if SMPS generates V15. All other options to generate V15 are forbidden, and in those cases you must always write 0 to LPM15EN. 0b - Not kept on target 1b - Kept on target
3-0 CFG	SMPS Configuration Select Selects a configuration for frequency and duty cycle (on-time) of the switched-mode power supply, which drives (via PMOS_CTRL) the external power FET, according to Table 202.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE As seen in the table, CFG[3:0] = 1111 allows for free customization of PERIOD[4:0], ONTIME5V[4:0], and ONTIME3V[3:0]. If you choose this option, you must carefully consider the value of these bits. To ensure proper functioning of SMPS, and to keep EMI in check, you must program the switching frequency and duty cycle within a reasonable range.

40.7.5 Version ID (VERID)

Offset

Register	Offset
VERID	Ch

Function

Returns the major and minor version numbers of hardware implementation.

Diagram

0 LMFEAT	Last Mile Regulator Feature Indicates whether the last mile regulator feature (1.5 V to 1.1 V) is available. 0b - Not available 1b - Available

40.8 Glossary

FPM	Full Performance mode
HVD	High voltage detector
IRC	Internal RC oscillator
LM	Last mile regulator
LPM	Low Performance mode
LVD	Low voltage detector
LVR	Low voltage reset
NVM	Nonvolatile memory
POR	Power on reset
XOSC	External crystal oscillator
SMPS	Switched-mode power supply

Chapter 41
Mode Entry Module (MC_ME)

41.1 Chip-specific MC_ME information

41.1.1 MC_ME modes

This chip implements these modes:

- Reset
- Run
- Standby

The chip always enters Run mode after exiting Reset mode wherein you can configure the chip to perform its computational and communication functions. In Run mode:

- The chip remains fully powered. The boot core is the only core enabled on Run entry.
- You can enable and disable application cores and peripherals as needed, based on functional and power requirements.
- You can configure the pins and self-test as needed. See "Self-Test programming sequence" section in the STCU2 chapter for the self-test programming sequence to be followed before initiating self-test, in which:
  - Pins are safe-stated.
  - No computational or communication activities are possible.
- The chip automatically enters Reset mode after self-test (BIST) is complete.

41.1.2 Core operation modes

The CM7_0 and CM7_1 cores support below two modes of operation. The CM7_2 and CM7_3 always operate in coupled/lockstep mode:

- Decoupled/independent operation
- Coupled/lockstep operation

The device configuration clients (utest_misc DCF client) control these modes of operation. See the DCF clients file attached to this document for details.

41.1.3 MC_ME partition mapping of cores and peripherals

MC_ME provides registers and interface signals to support multiple partitions. These MC_ME partitions are different from the chip's LBIST partitions described in the "Safety Overview" chapter. This chip has four MC_ME partitions:

- Partition 0: Contains application cores, the on-platform and the off-platform slots on AIPS_0 bridge.
- Partition 1: Contains the on-platform and the off-platform slots on AIPS_1 bridge.
- Partition 2: Contains the on-platform and the off-platform slots on AIPS_2 bridge.
- Partition 3: Contains the on-platform and the off-platform slots on AIPS_3 bridge.

Core clock gating and Peripheral clock gating specify the core and peripheral mapping on MC_ME partitions and their associated clock gating possibilities.

MC_ME also provides provisions to control the booting address for application cores, which can be configured to start from a non-default address location by appropriately configuring PRTN*x*_CORE*n*_ADDR[ADDR].

41.1.4 MC_ME partition 0 mapping

The following table shows partition 0 and its register mapping.

Table 204. MC_ME partition 0 mapping

Register	Register field	Description	Used for
MC_ME_PRTN0_PCONF	PCE	Partition clock enable	Read Only
MC_ME_PRTN0_PUPD	PCUD	Partition clock update	NA
MC_ME_PRTN0_STAT	PCS	Partition clock status	Read Only
MC_ME_PRTN0_CORE_LOCKSTEP	LS2	Lockstep 2	NA

41.1.5 MC_ME partition 1 mapping

The following table below shows partition 1 and its register mapping.

Table 205. MC_ME partition 1 mapping

Register	Register field	Description	Used for
MC_ME_PRTN1_PUPD	PCUD	Partition clock update	Reset domain 1
MC_ME_PRTN1_STAT	PCS	Partition clock status	Reset domain 1

41.1.6 MC_ME partition 2 mapping

The following table shows partition 2 and its register mapping.

Table 206. MC_ME partition 2 mapping

Register	Register field	Description	Used for
MC_ME_PRTN2_PUPD	PCUD	Partition clock update	Reset domain 2
MC_ME_PRTN2_STAT	PCS	Partition clock status	Reset domain 2

41.1.7 MC_ME partition 3 mapping

The following table shows partition 3 and its register mapping.

Table 207. MC_ME partition 3 mapping

Register	Register field	Description	Used for
MC_ME_PRTN3_PUPD	PCUD	Partition clock update	Reset domain 3
MC_ME_PRTN3_STAT	PCS	Partition clock status	Reset domain 3

41.1.8 Core clock gating

MC_ME has individual core-clock enable fields that gate the application core clocks, which can also be clock gated by executing Waiting for Interrupt (WFI).

You can enable the application cores by configuring the respective CCE fields. See Application core initialization process and Application core shutdown process for proper initialization and shutdown of application cores. There is no clock control for the HSE_B core. It needs to be only put into WFI if required to be shutdown (for example, in Standby mode).

Table 208. MC_ME partition core mapping

Core	MC_ME partition	MC_ME clock enable register field	Applicability
Cortex-M7_0	0	MC_ME.PRTN0_CORE0_PCONF[CCE]	Yes
Cortex-M7_1	0	MC_ME.PRTN0_CORE1_PCONF[CCE]	Yes
Cortex-M4	0	Not Applicable (Reserved)	Not Applicable
Reserved	0	Not Applicable (Reserved)	Not Applicable
Cortex-M7_2	0	MC_ME.PRTN0_CORE4_PCONF[CCE]	Yes
CM7_2 (Cortex M7_3)[1]	0	MC_ME_PRTN0_CORE5_PCONF[CCE]	Not Applicable (Cortex-M7_3 is always in lockstep with Cortex-M7_2)

1. In the lockstep configuration, the checker core controls are not applicable, i.e. Cortex-M7_3 clock is not programmable using MC_ME.PRTN0_CORE5_PCONF[CCE]. The main core (Cortex-M7_2) clock control register will control the checker core (Cortex-M7_3) clock.

41.1.9 Peripheral clock gating

See Peripheral initialization process and Peripheral shutdown process for proper initialization and shutdown of peripherals. See Table 209 for peripheral clock gating possibilities.

The application core can program the reserved configurations.

NOTE

Before accessing the registers of a peripheral to start using it, its clock must be turned on, otherwise, a Hard-Fault event will occur.

Table 209. MC_ME partition peripheral mapping and clock control

AIPS	Peripheral description	MC_ME COFB control register	MC_ME peripheral control register	MC_ME peripheral slot no. in partition	PRTNx_ COFBy_ CLKEN [REQn] is configurable	PRTNx_ COFBy_ CLKEN [REQn] default value	On Platform	IPS Slot Number

You cannot control all the peripherals. For example, you cannot turn on and turn off the peripherals required for chip functionality across reset or power-up. They always remain on.

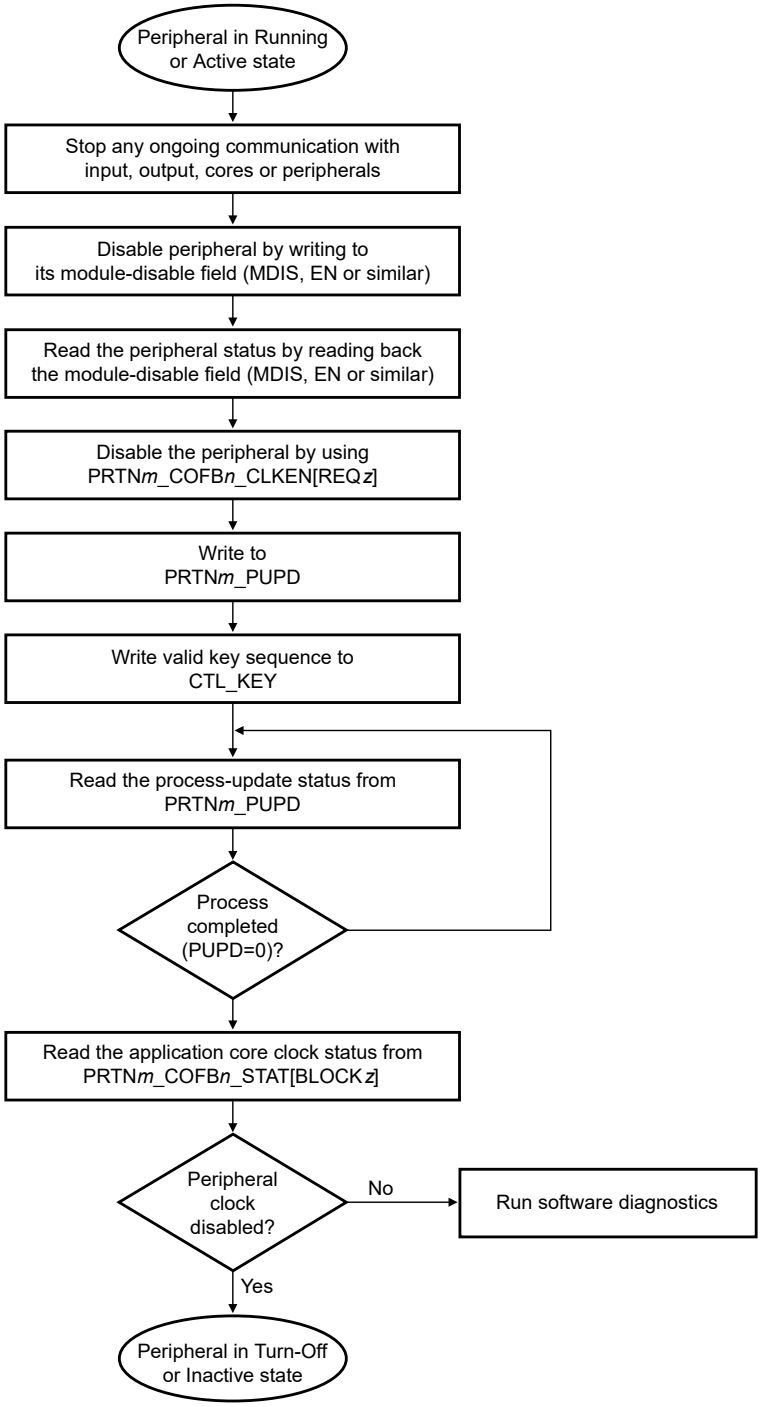

Figure 168. Peripheral shutdown process

41.2 Introduction

The MC_ME module generates control signals for a set of modules of the SoC. The set of signals are defined in corresponding 'Partition Configuration Registers'. It also implements a software-based mechanism for initiating a functional and destructive reset sequence and standby entry handshake with power management of SoC. See Figure 169 for the MC_ME block diagram.

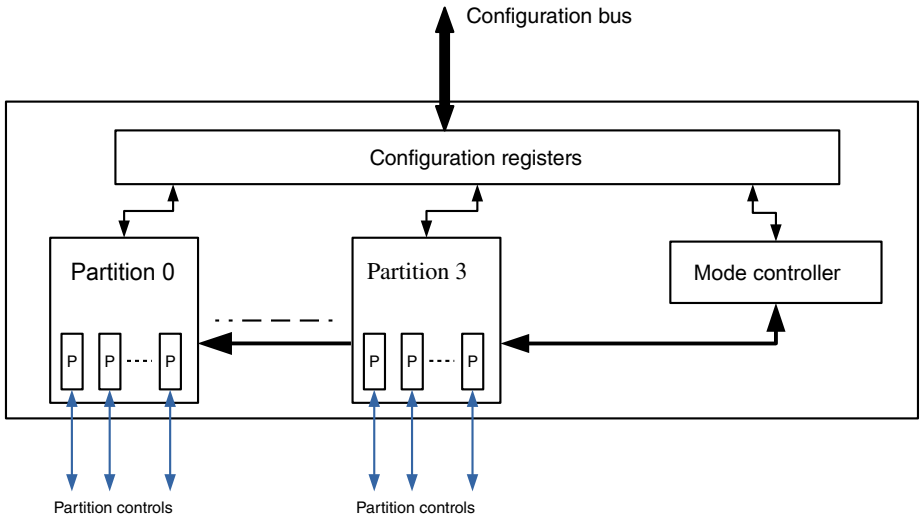

Figure 169. MC_ME block diagram

41.3 Features

MC_ME includes the following features:

- 4 logic partitions implementation and their controls
- Core clock controls
- Partition clock control
- Control mechanism for initiating a destructive or functional reset sequence to MC_RGM
- Control mechanism for initiating standby mode entry for SoC

The logic partition inside MC_ME refers to a certain group of on-chip resources (or IP blocks) that are clubbed together to represent a single 'Partition' inside MC_ME. The MC_ME partition can be the same or different than an LBIST partition. Each of the MC_ME partitions implements a certain number of hardware processes. These hardware processes provide a mechanism to regulate various control signals provided to or received from the IP blocks. The corresponding status signals can also be monitored from MC_ME register(s). Each of the hardware processes is bound to finish in 512 cycles of the MC_ME register configuration clocks. Therefore, the hardware processes are non blocking in nature. Mismatch in the expected versus actual status of any hardware process is controlled by a pre-defined software.

41.4 Partition processes

Each of the processes inside the partition controls register space and corresponds to a control signal provided to that partition. A partition can include a core, or COFBs, or both. The MC_ME hardware processes provide control and status via signals provided to partitions. Each partition can be assigned a signal for control and a signal for status. Each of the control signals implements functionality for the partition. For example, clock gating and peripheral control.

The hardware process can be triggered and monitored using a set of three registers:

- Configuration register; for example, Partition n Process Configuration register
- Update register; for example, Partition n Process Update register
- Status register; for example, Partition n Status register

Similar registers exist for cores inside the partition.

The process setup and triggering procedure is shown in Figure 170. Each of the processes is independent of others and can be triggered or re-triggered in parallel or sequential to other processes. The triggering or re-triggering mechanism remains the same.

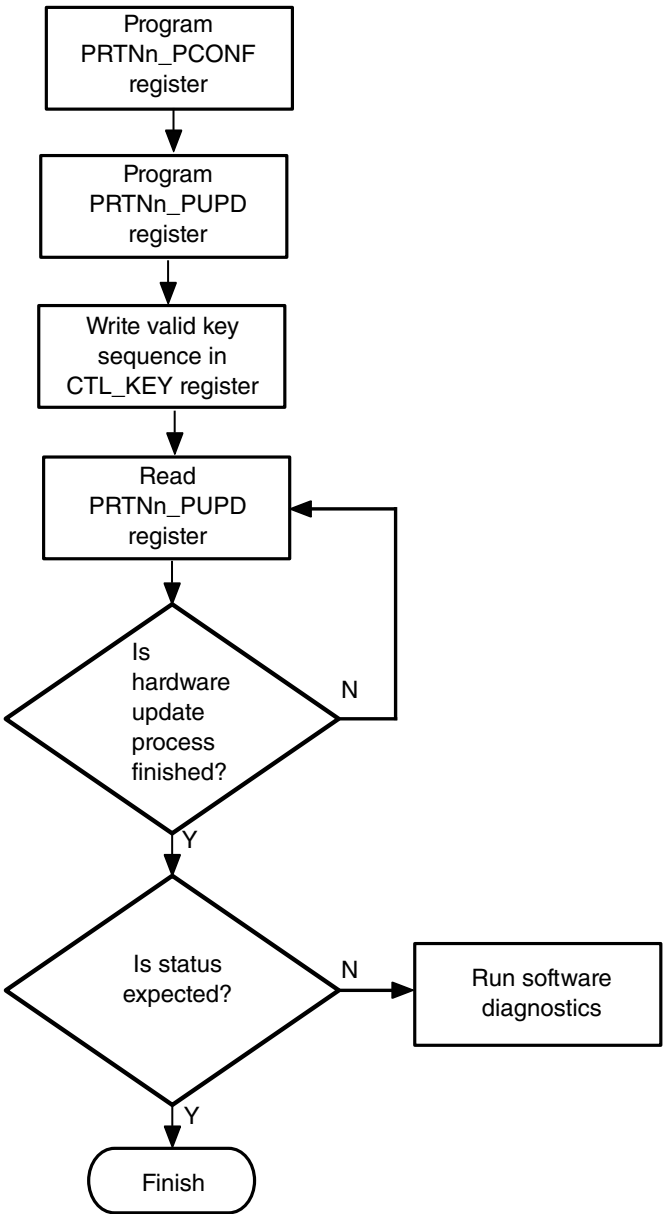

Figure 170. Partition process setup procedure

All the hardware processes are bound to finish in 512 cycles of the MC_ME configuration clock. If the actual and the expected status for a process does not match, then the diagnostics is left as a software responsibility. The software diagnostic can include further wait cycles for the status to match.

41.5 Mode transition

MC_ME implements a mode transition mechanism, whereby the mode of operation for SoC can be changed. Then module implements a mechanism that can lead to:

- Destructive reset
- Functional reset
- Standby mode entry

Destructive reset and functional reset requests from MC_ME are non-retractable transitions. After it is initiated, the other MC_ME functionality is rendered unusable and bus errors are provided for upcoming access to the MC_ME register until a reset sequence is executed by MC_RGM. Hence, it is vital that MC_RGM should never ignore or gate the reset requests from MC_ME.

For transition into the standby mode, the software should ensure that required IP blocks such as clock sources and I/O communication are in their respective inactive states before initiating a standby mode transition to MC_ME. After MC_ME initiates a power down sequence request, it cannot be retracted. The SoC enters a standby power down sequence and then reenter power-up sequence even for cases where the standby wakeup happens right at the time of initiating a power-down sequence request.

Steps for initiating the MC_ME mode transition:

1. Setup the MODE_CONF register with the corresponding target mode bit set to logic-1.
2. Perform the same update as done in the MODE_CONF register on the CONF_UPD register.
3. Write the valid control key (0x5AF0) on the CTL_KEY register.
4. Write the valid invert control key (0xA50F) on the CTL_KEY register.

Mode transition to MC_ME is initiated, after the sequence mentioned above is completed.

In step 1, if both FUNC_RST and DEST_RST in Mode Configuration Register (MODE_CONF) are 1:

- After step 4 is complete, MC_ME initiates a mode transition to a destructive (not functional) reset.
- After the chip exits reset, MC_RGM records that both MC_ME's destructive reset and MC_ME's functional reset were the reset source.

NOTE

Any hardware partition processes setup, along with mode transition, is executed in parallel to the mode transition of MC_ME.

41.6 Standby entry

MC_ME provides hardware processes that implement shutdown sequencing of on-chip resources, such as cores and COFBs. The standby entry sequencing can be achieved or implemented using these hardware processes. The order of the hardware process is determined by the software and MC_ME. It requires no restriction in sequencing of the operation. Following is an example sequence for initiating a power-down sequence for entering the standby mode for SoC. The standby entry sequence should include (but not limited to) the following steps:

1. Setting up wakeup lines
2. Shutting down cores and COFBs
3. Switching all MC_CGM muxes to FIRC with PCFS
4. Powering down all clock sources except FIRC
5. Setting up MC_ME using the main core and initiating a standby mode transition
6. Executing WFI instruction on the main core (per Arm specification)

41.6.1 Application core shutdown

This section describes a mechanism for shutting down an application core. The sequence proposed here is extendible with the housekeeping tasks required for other IPs. Each of the tasks mentioned in the following sequence, can be further integrated with an SoC-specific task.

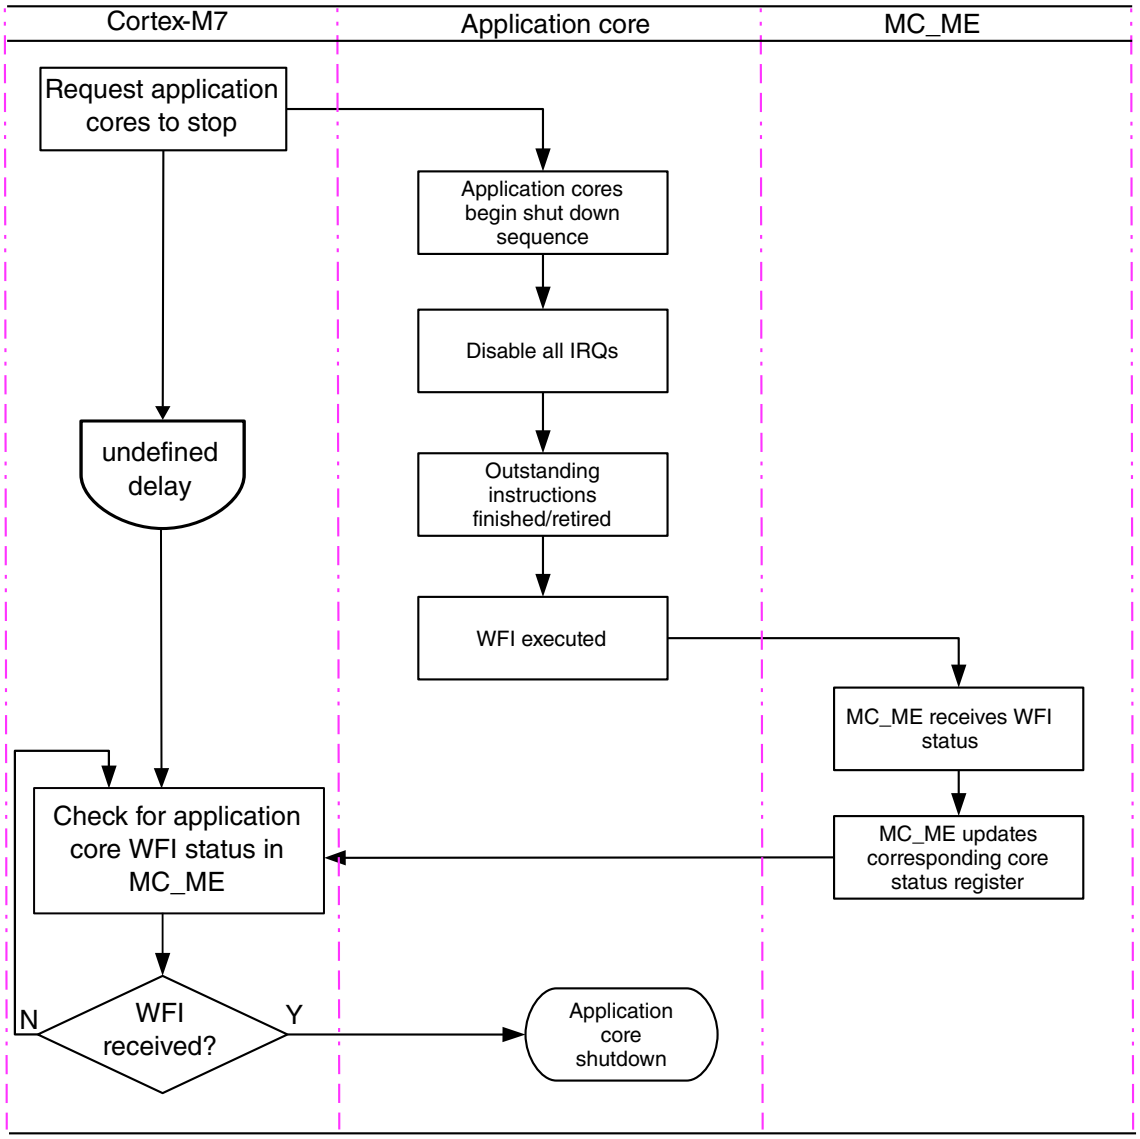

Figure 171. Application core shutdown

After the application core is shutdown, the main core can optionally decide to gate the respective core clock using the corresponding core clock hardware process.

41.6.2 Main core shutdown and standby entry

This section describes standby entry sequence along with the main core shutdown. This sequence should only be initiated after SoC is ready for entering standby and has completed all the housekeeping activities. It is necessary that the main core has completed all the operations pertaining to other (application cores) and is the last active core before initiating the standby entry sequence. See Figure 172.

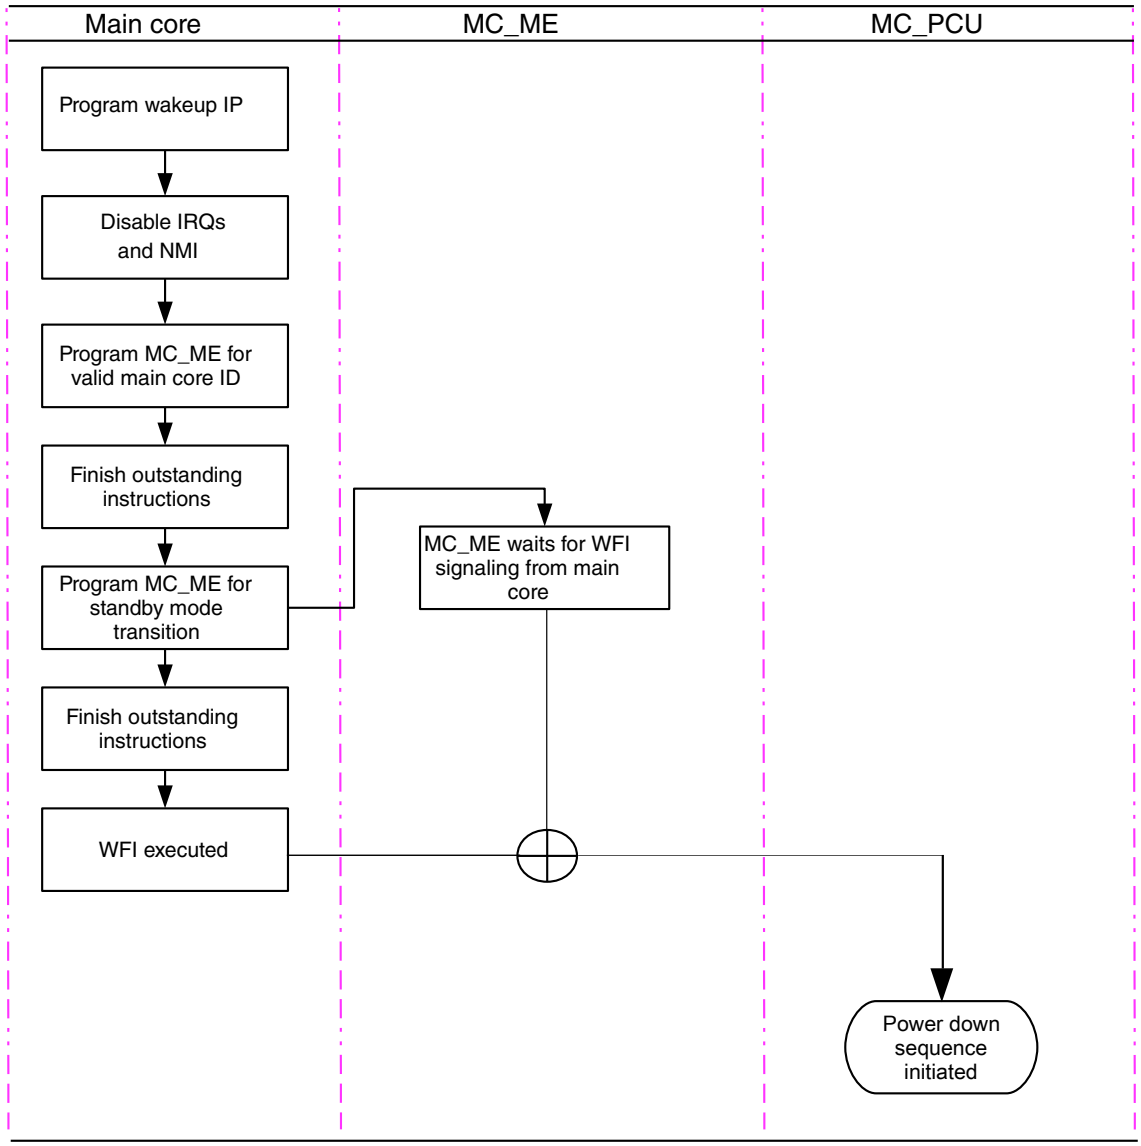

Figure 172. Standby entry sequence along with main core shutdown

NOTE

- MC_ME initiates the power sequence to MC_PCU. This enables the main core to remain inactive (WFI state) until it is reset and power-up again at standby exit.

41.7 MC_ME register descriptions

MC_ME implements set hardware processes that can be used by the software for changing the mode of operation for a partition. Following are the features of MC_ME registers:

- All registers are 32-bit wide.
- Only 32-bit read and write accesses are supported.
- Read/write accesses of less than 32 bits terminate with an error.
- Writes to read-only register fields in writable registers are ignored and do not provide an error message.

- Writes to read-only registers are aborted with an error message.

41.7.2 Control Key Register (CTL_KEY)

Offset

Register	Offset
CTL_KEY	0h

Function

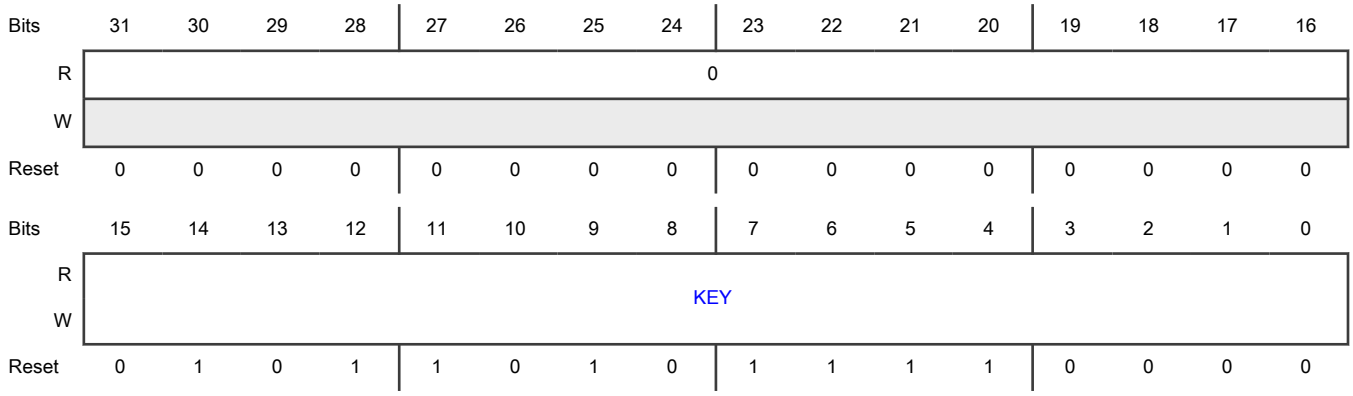
This register provides the mechanism to MC_ME for starting the hardware processes for the partition(s) and standby entry sequence. The hardware processes for partitions are triggered through the corresponding PRTNn_PCONF register. The mechanism to trigger the hardware processes of the respective partitions require two write operations: first time with key and second time with inverted key. The hexadecimal value of key is 0x5AF0 whereas for inverted key is 0xA50F.

For initiating a standby entry sequence, the MODE_CONF register is used for providing a standby entry request along with a valid key combination.

NOTE

Reads from this register return a valid key value to be written next.

Diagram



Fields

Field	Function
31-16 —	Reserved This field is reserved and read returns zeros.
15-0 KEY	Control key Key for starting the hardware processes. Writes with a value other than key or inverted key are ignored. Reads return bit inverted value corresponding to last write.

41.7.3 Mode Configuration Register (MODE_CONF)

Offset

Register	Offset
MODE_CONF	4h

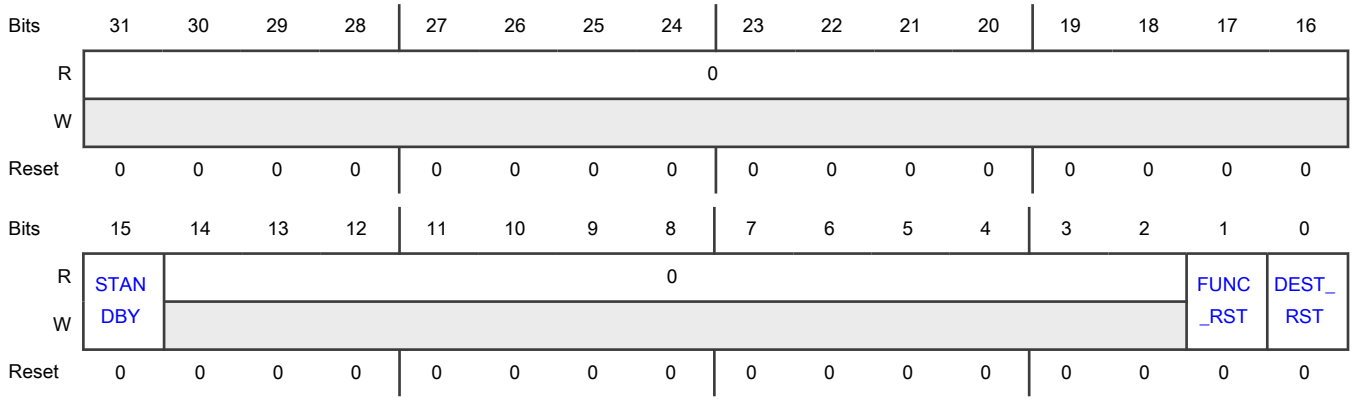
Function

This register is used for initiating a standby request or a reset event (destructive or functional) for the chip. The functional or destructive events are signaled to MC_RGM for further handling.

NOTE

Software must not enable mode entry if the value of multiple fields is 1 in the MODE_CONF register.

Diagram



Fields

Field	Function
31-16 —	Reserved This field is reserved and read returns zeros.
15 STANDBY	Standby request Writing a logic-1 to this bit along with the MODE_UPD register configuration and followed with a valid key combination makes a standby entry sequence request to MC_ME.
14-2 —	Reserved This field is reserved and read returns zeros.
1 FUNC_RST	Functional reset request Writing a logic-1 to this bit along with the MODE_UPD register configuration and followed with a valid key combination makes a functional reset event signaling to MC_RGM.
0 DEST_RST	Destructive reset request Writing a logic-1 to this bit along with the MODE_UPD register configuration and followed with a valid key combination makes a destructive reset event signaling to MC_RGM.

41.7.4 Mode Update Register (MODE_UPD)

Offset

Register	Offset
MODE_UPD	8h

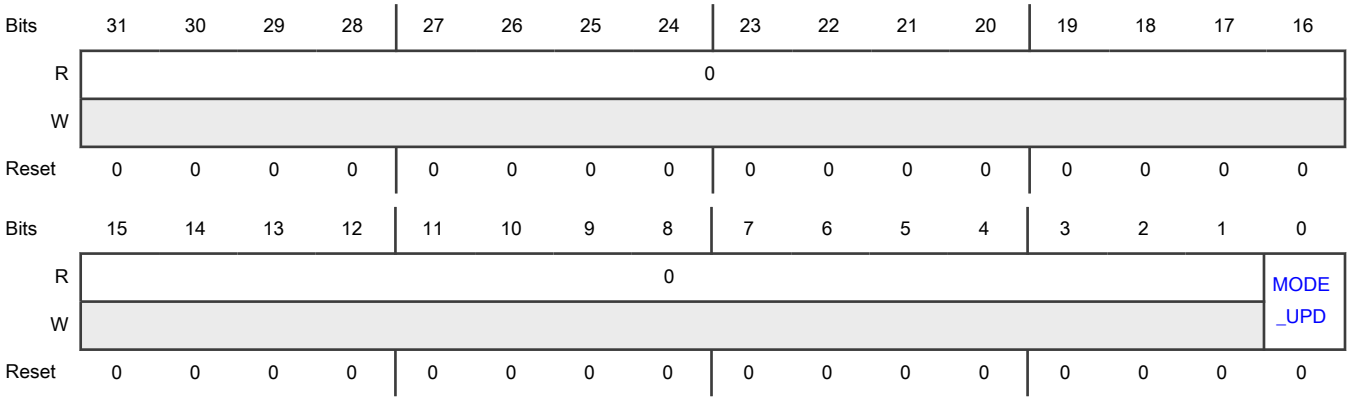
Function

This register is used for initiating a mode change. Mode change refers to initiating a standby request, or generating a destructive or functional reset event to MC_RGM. Setting mode update field to logic-1, along with programming MODE_CONF registers and then followed by a valid key combination will generate a mode transition request.

NOTE

The MODE_UPD register is implemented to make mode transition programming model the same as partition programming model. This is for future expansion inside MC_ME.

Diagram



Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 MODE_UPD	Mode update Writing a logic-1 to this bit, followed by a valid key combination initiates a mode change as per the MODE_CONF register.

41.7.5 Mode Status Register (MODE_STAT)

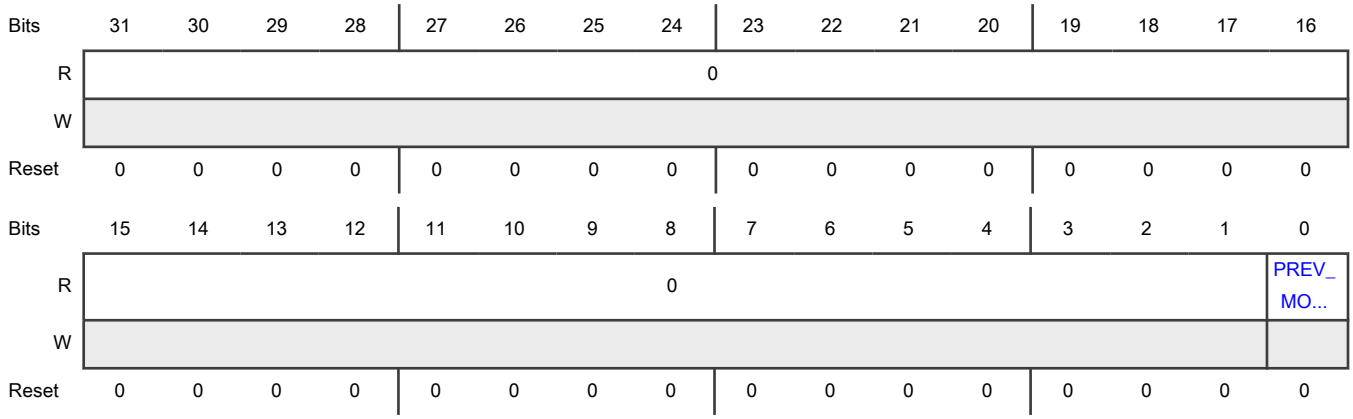
Offset

Register	Offset
MODE_STAT	Ch

Function

This register provides the status of the previous mode. In case of standby exit, if the reset event status register of MC_RGM are set, then contents of this register should be ignored.

Diagram



Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 PREV_MODE	Previous mode This bit shows the status of the previous mode. 0b - The previous mode was reset (any reset). 1b - The previous mode was standby.

41.7.6 Main Core ID Register (MAIN_COREID)

Offset

Register	Offset
MAIN_COREID	10h

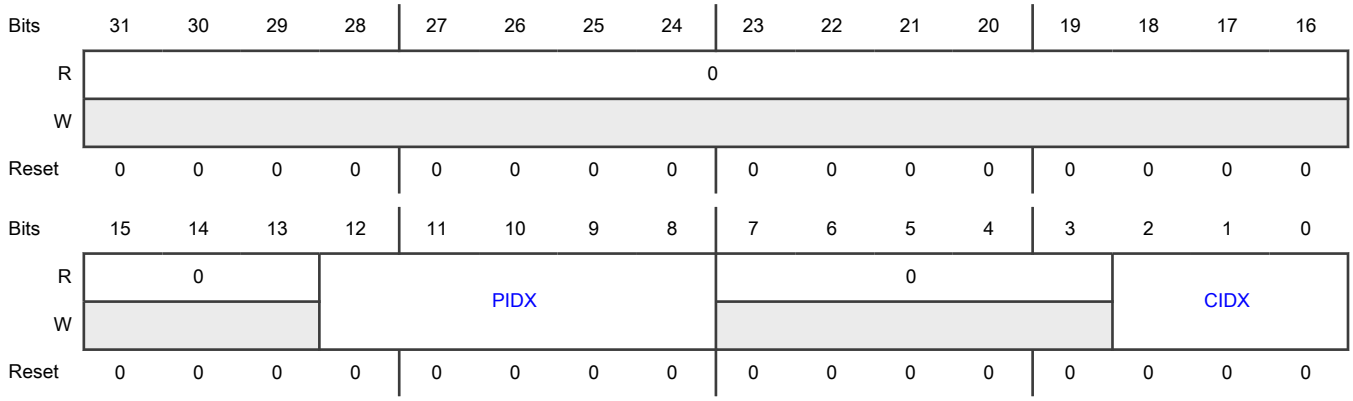
Function

This register provides the ID of the main core sequencing the operation for the standby sequence. Core ID is required for entering in the standby mode, and using this MC_ME locates the WFI instruction execution of the main core. The core ID in this register is specified by the partition index along with the core index.

NOTE

Before initiating a standby entry sequence, the contents of this register should point to the correct main core. Providing non-existing or incorrect core ID leads to unpredictable hardware behavior.

Diagram



Fields

Field	Function
31-13 —	Reserved This field is reserved and read returns zeros.
12-8 PIDX	Partition index Provides the partition index of the main core. Only values 0 - 3 can be written.
7-3 —	Reserved This field is reserved and read returns zeros.
2-0 CIDX	Core index Provides the core index of the main core inside the partition.

41.7.7 Partition 0 Process Configuration Register (PRTN0_PCONF)

Offset

Register	Offset
PRTN0_PCONF	100h

Function

This register provides a configuration for the hardware processes corresponding to Partition 0. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN0_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN0_PCONF and PRTN0_PUPD registers are used to determine the hardware processes to be executed. These are triggered in parallel and independent of each other. All dependent processes should be requested one after another from the software.

NOTE

The partition clock enable/disable are not standalone and must be done coherently in a fixed sequence. For details, see Software Reset Partition Turn-On Flow Chart and Software reset partition turn-off flowchart in Reset chapter.

NOTE

See chip-specific MC_ME information to check if this register is implemented on chip.

1 —	Reserved This field is reserved and read returns zeros.
0 PCE	Partition clock enable This bit controls whether the clock to IPs (other than core(s)) in the partition should be enabled or disabled. 1b - Enable the clock to IPs

41.7.8 Partition 0 Process Update Register (PRTN0_PUPD)

Offset

Register	Offset
PRTN0_PUPD	104h

Function

This register provides trigger signaling for the hardware processes corresponding to Partition 0. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN0_PCONF register. When the hardware process is finished the corresponding bit in this register is auto-cleared to logic-0.

NOTE

See chip-specific MC_ME information to check if this register is implemented on chip.

41.7.9 Partition 0 Status Register (PRTN0_STAT)

Offset

Register	Offset
PRTN0_STAT	108h

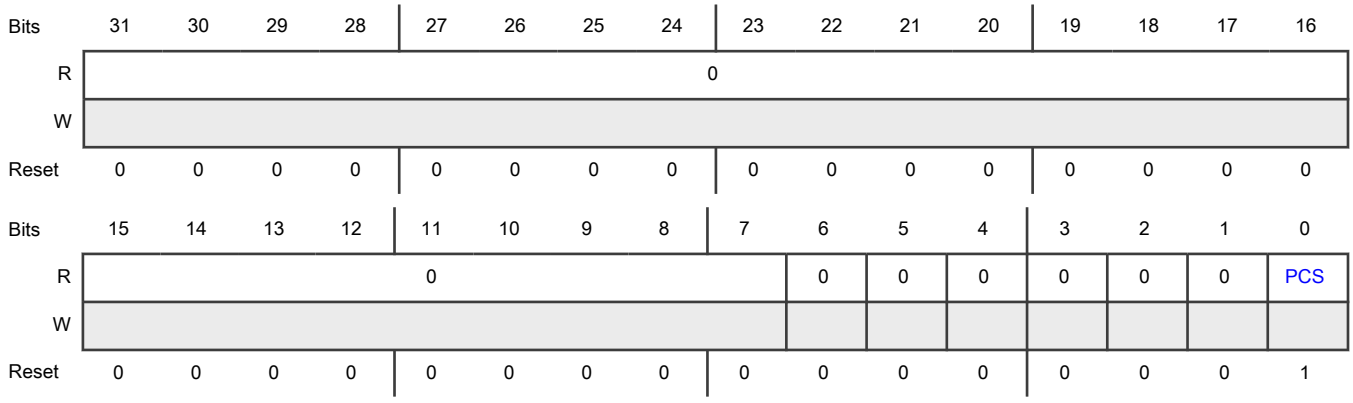
Function

This register provides the current status of the control signals from the Partition 0.

NOTE

See chip-specific MC_ME information to check if this register is implemented on chip.

Diagram



Fields

Field	Function
31-7 —	Reserved This field is reserved and read returns zeros.

41.7.10 Partition 0 Core Lockstep Control Register (PRTN0_CORE_LOCKSTEP)

Offset

Register	Offset
PRTN0_CORE_LOCKSTEP	10Ch

Function

This register provides the control for indicating a set of cores for lockstep execution in Partition 0. Writes to this register immediately provide the corresponding bit to the described cores. No hardware process updates are required.

NOTE

See chip-specific MC_ME information to check if this register is implemented on chip.

Diagram

41.7.11 Partition 0 COFB Set 0 Clock Status Register (PRTN0_COFB0_STAT)

Offset

Register	Offset
PRTN0_COFB0_STAT	110h

Function

This register provides the status of set 0 of COFBs inside Partition 0.

NOTE

The reset value of this register can vary depending on the availability of active clock pulses inside Partition 0.

41.7.13 Partition 0 Core 0 Process Configuration Register (PRTN0_CORE0_PCONF)

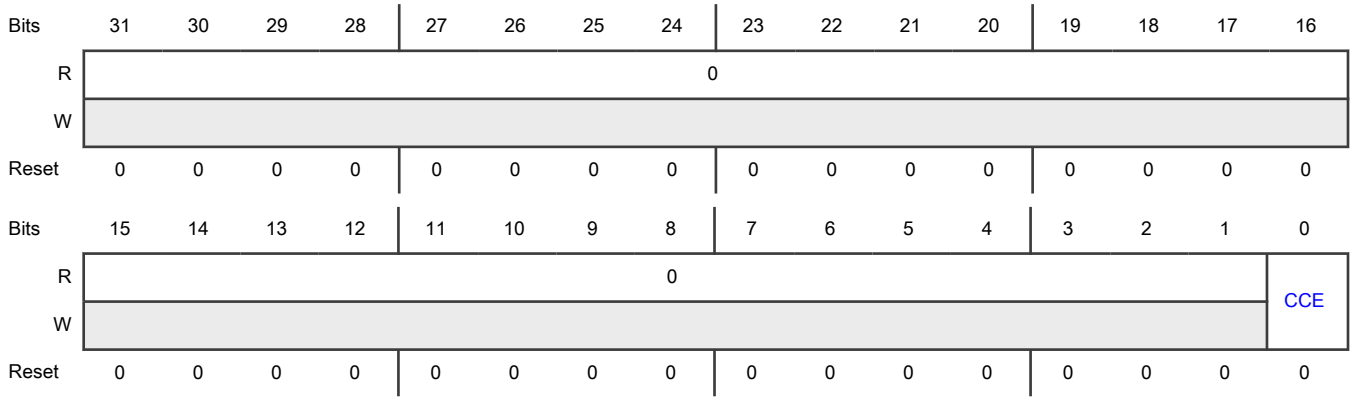
Offset

Register	Offset
PRTN0_CORE0_PCONF	140h

Function

This register provides configurations for the Core 0 hardware processes corresponding to Partition 0. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN0_CORE0_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN0_CORE0_PUPD and PRTN0_CORE0_PCONF registers are used to determine the hardware processes to be executed. These processes are triggered in parallel and are independent of each other. All dependent processes should be requested one after another from the software.

Diagram



Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 CCE	Core 0 clock enable This bit controls whether the clock to Core 0 in Partition 0 should be enabled or disabled. 0b - Disable the core clock 1b - Enable the core clock

41.7.14 Partition 0 Core 0 Process Update Register (PRTN0_CORE0_PUPD)

Offset

Register	Offset
PRTN0_CORE0_PUPD	144h

Function

This register provides trigger signaling for the core hardware processes corresponding to Partition 0. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN0_CORE0_PCONF register. When the hardware process is finished, the corresponding bit in this register is auto-cleared to logic-0.

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 CCUPD	Core 0 clock update This bit controls whether the hardware processes for enabling/disabling the clock to Core 0 in the Partition 0 should be triggered or not. 0b - Do not trigger the hardware process 1b - Trigger the hardware process

41.7.15 Partition 0 Core 0 Status Register (PRTN0_CORE0_STAT)

Offset

Register	Offset
PRTN0_CORE0_STAT	148h

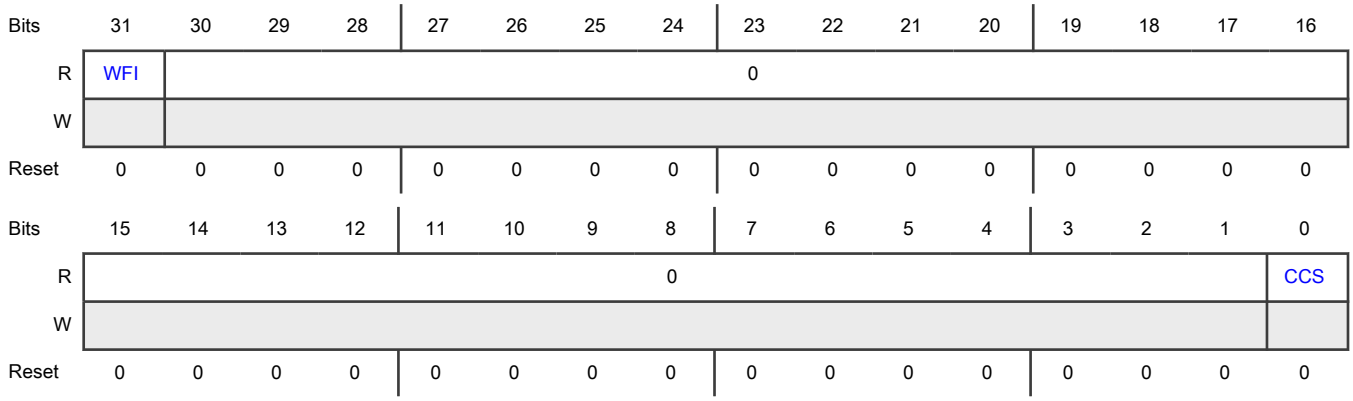
Function

This register provides the status corresponding to Core 0 in Partition 0. The status signal corresponds to clock states and the WFI signal included from Core 0.

NOTE

The value held in WFI field of this STATUS register is "current" value of the WFISTANDBY signal from the core. Hence out-of-reset, the reset value of this field will depend on the status of the core (core is running or in low power mode). So, simple reset read sweep will always return current value (different than other register reads such as on control registers).

Diagram



Fields

Field	Function
31 WFI	Wait for interrupt status This bit provides the WFI status approaching from Core 0 in Partition 0. 0b - No WFI executed 1b - WFI executed
30-1 —	Reserved This field is reserved and read returns zeros.
0 CCS	Core 0 clock process status This bit provides the status of the clock corresponding to core clock enablement/disablement. 0b - Clock is inactive. 1b - Clock is active.

41.7.16 Partition 0 Core 0 Address Register (PRTN0_CORE0_ADDR)

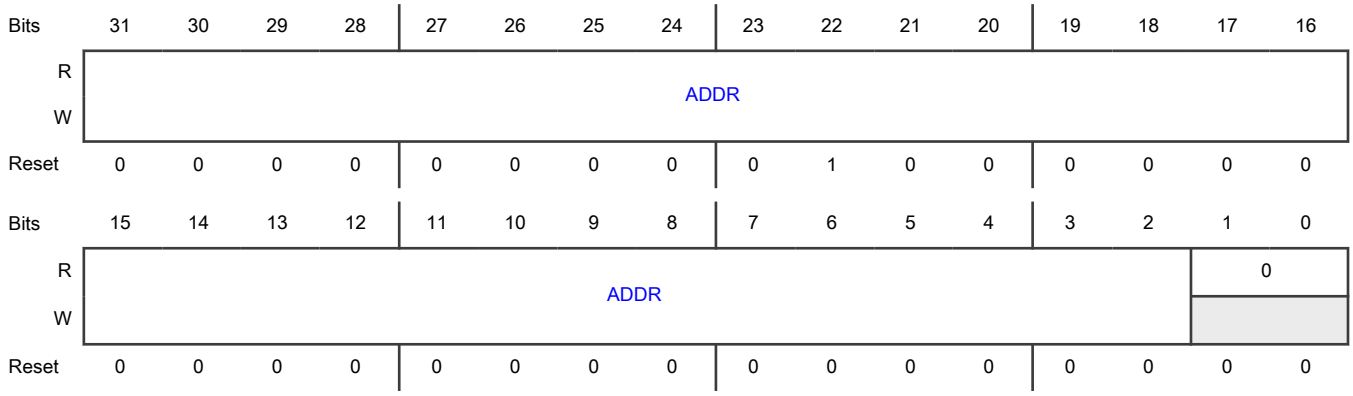
Offset

Register	Offset
PRTN0_CORE0_ADDR	14Ch

Function

This register contains the boot address for Core 0 in Partition 0.

Diagram



Fields

Field	Function
31-2 ADDR	Address Core 0 boot address
1-0 —	Reserved This field is reserved and read returns zeros.

41.7.17 Partition 0 Core 1 Process Configuration Register (PRTN0_CORE1_PCONF)

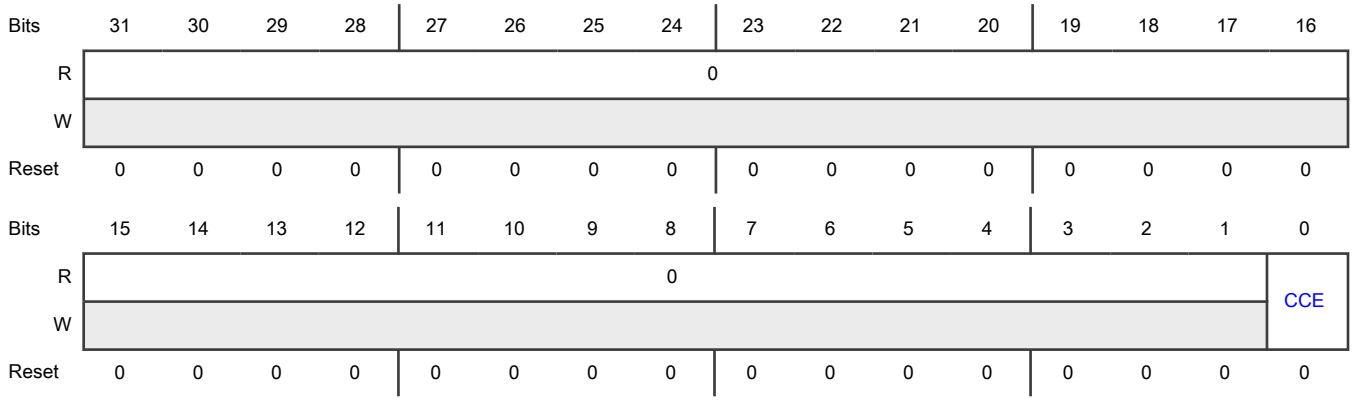
Offset

Register	Offset
PRTN0_CORE1_PCONF	160h

Function

This register provides configurations for the Core 1 hardware processes corresponding to Partition 0. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN0_CORE1_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN0_CORE1_PUPD and PRTN0_CORE1_PCONF registers are used to determine the hardware processes to be executed. These processes are triggered in parallel and are independent of each other. All dependent processes should be requested one after another from the software.

Diagram



Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 CCE	Core 1 clock enable This bit controls whether the clock to Core 1 in Partition 0 should be enabled or disabled. 0b - Disable the core clock 1b - Enable the core clock

41.7.18 Partition 0 Core 1 Process Update Register (PRTN0_CORE1_PUPD)

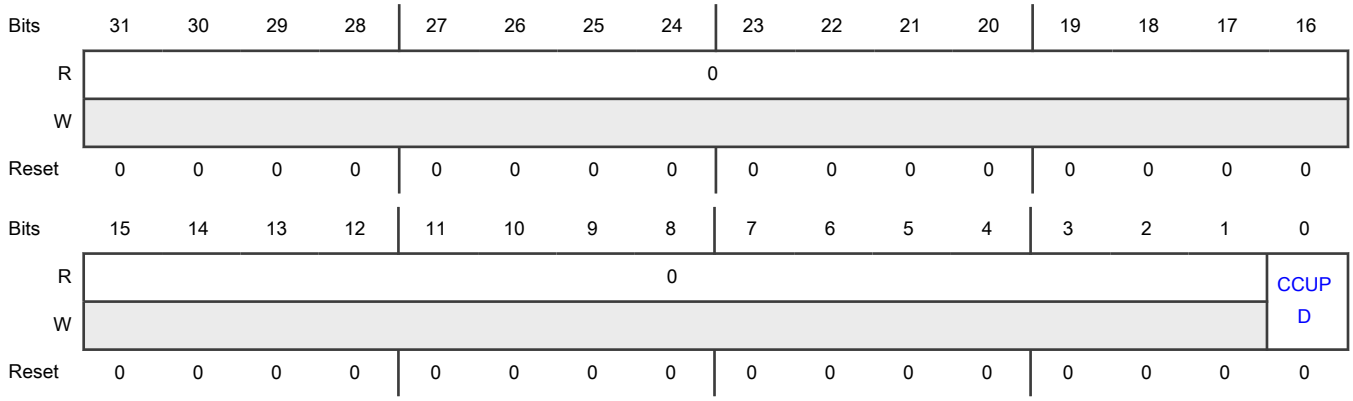
Offset

Register	Offset
PRTN0_CORE1_PUPD	164h

Function

This register provides trigger signaling for the core hardware processes corresponding to Partition 0. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN0_CORE1_PCONF register. When the hardware process is finished, the corresponding bit in this register is auto-cleared to logic-0.

Diagram



Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 CCUPD	Core 1 clock update This bit controls whether the hardware processes for enabling/disabling the clock to Core 1 in the Partition 0 should be triggered or not. 0b - Do not trigger the hardware process 1b - Trigger the hardware process

41.7.19 Partition 0 Core 1 Status Register (PRTN0_CORE1_STAT)

Offset

Register	Offset
PRTN0_CORE1_STAT	168h

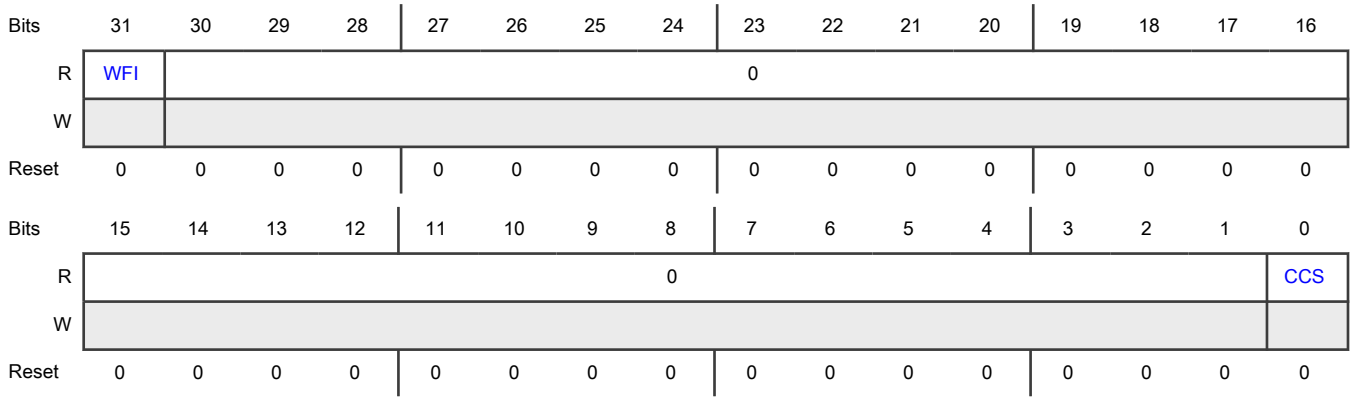
Function

This register provides the status corresponding to Core 1 in Partition 0. The status signal corresponds to clock states and the WFI signal included from Core 1.

NOTE

The value held in WFI field of this STATUS register is "current" value of the WFISTANDBY signal from the core. Hence out-of-reset, the reset value of this field will depend on the status of the core (core is running or in low power mode). So, simple reset read sweep will always return current value (different than other register reads such as on control registers).

Diagram



Fields

Field	Function
31 WFI	Wait for interrupt status This bit provides the WFI status approaching from Core 1 in Partition 0. 0b - No WFI executed 1b - WFI executed
30-1 —	Reserved This field is reserved and read returns zeros.
0 CCS	Core 1 clock process status This bit provides the status of the clock corresponding to core clock enablement/disablement. 0b - Clock is inactive. 1b - Clock is active.

41.7.20 Partition 0 Core 1 Address Register (PRTN0_CORE1_ADDR)

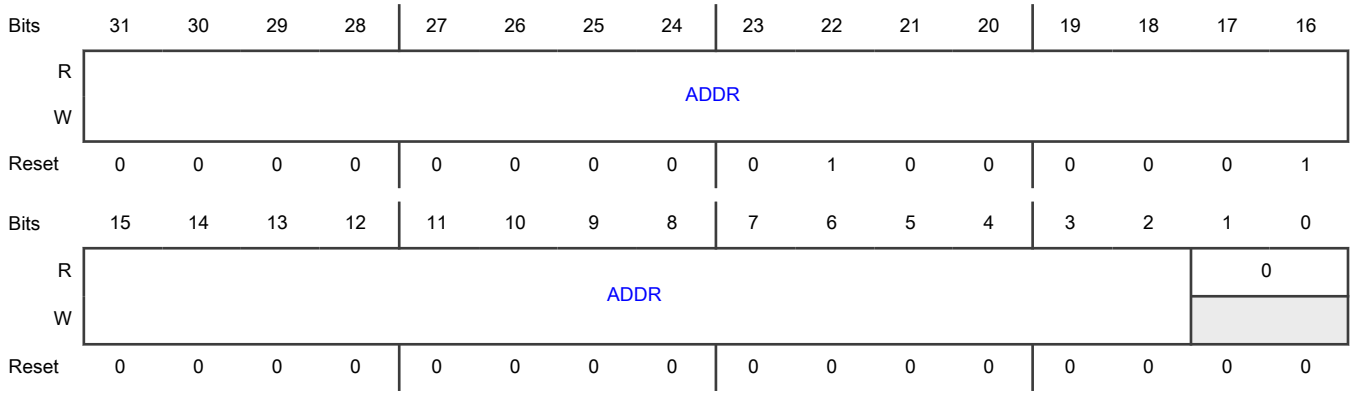
Offset

Register	Offset
PRTN0_CORE1_ADDR	16Ch

Function

This register contains the boot address for Core 1 in Partition 0.

Diagram



Fields

Field	Function
31-2 ADDR	Address Core 1 boot address
1-0 —	Reserved This field is reserved and read returns zeros.

41.7.21 Partition 0 Core 2 Status Register (PRTN0_CORE2_STAT)

Offset

Register	Offset
PRTN0_CORE2_STAT	188h

Function

This register provides the status corresponding to Core 2 in Partition 0. The status signal corresponds to clock states and the WFI signal included from Core 2.

NOTE

The value held in WFI field of this STATUS register is "current" value of the WFISTANDBY signal from the core. Hence out-of-reset, the reset value of this field will depend on the status of the core (core is running or in low power mode). So, simple reset read sweep will always return current value (different than other register reads such as on control registers).

Diagram

31 WFI	Wait for interrupt status This bit provides the WFI status approaching from Core 2 in Partition 0. 0b - No WFI executed 1b - WFI executed
30-1 —	Reserved This field is reserved and read returns zeros.
0 CCS	Core 2 clock process status This bit provides the status of the clock corresponding to core clock enablement/disablement. 1b - Clock is active.

41.7.22 Partition 0 Core 2 Address Register (PRTN0_CORE2_ADDR)

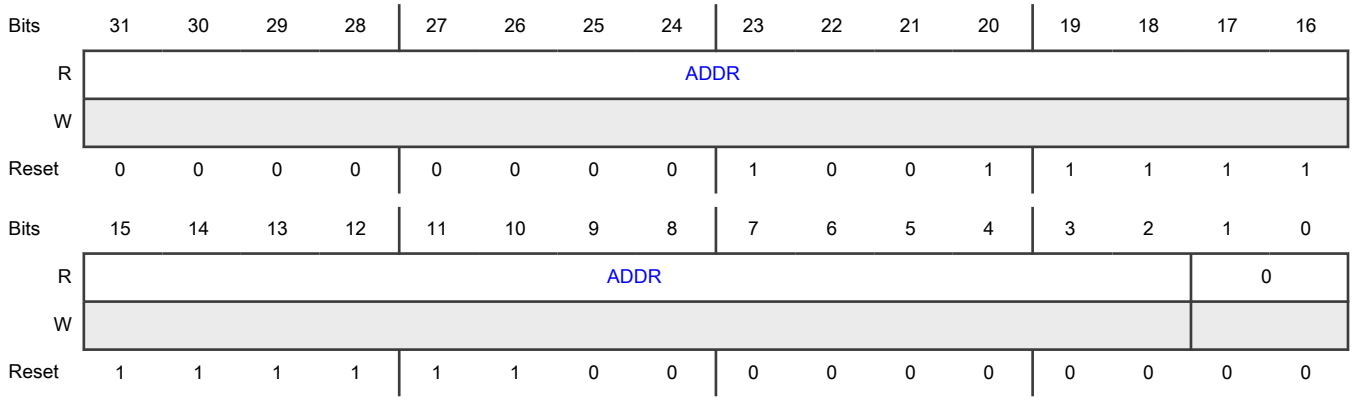
Offset

Register	Offset
PRTN0_CORE2_ADDR	18Ch

Function

This register contains the boot address for Core 2 in Partition 0.

Diagram



Fields

Field	Function
31-2 ADDR	Address Core 2 boot address
1-0 —	Reserved This field is reserved and read returns zeros.

41.7.23 Partition 0 Core 4 Process Configuration Register (PRTN0_CORE4_PCONF)

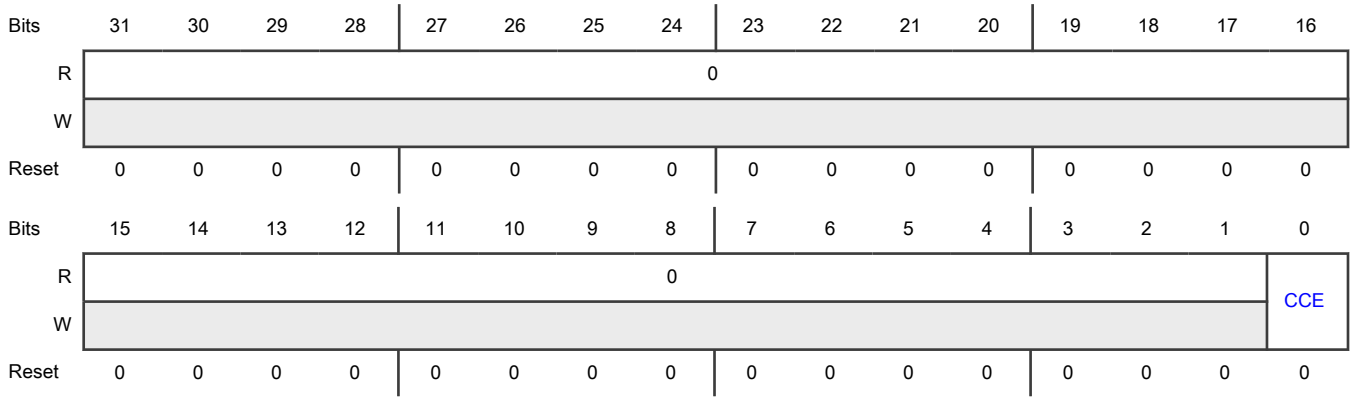
Offset

Register	Offset
PRTN0_CORE4_PCONF	1C0h

Function

This register provides configurations for the Core 4 hardware processes corresponding to Partition 0. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN0_CORE4_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN0_CORE4_PUPD and PRTN0_CORE4_PCONF registers are used to determine the hardware processes to be executed. These processes are triggered in parallel and are independent of each other. All dependent processes should be requested one after another from the software.

Diagram



Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 CCE	Core 4 clock enable This bit controls whether the clock to Core 4 in Partition 0 should be enabled or disabled. 0b - Disable the core clock 1b - Enable the core clock

41.7.24 Partition 0 Core 4 Process Update Register (PRTN0_CORE4_PUPD)

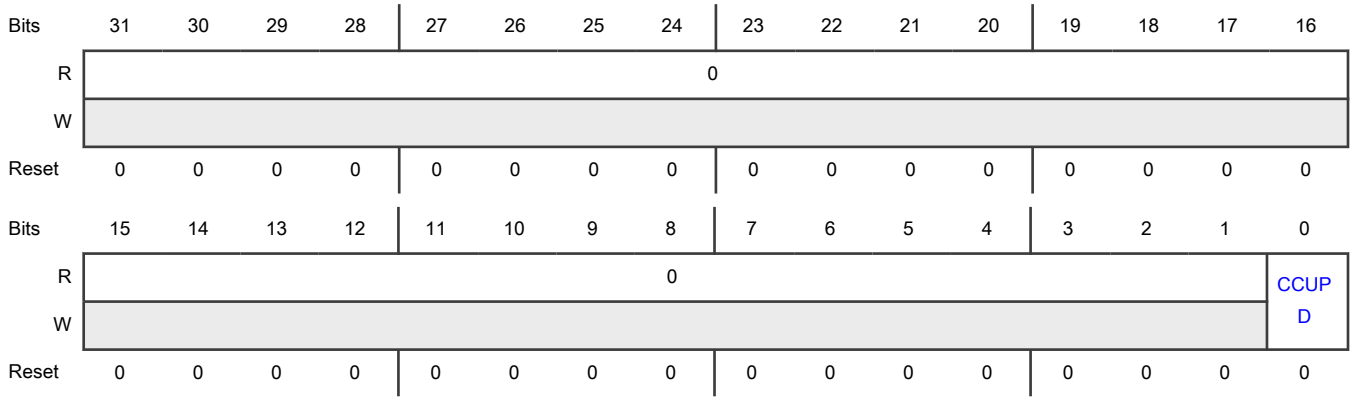
Offset

Register	Offset
PRTN0_CORE4_PUPD	1C4h

Function

This register provides trigger signaling for the core hardware processes corresponding to Partition 0. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN0_CORE4_PCONF register. When the hardware process is finished, the corresponding bit in this register is auto-cleared to logic-0.

Diagram



Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 CCUPD	Core 4 clock update This bit controls whether the hardware processes for enabling/disabling the clock to Core 4 in the Partition 0 should be triggered or not. 0b - Do not trigger the hardware process 1b - Trigger the hardware process

41.7.25 Partition 0 Core 4 Status Register (PRTN0_CORE4_STAT)

Offset

Register	Offset
PRTN0_CORE4_STAT	1C8h

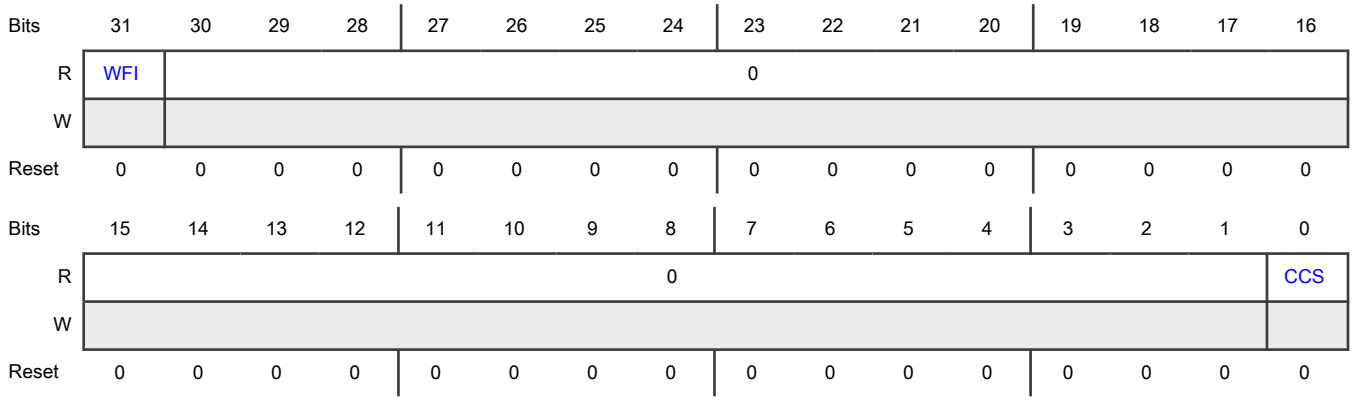
Function

This register provides the status corresponding to Core 4 in Partition 0. The status signal corresponds to clock states and the WFI signal included from Core 4.

NOTE

The value held in WFI field of this STATUS register is "current" value of the WFISTANDBY signal from the core. Hence out-of-reset, the reset value of this field will depend on the status of the core (core is running or in low power mode). So, simple reset read sweep will always return current value (different than other register reads such as on control registers).

Diagram



Fields

Field	Function

0 CCS	Core 4 clock process status This bit provides the status of the clock corresponding to core clock enablement/disablement. 0b - Clock is inactive. 1b - Clock is active.

41.7.26 Partition 0 Core 4 Address Register (PRTN0_CORE4_ADDR)

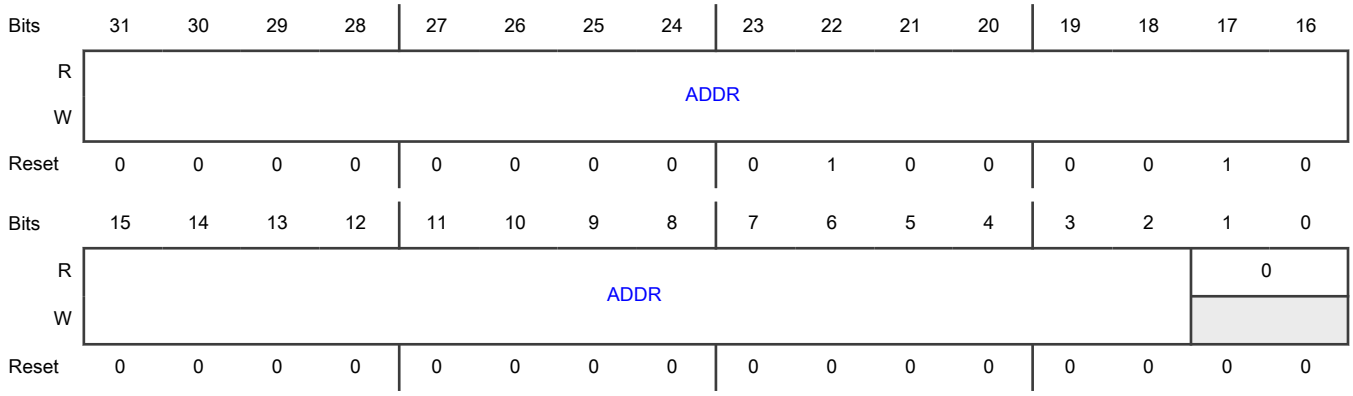
Offset

Register	Offset
PRTN0_CORE4_ADDR	1CCh

Function

This register contains the boot address for Core 4 in Partition 0.

Diagram



Fields

Field	Function
31-2 ADDR	Address Core 4 boot address
1-0 —	Reserved This field is reserved and read returns zeros.

41.7.27 Partition 0 Core 5 Process Configuration Register (PRTN0_CORE5_PCONF)

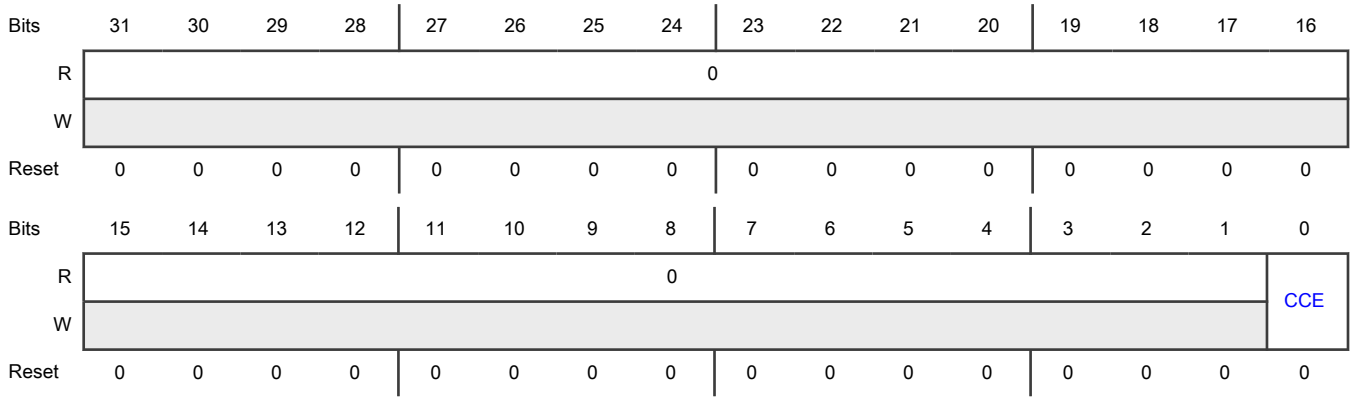
Offset

Register	Offset
PRTN0_CORE5_PCONF	1E0h

Function

This register provides configurations for the Core 5 hardware processes corresponding to Partition 0. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN0_CORE5_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN0_CORE5_PUPD and PRTN0_CORE5_PCONF registers are used to determine the hardware processes to be executed. These processes are triggered in parallel and are independent of each other. All dependent processes should be requested one after another from the software.

Diagram



Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 CCE	Core 5 clock enable This bit controls whether the clock to Core 5 in Partition 0 should be enabled or disabled. 0b - Disable the core clock 1b - Enable the core clock

41.7.28 Partition 0 Core 5 Process Update Register (PRTN0_CORE5_PUPD)

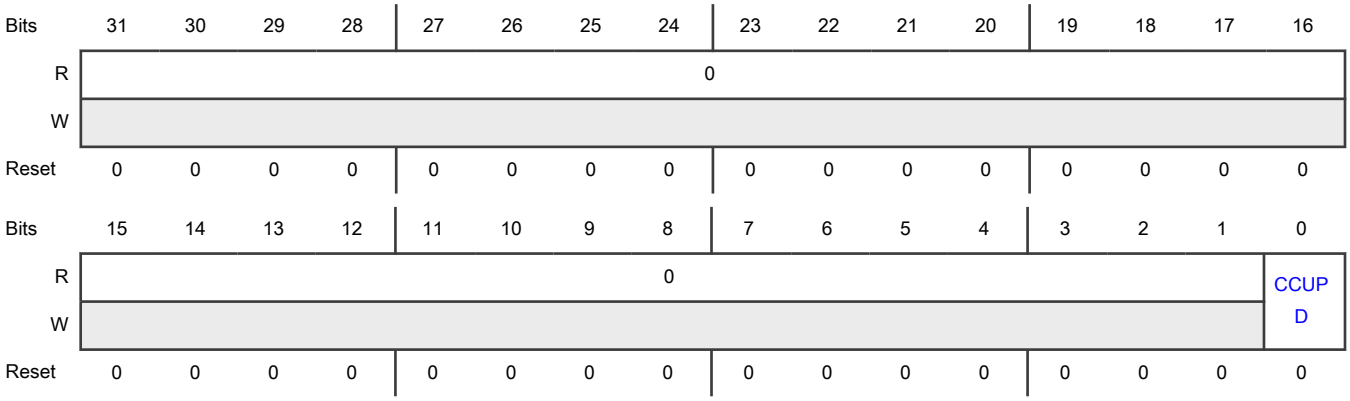
Offset

Register	Offset
PRTN0_CORE5_PUPD	1E4h

Function

This register provides trigger signaling for the core hardware processes corresponding to Partition 0. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN0_CORE5_PCONF register. When the hardware process is finished, the corresponding bit in this register is auto-cleared to logic-0.

Diagram



Fields

Field	Function
31-1 —	Reserved This field is reserved and read returns zeros.
0 CCUPD	Core 5 clock update This bit controls whether the hardware processes for enabling/disabling the clock to Core 5 in the Partition 0 should be triggered or not. 0b - Do not trigger the hardware process 1b - Trigger the hardware process

41.7.29 Partition 0 Core 5 Status Register (PRTN0_CORE5_STAT)

Offset

Register	Offset
PRTN0_CORE5_STAT	1E8h

Function

This register provides the status corresponding to Core 5 in Partition 0. The status signal corresponds to clock states and the WFI signal included from Core 5.

NOTE

The value held in WFI field of this STATUS register is "current" value of the WFISTANDBY signal from the core. Hence out-of-reset, the reset value of this field will depend on the status of the core (core is running or in low power mode). So, simple reset read sweep will always return current value (different than other register reads such as on control registers).

30-1 —	Reserved This field is reserved and read returns zeros.
0 CCS	Core 5 clock process status This bit provides the status of the clock corresponding to core clock enablement/disablement. 0b - Clock is inactive. 1b - Clock is active.

41.7.30 Partition 0 Core 5 Address Register (PRTN0_CORE5_ADDR)

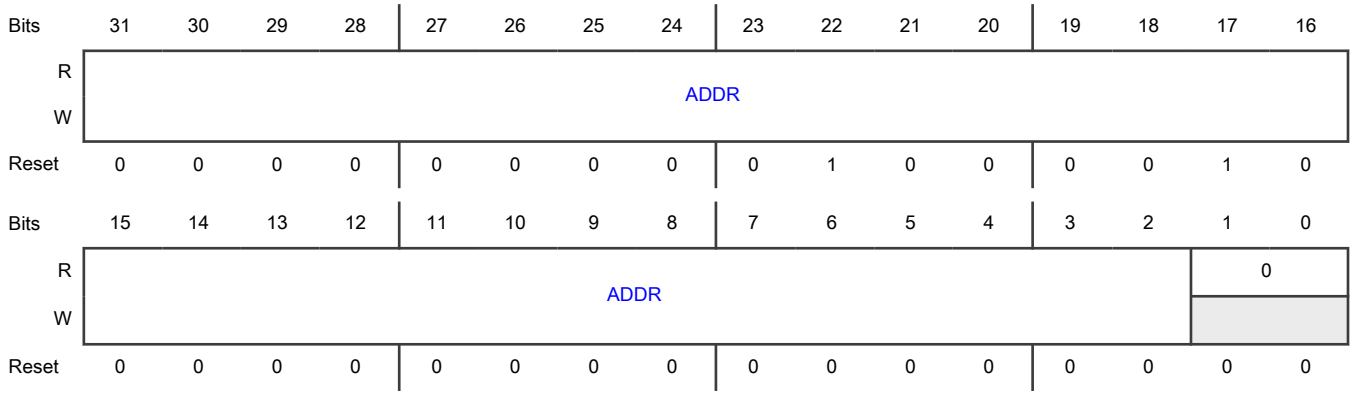
Offset

Register	Offset
PRTN0_CORE5_ADDR	1ECh

Function

This register contains the boot address for Core 5 in Partition 0.

Diagram



Fields

Field	Function
31-2 ADDR	Address Core 5 boot address
1-0 —	Reserved This field is reserved and read returns zeros.

41.7.31 Partition 1 Process Configuration Register (PRTN1_PCONF)

Offset

Register	Offset
PRTN1_PCONF	300h

Function

This register provides a configuration for the hardware processes corresponding to partition 1. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN1_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN1_PCONF and PRTN1_PUPD registers are used to determine the hardware processes to be executed. These are triggered in parallel and independent of each other. All dependent processes should be requested one after another from the software.

NOTE

The partition clock enable/disable are not standalone and must be done coherently in a fixed sequence. For details, see Software Reset Partition Turn-On Flow Chart and Software reset partition turn-off flowchart in Reset chapter.

NOTE

See chip-specific MC_ME information to check if this register is implemented on chip.

41.7.36 Partition 1 COFB Set 2 Clock Status Register (PRTN1_COFB2_STAT)

Offset

Register	Offset
PRTN1_COFB2_STAT	318h

Function

This register provides the status of set 2 of COFBs inside partition 1.

NOTE

The reset value of this register can vary depending on the availability of active clock pulses inside partition 1.

41.7.38 Partition 1 COFB Set 0 Clock Enable Register (PRTN1_COFB0_CLKEN)

Offset

Register	Offset
PRTN1_COFB0_CLKEN	330h

Function

This register provides clock control signaling to the individual COFBs in set 0 inside partition 1. Whenever a partition clock enable (non-core) hardware process is initiated, the value of logic-1 in the corresponding bit locations of this register enables the clock to the corresponding block in the partition.

NOTE

The reset value of this register is not defined and is as per the availability of the clock source. See Chip-specific MC_ME information for clock source availability.

41.7.42 Partition 2 Process Configuration Register (PRTN2_PCONF)

Offset

Register	Offset
PRTN2_PCONF	500h

Function

This register provides a configuration for the hardware processes corresponding to partition 2. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN2_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN2_PCONF

and PRTN2_PUPD registers are used to determine the hardware processes to be executed. These are triggered in parallel and independent of each other. All dependent processes should be requested one after another from the software.

NOTE

The partition clock enable/disable are not standalone and must be done coherently in a fixed sequence. For details, see Software Reset Partition Turn-On Flow Chart and Software reset partition turn-off flowchart in Reset chapter.

NOTE

See chip-specific MC_ME information to check if this register is implemented on chip.

0 PCE	Partition clock enable This bit controls whether the clock to IPs (other than core(s)) in the partition should be enabled or disabled. 0b - Disable the clock to IPs 1b - Enable the clock to IPs

41.7.43 Partition 2 Process Update Register (PRTN2_PUPD)

Offset

Register	Offset
PRTN2_PUPD	504h

Function

This register provides trigger signaling for the hardware processes corresponding to partition 2. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN2_PCONF register. When the hardware process is finished the corresponding bit in this register is auto-cleared to logic-0.

NOTE

See chip-specific MC_ME information to check if this register is implemented on chip.

41.7.48 Partition 2 COFB Set 0 Clock Enable Register (PRTN2_COFB0_CLKEN)

Offset

Register	Offset
PRTN2_COFB0_CLKEN	530h

Function

This register provides clock control signaling to the individual COFBs in set 0 inside partition 2. Whenever a partition clock enable (non-core) hardware process is initiated, the value of logic-1 in the corresponding bit locations of this register enables the clock to the corresponding block in the partition.

NOTE

The reset value of this register is not defined and is as per the availability of the clock source. See Chip-specific MC_ME information for clock source availability.

41.7.49 Partition 2 COFB Set 1 Clock Enable Register (PRTN2_COFB1_CLKEN)

Offset

Register	Offset
PRTN2_COFB1_CLKEN	534h

Function

This register provides clock control signaling to the individual COFBs in set 1 inside partition 2. Whenever a partition clock enable (non-core) hardware process is initiated, the value of logic-1 in the corresponding bit locations of this register enables the clock to the corresponding block in the partition.

NOTE

The reset value of this register is not defined and is as per the availability of the clock source. See Chip-specific MC_ME information for clock source availability.

41.7.51 Partition 3 Process Configuration Register (PRTN3_PCONF)

Offset

Register	Offset
PRTN3_PCONF	700h

Function

This register provides a configuration for the hardware processes corresponding to partition 3. Each of the configuration bit corresponds to the 'nature' of the processes; for example, enabling/disabling and the trigger is controlled by the corresponding field in the PRTN3_PUPD register. When valid KEY combinations are written onto the CTL_KEY register, the PRTN3_PCONF and PRTN3_PUPD registers are used to determine the hardware processes to be executed. These are triggered in parallel and independent of each other. All dependent processes should be requested one after another from the software.

NOTE

The partition clock enable/disable are not standalone and must be done coherently in a fixed sequence. For details, see Software Reset Partition Turn-On Flow Chart and Software reset partition turn-off flowchart in Reset chapter.

NOTE

See chip-specific MC_ME information to check if this register is implemented on chip.

0 PCE	Partition clock enable This bit controls whether the clock to IPs (other than core(s)) in the partition should be enabled or disabled. 0b - Disable the clock to IPs 1b - Enable the clock to IPs

41.7.52 Partition 3 Process Update Register (PRTN3_PUPD)

Offset

Register	Offset
PRTN3_PUPD	704h

Function

This register provides trigger signaling for the hardware processes corresponding to partition 3. Each of the control bit acts as a trigger for the corresponding hardware processes. When valid KEY combinations are written onto the CTL_KEY register, the hardware checks the bit fields that are programmed as logic-1 in this register, and then triggers the hardware process per the value in the corresponding bit field in the PRTN3_PCONF register. When the hardware process is finished the corresponding bit in this register is auto-cleared to logic-0.

NOTE

See chip-specific MC_ME information to check if this register is implemented on chip.

41.7.57 Partition 3 COFB Set 0 Clock Enable Register (PRTN3_COFB0_CLKEN)

Offset

Register	Offset
PRTN3_COFB0_CLKEN	730h

Function

This register provides clock control signaling to the individual COFBs in set 0 inside partition 3. Whenever a partition clock enable (non-core) hardware process is initiated, the value of logic-1 in the corresponding bit locations of this register enables the clock to the corresponding block in the partition.

NOTE

The reset value of this register is not defined and is as per the availability of the clock source. See Chip-specific MC_ME information for clock source availability.

41.7.58 Partition 3 COFB Set 1 Clock Enable Register (PRTN3_COFB1_CLKEN)

Offset

Register	Offset
PRTN3_COFB1_CLKEN	734h

Function

This register provides clock control signaling to the individual COFBs in set 1 inside partition 3. Whenever a partition clock enable (non-core) hardware process is initiated, the value of logic-1 in the corresponding bit locations of this register enables the clock to the corresponding block in the partition.

NOTE

The reset value of this register is not defined and is as per the availability of the clock source. See Chip-specific MC_ME information for clock source availability.

Chapter 42
Power Control Unit (MC_PCU)

42.1 Introduction

The power control unit (MC_PCU) is used for initiating a Standby mode entry that reduces the overall chip power consumption. Power can be saved by disconnecting parts of the chip from the power supply. The blocks inside the chip are grouped into multiple parts having this capability, which are called "power domains".

When a power domain is disconnected from the supply, the power consumption is reduced to zero in that domain. Any status information, such as, power domain is lost. When you reconnect a power domain to the supply voltage, the domain draws an increased current until the power domain reaches its operational voltage. Maximum power saving is achieved by entering the Standby mode.

After the MC_ME asserts a standby entry request, MC_PCU initiates the power sequence, which is non-retractable and includes the handshake with the chip power management controller. The power-up/down sequences are handled by FSMs to ensure a smooth and safe transition into and out of the Standby mode. Exiting the Standby mode can only be done through a system wakeup event, power-on reset, destructive reset, or a functional reset.

42.2 Power sequence FSM

MC_PCU implements an FSM to initiate the power sequencing of the Standby mode entry/exit sequence for the chip.

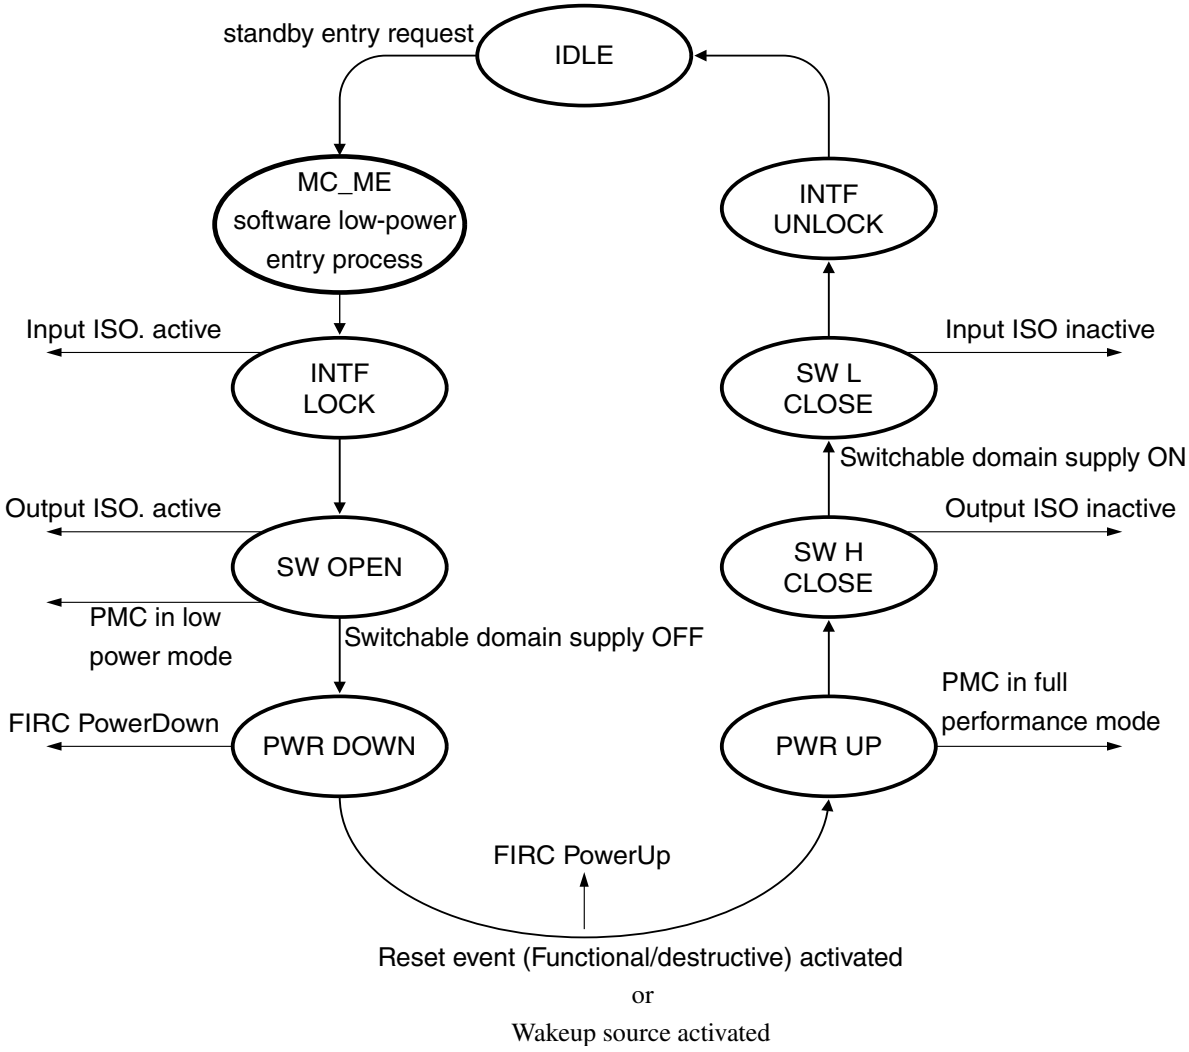

Figure 173. MC_PCU FSM

NOTE

When destructive reset is asserted from MC_RGM, MC_PCU FSM moves to the IDLE state immediately. Indication of this is not shown in the above figure.

Table 210. MC_PCU FSM transition description

State	Name	Exit condition	Signal controlled	Signal monitored
IDLE	Idle state	Standby request received from MC_ME	-	-

Chapter 43
Wakeup Unit (WKPU)

43.1 Chip-specific WKPU information

43.1.1 WKPU configuration on the chip

WKPU provides the following features:

- A configurable, low-power wake-up capability to the chip from multiple configurable asynchronous wake-up events.
- Support for four internal and 60 external sources that can generate interrupts or wake-up events.
- Support for an NMI input.

Table 211. WKPU configuration on the chip

Number of sources, interrupts, and vectors	Value	Description
NMI sources	1	Single NMI pin routed to all application cores
Internal wake-up sources	4	• SWT_0 wake-up, RTC-API wake-up • RTC timeout • Analog comparator round robin wake-up (from LPCMP_0 and 1 round robin wake-up)[1] • RTI wake-up
External wake-up sources	77	77 GPIO pins are muxed to 60 WKPU sources (WKPU[0]-WKPU[59]) support the wake-up functionality. See the IOMUX file and DCF sheet attached to this document for details.
Glitch filters for external interrupts	77	Glitch filter one on each external wake-up source
External interrupt vectors	8	—

1. Both wake-up sources 0 (RTC-API) and 2 (CMP_x trigger mode wake-up) use RTC-API wake-up, with Trigger mode having a higher priority. This means, if you configure LPCMP_x.RRCR0[ERR_EN] for either of the comparators, the RTC_API wake-up is used only for the CMP_x trigger mode operation. The RTC-API wake-up does not cause wake-up from Standby mode in this scenario.

All of the aforementioned wake-up sources can be enabled or disabled. Also, you can configure these wake-up sources, by using WKPU configuration registers, to provide wake-up on rising or falling events. See the WKPU register memory map for details.

NOTE

You must use SIUL2 to perform WKPU pin configurations (PUE, PUS, and IBE). For this, you must first configure SIUL2.MSCR[IBE] for the corresponding pin. This chip does not support WKPU-provided pin configurations; it supports only bypass control.

43.1.2 WKPU NMI configuration

WKPU supports one external source that can cause non-maskable interrupts to on-chip cores and wake-up events to the system.

The following figure shows two application cores, Cortex-M7_0 , Cortex-M7_1 and Cortex-M7_2. In case of a wake-up event (internal or external), WKPU initiates the recovery of the chip and feeds an interrupt to the core(s) depending on the configuration. The sections that follow provide details related to the associated configurations.

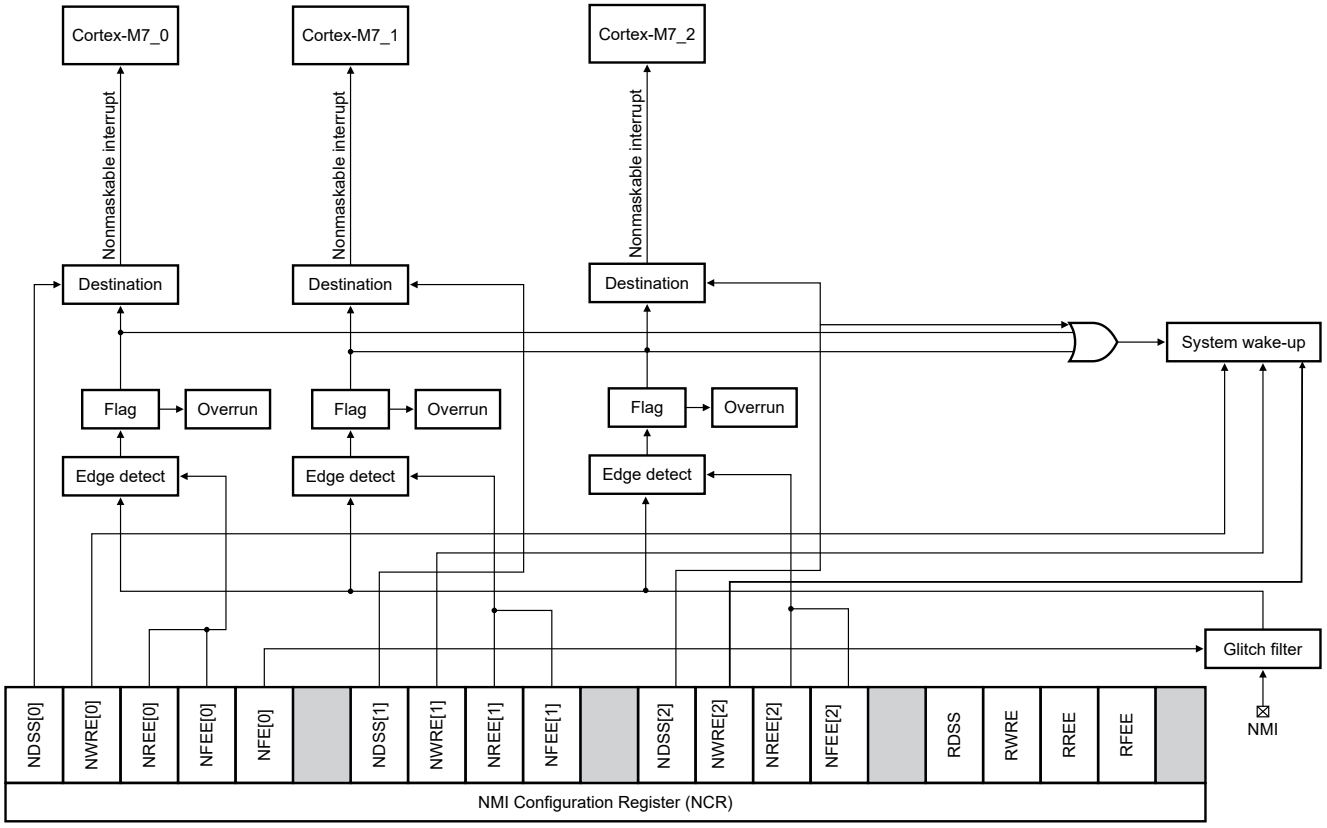

Figure 174. WKPU NMI configuration

43.1.3 WKPU wake-up source connectivity

WKPU allows the external NMI pin to assert the core NMIs on the chip. NMI supports NSR's status and overrun flags. This is what you could do using NCR:

- Control the NMI destination interrupt by configuring NCR[NDSS].
- Control the rising edge, falling edge, or either of the edge reactions to the NMI pin by using bits 2:0 of NCR[NFEE] and NCR[NREE]. The enabling of these edge reactions to the NMI pin is independent of each core.

WKPU supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event.

The following figure shows routing of external wake-up events or interrupts with WKPU and the system interrupt controller.

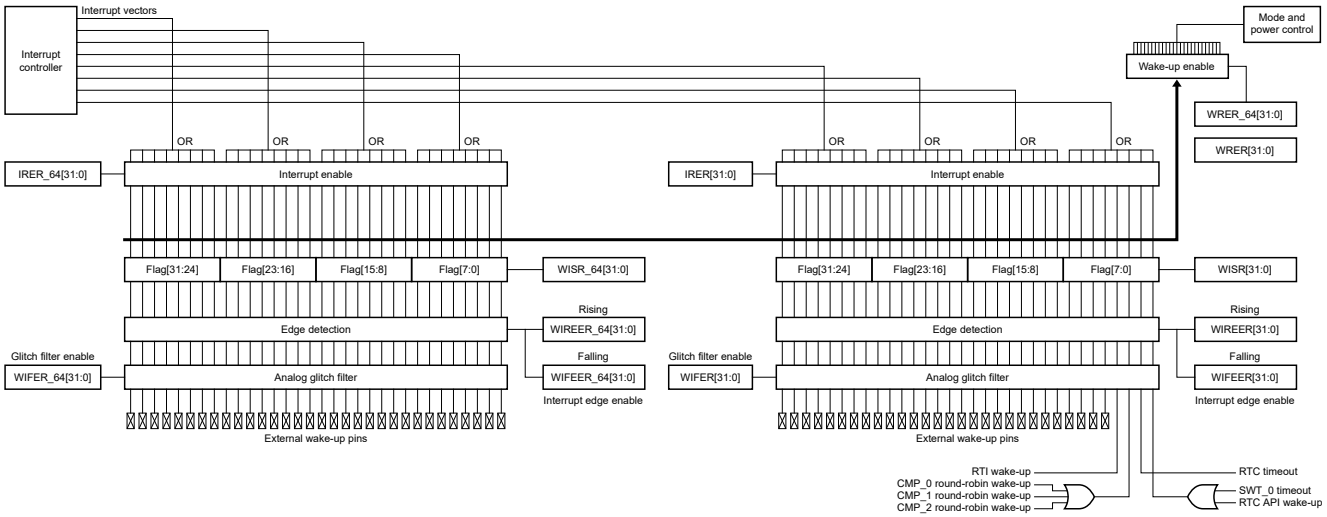

Figure 175. WKPU wake-up source connectivity

This is the wake-up source mapping to WKPU:

- Wake-up source 0 : SWT_0 timeout, RTC-API API wake-up
- Wake-up source 1 : RTC-API RTC timeout
- Wake-up source 2 : Round robin wake-up interrupt (Trigger mode interrupt) from LPCMP_0, or LPCMP_1
- Wake-up source 3 : RTI wake-up
- Wake-up source 4 : Wake-up source 77—external pin wake-up sources, WKPU[0] - WKPU[59]

If you configure any or all of the LPCMP_*x*.RRCR0[RR_EN] fields to be active, the corresponding CMP_*x* pins must be dedicated for the CMP_*x* operation. In case you are not using any of the CMPs, you can use SIUL2.MSCR*x*[SSS] to configure the pins for digital functionalities.

NOTE

You must enable WKPU (by using MC_ME.PRTN*x*_COFB*y*_CLKEN) before entering any of the chip's low-power modes.

43.2 Overview

The WKPU supports 64 external sources that can generate interrupts or wakeup events and 0 external source(s) that can cause non-maskable interrupt request(s) or wakeup event(s). In addition, it combines its wakeup events with those generated from other wakeup sources to supply a single wakeup to the system.

43.2.1 Block diagram

The block diagram of WKPU and its interfaces to other system components is shown below.

NOTE

The signal widths in the following diagram might not depict this device's particular configuration. See chip-specific WKPU for more information.

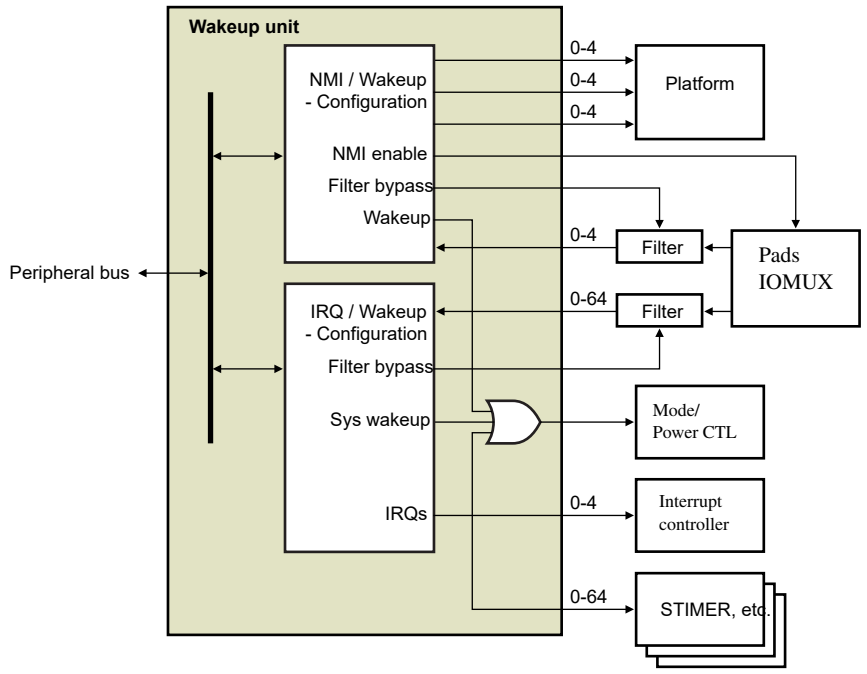

Figure 176. WKPU and connected system components

43.2.2 Features

The WKPU supports these features:

- Non-maskable interrupt support with:
  - 3 NMI sources
  - 3 analog glitch filters
  - Independent interrupt destination for each core:
    - Non-maskable interrupt
    - Critical interrupt
  - Active (rise/fall) edge selection control for events
  - Configurable system wakeup triggering from NMI sources
- External wakeup/interrupt support with:
  - One System interrupt vector for interrupt sources
  - 64 analog glitch filters
  - Independent interrupt mask
  - Edge detection
  - Configurable system wakeup triggering from all interrupt sources

43.3 Functional description

This section provides functional description of WKPU.

43.3.1 Non-maskable interrupts

The WKPU supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event, although it creates an overrun condition.

Each NMI passes through a bypassable analog glitch filter.

NOTE

Glitch filter control and pad configuration should be performed when NMI is disabled, to avoid erroneous triggering by glitches caused by the configuration process itself.

NOTE

The figure below represents a generic configuration and might not represent this particular device's configuration. See the chip-specific information for details on this chip's WKPU.

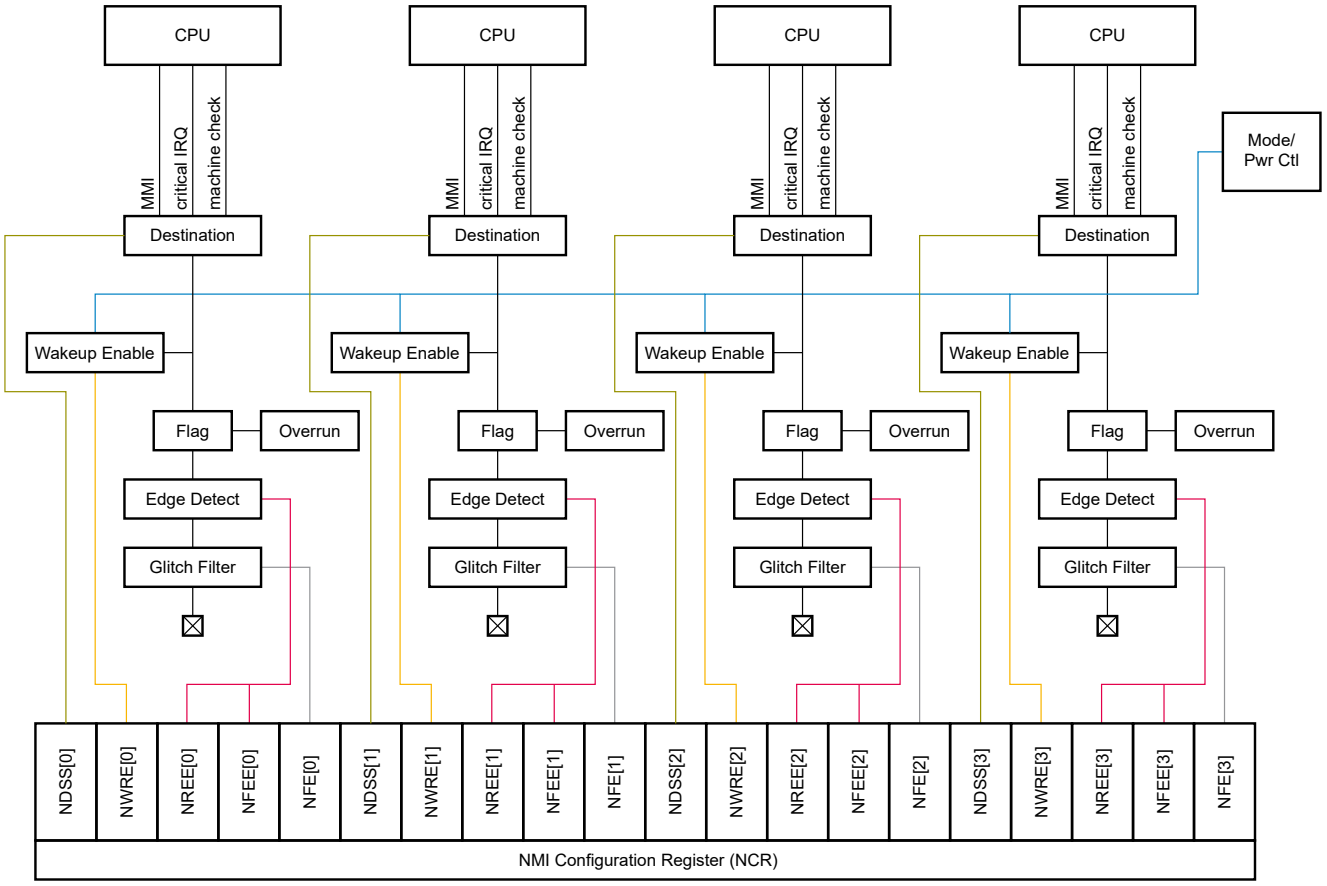

Figure 177. NMI pad diagram

43.3.1.1 NMI management

Each NMI can be enabled or disabled independently. This can be performed using the NCR laid out to contain all configuration bits for a given NMI in a single byte (see NMI Configuration Register (NCR)). A pad defined as an NMI can be configured by the user to recognize interrupts with an active rising edge, an active falling edge, or both edges being active. A setting of having both edge events disabled results in no interrupt being detected and should not be configured.

The active NMI edge is controlled by the user through the configuration of the NCR[NREEn] and NCR[NFEEn] bits. And for NMIS >4, active edge is controlled by NCR_8[NREEn] and NCR_8[NFEEn] bits.

NOTE

After reset, NREE and NFEE are set to '0'; therefore, the NMI functionality is disabled after reset and must be enabled explicitly by software.

After a pad's NMI functionality is enabled, the pad cannot be reconfigured to override or disable the NMI. See the chip-specific WKPU information for details of NMI implementation.

The NMI destination interrupt is controlled by the user through the configuration of the NCR[NDSSn] bits. See NMI Configuration Register (NCR) for details. For NMIS > 4, the NMI destination interrupt is controlled by the user through the configuration of the NCR_8[NDSSn] bits. See for details.

Each NMI supports a status flag and an overrun flag, which are located in the NSR register (see NMI Status Flag Register (NSR)). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register. The status flag is set whenever an NMI event is detected. The overrun flag is set whenever an NMI event is detected and the status flag is set (that is, status flag has not been cleared).

NOTE

The overrun flag is cleared by writing a '1' to the appropriate overrun bit in the NSR register. If the status bit is cleared and the overrun bit is still set, the pending interrupt is not cleared.

During an NMI ISR, on wakeup of the chip from an NMI, any writes to the ECC-protected memory must have the correct ECC.

43.3.2 Clocking

This module has no clocking considerations.

The WKPU has ipg_clk and ipg_clk_s as input clocks having same clock frequency for register configuration and internal logic.

43.3.3 Interrupts

The WKPU supports 4 interrupt vectors to the interrupt controller of the chip. Each interrupt vector can support up to the number of external interrupt sources from the device pads, with the total across all vectors being equal to the number of external interrupt sources. Each external interrupt source is assigned to exactly one interrupt vector. The interrupt vector assignment is sequential so that one interrupt vector is for external interrupt sources 0 through N-1, the next is for N through N+M-1, and so forth.

See the following figure for an overview of the external interrupt implementation, showing an example of four interrupt vectors with eight external interrupt sources each.

NOTE

The figure below shows a generic representation of WKPU. See the chip-specific WKPU information for details on how this device's configuration might differ from this figure.

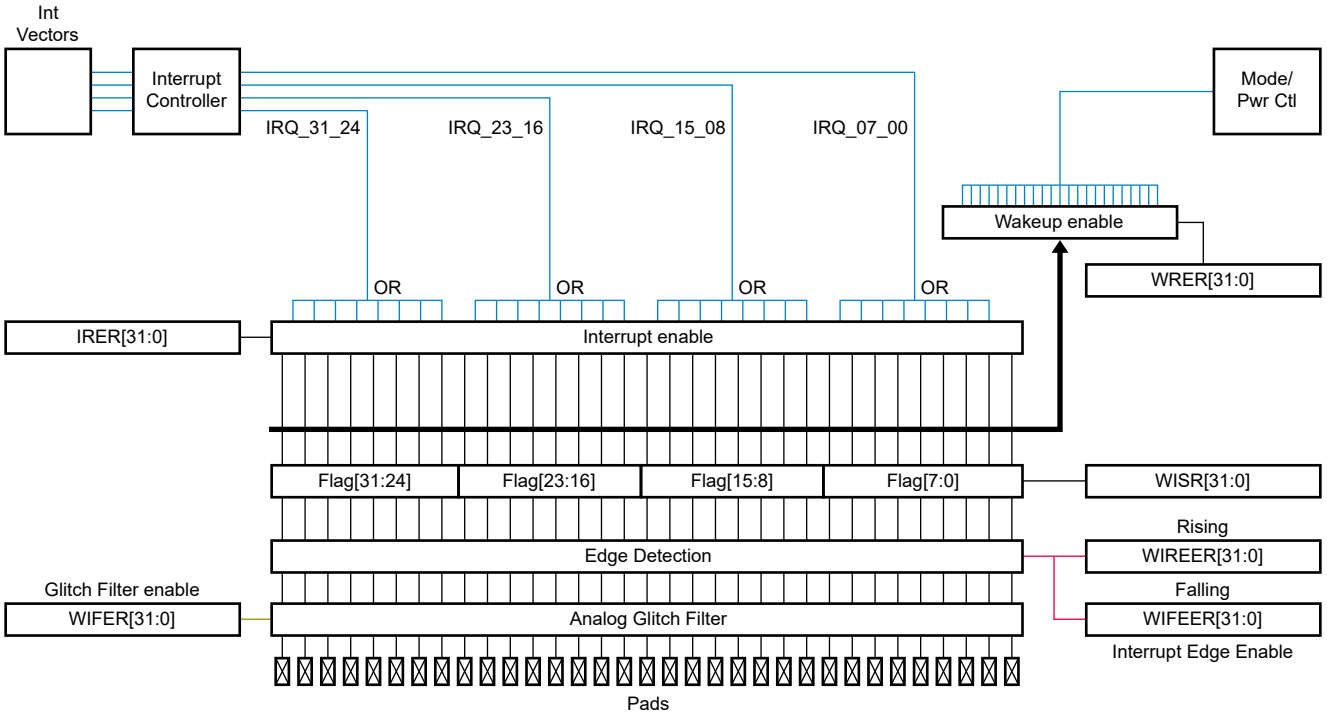

Figure 178. External interrupt pad diagram

All of the external interrupt pads within a single group have equal priority. It is the responsibility of the user software to search through the group of sources in the most appropriate way for their application.

The priority of the vectors used by the external interrupt pads is set based on the platform and the interrupt controller's priority levels, but the allocation of pads to each group of interrupts can be independently configured by the chip.

External interrupt lines have a digital glitch filter applied to them.

43.3.3.1 External interrupt management

Each interrupt can be enabled or disabled independently. This can be performed using a single rolled-up register (Interrupt Request Enable Register (IRER)). A pad defined as an external interrupt can be configured by the user to recognize interrupts with an active rising edge, an active falling edge, or both edges being active.

NOTE

Writing a '0' to both IREE[x] and IFEE[x] disables the external interrupt functionality for that pad completely (that is, no system wakeup or interrupt is generated on any activity of that pad).

The active IRQ edge is controlled by users through the configuration of the registers WIREER and WIFEER.

Each external interrupt supports an individual flag, which is held in the flag register, WISR. This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register.

43.3.4 External Signals

This module has no external signals.

43.4 Initialization

This section discusses initialization for the following features:

- Glitch filter and pad configuration

- Non-maskable interrupts

43.4.1 Glitch filter and pad configuration

Glitch filter control and pad configuration should be performed when the NMI is disabled. This is to avoid erroneous triggering by glitches caused by the configuration process.

When enabling the glitch filter, do not enable the rising-/falling-edge events bits, i.e., the NCR[NREE], NCR[NFEE], NCR[RREE], and NCR[RFEE] bits in the same register write.

43.4.2 Non-maskable interrupts

If the IBE of NMI is tied off to 1, no false interrupt is expected.

43.5 WKPU memory map and registers

43.5.1 WKPU register descriptions

This section provides a detailed description of all the registers accessible in the WKPU module.

NOTE

Reserved registers read as zero and writes have no effect. A transfer error is generated when trying to access a completely reserved register space. The field length of external pad control registers depends on the number of WKPU channels implemented in a chip.

43.5.1.1 WKPU memory map

WKPU base address: 402B_4000h

Offset	Register	Width (In bits)	Access	Reset value

5-0 —	Reserved

43.5.1.3 NMI Configuration Register (NCR)

Offset

Register	Offset
NCR	8h

Function

This register holds the configuration bits for the non-maskable interrupt settings.

NOTE

- This register is accessible by 8-, 16-, and 32-bit read/write operations.
- Writing 0 to both NREE[*n*] and NFEE[*n*] disables the NMI functionality completely (that is, no non-maskable interrupt is generated on any pad activity).

Access: User read/write

43.5.1.4 Wakeup/Interrupt Status Flag Register (WISR)

Offset

Register	Offset
WISR	14h

Function

This register holds the wakeup/interrupt flags.

NOTE

- This register is accessible only by 32-bit read/write operations.
- Status bits associated with on-chip wakeup sources are located at the left of the external wakeup/interrupt status bits and are read-only. The wakeup for these sources must be configured and cleared at the on-chip wakeup source. Also, the configuration registers for the external interrupts/wakeups do not have corresponding bits.

Access: User read/write

43.6 Glossary

NMI Non-maskable interrupts

Chapter 44
Safety Overview

44.1 Safety Concept

This chip is developed following the ISO 26262-2:2018 standard, intended to be used in an automotive safety-related system that fulfills the requirements of the ASIL D safety integrity levels.

The ASIL level targets the safety processing, which means the software functions are executed as intended:

1. Read instructions from memory.
2. Execute instructions.
3. Read data from memory.
4. Process data.
5. Write back the result data into memory.

Motor Control is the primary application for this chip and the safety concept of applicable I/O and peripherals has been developed in-context of the motor control application. Thus, the peripherals that are part of motor control application have been classified as SR (safety-related) in the safety concept. Some elements of the safety concept are based on the assumption that the chip is connected to an external SBC or PMIC. The SBC or PMIC performs observations and control functionalities that are essential to fulfill some related functional safety requirements. If you do not use an SBC or PMIC, you must ensure that the chip provides an equivalent functionality that properly manages the corresponding interface(s).

The following figure illustrates the safety interface between the chip and the SBC or PMIC.

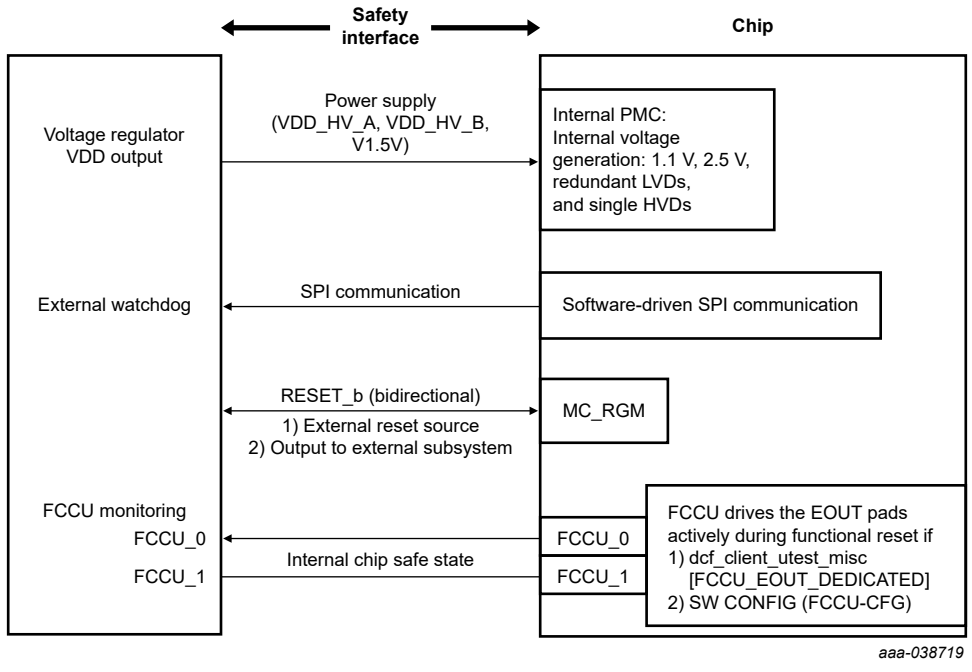

Figure 179. Safety interface between the chip and the SBC or PMIC

In the safety context, the chip interfaces can be classified into the groups shown in the table.

Table 212. Chip interface groups

Interface	Description
Power supply	This interface is between the SBC and the chip. It ensures that the supply to the chip is in the correct range. In case of any low-voltage event, the chip has POR, LVR, and LVD circuits in place and in case of any HVD event, the chip raises an interrupt. The SBC must ensure that the voltage regulator outputs never exceed the allowed range (more specifically for HVD range). In case the power supply to the chip is exceeding the allowed range, the SBC switches off the power supply.
Communication	Responsible for communication between the SBC and the chip. Though the chip supports multiple communication protocols (UART, LIN, SPI, I2C, FlexCAN, and so on), SPI is the preferred communication with SBC. This is relevant to program the SBC or PMIC registers during boot and to service the external watchdog periodically during runtime.
Reset	The chip consists of a reset bidirectional pin interfaced with SBC. The SBC can initiate a chip reset via this pin as a safety reaction in case of: • Extreme critical faults • An inoperative chip • Stuck cases based on the criticality and the application requirements The SBC also samples the reset pin state to identify the chip condition (whether in running state or in reset).
FCCU	The chip indicates the chip faults to the SBC via FCCU EOUT pins through this interface.

The interfaces in Table 212 ensure the chip's operational safety and integrity. Upon detecting an unrecoverable failure (one that can't be resolved by the application), the SBC must ensure the chip enters an appropriate safe state as defined in the chip safety manual. The SBC ensures that the system transitions to a safe state when the chip can no longer perform a safety function.

44.2 Safety architecture elements

The chip safety architecture consists of following elements that operate in an interconnected way to meet the ASIL requirements:

- Cortex-M7 core complex (including the cache controllers) operating in delayed lockstep (ASIL D only)
- eDMA controller operating in delayed lockstep
- Structural core self-test
- Internal windowed watchdogs with independent clock sources
- Power supply monitoring with redundant low-voltage detectors, single high-voltage detectors, and internal ADC connection to check the internal voltages during application
- Robust clock monitoring, including PLL loss of lock detection
- Embedded flash memory with ECC (single-bit data correction, double-bit data detection) and address encoding (parallel address path check)
- System RAM with ECC

  - Single-bit data correction
  - Double-bit data detection
  - Address detection
- Cortex-M7 cache memories with ECC (single-bit data correction, double-bit data detection)
- Peripherals memories (EMAC, FlexCAN, ETPU, Coolflux) with ECC (single-bit data correction, double-bit data detection).
- End-to-End EDC (E2E EDC), with address encoding and monitoring of the control signals done by a dedicated module (XBIC). This ensures the safety of storage and of the data path to the internal storage (RAM, flash memory, core cache) and peripherals across the crossbar switch. See the XBIC chapter for details.
- Hardware CRC module that supports end-to-end data check integrity for any data transfer in the system (SRAM to peripherals via DMA transfer, external interfaces to SRAM/peripherals, and so on)
- Cortex-M7 MPUs
- XRDC for memory and peripheral protection
- AIPS_Lite peripheral protection with trusted master-slave connection
- Register protection mechanism for safety-critical registers
- On-chip temperature sensor for temperature monitoring
- Self-test:
  - LBIST to detect latent faults in functional logic as well as in safety integrity mechanisms
  - MBIST to ensure integrity of the memories in the chip (SRAM, ITCM, DTCM, peripheral memories, and so on)
  - Check-the-checker software library
  - ADC self-test
  - SD-ADC BIST
  - Flash array integrity self check
- FCCU for error collection and reaction, including reporting error status to system; FCCU supports these programmable reaction types:
  - Interrupt
  - Functional reset
- Error pads indicate the chip's internal state to the external chip interface or SBC.
- EIM to inject errors into the memories and interface gaskets to verify the error-detection features of the memory controllers and the interface gaskets
- ERM to collect diagnostic information from memory controllers in case of an error event

44.3 I/O peripherals

Some peripherals on the chip are classified as SR-AD (safety-related; application-dependent) as their usage is highly system dependent. The integrity of such functional safety-relevant peripherals has to be ensured by application level measures (for example—connecting one sensor to different I/O modules, sensor validation by sensor redundancy).

The arrangement of I/O peripherals across peripheral bridges allows redundant use of peripherals while limiting possible causes of CCF. Redundant use includes using equivalent peripherals in a replicated way as well as using functionally different peripherals in, for example, feedback measurement loops. Comparison of redundant operation is the responsibility of the application software, not the safety hardware mechanism.

The peripherals are distributed evenly across the peripheral bridges (AIPS*n*), except for singular modules like EMAC, QuadSPI, and so on.

Some peripherals on the chip are classified as SR (safety-related) as they have been analyzed as part of the motor control application and their safety concept has been developed in-context of this application. The integrity of such functional safety-relevant peripherals is ensured by on-chip hardware and software safety mechanisms developed by NXP. The details of these safety mechanisms are available in the chip safety manual.

44.4 Latent Fault Checks

The chip supports BIST to fulfill the requirements of ISO 26262-2:2018 standard to check for latent faults. Your safety software must initiate self-test by configuring STCU2; the chip does not initiate it. STCU2 then controls the self-test operation. Self-test supports both MBIST and LBIST. After the self-test operation completes, the chip enters a reset sequence. Self-test results are stored in STCU2 and your safety software can read the results after the reset sequence.

Figure 180 depicts the processing steps related to the self-test operation, and its linkage to the chip reset and an application start. You decide whether to run a self-test or to skip it before starting an application. You must also specify the self-test configuration before relinquishing control to STCU2 for performing the self-test operation. This processing finishes by reentering the chip reset sequence, depending on whether the chip encountered an unrecoverable fault during the self-test operation. When an unrecoverable fault is encountered during the self-test operation, the chip enters a reset sequence by performing a destructive reset. When no such fault is encountered, the self-test operation completes by entering the chip sequence with a functional reset sequence. You can prevent reset cycling by limiting the amount of resets permitted; the chip shuts down when this limit has been reached. See the "Functional reset escalation" and "Destructive reset escalation" sections in the MC_RGM chapter.

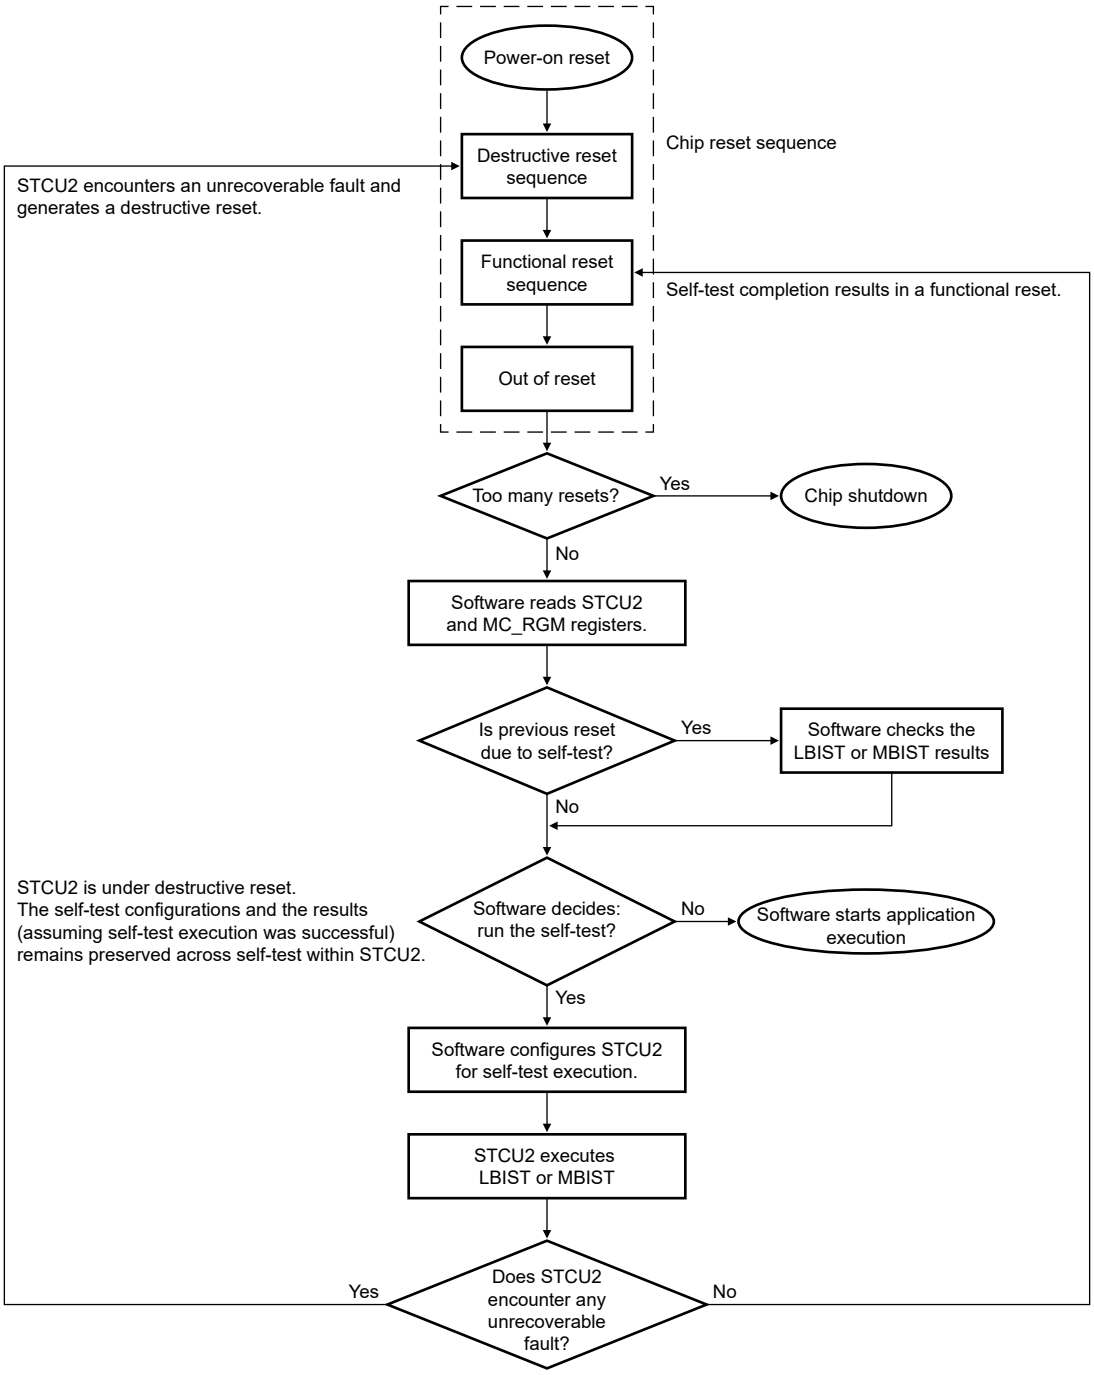

Figure 180. LBIST/MBIST execution

Figure 181 visualizes the top-level partitioning of the chip. The chip consists of two partitions, Run and Standby.

- Run: This partition consists of logic which is present in switchable domain and is shut off (has no supply) while the chip operates in low-power (Standby) mode.
- Standby: This partition consists of always-on logic which is functional even while the chip operates In low-power (Standby) mode.

The Run partition also contains the control logic that is essential for the chip self-test operation, as well as blocks that undergo self-test. The chip consists of a single LBIST partition, which is a subpartition within the Run partition. The LBIST subpartition

contains the logic over which self-test is executed. The logic outside the LBIST subpartition and within the Run partition consists of the LBIST control logic as well as logic which does not undergo LBIST.

The components within these different partitions are listed below the figure (they are not indicated in the figure for clarity).

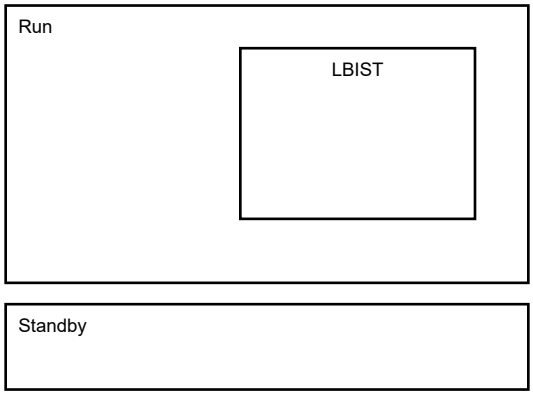

Figure 181. S32K396 chip top-level partition view

The following list specifies the content of the LBIST partition and both power domains related to their participation in the self-test operation:

- Modules participating in the LBIST operation:
  - eMIOS0
  - eDMA
  - EIM2
  - ERM0
  - ERM1
  - XRDC
    - MDAC0
    - MDAC1

  - CMU_FM_2
  - CMU_FC_3
  - CMU_FC_4
  - CMU_FC_5
  - CMU_FC_6
- IAHB gaskets

NOTE

An IAHB gasket is a frequency translation gasket in the system. These gaskets are used to add register walls and synchronize the timing domain across different operating frequencies. See the configurable gaskets in the 'Block diagram' in 'Introduction' chapter for the locations of the IAHB_GASKETs in the chip.

NOTE

REG_PROT of an IP undergoes (or does not undergo) LBIST in conjunction with the protected module that undergoes (or does not undergo) LBIST.

The modules that are vital to the self-test operation are excluded from LBIST regions to allow LBIST to execute successfully.

You must run self-test with PLLDIG configured as the system clock. The LBIST clock controller controls the clock during serial shift, but returns clock control to the functional nodes during the self-test.

NXP also provides a check-the-checker software library as part of SAF software package to test the on-chip hardware safety mechanisms during start-up or shutdown. For details, see the SquareCheck (sCheck) component in the S32 SAF documentation.

The complete details of the safety concept, including assumptions of use and the implementation of safety mechanisms are available in the chip safety manual.

44.5 Glossary

ASIL	Automotive safety integrity level. This is a risk classification scheme as defined by ISO 26262 for automotive standard.
CCF	Common cause failure
DTCM	Data tightly coupled memory
ECC	Error correction code
ITCM	Instruction tightly coupled memory
LBIST	Logic built-in self-test
MBIST	Memory built-in self-test
PLL	Phase-locked loop oscillator
PMIC	Power management integrated chip
SBC	System basis chip

Chapter 45
Error Injection Module (EIM)

45.1 Chip-specific EIM information

45.1.1 EIM instances

This chip supports three instances of EIM:

- EIM_0
- EIM_1
- EIM_2

45.1.2 EIM channel mapping

EIM integrates with the memory controller and memory array to enable error injection in a controlled way. Each memory controller has its own EIM channel.

Table 213. ACP_EIM_0

Channel Number	Target	Data bits	Check bits	Num of data bits	Num of check bits
0	cm7_0 ic tag	[43:22] - cm7_0 ic tag read data1[28:7] [21:0] - cm7_0 ic tag read data0[28:7]	[13:7] - cm7_0 ic tag read data1[6:0] [6:0] - cm7_0 ic tag read data0[6:0]	44	14

The two enables, GEIEN and EICHEN*n*, enable the error injection functionality. The former enables it globally and the latter does it for a particular channel. This double-layer enable provides protection against accidental enabling and reconfiguration of the error injection function for each channel.

EIM provides support for inducing single-bit and multi-bit inversions on read data when accessing peripheral RAMs through its data mask registers.

NOTE

For enabling error injection on EDC gaskets (corresponding to channel 28, channel 29, and channel 30), you must also enable the fields corresponding to the required EDC gasket in the MSCM_ENEDC register before enabling the EIM channel.

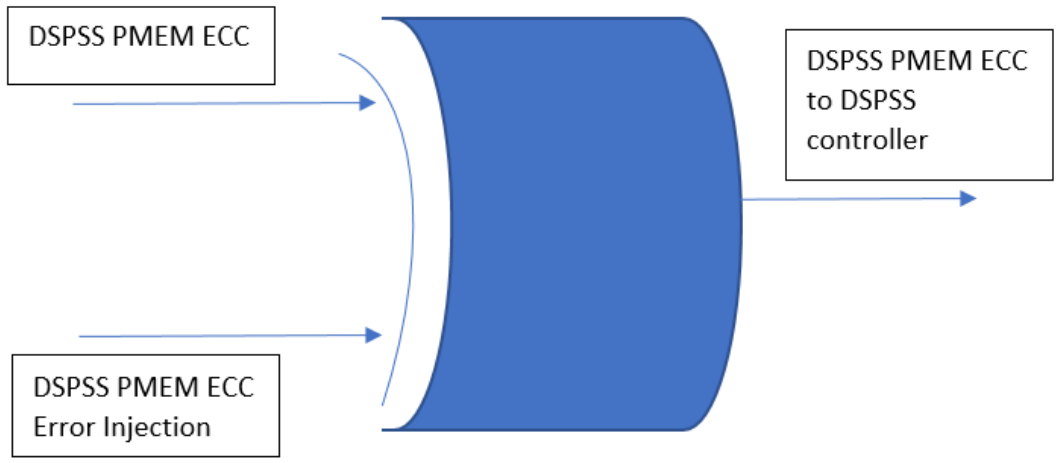
45.1.3 Coolflux

The Core and DSP PMEM and XMEM error injection signals are generated by EIM and then forwarded to DSPSS. The error injection is done on both RDATA and ECC. For PMEM, the RDATA and ECC error injections are symmetrical to RDATA and ECC but in case of XMEM.

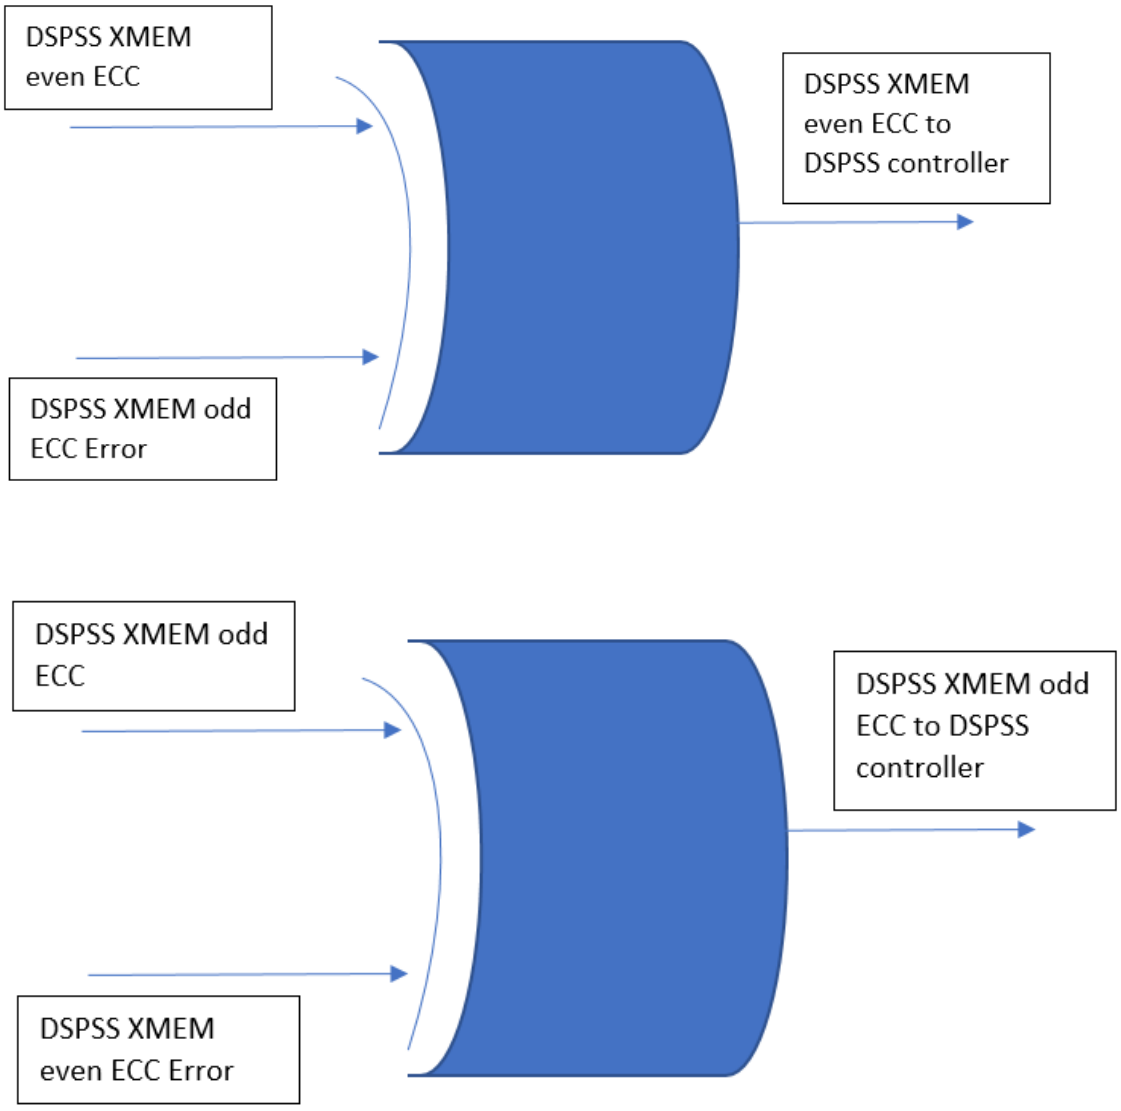
The ECC error injection of XMEM even is used with ECC of XMEM odd ECC and vice versa.

This can be explained with the help of following diagram:

In case of ECC, FOR PMEM, PMEM ECC is xored with PMEM Error Injection bus and then provided to DSPSS controller.



In case of ECC, FOR XMEM, XMEM odd ECC is xored with XMEM even ECC Error Injection bus and then provided to DSPSS controller. And vice versa.



45.1.4 Constraints to use EIM on CM7 cache memories

The Cortex-M7 processor has Error Correcting Code (ECC) functionality for error detection and correction which is included in the data and instruction caches when implemented. If hard, or permanent, errors occur on the cache RAM, the clean, invalidate and retry scheme might cause a deadlock, and the access is continuously replayed. To prevent this, error bank registers are provided to mask the faulty locations as unusable and invalid. To ensure such a deadlock scenario doesn't occur while testing the cache memory using EIM module, you should take care of the following points:

- Inject one single-bit error on a cache line at a time.
- Ensure that at least one error bank register of the tested cache is free before injecting any faults. This is to make sure that the fault recovery mechanism of the M7 core will work.

For further details, refer to 'Cache RAM protection' section in Arm Cortex-M7 Processor Technical Reference Manual.

NOTE

Error injection on 0th and 1st bit for Icache and Dcache is invalid for S32K396 since the Icache and Dcache size is 16KB.

45.2 Overview

The Error Injection Module (EIM) is mainly used for diagnostic purposes. It provides a method to test the diagnostics (memory ECC, interconnect parity) by error injection in the field. See the chip-specific EIM information to determine which functional safety features are supported by this method.

EIM enables you to inject artificial errors on error-checking mechanisms of a system, such as ECC for RAM read data and parity bits. For each such mechanism that EIM supports on the chip, EIM can inject single-bit and multi-bit inversions on data in the applicable target bus. Injecting faults on memory accesses can be used to exercise the SEC-DED ECC function of the related system.

45.2.1 Features

The EIM includes these features:

- Supports 19 error injection channels. See the chip-specific EIM information for channel assignment details.
- Protection against accidental enable and reconfiguration error injection function via two-stage enable mechanism

45.2.2 Block diagram

The following diagram shows an example of EIM implementation with a 64-bit read data bus and an 8-bit checkbit bus.

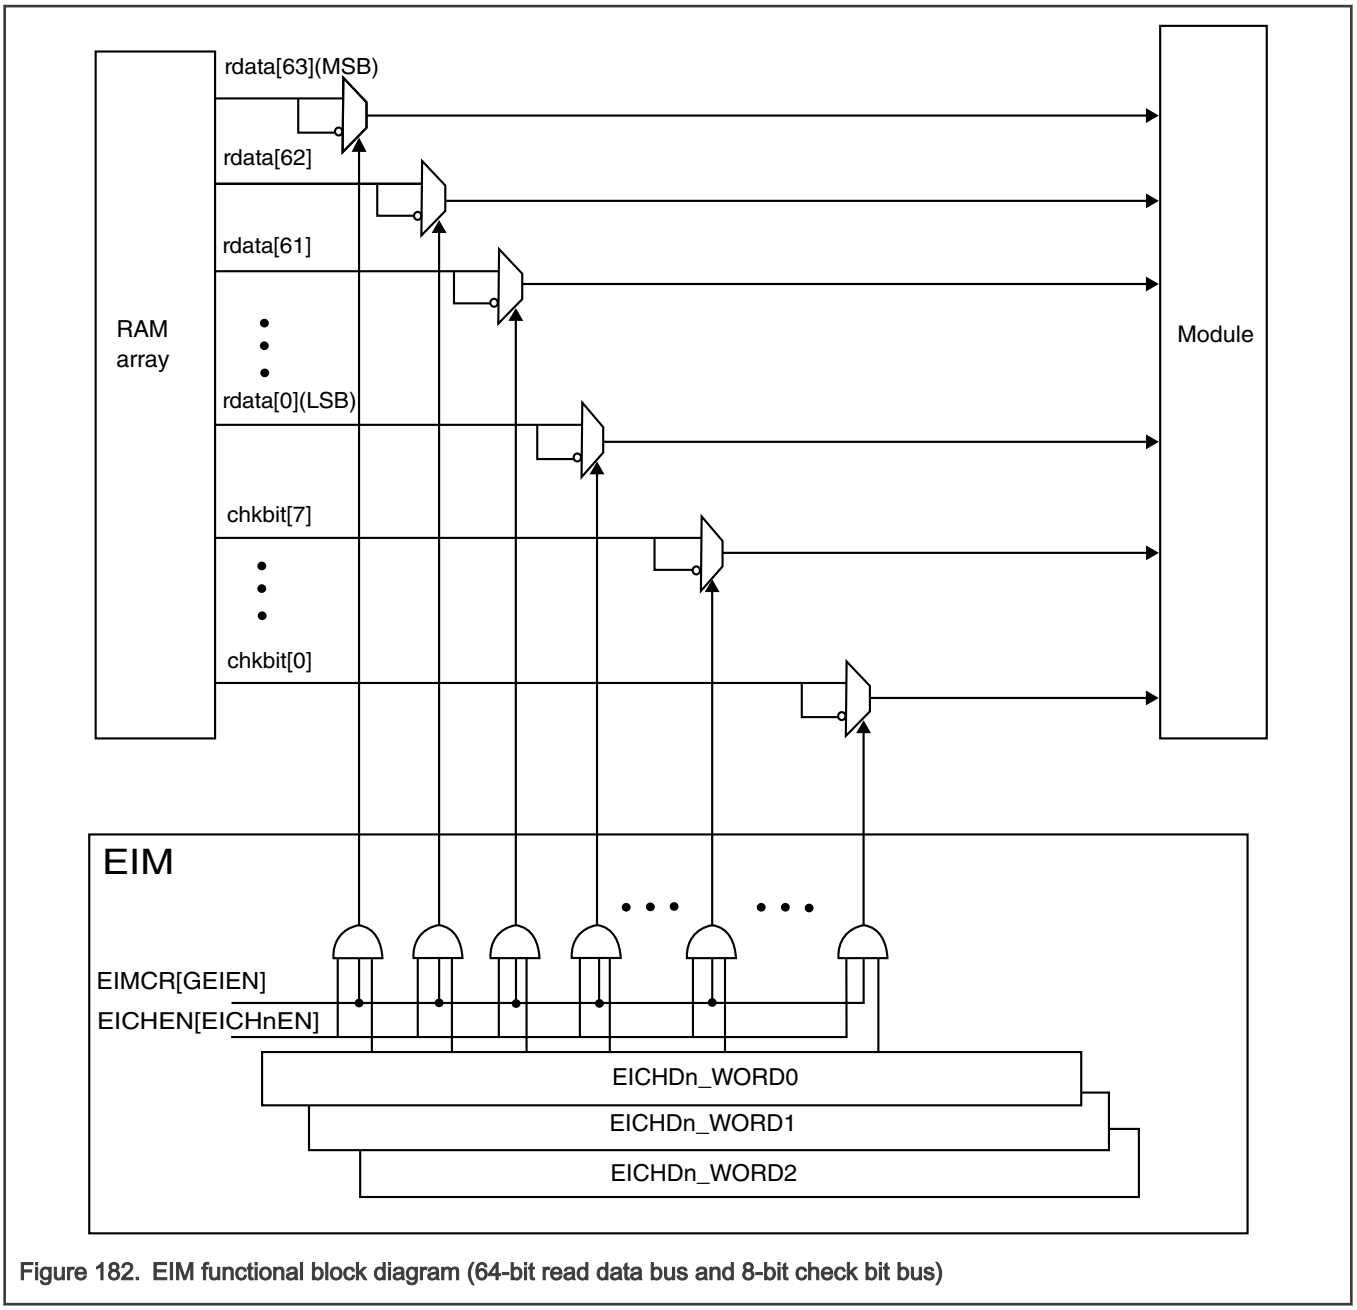


Figure 182. EIM functional block diagram (64-bit read data bus and 8-bit check bit bus)

Several memory elements are implemented within a device, which may not only be the large memory blocks (Flash and SRAM) but also smaller memories like caches, the TCD blocks, and the embedded peripheral memories. Some larger memories may actually be built from multiple memory elements, dependent on their size or function. Each of these memory elements implements its own control logic, the memory controller, that performs the accesses to the actual memory, the memory array. An EIM channel is associated with a memory controller and provides the capability to alter one or multiple signals in the read access path from the corresponding memory array(s). Only memory controllers controlling a safety related memory may be associated with an EIM channel.

45.3 Functional description

The EIM provides protection against accidental enabling and reconfiguration of the error injection function by enforcing a two-stage enablement mechanism. To properly enable the error injection mechanism for a channel:

- Write 1 to the EICHEN[EICH*n*EN] field, where *n* denotes the channel number.

- Write 1 to EIMCR[GEIEN].

NOTE

When the use case for a channel requires writing any EICHD*n*_WORD register, write the EICHD*n*_WORD register before executing the two-stage enablement mechanism. A successful write to any EICHD*n*_WORD register clears the corresponding EICHEN[EICH*n*EN] field.

The EIM supports 19 error injection channels. See the chip-specific EIM information for channel assignment details. Each channel:

- Can be assigned to a single memory array interface by intercepting the assigned memory read data bus and checkbit bus, and injects errors by inverting the value transmitted for selected bits on each bus line.
- Can be assigned to a redundant comparison unit by intercepting the signals being compared, and injecting errors by inverting the value transmitted for selected bits on each bus line.

On a memory read access, the applicable EICHD*n*_WORD registers define which bits of the read data and/or checkbit bus to invert.

Figure 182 depicts the interception and override of a 64-bit read data bus and an 8-bit checkbit data bus for an example memory array.

Error injection scenarios

The EIM supports these cases of error injection:

- To generate a single-bit error, invert only 1 bit of the CHKBIT_MASK or DATA_MASK in the EICHD*n*_WORD registers.
- To generate a multi-bit error, invert only 2 bits of the CHKBIT_MASK or DATA_MASK in the EICHD*n*_WORD registers.

NOTE

An attempt to invert more than 2 bits in one operation might result in undefined behavior.

To enable error injection:

1. Set the EICHD*n*_WORD*m*[CHKBIT_MASK] and EICHD*n*_WORD*m*[B*a*_*b*DATA_MASK] fields for each channel that will be driving an injection.
2. Program the EICHEN register to enable the channels that will be injecting errors.
3. Set the EIMCR[GEIEN] field to globally allow all enabled channels to actively inject errors.

To disable error injection, either disable the EIMCR[GEIEN] field or disable the individual channel enable fields of the EICHEN register.

45.4 Initialization

This module does not require initialization.

45.6 EIM_0 register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 288-bit (36-byte) structure, composed of nine 32-bit words, in the EIM programming model. Unused words are not documented.
  - Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.
  - Word1 (EICHD*n*_WORD1) and additional words, if present, define the data mask. Word registers subsequent to Word1 are present only when required by the total width of the channel's data mask. Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

Error injection channel descriptor: DATA_MASK details

For each channel: The following tables show the distribution of DATA_MASK's bits across the WORD registers. The first table shows the total width of DATA_MASK and the distribution of its bits across WORD1, WORD2, and WORD3. The second table shows the distribution of DATA_MASK's bits across WORD4 and subsequent registers.

Table 216. Error injection channel descriptor: DATA_MASK details

Channel	DATA_MASK total width (bits)	Specific bits of DATA_MASK in

The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 14 1b - Error injection is enabled on Error Injection Channel 14
16 EICH15EN	Error Injection Channel 15 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0b - Error injection is disabled on Error Injection Channel 15 1b - Error injection is enabled on Error Injection Channel 15
15 EICH16EN	Error Injection Channel 16 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel.

45.6.4 Error Injection Channel Descriptor 0, Word0 (EICHD0_WORD0)

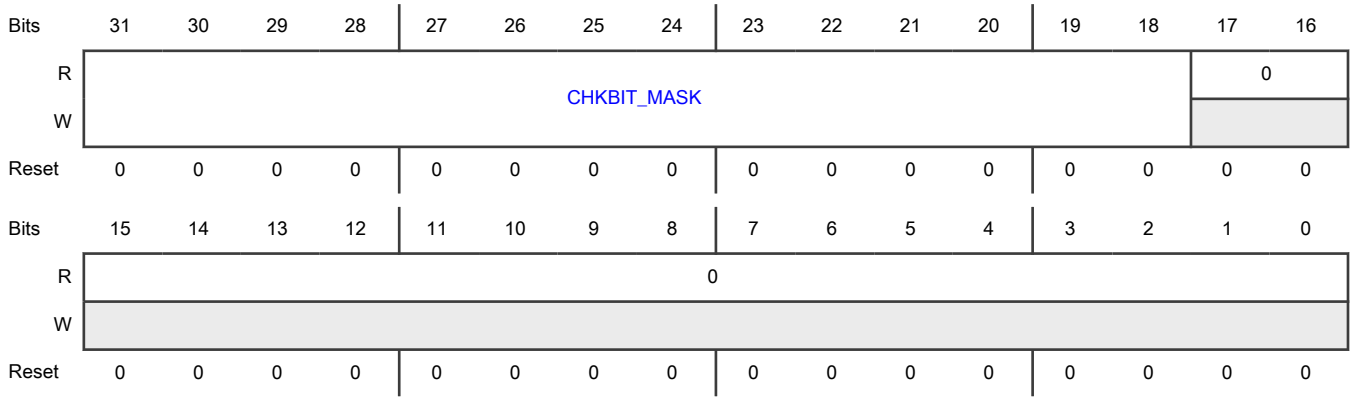
Offset

Register	Offset
EICHD0_WORD0	100h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-18 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[13:0] (14 bits wide), CHKBIT_MASK[13] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted.
17-0 —	Reserved

45.6.5 Error Injection Channel Descriptor 0, Word1 (EICHD0_WORD1)

Offset

Register	Offset
EICHD0_WORD1	104h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the target bus. Each bit specifies whether the corresponding bit of the target bus should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram

45.6.21 Error Injection Channel Descriptor n, Word0 (EICHD10_WORD0 - EICHD15_WORD0)

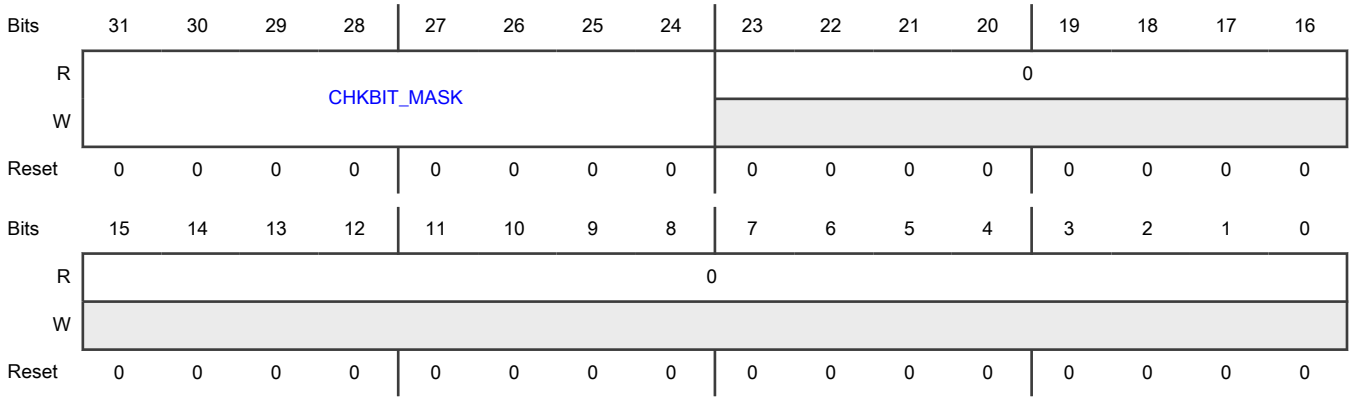
Offset

Register	Offset
EICHD10_WORD0	380h
EICHD11_WORD0	3C0h
EICHD12_WORD0	400h
EICHD13_WORD0	440h
EICHD14_WORD0	480h
EICHD15_WORD0	4C0h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-24 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[7:0] (8 bits wide), CHKBIT_MASK[7] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted.
23-0 —	Reserved

45.6.22 Error Injection Channel Descriptor 16, Word1 (EICHD16_WORD1)

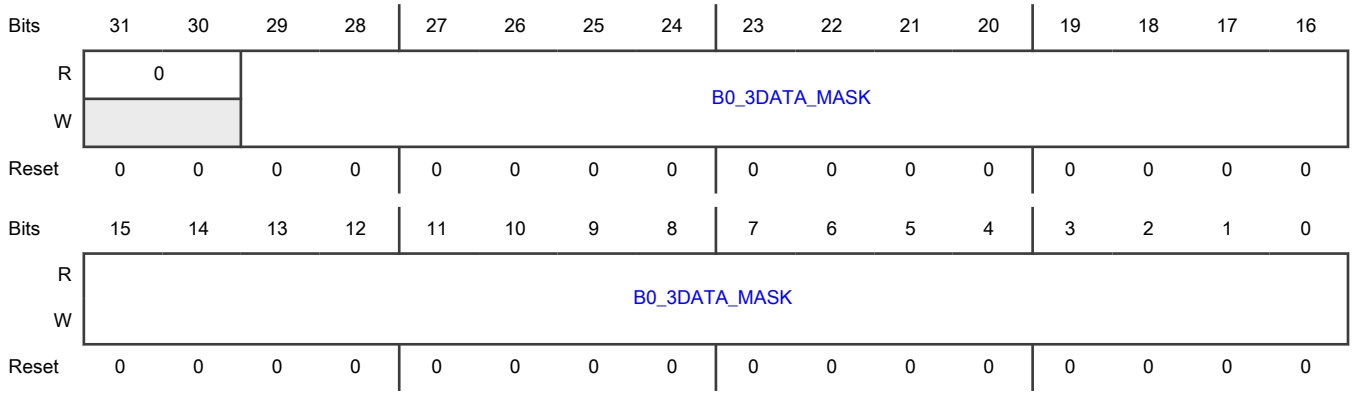
Offset

Register	Offset
EICHD16_WORD1	504h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the target bus. Each bit specifies whether the corresponding bit of the target bus should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-30 —	Reserved
29-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

45.6.23 Error Injection Channel Descriptor n, Word1 (EICHD17_WORD1 - EICHD18_WORD1)

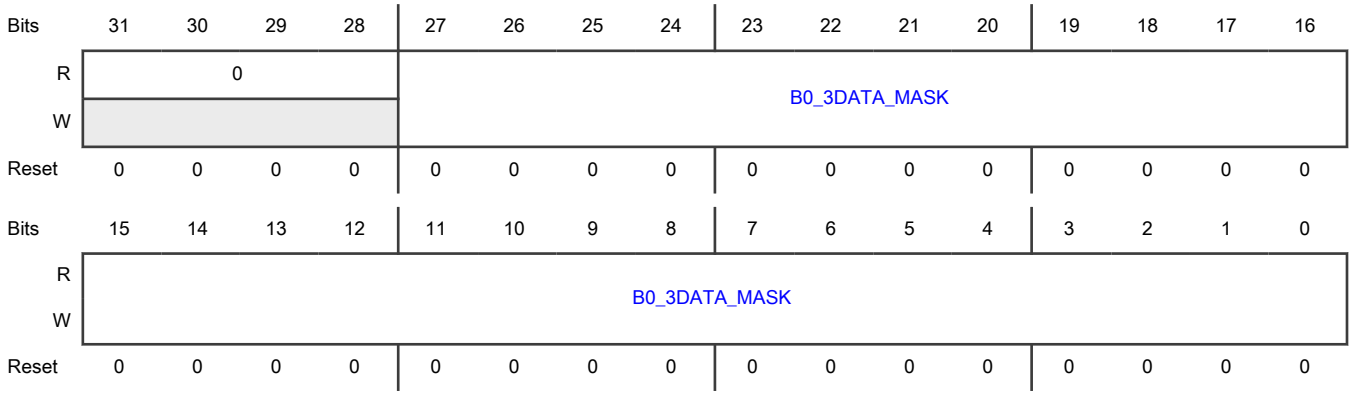
Offset

Register	Offset
EICHD17_WORD1	544h
EICHD18_WORD1	584h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the target bus. Each bit specifies whether the corresponding bit of the target bus should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-28 —	Reserved
27-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

45.7 EIM_1 register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 288-bit (36-byte) structure, composed of nine 32-bit words, in the EIM programming model. Unused words are not documented.
  - Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.
  - Word1 (EICHD*n*_WORD1) and additional words, if present, define the data mask. Word registers subsequent to Word1 are present only when required by the total width of the channel's data mask. Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

Error injection channel descriptor: DATA_MASK details

For each channel: The following tables show the distribution of DATA_MASK's bits across the WORD registers. The first table shows the total width of DATA_MASK and the distribution of its bits across WORD1, WORD2, and WORD3. The second table shows the distribution of DATA_MASK's bits across WORD4 and subsequent registers.

Table 218. Error injection channel descriptor: DATA_MASK details

Channel	DATA_MASK total width (bits)	Specific bits of DATA_MASK in		
		WORD1	WORD2	WORD3
0	44	43-32	31-0	—
1	128	127-96	95-64	63-32

45.7.10 Error Injection Channel Descriptor n, Word4 (EICHD1_WORD4 - EICHD4_WORD4)

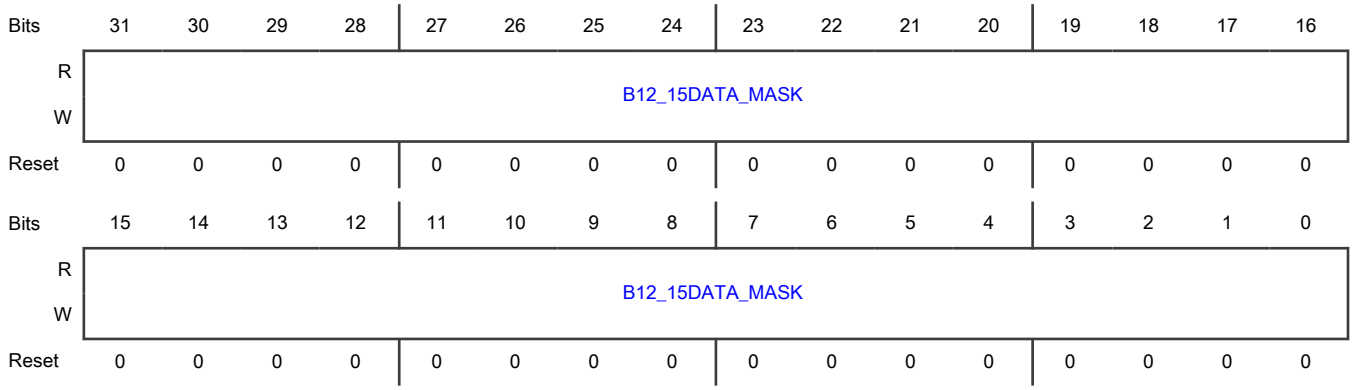
Offset

Register	Offset
EICHD1_WORD4	150h
EICHD2_WORD4	190h
EICHD3_WORD4	1D0h
EICHD4_WORD4	210h

Function

The fifth word of the Error Injection Channel Descriptor, when present, defines a right-justified mask field. The bits in B12_15DATA_MASK correspond to bytes 12–15 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-0 B12_15DATA_MASK	Data Mask Bytes 12-15 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. **NOTE** For each channel: For the specific DATA_MASK bits to which B12_15DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 12-15 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 12-15 on the read data bus is inverted.

45.7.11 Error Injection Channel Descriptor n, Word0 (EICHD2_WORD0 - EICHD4_WORD0)

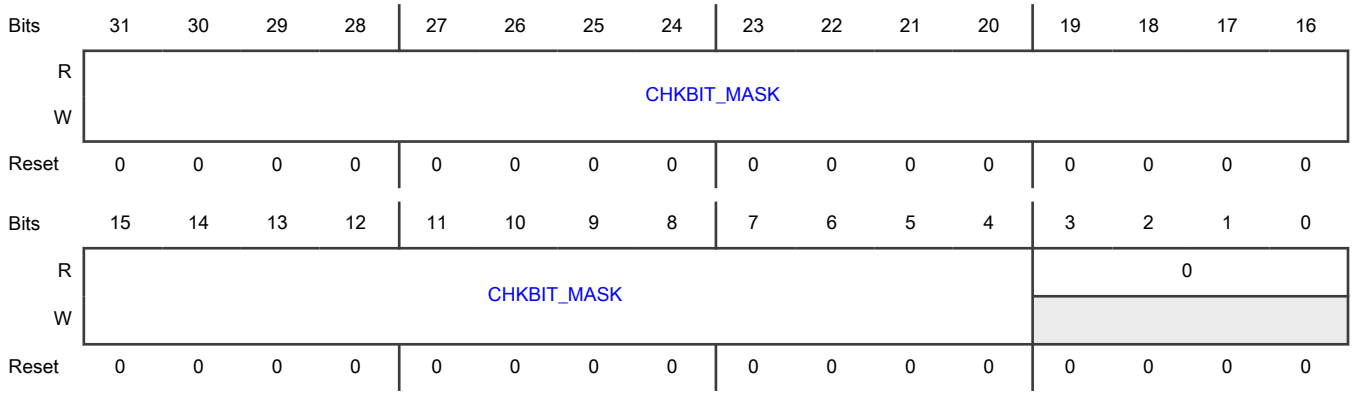
Offset

Register	Offset
EICHD2_WORD0	180h
EICHD3_WORD0	1C0h
EICHD4_WORD0	200h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-4 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[27:0] (28 bits wide), CHKBIT_MASK[27] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted.
3-0 —	Reserved

45.7.12 Error Injection Channel Descriptor 2, Word1 (EICHD2_WORD1)

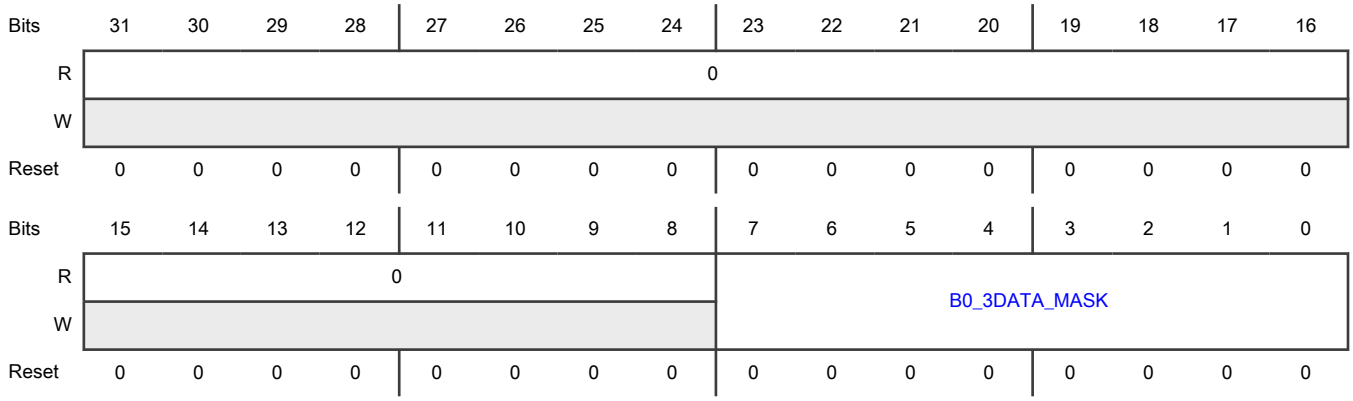
Offset

Register	Offset
EICHD2_WORD1	184h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the target bus. Each bit specifies whether the corresponding bit of the target bus should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

45.7.13 Error Injection Channel Descriptor n, Word1 (EICHD3_WORD1 - EICHD12_WORD1)

Offset

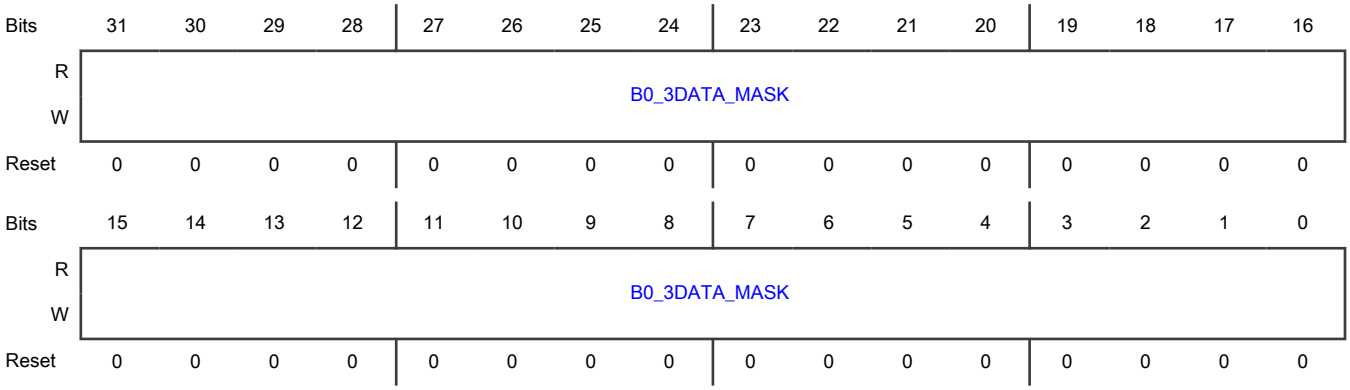
Register	Offset
EICHD3_WORD1	1C4h
EICHD4_WORD1	204h
EICHD10_WORD1	384h
EICHD11_WORD1	3C4h
EICHD12_WORD1	404h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the target bus. Each bit specifies whether the corresponding bit of the target bus should be inverted

or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

45.7.14 Error Injection Channel Descriptor n, Word0 (EICHD10_WORD0 - EICHD12_WORD0)

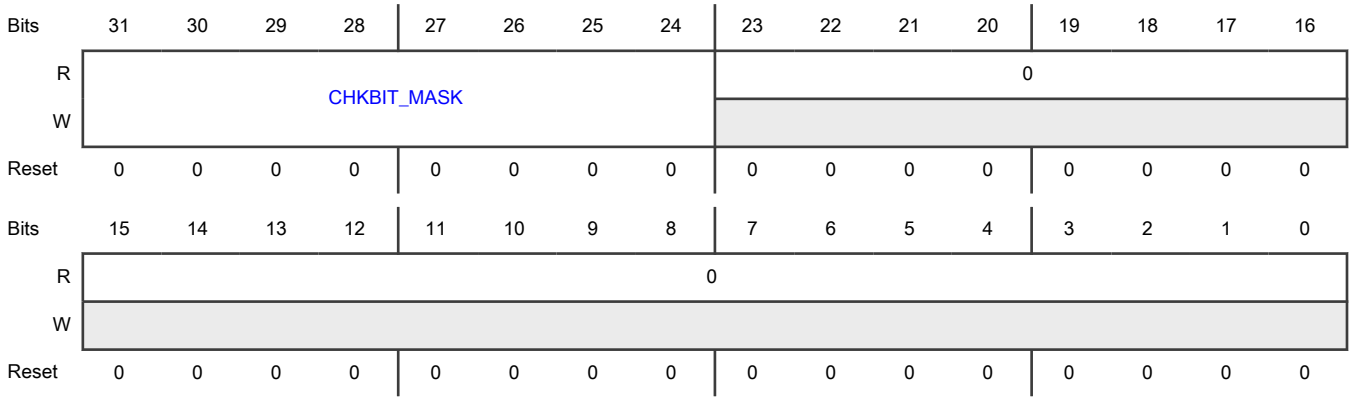
Offset

Register	Offset
EICHD10_WORD0	380h
EICHD11_WORD0	3C0h
EICHD12_WORD0	400h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-24 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[7:0] (8 bits wide), CHKBIT_MASK[7] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted.
23-0 —	Reserved

45.7.15 Error Injection Channel Descriptor 16, Word1 (EICHD16_WORD1)

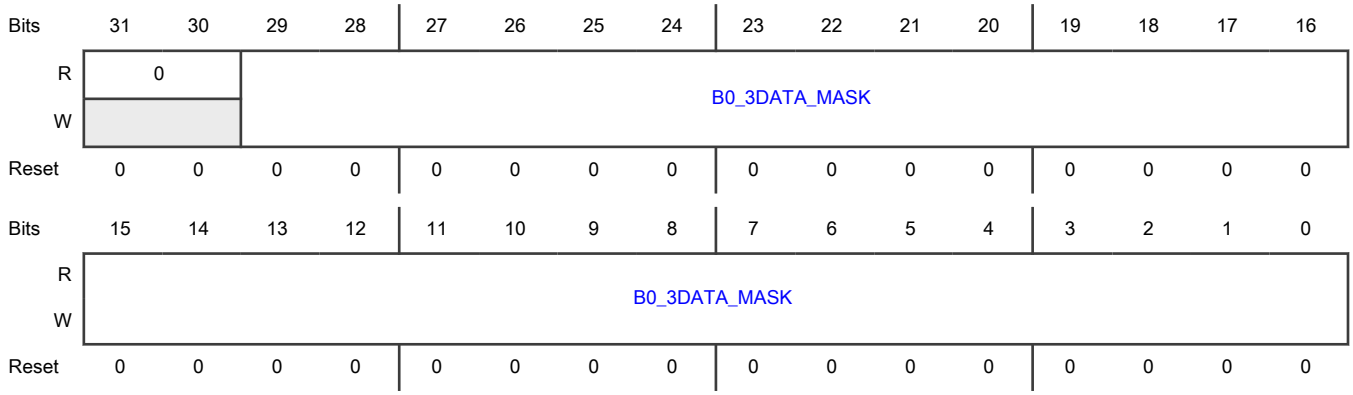
Offset

Register	Offset
EICHD16_WORD1	504h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the target bus. Each bit specifies whether the corresponding bit of the target bus should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-30 —	Reserved
29-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

45.7.16 Error Injection Channel Descriptor 17, Word1 (EICHD17_WORD1)

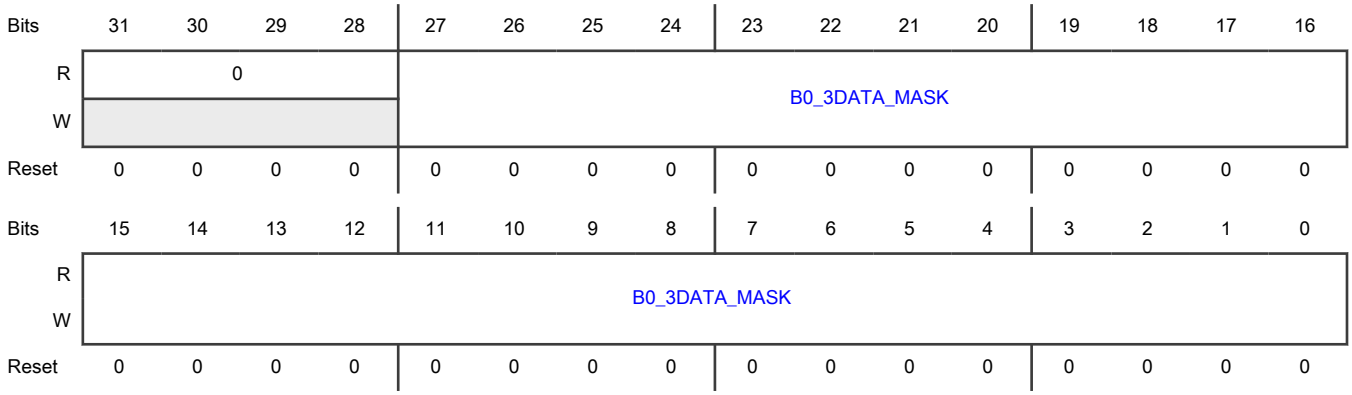
Offset

Register	Offset
EICHD17_WORD1	544h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the target bus. Each bit specifies whether the corresponding bit of the target bus should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-28 —	Reserved
27-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

45.8 EIM_2 register descriptions

The EIM provides a programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and/or checkbit bus from target RAM are inverted on a read access.
- Consists of a 288-bit (36-byte) structure, composed of nine 32-bit words, in the EIM programming model. Unused words are not documented.
  - Word0 (EICHD*n*_WORD0), if present, defines the checkbit mask.
  - Word1 (EICHD*n*_WORD1) and additional words, if present, define the data mask. Word registers subsequent to Word1 are present only when required by the total width of the channel's data mask. Error injection channel descriptor: DATA_MASK details.

The multiple channel descriptors are organized sequentially.

Error injection channel descriptor: DATA_MASK details

For each channel: The following tables show the distribution of DATA_MASK's bits across the WORD registers. The first table shows the total width of DATA_MASK and the distribution of its bits across WORD1, WORD2, and WORD3. The second table shows the distribution of DATA_MASK's bits across WORD4 and subsequent registers.

Table 220. Error injection channel descriptor: DATA_MASK details

Channel	DATA_MASK total width (bits)	Specific bits of DATA_MASK in		
		WORD1	WORD2	WORD3
0	64	63-32	31-0	—
1	64	63-32	31-0	—

45.8.4 Error Injection Channel Descriptor n, Word0 (EICHD0_WORD0 - EICHD4_WORD0)

Offset

Register	Offset
EICHD0_WORD0	100h
EICHD1_WORD0	140h
EICHD3_WORD0	1C0h
EICHD4_WORD0	200h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24	Checkbit Mask

Table continues on the next page...

Table continued from the previous page...

Field	Function
CHKBIT_MASK	This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[7:0] (8 bits wide), CHKBIT_MASK[7] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted.
23-0 —	Reserved

45.8.5 Error Injection Channel Descriptor n, Word1 (EICHD0_WORD1 - EICHD4_WORD1)

45.8.13 Error Injection Channel Descriptor 22, Word1 (EICHD22_WORD1)

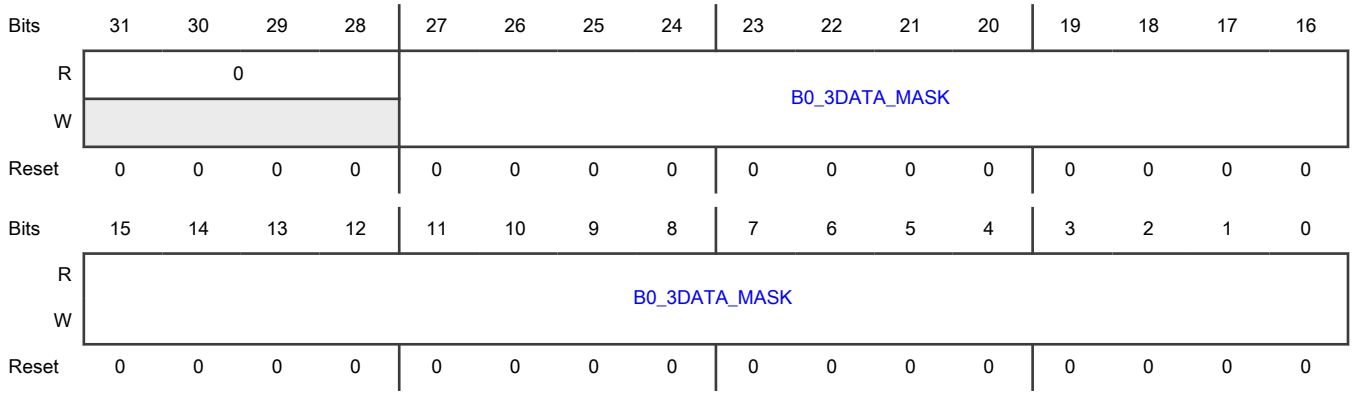
Offset

Register	Offset
EICHD22_WORD1	684h

Function

The second word of the Error Injection Channel Descriptor defines a right-justified mask field. The bits in B0_3DATA_MASK correspond to bytes 0–3 of the target bus. Each bit specifies whether the corresponding bit of the target bus should be inverted or remain unmodified on read accesses. A successful write to this field clears the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-28 —	Reserved
27-0 B0_3DATA_MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. **NOTE** For the specific DATA_MASK bits to which B0_3DATA_MASK corresponds, See Error injection channel descriptor: DATA_MASK details. 0b - The corresponding bit of bytes 0-3 on the read data bus remains unmodified. 1b - The corresponding bit of bytes 0-3 on the read data bus is inverted.

45.8.14 Error Injection Channel Descriptor 23, Word0 (EICHD23_WORD0)

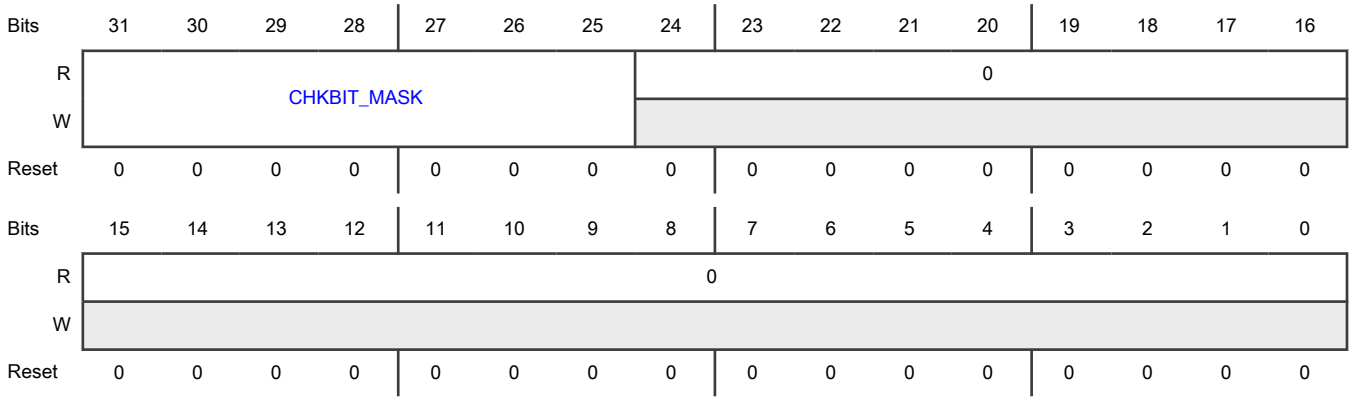
Offset

Register	Offset
EICHD23_WORD0	6C0h

Function

The first word of the Error Injection Channel Descriptor defines a left-justified mask field: CHKBIT_MASK. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful write to this field clears the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Diagram



Fields

Field	Function
31-25 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. Writes to unimplemented bits are ignored. For any unique details about the mapping of CHKBIT_MASK's bits to a channel's target RAM, see the chip-specific EIM information. **NOTE** Because CHKBIT_MASK is left-justified, the highest bit in the bit range is always in the position of the most significant bit. For CHKBIT_MASK[6:0] (7 bits wide), CHKBIT_MASK[6] is in the position of the most significant bit. 0b - The corresponding bit of the checkbit bus remains unmodified. 1b - The corresponding bit of the checkbit bus is inverted.

ECC	Error correction code

Chapter 46
Error Reporting Module (ERM)

46.1 Chip-specific ERM information

46.1.1 ERM channel mapping

ERM provides information on memory events associated with ECC and parity. It also provides you an option to enable interrupt notification for these events.

Table 222. ACP_ERM_0 channel mapping

CHANNEL NUMBER	MODULE	CAPTURED STATUS
0	SRAM0	single-bit error, multi-bit error, syndrome, absolute error address aligned to double, word (64-bit) boundary
1	SRAM1	single-bit error, multi-bit error, syndrome, absolute error address aligned to double, word (64-bit) boundary
2	CM7_0 I-cache tag RAM	single-bit error, multi-bit error
3	CM7_0 I-cache data RAM	single-bit error, multi-bit error
4	CM7_0 D-cache tag RAM	single-bit error, multi-bit error
5	CM7_0 D-cache data RAM	single-bit error, multi-bit error
6	CM7_1 I-cache tag RAM	single-bit error, multi-bit error
7	CM7_1 I-cache data RAM	single-bit error, multi-bit error
8	CM7_1 D-cache tag RAM	single-bit error, multi-bit error
9	CM7_1 D-cache data RAM	single-bit error, multi-bit error
10	CM7_0 ITCM	single-bit error, multi-bit error, syndrome, offset error address
11	CM7_0 D0TCM	single-bit error, multi-bit error, syndrome, offset error address
12	CM7_0 D1TCM	Single-bit error, multi-bit error, syndrome, offset error address[1]
13	CM7_1 ITCM	single-bit error, multi-bit error, syndrome, offset error address
14	CM7_1 D0TCM	single-bit error, multi-bit error, syndrome, offset error address
15	CM7_1 D1TCM	Single-bit error, multi-bit error, syndrome, offset error address[1]
16	DMA TCD	single-bit error, multi-bit error, syndrome, offset error address

Table continues on the next page...

Table 222. ACP_ERM_0 channel mapping (continued)

CHANNEL NUMBER	MODULE	CAPTURED STATUS
17	flash memory port p0	single-bit error, multi-bit error, absolute error address
18	flash memory port p1	single-bit error, multi-bit error, absolute error address
19	flash memory port p2	single-bit error, multi-bit error, absolute error address
20	-	
21	-	
22	-	
23	-	

1. For address reporting, bit 2 of the address is masked because this bit decides whether the access (read or write) is for D0TCM or D1TCM. For example, if the offset address is 0h or 8h, it is routed to D0TCM, but if the offset address is 4h or Ch, it is routed to D1TCM. The errors that are latched for these offset addresses are as follows:
   - Offset 0h : Address 0h is latched into the ERM channel corresponding to D0TCM.
   - Offset 4h : Address 0h is latched into the ERM channel corresponding to D1TCM.
   - Offset 8h : Address 8h is latched into the ERM channel corresponding to D0TCM.
   - Offset Ch : Address 8h is latched into the ERM channel corresponding to D1TCM.

15	-	
16	DMA1 TCD	single-bit error, multi-bit error, syndrome, offset error address
17	flash memory port p3	single-bit error, multi-bit error, absolute error address
18	dspss pmem core	single-bit error, multi-bit error, syndrome, offset error address (address is aligned to 32 bit offset memory address)
19	dspss pmem dsp	single-bit error, multi-bit error, syndrome, offset error address (address is aligned to 32 bit offset memory address)
20	dspss xmem even core	single-bit error, multi-bit error, syndrome, offset error address (address is aligned to 32 bit offset memory address)
21	dspss xmem even dsp	single-bit error, multi-bit error, syndrome, offset error address (address is aligned to 32 bit offset memory address)
22	dspss xmem odd core	single-bit error, multi-bit error, syndrome, offset error address (address is aligned to 32 bit offset memory address)
23	dspss xmem odd dsp	single-bit error, multi-bit error, syndrome, offset error address (address is aligned to 32 bit offset memory address)

NOTE

The eTPU ECC errors are not under ERM control. It needs to be reported separately.

46.1.2 Coolflux

COOLFLUX have Core and DSP. Both the components have two memories:

- PMEM : Program Memory
- XMEM: Data Memory

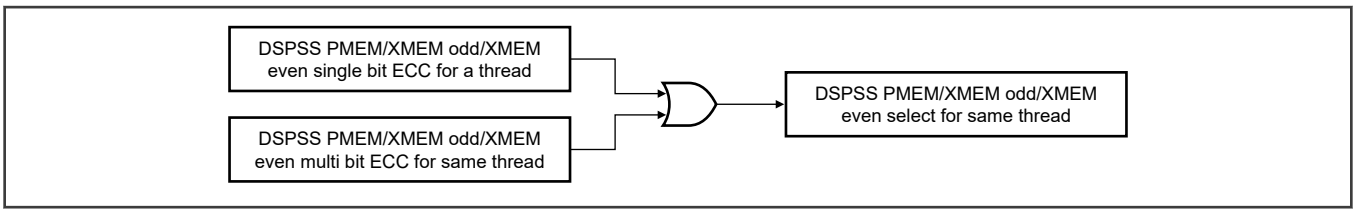
The XMEM memory is further divided into odd and even memory.

For PMEM and XMEM(both even and odd), single bit, multi bit and address ecc error (offset error address) and syndrome are generated.

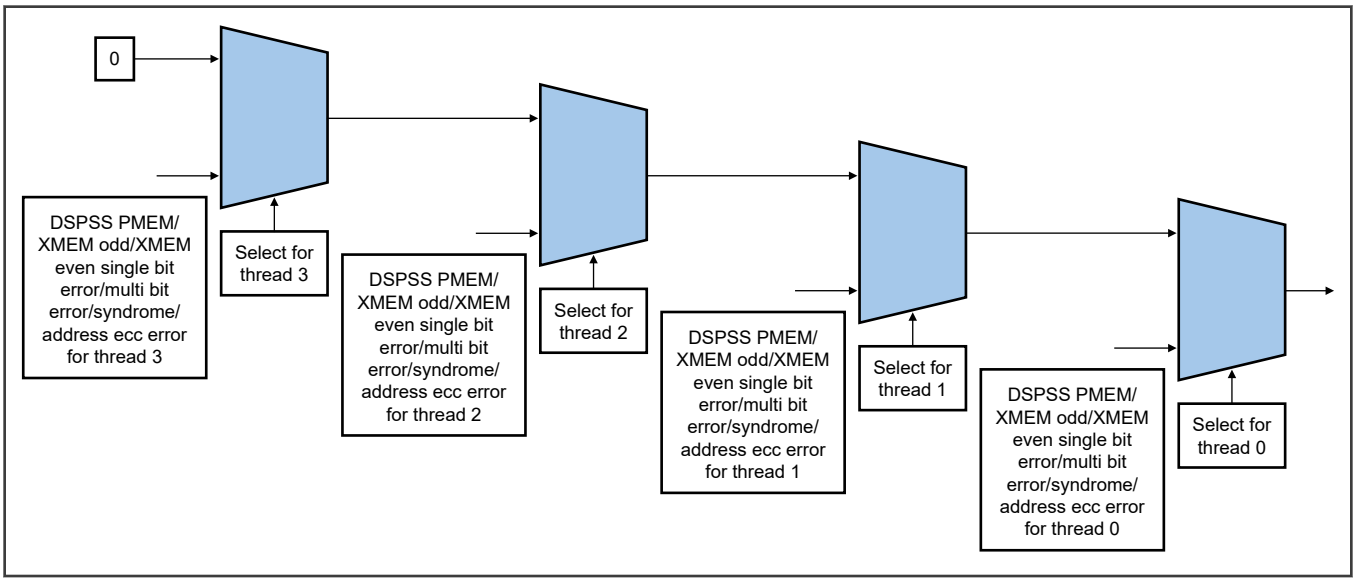
The single bit error, multi-bit error, syndrome and address ECC for both the memories from the CORE are directly connected to the ERM.

But DSP consist of 4 threads for each. All the data will be generated for all 4 threads. So, before connecting it to ERM the data from each thread is manipulated to generate single set of data to be connected to ERM. Along with that the information about that which thread is generating the error is provided to ERM with address ecc error for DSP. The data is manipulated the following way:

First for select to inform that which thread has been selected:



The single bit error, multi bit error, syndrome and address ecc for each thread is selected on the basis of select for each thread. A priority mux is used where 0 thread is at highest priority and 3 at lowest priority.



The output for the above priority mux will be connected to erm for all three single bit error, multi bit error and syndrome. For address ecc bit, the select bits will be concatenated from low to high priority level with the address and then provided to ERM.

[Select for thread 3, Select for thread 2, select for thread 1, select for thread 0, address ECC]

NOTE

The single bit errors for DSP are only connected to ERM but multi bit ones are connected to ERM as well as ported out to FCCU.

46.1.3 PMEM syndrome

The table below contains the ECC syndrome information for DSPSS PMEM (code memory). For an ECC error, the index of the bit equal to 1'b1 is equal to the index of the bit with error. For example if syndrome[2] = 1'b1 and other bits are 0, then bit 2 of the ECC has error.

The same is true for other ECC bits. This is valid for single bit error scenarios only.

For multibit error position/syndrome decoding is not useful.

Syndrome	Error bit position
7'b0000111	0
7'b0001011	1
7'b0001101	2

Table continues on the next page...

Table continued from the previous page...

Syndrome	Error bit position
7'b0001110	3
7'b0010011	4
7'b0010101	5
7'b0010110	6
7'b0011001	7

6'b100101	11
6'b100110	12
6'b101001	13
6'b101010	14
6'b101100	15
Any other value	No error in data

46.2 Overview

The Error Reporting Module (ERM) provides information and optional interrupt notification on memory error events associated with ECC and parity. The ERM collects error events on memory accesses for memory arrays, such as flash memory, system RAM, or peripheral RAMs. ERM supports various channels for memory sources where each ERM channel is associated with a different memory module. See the chip-specific ERM information for details about supported memory sources and specific memory channel assignments. If memory supports ECC then ERM syndrome and error address information is captured along with error event. ERM does not receive this information in case of cache or memory with parity along with error event.

46.2.1 Features

The ERM includes these features:

- Optional interrupt notification on captured error events
- Capturing of address and syndrome information on single-bit correction and non-correctable ECC events
- Support for error event capturing for memory sources, with individual reporting fields and interrupt configuration per memory channel

- Recording the count value of the number of corrected error events

46.2.2 Block diagram

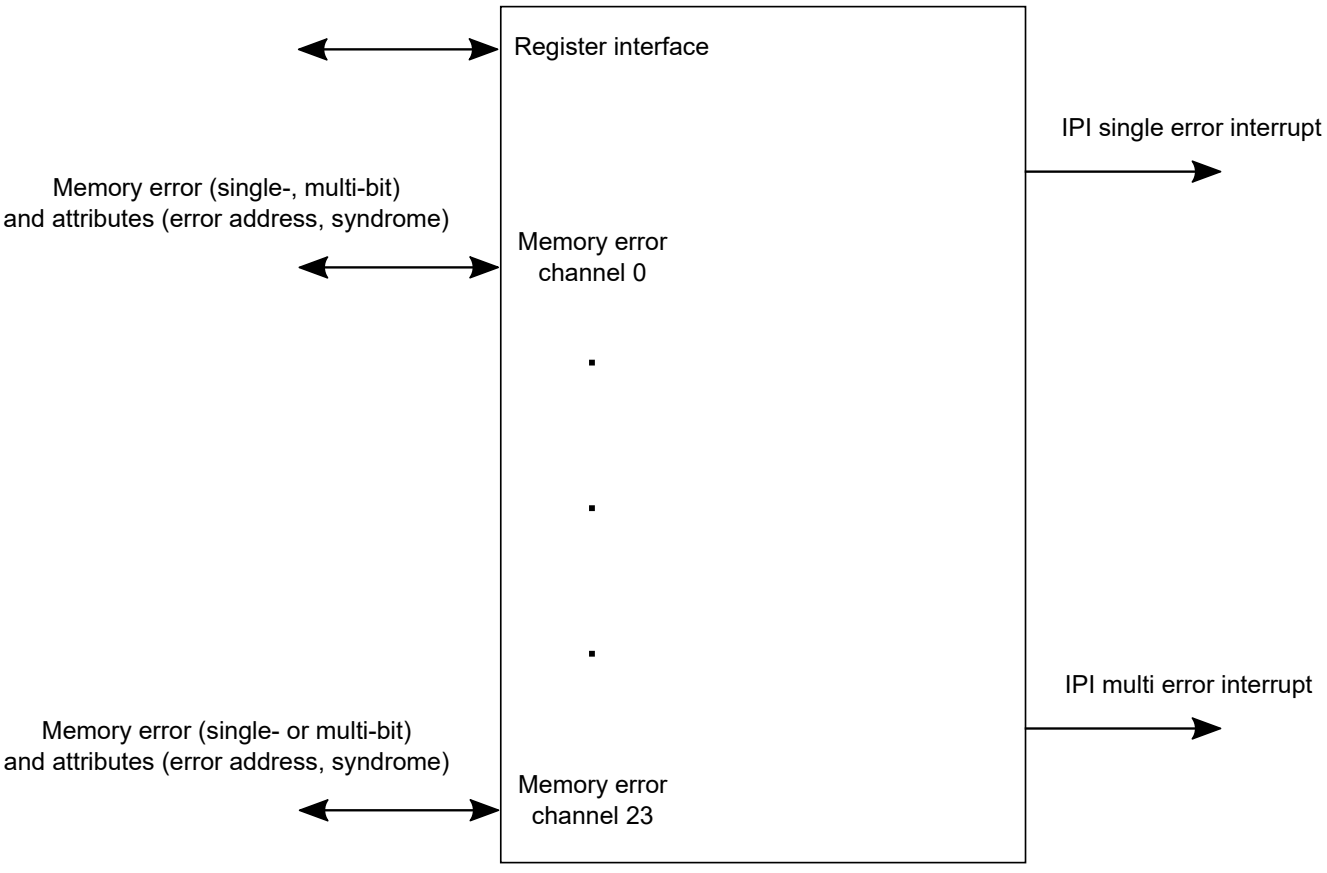

Figure 183. Block diagram

46.3 Functional description

46.3.1 Single-bit correction events

When a single-bit correction event on Memory *n* is detected, the ERM:

- Records the event by changing the value of the applicable Status Register bit SR*x*[SBC*n*] to 1.
- Increments the correctable error count value (until the counter reaches its maximum value): CORR_ERR_CNT*n*[COUNT].
- Records the corresponding access address that initiated the event in the Memory *n* Error Address Register: EAR*n* (if this register is present for the channel).
- Stores the corresponding ECC syndrome in the Memory *n* Error Syndrome Register: SYN*n* (if this register is present for the channel). This register identifies the bit position of the corrected data on single-bit data inversion.

The ERM holds event information only for the last reported event.

To clear the record of an event, write 1 to SR*x*[SBC*n*] to change its value to 0.

To reset the correctable error count value, write all zeros to CORR_ERR_CNT*n*[COUNT].

Optional interrupt notification for single-bit correction events

The ERM provides an option to generate an interrupt notification upon the report of a single-bit correction event. To enable single-bit correction interrupts for a channel:

1. To enable interrupt notification for single-bit correction events on Memory *n*, set CR*x*[ESCIE*n*] to 1.
2. Subsequently, when a single-bit correction event on Memory *n* is detected, the ERM:
   - Records the event and address, and stores the ECC syndrome as usual.
   - Additionally sends an interrupt notification corresponding to the event.
3. To clear both the record of an event and the corresponding interrupt notification, write 1 to SR*x*[SBC*n*] to change its value to 0.

46.3.2 Non-correctable error events

When a non-correctable ECC error event on Memory *n* is detected, the ERM:

- Records the event by changing the value of the applicable Status Register bit: SR*x*[NCE*n*] to 1.
- Records the corresponding access address that initiated the event in the Memory *n* Error Address Register: EAR*n* (if this register is present for the channel).
- Stores the corresponding ECC syndrome in the Memory *n* Error Syndrome Register: SYN*n* (if this register is present for the channel).
  - In the event of a non-correctable address bit inversion, SYN*n* identifies the pertinent address bit position.
  - In the event of a non-correctable, multi-bit data inversion, the syndrome value does not provide any additional diagnostic information.

The ERM holds event information only for the last reported event.

To clear the record of an event, write 1 to SR*x*[NCE*n*] to change its value to 0.

Optional interrupt notification for non-correctable error events

The ERM provides an option to generate an interrupt notification upon the report of a non-correctable ECC event. To enable non-correctable error interrupts for a channel:

1. To enable interrupt notifications for non-correctable error events on Memory *n*, set CR*x*[ENCIE*n*] to 1.
2. Subsequently, when a non-correctable error event on Memory *n* is detected, the ERM:
   - Records the event and address and stores the ECC syndrome as usual.
   - Additionally sends an interrupt notification corresponding to the event.
3. To clear both the record of an event and the corresponding interrupt notification, write 1 to SR*x*[NCE*n*] to change its value to 0.

NOTE

Parity errors can be mapped to non-correctable errors where error attributes like SYNDROME, ADDRESS are not provided.

46.4 Initialization

For each ERM channel supporting memory with ECC, prepare the corresponding memory array before enabling ERM interrupts about errors for that memory.

1. Initialize the memory to a known value so that the correct corresponding ECC codeword is stored.
2. During the memory's initialization, if the ERM captures information about any ECC error event, clear the corresponding SR*x*[SBC*n*] or SR*x*[NCE*n*] field that stores the record of the event.

3. Program the applicable CR*x*[ESCIE*n*] and CR*x*[ENCIE*n*] fields to enable ERM interrupts as desired.

46.5 ERM register descriptions

You can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an error termination:

- In user mode
- Using non-32-bit access sizes

Based on the design implementation, the following XFR error behavior is evident at the IPS interface.

- Within the ERM memory map, an XFR error is evident at reserved addresses from location 20h to FFh.
- No XFR error is evident at reserved addresses in memory spaces allocated to each channel. For example: For channel 0, for read/write accesses to reserved address 10Ch, the XFR error is 0.
- For accesses to locations beyond the addresses allocated for the final channel, the XFR error is 1.

NOTE

- See the chip-specific ERM information at the beginning of this chapter for details on Memory channel mapping.
- To access the channel registers, corresponding memory channel clock must be enabled.

46.5.8 ERM Memory a Error Address Register (EAR0 - EAR23)

Offset

Register	Offset
EAR0	100h
EAR1	110h
EAR10	1A0h
EAR11	1B0h

Table continues on the next page...

Table continued from the previous page...

Register	Offset
EAR12	1C0h
EAR13	1D0h
EAR14	1E0h
EAR15	1F0h
EAR16	200h
EAR17	210h
EAR18	220h
EAR19	230h
EAR20	240h
EAR21	250h
EAR22	260h
EAR23	270h

Function

Each ERM Memory n Error Address Register is a 32-bit register for capturing the address of the last ECC event in Memory*n*, where*n* denotes the memory channel. Any attempted write to EAR*n* is ignored.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ERM_0	EAR0–EAR1 EAR10–EAR19	EAR20–EAR23
ERM_1	EAR10–EAR12 EAR16–EAR23	EAR0–EAR1 EAR13–EAR15

SYN18	224h
SYN19	234h
SYN20	244h
SYN21	254h
SYN22	264h
SYN23	274h

Function

The ERM Memory *n* Syndrome Register is a 32-bit register for capturing the calculated syndrome of the last ECC event on Memory*n*, where*n* denotes the memory channel. Any attempted write to SYN*n* is ignored. The syndrome value identifies the pertinent bit position on a correctable, single-bit data inversion or a non-correctable, single-bit address inversion. The syndrome value does not provide any additional diagnostic information on non-correctable, multi-bit inversions.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ERM_0	SYN0–SYN1 SYN10–SYN16	SYN18–SYN23
ERM_1	SYN10–SYN12 SYN16 SYN18–SYN23	SYN0–SYN1 SYN13–SYN15

Table continues on the next page...

Table continued from the previous page...

Register	Offset
CORR_ERR_CNT22	268h
CORR_ERR_CNT23	278h

Function

Each 32-bit ERM Memory *n* Correctable Error Count Register records the count value of the number of correctable ECC error events for Memory*n*, where*n* denotes the memory channel.

NOTE

Non-correctable errors are considered a serious fault, so the ERM does not provide any mechanism to count non-correctable errors. Only correctable errors are counted.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ERM_0	CORR_ERR_CNT0–CORR_ERR_CNT5 CORR_ERR_CNT6–CORR_ERR_CNT9 CORR_ERR_CNT10–CORR_ERR_CNT12 CORR_ERR_CNT13–CORR_ERR_CNT15 CORR_ERR_CNT16–CORR_ERR_CNT19	CORR_ERR_CNT20–CORR_ERR_CNT23

CORR_ERR_CNT20–CORR_ERR_CNT23	0000_0000h

Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Memory n Correctable Error Count For each correctable error event, the ERM increments this field's error count value until the counter reaches its maximum value FFh. COUNT value will stop when it reaches maximum value FFh and will not wrap even if additional errors occur. Read this field to determine the correctable error count value so far. Write all zeros to this field to reset the counter. Writing a non-zero value has no effect.

46.6 Glossary

ECC Error correction code

Chapter 47
Fault Collection and Control Unit (FCCU)

47.1 Chip-specific FCCU information

47.1.1 NCF description

There are total 16 NCF slots on FCCU.

Table 224. NCF description

Channel number	Source module (error type)
NCF[0]	M7 LS and Core LOCKUP
NCF[1]	Interconnect: all EDC bus gaskets;XBIC monitors and platform gaskets
NCF[2]	ECC errors: PRAMC; TCMs; Caches; eDMA; EDC after ECC (PRAMC); QSPI FLASHA ECC errors
NCF[3]	All Flash Errors: FMU;PFALSH;DCM Flash
NCF[4]	Voltage related errors: PMC 1.1V and 2.5V GnG;PAD overvoltage;sdadc and swg gng
NCF[5][1]	Debug and Test Monitoring; STCU faults
NCF[6]	Interrupt Monitor Error
NCF[7]	SW Notification
NCF[8]	DSPSS Error
NCF[9]	SAR_ADC Faults
NCF[10]	OMU Error
NCF[11]	M7 Permanent Lockstep Error
NCF[12]	eDMA Lockstep Error
NCF[13]	LFAST LVDS pad fault
NCF[14]	eTPU global exception
NCF[15]	Reserved

1. The fault would be raised if DBGPWRUP_REQ toggles while any core is in halted state. If this operation is expected, the application can ignore/disable such an NCF event.

47.1.2 Chip-boundary FCCU signals

Fault state is indicated to off-chip logic by FCCU via EOUT pins.

Table 225. FCCU EOUT error pins

FCCU signal	Chip signal
EOUT0	FCCU_ERR0
EOUT1	FCCU_ERR1

47.1.3 Clock frequency

Table 226. FCCU clocking

FCCU clock signal	Chip clock signal
CLKSAFE	FIRC_CLK
CLKPRIM	AIPS_PLAT_CLK

47.1.4 FOSU timer interval

The FCCU Output Supervision Unit (FOSU) module timer interval is determined by the value of FOSU_COUNT. On this chip, FOSU_COUNT is 0x69780.

47.1.5 Supported internal chip reactions

- The short functional reset discussed in this chapter is equivalent to the device functional reset.

The interrupts from FCCU to NVIC can be found in the interrupt map file attached to this document.

NOTE

After the completion of self-testing procedure via Self-Test Control Unit (STCU2), device reboots and FCCU also gets reset.

47.1.6 Supported FCCU EOUT fault output modes (protocols)

Only Bistable protocol of FCCU EOUT is supported on this device. Other protocols—Dual-Rail and Time-Switching mentioned in this chapter does not apply to this device.

47.1.7 Recommended reaction programming for faults

It is possible to upgrade or downgrade the reaction of the faults with respect to the recommended reaction as per the attached fault map file attached to this document.

1. In case the reaction is upgraded no issue is expected in the behavior.
2. In case the reaction is downgraded the reaction / functionality is not guaranteed.

NOTE

Whenever there is fault due to lockstep error, you must follow the below recommendation:

1. FCCU must generate Functional Reset as a part of the Lockstep Error Fault Reaction
2. The core upon re-booting must do following things (This needs to be taken care by SW itself):
    a. Initialize the TCM (as there may be a possibility that the TCM's might have got corrupted)
    b. Invalidate the cache (as there may be a possibility that the caches might have got corrupted)
3. Clear the FCCU Fault Status register
4. If the FCCU fault gets cleared, nothing to do further related to Fault handling (This means the LOCKSTEP error has been recovered).
5. If the FCCU lockstep error still persist, this means that the internal registers of the two cores are having different values. So to bring the two cores internal registers to the same value, one of the below two steps can be followed:
    a. Give Destructive Reset through SW to recover from lockstep. In this approach the FCCU will also get initialized and there will not be any further pending faults.
    b. Initialize those CM7 registers which are sitting on destructive/POR reset. After initializing those registers, clear the FCCU faults. If it gets cleared, then perfectly fine else provide a Destructive reset to recover.

47.1.8 Fault NCF latching scheme and DCM control bit to disable NCF

In S32K396, NCF list contains sixteen NCFs. Therefore, multiple NCFs of similar nature are ored and then connected as a single NCF to FCCU. Hence a new feature has been implemented to enable/disable each NCF which is in cone of single NCF reported to FCCU, using configuration registers in DCM (DCMRWD3, DCMRWD4, DCMRWD5, DCMRWD14, and DCMRWD15). Also, there are capturing status registers (DCMROD3. DCMROD4, DCMROD5, DCMROD6, and DCMROD7) which captures each NCF being ored. These status bits numbered and NCF disable option DCM R/W register bits are same but on different bank. Capture status bits are on Read only register while control NCF disable option bits on R/W register of DCM.

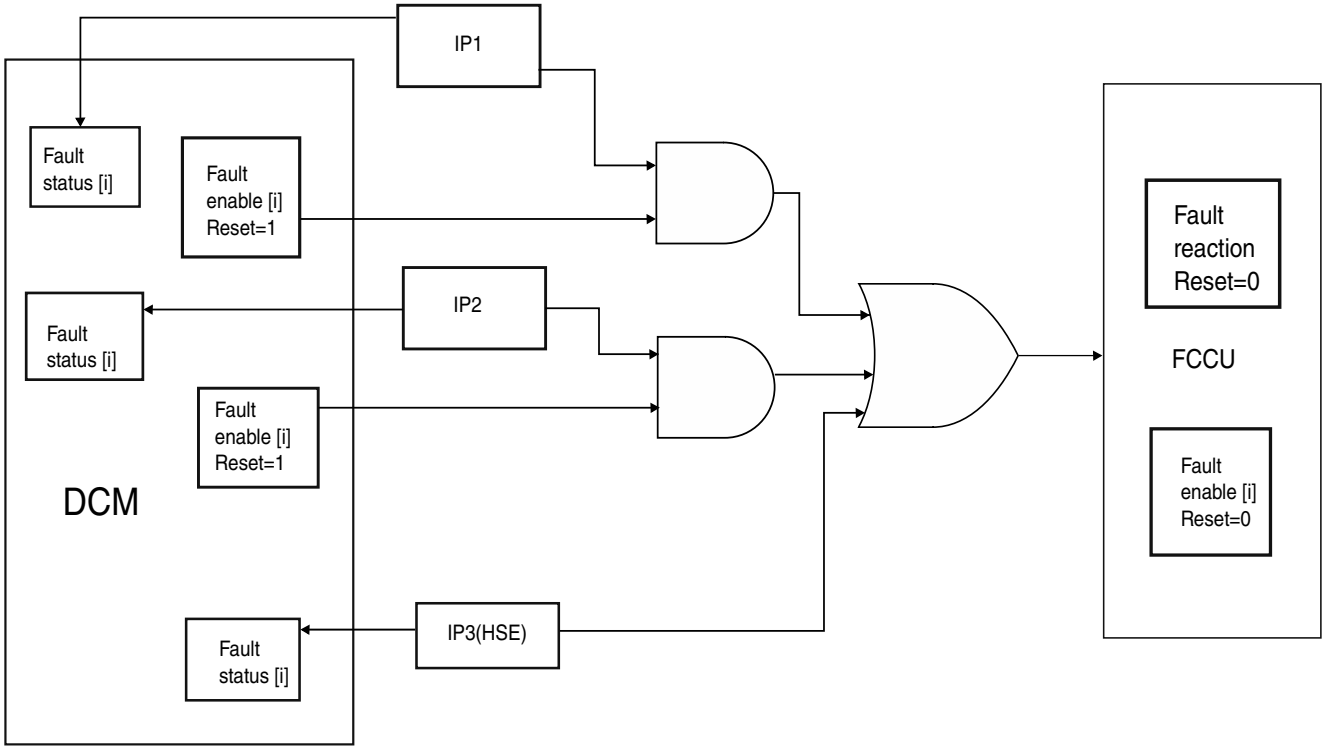

Figure 184. FCCU NCF handling architecture

DCM status registers will latch faults if triggered fakely from inside IP.

47.2 Overview

The FCCU provides a hardware interface to collect faults and to place the device into a safe state when a failure is detected in the device. No CPU intervention is requested for collection and control operations. FCCU offers a systematic approach to fault collection and control.

47.2.1 Block diagram

The following figure represents a top-level diagram of the FCCU module.

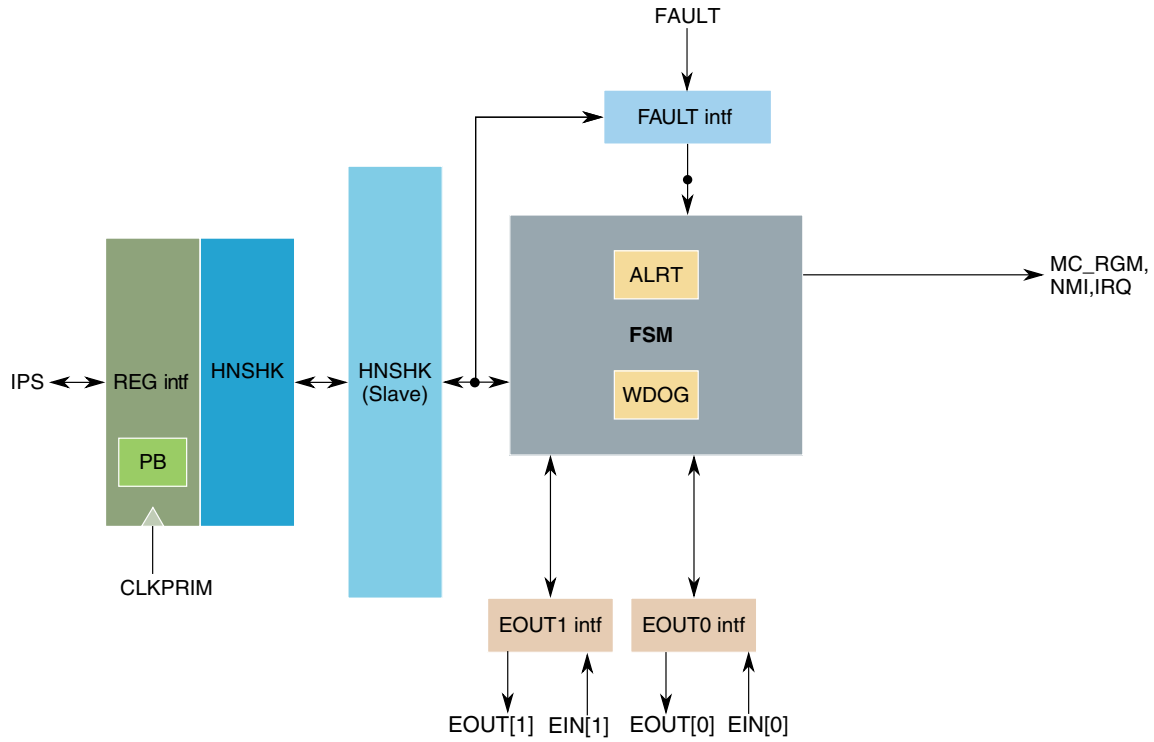

Figure 185. FCCU block diagram

This table describes the FCCU submodules.

Table 227. FCCU submodules

Submodule	Description
REG intf	Includes the register file, the IPS bus interface, the IRQ interface and the parity block (PB) for the configuration registers
HNSHK blocks (master and slave blocks)	Includes the FSM ability to support the handshake between the REG interface and the FSM unit because of the usage of two asynchronous clocks [CLKPRIM(module clock) and CLKSAFE(RC oscillator clock)]
FSM unit	Implements the main functions of FCCU. The FSM also includes the: • Watchdog timer (WDG) • Alarm timer (ALRT)
FAULT intf	Implements the interface for fault conditioning and management
EOUTx units	Implement the output stage to manage the EOUT interfaces

47.2.2 Features

The key features of the FCCU module are these:

- Management of non-critical faults
- HW or SW fault recovery management
- Fault collection from safety relevant modules on the device

- Fault injection (fake faults)
- Collection of test results
- Lockable configuration
  - Changes are only possible after entering the CONFIG state
  - Supports a transient and a permanent lock
  - Configuration changes observed by a watchdog timer
- Configurable fault control
- External reaction (FAULT state): EOUT signaling. Error indication via the pin(s) is controlled by FCCU.
- Internal chip reactions (ALARM state): interrupt request
- Configurable internal chip reactions for each NCF (FAULT state):
  - Short functional reset request pulse
  - NMI
  - No reaction
  - IRQ
- In Bi-Stable operational mode, one of the EOUT signals is high to indicate an OK operational state of FCCU.This is not true in case the error out protocol is configured to be a toggling protocol (for example, in Dual-Rail and Time-Switching operation modes).
- After power on, the EOUT signals have high impedance.[4] They indicate an operational state only after the software configures them.
- In case of a failure event or on software request for error pin indication, the pin(s) are set to faulty state for a minimum time T_{min} (see DELTA_T[DELTA_T]), even if the software tries to release it before (for the case of error pin configured in Bi-Stable mode only).

The self-checking procedure checks the FCCU circuitry at the start up. The FCCU is operational with the default configuration immediately after the completion of the self-checking procedure. Internal (short functional reset request pulse, interrupt request) and external (EOUT signaling) reactions are statically defined or programmable. The default configuration can be modified only in the Configuration (CONFIG) state. FCCU is designed to function when CLKPRIM is faster than the CLKSAFE clocks.

47.3 Functional description

47.3.1 Definitions

In general, the following definitions are applicable for fault management:

- HW recoverable fault: The fault indication is a level-sensitive signal that remains asserted until the fault cause is deasserted. That is, if logical 0 on the fault signal indicates fault, then the status flags are valid as long as the fault line stays at 0. The status is automatically cleared when the fault signal goes to 1. Typically the fault signal is latched external to the FCCU in the module where the fault occurred. The FCCU state transitions are consequently executed on the state changes of the input fault signal. No SW intervention in the FCCU is required to recover the fault condition.
- SW recoverable fault: The fault indication is a signal asserted without a defined time duration. The fault signal is latched in the FCCU. The fault recovery is executed following a SW recovery procedure (status/flag register clearing).

HW recoverable is an option to exclude the handling of error source/s by FCCU management SW, in case it is known that the fault is recoverable by itself when the fault condition is corrected.

For details related to reset interface, see the reset interface section in the chip reference manual.

[4] Actual value depends on device-specific setting at pad level.

47.3.2 FSM description

The functionality of FCCU is depicted by the FSM state diagram (see Figure 186).

FCCU has four states that are identified with the following meaning:

- CONFIG: Used only to modify the configuration of FCCU from its default. A subset of the FCCU registers, dedicated to define the FCCU configuration (global configuration, reactions to fault, timeout, non-critical fault masking) can be accessed in write mode only in the CONFIG state.

  The CONFIG state is accessible only in the NORMAL state and if the configuration is not locked. A permanent configuration lock can be disabled by a reset that also resets the FCCU. The transient lock register is unlocked by writing BCh into it. FCCU gets transiently locked again if an invalid key is written into TRANS_LOCK[TRANSKEY] (that is, other than BCh). To lock FCCU for configuration, write FFh to PERMNT_LOCK[PERMNTKEY].

  After the release of reset, the state of the transient lock is locked, and the state of the permanent lock is unlocked.

  The locking feature only restricts the FSM movement into CONFIG state. After the user enters the CONFIG state and then tries to lock the configuration, the locking of configuration is effective only after FCCU moves to the NORMAL state; it will not be effective in the current CONFIG state.

  The CONFIG to NORMAL state transition can be executed by SW or automatically following a timeout condition of the watchdog. In case the timeout information and the SW request for state change to NORMAL appears at the same time, watchdog timeout has the priority and hence the configuration registers (those that are writable only in the CONFIG state) are reset to their default values. The movement to the NORMAL state is made.

  The incoming faults, occurring during the configuration phase (CONFIG state) are latched in order to process them when FCCU is moved to the NORMAL state, according to the new configuration.

  All pending faults that occur during the CONFIG state result in both of the following:

  — Highest-priority state transition

  — Interrupt generation (NMI or alarm IRQ)

  If the state transition occurs, it gives the reset reaction corresponding to the worst case based on all the faults (pending or non-pending faults) that occurred during the CONFIG state.

- NORMAL: This is FCCU's operating state when no faults are occurring. It is also the default state on the reset exit. Following state transitions occur on one of the following events:

  — Unmasked non-critical faults with the timeout disabled: FCCU moves to the FAULT state.

  — Unmasked non-critical faults with the timeout enabled: FCCU moves to the ALARM state.

  — Masked non-critical faults: FCCU stays in the NORMAL state.

- ALARM: FCCU moves into the ALARM state when an unmasked non-critical fault occurs and the timeout is enabled. Transition to the ALARM state goes along with an interrupt alarm, if enabled. By definition, this fault may be recovered within a programmable timeout period, before it generates a transition to the FAULT state. The timeout is reinitialized if FCCU enters the NORMAL state. The timeout restarts following the recovery from the FAULT state.

- FAULT: FCCU moves into the FAULT state when one of the following condition occurs:

  — Timeout related to a non-critical fault when FCCU is in the ALARM state

  — Unmasked non-critical faults with the timeout disabled

The transition from the NORMAL or ALARM to the FAULT state goes along with the generation of:

- Internal chip reaction—NMI interrupt (optional)
- External reaction—EOUT signaling (optional)
- Internal chip reaction—SW option: Soft reaction (Short functional reset request pulse if configured)
- Non Maskable Interrupt (NMI) is routed to all cores.

After moving to the FAULT state, if there is either a previous pending fault or a new fault for which NMI is enabled, NMI generation takes place.

Multiple faults can occur at the same time.

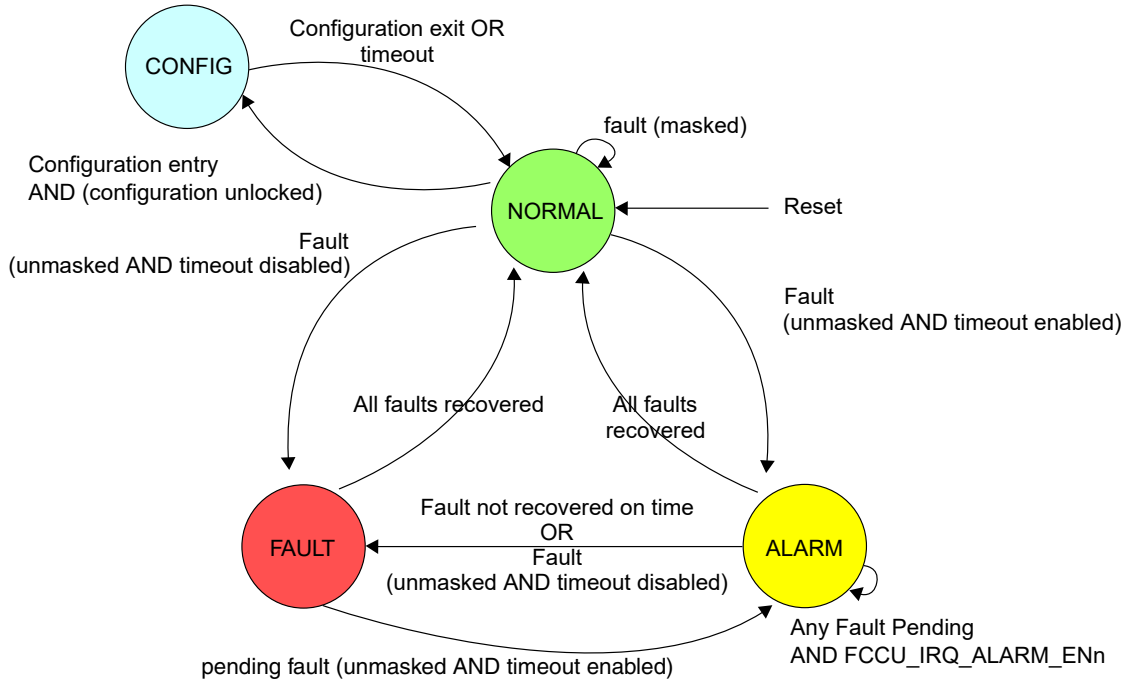

Figure 186. FCCU state diagram

47.3.3 Fault priority scheme and nesting

The FAULT state has a higher priority than the ALARM state in case of concurrent fault events (non-critical) that occur in the NORMAL state.

The ALARM to FAULT state transition occurs if a non-critical fault (unmasked and with timeout disabled) is asserted in the ALARM state.

The ALARM to NORMAL state transition occurs only if all the non-critical faults (including the faults that have been collected after the entry in the ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU remains in the ALARM state.

The FAULT to NORMAL state transition occurs only if all the non-critical faults (including the faults that have been collected after the entry in the FAULT/ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU moves to the ALARM state (if any non-critical fault is still pending and the timeout is not elapsed).

In general, no fault nesting is supported except for the non-critical faults that cause an ALARM to FAULT state transition. In this case, the NCF timer is stopped until the FAULT state is recovered. If FCCU is in the ALARM state and another fault occurs, which has its alarm timeout enabled, then the alarm timer shall not reload and shall not start again.

47.3.4 Fault recovery

The following timing diagrams describe the main use cases of FCCU in terms of fault events and related recovery.

A typical sequence related to non-critical fault management (ALARM state), see Figure 187 and Figure 188, is as follows:

1. Non-critical fault assertion
2. FCCU state transition (automatic): NORMAL to ALARM
   - Alarm interrupt request (if enabled)

- Timeout running

3. System state: RUN
4. Alarm interrupt management: fault recovery
   - FCCU state transition: ALARM to NORMAL

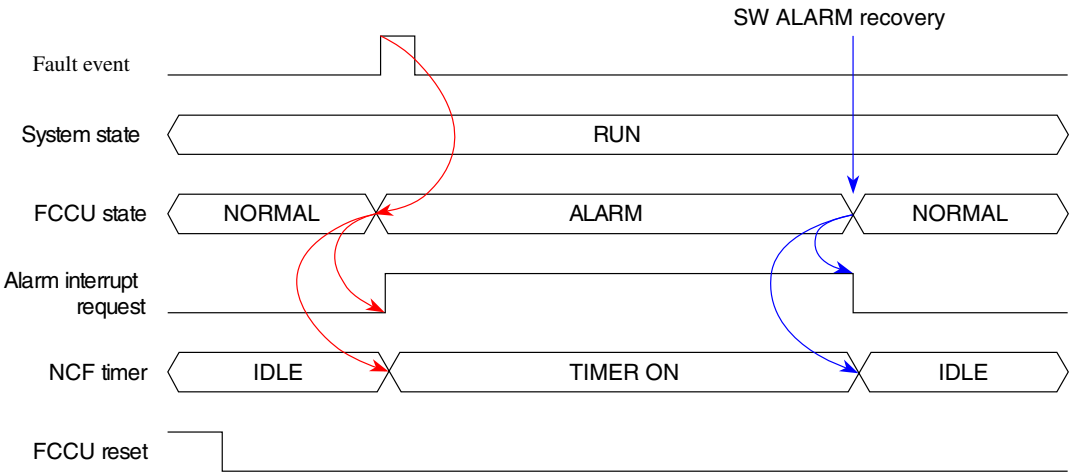

Figure 187. Non-critical fault (ALARM state) SW recovery

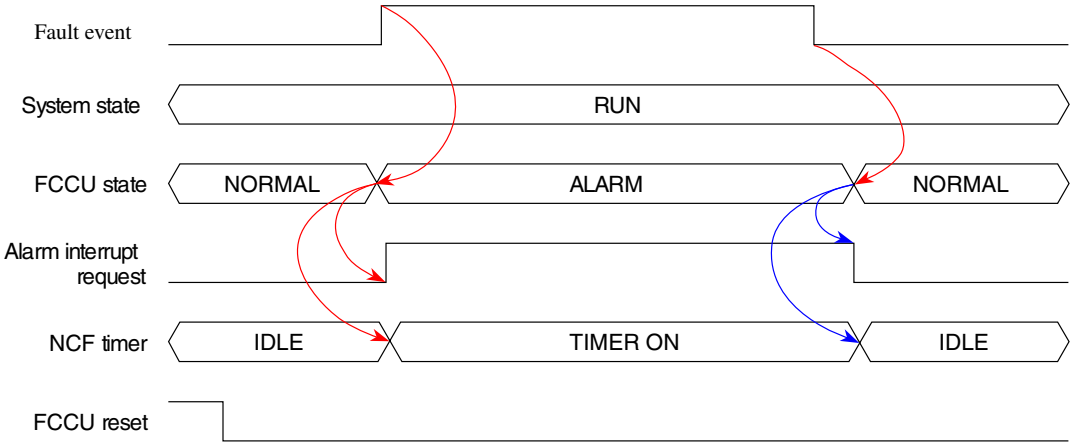

Figure 188. Non-critical fault (ALARM state) HW recovery

A typical sequence related to non-critical fault management (ALARM to FAULT state), see Figure 189, is as follows:

1. Non-critical fault assertion
2. FCCU state transition (automatic): NORMAL to ALARM
   - Alarm interrupt request (if enabled)
   - Timeout running
3. FCCU state transition (following the timeout trigger): ALARM to FAULT
   - NMI assertion (if enabled)
4. NMI interrupt management (if enabled)
   - Fault recovery (by software): FCCU state transition: FAULT to NORMAL

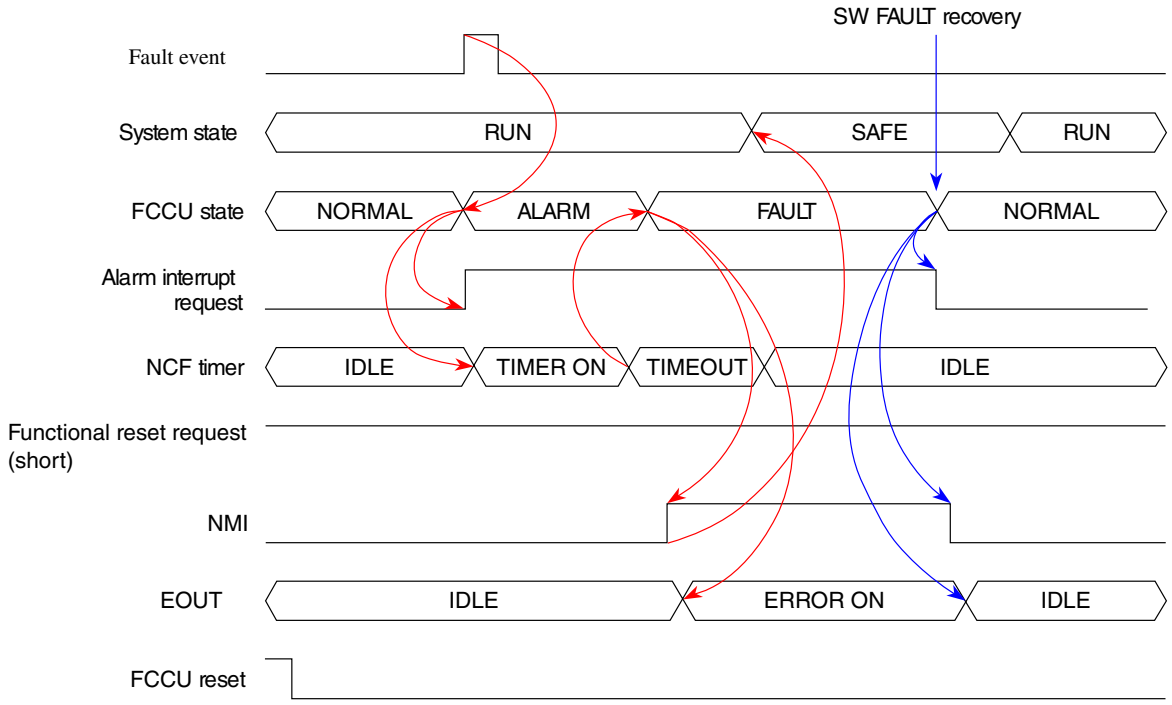

Figure 189. Non-critical fault (ALARM to FAULT state) recovery

47.3.5 EOUT interface

Introduction

You use the EOUT[1:0] signals to indicate FCCU's condition (or, for Fault-Toggle fault-output mode, faults only) to off-chip logic.

NOTE

For information on the availability and names of these FCCU signals on the boundary of this chip, see the chip-specific FCCU information.

The FCCU conditions

There are three FCCU conditions:

Condition	Description
Faulty	All of the following are true: • The fault-output (EOUT) timer is running (see How the fault-output (EOUT) timer works in Dual-Rail, Time-Switching, and Bi-Stable fault-output modes). • FCCU is in FAULT state.
Non-faulty	All of the following are true: • The fault-output (EOUT) timer is not running. • FCCU is in ALARM or NORMAL state.

Table continues on the next page...

Table continued from the previous page...

Condition	Description
Configuration	All of the following are true: • The fault-output (EOUT) timer is not running. • FCCU is in CONFIG state.

How the fault-output (EOUT) timer works in Dual-Rail, Time-Switching, and Bi-Stable fault-output modes

In Dual-Rail, Time-Switching, and Bi-Stable fault-output modes (FOM), FCCU starts the fault-output (EOUT) timer when all of the following are true:

- If the EOUT signals are in Bi-Stable FOM, and the EOUT signals are not programmed to be always low (CFG[FCCU_SET_CLEAR]).
- The EOUT timer is not already running.
- FCCU enters the FAULT state as the result of a fault.

When the fault-output (EOUT) timer is already running and a new fault occurs:

- If FCCU is in the CONFIG state: FCCU does not restart the EOUT timer.
- If FCCU is in the NORMAL or ALARM state:
  - And ALARM state is enabled for the fault (non-critical): FCCU enters (or remains in) the ALARM state but does not restart the EOUT timer.
  - And ALARM state is disabled for the fault (non-critical): FCCU enters the FAULT state and restarts the EOUT timer.
- If FCCU is in the FAULT state: FCCU restarts the fault-output (EOUT) timer.

FCCU stops and reinitializes the fault-output (EOUT) timer when all of the following are true:

- If the EOUT signals are in Bi-Stable fault-output mode (CFG[FOM]), and T_{min} (see DELTA_T[DELTA_T]) has expired.
- All faults that caused FCCU to enter or remain in the FAULT state since FCCU started the fault-output (EOUT) timer have been cleared, causing FCCU to return to the NORMAL state.

How the fault-output (EOUT) timer works in Fault-Toggle fault-output mode

In Fault-Toggle fault-output mode, FCCU initializes the fault-output (EOUT) timer with the value of T_{min} (see DELTA_T[DELTA_T]) and begins decrementing the timer when any of the following are true:

- FCCU enters the FAULT state as the result of a fault.
- In FAULT state, a fault occurs while the EOUT timer is 0 (idle).
- In FAULT state, a fault occurs while the EOUT timer is running because of a previous fault (also called a pending fault), and then in any state the EOUT timer reaches 0 (idle).

FCCU stops the EOUT timer when it reaches 0 (idle).

Prepare the EOUT signals to indicate FCCU's condition

- If the EOUT signals are in Bi-Stable or Fault-Toggle fault-output mode (CFG[FOM]), ensure that the EOUT signals are controlled by FCCU's FSM (CFG[FCCU_SET_CLEAR]).
- Ensure that the EOUT signals are active (CFG[FCCU_SET_AFTER_RESET]).

NOTE

If the EOUT signals are in Bi-Stable or Fault-Toggle fault-output mode, you must deactivate and then reactivate the EOUT signals (CFG[FCCU_SET_AFTER_RESET]) to correctly initialize them so they have opposite states.

More about the EOUT interface

Different fault-output modes (protocols) for the fault-output (EOUT) interface are supported (CFG[FOM]):

- Dual-Rail
- Time-Switching
- Bi-Stable
- Fault-Toggle

You can further configure the fault-output modes using the following attributes:

Attribute	Field	Setting used in the example diagrams and tables that follow
Configuration mode	CFG[CM]	Different
Switching mode	CFG[SM]	Slow
Polarity selection	CFG[PS]	For the faulty indication, EOUT1 is high, and EOUT0 is low.

EOUT frequency: This frequency is generated by dividing the CLKSAFE frequency by a fixed factor of 2^{18}.

$$EOUT_{freq} = \frac{CLKSAFE_{freq}}{2^{18}}$$

For example, with a CLKSAFE frequency of 16 MHz, this drives a signal of 61 Hz on EOUT.

The external monitor of the EOUT protocol should oversample the EOUT signals to synchronize periodically the external clock (used by the monitor) and CLKSAFE (which detects the edge transition of the EOUT protocol) in Dual-Rail or Time-Switching fault-output mode.

In case of a failure event or on software request for EOUT indication, the signal(s) are set to the faulty state for a minimum time (T_{min}), even if software tries to release it before. If software configures the error pins to OK(1), and if a fault comes trying to drive the pin to NOK(0), then priority is given to the fault indication and the error signals indicate NOK, such as an incoming fault is not masked even when software has set the error signal to high. Also, if the error signals are forced to low by software by writing to CFG[FCCU_SET_CLEAR], then the signals shall remain low (or high) for the entire duration of T_{min}. During the T_{min} by a non-software fault, the FCCU FSM moves independently of this signal state (low), and as soon as the timer expires, the pin behavior is dictated by the state in which the FSM finds itself in, and it is not possible to set the signals to OK by software moving FCCU to the CONFIG state, as long as this timer is running. No software intervention is needed to bring the signal from the low state.

Software can bring the pin back to OK state by clearing the faults and waiting for the T_{min} interval to expire, after which the FCCU automatically enters the NORMAL state and the error signal indicates OK.

In case another failure event happens within T_{min} after a first one, the T_{min} counter is restarted.

47.3.5.1 Dual-Rail protocol

Dual-Rail encoding is an alternate method for encoding bits. In contrast with classical encoding, where each signal carries a single-bit value, Dual-Rail encoded circuits use two wires to carry each bit. The encoding scheme is provided in Table 228 and the related timing diagram is shown in Figure 190 and Figure 191.

Table 228. Dual-Rail encoding

Condition	Reset phase3 indicator	EOUT[1:0]
Nonfaulty	0	Toggling between 01 and 10
	1	Retain same value on EOUT pins as present just before assertion of reset phase3 indicator (either 01 or 10) and no toggling
Faulty	0	Toggling between 00 and 11
	1	Retain same value on EOUT pins as present just before assertion of reset phase3 indicator (either 00 or 11) and no toggling
Reset	0	High-impedance (no toggling)[1]
	1	
Configuration (CFG[CM] is 1 and CFG[FCCU_SET_AFTER_RESET] is 0)		High-impedance (no toggling)[2]
Configuration (CFG[CM] is 1 and CFG[FCCU_SET_AFTER_RESET] is 1)		Toggling between 10 and 01

1. Final value depends on the chip setting at pad level.
2. Ensure that the EOUT signals are active (CFG[FCCU_SET_AFTER_RESET]); otherwise, the EOUT signals stay in a high-impedance state after reset lifts.

As long as FCCU is in the Normal or Alarm (non-faulty) state, output will show "nonfaulty" signal. Output pins EOUT[0:1] will toggle between 01 and 10 with EOUT frequency (See EOUT frequency).

NOTE

Figure 190 and Figure 191 are formatted to display the behavior in all four conditions (reset, nonfaulty, faulty, and configuration), not to imply transitions between one condition and another. In particular, a transition from the faulty condition to the configuration condition is not possible.

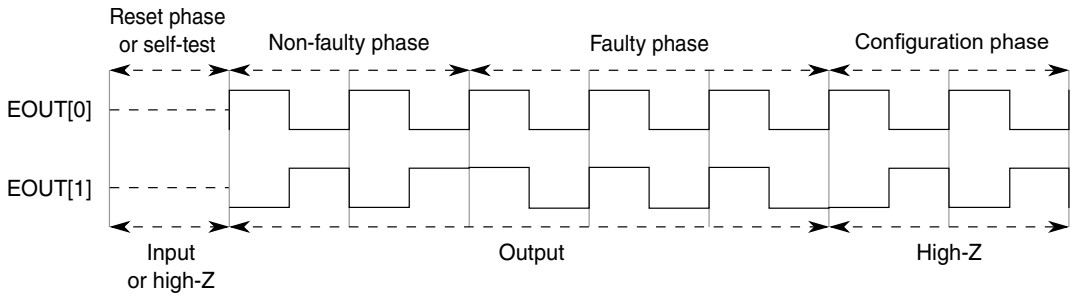

Figure 190. Dual-Rail protocol (slow-switching mode)

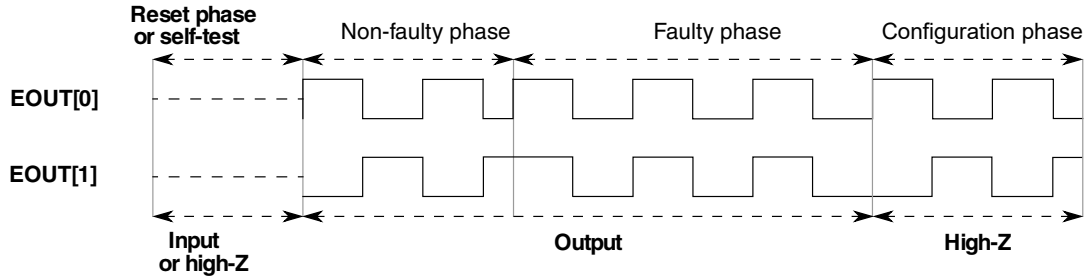

Figure 191. Dual-Rail protocol (fast-switching mode)

47.3.5.2 Time-Switching protocol

The encoding scheme is provided in Table 229 and the related timing diagram is shown in Figure 192.

Table 229. Time-Switching encoding

Condition	Reset phase3 indicator	EOUT[1:0] (CFG[PS] is 0)	EOUT[1:0] (CFG[PS] is 1)
Non-faulty	0	Toggling between 01 and 10	Toggling between 10 and 01
	1	Keep the current state of EOUT same as just before assertion of reset phase3 indicator (either 01 and 10) and no toggling	Keep the current state of EOUT same as just before assertion of Reset phase3 indicator (either 01 and 10) and no toggling
Faulty	0	Static 10	Static 01
	1	Static to 10 or 01 as per CFG[PS]	Static to 10 or 01 as per CFG[PS]
Reset	0	High-impedance (no toggling)[1]	High-impedance (no toggling)
	1		
Configuration (CFG[CM] is 1 and CFG[FCCU_SET_AFTER_RESET] is 0)		High-impedance (no toggling)[2]	High-impedance (no toggling)
Configuration (CFG[CM] is 1 and CFG[FCCU_SET_AFTER_RESET] is 1)		Toggling between 10 and 01	Toggling between 10 and 01

1. Final value depends on device specific settings at pad level.
2. Ensure that the EOUT signals are active (CFG[FCCU_SET_AFTER_RESET]); otherwise, the EOUT signals stay in a high-impedance state after reset lifts.

As long as FCCU is in the NORMAL or ALARM (non-faulty) state, outputs will show "non-faulty" signal. Output pins #0, #1 will toggle between 01 and 10 with EOUT frequency (See EOUT frequency).

Figure 192 is formatted to display the behavior in all four conditions (reset, non-faulty, faulty, and configuration), not to imply transitions between one condition and another. In particular, a transition from the faulty condition to the configuration condition is not possible.

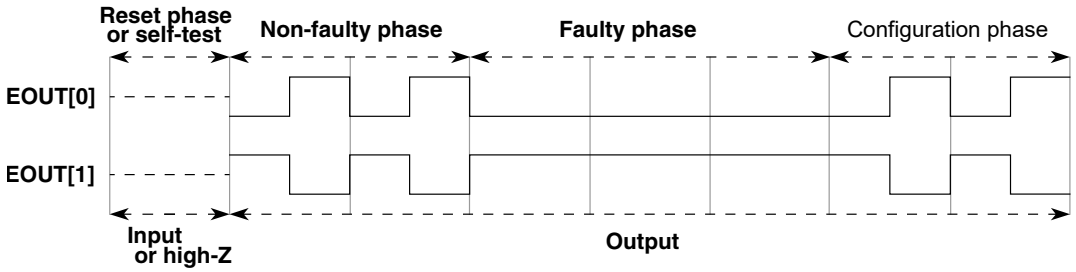

Figure 192. Time-Switching protocol

47.3.5.3 Bi-Stable protocol

The encoding scheme is provided in Table 230 and the related timing diagram is shown in Figure 193.

Table 230. Bi-Stable encoding

Condition	EOUT[1:0] (CFG[PS] is 0)	EOUT[1:0] (CFG[PS] is 1)
Non-faulty	Static 01	Static 10
Faulty	Static 10	Static 01
Reset	High-impedance (no toggling)[1]	High-impedance (no toggling)
Configuration (CFG[CM] is 1 and CFG[FCCU_SET_AFTER_RESET] is 0)	High-impedance (no toggling)[2]	High-impedance (no toggling)
Configuration (When CFG[CM] is 1 and CFG[FCCU_SET_AFTER_RESET] is 1)	Static 01	Static 10

1. Final value depends on device specific settings at pad level.
2. Ensure that the EOUT signals are active (CFG[FCCU_SET_AFTER_RESET]); otherwise, the EOUT signals stay in a high-impedance state after reset lifts.

NOTE

Figure 193 is formatted to display the behavior in all four conditions (reset, non-faulty, faulty, and configuration), not to imply transitions between one condition and another. In particular, a transition from the faulty condition to the configuration condition is not possible.

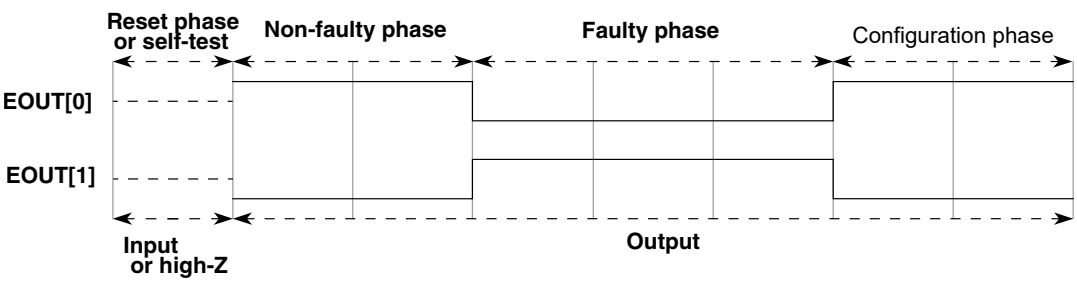

Figure 193. Bi-Stable protocol

47.3.5.4 Fault-Toggle protocol

The Fault-Toggle protocol uses the EOUT signals to indicate only the occurrences of faults, not FCCU's condition like the other protocols. In Fault-Toggle fault-output mode, when controlled by the FSM (CFG[FCCU_SET_CLEAR]), the EOUT signals:

- Have opposite states
- Toggle their states to indicate a fault and then maintain those new states for at least T_{min} (see DELTA_T[DELTA_T]), after which they are free to toggle to indicate another fault

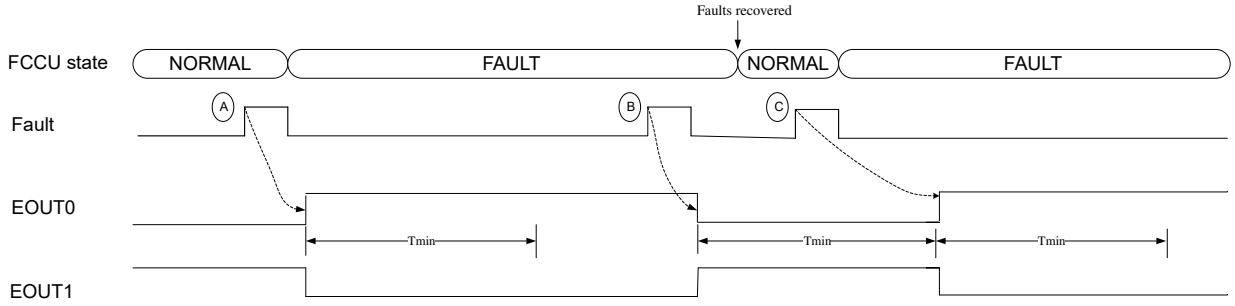
FCCU uses the fault-output (EOUT) timer to measure T_{min}. For more information, see How the fault-output (EOUT) timer works in Fault-Toggle fault-output mode.

The EOUT polarity selection (CFG[PS]) determines the initial states of the EOUT signals, which FCCU applies after you deactivate and then reactivate the EOUT signals (CFG[FCCU_SET_AFTER_RESET]).

If two or more faults occur while the EOUT timer is running, then the EOUT signals toggle only once after the EOUT timer reaches zero (idle). In other words, FCCU can pipeline only one fault.

Note that FCCU does not toggle the EOUT signals in CONFIG state. FCCU toggles the EOUT signals only when FCCU enters the FAULT state or when a fault occurs in the FAULT state.

Example 1



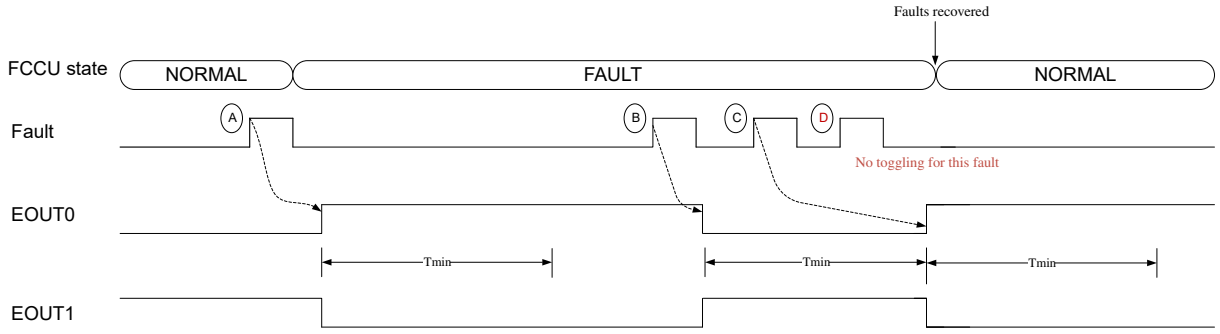
Stage	Description
1	A fault source indicates fault A to FCCU.
2	FCCU enters the FAULT state.
3	FCCU toggles the EOUT signals in response to fault A, initializes the fault-output (EOUT) timer with the value of T_{min} (see DELTA_T[DELTA_T]), and begins decrementing the timer.
4	A fault source indicates fault B to FCCU while FCCU is still in the FAULT state.
5	The EOUT timer has already reached 0 (idle), so FCCU toggles the EOUT signals in response to fault B, initializes the EOUT timer with the value of T_{min}, and begins decrementing the timer.
6	The source (for hardware-recoverable faults) and software (for software-recoverable faults) recovers the faults.
7	FCCU enters the NORMAL state.

Table continues on the next page...

Table continued from the previous page...

Stage	Description
8	A fault source indicates fault C to FCCU.
9	The EOUT timer has not yet reached 0 (idle), so FCCU leaves the EOUT signals as they are.
10	When the EOUT timer reaches 0 (idle), FCCU toggles the EOUT signals in response to fault C, initializes the EOUT timer with the value of T_{min}, and begins decrementing the timer.

Example 2



Stage	Description
1	A fault source indicates fault A to FCCU.
2	FCCU enters the FAULT state.
3	FCCU toggles the EOUT signals in response to fault A, initializes the fault-output (EOUT) timer with the value of T_{min} (see DELTA_T[DELTA_T]), and begins decrementing the timer.
4	A fault source indicates fault B to FCCU while FCCU is still in the FAULT state.
5	The EOUT timer has already reached 0 (idle), so FCCU toggles the EOUT signals in response to fault B, initializes the EOUT timer with the value of T_{min}, and begins decrementing the timer.
6	A fault source indicates fault C to FCCU while FCCU is still in the FAULT state.
7	The EOUT timer has not yet reached 0 (idle), so FCCU leaves the EOUT signals as they are. Fault C is now *pending*.

Table continues on the next page...

Table continued from the previous page...

Stage	Description
8	A fault source indicates fault D to FCCU while FCCU is still in the FAULT state. (FCCU can pipeline only one fault, so FCCU ignores fault D.)
9	The EOUT timer has not yet reached 0 (idle), so FCCU leaves the EOUT signals as they are.
10	When the EOUT timer reaches 0 (idle), FCCU toggles the EOUT signals in response to fault C, initializes the EOUT timer with the value of T_{min}, and begins decrementing the timer. FCCU never toggles the EOUT signals in response to fault D because FCCU can pipeline only one fault.

47.3.6 Modes of operation

47.3.6.1 Put FCCU in the NORMAL state

47.3.6.1.1 Introduction

You put FCCU in the NORMAL state to save changes to the configuration, and to allow FCCU to enter the ALARM or FAULT state when a fault occurs on an enabled fault channel.

47.3.6.1.2 About putting FCCU in NORMAL state

When putting FCCU in the NORMAL state:

- If you attempt to lock the configuration while FCCU is in CONFIG state, FCCU does not actually lock the configuration until FCCU leaves CONFIG state—that is, either you put FCCU in the NORMAL state, or FCCU puts itself in the NORMAL state because the Configuration-state timeout interval (CFG_TO[TO]) expires.
- After you permanently lock the configuration, you must reset FCCU before you can put FCCU in the CONFIG state.

47.3.6.1.3 Put FCCU in the NORMAL state

1. Check the FCCU status (STAT[STATUS]).
   - If the FCCU status is NORMAL, go to step 6.
   - If the FCCU status is CONFIG, go to step 2.
   - If the FCCU status is ALARM or FAULT, go to step 4.
2. Run the OP2 operation (see Run an operation).
3. Check the operation status (CTRL[OPS]).
   - If the operation status is Successful, FCCU is in the NORMAL state. Go to step 6.
   - If the operation status is Aborted, go to step 2.
4. Recover all faults (see Fault recovery).
5. Go to step 1.
6. Lock the configuration if you want to prevent any changes to it:

- To require a key to unlock the configuration, from Supervisor mode, temporarily lock the configuration (TRANS_LOCK[TRANSKEY]).
- To require a reset of FCCU to unlock the configuration, from Supervisor mode, permanently lock the configuration (PERMNT_LOCK[PERMNTKEY]).

  The configuration is permanently locked until FCCU is reset.

47.3.6.2 Manage faults

47.3.6.2.1 Introduction

After saving changes to the configuration, you are ready to use FCCU to manage faults.

47.3.6.2.2 Determine if there are any unrecovered non-critical faults

Check the unrecovered-fault indicators for the non-critical faults (NCF_Sa[NCFSn]).

47.3.6.2.3 Recover a software-recoverable non-critical fault

1. Resolve the source of the software-recoverable non-critical fault.
2. Unlock the NCF_Sa registers (NCFK[NCFK]) using a 32-bit write.
3. Initiate clearing of the unrecovered-fault indicator for the software-recoverable non-critical fault (NCF_Sa[NCFSn]) using a 32-bit write.

   FCCU initiates the OP12 operation.

   NOTE

   If you want to clear multiple unrecovered-fault indicators and those indicators reside in different NCF_Sa registers, you must perform steps 2 and 3 for each individual register.
4. Check the operation status (CTRL[OPS]).
   - If the operation status is In Progress, go to step 4.
   - If the operation status is Successful, go to step 5.
   - If the operation status is Aborted, go to step 2.
5. Check the unrecovered-fault indicator for the software-recoverable non-critical fault (NCF_Sa[NCFSn]).
   - If the indicator indicates no unrecovered fault, the fault has been recovered. Stop.
   - If the indicator still indicates an unrecovered fault, go to step 2.

47.3.6.2.4 Clear the freeze-status indicators

1. Run the OP13 operation (see Run an operation).
2. Check the operation status (CTRL[OPS]).
   - If the operation status is Successful, stop .
   - If the operation status is Aborted, go to step 1.

47.3.6.3 Run operations

47.3.6.3.1 Introduction

You run operations to perform actions such as putting FCCU in the CONFIG state or setting the operation status to Idle. For a complete list of operations you can run, see CTRL[OPR].

47.3.6.3.2 About running operations

When running operations:

- FCCU ignores any operations initiated while the operation status is In Progress.
- Certain operations must be unlocked before you can initiate them. After you initiate them, they are locked again.

47.3.6.3.3 Run an operation

1. Check the operation status (CTRL[OPS]).
2. Go to step 1 if the operation status is In Progress.
3. Unlock the operation (CTRLK[CTRLK]) using a 32-bit write, if the operation must be unlocked before you can initiate it.

   NOTE

   The Control Key (CTRLK) register used in this step and the Control (CTRL) register used in the next step must be written with consecutive instructions. Do not use read-modify-write instructions, such as bit-field instructions, to modify these registers.

4. Initiate the operation (CTRL[OPR]) using a 32-bit write.
5. Check the operation status (CTRL[OPS]).
6. Go to step 5 if the operation status is In Progress.

The operation status is now Idle (OP15 only), Aborted, or Successful.

47.3.7 FOSU

The FOSU provides a supervision of the primary fault notification path by analyzing FCCU's behavior for correctness. It waits for any reaction of the FCCU in a fixed time window after a fault is signaled.

The intention of the FOSU is to provide a secondary fault reaction path in most cases when the FCCU fails but not to needlessly propagate a fault which is already handled by the FCCU in a full chip reset. Only a failed primary fault reaction (that is, FCCU's failure) is a reason for the secondary reaction to take over (and generate a destructive reset request).

There is a 'do nothing' input coming from FCCU which indicates that the FCCU is programmed for no reaction for ALL FAULTS. It is a "static" input in the sense that it does not change after FCCU configuration. The FOSU masks the incoming faults with the 'do nothing' control from the FCCU, meaning that a fault is not captured by the FOSU if the 'do nothing' signal is asserted (that is, a disabled fault). There is no minimum pulse width requirement on the fault indication other than what is required by the technology, which is the same as that of the FCCU. FOSU does not monitor FCCU for the case of faults occurring during the CONFIG state.

The FOSU contains a timer with a duration of FOSU_COUNT, driven by CLKSAFE. The timer is initialized and started on any captured, enabled fault. While the timer is running, any subsequent captured fault will neither restart nor reinitialize the timer. The timer is stopped when the FCCU shows any of the following reactions (the FOSU does not check whether the reaction is the configured one for the faults which occurred):

- Reset: short functional reset
- IRQ (triggered by ALARM state)
- NMI
- Error out triggered (by FCCU or by SW)

When the timer is stopped, the fault capture logic is cleared to ensure that the timer is not restarted because of faults still 'stuck' in the capture logic. The timer is then restarted by the next new failure indication. When the timer expires, the FOSU's failure indicator output is asserted after it ensures that the fault is enabled and the static "fccu program to do nothing" signal is deasserted. This is because FCCU uses settings after it exits CONFIG state, even if fault captured before the exit.

The FOSU's failure indicator output is connected to one of the MC_RGM's 'destructive' reset inputs, so its assertion will cause a reset sequence to be initiated starting at DEST0. The FOSU module is reset with the same reset as is used by the FCCU. When

this reset is asserted, the FOSU's capture logic is cleared, its timer is kept stopped and in a non-expired state, and its failure indicator output is deasserted.

NOTE

FOSU is triggered on assertion of enabled fault. In case the triggering fault is disabled, FOSU times out without reaction.

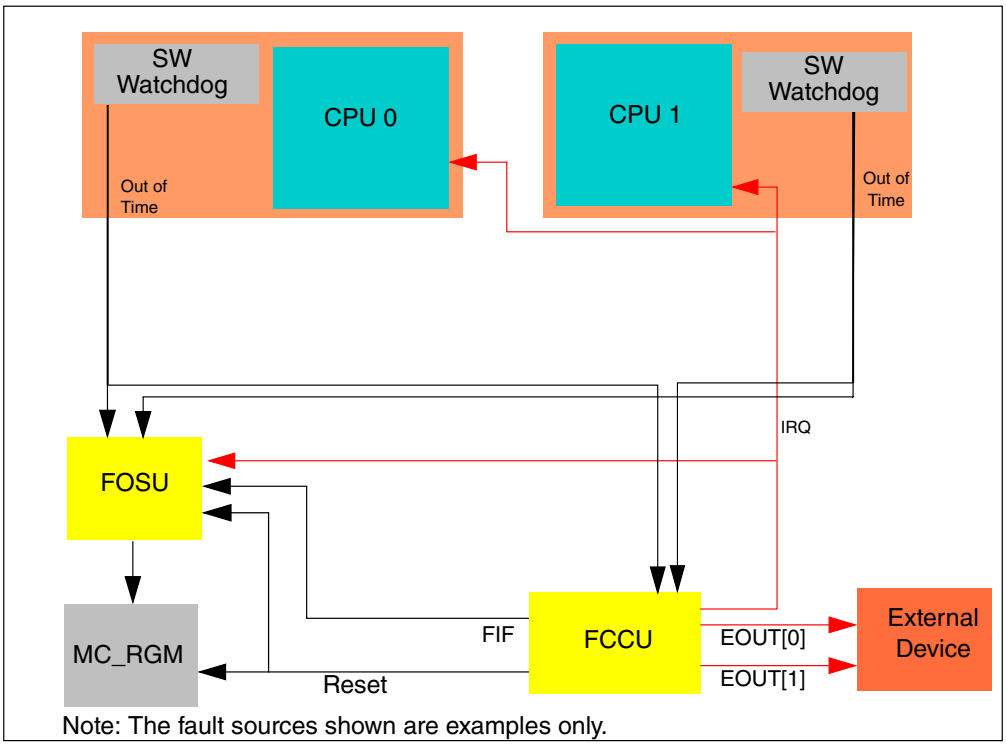


Figure 194. FOSU connections to the FCCU and MC_RGM

47.3.8 Clocking

This module has no clocking considerations.

47.3.9 Interrupts

This module has no interrupts.

47.4 External signals

This table describes the signals on the boundary of FCCU.

Signal	Direction	Function	Sensitivity	Clock
Clock and reset				
CLKPRIM	Input	Primary Clock—supplies the primary clock.	Rising edge	—

Table continues on the next page...

Table continued from the previous page...

Signal	Direction	Function	Sensitivity	Clock
CLKSAFE0	Input	Safe Clock 0—supplies one of two 48 MHz clocks for use by various redundant submodules. This clock and CLKSAFE1 are often referred to as the same clock (CLKSAFE).	Rising edge	—
CLKSAFE1	Input	Safe Clock 1—supplies one of two 48 MHz clocks for use by various redundant submodules. This clock and CLKSAFE0 are often referred to as the same clock (CLKSAFE).	Rising edge	—
Fault interface				
NCF[15:0]	Input	Non-critical Fault Channels—receive indications of non-critical faults from various sources. See the fault map file attached to this document.	Programmable	Asynchronous
EOUT interface				
EIN[1:0]	Input	Error Inputs—provide the mechanism for FCCU to capture the states that off-chip logic drives on the associated EOUT[1:0] signals. FCCU captures the states in the EINOUT[EIN1] and EINOUT[EIN0] fields.	—	Asynchronous
EOUT[1:0]	Output	Error Outputs—indicate FCCU's condition (faulty, nonfaulty, or configuration) (or, for Fault-Toggle fault-output mode, faults only) to off-chip logic.	Programmable	CLKSAFE0, CLKSAFE1
FOSU interface				
FIF	Output	FCCU In Fault—indicates to the FOSU module, if present, that FCCU is recognizing a fault. FCCU asserts and then deasserts this signal in two cases: *Case 1* When the EOUT signals are programmed to be always low (CFG[FCCU_SET_CLEAR]), FCCU asserts this signal until the EOUT	High	CLKSAFE0, CLKSAFE1

Table continues on the next page...

Table continued from the previous page...

Signal	Direction	Function	Sensitivity	Clock
		signals are programmed not to be always low. *Case 2* When the EOUT signals are programmed not to be always low (CFG[FCCU_SET_CLEAR]), FCCU asserts this signal when all of the following are true: • FCCU enters the FAULT state as the result of a fault. • If the fault is a non-critical fault, the associated EOUT_SIG_ENa[EOUTENn] field is set to enabled. FCCU deasserts this signal when FCCU leaves the FAULT state.		
Interrupt interface				
NMIOUT	Output	Non-maskable Interrupt Output—Sends a non-maskable interrupt request to the processor core or cores when FCCU enters the FAULT state as the result of a non-critical fault for which NMI is enabled as the reaction (NMI_ENa[NMIENn]).	Low	CLKPRIM

47.5 Initialization

47.5.1 Prepare FCCU for configuration

47.5.1.1 Introduction

You prepare FCCU for configuration by first configuring the CONFIG state and then putting FCCU in that state.

47.5.1.2 About preparing FCCU for configuration

When preparing FCCU for configuration, keep the following in mind:

- To put FCCU in CONFIG state, FCCU must be in NORMAL state.
- After FCCU is reset, the configuration is temporarily locked. You must temporarily unlock the configuration before you can put FCCU in the CONFIG state.
- When FCCU is in the CONFIG state, FCCU does not actually save the changes you make to the configuration. To save changes to the configuration, you must manually put FCCU in the NORMAL state. If FCCU automatically leaves the CONFIG state and enters the NORMAL state because the Configuration-state timeout interval (CFG_TO[TO]) expires (called a Configuration-state timeout), FCCU changes the value of the Configuration (CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. FCCU also changes the value of the

Configuration-State Timeout Interval (CFG_TO) register to its reset value. For information on the Configuration-state timeout value, see CFG register bit value at different events. For a list of configuration registers, see Configuration registers.

47.5.1.3 Configure the CONFIG state

1. Set the Configuration-state timeout interval (CFG_TO[TO]).
2. Enable the Configuration-state-timeout interrupt signal (IRQ_EN[CFG_TO_IEN]), if you want FCCU to request an interrupt when a Configuration-state timeout occurs.

47.5.1.4 Put FCCU in the CONFIG state

1. Unlock the configuration temporarily (TRANS_LOCK[TRANSKEY]) in Supervisor mode.
2. Check the FCCU status (STAT[STATUS]).
   - If the FCCU status is CONFIG, FCCU is in the CONFIG state. Stop.
   - If the FCCU status is NORMAL, go to step 3.
   - If the FCCU status is ALARM or FAULT, go to step 5.
3. Run the OP1 operation (see Run an operation).
4. Check the operation status (CTRL[OPS]).
   - If the operation status is Successful, FCCU is in the CONFIG state. Stop.
   - If the operation status is Aborted, the configuration is probably permanently locked. Go to step 7.
5. Recover all faults (see Fault recovery).
6. Go to step 2.
7. Reset FCCU.

47.5.2 Configure FCCU

47.5.2.1 Introduction

You configure FCCU so it functions according to the needs of your particular application.

47.5.2.2 About configuring FCCU

When configuring FCCU:

- If you enable a non-critical fault channel but disable all reactions for that channel, FCCU changes state when necessary but does not perform any reaction because reactions are disabled. If you enable reactions for a non-critical fault channel but disable that channel, and FCCU is in the NORMAL state when a fault occurs on the channel, FCCU does not enter the ALARM or FAULT state and therefore does not perform any reaction.

47.5.2.3 Configure the non-critical fault channels

For each non-critical fault channel that you want FCCU to monitor:

1. Set the recovery type (NCF_CFGa[NCFCn]).
2. Enable at least one type of Fault-state reaction:
   - Chip functional reset (NCFS_CFGa[NCFSCn])
   - Non-maskable interrupt (NMI_ENa[NMIENn])
   - EOUT signaling (EOUT_SIG_ENa[EOUTENn])

NOTE

If you enable the chip functional reset as the type of Fault-state reaction for a channel, enable at least one other type of Fault-state reaction for the channel or enable the ALARM state (step 4) for the channel.

3. Set the Alarm-state timeout interval (NCF_TO[TO]), if you plan to enable the ALARM state for any non-critical fault channel.

NOTE

Ensure that the Alarm-state timeout interval is less than the FOSU module's timeout interval; otherwise, FOSU generates a chip reset every time a fault occurs on the channel. The FOSU timeout interval (FOSU_COUNT) is a chip-specific value. See the chip-specific FCCU information.

4. Enable the ALARM state (NCF_TOEa[NCFTOEn]) for any non-critical fault channel for which you want FCCU to enter the ALARM state before entering the FAULT state.
5. Enable the Alarm-state reaction (IRQ_ALARM_ENa[IRQENn]) for each non-critical fault channel for which you enabled the ALARM state.
6. Enable the corresponding NCF_Ea[NCFEn] field for each non-critical fault channel that you want FCCU to monitor.

47.6 Application information

47.6.1 Use cases and limitations

Configuration guidelines

Follow these guidelines to configure FCCU:

- If you want FCCU to react to a fault on a non-critical fault channel:
  - Enable the channel (Non-critical Fault Enable (NCF_E0)).
  - Enable at least one type of Fault-state reaction for the channel: chip reset (Non-critical Fault-State Configuration (NCFS_CFG0)), fault-output (EOUT) signaling (Non-critical Fault-State EOUT Signaling Enable (EOUT_SIG_EN0)), or non-maskable interrupt (Non-critical Fault-State Non-maskable-Interrupt-Request Enable (NMI_EN0)).
  - If you enable chip reset as the type of Fault-state reaction for the channel (Non-critical Fault-State Configuration (NCFS_CFG0)), enable either ALARM state (Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0)) or at least one other type of Fault-state reaction for the channel: fault-output (EOUT) signaling (Non-critical Fault-State EOUT Signaling Enable (EOUT_SIG_EN0)) or non-maskable interrupt (Non-critical Fault-State Non-maskable-Interrupt-Request Enable (NMI_EN0)).
  - If you enable ALARM state for the channel (Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0)), enable the Alarm-state reaction (Non-critical Alarm-State Interrupt-Request Enable (IRQ_ALARM_EN0)).
  - If you enable ALARM state for the channel (Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0)), make sure the Alarm-state timer interval (Non-critical-Fault Alarm-State Timeout Interval (NCF_TO)) is less than the FOSU module's timer interval; otherwise, FOSU generates a chip reset every time a fault occurs on the channel. The FOSU timer interval (FOSU_COUNT) is chip-specific. See the chip-specific FCCU information.

Recommendations to configure FCCU

1. After a power on, or 'destructive' reset (when initiated by the assertion of the chip reset pin, RESET_B), where both system and FCCU are reset, the following steps could be followed to configure FCCU:
   a. Check and clear any pending fault status
   b. Verify FCCU is in NORMAL state, else repeat step(a) above
   c. Configure FCCU
2. After any 'functional' reset of the system, arising out of a reset request from FCCU or other sources, the following steps could be followed to reconfigure FCCU:

a. If active, wait for the Error out T_{min} to expire
b. Check and clear fault status
c. Error pin moves to "non faulty" state, once fault status is cleared and T_{min} expires
d. Verify FCCU is in NORMAL state, else repeat step(a) above
e. Read and verify value in NCF_En
f. Reconfigure FCCU, if necessary

47.7 Register descriptions

47.7.1 FCCU register descriptions

The FCCU registers are listed in the table below. Any address offset not explicitly mentioned in this table is reserved.

The FCCU supports word (32-bit), half-word (16-bit), and byte (8-bit) read and write accesses.

Follow these register-access guidelines:

- Do not read from or write to any addresses that are not shown in the following table. Doing so may or may not result in a transfer error.
- Do not write to any of the configuration registers unless FCCU is in the CONFIG state. Doing so results in a transfer error.
- Do not write to the Transient Configuration Lock (TRANS_LOCK) or Permanent Configuration Lock (PERMNT_LOCK) registers unless your code runs in the Supervisor mode. Doing so results in a transfer error.

For each possible NCF failure source, a different reaction—including no reaction—is configurable through the use of NMI, IRQ, and short reset selection registers. It is not possible for a single event upset to switch off all reactions on failures as implementation is per fault source (but it will be possible to switch them all off by SW if intended). Failures themselves are not able to disable all reactions and indications.

47.7.1.1 FCCU memory map

FCCU base address: 4038_4000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Control (CTRL)	32	RW	0000_00C0h

47.7.1.2 Control (CTRL)

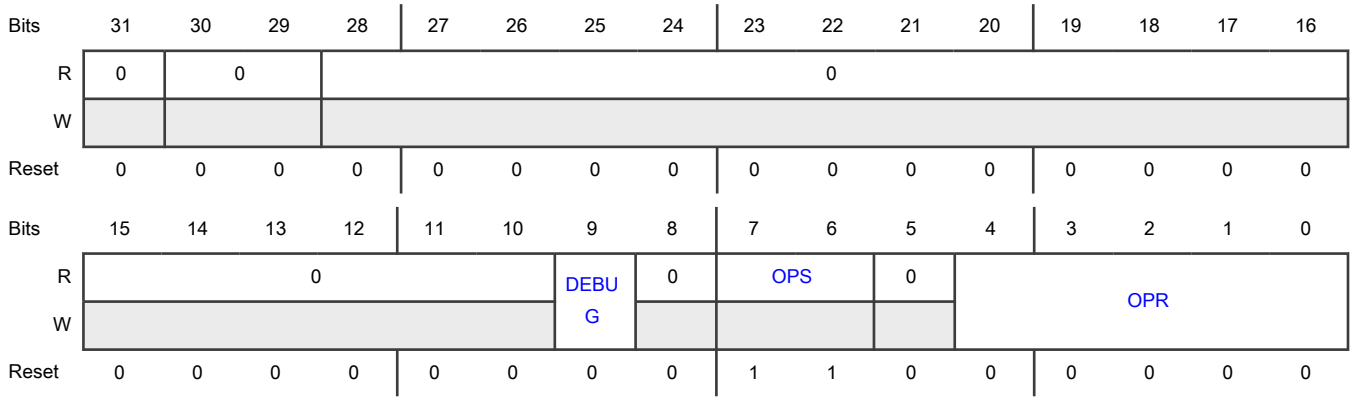
Offset

Register	Offset
CTRL	0h

Function

Initiates and indicates the status of operations—and enables the Debug mode.

Diagram



Fields

Field	Function
31 —	Reserved
30-29 —	Reserved
28-10 —	Reserved
9 DEBUG	Debug Mode Enable Specifies whether the Debug mode is enabled. If so, FCCU enters the Debug mode when the Debug signal is asserted. When FCCU enters the Debug mode, it halts operation and remains in the state it was in before it entered this mode. **NOTE** FOSU does not halt when FCCU enters the Debug mode. Therefore, FOSU can still cause a reset if a fault occurs while FCCU is in the Debug mode. 0b - Disabled 1b - Enabled
8 —	Reserved
7-6 OPS	Operation Status This field can be read and cleared (via OP15 operation) by the software. 00b - Idle 01b - In progress 10b - Aborted

Table continues on the next page...

Table continued from the previous page...

Field	Function
	11b - Successful
5 —	Reserved
4-0 OPR	Operation Run Initiates operations that perform actions such as putting FCCU in the CONFIG state or setting the operation status to Idle. For information on how to run operations, see Run operations. FCCU ignores any write to this field while the operation status (CTRL[OPS]) is "In progress". After completion of an operation, FCCU sets this field to OP0. The following events result in an operation status (CTRL[OPS]) of "Aborted": • Writing to a NCF_Sa register (which automatically initiates the OP12 operation) without first successfully unlocking the register (NCFK[NCFK]) • Initiating an OP1 operation when FCCU is not in the NORMAL state or the configuration is locked • Initiating an OP1, or OP2, operation without first unlocking the operation (CTRLK[CTRLK]) 00000 OP0—No operation 00001 OP1—Applies only when the configuration is unlocked, when FCCU is in the NORMAL state, and immediately after you unlock the operation (CTRLK[CTRLK]). Put FCCU in the CONFIG state. 00010 OP2—Applies only immediately after you unlock the operation (CTRLK[CTRLK]). Put FCCU in the NORMAL state. 00011 Reserved 00100 Reserved 00101 Reserved 00110 Reserved 00111 Reserved 01000 Reserved 01001 Reserved 01010 Reserved 01011 Reserved 01100 OP12—Do not initiate this operation; it is automatically initiated by the FCCU. A NCF_Sa register status clear operation is in progress. 01101 OP13—Clear the freeze status registers. 01110 OP14—Do not initiate this operation; it is automatically initiated by the FCCU. A Configuration-state timeout is in progress. For more information, see Configuration registers. 01111 OP15—Set the operation status (CTRL[OPS]) to Idle. 10000 Reserved 10001 Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10010 Reserved 10011 Reserved 10100 Reserved 10101—11110 Forbidden. Writing any of these values returns an operation status (CTRL[OPS]) of "Aborted" with no side effect. 11111 Reserved

47.7.1.3 Control Key (CTRLK)

Offset

Register	Offset
CTRLK	4h

Function

See CTRLK[CTRLK].

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R																
W	CTRLK															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 CTRLK	Locked-Operation Control Key Writable only with a 32-bit write. Unlocks locked operations (CTRL[OPR]) so you can initiate them. For information on how to unlock locked operations before you initiate them, see Run an operation.

Table continues on the next page...

Field	Function
	NOTE • You must initiate an operation in the FCCU register access that immediately follows the one that unlocks it; otherwise, the operation is again locked. • Reading from this register always returns the value 0000_0000h. Operations not listed here are not locked and do not need to be unlocked. 9137_56AFh: Unlock OP1. 825A_132Bh: Unlock OP2. Any other value: Do nothing.

47.7.1.4 Configuration (CFG)

Offset

Register	Offset
CFG	8h

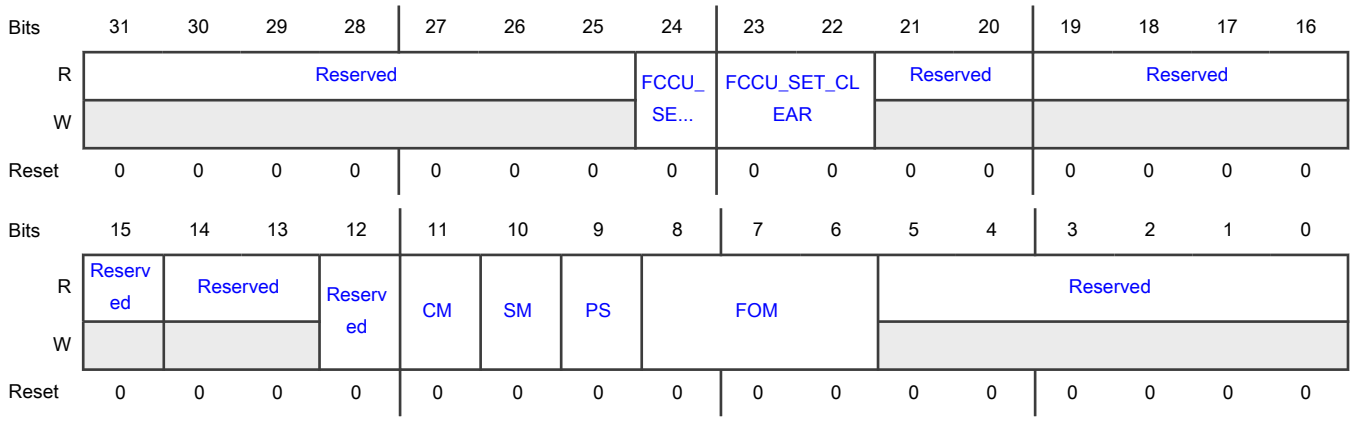
Function

Writable only when FCCU is in the CONFIG state. Changed by FCCU to another value when the chip resets FCCU, a Configuration-state timeout occurs, or you run an OP31 operation. See CFG register bit value at different events for more information. Specifies the global configuration for FCCU.

NOTE

If you specify a new value for any of the fields in this register that affect the EOUT signals while the fault-output (EOUT) timer is running (FCCU is indicating a fault on the EOUT signals), FCCU does not use the new settings you specified until after the fault-output (EOUT) timer expires (FCCU stops indicating a fault on the EOUT signals).

Diagram



Fields

Field	Function
31-25 —	Reserved
24 FCCU_SET_AFTER_RESET	Fault-Output (EOUT) Activate For fault-output (EOUT) signaling, controls whether the EOUT signals are active. 0b - Inactive (the EOUT signals are in a high-impedance state) 1b - Active (the EOUT signals indicate FCCU's condition)
23-22 FCCU_SET_CLEAR	Fault-Output (EOUT) Control Applies only to Bi-Stable and Fault-Toggle fault-output modes (CFG[FOM]) and when the EOUT signals are active (CFG[FCCU_SET_AFTER_RESET]). Controls whether the fault-output (EOUT) signals are managed by FCCU's FSM. **NOTE** When the EOUT signals are in the Fault-Toggle fault-output mode, if you change the value of this field, you must also deactivate and then reactivate the EOUT signals (CFG[FCCU_SET_AFTER_RESET]) to correctly initialize them so they have opposite states. 00b - Controlled by the FSM 01b - Always low 10b - Controlled by the FSM 11b - High until a fault occurs on a channel, regardless of whether that fault is disabled; thereafter, controlled by the FSM. Note: FCCU ignores an attempt to write this value if the fault-output (EOUT) timer is already running.
21-20 —	Reserved
19-16 —	Reserved
15 —	Reserved
14-13 —	Reserved
12 —	Reserved Always write the reset value to this field.
11 CM	Fault-Output (EOUT) Configuration-Indication Mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
	For fault-output (EOUT) signaling, this field controls whether the configuration indication is the same as the non-faulty indication. 0b - Different 1b - Same
10 SM	Fault-Output (EOUT) Switching Mode Applies only to Dual-Rail and Time-Switching fault-output modes (CFG[FOM]). For fault-output (EOUT) signaling, controls how quickly the signals switch between indicating the faulty and non-faulty conditions. 0b - Slow: No EOUT frequency violation during the FCCU state transition (NORMAL to FAULT or vice versa, and CONFIG to NORMAL). The indication transition occurs after a maximum delay equal to the duration of the semi period of the EOUT frequency. 1b - Fast: The indication transition (NORMAL to FAULT or vice versa, and CONFIG to NORMAL) occurs immediately. A pulse with the minimum duration corresponding to the CLKSAFE period can occur in this mode. It implies a frequency violation of the EOUT protocol.
9 PS	Fault-Output (EOUT) Polarity Selection Applies to fault-output (EOUT) signaling and controls the polarity of the signals for fault-output mode indications that hold the signals low or high (versus toggling them or placing them in a high-impedance state). Applies only to Time-Switching fault-output mode (for faulty and configuration indications) and Bi-Stable fault-output mode (for all indications). 0b - For the faulty indication, EOUT1 is high, and EOUT0 is low. 1b - For the faulty indication, EOUT1 is low, and EOUT0 is high.
8-6 FOM	Fault-Output (EOUT) Mode For fault-output (EOUT) signaling, controls the protocol of the signaling. **NOTE** See the chip-specific FCCU information for the fault-output modes supported by this chip. 000b - Dual-Rail 001b - Time-Switching 010b - Bi-Stable 011b - Fault-Toggle 100b - Reserved 101b - Test 0 (controlled by the EINOUT register; EOUT1 is an output; EOUT0 is an input) 110b - Test 1 (controlled by the EINOUT register; EOUT1 and EOUT0 are both outputs) 111b - Test 2 (controlled by the EINOUT register; EOUT1 is an input; EOUT0 is an output)
5-0 —	Reserved

47.7.1.5 Non-critical Fault Configuration (NCF_CFG0)

Offset

Register	Offset
NCF_CFG0	1Ch

Function

See NCF_CFGa[NCFCn].

Reset	1	0	1	0	1	0	0	1	1	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TO	Non-critical-Fault Alarm-State Timeout Interval Writable only when FCCU is in the CONFIG state. Changed by FCCU to its reset value when a Configuration-state timeout occurs. Controls the maximum amount of time that FCCU can be in the ALARM state ($T_{\text{Max Alarm}}$) according to this equation:

Table continues on the next page...

Field	Function
	$T_{Max\ Alarm}$ = TO × $T_{CLKSAFE}$ where $T_{CLKSAFE}$ is the safe-clock period. If FCCU enters the ALARM state (because a fault occurs on an enabled non-critical fault channel for which the ALARM state is enabled) and this timeout interval expires (called an Alarm-state timeout), then FCCU leaves the ALARM state and enters the FAULT state. **NOTE** Make sure the Alarm-state timeout interval is less than the FOSU module's timeout interval; otherwise, a fault that occurs while FCCU is in the ALARM state can cause FOSU to generate a chip reset. The FOSU timeout interval (FOSU_COUNT) is chip-specific. See the chip-specific FCCU information.

47.7.1.12 Configuration-State Timeout Interval (CFG_TO)

Offset

Register	Offset
CFG_TO	B8h

Function

See CFG_TO[TO]

Fields

Field	Function
31-3 —	Reserved
2-0	Configuration-State Timeout Interval

Table continues on the next page...

Table continued from the previous page...

Field	Function
TO	Writable only when FCCU is in the NORMAL, ALARM, or FAULT state (not in the CONFIG state). Changed by FCCU to its reset value when a Configuration-state timeout occurs. Not accessible while a Configuration-state timeout (OP14 operation) is in progress. Controls the maximum amount of time that FCCU can be in the CONFIG state ($T_{\text{Max configuration}}$) according to this equation: $T_{\text{Max configuration}} = T_{\text{CLKSAFE}} \times 2^{(\text{TO} + 13)}$ where T_{CLKSAFE} is the safe-clock period. If you put FCCU in the CONFIG state and this timeout interval expires (called a Configuration-state timeout), then FCCU: • Automatically leaves the CONFIG state and enters the NORMAL state • Changes the value of the Configuration (CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. For information on the Configuration (CFG) register's Configuration-state-timeout value, see CFG register bit value at different events. For a list of configuration registers, see Configuration registers.

47.7.1.13 IO Control (EINOUT)

Offset

Register	Offset
EINOUT	BCh

Function

The EINOUT register allows the following operations typically in the NORMAL state:

- To control the EOUT[1] output level when the FCCU is configured in "Test1" or "Test0" fault output mode (CFG[FOM])
- To control the EOUT[0] output level when the FCCU is configured in "Test1" or "Test2" fault output mode (CFG[FOM])
- to observe the state of signals at EIN[1:0] pins

The following table shows Bi-Stable encoding.

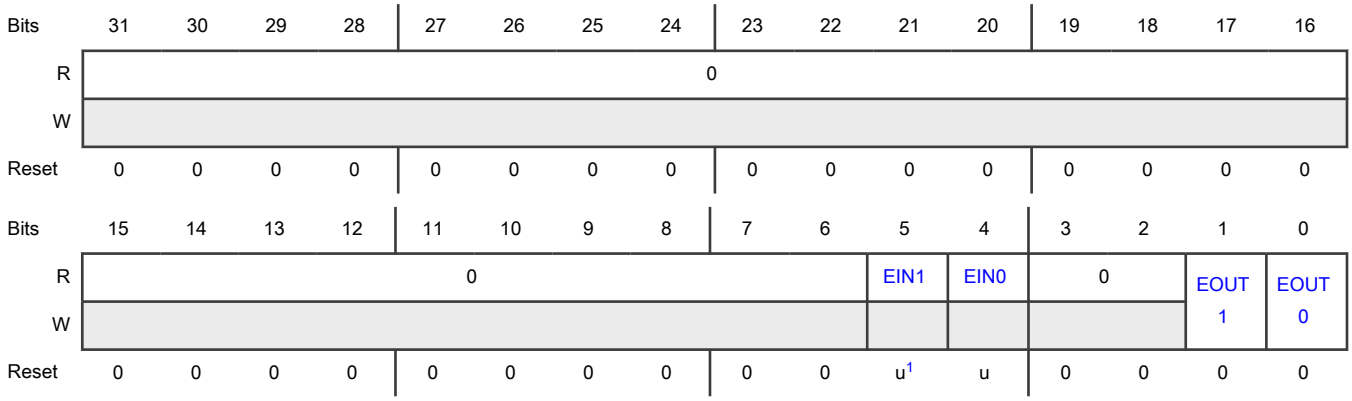
Table 231. Bi-Stable encoding

Mode = CFG[FOM]	EOUT[0]	EOUT[1]
Test1	output	output
Test2	output	input
Test0	input	output

NOTE

Because of the resynchronization stage of the EOUT interface, there is a latency of a few CLKSAFE cycles following a write/read operation of the EINOUT register.

Diagram



1. Reset value varies as per the corresponding EIN signal.

Fields

Field	Function
31-6 —	Reserved
5 EIN1	Error Input 1 Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Indicates the state of the EIN1 signal. 0b - Low 1b - High
4 EIN0	Error Input 0 Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Indicates the state of the EIN0 signal. 0b - Low 1b - High
3-2 —	Reserved
1 EOUT1	EOUT1 Error out 1 (significant only if the CFG.FOM = Test1 or Test0 => EOUT[1] configured in output mode). The EOUT1 set/clear the respective EOUT[1] output signal if CFG.FOM = 110 or 101, otherwise it is a "don't-care" value. **NOTE** When the configuration watchdog timer expires, FCCU changes the value of this field to its reset value. 0b - force EOUT[1] = 0

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - force EOUT[1] = 1
0 EOUT0	EOUT0 Error out 0 (significant only if the CFG.FOM = Test1 or Test2 => EOUT[0] configured in output mode). The EOUT0 set/clear the respective EOUT[0] output signal if CFG.FOM = 110 or 111, otherwise it is a "don't care" value. **NOTE** When the configuration watchdog timer expires, FCCU changes the value of this field to its reset value. 0b - force EOUT[0] = 0 1b - force EOUT[0] = 1

47.7.1.14 Status (STAT)

Offset

Register	Offset
STAT	C0h

Function

This register indicates the following:

- States that FCCU is driving on the EOUT signals
- Whether FCCU is in a faulty condition
- Current state of FCCU

Diagram

47.7.1.19 Non-critical Fault Fake (NCFF)

Offset

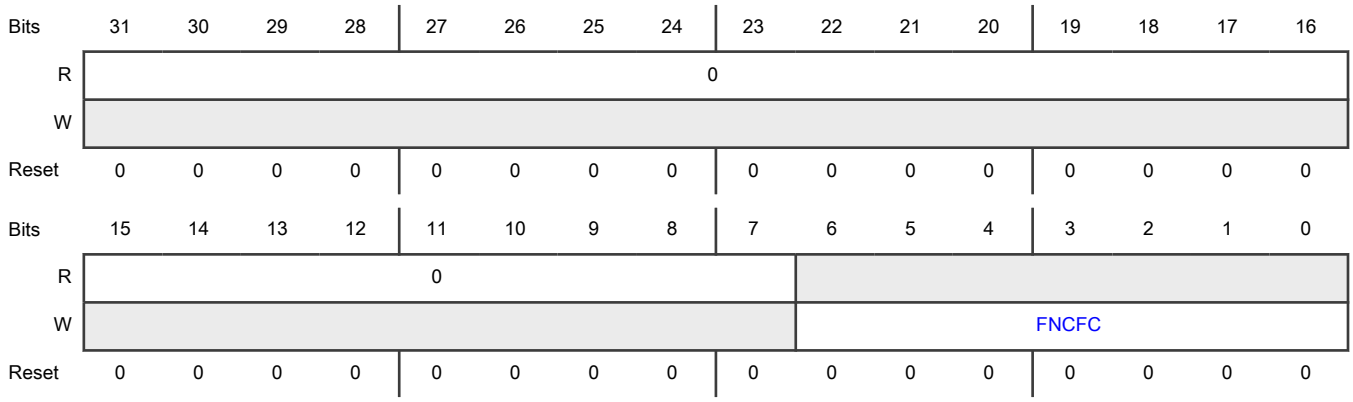
Register	Offset
NCFF	DCh

Function

This register contains a unique code to set a non-critical fault in mutually exclusive mode by the external FAULT interface (signal setting). It allows the SW emulation of the non-critical faults, by injecting the fault directly in the FAULT root, to verify the entire path and reaction. The reaction following a fake non-critical fault cannot be masked.

This is a write-only register with a set of codes corresponding to each non-critical fault injection.

Diagram



Fields

Field	Function
31-7 —	Reserved

47.7.1.20 IRQ Status (IRQ_STAT)

Offset

Register	Offset
IRQ_STAT	E0h

Function

This register provides the FCCU interrupt status related to the following events:

- Configuration-state timeout error
- Alarm interrupt
- NMI interrupt

The configuration-state timeout interrupt is asserted if both IRQ_STAT[CFG_TO_STAT] and IRQ_EN[CFG_TO_IEN] bits are asserted. It is cleared when a 1 is written to the IRQ_STAT[CFG_TO_STAT] bit.

The NMI and ALARM interrupts are asserted and cleared according to the FCCU state. The status bits of the IRQ_STAT trace the status of the related interrupt lines.

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 —	Reserved
15-0 EOUTENn	Non-critical Fault-State EOUT Signaling Enable n Writable only when FCCU is in the CONFIG state. Changed by FCCU to its reset value when a Configuration-state timeout occurs. Applies only when the EOUT signals are active (CFG[FCCU_SET_AFTER_RESET]). When FCCU is configured for Bi-Stable fault-output mode (CFG[FOM]), controls whether EOUT signaling is enabled as a Fault-state reaction for the associated non-critical fault channel (n). (For other fault-output modes, EOUT signaling is always enabled, regardless of the value of this field.) When EOUT signaling is enabled for an enabled non-critical fault channel, a fault on that channel causes FCCU to indicate the faulty condition on the EOUT[1:0] signals when FCCU enters the FAULT state. For information on how to configure the non-critical fault channels, see Configure the non-critical fault channels. For all fault-output modes, also controls whether FCCU asserts the FIF signal when a fault on the associated non-critical fault channel (n) causes FCCU to enter the FAULT state. **NOTE** For all fault-output modes, you must set this field to enabled to ensure that FCCU asserts the FIF signal when FCCU enters FAULT state as the result of a fault on the associated non-critical fault channel (n) so the FOSU module does not mistakenly generate a destructive chip reset. 0b - In Bi-Stable fault-output mode, both EOUT signaling and FIF assertion are disabled; in other fault-output modes, EOUT signaling is enabled and FIF assertion is disabled. 1b - Both EOUT signaling and FIF assertion are enabled in all fault-output modes.

47.7.1.28 Alarm-State Timer (TMR_ALARM)

Offset

Register	Offset
TMR_ALARM	12Ch

Function

See TMR_ALARM[COUNT].

This table shows how the Alarm-state timer's state and value vary by FCCU state:

Table 232. TMR_ALARM reset value

FCCU state	Timer state	Timer value
CONFIG	Idle	0000_0000h
NORMAL	Idle	Initial value: NCF_TO[TO]

Table continues on the next page...

47.7.2 Configuration registers

47.7.2.1 Definition

Configuration registers are registers that:

- Let you configure FCCU's Alarm-state timer interval, fault channels, and fault-output (EOUT) signals.
- You can write to only when the configuration is not locked and FCCU is in CONFIG state (see Put FCCU in the CONFIG state).
- Save the values you write to them while FCCU is in CONFIG state only after you manually put FCCU in NORMAL state. If FCCU automatically leaves CONFIG state and enters NORMAL state because the configuration-timer interval (CFG_TO[TO]) expires (called a Configuration-state timeout), FCCU changes the value of the Configuration (CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value; FCCU also

changes the value of the Configuration-State Timeout Interval (CFG_TO) register to its reset value. For information on the Configuration-state timeout value, see CFG register bit value at different events.

47.7.2.2 Configuration registers

Following is the list of configuration registers in this module. They are listed in an offset order from lowest to highest.

- Configuration (CFG)
- Non-critical Fault Configuration (NCF_CFGa)
- Non-critical Fault-State Configuration (NCFS_CFG0)
- Non-critical Fault Enable (NCF_E0)
- Non-critical-Fault Alarm-State Timeout Enable (NCF_TOE0)
- Non-critical-Fault Alarm-State Timeout Interval (NCF_TO)
- Delta T (DELTA_T)
- Non-critical Alarm-State Interrupt-Request Enable (IRQ_ALARM_EN0)
- Non-critical Fault-State Non-maskable-Interrupt-Request Enable (NMI_EN0)
- Non-critical Fault-State EOUT Signaling Enable (EOUT_SIG_EN0)

47.7.3 CFG register bit value at different events

In this chip, there are no events that affect the bits in the configuration register.

47.8 Glossary

CF	Critical fault
EOUT	Error out
FOSU	FCCU output supervision unit
FSM	Finite state machine
intf	Interface
IRQ	Interrupt request
NCF	Non-critical fault
NMI	Non-maskable interrupt

Chapter 48
Self-test General-Purpose Registers (SELFTEST_GPR)

48.1 Introduction

SELFTEST_GPR configures the STCU2 LBIST shift cycles. Programming self-test GPRs is a part of the self-test programming sequence. See the "Self-test programming sequence" section in the STCU2 chapter.

NXP supports only STCU2 Built-In Self-Test (BIST) sequences that have been validated by NXP for in-field testing usage.

The detailed programming sequences for supported configurations are available in a separate application note (contact your NXP sales representative).

The values for SELFTEST_GPR registers must be aligned with the NXP supported configurations only.

NOTE

While accessing SELFTEST_GPR space, software must ensure that the STCU2 block has its clock enabled, i.e., MC_ME.PRTN1_COFB3_CLKEN[REQ104] configured as 1'b1. Not ensuring this might result in unpredictable device behaviour.

48.2 Progressive shift clock switching (PCS)

The PCS feature is used to enable progressive switching of the operating frequency at the start and/or end of LBIST. Kindly configure the PCS as per the recommended self-test configurations.

With each PCS enabled, there are additional (SELFTEST_GPR.CONFIG_REG[PCS_STEP_SIZE] + 1)*16 patterns beyond the configured count. If enabled at the start of LBIST (using SELFTEST_GPR.CONFIG_REG[PCS_ENABLE_START]), it would cause the shift clock to scale up in this duration from divide by 16 to the original frequency (by changing divider in each step).

Similarly, if configured at the end of LBIST (using SELFTEST_GPR.CONFIG_REG[PCS_ENABLE_END]), the shift clock frequency will be scaled down from original frequency to divide by 16.

48.3 SELFTEST_GPR register descriptions

48.3.1 SELFTEST_GPR memory map

SELFTEST_GPR base address: 403B_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Configuration register (CONFIG_REG)	32	RW	0000_ADD5h

Fields

Field	Function
31-8 —	Reserved
7-0 LBIST_SHIFT_COUNT	LBIST Shift Count Specifies the number of shift cycles in a scan chain in one pattern count for the LBIST partition.

48.4 Glossary

LBIST Logic built-in self-test

Pattern count The pattern count refers to an empirically determined value of shift patterns run in LBIST on a scan chain to result in predetermined fault coverage, based on device safety integrity level. Since the LBIST scheme is

	Pseudo Random Testing, a sufficiently good value of pattern count is used which provides the required fault coverage.
Scan chain	A sequential chain of flops in scan mode over which one scan pattern (generated by PRPG, that is, Pseudo Random Pattern Generator) in LBIST will be shifted and the output MISR (Multi Input Signature Register) will be matched with earlier known value to determine pass or fail criterion of that particular chain.

Chapter 49
Self-Test Control Unit (STCU2)

49.1 Chip-specific STCU2 information

49.1.1 Supported BIST sequence

NXP supports only STCU2 Built-In Self-Test (BIST) sequences that have been validated by NXP for in-field testing usage. After the chip has been validated, this section is extended with information on the supported BIST sequences. The detailed programming sequences for supported configurations are available in a separate application note (contact your NXP sales representative).

49.1.2 Self-Test overview

STCU2 provides the overall control of both Logic Built-in Self Test (LBIST) and Memory Built-in Self-Test (MBIST) in serial or parallel depending on the power, timing, or coverage constraints.

STCU2 is a hardware module that manages the execution of BIST and indicates whether each BIST passed.

The Self-Test is initiated by the software. The application software has the provisions to bypass the Self-Test and directly move to normal RUN mode by bypassing the Self-Test configurations.

NOTE

Offline Self-Test (Hardware Initiated Self-Ttest) is not supported by the chip.

There is a programmable BIST-sequence-execution watchdog timer that specifies the maximum time allowed for the execution of a BIST sequence. In case the selected LBISTs or MBISTs are not yet completed during the assigned time, the current LBISTs or MBISTs execution is interrupted and a failure is flagged into ERR_STAT[WDTOSW] and MBESWx or LBESW.

The STCU2 execution has three phases:

- SW configuration (load/program test configuration parameters to be executed, depending on ASIL target and performance requirements). The "Self-Test configuration" parameters allow Self-Test to run with different times (depends on pattern numbers and type) and therefore different levels of coverage are achieved.
- Start BIST execution by SW register configuration in STCU2. The BIST completion is followed by a reset (functional reset).
- After BIST execution is finished and the functional reset is completed, the BIST results are made available to the SW and a decision how to continue (trigger a new reset or start safety application) is taken by SW. The BIST execution completion is signalized in an internal STCU2 register (LBESWn) bit which is not affected by the functional reset. The BIST test results are also not affected by the functional reset.

The following figure shows a pictorial representation of two LBIST partitions having two and one MBIST groups, respectively. The STCU2 interacts with LBIST_CTRL (Logic built-in-self-test control) for the respective partitions to configure and control the LBIST sequence and result comparison of LBIST. It also interacts with MBIST Master Controller (MCT) for MBIST. Each LBIST partition has its corresponding controller whereas a single MCT controller can cater to multiple MBIST groups.

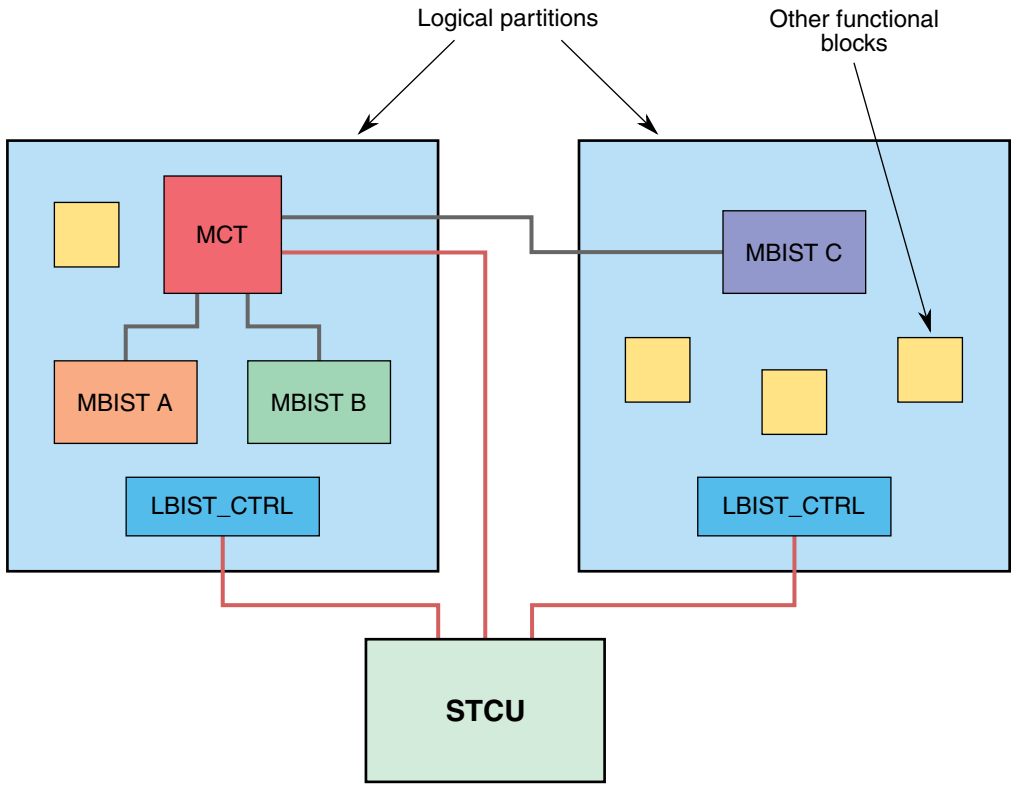

Figure 195. Self-Test overview

Each LBIST partition also includes a block called Self-Test GPR, a set of registers that provide miscellaneous configurations or parameters for LBIST operation.

If a Self-Test is triggered, the device becomes unavailable for software application during the Self-Test run.

49.1.3 STCU2 LBIST/MBIST mapping

This topic covers STCU2 LBIST/MBIST mapping.

LBIST mapping

The below table lists the LBIST mapping of the chip. The NLBIST value is 1.

Table 233. LBIST mapping

NOTE

The MBIST index 5 corresponds to CoolFlux memories. MBIST on MBIST index 5 should be executed with ADCBIST.BISTCFG[ADCBISTEN] configured as 1'b0 since the ADCBIST interacts with CoolFlux memories and will cause MBIST5 failures if MBIST is executed on Coolflux memories with ADCBIST enabled.

49.1.4 STCU2 clocking

STCU2 works on system clock domain. The scan operations while LBIST are done on TCK clock.

Table 235. STCU2 clock connectivity

STCU2 clock	SoC connected clock	Remarks
CORE_CLK	AIPS_SLOW_CLK	System clock divider output clock node for STCU2 operations and register interface accesses.
REG_INTF_CLK		
SHIFT_CLK	JTAG_TCK	JTAG_TCK used for shift operations while Self-Test is under progress.

49.1.5 Memory map for Self-Test GPRs

See the memory map file attached to this document and 'SELFTEST_GPR' chapter for details.

49.1.6 Handling unrecoverable faults

Only recoverable/non-critical faults are mapped to the FCCU. The unrecoverable faults from STCU2 are not mapped to the FCCU. The unrecoverable/critical faults are mapped to the RGM instead of FCCU. Therefore, any references to mapping of unrecoverable/critical faults with FCCU in the chapter Self-Test Control Unit (STCU2) should be ignored.

49.1.7 Indicating fault state during the main reset domain Self-Test

FCCU EOUT indicates the fault state during the Self-Test as soon as the UTEST_MISC[FCCU_EOUT_ DEDICATED] is enabled and DCMRWD2[EOUT_STAT_DUR_STEST] is enabled at the time of Self-Test setup steps.

The fault state remains asserted until the bit DCMRWD2[EOUT_STAT_DUR_STEST] is cleared post Self-Test reset sequence.

In case it is not required to indicate the fault state during the Self-Test, then the bit DCMRWD2[EOUT_STAT_DUR_STEST] should not be programmed.

49.1.8 Error events management in main reset domain Self-Test

Error events should be mapped to unrecoverable faults in STCU2_ERR_FM register for main reset domain Self-Test.

49.1.9 AUTOLOCK_VALUE for register write access via STCU2_SKC

Register write-access watchdog timer explains that access to STCU2 registers via the STCU2_SKC security-key mechanism times out after a number of STCU2 clock cycles equal to AUTOLOCK_VALUE. On this chip, AUTOLOCK_VALUE is 32'hFFFF_FFFF.

49.1.10 PLL loss of lock during Self-Test

Detection of PLL loss of lock during LBIST or MBIST causes a destructive reset in the system.

CMU0 programming is required before the Self-Test programming begins.

All the registers present in LBIST domains do not retain their content after Self-Test reset.

49.1.11 STCU2 BIST start (BSTART) register description

Attempted accesses with the undefined reserved values in the BSTART register can result in undefined behavior. The following table defines the BSTART field on this chip.

Table 236. BSTART description

Field value	Description
000b	NOP (reset value)

Table continues on the next page...

Table 236. BSTART description (continued)

Field value	Description
001b	RUN_ONLY: Run BISTs. MBIST Master Controller (MCT) runs the selected BISTs without programming them first.
010b	Reserved
011b	Reserved
100b	PROG_ONLY: Program BISTs only. MCT only programs BISTs and does not start them. This enables different BISTs to be programmed with different algorithms before all the selected BISTs are started using the RUN_ONLY command.
101b	PROG_RUN: Program BISTs and start them.
110b	Reserved
111b	Reserved

49.1.12 STCU2 algorithm select (ALGOSEL) register description

This register selects any one of the predefined algorithms. The value used in this register is mapped to a predefined algorithm register in BIST. After MCT has programmed information on this register and starts some BIST operation, this value is transferred to the predefined algorithm register in every BIST that is selected.

If multiple predefined algorithms are selected, the order of execution is from LSB to MSB.

Any field that does not have a predefined algorithm associated with it is a reserved bit. No data is written to reserved bits and when you read these bits, they always return 0. These predefined algorithms include:

- Backgrounds
- Address modes and other register programming that may be necessary
- The number of BIST runs needed to perform the exact coverage requested.

MCT decodes this information through a series of look-up tables. The following table describes the high-level BIST algorithms that can be invoked through the MCT. The columns in that table have the following meaning:

- Index: The position in this MCT register enables this algorithm.
- Name: The symbolic name for this algorithm.
- Description: The intent and use model for this algorithm.
- BIST runs: The sequence of BIST invocations comprising this algorithm.
- Sequences: The ordered list of march elements to run. Each march element consists of a direction indicator (for increasing addresses and for decreasing addresses) and a set of march phases. A march phase consists of reading (R) or writing (W), the non-inverted (0) or inverted (1) background pattern.
- Used by default: Whether this algorithm is selected in the post-reset state of this register.

Table 237. ALGOSEL description

Index	Name	Description	BIST runs	Sequences	Used by default
3	March C+ single	March C+ with column fast and solid background	MarchC+ column fast 1x (#4)	W0, R0W1, R1W0R0W1, R1W0, R0W1R1W0, R0	Yes
13	BasicChk	Basic self-contained checkerboard, using column fast	BasicChk (#18)	R0W1R1	-

49.1.13 Self-Test programming sequence

This section describes a high level programming sequence for executing Self-Test. The detailed programming sequences for supported configurations are available in a separate application note (contact your NXP sales representative).

- Program clock sources and MC_CGMs as per the clock configuration.

  NOTE

  While running MBIST on EMAC timestamp memory, MC_CGM.MUX_9_DC_0[DIV] should be appropriately configured to ensure EMAC_CLK_TS should be at least 1.5 times the AIPS_SLOW_CLK frequency.

- Program SELFTEST_GPR[CONFIG_REG] and SELFTEST_GPR[LBIST_PROG_REG] as per the LBIST configurations.
- Program STCU2 as per NXP recommended.
- Program dcf_client_utest_misc[FCCU_EOUT_DEDICATED] and DCMRWD2[EOUT_STAT_DUR_STEST] to configure EOUT pins as dedicated and to indicate FCCU error states on EOUT pins during Self-Test respectively.
- Configure ERCTRL[ERASSERT] register bit in MC_RGM to achieve desired behaviour of Reset Pin as documented in Reset Section and Pad States Section.
- Disable functional reset sources to avoid false Self-Test abort scenarios. For example, software watchdog timers cannot be serviced while Self-Test because the software is not accessible and can cause invalid timeout reset. See Reset events and configurations while Self-Test.
- Program the PCS_ENABLE[8:7] fields of the CONFIG_REG register (SELFTEST_GPR) to 0 to disable PCS.
- Trigger Self-Test execution by programming RUNSW register in STCU2.
- At the end of the Self-Test run, a functional reset is generated. Out of reset, the software can check the status registers inside STCU2 and take actions accordingly.

NOTE

EIM should be disabled when running STCU based Self-Test.

49.1.14 Modules operation during/post Self-Test

The clock, reset, power generation modules, such as RGM, PMC, CGM, FIRC, PLL, and SIRC will be available during and post Self-Test. However, because the chip undergoes the reset sequence, PLL and CGM will be reset.

CMU0 and CMU3 will be available during Self-Test if enabled prior to Self-Test, but will be Reset post Self-Test.

STCU2 will also be available during Self-Test and the results can be read post Self-Test.

49.1.15 Reset events and configurations while Self-Test

As Self-Test is a software initiated Self-Test, it is expected by software to ensure all the peripherals are disabled as documented in Software considerations before Self-Test.

The functional reset sources should be appropriately configured to avoid any functional reset while Self-Test is running (disable SWT_RST and HSE_SWT_RST. JTAGC should not be in EXTEST, HIGHZ or CLAMP instructions). This ensures no selftest abort while running selftest due to functional reset source. The below table specifies the state of functional reset sources for Self-Test.

Table 238. Reset events and configurations while self-test

Reset source	Reset description	Configurations/remarks for selftest
FCCU_RST	FCCU reset reaction	The FCCU is a part of logic which is under Self-Test and thus it would be disabled during the Self-Test
ST_DONE	Self-Test done reset	The selftest done indication resets the device post selftest. While Self-Test is running, the Self-Test done indication will be in disabled state
SWT_RST	SWT reset request	SWT should be disabled in Self-Test configuration sequence.
JTAG_RST	JTAG Reset	JTAG communication should be inactive while Self-Test and JTAGC state machine should not be in EXTEST, HIGHZ or CLAMP instructions
HSE_SWT_RST	HSE SWT timeout	HSE_SWT should be disabled in Self-Test configuration sequence.
SW_FUNC	software 'functional' reset	The software is inactive during Self-Test and hence software functional reset will not arrive while the chip is under Self-Test.
DEBUG_FUNC	debug 'functional' reset	MDM DAP should not be configured for debug functional reset generation while Self-Test is running.

The destructive reset sources are available while in Self-Test. In case of any destructive reset event, the device undergoes a destructive reset sequence, thereby resetting the STCU2 and Self-Test logic itself.

After completion of Self-Test (LBIST or MBIST), a functional reset sequence is executed by MC_RGM.

49.1.16 Software considerations before Self-Test

1. As all the communication peripherals are not in LBIST partitions; hence, it is required by SW to stop all communications and disable all the PCTLs of the communication peripherals before initiating Self-Test as the device will be unusable in Self-Test. This is needed so that there is graceful safe stating of inputs of non-lbisted peripheral modules.
2. Configure RGM functional reset sources before Self-Test as per the considerations mentioned in Reset events and configurations while Self-Test, that is, the SWTs should be disabled, the JTAGC should not be in states which can cause a JTAG reset event (EXTEST, HIGHZ or CLAMP instructions) and the software should not trigger a functional reset event via MC_ME or MDM_AP while Self-Test is ongoing. This is to avoid any abort scenario due to any functional reset source as Self-Test is initiated by SW.

There is no issue with Reset pin as Reset pin is a source of destructive Reset and will reset STCU2 and Self-Test related logic etc.

49.1.17 End of Self-Test

The Self-Test completion is a source of functional reset to the device, by which the device executes a functional reset sequence. The logic which is LBISTed additionally undergoes a complete POR sequence to ensure that the random content shifted during BIST sequence get cleared.

At the end of MBIST, the software should execute below steps:

1. Software reads the MBIST end flag to identify that the MBIST sequence had ended properly without any interruption or abort, by reading STCU2.MBESWn.
2. Software reads the MBIST status to identify whether the MBIST was successful or not, by reading STCU2.MBSSWn.

NOTE

The MBIST status should always be read in accordance with MBIST end flag. The STCU2.MBSSWn status is irrelevant if STCU2.MBESWn indicates that MBIST execution is incomplete.

At the end of LBIST, the software should execute below steps:

1. Software reads the LBIST end flag to identify that the LBIST sequence had ended properly without any interruption or abort, by reading STCU2.LBESWn.
2. Software reads the LBIST status to identify whether the LBIST was successful or not, by reading STCU2.LBSSWn.

NOTE

The LBIST status should always be read in accordance with LBIST end flag. The STCU2.LBSSWn status is irrelevant if STCU2.LBESWn indicates that LBIST execution is incomplete.

49.2 Introduction

STCU2 is a comprehensive programmable hardware module that:

- Manages the execution of BISTs
- Indicates whether each BIST passed
- Manages the chip's LBIST and the MBIST blocks

49.3 Main features

STCU2 includes:

- System interface for reading from and writing to the STCU2 registers (online) via the CPU
- Programmable scheduler for BIST execution
- Control over LBIST concurrent or sequential execution
- Control over MBIST concurrent or sequential execution
- Programmable LBIST delayed concurrent start
- Programmable internal clock prescaler to reduce internal and BIST clocks
- PLL lock signal monitoring during BIST sequences
- Programmable BIST-sequence-execution watchdog timer that specifies the maximum time allowed for the execution of a BIST sequence
- Fixed register-write-access watchdog timer that specifies the maximum amount of time that STCU2 allows you to write to its registers after you unlock them
- Fields that indicate the pass/fail indication of each BIST, see Types of BIST sequences and Types of BIST partitions
- Fields that indicate the status of each type of online STCU2 internal error condition
- Programmable fault mapping of each BIST for controlling the type of fault that STCU2 reports (recoverable or unrecoverable) when the BIST fails to execute
- Programmable fault mapping of each STCU2 internal error condition for controlling the type of fault that STCU2 reports (recoverable or unrecoverable) when the condition occurs
- Signals to report recoverable and unrecoverable faults to the FCCU module
- Redundant recoverable and unrecoverable fault-generation logic to improve reliability
- FCCU recoverable and unrecoverable fault-injection mechanism
- Global register write-protection mechanism that requires two security key codes
- Global automatic power saving after a BIST sequence is completed when watchdog timer time-out is detected

- Watchdog automatic clock wake-up mechanism when software unlocks the STCU2 registers for write access
- Watchdog automatic power saving when the fixed register-write-access watchdog timer times out

49.4 Block diagram

This diagram shows the parts of STCU2:

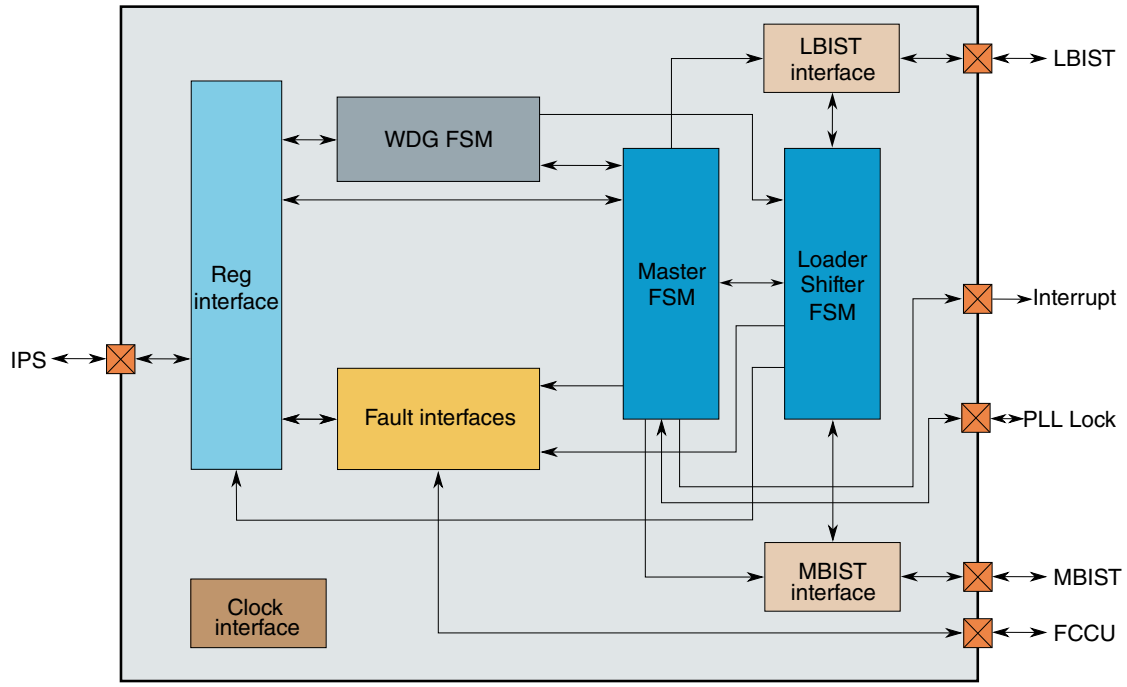

Figure 196. STCU2 block diagram

This table describes the parts of STCU2:

Table 239. STCU2 parts

Part	Function
Reg interface	Provides access to: • Registers • The security key logic • The IPS interface
Fault interfaces	Performs the following tasks: • Collects the fault conditions caused by STCU2 internal error conditions and each BIST executed in a sequence • Sets the global recoverable or unrecoverable status flag, depending on the fault mapping for a given BIST • Manages the recoverable and unrecoverable fault lines to and from the FCCU module

Table continues on the next page...

Table 239. STCU2 parts (continued)

Part	Function
	• Manages the set/clear injection mechanism provided by the FCCU module To improve the intrinsic reliability of this critical logic, the generation logic is duplicated.
Clock interface	Manages the internal and the BIST clock prescaler, the internal clock-gating power saving, and the wake-up clock feature
WDG FSM	Provides the following: • A programmable BIST-sequence-execution watchdog timer that specifies the maximum time allowed for the execution of a BIST sequence • A fixed register-write-access watchdog timer that specifies the maximum amount of time that STCU2 allows you to write to its registers after you unlock them
Master FSM	Coordinates and schedules all of the operations performed during a BIST sequence
Loader Shifter FSM	Programs the BIST registers and reads back the data to be checked at the end of each test operation
LBIST interface	Provides the interface between the chip's LBIST engines and the STCU2 controllers
MBIST interface	Provides the interface between the MBIST controller and the STCU2 controller

49.5 Peripheral bus interface

The peripheral bus interface is a slave bus used for configuration purposes via CPU. The module supports the following bus read operations:

- Word (32 bits) data read operations to any registers
- Any other operation is not supported.

Word, low and high half-words, byte operations are supported in write mode only:

- Write access is allowed by software only when CFG[WRP] is cleared. The default value of CFG[WRP] is cleared, exceptions are the following read/write fields: CFG[WRP], ERR_STAT[UFSF] and ERR_STAT[RFSF].
- STCU2 Configuration (CFG) should only be accessed in 32 bit (partial access not allowed).

The STCU2 module generates a transfer error in the following cases:

- Any read access to the registers after writing Key1 and before writing Key2 (in online) and before register write-access watchdog timer expires.
- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register
- Any write operation on Double Security Key register applying a wrong sequence of keys (the two write operations cannot be interleaved with other access to STCU2 registers)
- Any write operation performed on a register when the Double Security keys have not been applied

- Any write operation performed on registers when CFG[WRP] is set and the access is performed through software (internal peripheral interface). The exceptions are SKC register (for valid keys value and sequence) in which STCU2 does not assert transfer error.
- Any write operation performed on Read Only registers

The registers of the STCU2 module are accessible (read/write) in each access mode: user, supervisor, or test.

In case there are write operations on bits marked as reserved, the transfer error is not generated.

NOTE

See the chip-specific STCU2 information for the wait time necessary to write to the online registers.

49.6 BISTs and BIST partitions

49.6.1 Definition: BIST

A BIST is a test that the chip can execute to verify the functional integrity of a part of itself. The chip uses STCU2 and other on-chip hardware to execute a BIST.

49.6.2 Definition: BIST partition

A BIST partition is a part of a chip for which a BIST has been defined. The hardware that is included in a given BIST partition is chip-specific. For a list of the hardware included in each of the BIST partitions on this chip, see the chip-specific STCU2 information.

49.6.3 Example: BIST partitions on a chip

This is an example of a chip with six BIST partitions:

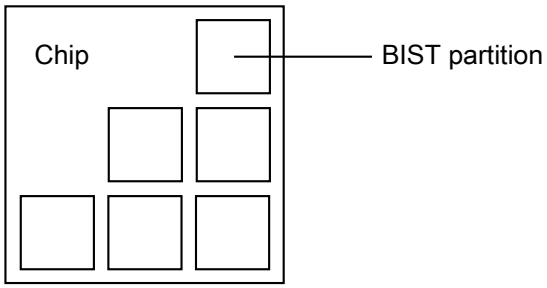

Figure 197. BIST partitions on a chip

49.6.4 Types of BIST partitions

The STCU2 module on this chip supports the following types of BIST partitions:

Table 240. Types of BIST partitions

BIST partition type	Description
MBIST partition	An SRAM or ROM block
LBIST partition	One or more digital modules

49.7 BIST sequences

49.7.1 Definition: BIST sequence

A BIST sequence is a programmable series of one or more phases, each of which executes one or more individual BISTs.

49.7.2 STCU2 executes MBISTs before LBISTs

If a BIST sequence includes both MBISTs and LBISTs; STCU2 executes the MBISTs first.

49.7.3 Example: Single-phase BIST sequence

This is an example of a single-phase BIST sequence in which STCU2 executes only one BIST:

Table 241. Example: Single-phase BIST sequence

Phase	BIST executed
0	MBIST 16

49.7.4 Example: Multi-phase BIST sequence

This is an example of a multiphase BIST sequence in which STCU2 executes more than one BIST in parallel in some phases:

Table 242. Example: Multi-phase BIST sequence

Phase	BISTs executed
0	MBISTs 7, 30
1	MBIST 23
2	MBISTs 6, 16, 29, 23
3	LBIST 12
4	LBISTs 13, 8, 11
5	LBISTs 19, 6

49.7.5 Types of BIST sequences

The STCU2 module on this chip supports these types of BIST sequences:

Table 243. Example: Types of BIST sequences

BIST sequence type	Description
Online BIST sequence	A BIST sequence that STCU2 executes during runtime at the request of software. Application software configures and initiates execution of the BIST sequence by loading values into STCU2 registers.

49.7.6 Supported BIST sequences

NXP supports only a specific set of BIST sequences for this chip. For the list of supported BIST sequences, see the chip-specific STCU2 information.

49.8 Functional description

49.8.1 FSM description

The module has three FSM that work together: Master FSM, Loader/Shifter FSM, and the Watchdog FSM. Basically the Master FSM is the core unit of the STCU2 module. It coordinates all the self-test operations and the other FSM. The Loader/Shifter FSM is used to program the MBIST and the LBIST parameters and to retrieve the related results depending on the parameters stored into the STCU2 registers and under the control of the Master FSM. The Watchdog FSM evaluates all the schedule time for MBIST and LBIST and the time-out in case of wrong STCU2 programming.

49.8.2 Reset management

STCU2 generates reset signals at the end of the self-test execution phase depending upon on the self-test conditions and configurations.

49.8.2.1 Online reset generation

See the chip-specific STCU2 information for details about online reset generation.

49.8.3 BIST scheduling

STCU2 is designed to program the parallel/serial execution of the MBIST or LBIST depending on the power, timing, and coverage constraints.

The mechanism used to provide this flexibility is a linked list of BIST descriptors where the starting pointer is defined in CFG[PTR]. The first LBIST is mapped on 0, the second on 1, and so on. A BIST descriptor identifies a LBIST or MBIST via an index that is associated with its control register (STCU2 LBIST Control (LB_CTRL0) or STCU2 MBIST Control (MB_CTRL0 - MB_CTRL11)). The first MBIST is mapped on (00000080h + 0), the second on (00000080h + 1), and so on. The additional pointers of the linked list are in LB_CTRL*n*[PTR] for LBIST *n* (where *n* is the selected LBIST) and MB_CTRL*m*[PTR] for MBIST *m* (where *m* is the selected MBIST) and must be populated depending on the selected run sequence. The additional fields LB_CTRL[CSM] and MB_CTRL[CSM] provide the flexibility to run concurrently or sequentially the chosen set of the LBIST or MBIST or to close the linked list by setting the NIL pointer.

49.8.4 FCCU interface

The FCCU interface is the hardware flag mechanism towards the system, to indicate the occurrence of an Unrecoverable fault and/or a Recoverable fault failure during the Self Test sequence. Two independent signals have been used to mitigate the common cause faults.

To diagnose physical defects on the two fault signals, a fault injection mechanism is also provided. In this case, the FCCU interface allows the user application to check the integrity of the UF and RF connection lines between the STCU2 and the FCCU. Refer to the description of FCCU fault injection mechanism to understand how the UF/RF set/clear mechanism works.

49.8.5 Watchdogs

The STCU2 implements different watchdogs to ensure that operations are finished in time.

49.8.5.1 BIST watchdog timer

The LBIST and MBIST execution time has to be configured as described in STCU2 Watchdog Granularity (WDG), to account for the overall execution time of the self test sequence. In case the selected LBISTs or MBISTs are not yet completed during assigned time, the current LBISTs or MBISTs execution is interrupted and a failure is flagged into ERR_STAT[WDTOSW] and MBESWx or LBESW.

In case of multiple sequential run in the same online session and the time-out happens in the middle of a sequential run, the next sequential run will be skipped and the execution ends with the current updated status of the registers reported above.

In all the cases, the STCU2 reset generation is managed in one of the modes described in Reset management.

49.8.5.2 Register write-access watchdog timer

As explained in the STCU2 SK Code (SKC):

- A key mechanism protects STCU2 registers during the self-test configuration phase by preventing any unwanted access.
- A hardware watchdog timer locks register-write access after a number of STCU2 clock cycles. To refresh the hardware watchdog timer before it times out, write Key1 and Key2 sequences.

AUTOLOCK_VALUE is the number of STCU2 clock cycles after which the hardware watchdog timer locks register-write access. See the chip-specific STCU2 information for the value of AUTOLOCK_VALUE.

The hardware watchdog timer is particularly useful in case CFG[WRP] is 0 during the software self-test configuration. In this case, the software application might enable write access to the STCU2 registers.

49.9 STCU2 register descriptions

The STCU2 registers are listed in this section.

NOTE

Always write the reset value for the Reserved fields.

During online self-test, after the STCU2 registers are configured, they must not be overridden via internal peripheral system until the self-test is complete.

49.9.1 STCU2 memory map

STCU base address: 403A_0000h

49.9.2 STCU2 Run Software (RUNSW)

Offset

Register	Offset
RUNSW	4h

Function

The RUNSW register defines the RUNSW bit to start the online self-testing procedure.

The R/W fields in this register are readable at any time. However, you can write to these fields only when CFG[WRP] = 0.

49.9.3 STCU2 SK Code (SKC)

Offset

Register	Offset
SKC	8h

Function

The SKC register implements the security key code mechanism needed to access in write mode to the other STCU2 registers.

To unlock STCU2 access after the STCU2 asynchronous reset and at the end of the STCU2 run, the software (IPS bus) need to apply the following sequence:

- write the key1 into the SKC register

- write the key2 into the SKC register

Depending on the online test step, the two keys are different. Byte write operation is not allowed because the full key has to be recognized as one unit.

A hard-coded WDG counter (Register write-access watchdog timer) starts decrementing its value right after POR is deasserted. Therefore, user must ensure to complete unlocking and programming sequence before its expiry. In case the STCU2 register access lasts more cycles than the one defined in the hard-coded WDG timeout, the STCU2 write access is locked and the WDG and register interface clocks are switched off. Also, in this case, to enable the write access to the STCU2 again and the WDG and register interface clocks, it is required to apply the sequence again. In case of invalid access or sequence (Key1/2 have to be applied consecutively), a transfer error on the IPS is asserted. The STCU2 write access is locked and to unlock the access, the sequence has to be applied again. This can also happen if watchdog expires between key1 and key2. In this case, user needs to apply the key1-key2 sequence again. In case it is required to extend the STCU2 register access cycles before the hard-coded WDG timeout expires, Key1 and Key2 sequences need to be applied. The effect of this write operation is to re-initialize the WDG timeout counter. The STCU2 write access is locked and to unlock the access, the sequence has to be applied again.

The SKC register is not readable. The value 00000000h is always returned in case of read operation.

49.9.4 STCU2 Configuration (CFG)

Offset

Register	Offset
CFG	Ch

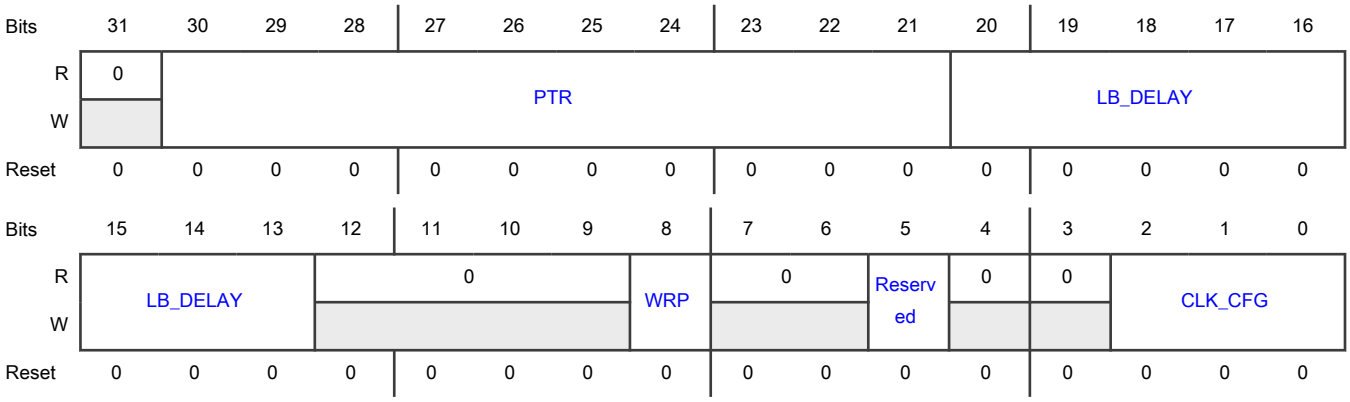
Function

The CFG register includes the global configuration of the STCU2 and can be updated in the online test steps.

The access to this register is described in the following figure. It further depends on the state of the WRP bit as follows:

- When WRP = 0: The register can be written during the online self-test case without restrictions.
- When WRP = 1:
  - The only bit that can be written without any restriction is WRP.
  - In case there are software operations that write all the register's bits, a transfer error is raised only if the value of the selected byte written differs from the current status of the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate this single bit clean capability.

Diagram



Fields

Field	Function
31 —	Reserved
30-21 PTR	First LBIST or MBIST pointer PTR defines the logical pointer to the first LBIST or MBIST to be scheduled when the self-testing procedure is enabled. PTR is the entry pointer to a linked list of BIST descriptors. If PTR = 0 then the LBIST0 is initially scheduled. See BIST scheduling for details. 0h to (01h - 1): pointer to LBIST 00000080h to (00000080h + 00Ch - 1): pointer to MBIST 3FFh: pointer to NIL. No BIST execution. others: invalid pointer => an error is set into the ERR_STAT[INVPSW].
20-13 LB_DELAY	Delay LBIST run LB_DELAY defines the delay between the LBIST starts when more than a single LBIST is selected to be executed concurrently with the purpose of smoothing the power consumption transient. 5 —	Reserved
4 —	Reserved
3 —	Reserved
2-0 CLK_CFG	Logic, Memory BIST, and STCU2 CORE_CLK configuration CLK_CFG defines the ratio between the sys_clk and the internal clock used to program both the LBIST and the MBIST and the STCU2 CORE_CLK. The punch-out mechanism is used to generate the derived clocks. The following configurations are allowed: 000b - sys_clk/1 001b - sys_clk/2 010b - sys_clk/3 011b - sys_clk/4 100b - sys_clk/5 101b - sys_clk/6 110b - sys_clk/7 111b - sys_clk/8

49.9.5 STCU2 Watchdog Granularity (WDG)

Offset

Register	Offset
WDG	14h

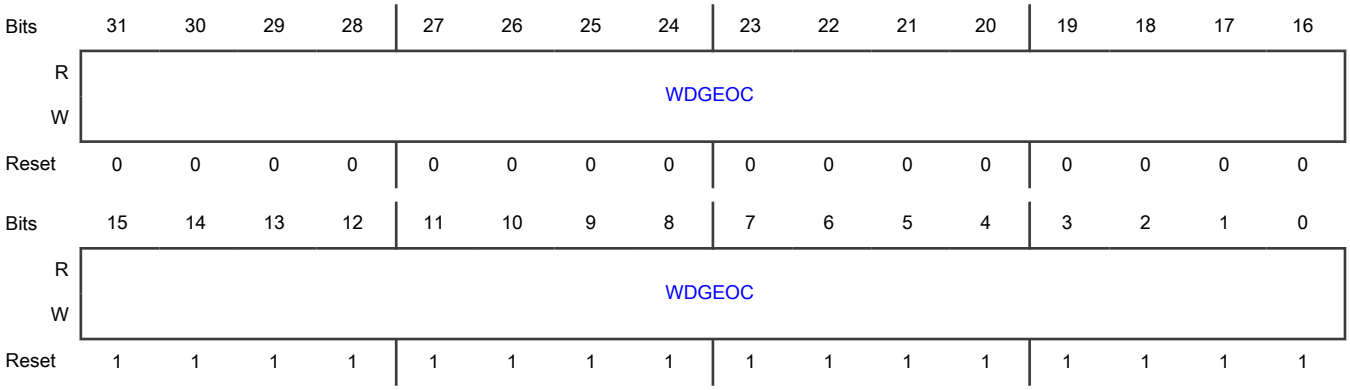
Function

The WDG register defines the time budget of LBIST and MBIST execution providing a protection mechanism in case of dead-lock or endless conditions during the self-test procedure.

In case online self-test sequence is run, it defines the timeout of the execution run.

The R/W fields in this register are readable at any time. You can write to these fields when online self-test phase is active and CFG[WRP] = 0.

Diagram



Fields

Field	Function
31-0 WDGEOC	Watchdog End of Count Timer This value has to be set to define the time budget related to the online self-test execution and check that everything is correctly working within this slot of time. The delay time slots that are allowed are as follows: 0000 0000h: 1 x 16 STCU2 CORE_CLK cycles 0000 0001h: 2 x 16 STCU2 CORE_CLK cycles 0000 0002h: 3 x 16 STCU2 CORE_CLK cycles ... FFFF FFFDh: 4294967294 x 16 STCU2 CORE_CLK cycles FFFF FFFEh: 4294967295 x 16 STCU2 CORE_CLK cycles FFFF FFFFh: 4294967296 x 16 STCU2 CORE_CLK cycles

49.9.6 STCU2 Error (ERR_STAT)

Offset

Register	Offset
ERR_STAT	24h

Function

The ERR_STAT register includes the status flags related to the STCU2 internal error conditions occurred during the configuration or the online self-testing execution.

The UFSF and RFSF can be set/cleared using the FCCU dedicated channels.

The access to this register is described in the following figure and as follows:

- If you select the byte write capability to write only UFSF and RFSF, then there is no restriction in writing these bits.
- If your software performs the write operations on other bits besides UFSF/RFSF, then a transfer error is generated only if the value you are writing to the other bits differs from their value currently stored in the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate the UFSF/RFSF single bit set/clean capability.

Diagram

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
20 LOCKESW	Online LOCK error You can always read this field. The content of this field is initialized to its reset value when RUNSW[RUNSW] is set to 1. 0b - In case PLL is enabled, it is correctly locked during the self-test sequence 1b - When the PLL is enabled, this flag highlights that there has been an unexpected PLL unlock(loss-of-lock) event during the online self-test sequence execution. The online self-test run is stopped and the status of the currently running LBISTs or MBISTs is saved in the related registers. The LOCK signal is monitored during the LBIST run when RUNSW[LBSWPLLEN] is set and/or during the MBIST run when RUNSW[MBSWPLLEN] = 1.
19 WDTOSW	Online watchdog timeout You can always read this field. The content of this field is initialized to its reset value when RUNSW[RUNSW] is set to 1. 0b - LBIST and MBIST time slots completed within the assigned watchdog time. 1b - LBIST and MBIST time slots not completed within the assigned watchdog time or there are internal mismatches among End of Execution signals.
18 —	Reserved
17 ENGESW	Online engine error You can always read this field. The content of this field is initialized to its reset value when RUNSW[RUNSW] is set to 1. 0b - Valid engine execution 1b - Invalid engine execution. The error conditions that set this bit are FSM, protocol error, and so on.
16 INVPSW	Online invalid pointer You can always read this field. The content of this field is initialized to its reset value when RUNSW[RUNSW] is set to 1. 0b - Valid linked pointer list 1b - Invalid linked pointer list. The following conditions set this bit: Initial LBIST or MBIST pointer is out of range; LBIST is selected when MBIST is concurrently running or vice versa; Error in the LBIST/MBIST linking (execution generates an infinite loop).
15-10 —	Reserved
9 UFSF	Unrecoverable Faults Status Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This flag reports the global status of the Unrecoverable Faults(UF). This field can be set or cleared using the FCCU dedicated channel, and can also be set or cleared by software. 0b - No errors that trigger the UF condition. 1b - There are errors that trigger the UF condition.
8 RFSF	Recoverable Faults Status Flag This flag reports the global status of the Recoverable Fault (RF). This field can be set or cleared using the FCCU dedicated channel, and can also be set or cleared by software. 0b - No errors that trigger the Recoverable Faults condition 1b - There are errors that trigger the Recoverable Faults condition
7-5 —	Reserved
4-0 —	Reserved Write may occur on these fields but writes have no effect.

49.9.7 STCU2 Error FM (ERR_FM)

Offset

Register	Offset
ERR_FM	28h

Function

The ERR_FM register defines the fault mapping of the STCU2 faults described in the register ERR_STAT in terms of UF or RF. All sources of internal faults can be routed to UF and RF.

The R/W fields in this register are readable at any time. You can write to these fields when online self-test phase is active and CFG[WRP] = 0.

49.9.10 STCU2 Online LBIST Reset Management (LBRMSW0)

Offset

Register	Offset
LBRMSW0	6Ch

Function

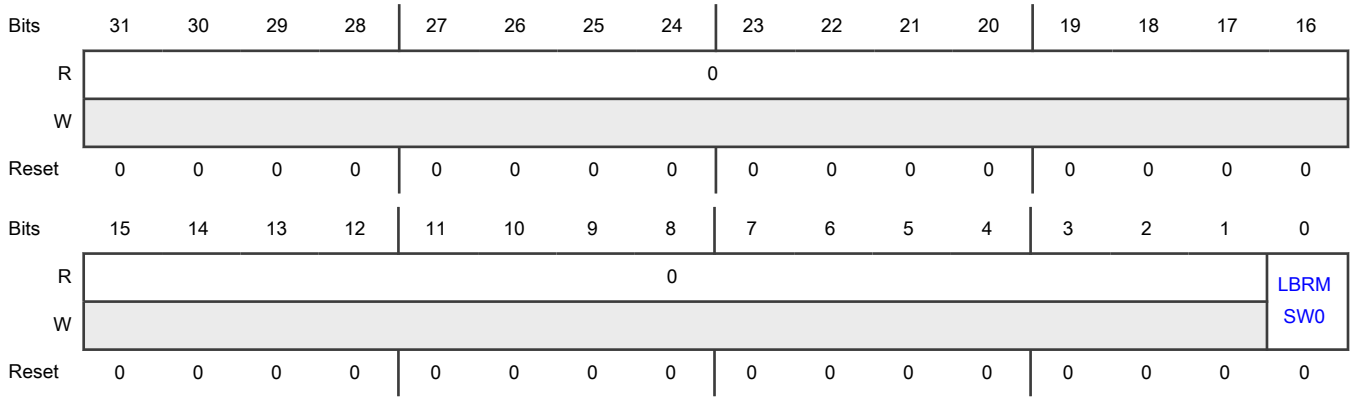
The LBRMSW register defines the online reset mapping for each LBIST. Global or specific functional reset can be programmed depending on the online self-test requirements and top-level integration architecture .

The size of the register depends on the number of LBIST .

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Online self-test phase is active and CFG[WRP] = 0

Diagram



Fields

Field	Function
31-1 —	Reserved
0-0 LBRMSWn	LBRMSW Online LBIST Reset Management **NOTE** In case one of the selected LBIST has this bit set to '1', then only the Global functional reset is pulsed. 0b - Dedicated functional reset is pulsed at the end of LBIST run 1b - Global functional reset is pulsed at the end of LBIST run

49.9.11 STCU2 Online LBIST Unrecoverable FM (LBUFM0)

Offset

Register	Offset
LBUFM0	7Ch

Function

This register defines the fault mapping of each LBIST in terms of UF or RF.

The size of the register 0 depends on the number of LBIST .

Table continues on the next page...

Table continued from the previous page...

Field	Function
PTR	Next LBIST or MBIST pointer PTR defines the logical pointer to the next LBIST or MBIST to be scheduled. The next LBIST or MBIST is scheduled concurrently to the current one if the CSM bit is set to 1; otherwise it is scheduled sequentially to the completion of the current MBIST execution. In case of NIL pointer the CSM bit must be set Sequential (0) to define this is the end of the list. The self-testing procedure stops after the last BIST in the configuration chain is complete. See BIST scheduling for details. **NOTE** If the pointer is invalid and MBIST is scheduled to run concurrently than this invalid scenario is handled by watchdog timeout feature and corresponding watchdog timeout status bit will be updated in ERR_STAT[WDTOSW]. In this particular case ERR_STAT[INVPSW] will not be set. 0h to (01h - 1): pointer to LBIST 00000080h to (00000080h + 00Ch - 1): pointer to MBIST 3FFh: pointer to NIL. No next BIST execution. others: invalid pointer => an error is set into the ERR_STAT[INVPSW].
20 BSEL	BSEL BIST Select 0b - Selected BIST is not selected for execution. 1b - Selected BIST is selected for execution.
19-0 —	Reserved

49.10 Glossary

BIST	Built-in self-test
BIST Clock	BIST controller clock corresponding to the specific BIST
CORE_CLK	Clock specified by the CFG register
FSM	Finite state machine
IPS	Internal peripheral system
LBIST	Logic BIST
MBIST	Memory BIST
NLBIST	Number of logic built-in self-test controller
NMCUT	Number of memory checked using memory built-in self-test controller
Online self-test phase	In this condition, system is alive and the SW can program STCU2
RF	Recoverable faults
UF	Unrecoverable faults

WDG FSM	Watchdog finite state machine

Chapter 50
Register Protection (REG_PROT)

50.1 Chip-specific REG_PROT information

50.1.1 REG_PROT configuration

The MCU safety relevant configuration registers are protected against unauthorized HW/S changes during read/write/clear access by implementing them with register protection module. See the REG_PROT details file attached to this document.

50.1.1.1 CMU_BRIDGE register protection

The CMUs in the device reside on a common peripheral slot as CMU_BRIDGE in the system memory map. Figure 198 indicates the locations of the CMUs along with the memory map.

Based on the CMU location in system peripheral memory map, the below locations in the CMU 16KB space are reserved and any access on these locations results in a bus transfer error.

402B_C018 – 402B_C01F

402B_C030 – 402B_C03F

402B_C050 – 402B_C05F

402B_C078 – 402B_C07F

402B_C098 – 402B_C09F

402B_C0B8 – 402B_C0BF

402B_C0D8 – 402B_CFFF

Since the register protection is available in the device for CMU_BRIDGE, the 4KB offset locations (refers as the Area 2 in register protection) are also reserved and accesses over these regions also result in bus transfer error.

402B_D018 – 402B_D01F

402B_D030 – 402B_D03F

402B_D050 – 402B_D05F

402B_D078 – 402B_D07F

402B_D098 – 402B_D09F

402B_D0B8 – 402B_D0BF

402B_D0D8 – 402B_DFFF

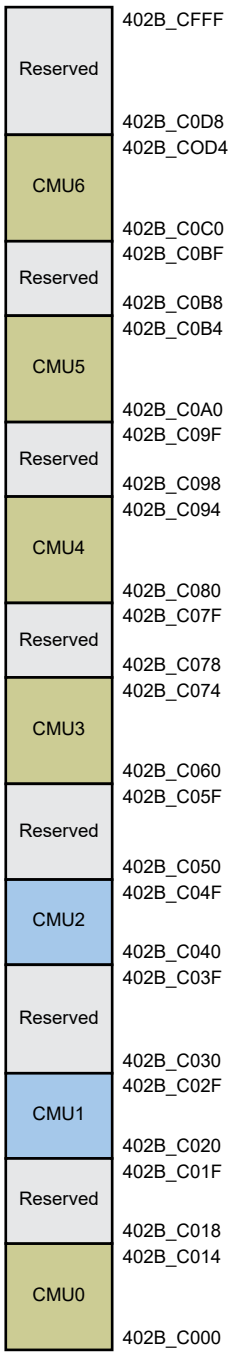

Figure 198. Location of CMUs

50.2 Overview

REG_PROT offers a mechanism to protect defined memory-mapped address locations, in a module under protection, from being written.

REG_PROT is a protection module that is located between the module under protection and the peripheral interface. The address locations to be protected exist in the module under protection and the address locations that can be protected are module specific. Writes to these protected address locations are locked using a Soft Lock Bit Register (SLBR*n*). Any access to address locations in the module under protection is restricted if their corresponding Soft lock fields in a Soft Lock Bit Register (SLBR*n*) are 1.

The configured soft-lock fields can also be write-restricted by using GCR[HLB]. When GCR[HLB]=1, you cannot write to the soft-lock fields. The address locations in the module under protection can be restricted to Supervisor mode access using GCR[UAA].

50.2.1 Block Diagram

The following figure shows the block diagram of this module.

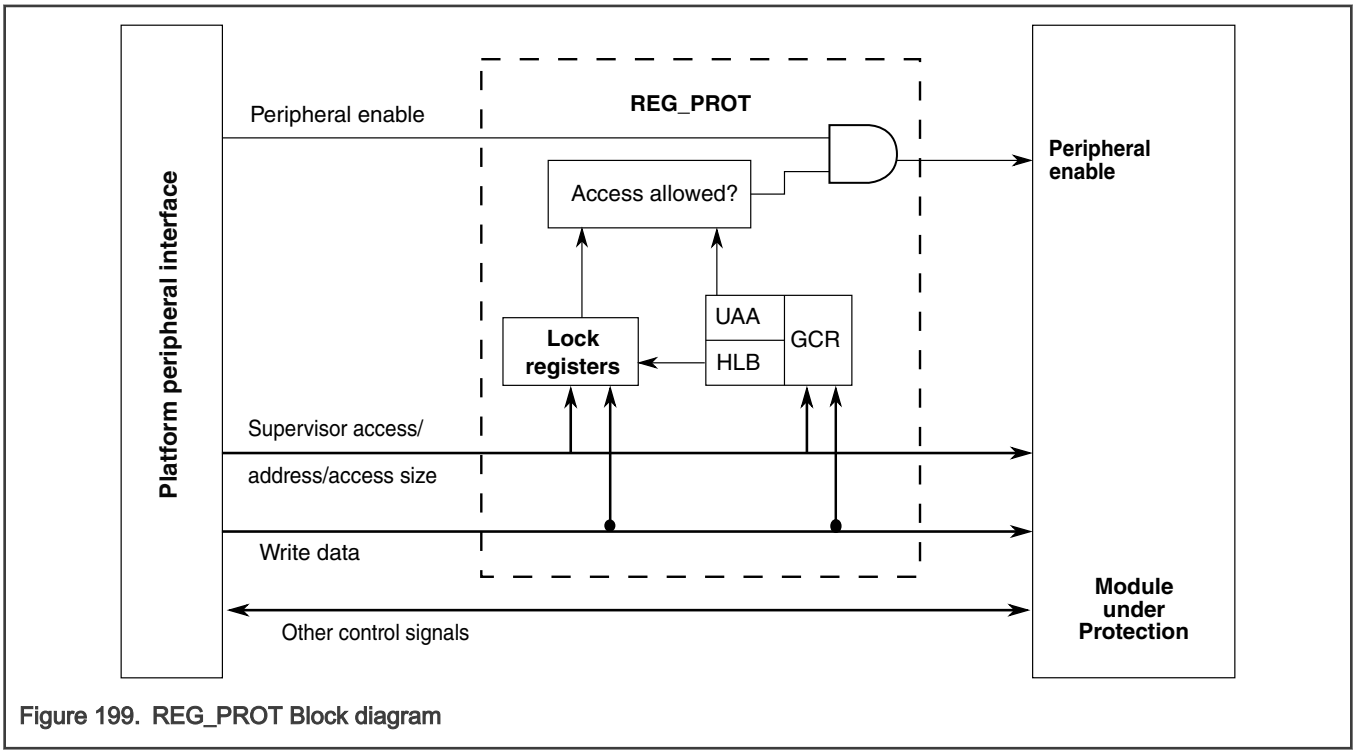

Figure 199. REG_PROT Block diagram

50.2.2 Features

REG_PROT includes these distinctive features:

- Write accesses for the module under protection can be restricted to the supervisor mode only.
- Registers of modules with their register slot size occupying 1 KB to 32 KB of memory-mapped address space, depending on the PROT_MEM parameter, can be dynamically locked. See Memory space and Protection size.
- Multiple ways are present to set the lock bits.
- After the lock bits are configured, they can be protected from changes.

50.3 Functional description

The following sections describe the functional characteristics of the REG_PROT module.

50.3.1 Modes of operation

The mode of REG_PROT depends on the Module Under Protection (MUP). The REG_PROT is operable when the MUP is operable.

The below table shows the write operations in user mode.

Table 244. User mode access table

GCR[UAA]	SLBRn[SLBm]	Write Operation on MUP	Write Operation on REG_PROT
0	0	Transfer error generated, write operation unsuccessful.	Transfer error generated, write operation unsuccessful.
0	1	Transfer error generated, write operation unsuccessful.	Transfer error generated, write operation unsuccessful.
1	0	• If register is implemented and write operation allowed on accessed address location then write operation is successful. • If register is not implemented or write operation is not allowed on accessed address location then transfer error is generated, write operation is unsuccessful.	• If register is implemented and write operation allowed on accessed address location then write operation is successful. • If register is not implemented or write operation is not allowed on accessed address location then transfer error is generated, write operation is unsuccessful.
1	1	Transfer error generated, write operation unsuccessful.	• If register is implemented and write operation allowed on accessed address location then write operation is successful. • If register is not implemented or write operation is not allowed on accessed address location then transfer error is generated.

Note:

- Read operation is always allowed
- n >= 0, m = [0,3]

50.3.2 Memory space and Protection size

This section provides a detailed description of the memory space and protection size of a module using REG_PROT.

The PROT_MEM size varies per chips. It can be:

- 1 KB
- 2 KB
- 4 KB
- 8 KB
- 16 KB
- 32 KB

The resulting memory space is divided into four areas. Memory locations within area #1 and area #2 are a part of the module under protection. Area #3 and area #4 are a part of REG_PROT.

The proper register slot size for each protected module is mentioned in the REG_PROT details file attached to this document.

Following is the memory space for a module that is protected by the REG_PROT module. Reserved registers in area #1 are handled as specified in the protected module's documentation. There is a single register in configuration space that corresponds

to area #4 while the size mentioned in Area size column is to turn the whole area multiple of 4 KB. See the Offset column to know the exact location of the GCR register.

Table 245. Area offset based on protection size

PROT_MEM	Area	Area size	Use	Offset
1 KB	Area 1	1 KB	Module Register(MR0—MR1023)	0000h—03FFh
	Area 2	1 KB	Module Register and Set Soft Lock Bit (LMR0—LMR1023)	0400h—07FFh
	Area 3	256 B	Soft Lock Bit Register (SLBR0—255)	0800h—08FFh
	Area 4	256 B	Global Configuration Register (GCR)	0900h—09FFh
		1.5 KB	Reserved	0A00h— 0FFFh
2 KB	Area 1	2 KB	Module Register (MR0—MR2047)	0000h—07FFh
	Area 2	2KB	Module Register and Set Soft Lock Bit (LMR0—LMR2047)	0800h—0FFFh
	Area 3	512 B	Soft Lock Bit Register (SLBR0—511)	1000h—11FFh
	Area 4	256 B	Global Configuration Register (GCR)	1200h—12FFh
		3.25 KB	Reserved	1300h—1FFFh
4 KB	Area 1	4 KB	Module Register (MR0—MR4095)	0000h—0FFFh
	Area 2	4 KB	Module Register and Set Soft Lock Bit (LMR0—LMR4095)	1000h—1FFFh
	Area 3	1 KB	Soft Lock Bit Register (SLBR0—1023)	2000h—23FFh
	Area 4	256 B	Global Configuration Register (GCR)	2400h—24FFh
		6.75 KB	Reserved	2500h—3FFFh
8 KB	Area 1	8 KB	Module Register (MR0—MR8191)	0000h—1FFFh
	Area 2	8 KB	Module Register and Set Soft Lock Bit (LMR0—LMR8191)	2000h—3FFFh
	Area 3	2 KB	Soft Lock Bit Register (SLBR0—2047)	4000h—47FFh
	Area 4	256 B	Global Configuration Register (GCR)	4800h—48FFh
		1.75 KB	Reserved	4900h—4FFFh
16 KB	Area 1	16 KB	Module Register (MR0—MR16383)	0000h—3FFFh
	Area 2	16 KB	Module Register and Set Soft Lock Bit (LMR0—LMR16383)	4000h—7FFFh
	Area 3	4 KB	Soft Lock Bit Register (SLBR0—4095)	8000h—8FFFh
	Area 4	4 KB	Global Configuration Register (GCR)	9000h—9FFFh
32 KB	Area 1	32 KB	Module Register (MR0—MR32767)	0000h—7FFFh
	Area 2	32 KB	Module Register and Set Soft Lock Bit (LMR0—LMR32767)	8000h—FFFFh
	Area 3	8 KB	Soft Lock Bit Register (SLBR0—8191)	10000h—11FFFh
	Area 4	4 KB	Global Configuration Register (GCR)	12000h—12FFFh

- Area #1 can take the memory space of 1 KB/2 KB/4 KB/8 KB/16 KB/32 KB, which holds the normal functional module registers and is transparent for all read/write operations.
- Area #2 can take the memory space of 1 KB/2 KB/4 KB/8 KB/16 KB/32 KB and is a mirror of area #1. For an example, if area #1 takes 8 KB of memory space, then read/write access to an offset 2000+X reads/writes the register at offset X. However, a write access to offset 2000+X additionally sets the optional soft lock bits for this offset X in the same cycle

as the register at offset X is written. This provides for an automatic write and lock operation. Not all registers in area #1 need to have protection defined by the associated soft lock bits. For unprotected registers at offset Y, accesses to offset 2000+Y are identical to accesses at offset Y.

- Area #3 can take the memory space of 256 B/512 B/1 KB/2 KB/4 KB/8 KB and hold soft lock bits, one bit per byte in area #1. The four soft lock bits associated with one module register word are arranged at byte boundaries in the memory map. The Soft Lock Bit registers can be directly written using a bit mask.
- Area #4 can take the memory space of 1.75 KB/3.5 KB/7 KB/2 KB/4 KB/4 KB and holds the configuration bits of the protection mode. There is one configuration Hard lock bit per module that prevents all further modifications to the soft lock bits and can only be cleared by a system reset after it is set. When user access allowed bit is set, it allows user access to the protected module.

If you access a locked byte with a write transaction, a bus error is issued to the system and the write transaction is not executed. This is true even if not all accessed bytes are locked.

Accessing unimplemented 32—bit registers in area #3 results in a bus transfer error. In area #4, there will not be any transfer error for the address range mentioned in the table above because these address spaces of area #4 are mapped to the GCR register. Accesses in area #4, beyond the address range mentioned in the Module memory map table, are prohibited and might or might not result into a bus abort.

50.3.2.1 Module register (MR)

Each functional module has its own unique set of registers. This chapter refers to these registers generically as module registers (MR), which exist in the lower module memory space (memory area 1), and receive protection from the REG_PROT module.

50.3.2.2 Module Register and Set Soft Lock Bit (LMR)

This is memory area #2 that provides mirrored access to module registers with the side-effect of setting soft lock bits in case of a write access to a register that is defined as protectable by the locking mechanism. Each MR byte is protectable by one associated bit in SLBR*n* [SLB*m*], according to the mapping described in Soft Lock Bit Register (SLBR*n*).

50.3.3 General

This module provides a generic register (address) write-protection mechanism. The register protection size can be:

- 32 bits (address == multiples of 4)
- 16 bits (address == multiples of 2)
- 8 bits (address == multiples of 1)

The addresses that are protected and the register protection size depends on the chip and/or module.

For all addresses that are protected, there are SLBR*n*[SLB*m*] bits that specify whether the address is locked. When an address is locked, it can only be read but not written in any mode (supervisor/normal). If an address is unprotected, the corresponding SLBR*n*[SLB*m*] bit is always 0, regardless of what the software writes to that field.

NOTE

For more information on register protection specification, see the REG_PROT details file attached to this document.

50.3.4 Change lock settings

To change the setting whether an address is locked or unlocked, the corresponding SLBR*n*[SLB*m*] bit needs to be changed. This can be done using the following methods:

- Set the SLBR*n*[SLB*m*] bit(s) by writing to area #2
- Modify the SLBR*n*[SLB*m*] directly by writing to area #3

Both methods are explained in the following sections.

50.3.4.1 Change lock settings via area #2

You can lock a register after writing to it. Note that reading area #2 does not affect soft lock bits. To do so, you must use area # 2.

The following shows an example with PROT_MEM = 8 KB where SLBs are modified using area #2.

When writing 16-bit to address 0008h, MR9 and MR8 in the protected module are updated. The corresponding lock fields remain unchanged (see the left part of Figure 200).

When writing 16-bit to address 2008h, MR9 and MR8 in the protected module are updated. The corresponding lock fields SLBR2[SLB0:1] become 1, and the lock fields SLBR2[SLB2:3] remain unchanged (see the right part of Figure 200).

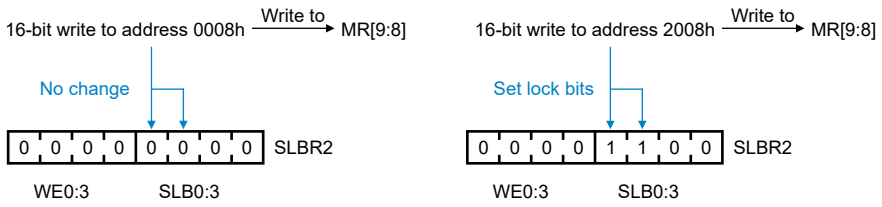

Figure 200. Enable locking via area #2

The following figure shows an example where some addresses are protected and some are not.

In Figure 201, addresses 000Ch and 000Dh are unprotected. Therefore, their corresponding lock fields SLBR3[SLB0:1] are always 0 (shown in bold). During a 32-bit write access to address 200Ch, the lock fields in SLBR3 change as follows:

- SLBR3[SLB2:3] become 1.
- SLBR3[SLB0:1] remain 0.

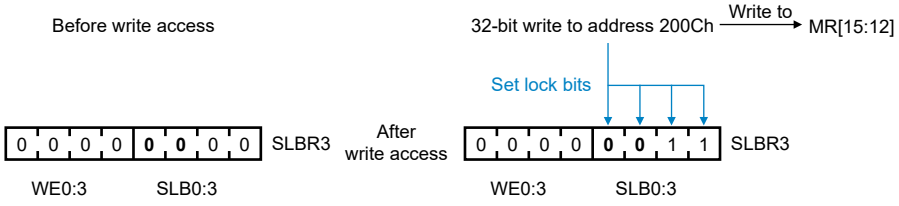

Figure 201. Enable locking for protected and unprotected addresses

50.3.4.2 Change lock settings via area #3

The lock bits are located in area #3 (see Table 245). You can modify them by writing to them. Each SLB*m* field in Soft Lock Bit Register (SLBR*n*) has a mask field, WE*m*, that protects SLB*m* from modification. This masking makes read-modify-write operations unnecessary.

Figure 202 shows two modification examples for registers with 8-bit protection. In part A, a write access to SLBR*n* specifies a mask value that allows modification of all SLBR*n*[SLB0:3] fields. Part B specifies a mask that allows modification only to SLBR*n*[SLB1:3].

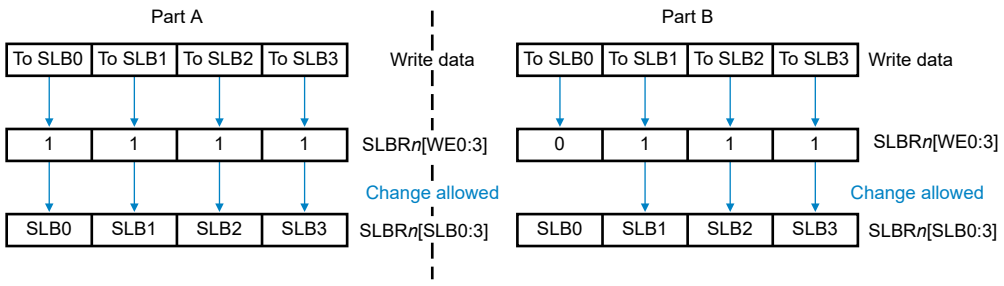

Figure 202. Change lock settings directly via area #3

Figure 203 shows examples for registers with 16-bit protection.

Part A of Figure 203 shows that for SLBR*n*:

- The data written to SLBR*n*[SLB0] is automatically written to SLBR*n*[SLB1].
- The data written to SLBR*n*[SLB2] is automatically written to SLBR*n*[SLB3].

This is because the address reflected by SLBR*n*[SLB0] and SLBR*n*[SLB2] are protected 16-bit wise. Note that in this case, the write enable SLBR*n*[WE0] and SLBR*n*[WE2] must be set while SLBR*n*[WE1] and SLBR*n*[WE3] don't matter.

Part B of Figure 203 shows that the data written to SLBR*n*[SLB0] is automatically written to SLBR*n*[SLB1]. This is done because the address reflected by SLBR*n*[SLB0] has 16-bit protection. In this case, SLBR*n*[WE0] must be 1 and SLBR*n*[WE1] does not matter. SLBR*n*[SLB2] and SLBR*n*[SLB3] remain unchanged because SLBR*n*[WE2] and SLBR*n*[WE3] are 0.

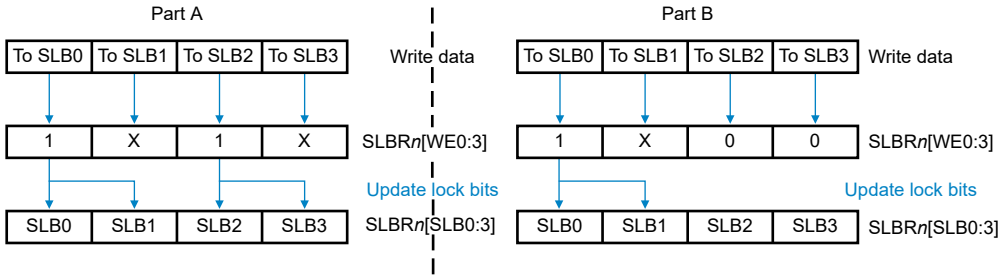

Figure 203. Change lock settings for addresses with 16-bit protection

Figure 204 shows a register with 32-bit protection. In SLBR*n*:

- When SLBR*n*[WE0]=1, the data written to SLBR*n*[SLB0] is automatically written to SLBR*n*[SLB1:3] as well.
- When SLBR*n*[WE0]=0, then SLBR*n*[SLB0:3] remain unchanged. Note that in this case, the write enable SLBR*n*[WE0] must be set while SLBR*n*[WE1:3] does not matter.

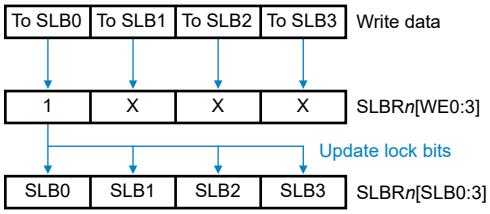

Figure 204. Change lock settings for addresses with 32-bit protection

The following figure shows a mixed protection size configuration.

In SLBR*n*:

- The data written to SLBR*n*[SLB0] is mirrored to SLBR*n*[SLB1] because the corresponding register has 16-bit protection.
- The data written to SLBR*n*[SLB2] is blocked because the corresponding register is unprotected.
- The data written to SLBR*n*[SLB3] is successfully written to SLBR*n*[SLB3] because the corresponding register has 8-bit protection.

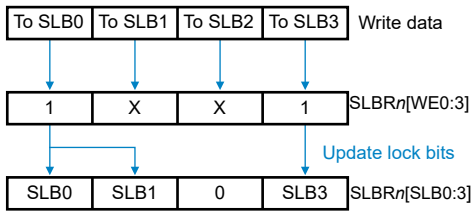

Figure 205. Change lock settings for mixed protection

50.3.4.3 Write protection for locking bits

Changing the locking bits through any of the procedures mentioned in Change lock settings via area #3 and Change lock settings via area #2 is only possible as long as the field GCR.HLB is cleared. After you write 1 to this field, the locking bits cannot be modified until there is a system reset.

50.3.5 Access errors

REG_PROT generates transfer errors under several circumstances, as described below. For the area definition, see Memory space and Protection size.

- If accessing area #1 or area #2, REG_PROT sends any access error from the underlying module under protection.
- If User mode is not allowed, the attempted User mode writes to all areas cause a transfer error, and the writes are blocked.
- If accessing the reserved area, a transfer error is asserted.
- If accessing unimplemented 32-bit registers in areas #3 and #4, a transfer error is asserted.
- If writing to a register in areas #1 and #2, and an SLB field is 1 for any of the affected bytes, then:
  - A transfer error is asserted.
  - The write is blocked.
  - The complete write operation to non-protected bytes in this word is ignored.
- If writing to an SLBR in area #3 with GCR[HLB]=1, a transfer error is asserted.
- Any write operation in any access mode to area #2, when GCR[HLB]=1, is not allowed.

NOTE

The transfer error generated by REG_PROT can only be observed on the CPU that initiates the target register write and has defined the strongly ordered memory region (through its MPU or MMU) covering the target register address.

50.4 External Signals

There are no external signals.

50.5 Initialization

The following sections contain information related to initialization of the Register Protection module.

50.5.1 Sequence

You must configure the REG_PROT first. And then, you need to write 1 to the HLB field in REG_PROT. This ensures that registers under protection are not updated in the user access mode. You need to follow these steps:

1. Enable XRDC protection for the module to enable writes in the supervisor mode only. This step is mandatory, if protected registers of the module are expected to be configured multiple times.
2. Configure REG_PROT to enable write on registers of module under protection.
3. Configure the registers of module under protection.
4. Configure the REG_PROT for the required SLB fields.
5. Set the HLB field in REG_PROT. This step is mandatory, if protected registers of module are expected to be configured only once.

50.5.2 Reset

It is a single clock IP, with single reset.

50.6 Writing C code using the register protection scheme

There is a set of macros provided as part of the device specific header file, which defines the memory map, the peripheral registers, and the fields of these registers. These macros are intended to make working with the register protection scheme easier for the developers of device driver software and/or other application code. This section describes these macros and how to use them.

A first macro is made available to perform a write to the mirrored module register space (Area 2). As described in this document, this results in concurrently setting the corresponding soft lock bit while writing to the module register. There are three types of this macro for each memory protection size `<PROT_MEM>`, to account for the different size of the related module register `<thereg>` (the value of `<size>` is either 8-bit, 16-bit, or 32-bit):

```
          WRITE_WITH_LOCK_<PROT_MEM>_<size>(<thereg>,
        <newvalue>)
```

This macro writes the value `<newvalue>` into the register `<thereg>` assuming a register size of `<size>`. The parameter `<thereg>` must be the name of a register using the notation in the device specific header file.

Example of using the macro for EMIOS_0.UCDIS.R register which is 32-bit width and the module has 4k memory protection size:

```
 WRITE_WITH_LOCK_4K_32BIT(&EMIOS_0.UCDIS.R, 0x000000FF);
```

A second set of macros is made available to work with the soft lock bits provided by the register protection scheme. The value of these bits associated with a particular module register `<thereg>` can be retrieved, set, and cleared. And, these macros are:

```
GET_SOFTLOCK_<PROT_MEM>
        (<modulebase>,<thereg>,<dest>)
```

```
SET_SOFTLOCK_<PROT_MEM>_<size>(<modulebase>,<thereg>)
```

```
CLR_SOFTLOCK_<PROT_MEM>_<size>(<modulebase>,<thereg>)
```

The macro GET_SOFTLOCK retrieves the value of the soft lock bit register associated with the given register `<thereg>` and stores it in the variable `<dest>`; which is always an 8-bit value. The other two macros (SET_SOFTLOCK, CLR_SOFTLOCK) set or clear the softlock bits associated with the given register `<thereg>`; assuming this register has a `<size>` of 8BIT, 16BIT, or 32BIT as indicated by the macro name. For all three macros, the parameter `<thereg>` must be the name of a register and the parameter `<modulebase>` base address of the module using the notation in the device specific header file.

Example of using the macros for SIUL2_0.PGPDO0.R register which is 16-bit width and the module has 8k memory protection size:

```
GET_SOFTLOCK_8K(&SIUL2_0, &SIUL2_0.PGPDO0.R, &variable);
```

```
SET_SOFTLOCK_8K_16BIT(&SIUL2_0, &SIUL2_0.PGPDO0.R);
```

```
CLR_SOFTLOCK_8K_16BIT(&SIUL2_0, &SIUL2_0.PGPDO0.R);
```

Three more macros are available to modify bits in the Global Configuration Register (GCR) of the protection gasket for the corresponding block. These macros receive the base address of the corresponding module `<modulebase>` as a parameter.

```
SET_HARDLOCK_<PROT_MEM>
      (<modulebase>)
```

Sets the Hard Lock Bit HLB in the Global Configuration Register associated with the module identified by the given module base address `<modulebase>`.

Example of using macro for DMAMUX_0 module which has 4k memory protection size:

```
SET_HARDLOCK_4K(&DMAMUX_0);
```

```
USER_ACCESS_FORBIDDEN_<PROT_MEM>
        (<modulebase>)
```

Clears the User Access Allowed Bit UAA in the Global Configuration Register associated with the module identified by the given module base address `<modulebase>`. When it is cleared, this bit denies any write access to the protected module in user mode and generates a transfer error in case of an attempt to write a protected register.

Example of using macro for DMAMUX_0 module which has 4k memory protection size:

```
USER_ACCESS_FORBIDDEN_4K(&DMAMUX_0);
```

```
USER_ACCESS_ALLOWED_<PROT_MEM>
        (<modulebase>)
```

Sets the User Access Allowed Bit UAA in the GCR register associated with the module identified by the given module base address `<modulebase>`. When it is set, this bit permits write accesses to the protected module in user mode when the corresponding register are not additionally protected by other means.

Example of using macro for DMAMUX_0 module which has 4k memory protection size:

```
USER_ACCESS_ALLOWED_4K(&DMAMUX_0);
```

The following macro is for reading the content of the GCR register.

```
GET_GCR_<PROT_MEM>
        (<modulebase>,<dest>)
```

Provides the content of the Global Configuration Register (GCR) for the block identified by its module base address `<modulebase>` and stores it in the variable `<dest>`; which is always 32-bit value.

Example of using macro for DMAMUX_0 module which has 4 k memory protection size:

```
GET_GCR_4K(&DMAMUX_0, &variable);
```

50.7 REG_PROT register descriptions

This register information documents memory area #3 and area #4.

50.7.1 REG_PROT memory map

REG_PROT base address: base address of protected module instance

Table 246. REG_PROT memory map

PROT_MEM	Offset	Register	Width (In bits)	Access	Reset value
1kB	0x800 – 0x8FF	Soft Lock Bit Register (SLBR0-255)	8	RW	00h
	0x900 – 0x9FF	Global Configuration Register (GCR)	32	RW	0000_0000h

	0x1200 – 0x12FF	Global Configuration Register (GCR)	32	RW	0000_0000h
4kB	0x2000 – 0x23FF	Soft Lock Bit Register (SLBR0-1023)	8	RW	00h
	0x2400 – 0x24FF	Global Configuration Register (GCR)	32	RW	0000_0000h
8kB	0x4000 – 0x47FF	Soft Lock Bit Register (SLBR0-2047)	8	RW	00h
	0x4800 – 0x48FF	Global Configuration Register (GCR)	32	RW	0000_0000h
16kB	0x8000 – 0x8FFF	Soft Lock Bit Register (SLBR0-4095)	8	RW	00h
	0x9000-0x9FFF	Global Configuration Register (GCR)	32	RW	0000_0000h
32kB	0x10000-0x11FFF	Soft Lock Bit Register (SLBR0-8191)	8	RW	00h
	0x12000 – 0x12FFF	Global Configuration Register (GCR)	32	RW	0000_0000h

50.7.2 Soft Lock Bit Register (SLBR*n*)

Offset

See REG_PROT memory map for SLBR*n* offset ranges. For SLBR*n* addresses, see the REG_PROT details file attached to this document.

Function

These registers hold the Soft Lock Bits (SLBs) for the protected registers in memory area #1, which is the normal register address space of the protected module. Multiple Soft Lock Bit Registers (SLBR*n*) can be implemented, depending on the number of protected module register bytes. Each SLBR*n* has four soft lock fields (SLB0-SLB3), each of which controls write access to a byte in memory area #1. Each soft lock field also has a corresponding write enable field in the same register that controls whether the soft lock field can be written. The following table shows the mapping between the soft lock fields to the bytes in memory area #1.

Table 247. SLBs vs. protected address

SLB	Protected address
SLBR0[SLB0]	MR0
SLBR0[SLB1]	MR1
SLBR0[SLB2]	MR2

Table continues on the next page...

Table 247. SLBs vs. protected address (continued)

SLB	Protected address

50.7.3 Global Configuration Register (GCR)

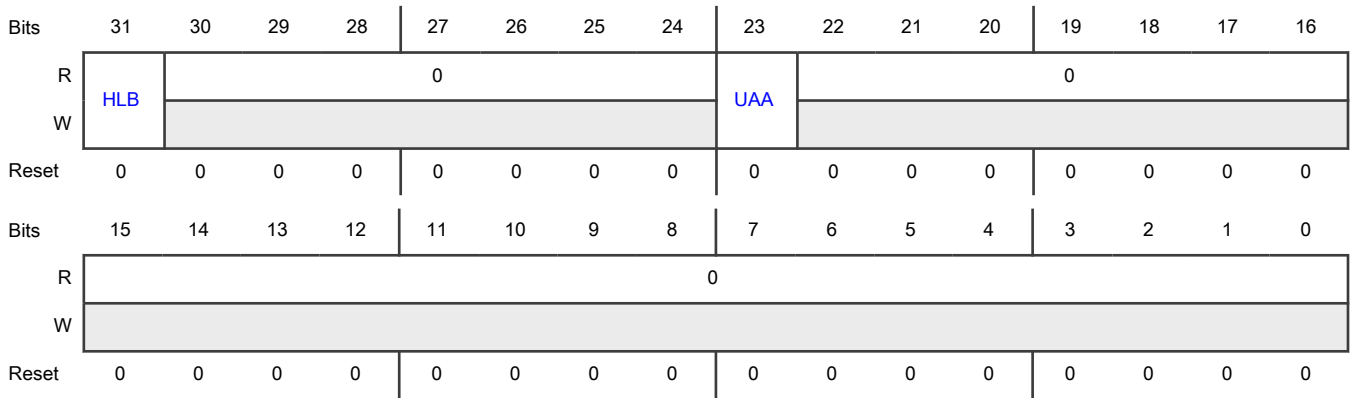
Offset

See REG_PROT memory map for GCR offset.

Function

This register controls module level configurations.

Diagram



Fields

Field	Function
31 HLB	Hard Lock Bit This field cannot be cleared after it is set by the software. It can only be cleared by a system reset. 0b - All SLB fields are accessible and can be modified. 1b - All SLB fields are write protected and cannot be modified. **NOTE** Once this bit is set, it will set all registers under the same PROT_MEM region.
30-24 —	Reserved
23 UAA	User Access Allowed Controls the user and supervisor mode access to registers of the module under protection. 0b - The registers in the module under protection can only be written in the supervisor mode (user access is not allowed). All the write accesses in user (non-supervisor) mode are not executed and a transfer error is issued. This access restriction is in addition to any access restrictions imposed by the protected IP module. 1b - The registers in the module under protection can be accessed in the mode defined for the module registers without any additional restrictions. It can be modified in both user (non-supervisor) and supervisory mode.
22-0 —	Reserved

50.8 Glossary

PROT_MEM Integration parameter that specifies the size of the module register slot protected. The PROT_MEM size depends on the chip or module.

Hard lock A lock that restricts access to any register bit. You can unlock or clear this lock through the hardware reset.

Soft lock A lock that restricts access to any register bit. You can unlock or clear this lock through the software.

Chapter 51
Clock Monitoring Unit – Frequency Check (CMU_FC)

51.1 Chip-specific CMU_FC information

51.1.1 CMU_FC configuration

The device consists of a robust clock monitoring architecture targeted to monitor various clock nodes to ensure device clock robustness. There are 7 clock monitoring units present in the device out of which 5 are of type CMU_FC. See 'Clock monitoring' section in Clocking chapter for details on device clock monitoring architecture.

NOTE

CMU_5 is accessible by Cortex-M0+ core only.

CMU_FC combined spec variation: The combined spec variation for CMU (used for configuring CMU_FCx.HTCR[HFREF] and CMU_FCx.HTCR[LFREF]) is the absolute sum of frequency variations of the clock sources. Refer device datasheet for frequency variations for the corresponding clock sources.

51.2 Overview

CMU_FC ensures the clock integrity of selected clocks and allows continuous clock integrity verification.

CMU_FC checks if the frequency of a monitored clock (*monitored_clock*) is within a programmable frequency range specified by the user. If the frequency is outside the specified limits, it could lead to performance, protocol, and timing failures. CMU_FC requires a clock used as a base reference for the frequency check operation. This reference clock (*reference_clock*) must be within documented limits for correct CMU_FC operation.

51.2.1 Block diagram

CMU_FC counts clock cycles of the monitored clock during a user programmable time duration of *n* clock cycles of the reference clock. There is a comparison between the final count of the monitored clock and the user programmable upper and lower threshold count limits. The control logic determines whether the cycle count is within the programmed limits. If not it sets the Frequency Higher than High frequency reference threshold event status (FHH) field or the Frequency Lower than Low frequency reference threshold event status (FLL) field in the Status Register (SR). If you enable interrupts, an interrupt asserts when the status flag sets.

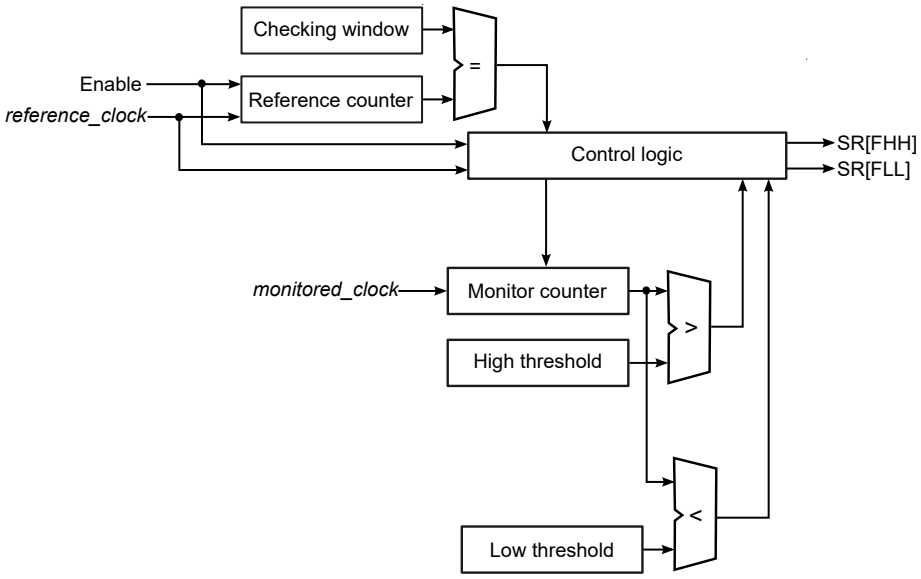


Figure 206. CMU_FC block diagram

CMU_FC cannot detect the following:

- Monitored clock duty cycle variations
- Instantaneous monitored clock frequency variations that do not cross upper or lower threshold limits

51.2.2 Features

The CMU_FC features are:

- Programmable duration of reference clock cycles
- Initiates an event if a monitored clock frequency is higher than high frequency reference (FHH)
- Initiates an event if a monitored clock frequency is lower than low frequency reference (FLL)
- FLL event (if enabled) is generated when monitored clock is very slow or stops functioning
- Masking of FHH event interrupt
- Masking of FLL event interrupt

51.3 Functional description

51.3.1 Operating modes

CMU_FC supports the following operating modes:

- Frequency checking

See the succeeding sections for detailed descriptions of the functions.

51.3.2 Frequency checking

Frequency checking starts when software writes GCR[FCE] = 1. The Run Status field SR[RS] shows 1 after frequency check operation starts.

CMU_FC performs continuous periodic clock checking of the monitored clock. Each checking window involves the following operations:

- Stage 1 – Reference clock counter runs for RCCR[REF_CNT] reference clock cycles. Monitored clock counter runs in parallel for the same time duration as reference clock counter.
- Stage 2 – After stage 1, the module compares the final monitored clock count against the programmed thresholds.

If the monitored clock count is greater than the high threshold value in HTCR[HFREF], an FHH event occurs.

If the monitored clock count is lower than the low threshold value in LTCR[LFREF], an FLL event occurs.

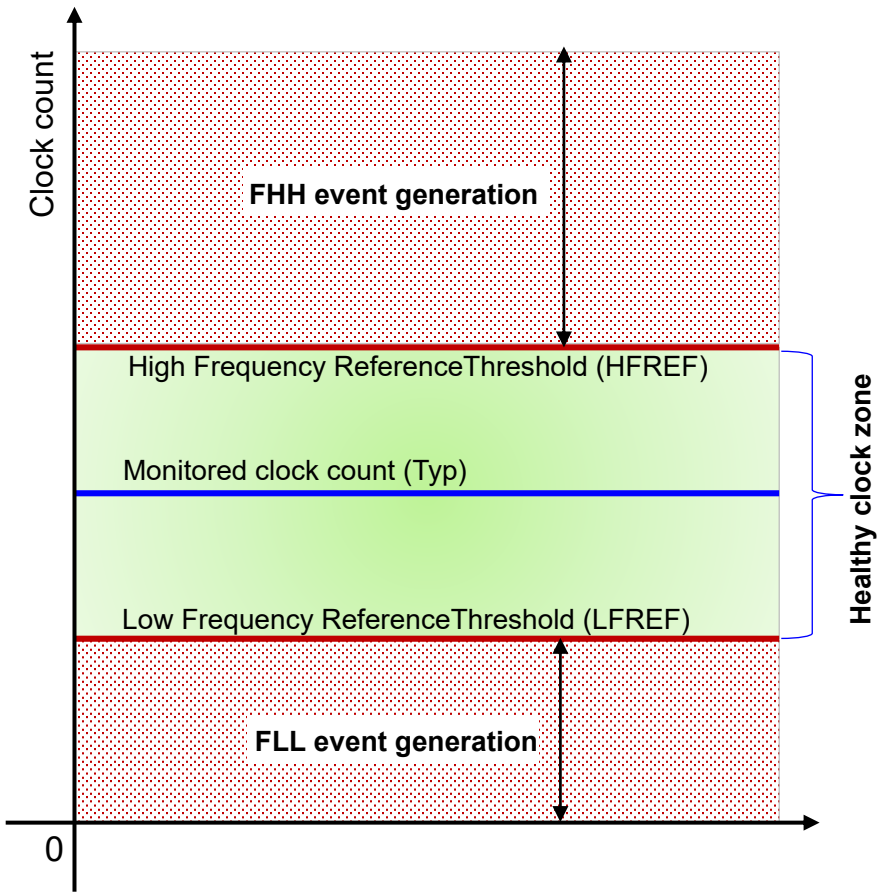

Figure 207. Frequency checking HFREF and LFREF thresholds

51.3.2.1 Monitored clock lost

If a monitored clock ceases operation before evaluation of that clock (Stage 2, see Frequency checking), CMU_FC waits for RCCR[REF_CNT] reference clock periods by extending Stage 2 before triggering an FLL event.

- If *monitored_clock* is not running when enabling CMU_FC:

Worst case FLL response time = (2 × RCCR[REF_CNT] + 12) *reference_clock* cycles + 15 *bus_clock* cycles

- If *monitored_clock* stops when the CMU_FC is running:

Worst case FLL response time = (2 × RCCR[REF_CNT] + 2) *reference_clock* cycles + 3 *bus_clock* cycles

51.3.3 Clocking

This module has the following clock sources.

Table 248. Clock description

Clock	I/O	Description
reference_clock	I	Clock signal that the module uses as a reference to evaluate *monitored_clock*
monitored_clock	I	Clock signal on which frequency check is performed
bus_clock	I	Clock signal on which register read/write operation is performed

NOTE

See the Clocking chapter for details of monitored and reference clocks used on this chip.

51.3.4 Reset

This module has the following reset sources.

- Global hard reset input
- Reset port synchronized to reference clock domain input
- Reset port synchronized to monitored clock domain input

51.4 External signals

This module has no external signals.

51.5 Programming guidelines

51.5.1 Programming RCCR[REF_CNT]

RCCR[REF_CNT] defines the duration of the checking operation in number of *reference_clock* cycles. The minimum RCCR[REF_CNT] value can be calculated using the following formula:

$$\textbf{Minimum RCCR [REF_CNT]} = \text{CEILING value of MAX}\left(3 \text{ X } \left(\frac{f_{reference_clock}}{f_{bus_clock}}\right), 8 + 5 \text{ X } \left(\frac{f_{reference_clock}}{f_{monitored_clock}}\right)\right)$$

...where:

- $f_{reference_clock}$ is the frequency of the reference clock
- f_{bus_clock} is the frequency of the bus clock
- $f_{monitored_clock}$ is the frequency of the monitored clock

Example to determine RCCR[REF_CNT]:

- f_{bus_clock} = 16 MHz
- $f_{reference_clock}$ = 8 MHz
- $f_{monitored_clock}$ = 48 MHz

Formula #1:	$3 \times \left(\frac{f_{reference_clock}}{f_{bus_clock}} \right)$
Inserting the values:	3 × (8 / 16) = 1.5
Formula #2:	$8 + 5 \times \left(\frac{f_{reference_clock}}{f_{monitored_clock}} \right)$
Inserting the values:	8 + 5 × (8 / 48) ≈ 8.83
MAX (1.5, 8.83):	8.83
CEILING value of MAX:	9
Therefore, minimum RCCR[REF_CNT]:	9

Programmed RCCR[REF_CNT] value must be greater than or equal to the calculated minimum value and should be decided after considering application requirements of frequency check completion response time and overall accuracy required from CMU_FC.

- Higher values of RCCR[REF_CNT] results in longer measurement window, leading to better accuracy in monitored clock check.
- Lower values of RCCR[REF_CNT] results in shorter measurement window, leading to faster FHH and FLL event response, but higher inaccuracy in reported result.

For measurement window calculation, see step 8 in Programming HFREF and LFREF

51.5.2 Programming HFREF and LFREF

You must consider the following when programming HFREF/LFREF:

- Tolerable monitored clock frequency variation
- Maximum reference clock frequency variation
- Inherent module inaccuracy

CMU_FC has an expected maximum deviation of ± 3 *monitored_clock* cycles (CMU_FC_{VAR+} = 3, CMU_FC_{VAR-} = –3).

The following procedure shows how to calculate optimum values for HTCR[HFREF] and LTCR[LFREF] (numbers shown are from example in table):

1. Determine the ideal *monitored_clock* frequency ($f_{monitored_clock}$ (ideal), 48 MHz).
2. Determine the specified variation of the *monitored_clock* (1.1%).
3. Calculate *monitored_clock* frequency variation: .

   $$f_{monitored_clock}\,(ideal) \times (1 \pm variation\,(\text{step 2}))$$

   - $f_{monitored_clock}$ (max) = 48 MHz × (1 + (1.1 ÷ 100)) = 48.53 MHz
   - $f_{monitored_clock}$ (min)= 48 MHz × (1 – (1.1 ÷ 100)) = 47.47 MHz
4. Determine the ideal *reference_clock* frequency ($f_{reference_clock}$ (ideal), 8 MHz).
5. Determine the specified variation of the *reference_clock* (3.3%).

6. Calculate ideal *reference_clock* frequency variation:

$$f_{reference_clock}\ (ideal) \times (1 \pm variation\ (\text{step 5}))$$

   - $f_{reference_clock}$ (max) = 8 MHz × (1 + (3.3 ÷ 100)) = 8.26 MHz
   - $f_{reference_clock}$ (min) = 8 MHz × (1 – (3.3 ÷ 100)) = 7.74 MHz
7. Select the value of RCCR[REF_CNT] needed (80). See Programming RCCR[REF_CNT].
8. Calculate ideal measurement window:

$$\frac{RCCR\,[REF_CNT]}{f_{reference_clock}\ (ideal)}$$

   - 80 ÷ 8 MHz = 10000 ns
9. Calculate ideal *monitored_clock* count:

$$\frac{RCCR[REF_CNT]}{f_{reference_clock}(ideal)} \times f_{monitored_clock}\ (ideal)$$

   - 80 ÷ 8 MHz × 48 MHz = 480.00 (round off this value, 480 in this case)
10. Calculate high threshold value (HTCR[HFREF]):

$$\text{Ceiling value of } \left(\frac{f_{monitored_clock}\ (max)}{f_{reference_clock}\ (min)} \times RCCR[REF_CNT]\right) + CMU_FC_{VAR+}$$

    - HTCR[HFREF] = Ceiling(48.53 MHz ÷ 7.74 MHz × 80 + 3) = 505
11. Calculate low threshold value (LTCR[LFREF]):

$$\text{Floor value of } \left(\frac{f_{monitored_clock}\ (min)}{f_{reference_clock}\ (max)} \times RCCR[REF_CNT]\right) - CMU_FC_{VAR-}$$

    - LTCR[LFREF] = Floor(47.47 MHz ÷ 8.26 MHz × 80 – 3) = 456

Table 249. HTCR[HFREF] and LTCR[LFREF] calculation example

Property	Value	Unit
Bus clock frequency (f_{bus_clock})	16	MHz
Monitored clock frequency ($f_{monitored_clock}$ (ideal))	48	MHz
Specified variation of monitored clock	1.1	%
Monitored clock frequency (maximum after specified variation, $f_{monitored_clock}$ (max))	48.53	MHz

Table continues on the next page...

Module negative variation (CMU_FC_{VAR-})	-3	—
Programmed higher threshold (HTCR[HFREF])	505	—
Programmed lower threshold (LTCR[LFREF])	456	—

51.5.3 Module programming sequence

51.5.3.1 Module programming sequence

The recommended programming sequence for CMU_FC frequency checking is:

1. In any order, complete the following:
   - Program RCCR[REF_CNT] to define the frequency measuring window duration in *reference_clock* cycles.
   - Program LTCR[LFREF] and HTCR[HFREF] to set the permissible frequency range of the *monitored_clock*.
   - Program IER to enable interrupt.
2. Write GCR[FCE] = 1 to start the frequency check operation.

   NOTE

   When GCR[FCE] = 1, you must not write to RCCR, HTCR, LTCR, or IER. Attempting to do so generates a bus transfer error.

3. To reconfigure RCCR, LTCR, HTCR , and IER or to stop frequency check operation, wait for SR[RS] = 1, then write GCR[FCE] = 0.

51.6 CMU_FC register descriptions

51.6.1 CMU_FC memory map

This section describes the address order of all the CMU_FC registers. Each description includes a standard register diagram and associated field descriptions.

CMU_0 base address: 402B_C000h

CMU_3 base address: 402B_C060h

CMU_4 base address: 402B_C080h

CMU_5 base address: 402B_C0A0h

CMU_6 base address: 402B_C0C0h

Offset	Register	Width (In bits)	Access	Reset value
0h	Global Configuration Register (GCR)	32	RW	0000_0000h
4h	Reference Count Configuration Register (RCCR)	32	RW	0000_0000h
8h	High Threshold Configuration Register (HTCR)	32	RW	00FF_FFFFh
Ch	Low Threshold Configuration Register (LTCR)	32	RW	0000_0000h
10h	Status Register (SR)	32	RW	0000_0000h
14h	Interrupt Enable Register (IER)	32	RW	0000_0000h

51.6.2 Global Configuration Register (GCR)

Offset

Fields

Field	Function
31-5 —	Reserved
4 RS	Run Status Shows the running status of module internal operation. After enabling the frequency check operation (GCR[FCE] = 1), there is a fixed delay before this field shows running status. If the system wants to disable the frequency check operation, then the software should read this register and write GCR[FCE] = 0 only when this field is 1. 0b - Frequency check stopped 1b - Frequency check running
3-2 —	Reserved
1 FHH	Frequency higher than high frequency reference threshold event status Hardware writes 1 to FHH when the monitored clock frequency becomes higher than the high threshold value in HTCR[HFREF]. FHH clears when software writes 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No FHH event 1b - FHH event occurred
0 FLL	Frequency lower than low frequency reference threshold event status Hardware writes 1 to FLL when the monitored clock frequency becomes lower than the low threshold value in LTCR[LFREF]. FLL clears when software writes 1. 0b - No FLL event 1b - FLL event occurred

51.6.7 Interrupt Enable Register (IER)

Offset

Register	Offset
IER	14h

Function

Enables CMU_FC interrupts.

NOTE

Write IER only when GCR[FCE] = 0. A bus transfer error results if software writes IER when GCR[FCE] = 1.

Enable only either asynchronous FHH event interrupt or synchronous FHH event interrupt at a time.

For example:

- If IER[FHHIE] is set to 1 then set IER[FHHAIE] to 0.
- If IER[FHHAIE] is set to 1 then set IER[FHHIE] to 0.

Enable only either asynchronous FLL event interrupt or synchronous FLL event interrupt at a time.

For example:

- If IER[FLLIE] is set to 1 then set IER[FLLAIE] to 0.
- If IER[FLLAIE] is set to 1 then set IER[FLLIE] to 0.

See Clocking chapter for interrupt usage information based on CMU_FC instances.

51.7 Glossary

FHH The state that the monitored clock frequency is higher than the high frequency reference. FHH is also the name of the register field that indicates this state.

FHH event The event that the module triggers when it detects FHH.

FLL The state that the monitored clock frequency is lower than the lower frequency reference. FLL is also the name of the register field that indicates this state.

FLL event The event that the module triggers when it detects FLL.

Chapter 52
Clock Monitoring Unit – Frequency Meter (CMU_FM)

52.1 Chip-specific CMU_FM information

52.1.1 CMU_FM configuration

The device consists of a robust clock monitoring architecture targeted to monitor various clock nodes to ensure device clock robustness. There are 7 clock monitoring units present in the device out of which 2 are of type CMU_FM. See 'Clock monitoring' section in Clocking chapter for details on device clock monitoring architecture.

NOTE

CMU metering interrupt is not generated if the clock which is being metered is lost. A timeout status flag, CMU.SR[FMTO] is updated in this case.

NOTE

Software must ensure that CMU1 interrupt is serviced within POR_WDG timeout. In absence of CMU1 interrupt servicing, the POR_WDG detects this as an FIRC failure and initiates a POR recovery.

52.2 Overview

CMU_FM measures the frequency of the metered clock (*metered_clock*) using another clock as reference. This reference clock (*reference_clock*) must be within documented limits for correct CMU_FM operation. CMU_FM operation is only guaranteed if a reference clock is within normal operating parameters.

52.2.1 Block diagram

The CMU_FM counts the clock cycles of a metered clock in the user programmable time duration *n* number of clock cycles of the reference clock. After completion of a metered clock operation, a register field sets, indicating the operation has completed. The count of the metered clock also updates in the Status Register (SR) after completion of a metered clock operation.

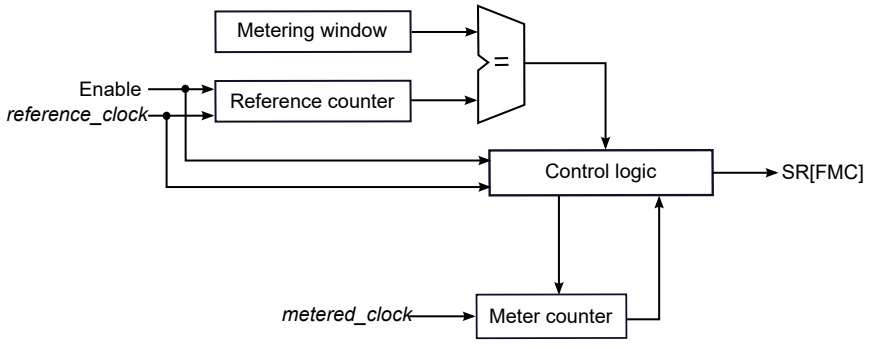

Figure 208. Block diagram

52.2.2 Features

Features of the CMU_FM are:

- Programmable duration of *reference_clock* cycles
- Maskable interrupt generation when frequency metering completes
- Timeout feature indicates loss of *metered_clock*

52.3 Functional description

The frequency meter operation initiates when software writes GCR[FME] = 1. When the operation starts, hardware writes SR[RS] = 1. Safety critical applications must poll SR[RS] to determine when metering operation starts.

Frequency metering window involves these operations:

1. Stage 1 — The reference clock counter runs for RCCR[REF_CNT] cycles of *reference_clock*. The metered clock counter runs in parallel for the same time duration as the *reference_clock* counter.
2. Stage 2 — At the end of stage 1, SR[FMC] = 1, SR[MET_CNT] updates with the *metered_clock* count, and CMU_FM writes GCR[FME] = 0.

52.3.1 Clocking

The following table lists the clock sources for this module.

Table 250. Clock description

Clock	I/O	Description
reference_clock	I	Clock signal that the module uses as a reference to evaluate *metered_clock*
metered_clock	I	Clock signal on which frequency metering is performed
bus_clock	I	Clock signal on which register read/write operation is performed

NOTE

See the Clocking chapter for details of metered and reference clocks used on this chip.

52.3.2 Reset

This module has the following reset sources.

- Global hard reset input
- Reset port synchronized to reference clock domain input
- Reset port synchronized to monitored clock domain input

52.4 Programming guidelines

52.4.1 Programming RCCR[REF_CNT]

RCCR[REF_CNT] defines the duration of the metering operation in number of *reference_clock* cycles. The minimum RCCR[REF_CNT] value can be calculated using the following formula:

$$\textbf{Minimum RCCR [REF_CNT]} = \text{CEILING value of MAX}\left(3 \text{ X } \left(\frac{f_{reference_clock}}{f_{bus_clock}}\right), 8 + 5 \text{ X } \left(\frac{f_{reference_clock}}{f_{monitored_clock}}\right)\right)$$

...where:

- $f_{reference_clock}$ is the frequency of the reference clock
- f_{bus_clock} is the frequency of the bus clock
- $f_{metering_clock}$ is the frequency of the metered clock

Example to determine RCCR[REF_CNT]:

- f_{bus_clock} = 16 MHz
- $f_{reference_clock}$ = 8 MHz
- $f_{metered_clock}$ = 48 MHz

Formula #1:

$$3 \text{ X } \left(\frac{f_{reference_clock}}{f_{bus_clock}} \right)$$

Inserting the values: 3 × (8 / 16) = 1.5

Formula #2:

$$8 + 5 \text{ X } \left(\frac{f_{reference_clock}}{f_{monitored_clock}} \right)$$

Inserting the values: 8 + 5 × (8 / 48) ≈ 8.83

MAX (1.5, 8.83): 8.83

CEILING value of MAX: 9

Therefore, minimum RCCR[REF_CNT]: 9

Programmed RCCR[REF_CNT] value must be greater than or equal to the calculated minimum value and should be decided after considering application requirements of frequency metering completion response time and overall accuracy required from CMU_FM.

- Higher values of RCCR[REF_CNT] results in longer metering window, leading to better accuracy in metered clock measurement.
- Lower values of RCCR[REF_CNT] results in shorter metering window, leading to faster FMC response, but higher inaccuracy in reported result.

52.4.2 Module programming sequence

The recommended programming sequence of CMU_FM is:

1. In any order, complete the following:
   - Program RCCR[REF_CNT] to define the frequency metering window duration in *reference_clock* cycles.
   - Program IER[FMCIE] to enable interrupt.
2. Write GCR[FME] = 1 to start frequency metering operation. Writes to RCCR and IER are disabled after GCR[FME] = 1. Attempting a write to any of them after GCR[FME] = 1 generates a bus transfer error.
3. To reconfigure RCCR and IER or to stop frequency metering operation, wait for SR[RS] = 1, then write GCR[FME] = 0.

Upon completion of metering operations:

- Hardware writes SR[FMC] = 1
- SR[MET_CNT] updates with metered count value
- Hardware writes GCR[FME] = 0

52.5 External signals

This module has no external signals.

52.6 CMU_FM register descriptions

52.6.1 CMU_FM memory map

This section describes the address order of all the CMU_FM registers. Each description includes a standard register diagram and associated field descriptions.

CMU_1 base address: 402B_C020h

CMU_2 base address: 402B_C040h

Offset	Register	Width (In bits)	Access	Reset value
0h	Global Configuration Register (GCR)	32	RW	0000_0000h
4h	Reference Count Configuration Register (RCCR)	32	RW	0000_0000h
8h	Status Register (SR)	32	RW	0000_0000h
Ch	Interrupt Enable Register (IER)	32	RW	0000_0000h

52.6.2 Global Configuration Register (GCR)

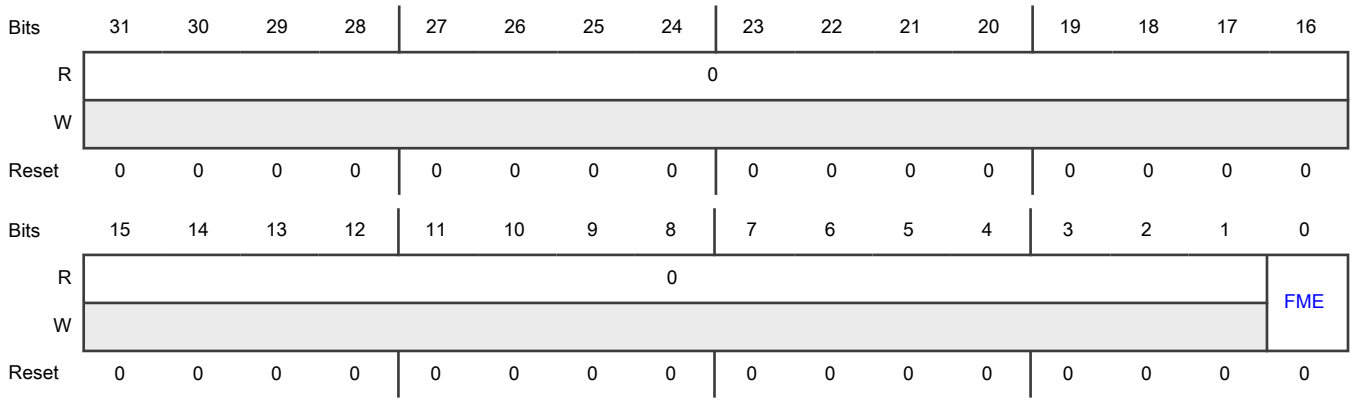
Offset

Register	Offset
GCR	0h

Function

Controls module level configurations such as enabling frequency metering.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 FME	Frequency Meter Enable Starts or stops frequency metering. FME is disabled by default. Software can enable FME at any time. To stop the ongoing operation, write 0 to FME only when SR[RS] = 1. FME automatically clears upon frequency metering completion or timeout event. 0b - Stops frequency metering 1b - Starts frequency metering

52.6.3 Reference Count Configuration Register (RCCR)

Offset

Register	Offset
RCCR	4h

Function

Programs reference count duration of the frequency meter window.

NOTE

Write to RCCR only when GCR[FME] = 0. A bus transfer error results if software writes RCCR when GCR[FME] = 1.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-8 MET_CNT	Meter Clock Count This field stores the count value of the metered clock cycles when frequency metering operation is complete, in other words, SR[FMC] = 1. CMU_FM has a maximum deviation of ± 3 *metered_clock* cycles over the ideal *metered_clock* cycles expected by the user.
7-5 —	Reserved
4	Run Status

Table continues on the next page...

Table continued from the previous page...

Field	Function
RS	Shows the running status of module internal operation. After enabling the frequency metering operation (GCR[FME] = 1), there is a fixed delay before this field shows running status. If the system wants to disable the frequency metering operation, then the software should read this register and write GCR[FME] = 0 only when this field is 1. 0b - Frequency meter stopped 1b - Frequency meter running
3-2 —	Reserved
1 FMTO	Frequency Meter Time Out Sets if there is a loss of metered clock during the metering operation. After metering window, the module waits for a timeout duration of RCCR[REF_CNT] cycles before writing one to this field. GCR[FME] = 0 and SR[FMC] = 0 when FMTO = 1. Writing one clears this field.
0 FMC	Frequency Meter Operation Complete On completion of frequency metering operation, FMC = 1, SR[MET_CNT] field updates, and GCR[FME] clears. Writing one clears this field.

52.6.5 Interrupt Enable Register (IER)

Offset

Register	Offset
IER	Ch

Function

Enables CMU_FM interrupts.

NOTE

Write IER only when GCR[FME] = 0. A bus transfer error results if software writes IER when GCR[FME] = 1.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Chapter 53
Cyclic Redundancy Check (CRC)

53.1 Chip specific CRC information

53.1.1 CRC configuration

This chip supports one instance of CRC module.

53.2 Overview

CRC generates 16-bit or 32-bit CRC codes output for error detection. You can calculate these codes for up to 32 bits input data at a time.

CRC provides a programmable polynomial and other parameters to meet 16-bit or 32-bit CRC standards.

53.2.1 Block diagram

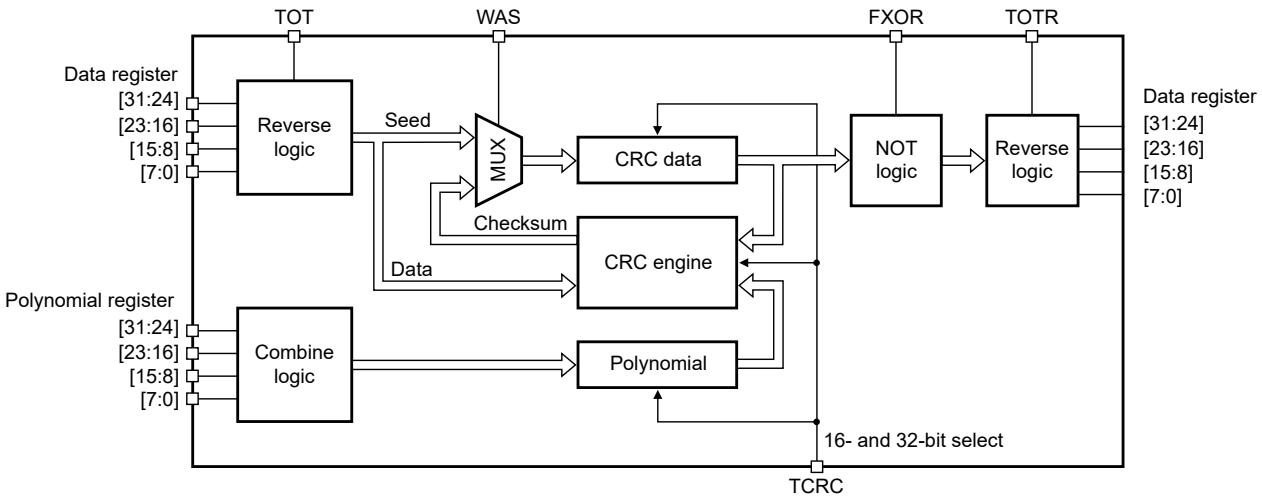

Figure 209. Block diagram

53.2.2 Features

CRC has the following features:

- Hardware CRC generator circuit using 16-bit or 32-bit programmable shift registers
- Programmable initial seed value and polynomial
- Transpose of input or output data (CRC result) in bitwise or bytewise (this option is required for certain CRC standards. You cannot perform a bytewise transpose operation when accessing DATA via 8-bit access.)
- Invert final CRC result
- 32-bit CPU register programming interface

53.3 Functional description

53.3.1 Modes of operation

The following sections describe various modes of operation that affect the functionality of CRC: Run mode and Low power mode.

53.3.1.1 Run mode

Run mode is the basic mode of operation.

53.3.1.2 Low power mode

When the chip enters the lower power mode, the CRC module clock (ipg_clk and ipg_clk_s) is disabled and the in-progress CRC calculation stops. The calculation resumes after the CRC module clock is enabled or the chip exits low power mode via system reset.

53.3.2 CRC calculations

In 16-bit and 32-bit CRC modes, you can program data values as 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous. Noncontiguous bytes lead to an incorrect CRC calculation.

53.3.2.1 Calculating a 16-bit CRC

Perform these steps to calculate a 16-bit CRC:

1. Write 0 to CTRL[TCRC] to enable 16-bit CRC mode.
2. Program the transpose and complement options in Data (DATA) as required for the CRC calculation.
3. Write a 16-bit polynomial to GPOLY[LOW].

   GPOLY[HIGH] is not usable in 16-bit CRC mode.
4. Write 1 to CTRL[WAS] to program the seed value.
5. Write a 16-bit seed to DATA[LU] and DATA[LL].

   DATA[HU] and DATA[HL] are not used.
6. Write 0 to CTRL[WAS] to start writing data values.
7. Write data values into DATA[LU], and DATA[LL]

   CRC is calculated on every data value write and the intermediate CRC result is stored back into DATA[LU] and DATA[LL]
8. After writing all the data values, read the final CRC result from DATA[LU] and DATA[LL].

CRC is calculated bytewise and two clocks are required to complete one CRC calculation.

The transpose and complement operations are performed on-the-fly when reading or writing values. See Transpose feature and Result complement for details.

53.3.2.2 Calculating a 32-bit CRC

Perform these steps to calculate a 32-bit CRC:

1. Write 1 to CTRL[TCRC] to enable 32-bit CRC mode.
2. Program the transpose and complement options in Control (CTRL) as required for CRC calculation. See Transpose feature and Result complement for details.
3. Write a 32-bit polynomial to GPOLY[HIGH] and GPOLY[LOW] .
4. Write 1 to CTRL[WAS] to program the seed value.
5. Write a 32-bit seed to DATA[HU], DATA[HL], DATA[LU], and DATA[LL].

6. Write 0 to CTRL[WAS] to start writing data values.
7. Write data values into DATA[HU], DATA[HL], DATA[LU], and DATA[LL]

   CRC is computed on every data value write and the intermediate CRC result is stored back into DATA[LU] and DATA[LL]
8. After writing all the values, read the final CRC result from DATA[HU], DATA[HL], DATA[LU], and DATA[LL].

   CRC is calculated bytewise and two clocks are required to complete one CRC calculation.

The transpose and complement operations are performed on-the-fly when reading or writing values. See Transpose feature and Result complement for details.

53.3.3 Transpose feature

Transpose is not enabled by default. However, CRC requires input data and/or final checksum to be transposed. You have an option to configure each transpose operation separately to meet CRC standards. The data is transposed on-the-fly while being read or written.

Some protocols use the little-endian format for data stream to calculateCRC. In this case, transpose flips bits.

53.3.3.1 Types of transpose

CRC provides several types of transpose to flip bits and/or bytes for both writing input data and reading result separately using the CTRL[TOT] and CTRL[TOTR] according to the CRC calculation being used.

The following types of transpose are available for writing to and reading from DATA.

1. CTRL[TOT] or CTRL[TOTR] is 0.

   No transposition occurs.
2. CTRL[TOT] or CTRL[TOTR] is 1.

   Bits in a byte are transposed when bytes are not transposed.

   reg[31:0] becomes {reg[24:31], reg[16:23], reg[8:15], reg[0:7]}.

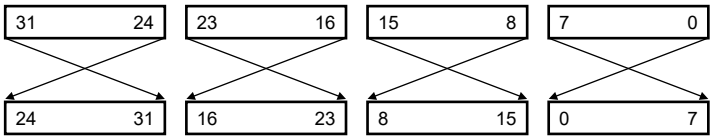

Figure 210. Transpose type 1b

3. CTRL[TOT] or CTRL[TOTR] is 10b.

   Both bits in bytes and bytes are transposed.

   reg[31:0] becomes {reg[0:7], reg[8:15], reg[16:23], reg[24:31]}.

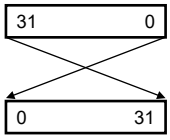

Figure 211. Transpose type 10b

4. CTRL[TOT] or CTRL[TOTR] is 11b.

   Bytes are transposed but bits are not transposed.

   reg[31:0] becomes {reg[7:0], reg[15:8], reg[23:16], reg[31:24]}.

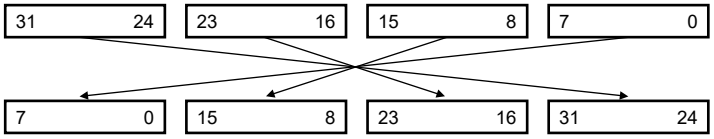

Figure 212. Transpose type 11b

NOTE

For 8-bit and 16-bit write accesses to Data (DATA), the data is transposed with 0s on the unused byte or bytes (taking 32 bits as a whole), but CRC is calculated on the valid byte(s) only. When reading the Data (DATA) for a 16-bit CRC result and using transpose options 10 and 11, the resulting value after transposition resides in DATA[HU] and DATA[HL]. You must account for this situation when reading the 16-bit CRC result, so reading 32 bits is preferred.

53.3.4 Result complement

When CTRL[FXOR] = 1, the checksum is complemented. The CRC result complement function outputs the complement of the checksum value stored in Data (DATA) every time Data (DATA) is read. When CTRL[FXOR] = 0,, reading Data (DATA) accesses the raw checksum value.

53.3.5 Clocking

Table 251. CRC clocks

Type of clock	Description
Bus clock (ipg_clk/ipg_clk_s)	ipg_clk_s controls the access to the CRC registers. ipg_clk and ipg_clk_s function the CRC module.

53.3.6 Interrupts

This module has no interrupts.

53.4 External signals

There is no CRC signal that connects off chip.

53.5 Initialization

To enable CRC calculation, you must program:

- CTRL[WAS] .
- Polynomial (GPOLY).
- Parameters for transposition and CRC result inversion in the applicable registers.

Writing 1 to CTRL[WAS] enables you to program the seed value into CRC Data registers.

After writing all the data, you must wait for at least two clock cycles to read the data from CRC Data (DATA) register.

After a CRC calculation completes, you can reinitialize the module for a new CRC computation by again writing 1 to CTRL[WAS] and programming a new, or previously used, seed value. You must set all other parameters before programming the seed value and subsequent data values.

53.6 Use cases

The following tables use the little-endian format.

53.6.1 CTRL programming

The following table shows Control (CTRL) programming for 16-bit CRC.

Table 252. CTRL programming for 16-bit CRC

Algorithm	Polynomial	Seed	Ref in	Ref out	XOR out	CTRL[TOT]	CTRL[TOTR]	CTRL[FXOR]

53.7 Memory map and register descriptions

NOTE

You must reconfigure CRC engine in case an IPS transfer error occurs (ips_xfr_err).

The CRC module generates a transfer error in the following cases:

- Write accesses to the register addresses that are not mapped to the peripherals but included in the address spaces of the peripherals.

53.7.1 CRC register descriptions

53.7.1.1 CRC memory map

CRC base address: 4038_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Data (DATA)	32	RW	FFFF_FFFFh
4h	Polynomial (GPOLY)	32	RW	0000_1021h
8h	Control (CTRL)	32	RW	0000_0000h

53.7.1.2 Data (DATA)

Offset

Register	Offset
DATA	0h

Function

Configures the value of seed, data, and checksum. When CTRL[WAS] = 1, any write to this register is regarded as the seed value. When CTRL[WAS] becomes 0, any write to this register is regarded as data for general CRC calculation.

In 16-bit CRC mode, DATA[HU] and DATA[HL] are not used for programming the seed value, and reads of these fields return an indeterminate value. In 32-bit CRC mode, all fields are used for programming the seed value.

When programming data values, you can program to write 8 bits, 16 bits, or 32 bits in big endian order, provided all bytes are contiguous.

After writing all data values, you can read the CRC result from DATA register. In 16-bit CRC mode, the CRC result is available in DATA[LU] and DATA[LL]. In 32-bit CRC mode, all fields contain the result. After writing all data, you must wait for at least two clock cycles to read the data from CRC data (DATA) register.

Fields

Field	Function
31-24 HU	Upper Part of High Byte Generates CRC checksum in both 16-bit and 32-bit CRC modes if CTRL[WAS] = 0. • In 16-bit CRC mode (CTRL[TCRC] = 0), this field is not used for programming a seed value. • In 32-bit CRC mode (CTRL[TCRC] = 1), the values written to this field are part of the seed value when CTRL[WAS] = 1.
23-16 HL	Lower Part of High Byte Generates CRC checksum in both 16-bit and 32-bit CRC modes if CTRL[WAS] = 1. • In 16-bit CRC mode (CTRL[TCRC] = 0), this field is not used for programming a seed value.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• In 32-bit CRC mode (CTRL[TCRC] = 1), the values written to this field are part of the seed value when CTRL[WAS] = 1.
15-8 LU	Upper Part of Low Byte Generates CRC checksum when CTRL[WAS] = 0. When CTRL[WAS] = 1,the values written to this field are part of the seed value.
7-0 LL	Lower Part of Low Byte Generates CRC checksum when CTRL[WAS] = 0. When CTRL[WAS] = 0, the values written to this field are part of the seed value.

53.7.1.3 Polynomial (GPOLY)

Offset

Register	Offset
GPOLY	4h

Function

Configures polynomial value for CRC calculation.

- Sets the upper 16 bits of polynomial that are used only in 32-bit CRC mode. Writes to this field are ignored in 16-bit CRC mode.
- Sets the lower 16 bits of polynomial that are used in both 16-bit and 32-bit CRC modes.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	HIGH															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	LOW															
Reset	0	0	0	1	0	0	0	0	0	0	1	0	0	0	0	1

Fields

Field	Function
31-16 HIGH	High Half-Word Writable and readable in 32-bit CRC mode (CTRL[TCRC] = 1). You cannot write to this field in 16-bit CRC mode (CTRL[TCRC] = 0).
15-0 LOW	Low Half-Word Writable and readable in both 16-bit and 32-bit CRC modes.

53.7.1.4 Control (CTRL)

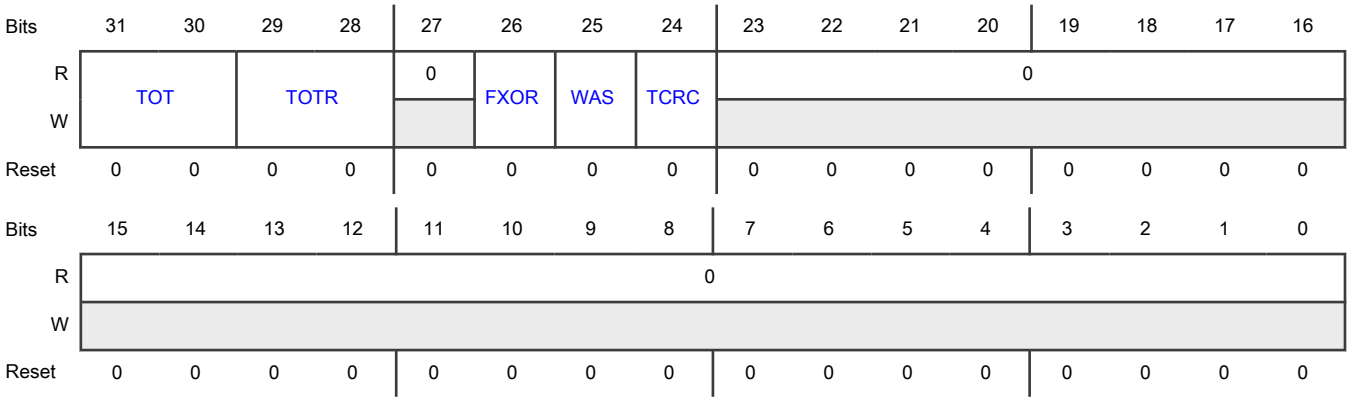
Offset

Register	Offset
CTRL	8h

Function

Sets control for CRC. You must write 1 to the appropriate fields of this register before starting a new CRC calculation, which you can initialize by writing 1 to CTRL[WAS] and then writing the seed into DATA.

Diagram



Fields

Field	Function
31-30 TOT	Transpose Type for Write Sets transpose type for the values written to DATA. See Transpose feature for the available transpose options. 00b - No transposition 01b - Bits in bytes are transposed, but bytes are not transposed.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - Both bits in bytes and bytes are transposed. 11b - Only bytes are transposed, no bits in a byte are transposed.
29-28 TOTR	Transpose Type for Read Sets transpose type for the values read from DATA . See Transpose feature for the available transpose options. 00b - No transposition 01b - Bits in bytes are transposed, but bytes are not transposed. 10b - Both bits in bytes and bytes are transposed. 11b - Only bytes are transposed, no bits in a byte are transposed.
27 —	Reserved
26 FXOR	Complement Read of CRC Data Register Enables on-the-fly complementing of read data. Some CRC protocols require the final checksum to be XORed with FFFFFFFFh or FFFFh. 0b - Disables XOR on reading data. 1b - Inverts or complements the read value of the CRC Data.
25 WAS	Write as Seed Specifies whether writes to DATA are data values or seed values. When this field = 1, the value that you write to is considered as seed value. When this field = 0, the value that you write to is considered as data for CRC calculation. 0b - Data values 1b - Seed values
24 TCRC	TCRC Defines the width of CRC. 0b - 16 bits 1b - 32 bits
23-0 —	Reserved

53.8 Glossary

Transpose	Flipping input or output data bits (or bytes)
Seed value	Initial value of CRC calculation

Chapter 54
Power Conversion and Motor Control (PCMC)

54.1 Introduction

The PCMC subsystem is a group of modules that can be interconnected to perform a variety of real-time tasks, such as:

- Motor control
- Power conversion
- Advanced PWM generation

The modules that make up the PCMC subsystem are:

- SAR ADC
- BCTU
- eMIOS
- LCU
- LPCMP
- TRGMUX
- IGF
- eFlexPWM
- eTPU
- SDADC
- CoolFlux (DSPSS)

See Feature comparison for the number of instances of each module in your chip.

54.2 Block diagram and description of components

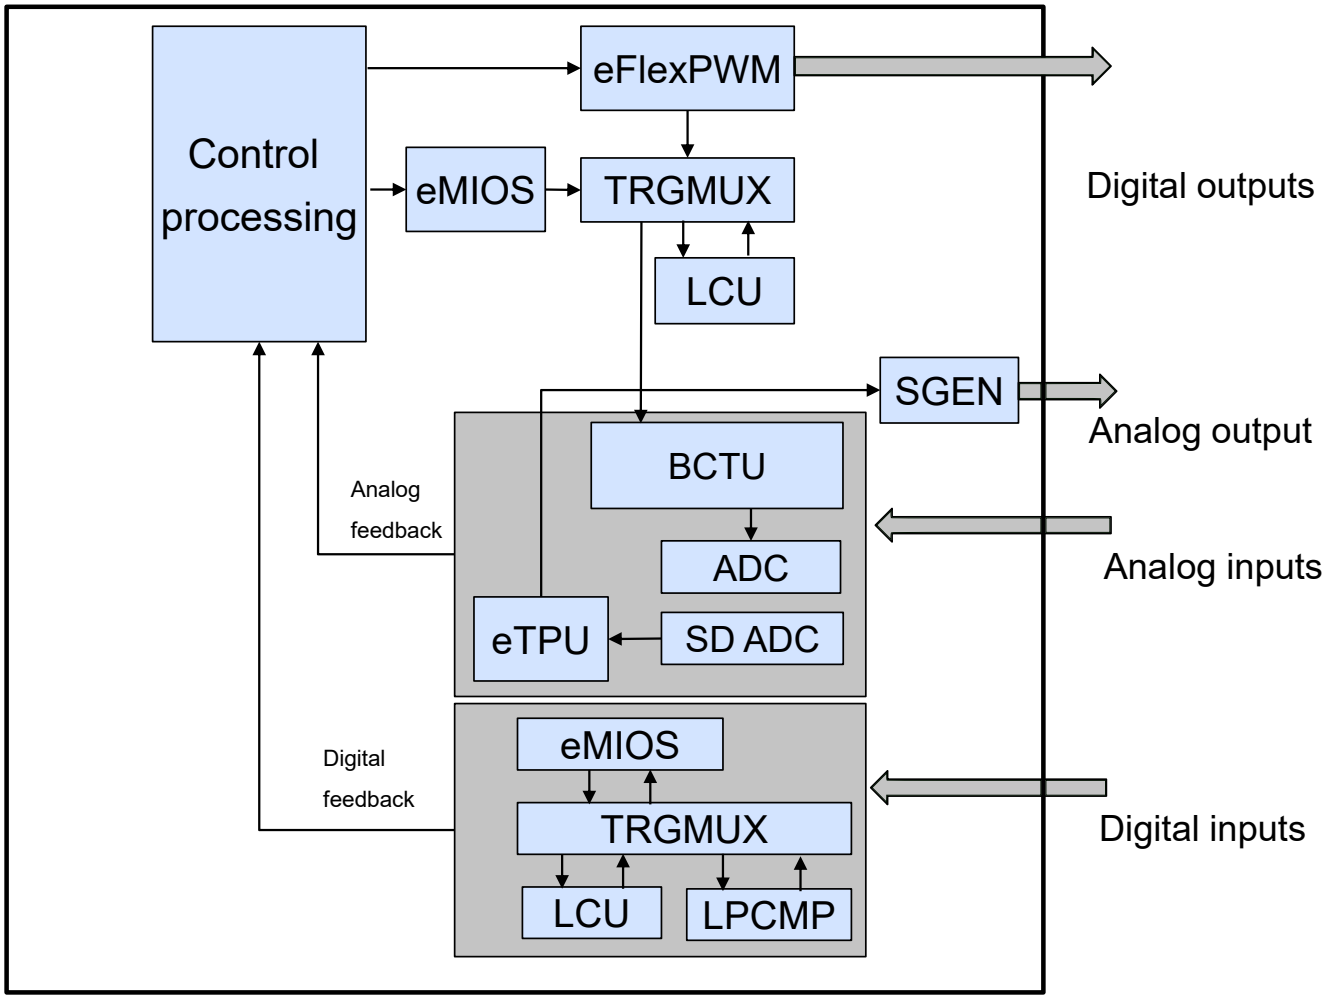


Figure 213. Block diagram

NOTE

Other blocks, such as eMIOS interacts with eTPU via TRGMUX.

Table 256. Block diagram components

Component	Description
ADC	Measures external analog signals
BCTU	Performs advanced ADC triggering
Control processing	The Arm Cortex-M7 core: • Processes digital and analog inputs to generate control outputs • Writes control outputs to peripherals
eMIOS	• Processes the digital feedback • Measures time-based digital inputs

Table continues on the next page...

Table 256. Block diagram components (continued)

Component	Description
LCU	Performs programmable logic functions and fault control
LPCMP	Compares analog values to detect faults
TRGMUX	• Routes signals between internal peripherals • Routes external signals to internal peripherals
GlitchFilter	Enables the filtering of eTPU channel inputs
eTPU	Is a coprocessor designed for timing control, capable of: • Resolver feedback processing • Generating Motor control PWM to drive 3 phs motor • Triggering and synchronization
SGEN	Generates a high-quality sinusoidal voltage signal
eFlexPWM	• Generates PWM signals in motor control applications with at least six channels enabled • Helps with digital power conversion application with at least eight channels enabled
SDADC	Decodes resolver signals and performs other tasks
CoolFlux (DSPSS)	Processes SDADC data output

54.3 Functional overview

54.3.1 Analog signal measurement

ADC measures the voltage of external analog signals and converts that voltage to a digital value. Each ADC instance operates independently of other instances. Either you or ADC can trigger conversions. Together with BCTU, eFlexPWM, and/or eMIOS, ADC can preempt normal measurements by injecting high-priority measurements when needed.

See the "Analog-to-Digital Converter" chapter for more information.

54.3.2 Advanced ADC triggering

BCTU works with ADC to initiate conversions that other modules trigger in the PCMC subsystem, such as PWM signals from eFlexPWM and eTPU or LCU sequential logic outputs.

With BCTU, you can group measurements into configuration lists containing up to 32 items. Each item contains information pertaining to the following:

- An ADC instance to use for the conversion
- The ADC channel
- The trigger event for initiating the next conversion
- The conversion list address

BCTU can store conversion results by routing them through eDMA or adding them to FIFO queues, which enable conversions to occur seamlessly by storing conversion results without your intervention.

BCTU_0 and BCTU_1 are instances of BCTU integrated in the S32K396 chip. The timer trigger configuration for both these instances is as follows:

- 0–22: eMIOS_0 (CH0–22)

- 23–30: eTPU_A (channels 0-7)
- 31–38: eTPU_B (channels 0-7)
- 39–41: TRGMUX_APP

BCTU can issue a single conversion or a list of conversions based on a single-trigger occurrence. BCTU signals the eMIOS timers when ADC receives a single command or a list of commands. Next, ADC sends conversion data back to BCTU, which loads the data in BCTU.ADC*n*DR for the CPU to read.

BCTU-to-ADC interface illustrates the connections between BCTU and an ADC. For more information, see:

- The "Body Cross-triggering Unit (BCTU)" chapter.
- The PCDR*n*, ICDR*n*, and ECDR*n* register descriptions in the "Analog-to-Digital Converter (ADC)" chapter.

54.3.3 BCTU-to-ADC interface

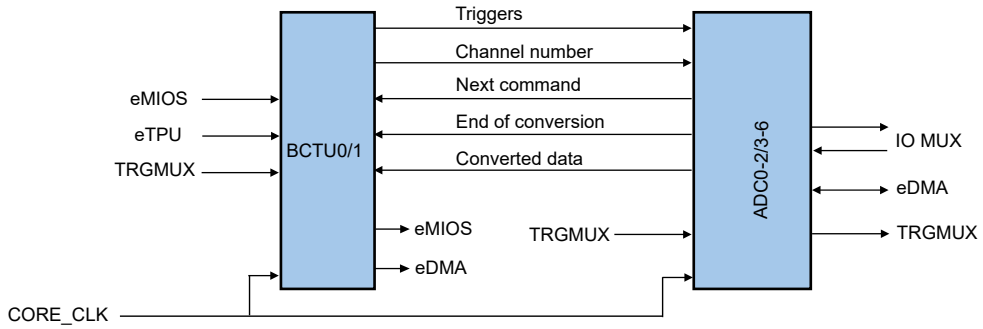

Figure 214. BCTU-to-ADC interface

54.3.4 Generate PWM outputs and measure digital inputs

The main periphery to generate PWM signals to drive motor, it is dedicated eFlexPWM. The second one to generate PWM outputs is eTPU. eMIOS is the third one.

eMIOS is the best fit for the digital inputs processing and measurement.

54.3.4.1 Generate PWM outputs

The enhance Flex Pulse Width Modulator (eFlexPWM) module can generate various switching patterns, including highly sophisticated waveforms. You can use it to control all known motor types and is ideal for controlling different Switched Mode Power Supply (SMPS) topologies as well. eFlexPWM contains PWM submodules (four per instance), each set up to control a single half-bridge, containing A and B channels primarily intended to generate complementary PWM outputs with independent hardware dead-time and one X auxiliary channel. eFlexPWM also provides fault channel support.

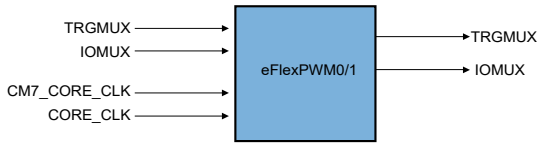

Figure 215. eFlexPWM connections

The enhanced Time Processing Unit is a programmable I/O controller with it's own core and memory system, allowing it to perform complex timing and I/O management independently on the CPU. It can generate various output patterns, process inputs and master low level timing. eTPU needs CPU to be loaded with binary and execute so called eTPU functions. Main functions to be executed for this device:

- SW Resolver

- Motor control PWM

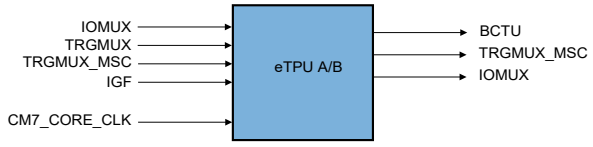

Figure 216. eTPU connections

eMIOS has 24 channels. You can configure each channel to operate in a different mode. Depending on the mode, eMIOS channels can:

- Measure the period of an input signal.
- Measure the width of an input pulse.
- Function as general-purpose I/O.
- Count pulses or edges.
- Capture input values.
- Compare outputs.

For example, eMIOS can generate periodic ADC triggers. Using TRGMUX, you can route eMIOS triggers to other on-chip peripherals, such as LCU, external chip I/O, and so on.

The image shown below illustrates the input and output connections for eMIOS. For more information, see the following chapters:

- Enhanced Modular IO Subsystem (eMIOS)
- Body Cross-triggering Unit (BCTU)
- Trigger MUX (TRGMUX)

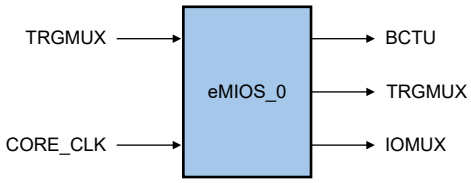

Figure 217. eMIOS connections

54.3.5 Combinatorial and sequential logic functions

You can use LCU to implement a variety of chip-based combinatorial and sequential logic functions with no CPU intervention, including a simple OR gate, flip-flops, and motor control logic. This capability reduces cost and decreases application size.

Each LCU instance includes 12 dedicated inputs and 12 outputs. As detailed in Fault detection, LCU also plays a significant role in fault management.

LCU connections shows the I/O connections for LCU. For more information, see:

- The "Logic Control Unit (LCU)" chapter
- LCU use case examples
- The "Trigger MUX (TRGMUX)" chapter

See the TRGMUX connectivity file attached to this document for more information.

54.3.6 LCU connections

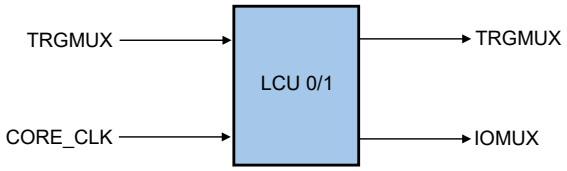

Figure 218. LCU connections

54.3.7 Fault detection

The PCMC subsystem uses LPCMP and LCU to implement fault detection.

LPCMP can detect fault conditions (such as short circuits, overvoltages, and excessive temperature) by comparing an external input voltage with a programmable reference voltage. It produces a digital output that indicates whether the input voltage is higher or lower than the reference voltage.

The chip can detect faults via external digital or analog signals. TRGMUX routes digital signals from SIUL to a peripheral to trigger the appropriate behavior.

LCU includes four force inputs that you can use to manage fault assertion via its own internal logic mechanism.

The typical reaction to the presence of fault is to put the system in a safe state by:

- De-asserting output signals such as PWM outputs controlling a power stage.
- Disconnecting an entire circuit by switching off a relay.

See the "Low Power Comparator (LPCMP)" chapter for more information.

54.3.8 Programmable module interconnections

TRGMUX enables you to interconnect on-chip peripherals to create application-specific configurations. For more information on TRGMUX and TRGMUX MSC configurations, see the S32K39_and_S32K37_TRGMUX_connectivity.xlsx attached to this document. TRGMUX enables the interconnection in hundreds of combinations using the software during runtime.

You can also route on-chip peripheral outputs to chip I/O pins to enable signal debugging. Similarly, you can route external signals to on-chip peripheral inputs.

NOTE

There is a two-cycle AIPS_SLOW_CLK delay through TRGMUX.

For more on PCMC interconnections, see PCMC connections diagram.

The following figure shows a portion of the S32K39_and_S32K37_TRGMUX_connectivity.xlsx, which specifies the possible interconnections between module instances. Column B in the spreadsheet lists TRGMUX inputs. Row 3 lists TRGMUX outputs. A connection between an input and an output is possible if the intersecting cell of the input row and the output column is blank. "NA" indicates that a connection is not possible.

	A	B	C	D	E	F
1		**Output no.**	**0**	**1**	**2**	**4**
2		**Output register no.**	**0**	**0**	**0**	**1**
3		**TRGMUX output**	ADC12_0_External trigger for normal conversion	ADC12_0_External trigger for injected conversion	ADC12_0_External trigger to sync the start pulses	ADC12_1_External trigger for normal conversion
4			yes	yes	yes	yes
6	**0**	LOGIC 0 (VSS)	NA	NA	NA	NA
7	**1**	LOGIC 1 (VDD)	NA	NA	NA	NA
8	**2**	Trigger_monitor_mux0 (disabled by default)				
9	**3**	Trigger_monitor_mux1 (disabled by default)				
10	**4**	Trigger_monitor_mux2 (disabled by default)				
11	**5**	SD_0_End of conversion (valid_data_available)				
12		SD_1_End of conversion (valid_data_available)				
13	**6**	SD_2_End of conversion (valid_data_available)				
14		SD_3_End of conversion (valid_data_available)				

Figure 219. Portion of TRGMUX connectivity

For more information, see:

- The "Trigger MUX (TRGMUX)" chapter.
- The S32K39_and_S32K37_TRGMUX_connectivity.xlsx attached to this document.

54.3.8.1 PCMC connections diagram

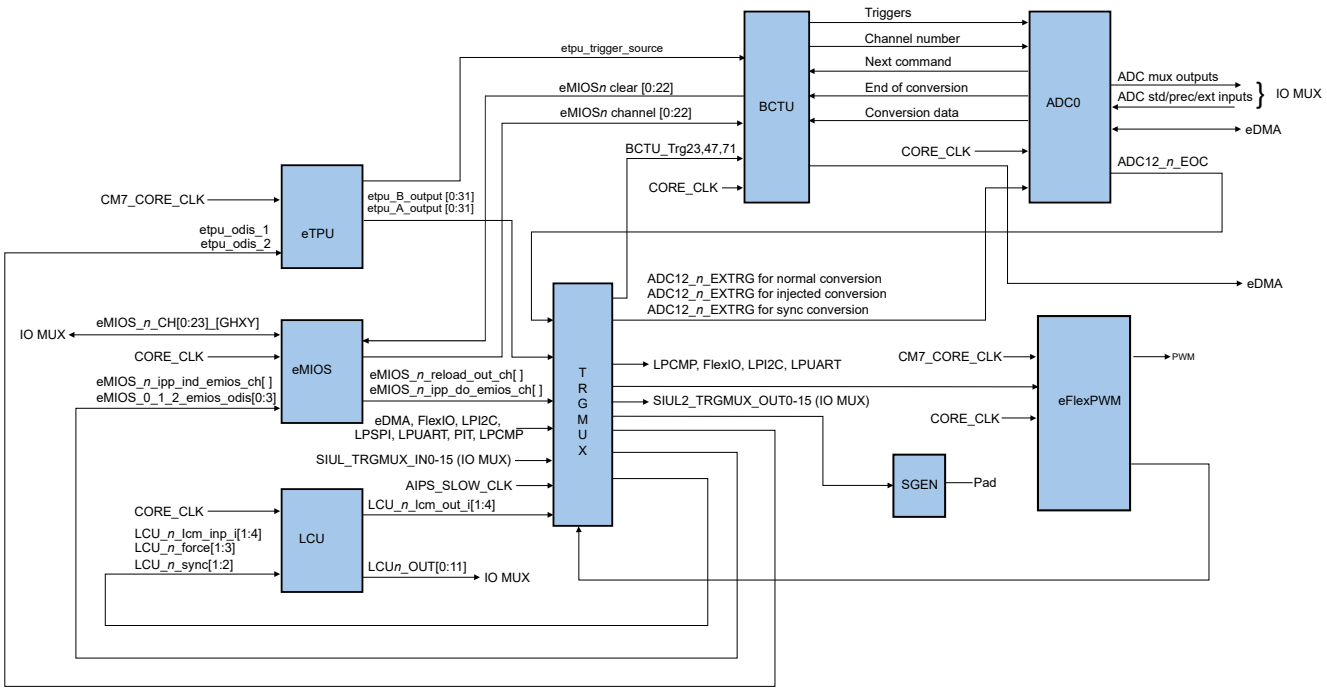

Figure 220. PCMC connections diagram

54.4 Reset, clocking, and other considerations

54.4.1 Reset

ADC, BCTU, eMIOS, LCU, TRGMUX, eFlexPWM, eTPU, SGEN, IGF, SDADC, LPCMP and DSPSS fully reset during a POR, destructive reset, or functional reset.

For more information, see:

- Module reset status
- Software reset

54.4.2 Clocking

See the following resources for detailed clocking information. To summarize:

- CORE_CLK clocks ADC, BCTU, eMIOS, and LCU.
- AIPS_SLOW_CLK clocks TRGMUX.
- In general, you must set AIPS_SLOW_CLK to one-fourth or one-half of the frequency of CORE_CLK.
- eTPU: CM7_CORE_CLOCK.
- eFlexPWM: CM7_CORE_CLK, CORE_CLOCK.
- DSPSS: CORE_CLK, CM7_CORE_CLK.
- SDADC,SGEN: AIPS_PLAT_CLK
- LPCMP: AIPS_SLOW_CLK

For more information, see:

- ADC and motor control modules
- System clocking configurations
- System clock frequency limitations
- Clock frequency

54.4.3 Power modes

All ADC, BCTU, eMIOS, LCU, TRGMUX, eTPU, eFlexPWM, SGEN, LPCMP, SDADC, IGF and DSPSS instances operate only in Run mode. None of the instances operate in Standby mode.

LPCMP operates in Standby mode.

For more information, see:

- Module reset status
- Modes of operation

54.5 Use case examples

54.5.1 Motor control use case

The following sections show:

- A PMSM control system.
- A BLDC control system.
- A EESM control system
- A ACIM control system

All listed machines, both PMSM and BLDC, EESM, and ACIM use a rotating magnetic stator field to turn the stator consisting of permanent magnets rotor flux. Rotor flux can be created by permanent magnets, excitation winding, or other constructions like a squirrel cage. Symmetrical three-phase AC voltage drives the stator. The difference between PMSM and BLDC is the way that the stator position is calculated:

- PMSM calculates the stator position by measuring feedback from motor sensors, typically resolver.

- PMSM calculates the stator position by measuring back EMF from the motor.
- BLDC calculates the stator position based on feedback from motor sensors.

EESM is a new type of machine used in the main traction drive use case. Traditionally used permanent magnets were replaced by a rotor winding with external excitation.

- EESM calculates the stator position by measuring feedback from motor sensors, typically resolver

ACIM also known as asynchronous induction machine is used in main traction drive use-case due to its robustness and manufacturing cost.

- ACIM calculates the stator position by measuring feedback from motor sensors, typically resolver.

54.5.1.1 PMSM motor control use case

54.5.1.1.1 Generic PMSM motor control

The following figure and table illustrate a generic PMSM motor control system. The feedback loops in the system create a motor control loop.

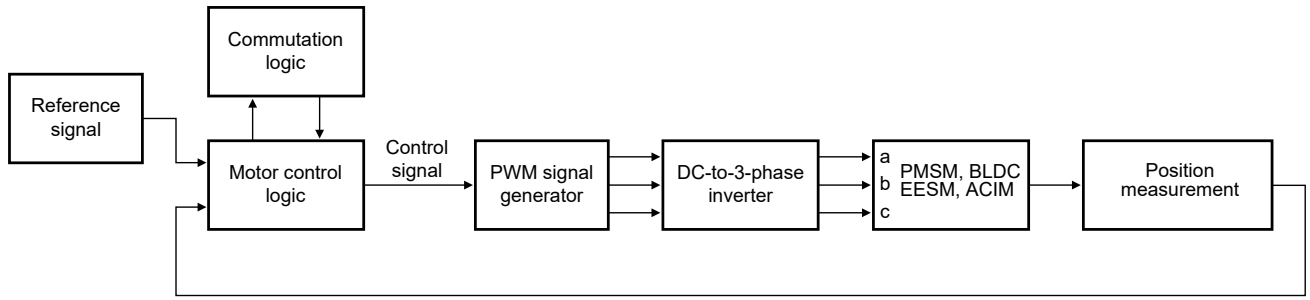

Figure 221. Generic motor control diagram

Table 257. Generic PMSM motor control: description of components

Component	Description
Angular position sensor	Generates data that enables commutation logic to calculate the rotor position.
PMSM,BLDC,EESM,ACIM	Represents an electric motor.
Commutation logic	Compares values from the rotor angular position sensors in the case of BLDC motor control to entries in a lookup table and applies voltage to the stator winding that corresponds to the same set of values in the lookup table.
DC-to-3-phase inverter	Helps in switching network that transmits power to the motor stator windings according to a control signal.
Motor control logic	• Compares speed measurement to the required speed and adjusts the PWM signal generator. • Generates assertions for the PWM signal generator according to the commutation logic input.
PWM signal generator	Generates the PWM signal voltage source.
Reference signal	Gives signal that indicates the required motor speed.
Position measurement	Gets linked as an ADC to a shunt resistor or resolver output signals to perform measurements and detect also overcurrent conditions. If one is found, the hardware generates a fault interrupt.

54.5.1.1.2 PMSM motor control

The PCMC subsystem consists of a group of modules that enables you to implement PMSM motor control loops in a variety of ways. The following figure and table illustrate a possible implementation.

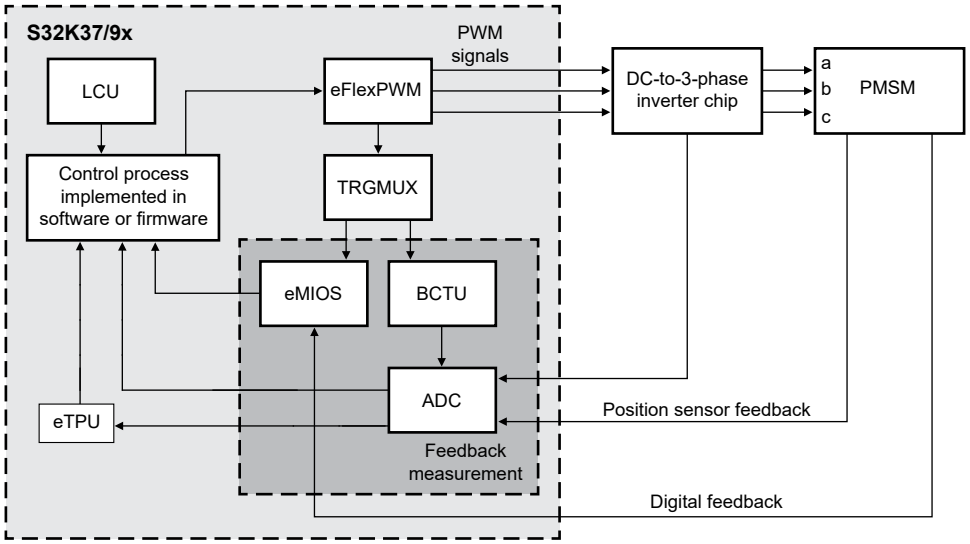

Figure 222. PMSM motor control diagram

Table 258. PMSM motor control: description of components

Component	Description
ADC	Measures analog inputs (currents and/or voltages) and converts them to digital values. Typically, ADC measures currents and can be configured to generate a fault interrupt when a measured input is outside a predefined acceptable range.
BCTU	Triggers conversions by ADC.
Control process	Provides top-level system control functions for FOC or another feasible control algorithm: • Compares speed measurement to the required speed and adjusts the PWM signal generator. • Generates assertions for the PWM signal generator according to the commutation logic input.
DC-to-3-phase inverter	Helps in switching network that transmits power to the motor stator windings according to a control signal.
eFlexPWM	Generates a PWM input for the DC-to-3-phase inverter.
eTPU	Is a coprocessor designed for timing control capable of: • Resolver feedback processing • Generating Motor control PWM to drive 3-phs motor • Triggering and synchronization
eMIOS	Measures digital feedback inputs, for example, BLDC position sensors.

Table continues on the next page...

Table 258. PMSM motor control: description of components (continued)

Component	Description
LCU	Implements the commutation lookup table. The control process compares values from the angular position sensors to entries in the lookup table. It then applies voltage to stator winding that corresponds to the same set of values in the lookup table.
TRGMUX	• Enables interconnect to the required set of on-chip peripherals. • Indirectly triggers ADC sampling via BCTU. • Triggers eMIOS to measure digital feedback signals.

54.5.1.2 Sensored BLDC motor control use case

54.5.1.2.1 Generic sensored BLDC motor control

The following figure and table illustrate a generic sensored BLDC motor control system. The feedback loops in the system create a motor control loop.

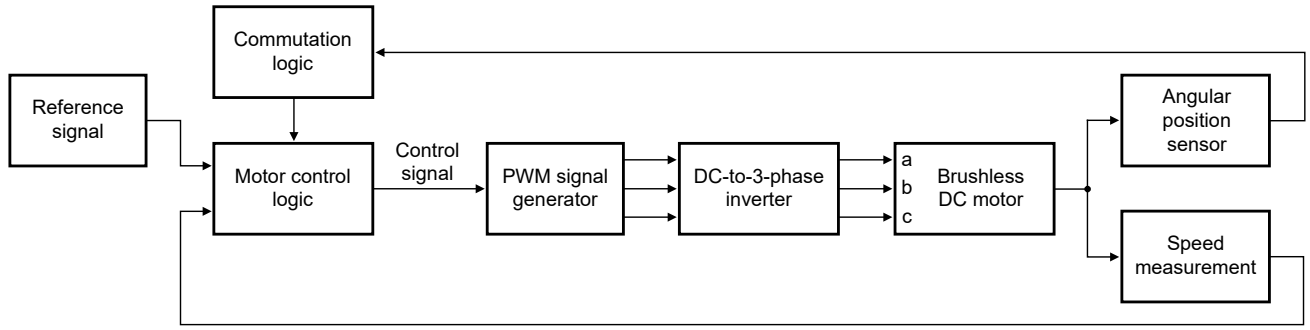

Figure 223. Generic sensored BLDC motor control: diagram

Table 259. Generic sensored BLDC motor control: description of components

Component	Description
Angular position sensor	Acts as a Hall effect sensor or an optical decoder to detect the rotor position.
Commutation logic	Compares values from the angular position sensors to entries in a lookup table and applies voltage to the stator winding that corresponds to the same set of values in the lookup table.
Reference signal	Sends a signal that indicates the required motor speed.
DC-to-3-phase inverter	Helps in switching network that transmits power to the stator windings according to a control signal.
Motor control logic	• Compares speed measurement to the required speed and adjusts the PWM signal generator. • Generates assertions for the PWM signal generator according to the commutation logic input.
Speed measurement	Uses an ADC linked to a shunt resistor to perform measurements and detect overcurrent conditions, in which case hardware generates an interrupt.

54.5.1.2.2 Three-phase FOC of the BLDC motor

FOC is a VFD control method in which the stator current of a three-phase AC electric motor (such as BLDC, PMCM, reluctance motor, or any other spinning electrical machine) is identified as a vector.

The PCMC subsystem consists of a group of modules that enables you to implement sensored FOC BLDC motor control loops in a variety of ways. The following figure and table show one of the possible implementations.

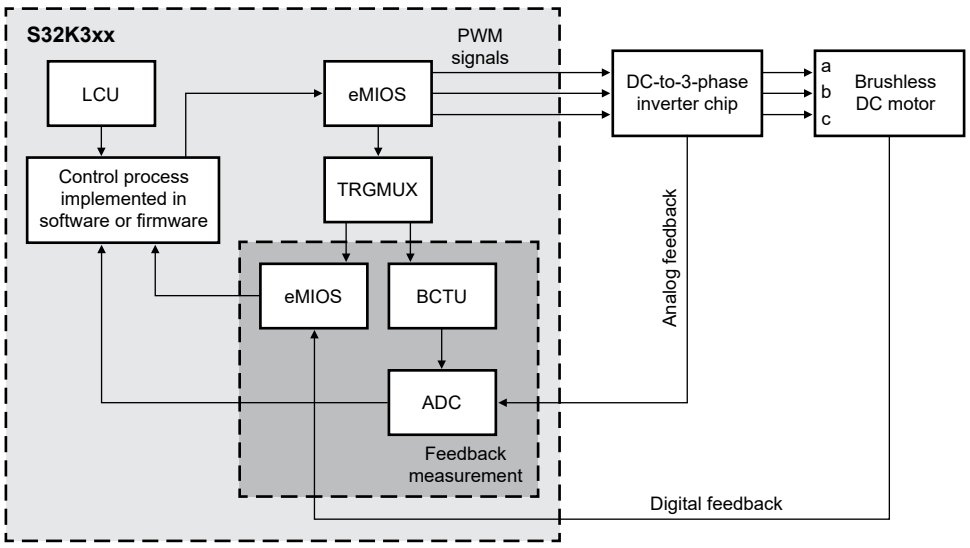

Figure 224. Three-phase FOC of the BLDC motor: diagram

Table 260. Three-phase FOC of the BLDC motor: description of components

Component	Description
ADC	Measures analog inputs (currents and/or voltages) and converts them to digital values. Typically, ADC measures currents and can be configured to generate a fault interrupt when a measured input is outside a predefined acceptable range.
BCTU	Triggers conversions by ADC.
Control process	Provides top-level system control functions for FOC control: • Compares speed measurement to the required speed and adjusts the PWM signal generator. • Generates assertions for the PWM signal generator according to the commutation logic input.
DC-to-3-phase inverter	Helps in switching network that transmits power to the motor stator windings according to a control signal.
eMIOS	• Generates PWM input for DC-to-3-phase inverter. • Measures digital feedback inputs, for example, BLDC position sensors.
LCU	Implements the commutation lookup table. The control process compares values from the angular position sensors to entries in the lookup table. It then applies voltage to the stator winding that corresponds to the same set of values in the lookup table.
TRGMUX	• Enables interconnect of the required set on on-chip peripherals.

Table continues on the next page...

Table 260. Three-phase FOC of the BLDC motor: description of components (continued)

Component	Description
	• Indirectly triggers ADC sampling via BCTU. • Triggers eMIOS to measure digital feedback signals.

54.6 ADC design considerations

The following topics discuss factors that affect the ADC function in applications.

54.6.1 Measurement accuracy

The FOC motor control algorithm requires a high degree of confidence in the reliability of conversion data. Here are some of the best practices that contribute to ADC precision:

- Use precision channels (see Precision channels).
- Minimize input noise (see Input noise).
- Use BCTU triggering (see Triggering).

54.6.1.1 Precision channels

See the chip-specific ADC configuration information for the number of precision channels in each ADC instance.

You can find the channel numbers for the precision channels in the channel mapping table.

54.6.1.2 Input noise

Regardless of the application, ADCs are inherently sensitive to input noise. The following best practices help minimize input noise:

- Avoid simultaneous conversions.
- Consider using a low-pass filter on input pins.

All variants of this chip include multiple, independent ADC instances. Therefore, it is possible to have simultaneous sampling by different ADC instances. However, you must avoid simultaneous sampling because ADC sampling can cause noise on adjacent device ADC inputs. This is an important consideration for implementation of the FOC algorithm.

Additionally, an RC low-pass filter on ADC input pins can help reduce noise and enhance accuracy.

54.6.1.3 Triggering

Some applications, including FOC motor control, must use BCTU for precise triggering of ADC measurement. This is because the FOC algorithm requires sampling at specific times to implement the observer or predictor. BCTU helps you perform precisely-timed ADC measurement.

For less exigent algorithms or nonclosed loop-controlled motors, BCTU triggering and precision ADC channels are not necessarily required.

54.6.2 Examples of ADC configurations

Following are some of the ADC configurations that you may use for FOC motor control.

Table 261. Examples of ADC configurations

Mode	Settings
Single-Shot	• ADC.MCR[OWREN] = 1

Table continues on the next page...

Table 261. Examples of ADC configurations (continued)

Mode	Settings
	• ADC.MCR[WLSIDE] = 0 • ADC.MCR[MODE] = 0 • ADC.MCR[TRGEN] = 0 • ADC.MCR[JTRGEN] = 0 • ADC.MCR[BCTUEN] = 0 • ADC.MCR[AVGEN] = 0 • ADC.MCR[ADCCLKSEL] = 01 (1/2 module clock)
Normal Conversion Scan	• ADC.MCR[OWREN] = 1 • ADC.MCR[WLSIDE] = 0 • ADC.MCR[MODE] = 1 • ADC.MCR[TRGEN] = 0 • ADC.MCR[JTRGEN] = 0 • ADC.MCR[BCTUEN] = 0 • ADC.MCR[AVGEN] = 0 • ADC.MCR[ADCCLKSEL] = 01 (1/2 module clock)
BCTU Control	• ADC.MCR[OWREN] = 1 • ADC.MCR[WLSIDE] = 0 • ADC.MCR[MODE] = 0 • ADC.MCR[TRGEN] = 0 • ADC.MCR[JTRGEN] = 0 • ADC.MCR[BCTUEN] = 1 • ADC.MCR[AVGEN] = 0 • ADC.MCR[ADCCLKSEL] = 01 (1/2 module clock)
BCTU Trigger	• ADC.MCR[OWREN] = 1 • ADC.MCR[WLSIDE] = 0 • ADC.MCR[MODE] = 0 • ADC.MCR[TRGEN] = 0 • ADC.MCR[JTRGEN] = 0 • ADC.MCR[BCTUEN] = 1 • ADC.MCR[BCTU_MODE] = 1 • ADC.MCR[AVGEN] = 0 • ADC.MCR[ADCCLKSEL] = 01 (1/2 module clock)

54.7 BCTU design considerations

For reasons discussed in Triggering, some applications require precise ADC triggering and BCTU provides that capability. The following topics discuss some of the BCTU design considerations.

54.7.1 BCTU or ADC data retrieval

The primary function of BCTU is to provide precisely timed triggers for ADC conversions. However, there is some overlap in BCTU and ADC functions and data for conversion can be retrieved from either of the modules. For applications in which frequent conversions are performed, such as real-time motor control, BCTU offers a distinct advantage over ADC. This is because BCTU trigger sources can be configured to route conversion results to a BCTU-internal FIFO. Doing so prevents subsequent conversion data from overwriting previous data, making it available for either direct access or DMA transfer to system RAM.

54.7.2 Disabling BCTU triggers

In some fault scenarios, you must disable BCTU triggers as part of placing the system into a safe state. Examples of these scenarios include:

- Overvoltage condition
- Undervoltage condition
- Calibration parameter mismatch between the embedded motor control system and motor

An application fault reaction design must include the disabling of BCTU triggers in scenarios wherein either system conditions indicate an impending failure or ADC conversion data is outside control boundaries.

54.8 Glossary

BLDC Brushless DC. An electronically-commutated DC motor.

CF Crest factor. A waveform parameter that is the ratio of peak values to its RMS value.

DF Distortion factor

DPF Displacement power factor. In power electronics, the phase relationship between voltage and current is $\cos(\theta_v - \theta_i)$, where θ_v is the phase of the voltage and θ_i is the phase of the current.

DVA Distortion volt-amperes

FF Form factor

FOC Field-oriented control

GM Gain margin

PF Power factor. In power electronics, it is the ratio of average power to RMS power.

PMSM Permanent magnet synchronous motor

THD Total harmonic distortion

VFD Variable-frequency drive

55.2 Overview

The Input Glitch Filter provides programmable glitch rejection filtering of digital input signals.

55.2.1 Block diagram

The figure below is the block diagram for the Input Glitch Filter module.

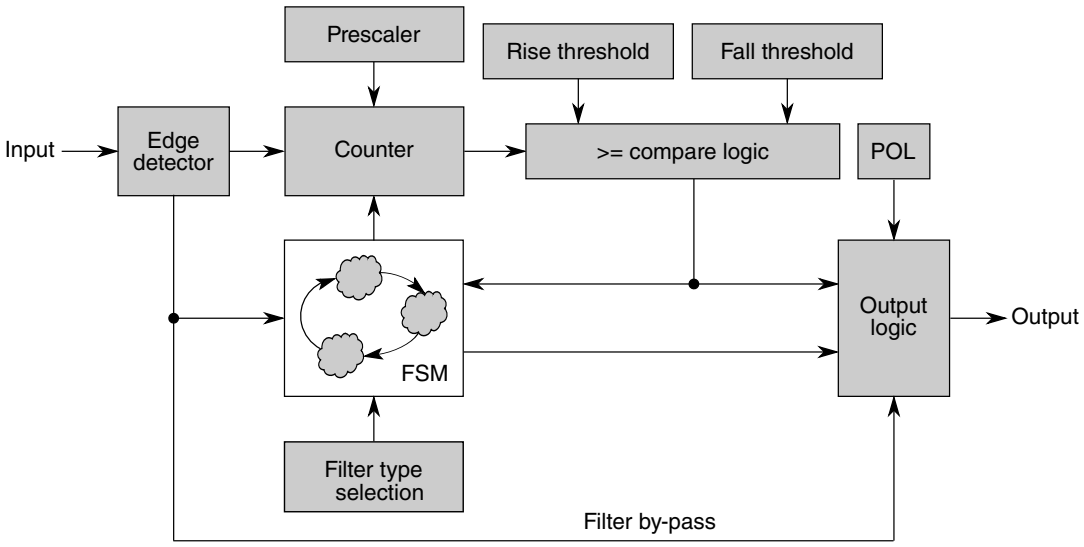

Figure 226. Input Glitch Filter block diagram

NOTE

Each filter counter needs of (rising edge threshold + 2) counts to achieve the rising threshold. Similarly, it needs (falling edge threshold + 2) counts to achieve the falling threshold. It is valid for all filters type that use the threshold values. The rate of these counts depends the prescaler settings and the system clock frequency.

55.2.2 Features

Input Glitch Filter includes the following features:

1. Supports several filtering modes on the input signal
2. Filter output polarity selection
3. Allows forcing filter outputs to defined values
4. Allows edge selection for different filtering modes
5. Supports prescaling
6. Supports debug on freeze
7. Supports low power mode of operation

55.3 Functional description

The Input Glitch Filter receives an input signal usually from a device PAD. Signals generated externally to the device are affected by environmental noise or glitches. The signal level has to be evaluated with some criteria in order to remove the noise which could affect the measurements done over this signal, such as transition time, period and level.

In a typical application, the Input Glitch Filter interfaces with one or more timer peripherals.

The strategy to remove glitches from an input signal is to monitor the level of the signal during a wide time window thus the glitches can be evaluated and removed.

55.3.1 Interaction with other peripherals

The figure below shows an example of how the Input Glitch Filter interacts with on-chip peripherals.

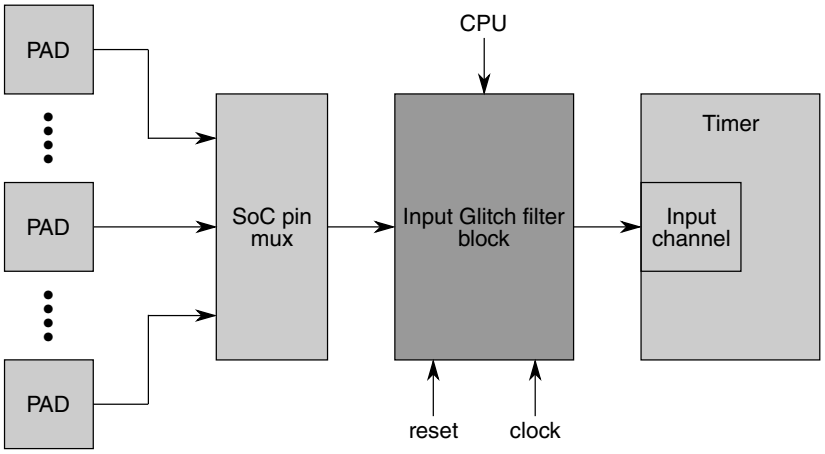

Figure 227. Input Glitch Filter application example

55.3.2 Input double sampling

The filter input is double sampled for clock domain translation thus avoiding asynchronous signals to propagate through the filter internal logic. This stage is composed by two flip-flops connected back to back. The delay caused by this logic is therefore two clock cycles.

Note that due to the synchronous nature of the Input Glitch Filter design, if a glitch smaller than one clock cycle occurs at the filter input it will not propagate to the filter internal logic and thus will not propagate to the filter output. Also, if clock is not applied to the filter (i.e. in low power mode) any transition at the filter input will not propagate to the filter output.

55.3.3 Filter types

The Input Glitch Filter implements four main filter types:

- Windowing
- Windowing with post sample
- Integrating
- Integrating hold

These filter types can be selected for the rising and falling edges independently, thus allowing different filter types to be selected for different edges (i.e. rising edge filtered with windowing filter and falling edge filtered with integrating).

55.3.3.1 Windowing filter

This filter type detects an edge (positive or negative edge) at the filter input and then mask out detection of subsequent edges over a period of time, which is defined as the blanking period, thus effectively behaving as a high pass filter. After an edge is detected the level at the filter input is propagated to the filter output within three clock cycles. The delay is caused by the synchronization stage at the input and by the filter output register stage. During the blanking period any transition at the filter input is disregarded. After the blanking period has elapsed, the filter compares the input level state with the filter output state. In case they are different a transition is inferred and re-evaluate according to the filter type assigned to that transition (positive or negative edges). Since, in this example, the windowing filter type is programed for both edges, the inferred negative edge is propagated to the filter output and another blanking period is initiated. The figure below describes the windowing filter type behavior.

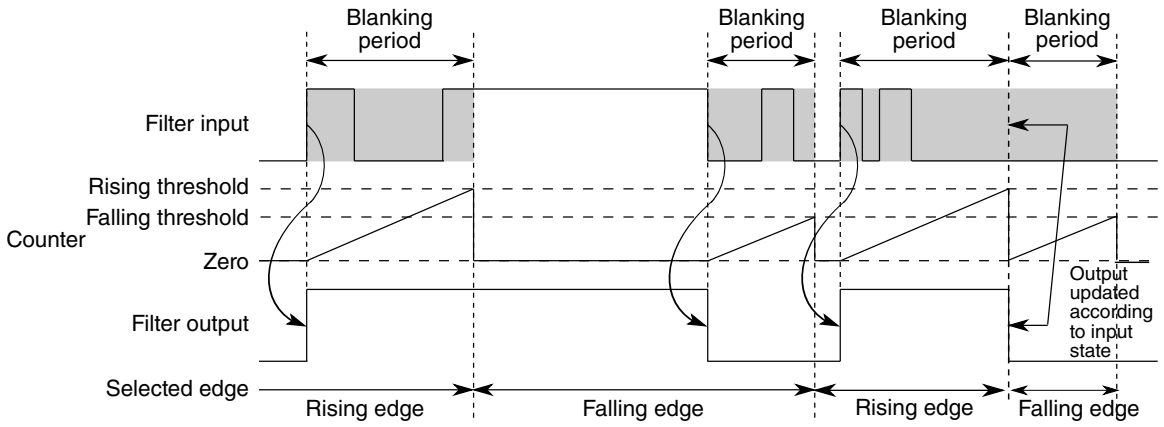

Figure 228. Windowing filter type

The windowing filter type is used when no delay is allowed in the detection of a signal transition. This filter also removes glitches that occurs after a transition is detected which could affect the correct capturing of the signal transition, i.e. by a Timer channel set to input capture.

In the figure above the blanking period starts when a rising edge is detected. The duration of this period is defined by the 'rising threshold ' value. If a falling edge is detected the ‘falling threshold’ value is used as the compare limits for the filter counter.

A transition that had occurred within a blanking period is delayed to the end of the blanking period. In this case it is not possible to determine the exact moment that transition occurred.

55.3.3.2 Windowing filter with post sample

This filter type detects an edge (positive or negative edge) at the filter input and then masks out detection of subsequent edges over a period of time, which is defined as the blanking period. During the blanking period, any transition at the filter input is disregarded.

When the blanking period finishes, the filter input level is propagated to the filter output. If the filter input is equal to the filter output when the blanking period finishes, then the filter output is not changed at the end of blanking period.

The figure below describes the windowing filter with post sample.

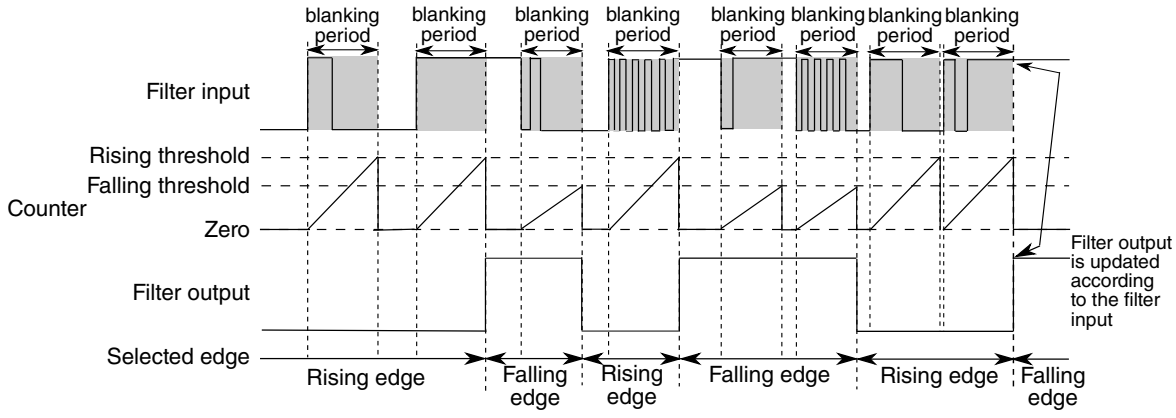

Figure 229. Windowing filter with post sample type

The windowing filter with post sample type is used to remove glitches and sparks around an edge.

55.3.3.3 Integrating filter

The integrating filter behaves like a low-pass filter, thus removing high frequency bursts from the input signal. The input and output signals are compared and if they are at different states an internal filter counter is enabled.

The direction of the counter (up or down counting) is defined by the states of the input and output filter signals as follows:

- Filter output is at the same state as the filter input: down-counting
- Filter output is at different state as the filter input: up-counting

The counter is compared with the rising or falling threshold register according to:

- Rising threshold register is selected if the rising edge is being filtered.
- Falling threshold register is selected if the falling edge is being filtered.

The filter output changes state to the same state as the filter input:

- If filter counter reaches the selected threshold for the edge being filtered.

The internal counter is disabled and cleared:

- If filter counter reaches the selected threshold for the edge being filtered.

The figure below describes an example of the Integrating filter type operation.

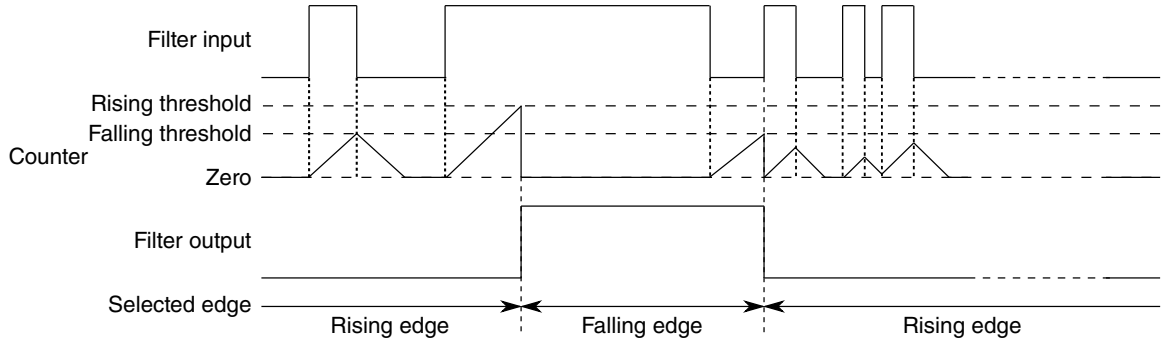

Figure 230. Integrating filter type

55.3.3.4 Integrating-hold filter

The integrating-hold filter type is similar to the integrating filter. The difference is the counter, which only counts in up direction instead of up-down in the integrating mode. In this filter configuration the input and output signals are compared and if they are at different states the filter counter is enabled. This counter is controlled by the state of the filter input and filter output signals as follows:

- Filter output is at the same state as the filter input: counter is in hold state (no-counting).
- Filter output is at different state as the filter input: counter is counting up.

The counter is compared with the rising or falling threshold register according to:

- Rising threshold register is selected if the rising edge is being filtered.
- Falling threshold register is selected if the falling edge is being filtered.

The filter output changes state to the same state as the filter input:

- If the filter counter reaches the selected threshold for the edge being filtered.

The internal counter is disabled and cleared:

- If the filter counter reaches the selected threshold for the edge being filtered.

The figure below shows an example of the Integrating-hold filter type operation.

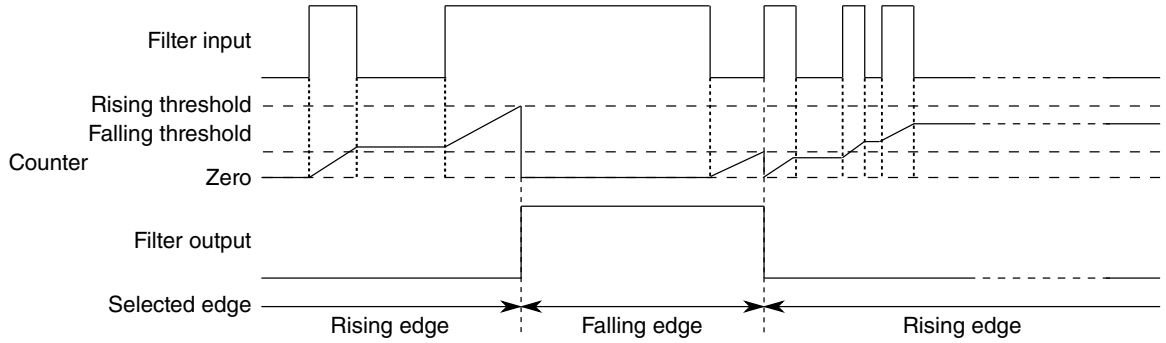

Figure 231. Integrating-hold filter type

55.3.3.5 Bypass filter

In the bypass filter type, the Input Glitch Filter immediately propagates any transition on the filter input to the filter output. This filter type does not provide any protection against glitches in the input signal. It is intended to be used in situations where the input signal is already filtered, or it is a glitch free signal, or the filter output is connected to a module that already has filtering capabilities. The bypass filter type is independently selected for rising or falling edges. Thus rising edges may be not filtered by the bypass filter type while the falling edges are filtered by any of the available filter types.

The bypass filter presents a delay in the edge propagation through the filter that is caused by the double sampling at the filter input and by the output filter register. Therefore, the total delay is three clock cycles.

55.3.3.6 Combined filter

The Input Glitch Filter allows the combination of filter types for different edges, positive and negative. As an example, the rising edges may be filtered using the windowing filter while the falling edges are filtered with an integrating filter. This configuration of the Input Glitch Filter is provided for situations where the noise present in the rising edges is different from the noise in the falling edges. Another use case is when the delay requirements of the input signal is different for rising and falling edges.

The figure below shows the combined filter operation. The windowing filter type is applied to the rising edges. The integrating filter is used for the falling edges.

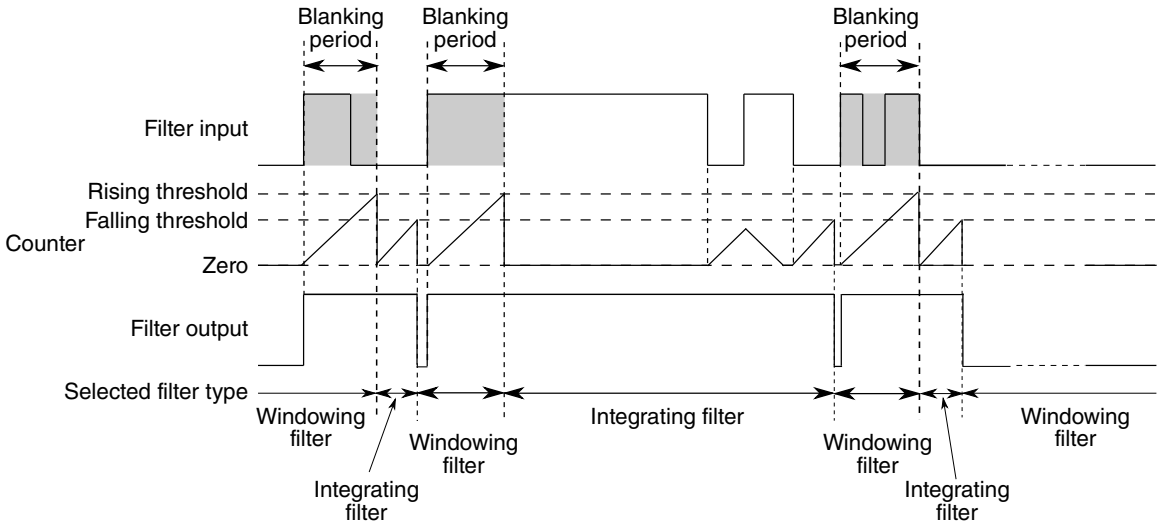

Figure 232. Combined filter type (windowing + integrating)

55.3.4 Mode of operation

The Input Glitch Filter has the following modes of operation:

- Configuration mode
- Normal mode
- Debug mode
- Low power mode

55.3.4.1 Configuration mode

The configuration mode is the initial mode of the Input Glitch filter after system reset is applied. The configuration mode is selected when FGEN = ‘0’ in the MCR register. The filter parameters such as rising and falling thresholds can be programmed when the filter is in configuration mode without disturbing the internal device logic since the filter output is kept at logic '0' state. Once FGEN is programmed with logic ‘1’ the filter enters the normal operating mode and is able to initiate the filtering process.

NOTE

The MDIS bit in the MCR register, if set to logic '1', makes the filter transition to low power mode independent of FGEN bit settings. Thus, in order to enter the configuration mode MDIS bit needs to be at logic '0'.

55.3.4.2 Normal mode

The normal mode of operation is entered when MCR register FGEN = ‘1’. In this mode the filter implements one of the filter types:

- Bypass filter
- Windowing filter
- Windowing filter with post-sample
- Integrating filter
- Integrating-hold filter

These filter types are described in the following sections. Before entering the normal mode, the filter parameters, such as rise and fall thresholds, need to be programmed in the appropriate registers, as well as the type needs to be defined in the corresponding register.

NOTE

In the normal mode it is still possible to change the filter parameters, such as rise and fall thresholds. See section On-the-fly filter reconfiguration for more details.

55.3.4.3 Debug mode

The debug mode is entered when the MCR FRZ bit is set and a system level debug request occurs. Once the debug mode is entered, the internal filter counter is halted and the debug functions controlled by the FBP, FOH, and FOL bits are enabled. The filter output is frozen and remains at the state it was immediately before the debug mode was entered. The FOH and FOL MCR bits can be used to force the filter output to logic '1' or '0', respectively. These bits are self-negating, thus they always read as zero.

By setting the MCR FBP bit, the filter input state is copied to the filter output, thus allowing to control the filter output based on the filter input state. The output is forced during one clock cycle. After that the filter output remains at the new forced state until it is changed again by using a debug control bit or if the filter returns to the normal mode of operation.

NOTE

The system level debug request occurs when a specific event, or a series of events, occurs in one of the device sub-modules and is interpreted by the device debug logic as a debug request. The Input Glitch Filter is not capable of generating an event that causes the assertion of the system level debug request.

55.3.4.4 Low power mode

The low power mode is controlled by the MDIS bit in the MCR register or by the STOP signal which is the system level low power control signal. When entering low power mode the filter output remains unchanged at the state it was just before the low power mode was entered. Since the Input Glitch Filter clocks are stopped in this mode, the internal counter remains inactive. The description of this mode is covered in the Low Power Mode section of this document.

55.3.5 Power saving mode

The Input Glitch Filter implements power saving mode thus allowing to reduce power consumption when device inputs connected to the filter are not used or the filter is not necessary to be functioning in a specific SoC mode of operation.

55.3.6 Clocking

This module has no clocking considerations.

55.3.7 Interrupts

This module has no interrupts.

55.4 External signals

This section describes the block's input/output signals.

Table 264. FlexSPI_FLR External Signals

Signal	Description	Direction
ipp_ind_gf_in	Input signal from device PAD	I

55.5 Initialization

The following generalized procedure may be used to configure the Input Glitch Filter Block:

1. Program the SoC pin mux logic to route an external signal to the input of the selected glitch filter.
2. Enable the destination module to receive the Input Glitch filter output.
3. Enable the clock source at the SoC level.
4. Program the Glitch Filter counter prescaler(s) to the desired rate.
5. Select the filter type for each edge using MCR[FFM] and MCR[RFM].
6. Clear any status bits if necessary.
7. Enable the filter using MCR[FGEN]

55.5.1 On-the-fly filter reconfiguration

The architecture of the Input Glitch Filter allows for on the fly reconfiguration of filter parameters such as rise and fall threshold values.

If a parameter is changed it influences the filter operation immediately after the new parameter value was written. The main problem when changing parameters, such as a threshold value, when the filter is enabled is that the filter counter could lose a match due to the parameter change. A great or equal comparator is used in the threshold match logic which allows correct filter operation when the threshold parameters are changed. The figure below shows an example of changing the rising edge parameter value. Note that in this case the match occurs immediately after the parameter is changed since the new parameter value is below the current counter value.

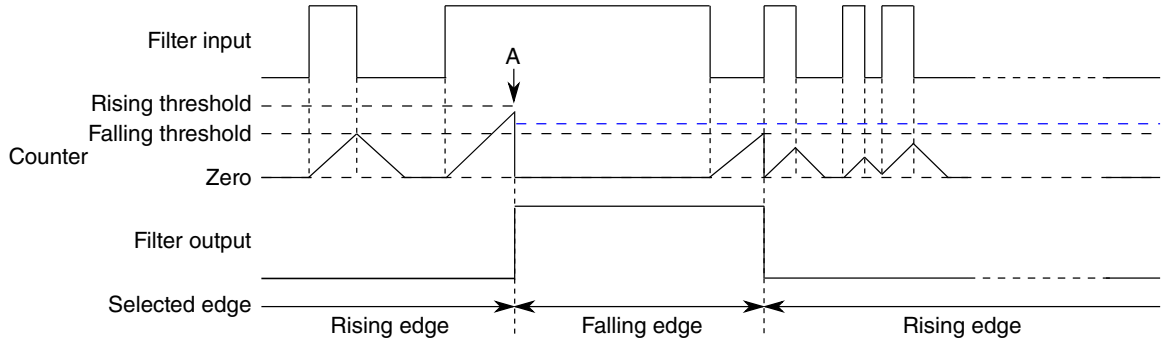

Figure 233. On-the-fly rising threshold parameter change

In the case shown in the figure above the match occurs immediately after the new rising threshold is programmed at 'A'.

NOTE

Note that when changing the threshold values the match may not occur when the counter is equal to the threshold value (the old or the new programmed value). Instead, the match may occur in between the old and new programmed thresholds when the threshold re-programming instant A is done when the counter is greater than the new value. This is a transitory effect which may occur when the threshold value is changed and should be considered by the application.

55.6 Application information

This section describes several applications for the Input Glitch filter module.

55.6.1 Application use case 1: integrating filter

The integrating filter type is particularly useful in applications where glitches occur spuriously while the signal is expected to be in a steady state (either 1 or 0). Choosing correct up and down filter clock rates can ensure that the effects of spurious glitches can be completely eliminated, whilst minimizing propagation delays.

The application must be able to tolerate delays between the actual edge occurrence and the time that the signal is propagated through the filter logic. Because the delays are constants defined by the detection thresholds, application software may compensate for them, provided little or no noise occurs on the detected edge.

55.6.2 Application use case 2: windowing filter

The windowing filter type is particularly useful for removing noise bounce produced by a switch or sensor when its signal changes state. In this case, there is no propagation delay (except for the filter input synchronization logic and output register) between the filter input and filter output signals. This type of filter would not necessarily provide much immunity to spurious noise that occurred during the steady state portion of the signal. In order to optimize the characteristics of this filter, the blanking period should be of the same magnitude as the expected input signal rate. Signals that change frequency can be accommodated by software by dynamically updating the blanking period.

55.6.3 Application use case 3: windowing filter

Safety applications may need to compare the inputs obtained from different input pins, but derived from a single external source. This form of redundancy may detect non-common mode faults that may occur in the portions of the SoC that route and process the incoming signal. Having two different instances of windowing filter used on each input pin will ensure that the signal edge timing for both input paths is equal. Applying different filter characteristics for each input path can enhance the ability to detect SoC fault conditions.

55.6.4 Application use case 4: combined filter

Some applications may have rising edge signals that exhibit different characteristics to falling edge signals which might require different filtering to optimize the filtering effect. For example the “first” rising edge may represent a true real time event with a fast slew rate that must be captured without delay, while the falling edge signal may have a slow slew rate with many noisy transitions. The Input Glitch Filter can apply, for example, a windowing filter on the rising edge to ensure no loss of real time information and an integrating filter on the falling edge to eliminate noise from being detected as a new rising transition.

55.6.5 Application use case 5: prescaler settings in windowing filter

The prescaler settings influence the timing for an edge to propagate through the filter. In windowing filter the IMM bit in the MCR register controls the way an edge is propagated through the filter. The figure below describes the windowing filter operation with regard to the IMM bit settings.

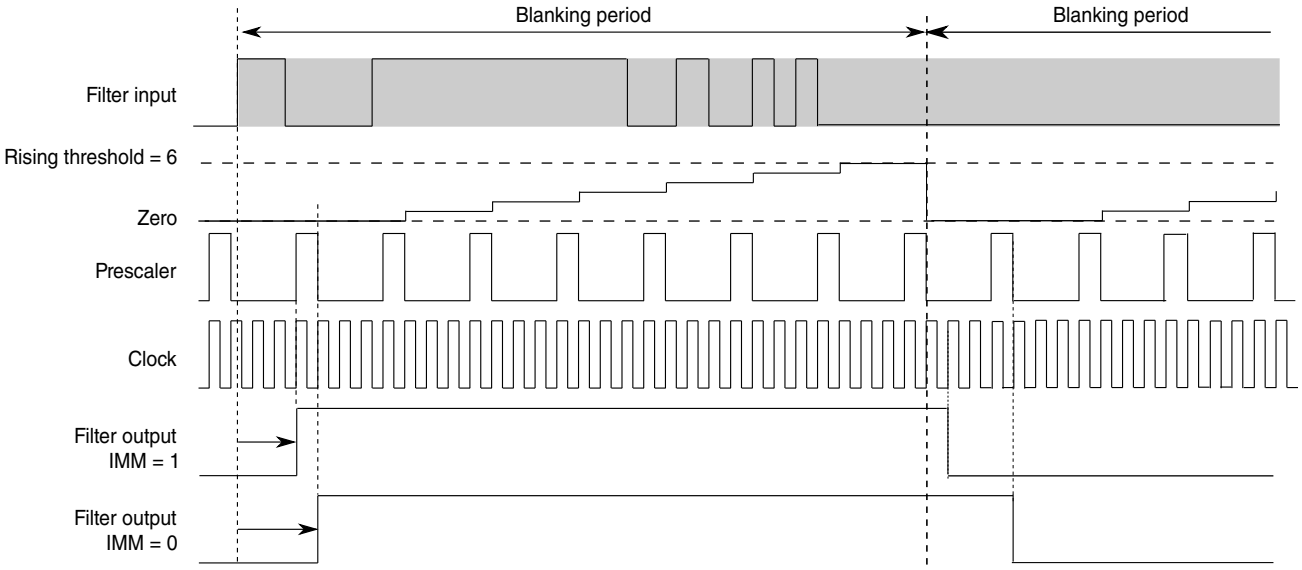

Figure 234. Input signal propagation through the filter in windowing filter type

If IMM = 0 then the input signal edges are propagated according to the prescaler ticks. If IMM = 1 then the input edges are propagated immediately (within 3 clock cycles) to the filter output.

55.6.6 Application use case 6: prescaler settings in bypass

The prescaler settings settings of the external prescaler influence the timing for an input signal edge to propagate through the filter. In bypass, the IMM bit in the MCR register controls the way an edge is propagated through the filter. If IMM= 0, the prescaled clock is used to sample the input filter signal. The resolution the input signal is sampled is therefore related to the prescaler frequency. Glitches narrower than the prescaler period that are not aligned with the prescaler clock are not captured by the filter. If IMM = 1, the system clock is used to sample the filter input signal instead of the prescaled clock. In this case, the resolution of the sampled input signal is the system clock.

The figure below describes the filter input signal sampling behavior for IMM = 0 and IMM = 1.

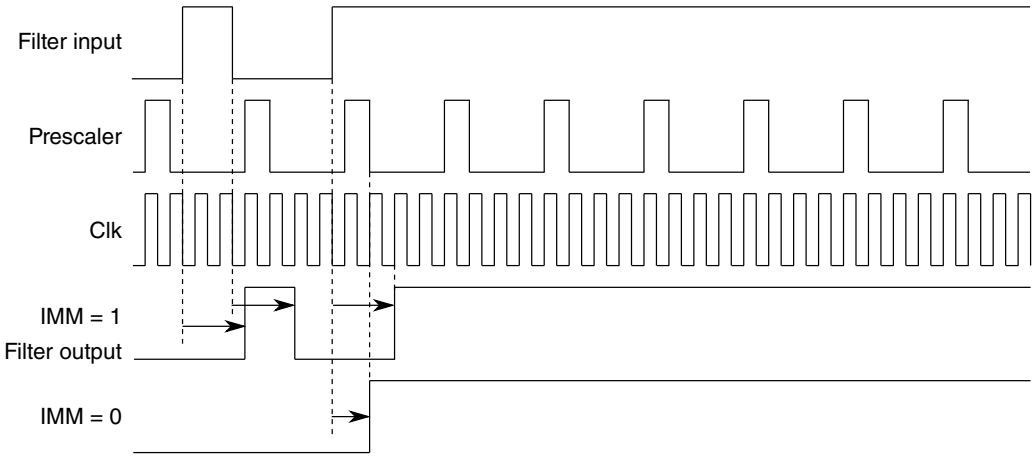

Figure 235. Input signal propagation through the filter in bypass

55.7 IGF register descriptions

The Input Glitch Filter registers are implemented in 32-bit. 8-bit write operations are allowed. The coherency in case of 8-bit access must be provided by the application software since there is no coherence mechanism built into the hardware.

NOTE

RESERVED bit registers, when available for write operations, should be written always with logic '0'. Read access does not return meaningful data from RESERVED bit registers.

55.7.2 Module Configuration Register (MCR0 - MCR31)

Offset

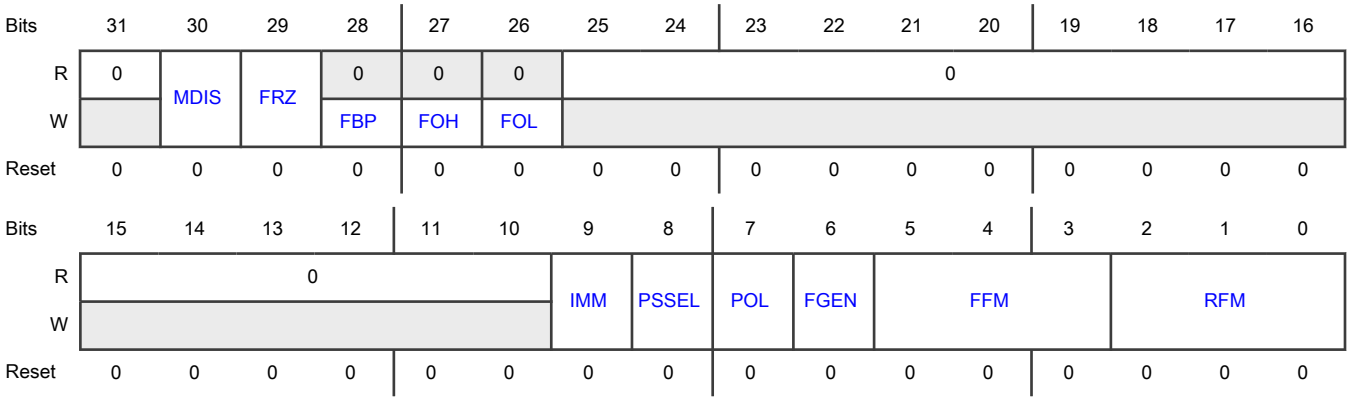
For n = 0 to 31:

Register	Offset
MCRn	0h + (n × 40h)

Function

The Module Configuration register (MCR) provides access to low power, debug, and filter control bits.

Diagram



Fields

Field	Function
31 —	Reserved
30 MDIS	Module Disable The MDIS bit forces the filter to enter a low power state. After this bit is asserted the clock for the module is removed thus filter operation is not possible. The access to filter registers is allowed. 0b - Input Glitch Filter is not in low power mode due to MDIS bit 1b - Input Glitch Filter is in low power mode
29 FRZ	Freeze bit for debug operation The FRZ bit enables the Input Glitch Filter to enter freeze mode (debug mode) when a system level signal request the module enters freeze (debug) mode. Once in freeze mode the filter operation is disabled meaning that transitions on the input signal will not propagate through the filter output. The bypass FBP bit can be used by the software to force the filter output to be the same as the filter input. In this mode FOH and FOL also can be used to define the filter output state. 0b - Freeze mode disabled 1b - Freeze mode enabled
28 FBP	Force Bypass This bit is self-negated thus is only read as zero. Writing 1 to this bit while in freeze mode forces the filter to bypass the value in the input to the filter output, thus allowing a software control on the filter. This bit is functional only in freeze mode. 0b - no filter bypass 1b - transfer input signal value to the filter output
27	Force filter output high

Table continues on the next page...

Table continued from the previous page...

Field	Function
FOH	If set, this bit forces the Input Glitch Filter output to ‘1’. This bit is functional only in debug mode. It is self-negated thus always read as zero. 0b - no action 1b - forces the filter output to ‘1’
26 FOL	Force filter output low If set this bit forces the Input Glitch Filter output to ‘0’. This bit is functional only in debug mode. It is self-negated thus always read as zero. 0b - no action 1b - forces the filter output to ‘0’
25-10 —	Reserved
9 IMM	Immediate edge propagation control bit The IMM bit controls the propagation of an edge through the filter. If asserted, this bit defines that an edge at the filter input propagates through the filter output independent of the prescaler settings. In bypass mode the propagation delay is three system clock cycles. If negated, the signal propagation depends upon the prescaler settings. The filter hardware will only allow changes to this bit if the filter is disabled, FGEN = 0 0b - edge propagation depends on prescaler 1b - edge propagation within three system clock cycles
8 PSSEL	Prescaler selection bit The PSSEL selects if the prescaler used by the Input Glitch Filter is from internal source (internal prescaler counter) or from external source. The filter hardware will only allow changes to this bit if the filter is disabled, FGEN=0. 0b - Internal prescaler selected 1b - external prescaler selected
7 POL	Output polarity bit This bit sets the polarity of the filter output to inverted or not inverted. The polarity control implemented by the POL bit is applied at the filter output stage thus also changing the reset state of the output, even if the filter is disabled by the FGEN bit. The filter hardware will only allow changes to this bit if the filter is disabled, FGEN=0. 0b - not inverted output 1b - inverted output
6 FGEN	Filter global enable This control bit enables the filter operation, meaning that if the filter is enabled the filtering selected types are applied to the rising and falling edges of the input signal. If the filter is not enabled, then the filter output remains unchanged independent of the filter input signal. Note that the filter output state is affected by the POL bit when the filter is disabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - filter is disabled: filter output keeps current state. 1b - filter is enabled: filtering is applied to selected edges.
5-3 FFM	Falling edge filter type selection This bit field selects the filter type for the filter input signal falling edge. The filter hardware will only allow changes to this bit if the filter is disabled, FGEN=0. 000b - bypass: edge is propagated to filter output without any filtering in three system clock cycles 001b - windowing: windowing filter is selected for the falling edge 010b - integrating: integrating filter is selected for the falling edge 011b - integrating-hold: integrating-hold filter is selected for the falling edge 100b - windowing with post sample: windowing filter with post sample is selected for the falling edge
2-0 RFM	Rising edge filter type selection This bit field selects the filter type for the input signal rising edge. The filter hardware will only allow changes to this bit if the filter is disabled, FGEN=0. 000b - bypass: edge is propagated to filter output without any filtering in three system clock cycles 001b - windowing: windowing filter is selected for the rising edge 010b - integrating: integrating filter is selected for the rising edge 011b - integrating-hold: integrating-hold filter is selected for the rising edge 100b - windowing with post sample: windowing filter with post sample is selected for the rising edge

55.7.3 Module Status Register (MSR0 - MSR31)

Offset

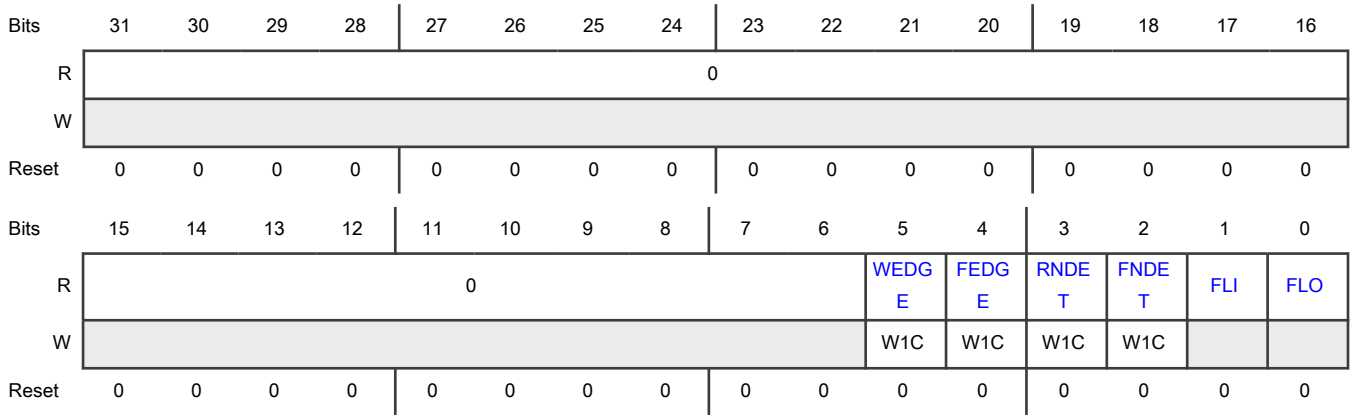
For n = 0 to 31:

Register	Offset
MSRn	4h + (n × 40h)

Function

The Module status register (MSR) provides access to filter status bits and corresponding clear bits as well as access to the state of filter input and output signals.

Diagram



Fields

Field	Function
31-6 —	Reserved
5 WEDGE	Filter is active waiting for an edge This bit is set when the filter is enabled but the internal counter is not active. It indicates that the filter is waiting for an edge to occur at the filter input. It is set by the Input Glitch Filter hardware and cleared by the software by writing 1 to the bit. Since the intention of this bit is to capture the dynamic of the filter hardware, it should be cleared after the read thus being able to capture a new event. 0b - Input Glitch Filter is disabled or the internal counter is active 1b - Input Glitch Filter is waiting for an edge
4 FEDGE	Filter is active processing an edge This bit is set during the filter active state thus when the filter internal counter is counting, processing an edge in a filtering mode. It is cleared by the software by writing 1 to the bit. Since the intention of this bit is to capture the dynamic of the filter hardware, it should be cleared after the read thus being able to capture a new event. 0b - Input Glitch Filter internal counter is not active 1b - Input Glitch Filter internal counter is active
3 RNDET	Rise noise detected bit This bit indicates that the filter filtered out noise in the input signal after a rising edge was detected. The criteria to set this bit is when a rising edge is detected thus starting the filter counter and before this edge pass through the filter (if filter is in integrating filter types) or during a window (if filter is in windowing filter types) another edge occurs in the input signal. This bit is set by a noise detection and cleared by the software by writing 1 to this bit. 0b - noise was not detected 1b - noise was detected after a rising edge
2	Fall noise detected bit

Table continues on the next page...

Table continued from the previous page...

Field	Function
FNDET	This bit indicates that the filter filtered out noise in the input signal after a falling edge was detected. The criteria to set this bit is when a falling edge is detected, thus starting the filter counter, and, if the filter is in integrating types, before this edge passes through the filter, or, in windowing types, when another edge occurs in the input signal during a window. This bit is set by a noise detection and cleared by the software by writing 1 to this bit. 0b - noise was not detected 1b - noise was detected after a falling edge
1 FLI	Filter input The FLI bit follows the state of the filter input value as captured by the filter input logic, which is affected by the IMM bit and prescaler settings.
0 FLO	Filter output The FLO bit follows the state of the filter output value considering the POL bit state.

55.7.4 Prescaler Register (PRESR0 - PRESR16)

Offset

Register	Offset
PRESR0	10h
PRESR16	410h

Chapter 56
Enhanced Flex Pulse Width Modulator (eFlexPWM)

56.1 Chip specific eFlexPWM information

56.1.1 eFlexPWM instances and configuration

The chip supports two instances of eFlexPWM.

Table 265. eFlexPWM configuration

Parameter	eFlexPWM_0	eFlexPWM_1
FIFO_DEPTH (Input capture FIFO depth)	4	4
CYC_WIDTH (Width of capture value cycle)	4	4
FNUM (Number of fault inputs)	4	4

56.2 Overview

eFlexPWM contains PWM submodules, each set up to control a single half-bridge power stage. eFlexPWM also provides fault channel support.

- AC Induction Motor (ACIM)
- Permanent Magnet AC (PMAC) Motor
- Brush DC (BDC) Motor
- Brushless DC (BLDC) motor
- Switched Reluctance Motor (SRM)
- Variable Reluctance Motor (VRM)
- Stepper Motors

eFlexPWM can generate various switching patterns, including highly sophisticated waveforms. You can use it to control all known motor types and is ideal for controlling different Switched Mode Power Supply (SMPS) topologies as well.

56.2.1 Block diagram

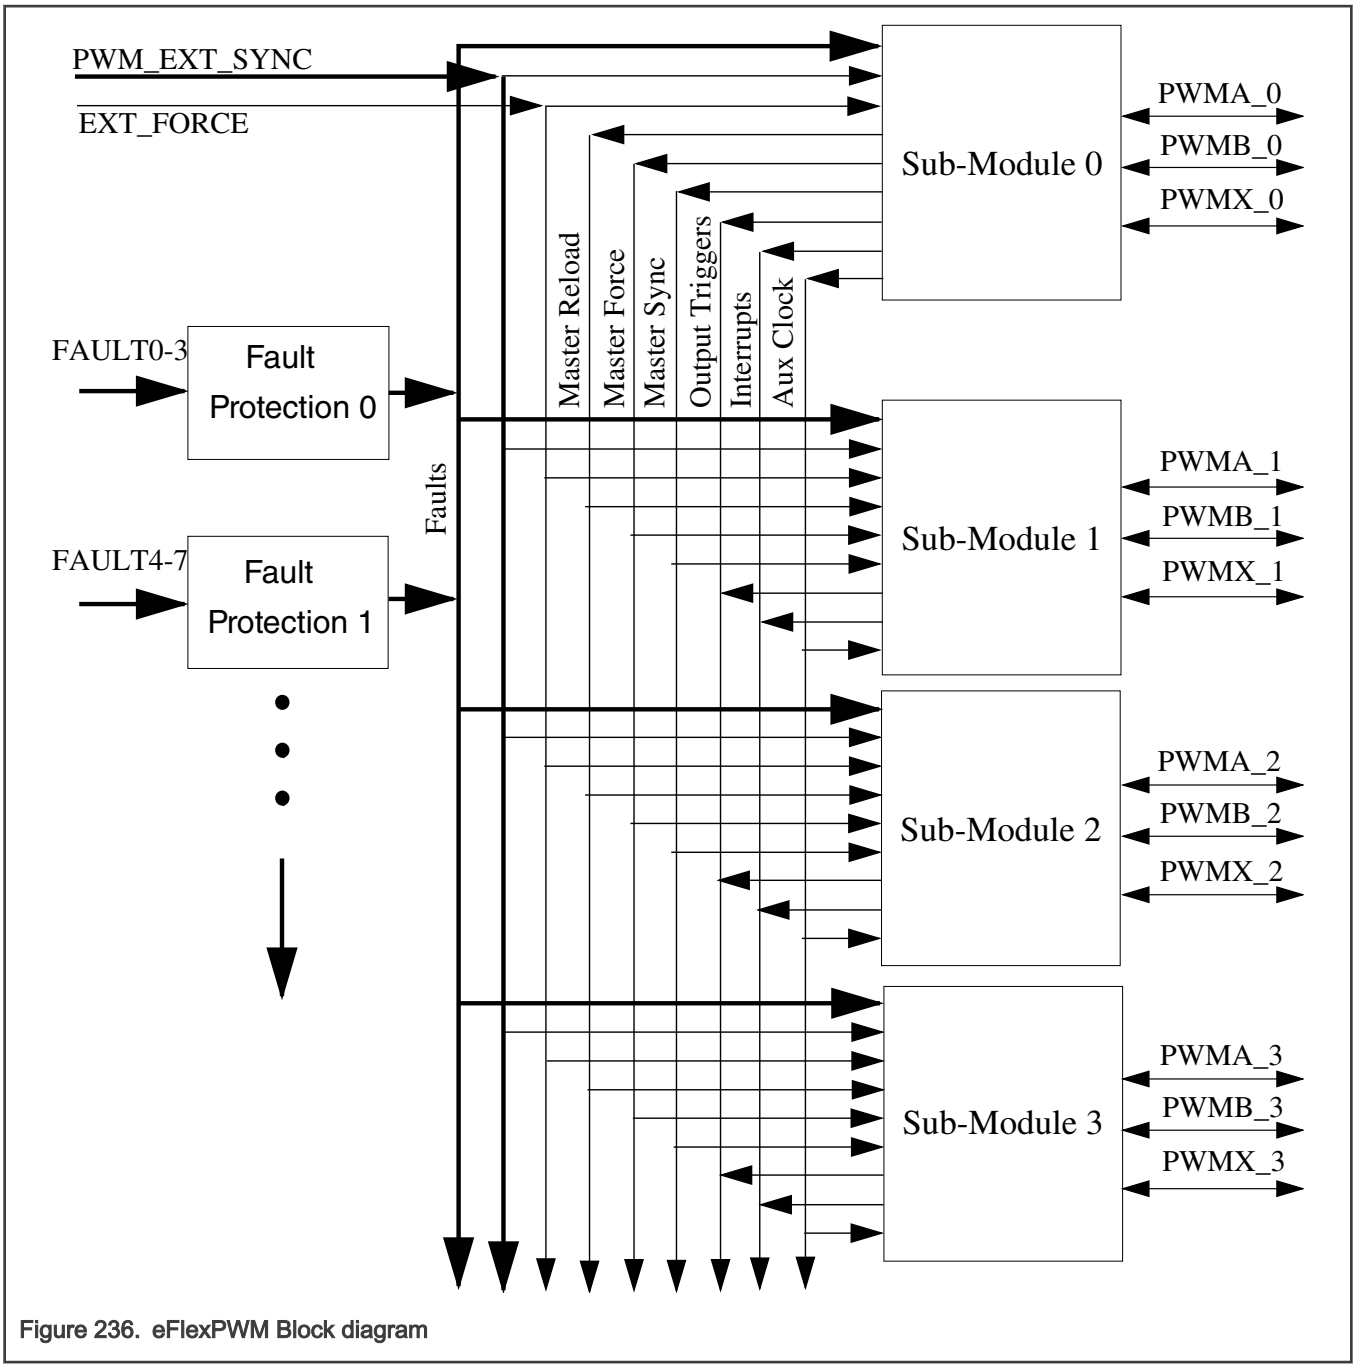

Figure 236. eFlexPWM Block diagram

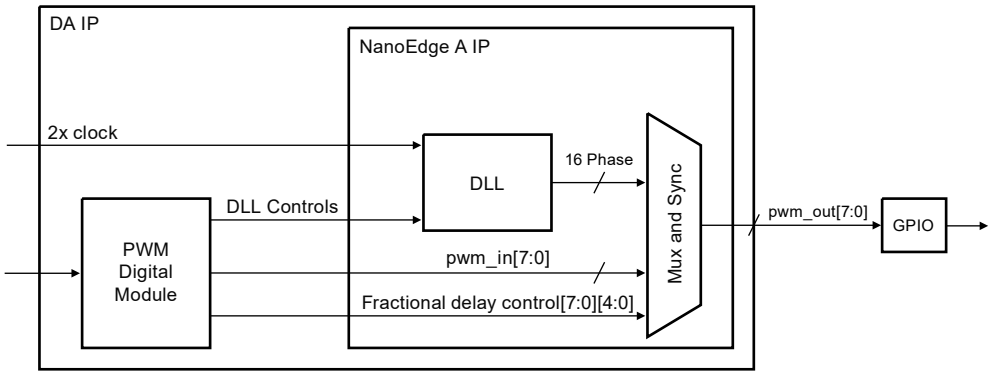

Figure 237. NanoEdge Block diagram

56.2.2 Features

56.2.2.1 eFlexPWM features

- 16 bits of resolution for center, edge-aligned, and asymmetrical PWMs
- Fractional PWM clock generation for enhanced resolution of the PWM timing values
- PWM outputs that can operate as complementary pairs or independent channels
- Ability to accept signed numbers for PWM generation
- Independent control of both edges of each PWM output
- Support for synchronization with external hardware or other PWM, including:
  - Crossbar module outputs
  - External ADC input, taking into account values set in ADC high and low limit registers
- Double buffered PWM registers
  - Integral reload rates from 1 to 16
  - Half-cycle reload capability
- Multiple output trigger events per PWM period via hardware
- Support for double switching PWM outputs
- Ability to assign fault inputs to control multiple PWM outputs
- Programmable filters for fault inputs
- Independently programmable PWM output polarity
- Independent top and bottom deadtime insertion
- Complementary pair output that can operate with its own PWM frequency and deadtime values
- Individual software control for each PWM output
- Programmable output transitions triggered by a FORCE_OUT event
- PWM_X pin for an optional third PWM output signal from each submodule
- Unused PWM channels available for buffered output compare functions
- Unused PWM channels available for input capture functions
- Enhanced dual-edge capture functionality

- Selectable controls for each complementary PWM signal pair

56.2.2.2 NanoEdge features

- Programs and generates 8 PWM outputs in parallel.
- Digital module generates PWM on 1x clock and analog module adjusts it by 1/32 period of the same clock.
- 2x clock is 320 MHz - 400 MHz.
- Provides smaller incremental shifts.
- Generates 32 system clock replicas separated by 156.25pS.

56.3 Functional description

56.3.1 PWM submodule

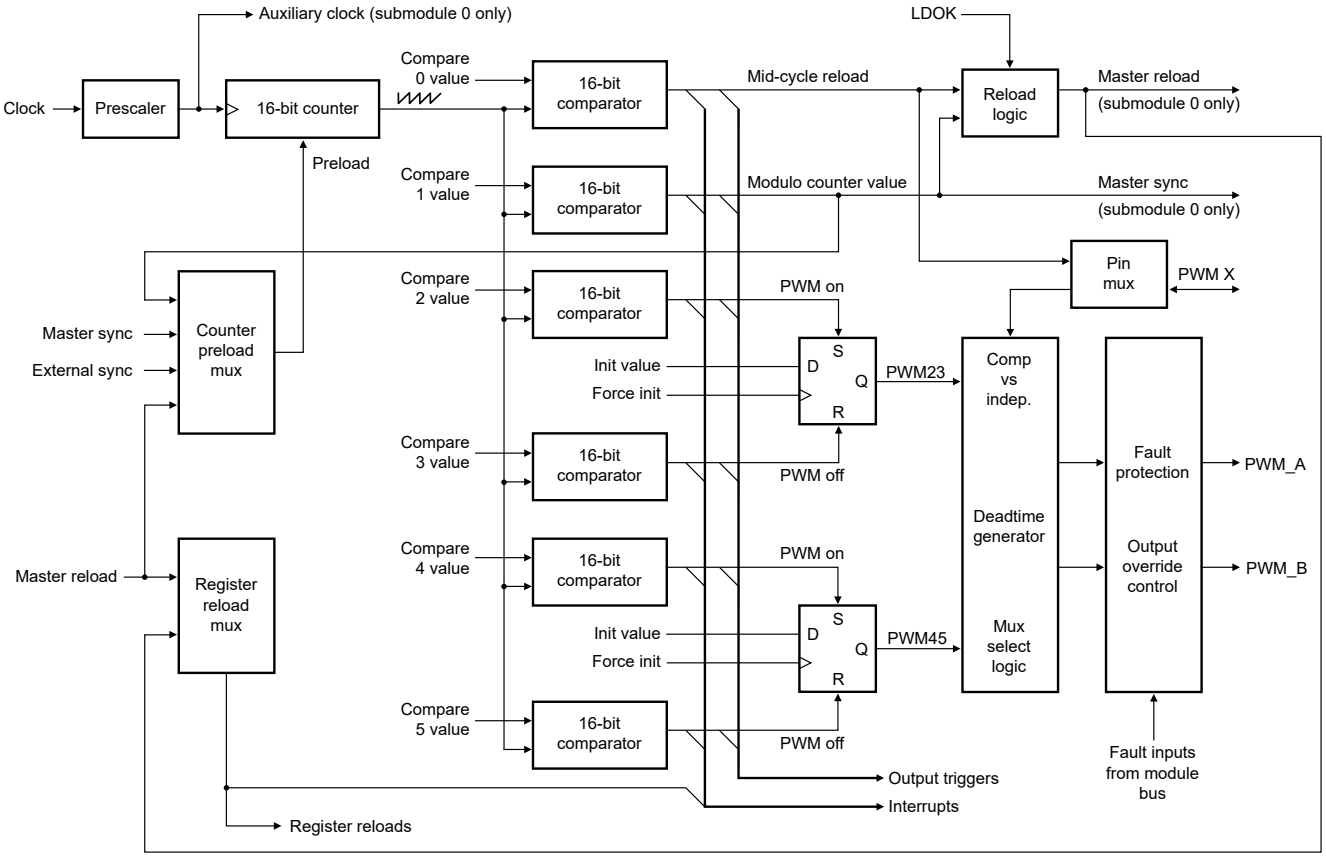

Figure 238. PWM submodule

56.3.2 PWM operation

This section provides information about how eFlexPWM operates and how to control that operation. It is followed by sections that explain how to use eFlexPWM to produce different kinds of PWM pulses for particular use cases.

56.3.2.1 PWM operation overview

eFlexPWM has a number of submodules. Each submodule generates three pulse outputs: PWM*n*_A, PWM*n*_B, and PWM*n*_X. You can control several characteristics of submodule operation, including:

- submodule counter frequency
- length of the submodule PWM period:
  - initial count value
  - counter reload timing
- turn-on and turn-off timing of the outputs to create PWM pulses within that PWM period
- polarity of the outputs

You can use the PWM outputs from a single submodule individually or in combination to create different types of output pulses, and you can align those pulses within the PWM period. You can also coordinate the outputs from more than one submodule. eFlexPWM provides additional controls to meet the requirements for many PWM use cases.

56.3.2.2 Pulse width and alignment

Unlike other PWMs that may use only a single value to specify the pulse width, eFlexPWM controls pulse width using two timing values: the turn-on edge and the turn-off edge. This double-action edge generation provides precise control of the pulse width as well as the alignment of the pulse within the PWM period for each PWM output. As a result, eFlexPWM does not need to support separate PWM alignment modes because pulse width and alignment are inherent in the turn-on and turn-off edge values.

See Pulse characteristics and Pulse control for information about the pulse timing values for all of the PWM output edges.

56.3.2.3 Pulse characteristics

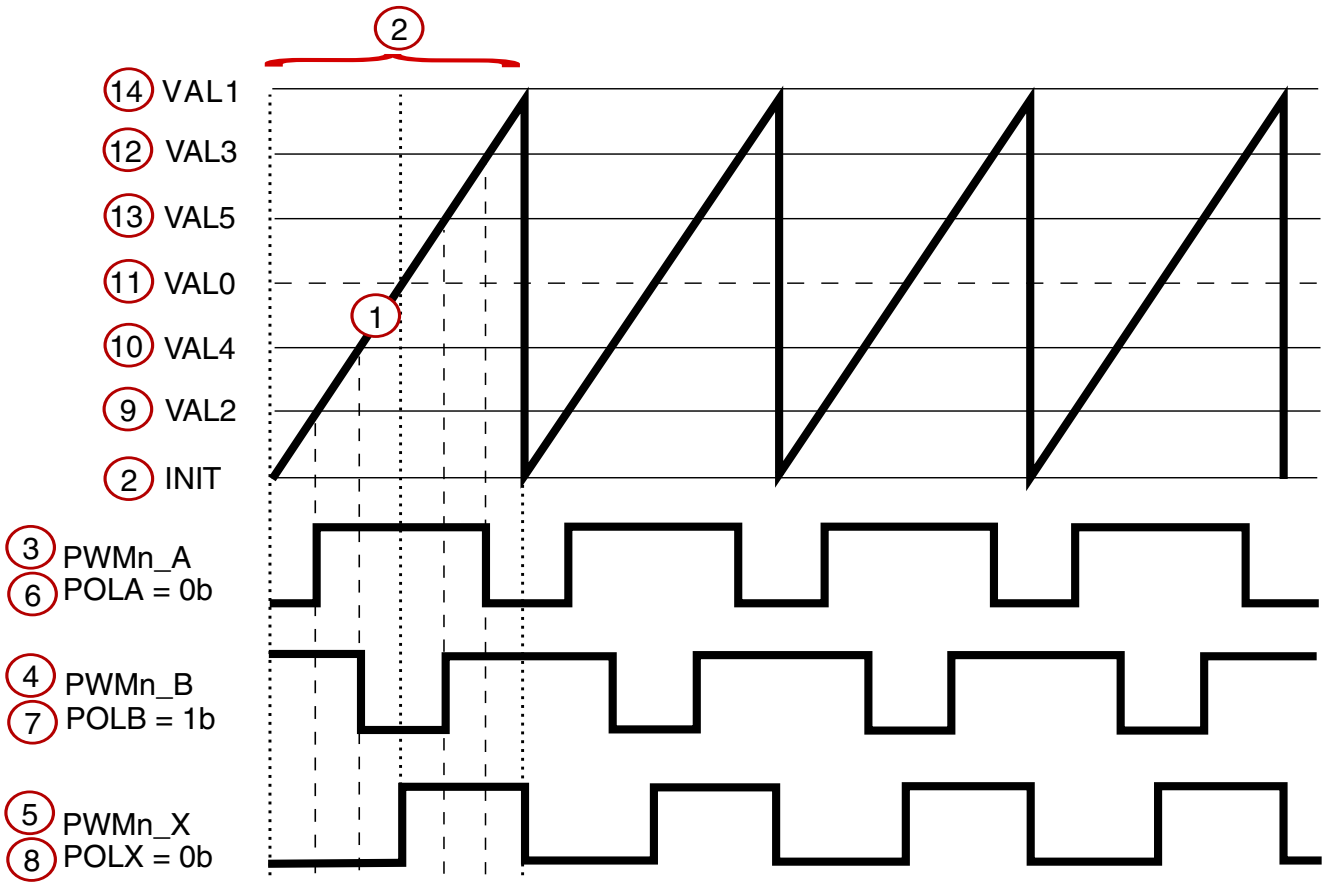

Figure 239. Pulse characteristics

56.3.2.4 Pulse control

The following table describes several characteristics of submodule operation. Call outs refer to Pulse characteristics:

Call out	Characteristic	Description	Control or read
—	Source clock	The clock signal source that drives the PWM submodule counter and prescaler circuit.	SM*n*_CTRL2[CLK_SEL]
—	Prescaler	A clock divider that interacts with the source clock to determine the number of source clock cycles represented by each increment of the submodule counter. The range is 1 to 128, by powers of 2.	SM*n*_CTRL[PRSC]
1	Submodule counter	A countup rollover timer that the PWM generator compares against timing values to determine when to turn on or turn off the PWM outputs or to reload the submodule counter. The counter represents source clock cycles divided by the prescaler. In other words, if the prescaler is Divide by 16, the counter increments one unit every 16 clock cycles.	SM*n*_CNT[CNT]
2	PWM period	The length in counter units from the start of counting to reload of the counter. To begin operation, the submodule loads the initial count into the counter. The counter increments every *n* clock cycles, where *n* is the prescaler factor, until the counter matches the reload point, specified in timing value 1, at which time the submodule reloads the counter. Therefore, the PWM period is (VAL1 – INIT) counter units long. **NOTE** Other events can cause reinitialization of the counter before the end of the full PWM period.	SM*n*_INIT[INIT], SM*n*_VAL1[VAL1]
3 4 5	PWM outputs	The submodule outputs that provide the PWM pulses. Each submodule can generate up to three pulse outputs. These outputs have the following characteristics: • Polarity • Turn-on edge • Turn-off edge	
6 7 8	PWM output polarity	The polarity (active low or active high) of the output signal when it is asserted or turned on.	SM*n*_OCTRL[POLA] SM*n*_OCTRL[POLB] SM*n*_OCTRL[POLX]
9 10 11	PWM output turn-on edge	The assertion of the PWM output at the beginning of a pulse, controlled by the relevant timing value.	PWM*n*_A: SM*n*_VAL2[VAL2] PWM*n*_B: SM*n*_VAL4[VAL4] PWM*n*_X: SM*n*_VAL0[VAL0]
12	PWM output turn-off edge	The deassertion of the PWM output at the end of a pulse, controlled by the relevant timing value.	PWM*n*_A: SM*n*_VAL3[VAL3]

Table continues on the next page...

Table continued from the previous page...

Call out	Characteristic	Description	Control or read
13 14			PWM*n*_B: SM*n*_VAL5[VAL5] PWM*n*_X: SM*n*_VAL1[VAL1]

56.3.2.5 Rollover submodule counter

When generating different kinds of pulse alignments, some applications benefit from aligning or timing the pulse edges relative to the mid-point of the PWM period. To make the timing value calculations for such alignments easier, each submodule uses a rollover countup timer, called the submodule counter, for period and pulse timing.

When the submodule counter (SM*n*_CNT[CNT]) reaches FFFFh, it rolls over to 0000h and continues counting up from there. You can take advantage of this rollover to treat the counter value as a two's-complement signed integer. If you specify a two's-complement negative value for the Initial Count (SM*n*_INIT[INIT]) and a positive value for the counter reload point, timing value 1 (SM*n*_VAL1[VAL1]), you can view the counter as counting from the negative initial value up through zero and on to the positive reload value.

Therefore, to create a PWM period whose mid-point occurs when the submodule counter is 0000h, specify a positive integer value for timing value 1 and the two's-complement negative of that value for the initial count.

56.3.2.6 Rollover submodule counter example

The following diagram illustrates initializing the submodule counter with the two's complement negative of the reload timing value, resulting in a PWM period mid-point of 0000h. As is typical, the half-period timing value, timing value 0 (SM*n*_VAL0[VAL0])VAL0, is set to match the period mid-point.

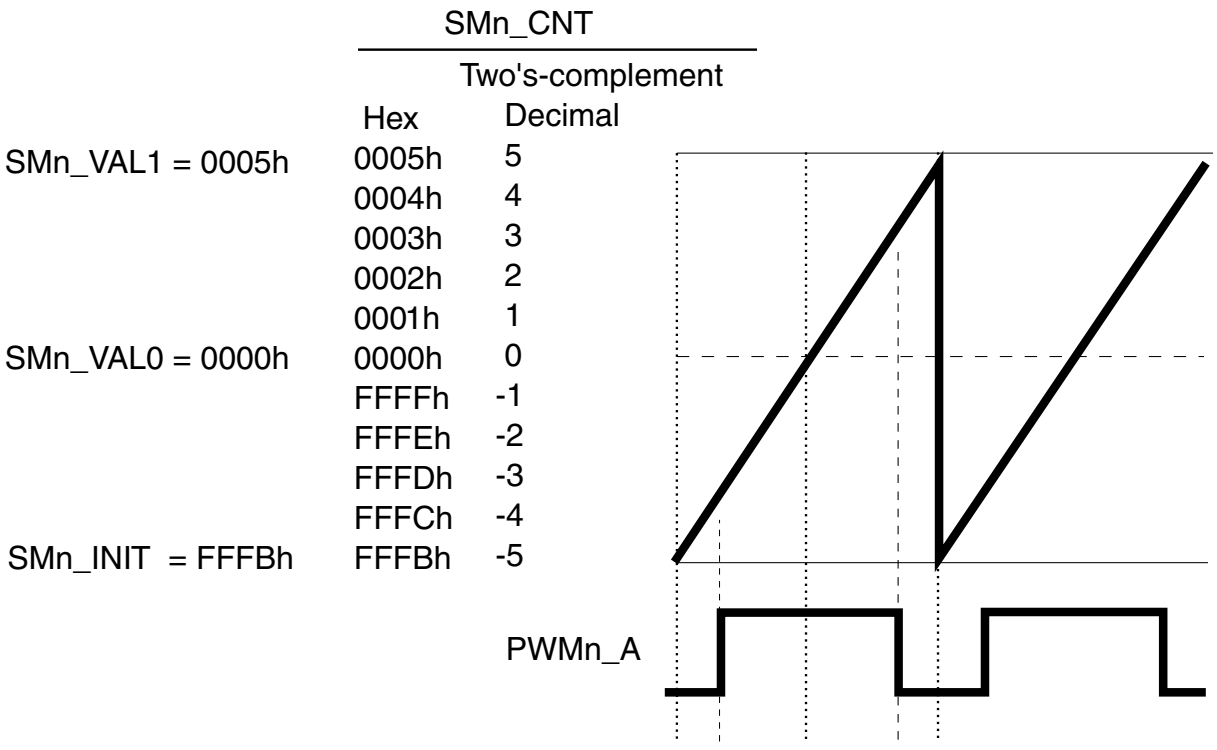

Figure 240. Rollover submodule counter example

56.3.3 Modes of operation

The following table describes eFlexPWM behavior during the listed operational modes.

CAUTION

Be careful when using eFlexPWM in Stop, Wait, and Debug operating modes.

Some applications (such as three-phase AC motors) require regular software updates for proper operation. Failure to provide regular software updates could result in destroying the hardware setup.

To accommodate this situation, eFlexPWM places PWM outputs in their inactive states in stop mode, and you can optionally placed them in inactive states in wait and debug (EOnCE) modes. Upon exiting these modes, eFlexPWM reactivates PWM outputs that were active before entering the mode.

Table 266. PMW restrictions is operational modes

Mode	Description
Stop	PWM outputs are inactive.
Wait	PWM outputs are driven or inactive depending on run in wait enable (SM*n*_CTRL2[WAITEN]).
Debug	PWM outputs are driven or inactive depending on run in debug enable (SM*n*_CTRL2[DBGEN]).

56.3.4 High-level PWM generation output diagram

This figure is a high-level block diagram of PWM generation output.

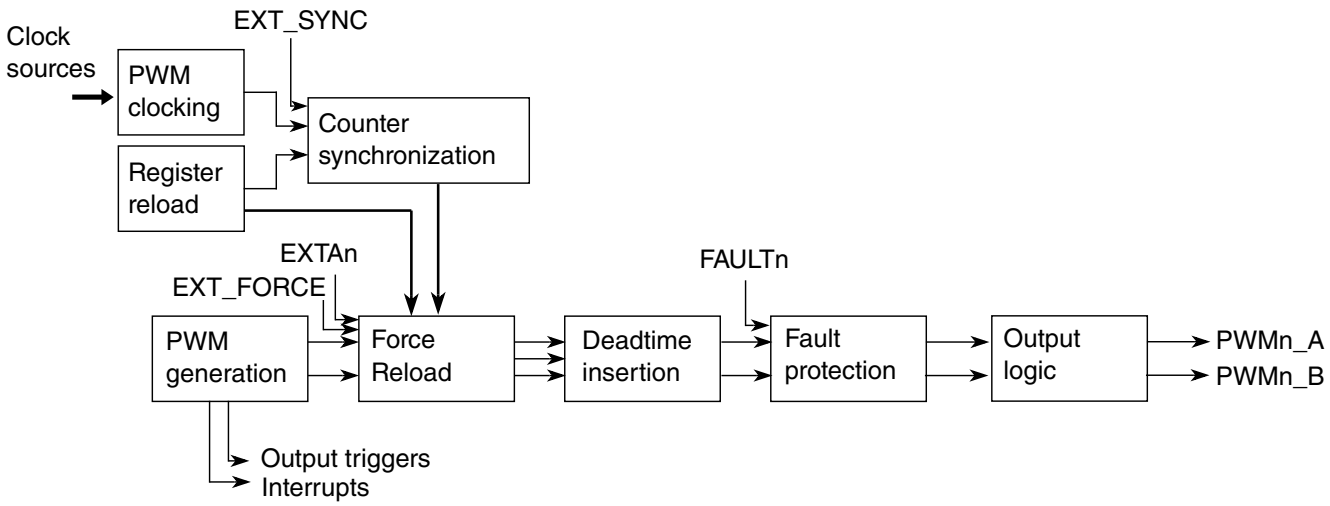

Figure 241. High-level PWM generation output

56.3.5 Register reload

The register reload logic determines when the submodule transfers the contents of the outer set of registers for all double-buffered register pairs to the inner set of registers. You schedule register reload to occur after a certain number of PWM opportunities. Specify the number of PWM opportunities between each reload with load frequency (SM*n*_CTRL[LDFQ]).

If you enable half-period reload (SM*n*_CTRL[HALF]), every half-period point, defined by timing value 0 (SM*n*_VAL0[VAL0]) counts as one PWM opportunity.

If you enable full-period reload (SM*n*_CTRL[FULL]), every PWM period, defined by timing value 1 (SM*n*_VAL1[VAL1]), counts as a PWM opportunity.

NOTE

The half-period point does not necessarily occur at the precise half-way point in the PWM period.

As illustrated in Register reload logic, you can use the reload signal from submodule 0 as a master reload signal to trigger reload in the other submodules.

56.3.5.1 Register reload logic

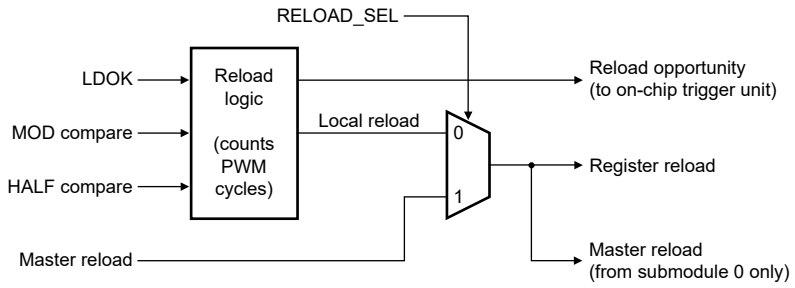

Figure 242. Register reload logic

56.3.6 Counter synchronization

56.3.6.1 Counter synchronization overview

As illustrated in Submodule counter synchronization logic, the 16-bit submodule counter, which counts up from the initial count (SM*n*_INIT[INIT]) to timing value 1 (SM*n*_VAL1[VAL1]), begins counting when it receives the initialization signal. You can select one of four sources for the counter initialization signal (SM*n*_CTRL2[INIT_SEL]) and force reload (assertion of the FORCE_OUT signal) can also start the counter.

56.3.6.1.1 Submodule counter synchronization logic

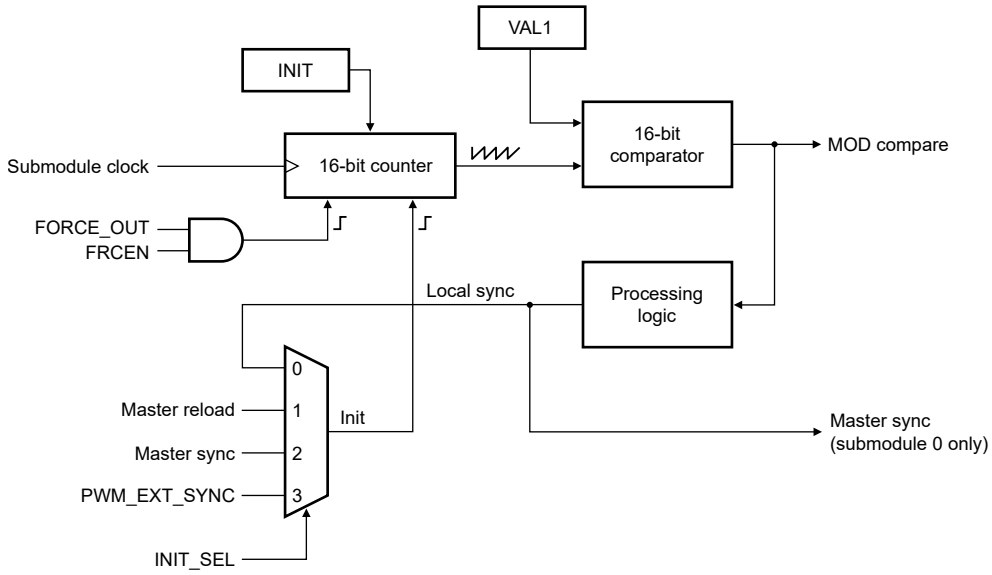

Figure 243. Submodule counter synchronization logic

56.3.6.2 Local synchronization

When you select Local Sync as the initialization source, the submodule operates at the local level. When the counter equals the submodule's own timing value 1 (SM*n*_VAL1[VAL1]), the submodule reloads the counter with the initial count (SM*n*_INIT[INIT]) and asserts local sync, which starts the counter. Therefore, SM*n*_INIT[INIT] and VAL1 determine the PWM period (and therefore the PWM frequency of the submodule).

56.3.6.3 Master synchronization

The master sync signal is the local sync output from submodule 0. When you select master sync as the initialization source for a submodule other than submodule 0, you lock the PWM period of that submodule to the submodule 0 PWM period.

56.3.6.4 External synchronization

When you select the external initialization source, the submodule counter begins counting on assertion of the PWM_EXT_SYNC signal.

PWM_EXT_SYNC can originate on- or off-chip, depending on the system architecture. See eFlexPWM chip configuration information for the source of PWM_EXT_SYNC.

56.3.6.5 Master reload synchronization

The master reload signal is the register reload output from submodule 0. When you select master reload as the initialization source for a submodule other than submodule 0, you lock the submodule PWM period to the register reload frequency of submodule 0. If the master reload frequency is controlled by the sampling frequency of a software control algorithm, the submodule PWM period equals the sampling period. As a result, you can use this submodule's counter to generate output compares or output triggers over the entire sampling period, which may consist of several submodule 0 PWM periods.

56.3.6.6 Force reload synchronization

Each submodule counter has the FORCE_OUT signal as an optional initialization input. If you enable force reload (SM*n*_CTRL2[FRCEN]), assertion of FORCE_OUT starts the counter regardless of the selected initialization source. If you enable load okay (MCTRL[LDOK]), a forced initialization also causes a register reload.

56.3.6.7 Force reload and commutated applications

Force reload (assertion of the FORCE_OUT signal) supports commutated applications. When you commutate the PWM outputs on an inverter that controls a brushless DC motor, you must restart the PWM period at the beginning of the commutation interval. This action effectively resynchronizes the PWM waveform to the commutation timing. Otherwise, the average voltage applied to a motor winding integrated over the entire commutation interval is a function of the timing between the asynchronous commutation event with respect to the PWM period. The effect is more critical at higher motor speeds where each commutation interval may consist of only a few PWM periods. If the counter is not started at the start of each commutation interval, the result is an oscillation caused by the beating between the PWM frequency and the commutation frequency.

56.3.7 PWM generation

56.3.7.1 PWM generation overview

Each submodule can generate three PWM outputs, two primary PWM signals and the local sync signal, with complete software control over the rising and falling edges of each signal.

For each output, the submodule compares a pair of timing values (SM*n*VALm) against the submodule counter to control the output pulse, one timing value to control the turn-on edge and one to control the turn-off edge.

You can also specify the polarity of each output as not inverted or inverted (SM*n*_OCTRL[POL*m*]). An inverted signal goes low on the rising-edge timing value and high on the falling-edge value.

PWM generation logic illustrates PWM generation in each submodule.

56.3.7.1.1 PWM generation logic

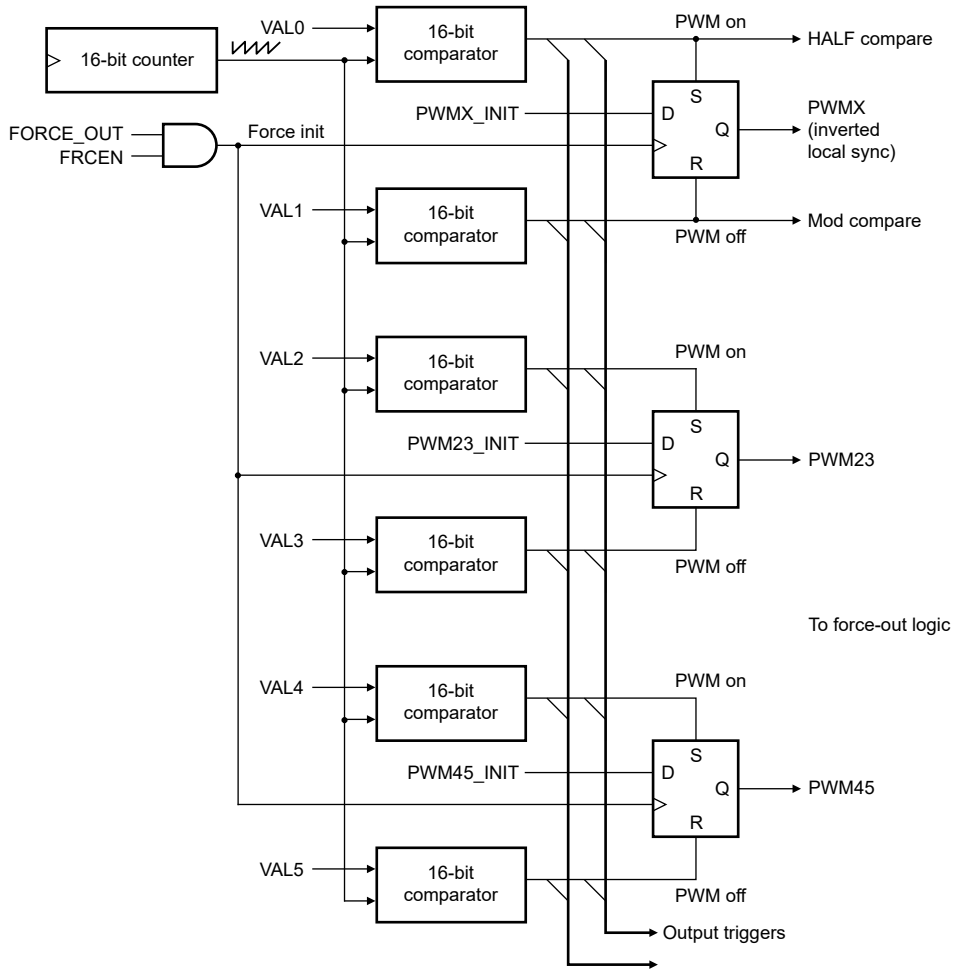

Figure 244. PWM generation logic

56.3.7.2 Comparator and flip-flop operation

The 16-bit comparators shown in PWM generation logic are "equal to" comparators. In other words, when the submodule counter value is equal to the specified timing value, the comparator asserts its signal to the output flip-flop. In addition, if both the set and reset are asserted to the flip-flop, the flip-flop output goes to 0.

56.3.7.3 Local synchronization and reload

The submodule generates its local sync signal in the same way as the other PWM output signals. The comparator for timing value 0 causes a falling edge of the local sync signal and the comparator for timing value 1 generates a rising edge. The timing value 1 comparator also drives the reload logic to generate the full-period reload indicator.

56.3.7.4 Local sync as auxiliary PWM output (PWM*n*_X)

Timing value 1 (SM*n*_VAL1[VAL1]) determines the modulus counter value that triggers reinitialization of the counter and asserts local sync. Timing value 0 (SM*n*_VAL0[VAL0]) determines the half-period point and deasserts local sync. Therefore, if you don't need VAL0 and VAL1 to trigger register reload or counter initialization, you can use them to modulate the duty cycle of the local sync signal, as long as you are not using it for another purpose, such as input capture or deadtime distortion correction. The submodule outputs the inversion of local sync as the auxiliary PWM signal (PWM*n*_X).

For example, if VAL0, the half-period point, is half of VAL1 minus the initial count (SM*n*_INIT[INIT]), then the half-period reload pulse occurs exactly halfway through the PWM period and the local sync has a 50% duty cycle.

56.3.7.5 Optional uses for PWM outputs

If you do not need a set of edge timing values for PWM output, you can use it for other functions such as output-compare events, generating output triggers, or generating interrupts at timed intervals.

56.3.8 Output-compare events

56.3.8.1 Output-compare events overview

You can use individual timing values to create programmed buffered output-compare events with no additional hardware required. Specifically, you can:

- Drive an output high
- Drive an output low
- Generate an interrupt
- Generate an output trigger

56.3.8.2 Program an output-compare event

To generate an output-compare event, program one of a pair of timing values with the counter value for the moment in the PWM period you want the event to occur, and program the other timing value in the pair with a value outside the modulus range of the submodule counter. Depending on which timing value you use, the output-compare event (the moment the submodule counter equals the timing value) causes the output of the flip-flop to either set or reset.

56.3.8.3 Output-compare high

For example, if you want an output compare on the PWM*n*_A output to set it high, program timing value 2 (SM*n*_VAL2[VAL2]) with the counter value for when you want the output compare to take place. However, to prevent the D flip-flop from being reset again after the compare occurs, program timing value 3 (SM*n*_VAL3[VAL3]) to a value outside of the modulus range of the counter, that is, a value greater than timing value 1 (SM*n*_VAL1[VAL1])and lower than the initial count (SM*n*_INIT[INIT]). Therefore, a compare that would reset the D flip-flop output never occurs.

56.3.8.4 Output-compare low

Conversely, if you want an output compare on the PWM*n*_A output to set it low, program timing value 3 (SM*n*_VAL3[VAL3]) with the desired count value and program timing value 2 (SM*n*_VAL2[VAL2]) with a value outside the counter modulus range.

56.3.8.5 Output-compare interrupt

Regardless of whether you program an output high or low compare event, you can generate an interrupt when the event occurs.

To generate an interrupt request to the CPU on the occurrence of an output-compare event, enable the appropriate Compare Interrupt (SM*n*_INTEN[CMPIE]). After compare interrupt occurs, you must clear the corresponding compare flag (SM*n*_STS[CMPF]).

56.3.8.6 Output-compare trigger

As with interrupts generated by output-compare events, you can also generate an output trigger when the event occurs.

To generate an output trigger on the occurrence of an output-compare event, enable output trigger for the specific output signal (SM*n*_TCTRL[OUT_TRIG_EN]).

56.3.9 Force reload

56.3.9.1 Force reload overview

Before the PWM signals reach the output pins, they pass through force reload logic that can switch all submodule outputs simultaneously. You select a source trigger from one of several external signals or local events. The selected trigger causes assertion of the internal FORCE_OUT signal, which in turn causes all PWM generator parameters to be reloaded synchronously (simultaneously) from the register buffers.

56.3.9.2 Force reload sources

For each submodule, you can select one of the following sources (SM*n*_CTRL2[FORCE_SEL]) to assert force reload (FORCE_OUT):

- Local force (SM*n*_CTRL2[FORCE], for all submodules)
- Master force (the local Force from submodule 0)
- Local reload (for all submodules)
- Master reload (local reload from submodule 0)
- Local sync
- Master sync (local sync from submodule 0)
- External force signal (EXT_FORCE)
- External sync signal (EXT_SYNC)

56.3.9.3 Local control

Use the local signals when you do not need to synchronize the submodule output signals with another submodule. However, to change the output signals on more than one submodule at the same time, use the Master or external signal sources.

56.3.9.4 Master control

You can use the submodule 0 local force signal (SM*n*_CTRL2[FORCE]) as the master force signal to other submodules. This ability allows submodule 0 to force the synchronous update of some or all submodule outputs.

56.3.9.5 External control

The external signals can come from on- or off-chip, depending on the chip architecture. See eFlexPWM chip-configuration information for the source of the external force and sync signals. A common technique is to connect EXT_FORCE to an input signal from an external timer channel configured for output compare, or from digital comparators from an ADC.

56.3.9.6 Force reload logic

As illustrated in Force reload logic, submodule 0 PWM23 and PWM45 control select (DTSRCSEL[SM*n*SEL23] and DTSRCSEL[SM*n*SEL45]) each select from one of the following signals to be supplied to the submodule outputs:

- Internal PWM signal (PWM23 or PWM45)
- Inversion of PWM23 or PWM45
- Software-controlled output (SWCOUT[SM*n*OUT23] or SWCOUT[SM*n*OUT45])
- Alternate PWM control signal (PWMn_EXTA or PWMn_EXTB)

56.3.9.6.1 Force reload logic

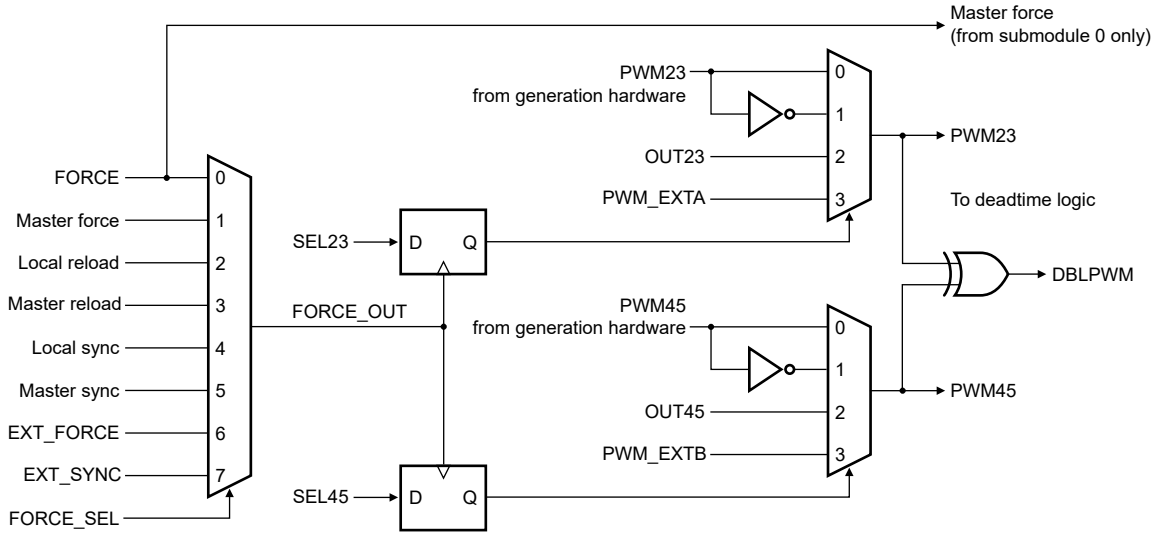

Figure 245. Force reload logic

56.3.9.7 Synchronous output switching with force reload

Force reload is useful in commutated motor applications. You can configure the next commutation state ahead of time and then immediately switch the outputs when the appropriate condition or time is reached. Not only do all the changes occur synchronously on all configured submodule outputs, they occur immediately after the trigger event thus eliminating any interrupt latency.

56.3.9.8 Typical force reload application

In a typical application, you set up the desired states of the output pins in preparation for the next force reload event (FORCE_OUT assertion). When the force reload event occurs, the submodule loads all of the PWM generation registers from the buffers and the outputs switch simultaneously. This signal switching occurs upstream from the deadtime generator to ensure that any abrupt changes do not violate deadtime on the power stage when operating the submodule in complementary mode.

56.3.9.9 Sensorless BLDC commutation with force reload

Sensorless BLDC commutation using force reload illustrates a popular application that benefits from force reload. On a brushless DC motor, you often want to spin the motor without the need of hall-effect sensor feedback. Instead, you monitor the back EMF of the motor phases and use that information to schedule the next commutation event.

In the diagram, the top waveforms are a simplified representation of these back EMF signals. Output-compare events, represented by the long vertical lines, are scheduled based on the zero crossings of the back-EMF waveforms. You configure the PWM submodule ahead of time with the next state of the PWM pins to anticipate the compare event. When it happens, the output compare of the timer asserts the FORCE_OUT signal, which immediately switches the PWM pins to the next commutation state with no software latency.

56.3.9.9.1 Sensorless BLDC commutation using force reload

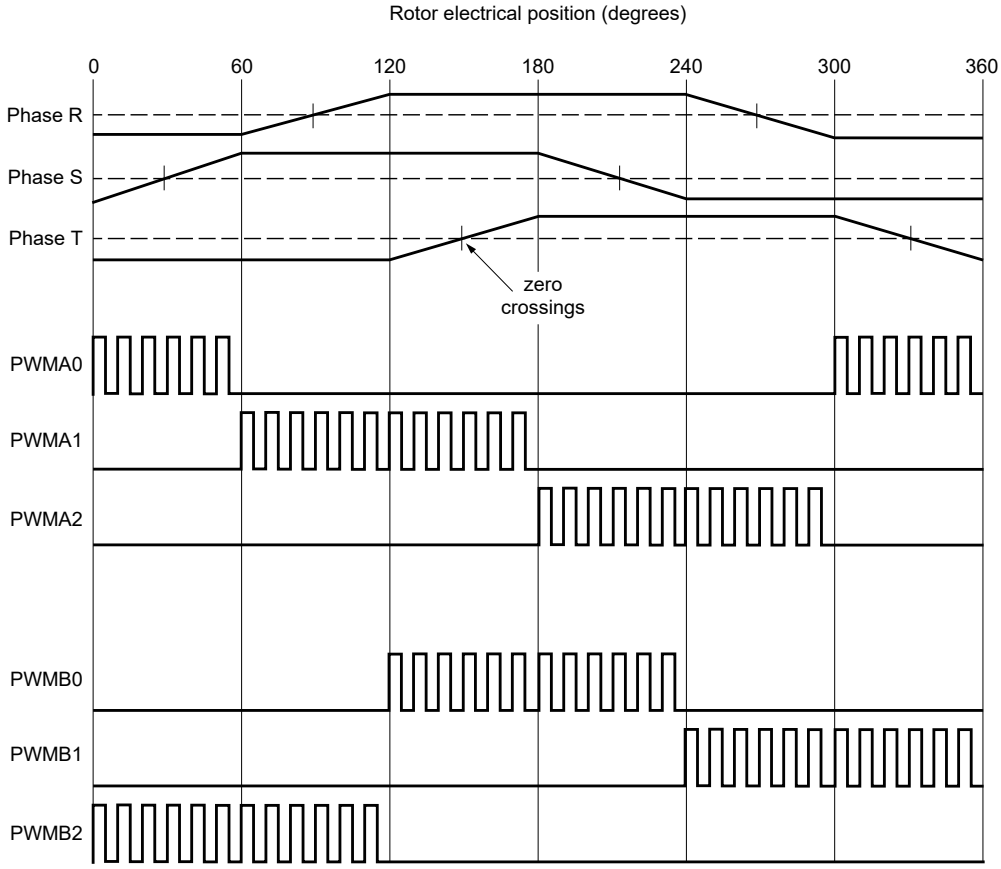

Figure 246. Sensorless BLDC commutation using force reload

56.3.10 Independent or complementary channel operation

You can operate the primary submodule PWM outputs (PWMn_A and PWMn_B) as independent channels or as a complementary pair.

56.3.10.1 Independent operation

In independent operation (write 1 to SM*n*_CTRL2[INDEP]), you control each PWM output with its own timing value pair: PWM23 controlled by timing value 2 (VAL2) and 3 (VAL3); PWM45 controlled by timing value 4 (VAL4) and 5 (VAL5).

56.3.10.2 Complementary operation

In complementary operation (write 0 to SM*n*_CTRL2[INDEP]), when one of the pair of signals is high, the other is low. Complementary channel pair illustrates the pairing of signals. You select whether to connect the internally generated PWM23 or PWM45 signal to the output pins (MCTRL[IPOL]).

Complementary channel operation can drive the top and bottom transistors in a motor drive circuit, as illustrated in Typical 3-phase AC motor drive.

Complementary operation allows the use of the deadtime insertion feature. See Deadtime insertion.

56.3.10.2.1 Complementary channel pair

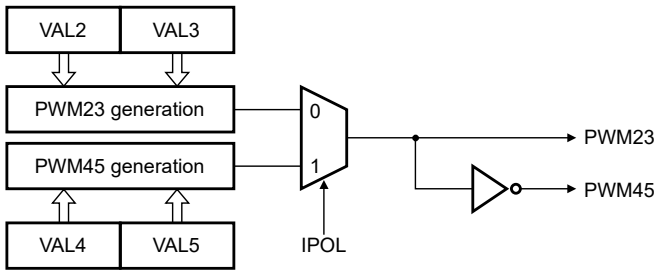

Figure 247. Complementary channel pair

56.3.10.2.2 Typical 3-phase AC motor drive

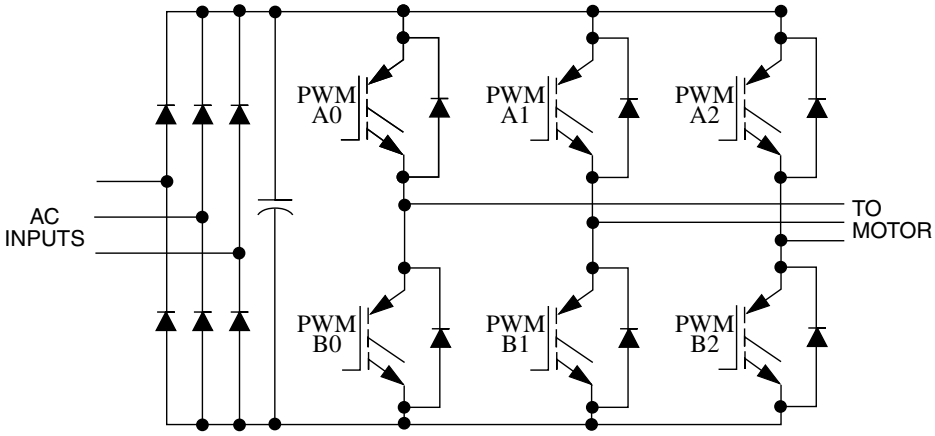

Figure 248. Typical 3-phase AC motor drive

56.3.11 Deadtime insertion

56.3.11.1 Deadtime insertion overview

Deadtime insertion allows you to create non-overlapping complementary PWM outputs. In complementary mode, when one PWM output (or channel) is active, the other PWM output is inactive, and vice versa. Deadtime insertion logic illustrates the deadtime insertion logic.

56.3.11.1.1 Deadtime insertion logic

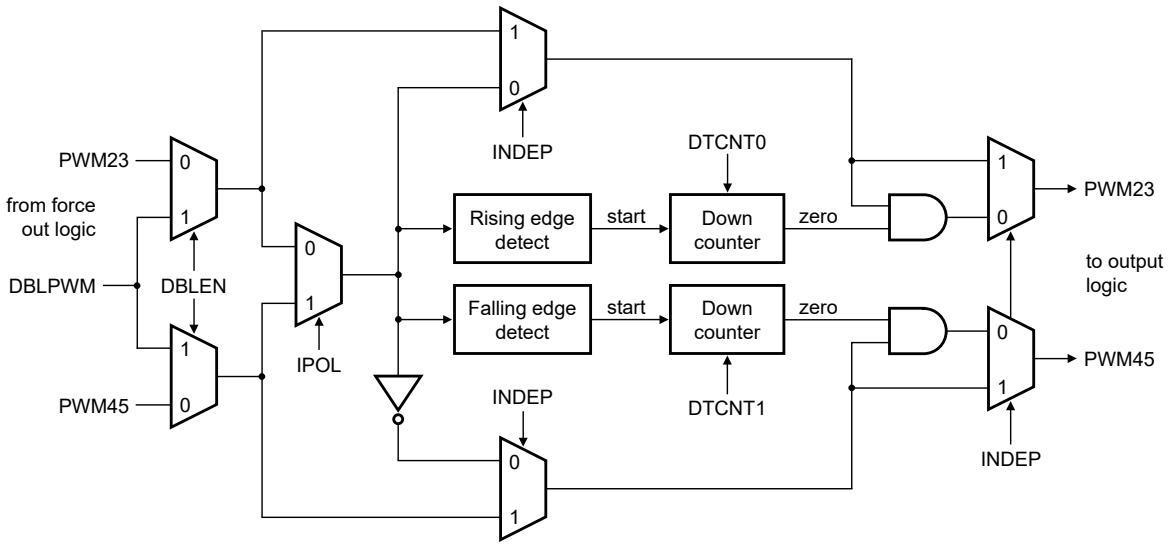

Figure 249. Deadtime insertion logic

56.3.11.2 Deadtime insertion operation

When you specify a deadtime delay (SM*n*_DTCNT0[DTCNT0] or SM*n*_DTCNT1[DTCNT1]), the deadtime generator inserts an activation delay of the specified number of IPBus clock cycles into the edge timing of the PWM outputs. Every time an input to the deadtime generator changes state, the generator inserts the deadtime delay before passing that signal on. Deadtime forces both PWM outputs of the pair to the inactive state, as illustrated in Deadtime insertion timing.

56.3.11.2.1 Deadtime insertion timing

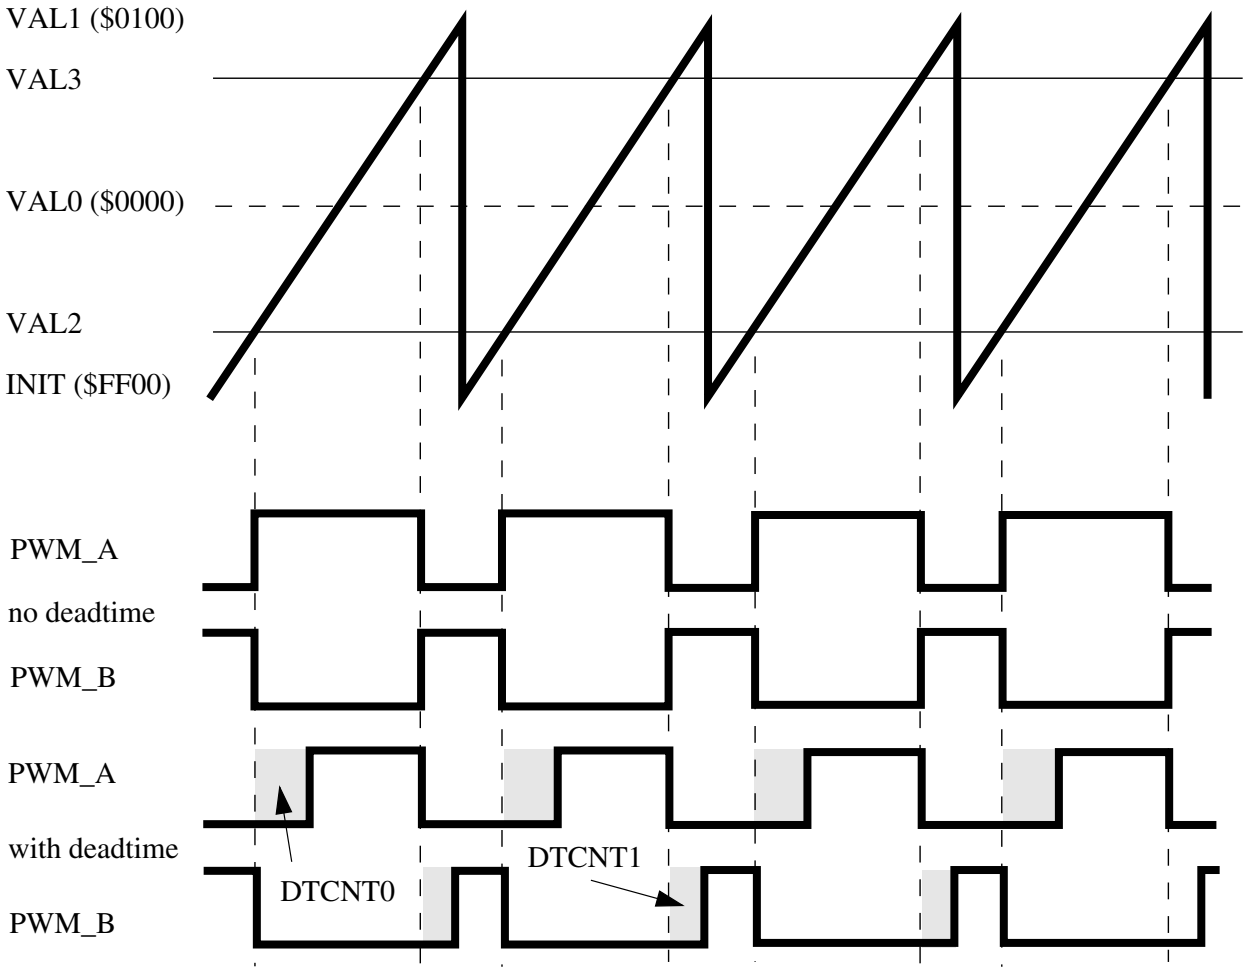

Figure 250. Deadtime insertion timing

56.3.11.3 Deadtime use case: avoiding overlapping conduction

A typical application for complementary channel operation is to use the pair of PWM outputs to drive a top/bottom transistor pair. However, when driving a top/bottom transistor pair, the transistor's characteristics may result in its switch-off time being longer than its switch-on time. This difference can cause overlapping conducting intervals which short circuit the DC bus and possibly damage the transistors.

To avoid overlapping conducting intervals, you must insert deadtime in the switching period.

56.3.11.4 Output voltage distortion resulting from deadtime insertion

When you connect a complementary pair of PWM outputs to an inverter to drive an inductive load, either the top or the bottom transistor controls the output voltage. you must insert a deadtime delay to avoid overlapping conducting intervals and the resulting DC bus short circuits. Deadtime drives both signals inactive and therefore turns both transistors off. With both transistors off, the output voltage is determined by the current load status, which in turn causes the waveform on the inverter output to have a different duty cycle than what appears on the output pins of the PWM module. This condition introduces distortion in the output voltage applied to the load.

See Deadtime distortion. On AC induction motors running open-loop, the distortion typically manifests itself as poor low-speed performance, such as torque ripple and rough operation.

During deadtime, load inductance distorts the output voltage by keeping current flowing through the diodes. This deadtime current flow creates a load voltage that varies with current direction. With a positive current flow, the load voltage during deadtime equals the bottom supply, putting the top transistor in control. With a negative current flow, the load voltage during deadtime equals the top supply, putting the bottom transistor in control.

56.3.11.4.1 Deadtime distortion

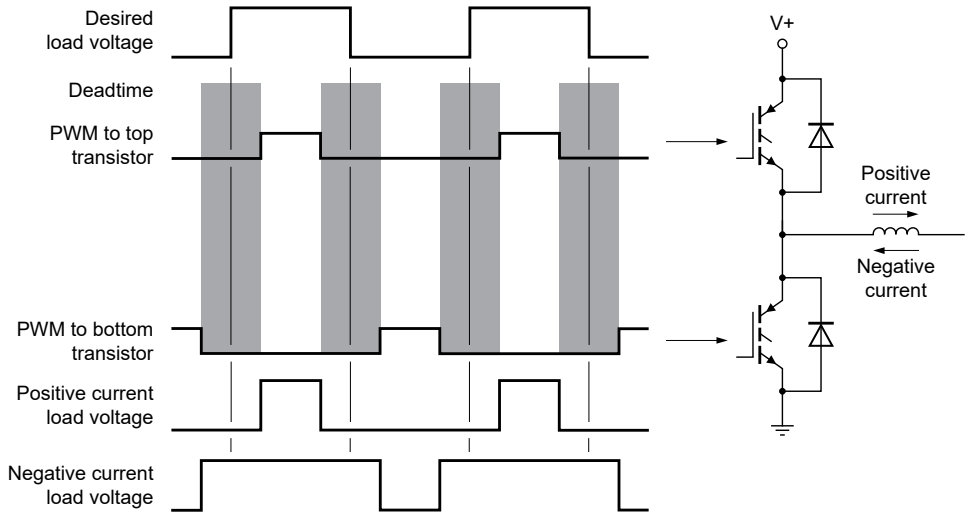

Figure 251. Deadtime distortion

56.3.11.5 Correcting deadtime-induced voltage distortion

One method for correcting deadtime-induced voltage distortion is to add or subtract a correction factor to or from the PWM timing values.

Remember that the original PWM pulse widths were shortened by deadtime insertion, and the averaged sinusoidal output is less than the desired value. However, inserting deadtime creates a distortion in the motor current waveform. This distortion is aggravated by dissimilar turn-on and turn-off delays of each of the transistors. By giving the submodule information about which transistor is in control at a given time, you can correct the distortion.

For a typical circuit in complementary channel operation, only one of the transistors control the output voltage at any given time, depending on the direction of the motor inverter current for that pair, as shown in Deadtime distortion. To correct the distortion, you must add one of two different factors to the appropriate timing value, depending on whether the top or bottom transistor controls the output voltage. Therefore, you must calculate both compensated timing values before writing them to the timing value registers.

Either the timing value 2-3 pair (SM*n*_VAL2[VAL2] and SM*n*_VAL3[VAL3]) or the Timing Value 4-5 pair (SM*n*_VAL4[VAL4] and SM*n*_VAL5[VAL5]) controls the pulse width at any given time. For a given pair, whether the pair is active depends on either:

- PWM*n*_X
- Corresponding bit of submodule current polarity (MCTRL[IPOL])

To correct deadtime distortion, decrease or increase the appropriate timing value:

- In edge-aligned operation, decrease or increase the timing value by a correction value equal to the deadtime.
- In center-aligned operation, decrease or increase the timing value by a correction value equal to one-half the deadtime.

56.3.11.6 Manual correction of output distortion

To detect the current deadtime status, poll deadtime (SM*n*_CTRL[DT]). The submodule samples the voltage of PWM*n*_X twice in each PWM period, at the end of each inserted deadtime, and stores the values in the deadtime bits. These bits provide a

timing marker to indicate when to toggle between PWM value registers. You poll the bits to know when to set current polarity (MCTRL[IPOL]) to switch between the timing value 2-3 (VAL2 and VAL3) and timing value 4-5 (VAL4 and VAL5) pairs.

56.3.11.7 Best time for switching between timing value pairs

If current is large and flowing out of the complementary circuit, both deadtime flip-flops latch low (SM*n*_CTRL[DT] equals 00b), during deadtime periods. If current is large and flowing into the complementary circuit, both flip-flops latch high (SM*n*_CTRL[DT] equals 11b) during deadtime periods. See Current status sense scheme for deadtime correction.

However, under low current, the output voltage of the complementary circuit during deadtime is somewhere between the high and low levels. The current cannot freewheel through the opposition anti-body diode, regardless of polarity, giving additional distortion when the current crosses zero. In this situation, the sampled Deadtime bits (SM*n*_CTRL[DT]) read 10b. Therefore, the best time to change one PWM value register to another is just before the current zero crossing. See Output voltage waveforms.

56.3.11.7.1 Current status sense scheme for deadtime correction

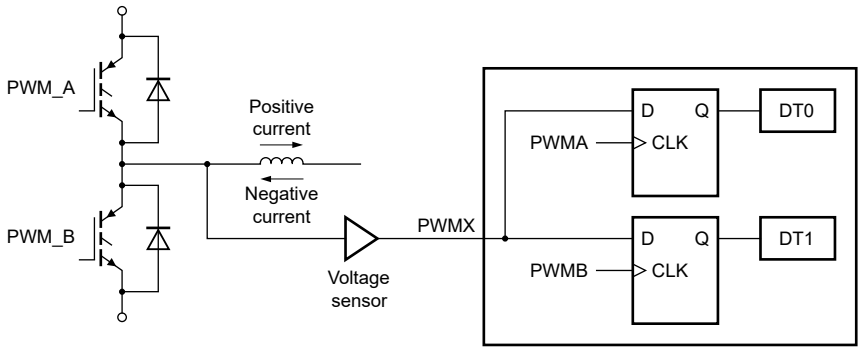

Figure 252. Current status sense scheme for deadtime correction

56.3.11.7.2 Output voltage waveforms

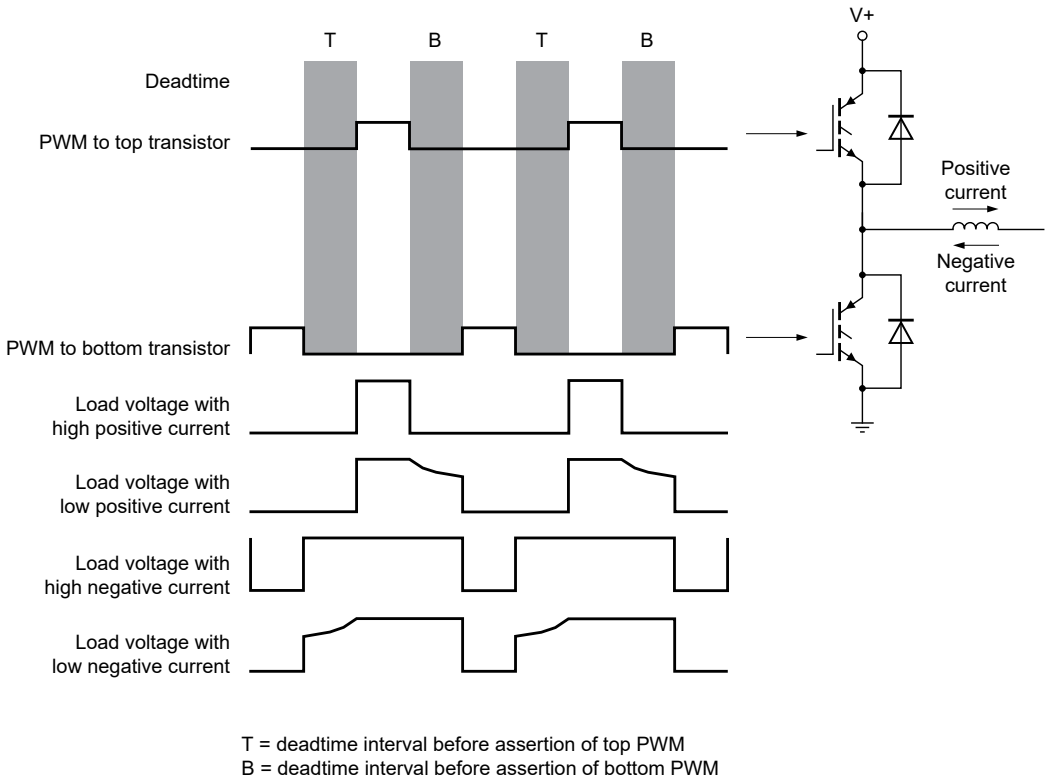

Figure 253. Output voltage waveforms

56.3.12 Fractional delay

56.3.12.1 Fractional delay overview

Fractional delay provides greater resolution for rising or falling edge timing, or for the PWM period width, than is possible with the submodule counter value by itself. When you enable fractional cycle placement (SM*n*_FRCTRL[FRAC*mm*_EN]), the submodule adds the fractional value to the corresponding timing value. See Fractional delay control.

56.3.12.2 Fractional delay control

Table 267. Fractional delay control

Output	Timing event	Enable fractional delay	Timing value	Fractional value
—	PWM period	SM*n*_FRCTRL[FRAC1_EN]	VAL1	SM*n*_FRACVAL1[FRACVAL1]
PWM*n*_A	Turn-on edge	SM*n*_FRCTRL[FRAC23_EN]	VAL2	SM*n*_FRACVAL2[FRACVAL2]
PWM*n*_A	Turn-off edge	SM*n*_FRCTRL[FRAC23_EN]	VAL3	SM*n*_FRACVAL3[FRACVAL3]
PWM*n*_B	Turn-on edge	SM*n*_FRCTRL[FRAC45_EN]	VAL4	SM*n*_FRACVAL4[FRACVAL4]

Table continues on the next page...

Table 267. Fractional delay control (continued)

Output	Timing event	Enable fractional delay	Timing value	Fractional value
PWM*n*_B	Turn-off edge	SM*n*_FRCTRL[FRAC45_EN]	VAL5	SM*n*_FRACVAL5[FRACVAL5]

56.3.12.3 Fractional delay behavior with NanoEdge placement

NanoEdge placement allows you to control every timing event—the rising or falling edge of a PWM pulse or the PWM period—to a granularity of 1/32 of the input clock cycle for every occurrence of the timing event.

To use NanoEdge placement:

1. Select no divider (000b) for the prescaler (SM*n*_CTRL[PRSC]).
2. Power up the submodule NanoEdge placer (SM*n*_FRCTRL[FRAC_PU])
3. Enable fractional placement for the selected timing events (SM*n*_FRCTRL[FRAC23_EN]).
4. Specify a fractional value for the corresponding event.

   The fractional value specifies how many 32nds of an input clock cycle to add to the timing value for the corresponding timing event.

Example 1: To cause the rising edge of the PWM*n*_A output to occur at 12.25 clock cycles into the PWM period, specify Ch (12d) for Timing Value 2 (VAL2) and 8h (8/32 equals .25) for fractional value 2 (SM*n*_FRACVAL2[FRACVAL2]).

Example 2: To cause the PWM period to be 20.5 clock cycles long, specify 14h (20d) for timing value 1 (VAL1) and 10h (16/32 equals .5) for Fractional Value 1 (SM*n*_FRACVAL1[FRACVAL1]).

NOTE

Check the data sheet for this chip to determine the necessary clock frequency for proper NanoEdge operation. Submodules that do not support the NanoEdge placer have no clock frequency restrictions.

If all submodule NanoEdge placers are powered down (SM*n*_FRCTRL[FRAC_PU] is 0000b), eFlexPWM can operate at alternate clock frequencies.

56.3.12.4 Fractional delay behavior without NanoEdge placement

If NanoEdge is powered down (SM*n*_FRCTRL[FRAC_PU] is 0000b), fractional delay uses dithering to specify the average time for timing events—the rising or falling edge of a PWM pulse or the PWM period—to a granularity of 1/32 of a submodule counter unit. Dithering involves accumulating the specified fractional delay value until it equals a full submodule counter unit. When the accumulated delay equals a full counter unit, the submodule adds one count to the corresponding timing value for a single event and clears the accumulated delay. Over time, the dithered (periodic) addition of a counter unit causes the timing to average out to the specified timing value plus fractional delay.

Example: To generate a PWM period of 50.25 counts, specify 32h (50d) for timing value 1 (VAL1) and 8h (8/32 equals .25) for fractional value 1 (SM*n*_FRACVAL1[FRACVAL1]). The PWM period is 50 counts for three periods, then 51 counts for one period. In other words, the PWM period is 51 counts every fourth period, for an average over time of 50.25 counts.

56.3.13 Output logic

For maximum flexibility, each PWM output has individual fault disabling, polarity control, and output enable. Output logic illustrates the output logic of each submodule.

The PWM23 and PWM45 signals coming from the deadtime logic are positive true signals. In other words, a high level on one of these signals causes the corresponding transistor in the PWM inverter to be turned on. The voltage level required at the PWM output pin to turn the transistor on or off is a function of the logic between the pin and the transistor. Therefore, you must program the output polarity (SM*n*_OCTRL[POLA] and SM*n*_OCTRL[POLB]) before enabling the output pins. A fault condition can cause the PWM output to be tristated, forced to a logic 1, or forced to a logic 0, depending on the corresponding fault state (SM*n*_OCTRL[PWMAFS]).

56.3.13.1 Output logic

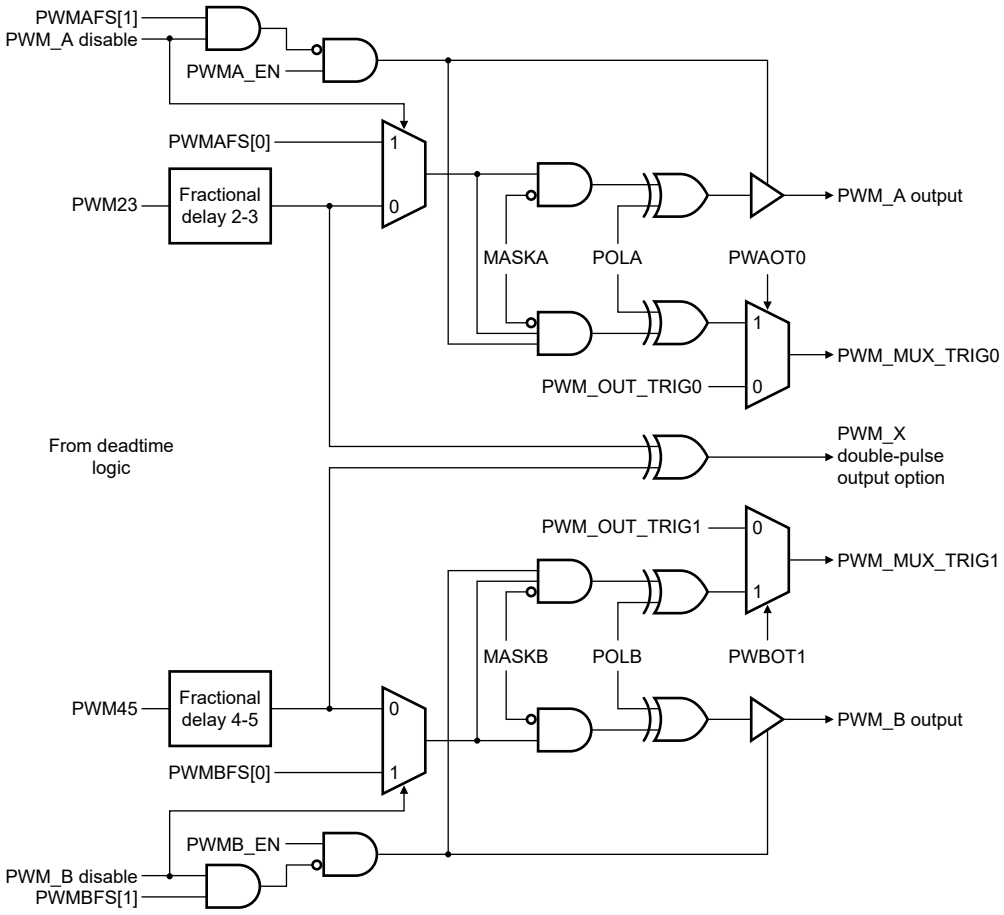

Figure 254. Output logic

56.3.14 Enhanced capture (E-Capture)

56.3.14.1 E-Capture overview

Each eFlexPWM submodule uses a counter and several timing value registers to generate the rising and falling edges of pulses on the PWM*n*_A, PWM*n*_B, PWM*n*_X signals. If you do not use one of these signals for PWM output, you can use that signal as an input to the Enhanced Capture (E-Capture) logic to detect and capture the rising and falling edges of pulses on a PWM input signal. You can use that information to measure the period or pulse width, count the number of edges, and trigger CPU Interrupt Requests (IRQs) or DMA read requests based on those edges.

See E-Capture logic and E-Capture capabilities.

56.3.14.1.1 E-Capture logic

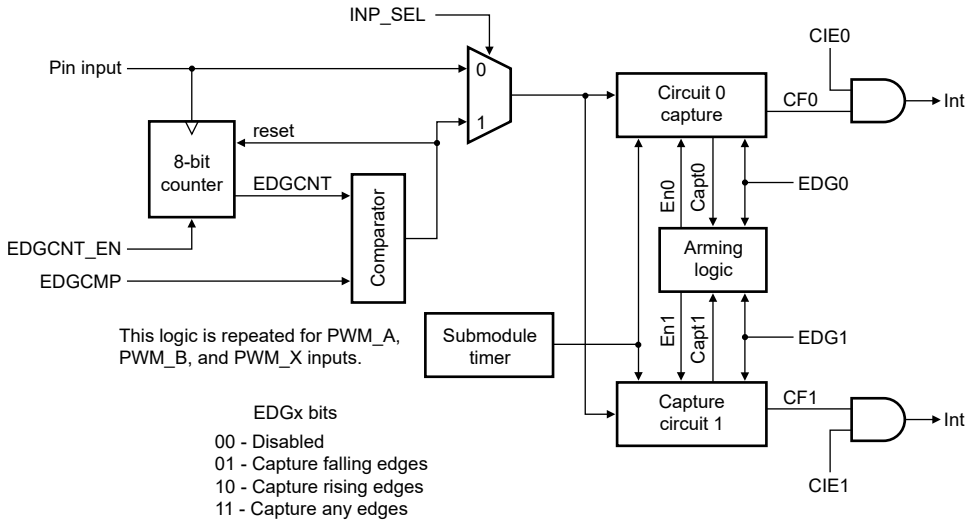

Figure 255. E-Capture logic

56.3.14.1.2 E-Capture capabilities

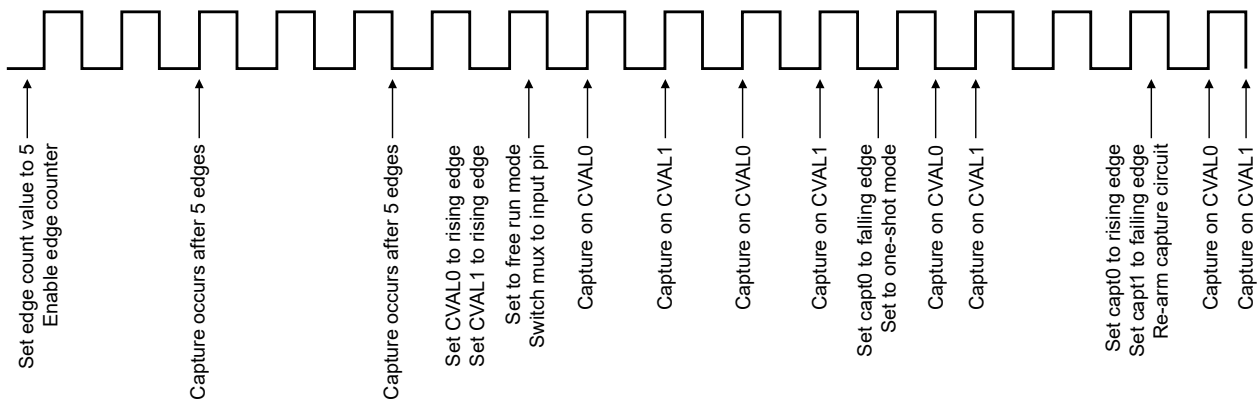

Figure 256. E-Capture capabilities

56.3.14.2 Capture circuits and input selection

As illustrated in E-Capture logic, you can route the raw input signal directly to a pair of capture circuits (SM*n*_CAPTCTRL*m*[INP_SEL*m*]). The capture circuits work singly or in tandem to capture sequential edges on the input signal. Each circuit can capture:

- Only rising edges
- Only falling edges
- Both rising and falling edges

To select which edges each capture circuit is to capture or to disable the circuit, use the edge fields (SM*n*_CAPTCTRL*m*[EDG*m*0] and SM*n*_CAPTCTRL*m*[EDG*m*1]).

By selecting the edges to be captured by each circuit, you can measure the PWM period (for example, from first rising edge to next rising edge) or pulse width (from rising edge to next falling edge) of an input signal.

56.3.14.3 Edge counter

Before the input signal reaches the capture circuits, you can route it through an 8-bit edge counter and specify a target count value. The counter increments on every edge of the input signal. When the target number of edges occur, the counter arms the capture circuits and resets. For example, if the target count value is five, the counter arms the capture circuits every five edges.

56.3.14.4 Enabling and arming edge capture

To capture edges on the input signal, you must enable one or both capture circuits (SM*n*_CAPTCTRL*m*[EDG*m*0] or SM*n*_CAPTCTRL*m*[EDG*m*1]) and arm the capture logic (SM*n*_CAPTCTRL*m*[ARM*m*]).

56.3.14.5 Edge capture action

When you enable and arm a capture circuit, it detects and captures the type of edge that you configure it to capture. The capture action saves the submodule counter value and the number of PWM periods (SM*n*_CVAL*m*CYC) and reloads the submodule counter with the initial count (SM*n*_INIT[INIT]).

56.3.14.5.1 One-shot capture operation

The pair of capture circuits supports one-shot or free-running (continuous) operation (SM*n*_CAPTCTRL*m*[ONESHOT*m*]).

In one-shot operation, the circuits capture one or two edges, depending on which capture circuits you enable.

If you enable only one capture circuit and arm the capture logic, the enabled circuit captures the next edge of the type it is configured to capture and then disarms.

If you enable both capture circuits and arm the capture logic, capture circuit 0 arms first. When it captures an edge, it becomes disarmed and arms capture circuit 1. When capture circuit 1 captures an edge, it also becomes disarmed.

After a one-shot capture operation occurs, you must re-arm the logic for another capture operation.

56.3.14.5.2 Enabling and arming edge capture

For free-running operation, you must enable both capture circuits, select free-running mode, and arm the capture logic. Capture circuit 0 becomes armed first. When it has captured an edge, it becomes disarmed and arms capture circuit 1. When capture circuit 1 captures an edge, it becomes disarmed and rearms circuit 0. In this way, the two circuits continue taking turns capturing edges until you disarm them.

56.3.14.6 Begin E-Capture process

To being capture operation:

1. Select the raw input signal or the edge-counter-and-compare output for capturing (SM*n*_CAPTCTRL*m*[INP_SEL*m*]).
2. On each capture circuit, disable the circuit or select which edges to capture (SM*n*_CAPTCTRL*m*[EDG*m*1] and SM*n*_CAPTCTRL*m*[EDG*m*0]).
3. To enable CPU interrupt requests, see Enable E-Capture CPU interrupt requests.
4. To enable DMA read requests, see Enable E-Capture DMA read requests.

NOTE

Do not enable both CPU interrupt requests and DMA read requests on the same capture circuit.

5. Select free-running or one-shot operation (SM*n*_CAPTCTRL*m*[ONESHOT*m*]).
6. Arm the input capture process (write 1 to SM*n*_CAPTCTRL*m*[ARM*m*]).

56.3.14.6.1 Enable E-Capture CPU interrupt requests

To trigger an interrupt request (IRQ) to the CPU on the occurrence of a capture event:

- Enable capture interrupt on the desired PWM signal and capture circuit (SM*n*_INTEN[CA1IE], SM*n*_INTEN[CA0IE], SM*n*_INTEN[CB1IE], SM*n*_INTEN[CB0IE], SM*n*_INTEN[CX1IE] or SM*n*_INTEN[CX0IE]).

When the associated capture FIFO (SM*n*_CAPTCTRL*m*[C*m*1CNT] or SM*n*_CAPTCTRL*m*[C*m*0CNT]) exceeds the capture FIFOs watermark (SM*n*_CAPTCTRL*m*[CF*m*WM]), the submodule sets the associated capture flag (SM*n*_STS[CFA1], SM*n*_STS[CFA0], SM*n*_STS[CFB1], SM*n*_STS[CFB0], SM*n*_STS[CFX1] or SM*n*_STS[CFX0]), which in turn triggers an IRQ to the CPU.

56.3.14.6.2 Enable E-Capture DMA read requests

To trigger a DMA read request on the occurrence of a capture event:

1. Specify the logic operation for FIFO watermark control (SM*n*_DMAEN[FAND]).

   The logic operation determines if exceeding any enabled FIFO watermark (OR operation) triggers the request, of if all enabled FIFO watermarks (AND operation) must be exceeded to trigger the request.

2. Select "exceeding a FIFO watermark" for the capture DMA enable source (SM*n*_DMAEN[CAPTDE]).
3. Enable FIFO DMA request for the required PWM signals and capture circuits (SM*n*_DMAEN[CA1DE], SM*n*_DMAEN[CA0DE], SM*n*_DMAEN[CB1DE], SM*n*_DMAEN[CB0DE], SM*n*_DMAEN[CX1DE] or SM*n*_DMAEN[CX0DE]).

When the capture FIFO word count (SM*n*_CAPTCTRL*m*[C*m*1CNT] or SM*n*_CAPTCTRL*m*[C*m*0CNT]) exceeds the capture FIFOs watermark (SM*n*_CAPTCTRL*m*[CF*m*WM]), the submodule sets the associated capture flag (SM*n*_STS[CFA1], SM*n*_STS[CFA0], SM*n*_STS[CFB1], SM*n*_STS[CFB0], SM*n*_STS[CFX1] or SM*n*_STS[CFX0]), which in turn triggers the DMA read request.

56.3.14.7 Measuring output period or pulse width

When you use a submodule for PWM generation, the submodule loads the submodule counter (SM*n*_CNT[CNT]) with the initial counter value (SM*n*_INIT[INIT]) and the counter counts up to timing value 1 (SM*n*_VAL1[VAL1]), the modulo value that specifies the PWM period. When the counter reaches VAL1, the submodule reloads the counter with INIT. Therefore, using this counter for input captures on one of the other outputs (for example, PWM*n*_X) has limited utility because it does not count through the full range of the 16-bit counter value.

However, the submodule counter modulus range is perfectly suited to measuring a signal that is synchronous to the PWM frequency. See E-Capture output pulse width measurement for an illustration. In this application the output of a PWM power stage is connected to the PWM*n*_X pin, which in turn is routed to the capture circuits for free-running captures. Specifically, capture circuit 0 (SM0_CVAL0[CAPTVAL0]) is capturing rising edges and capture circuit 1 (SM0_CVAL1[CAPTVAL1]) is capturing falling edges. Between the two circuits, they capture new pulse width data every PWM period. To calculate the pulse width, simply subtract CAPTVAL0 from CAPTVAL1.

This measurement is extremely helpful when performing dead-time distortion correction on a half-bridge circuit driving an inductive load. Also, you can measure system propagation delays by comparing these values to the timing value registers (SMnVALm) that control the PWM output.

56.3.14.7.1 E-Capture output pulse width measurement

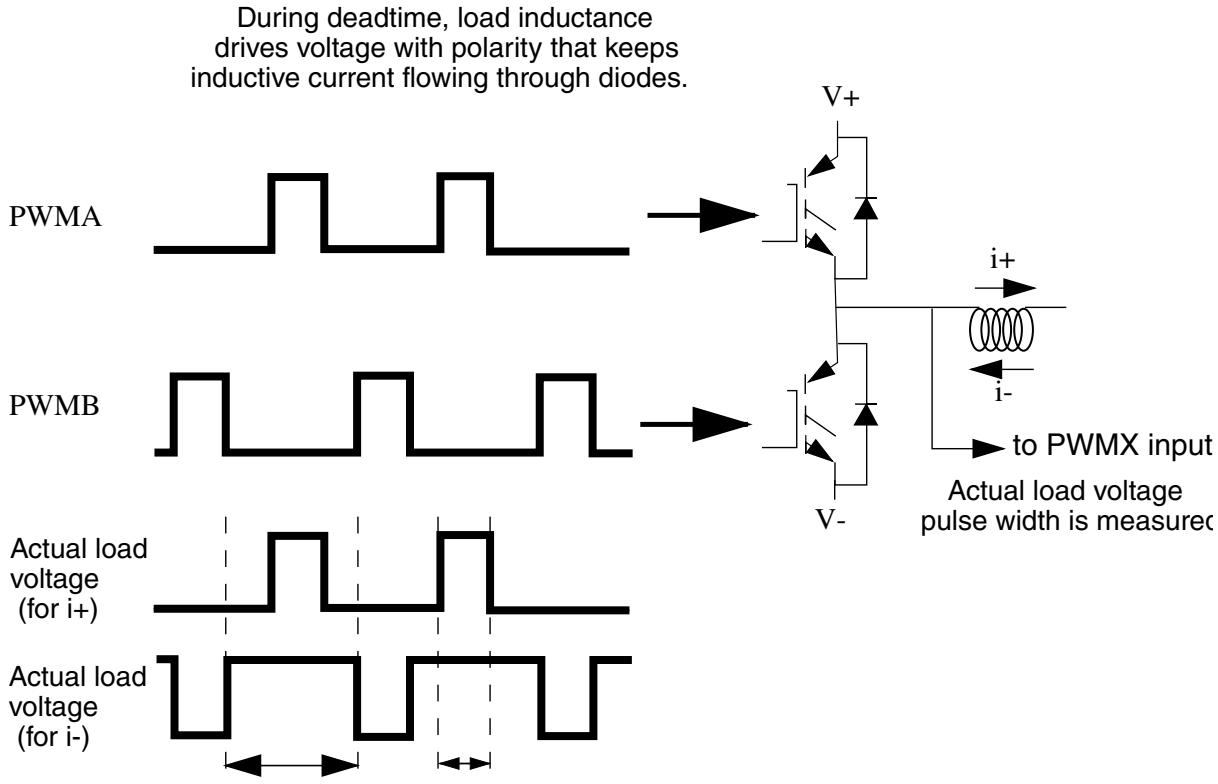

Figure 257. E-Capture output pulse width measurement

56.3.15 Fault protection

eFlexPWM provides a fault protection mechanism that can control any combination of PWM output pins based on fault signal inputs.

56.3.15.1 Fault protection overview

Either a logic 0 or a logic 1 on any FAULT*m* pin generates a fault, depending on the Fault Level (FP*n*_CTRL[FLVL]).

Use the Submodule Fault Channel Mapping (Submodule a Fault Disable Mapping (SM0_DISMAP0 - SM3_DISMAP0) or Submodule a Fault Disable Mapping (SM0_DISMAP1 - SM3_DISMAP1)) registers to map each FAULT*m* pin to any of the PWM outputs. Each field of Submodule a Fault Disable Mapping (SM0_DISMAP0 - SM3_DISMAP0) or Submodule a Fault Disable Mapping (SM0_DISMAP1 - SM3_DISMAP1) controls the mapping for a single PWM pin.

When the fault decoder detects a triggering level on one of the FAULT*m* pins, the PWM generator continues to run but the fault decoder forces the mapped output pins to logic 0, logic 1, or tristated, based on the PWM*n*_A, PWM*n*_B, and PWM*n*_X Fault States (SM*n*_OCTRL[PWMAFS]).

See Fault decoder for PWM*n*_A for an example of the fault disable logic.

Fault protection operates even when the PWM generator is not running; therefore, to prevent an interrupt when a PWM generator starts, you must clear any latched-in faults before starting the PWM generator.

56.3.15.1.1 Fault decoder for PWM*n*_A

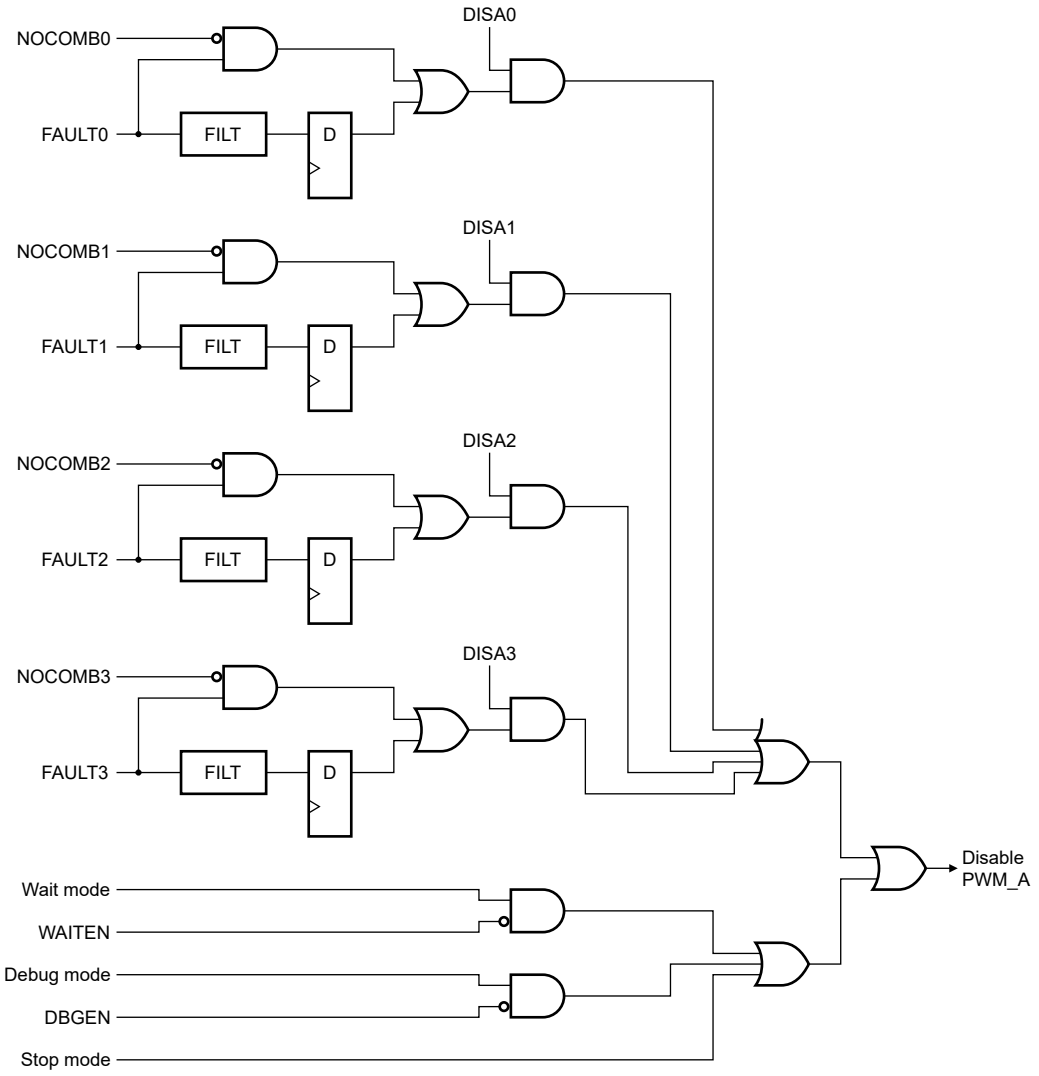

Figure 258. Fault decoder for PWMn_A

56.3.15.2 Fault pin filter

Each fault pin has a programmable filter with the following controls:

Control	Description	Register[field]
Fault level	The polarity (logic 0 or 1) of a FAULT*m* pin that triggers a fault	FP*n*_CTRL[FLVL]
Fault filter sampling period	The filter sampling period in clock cycles	FP*n*_FILT[FILT_PER] > 00h
Fault filter count	The number of consecutive samples minus three that must agree before the input filter accepts an input transition	FP*n*_FILT[FILT_CNT]
Filter bypass	The fault channel bypasses the input filter	FP*n*_FILT[FILT_CNT] = 00h

When eFlexPWM detects a logic 0 or logic 1 on the filtered FAULT*m* pin, depending on the corresponding Fault Level bit (FP*n*_CTRL[FLVL], it sets the corresponding Filtered Fault Pin (FP*n*_STS[FFPIN]) and Fault Flag (FP*n*_STS[FFLAG]). The Filtered Fault Pin bit remains set as long as the filtered FAULT*m* pin remains at the triggering level.

Clear the Fault Flag (FP*n*_STS[FFLAG]) by writing 1 to it.

If the corresponding Fault Interrupt Enable (FP*n*_CTRL[FIE]) is enabled, a Fault Flag generates a CPU interrupt request. The interrupt request remains latched until one of the following conditions occurs:

- You clear the corresponding Fault Flag (FP*n*_STS[FFLAG]) by writing 1 to it.
- You disable the corresponding Fault Interrupt (FP*n*_CTRL[FIE]) by writing 0 to it.
- The system resets.

NOTE

Even with the filter enabled, there is a combinational path from the FAULT*m* inputs to the PWM pins. This logic can also hold a fault condition in the event of loss of clock to eFlexPWM.

56.3.15.3 Automatic fault clearing

To automatically clear faults triggered by a FAULT*m* pin, enable automatic fault clearing (FP*n*_CTRL[FAUTO]) for that pin. Each bit of FAUTO corresponds to the like-numbered fault.

If you enable automatic fault clearing, eFlexPWM clears faults and re-enables any disabled PWM pins when the FAULT*m* pin returns to logic 1 and:

- If full period fault recovery (FP*n*_STS[FFULL]) is enabled, at the beginning of a full period.
- If half period fault recovery (FP*n*_STS[FHALF]) is enabled, at the beginning of a half period.

If you enable automatic fault clearing, clearing a fault flag (FP*n*_STS[FFLAG]) does not affect disabled PWM pins.

See Automatic fault clearing.

56.3.15.3.1 Automatic fault clearing

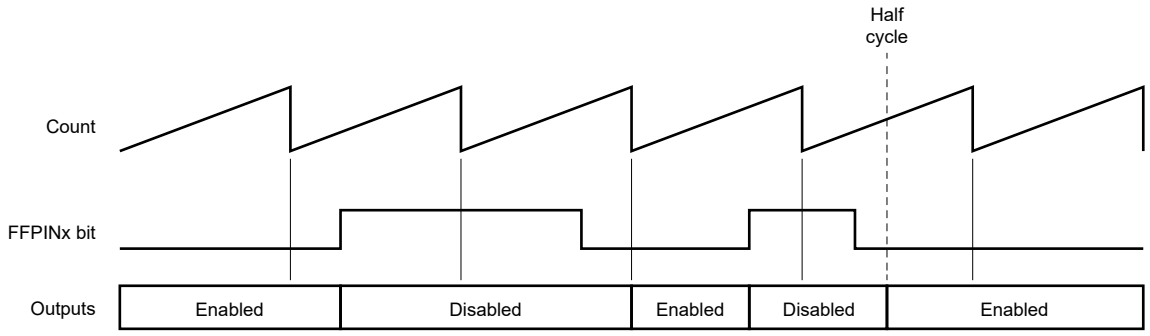

Figure 259. Automatic fault clearing

56.3.15.4 Manual fault clearing

To manually clear faults triggered by FAULT*m* pin, disable automatic fault clearing (FP*n*_CTRL[FAUTO]) for that pin. Each bit of FAUTO corresponds to the like-numbered fault.

If you disable automatic fault clearing, when eFlexPWM clears faults depends on the fault safety Mode (FP*n*_CTRL[FSAFE]):

- In Normal mode, eFlexPWM re-enables FAULT-disabled PWM pins:
  - When you clear the corresponding fault flag (FP*n*_STS[FFLAG])

— If the corresponding full period fault recovery bit (FP*n*_STS[FFULL]) is 1, at the start of a full period, regardless of the logic level detected by the filter at the FAULT*m* pin (see Manual fault clearing in normal mode).

— If the corresponding half period fault recovery bit (FP*n*_STS[FHALF]) is 1, at the start of a half period, regardless of the logic level detected by the filter at the FAULT*m* pin (see Manual fault clearing in normal mode).

- In Safe mode, eFlexPWM re-enables FAULT-disabled PWM pins:
  — When you clear the corresponding fault flag (FP*n*_STS[FFLAG])
  — The filter detects a logic zero on the FAULT*m* pin at the start of the next PWM full-period boundary and the corresponding full period fault recovery bit (FP*n*_STS[FFULL]) is 1 (see Manual fault clearing in safe mode).
  — The filter detects a logic zero on the FAULT*m* pin at the start of the next PWM half-period boundary and the corresponding half period fault recovery bit (FP*n*_STS[FHALF]) is 1 (see Manual fault clearing in safe mode).

NOTE

Fault protection also applies during software output control (DTSRCSEL[SM*n*SEL23] is 10b; DTSRCSEL[SM*n*SEL45] is 10b) or external signal control (DTSRCSEL[SM*n*SEL23] is 11b; DTSRCSEL[SM*n*SEL45] is 11b). Fault clearing still occurs at half-period boundaries while the PWM generator is enabled (MCTRL[RUN]). But SWCOUT[SM*n*OUT23] or SWCOUT[SM*n*OUT45] can control the PWM pins while the PWM generator is disabled. Therefore, fault clearing occurs at IPBus cycles while the PWM generator is off and at the start of PWM periods when the generator is running.

56.3.15.4.1 Manual fault clearing in normal mode

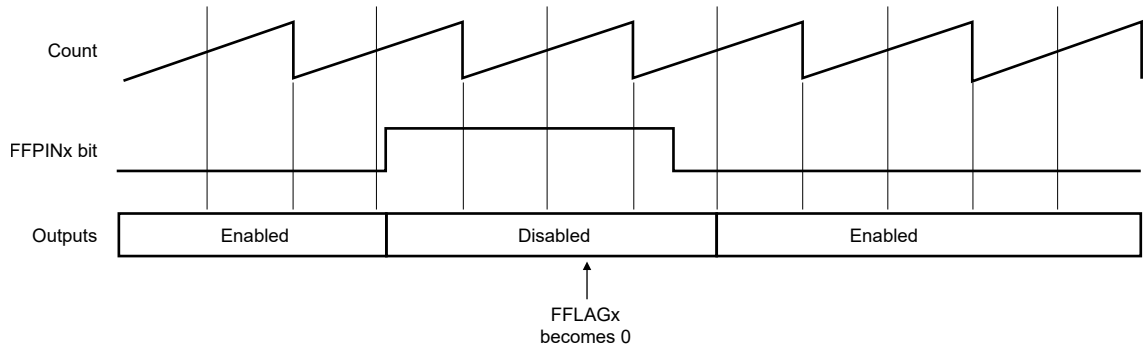

Figure 260. Manual fault clearing in normal mode

56.3.15.4.2 Manual fault clearing in safe mode

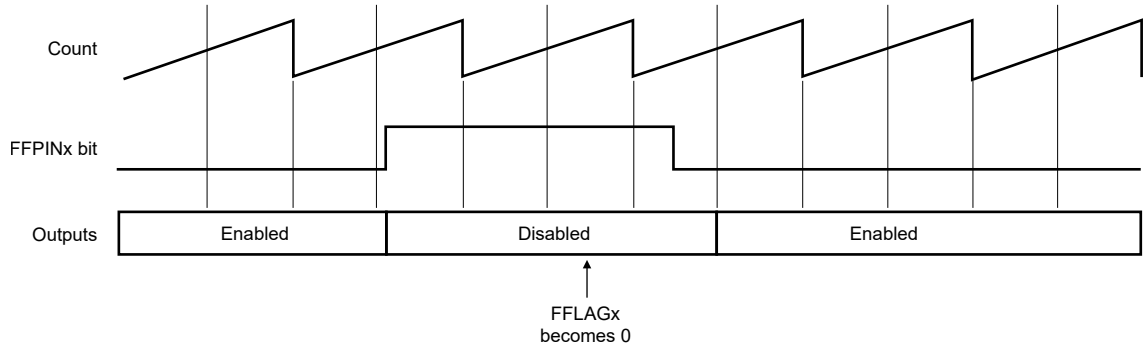

Figure 261. Manual fault clearing in safe mode

56.3.15.4.3 Fault testing

Use fault test (FP*n*_TST[FTEST]) to simulate a fault condition on each of the fault inputs within the fault channel.

56.3.16 PWM generator loading

56.3.16.1 Load PWM generator parameters

eFlexPWM provides a mechanism to update all of the PWM generator parameters for a specific submodule synchronously.

To load the submodule PWM generator parameters:

1. Select the submodule load mode (SM*n*_CTRL[LDMOD]).

   Load mode determines when to load the registers from their buffers, either on the next PWM reload or on load okay assertion.

2. If you select next PWM reload, you can also select half-period reload (HALF), full-period reload (FULL), or both.

   Half-period reload loads the buffered data into the PWM generator registers when the submodule counter matches timing value 0.

   Full-period reload loads the buffered data when the counter matches timing value 1.

3. Calculate and write values for the following submodule parameters to their respective buffered registers:
   - Prescaler divisor (SM*n*_CTRL[PRSC])
   - Initial count (SM*n*_INIT[INIT])
   - Timing values (VAL0, VAL1, VAL2, VAL3, VAL4, VAL5)
   - Fractional timing values (SM*n*_FRACVAL1[FRACVAL1], SM*n*_FRACVAL2[FRACVAL2], SM*n*_FRACVAL3[FRACVAL3], SM*n*_FRACVAL4[FRACVAL4], SM*n*_FRACVAL5[FRACVAL5])
4. Read the submodule load okay bit (MCTRL[LDOK]). If it is zero, proceed to step 5.
5. Write 1 to the submodule load okay bit (MCTRL[LDOK]).

   Bit 0 controls submodule 0 loading, bit 1 controls submodule 1, and so on.

   When you set the bit, eFlexPWM transfers the buffered values to the registers as specified by the load mode (see step 1).

56.3.16.2 Select load frequency

eFlexPWM allows you to specify the load frequency, or how often to load the PWM generator parameters. The frequency is specified in PWM opportunities.

You determine the PWM opportunities by enabling half-period reload (SM*n*_CTRL[HALF]), full-period reload (SM*n*_CTRL[FULL]), or both. If you enable only half-period reload, the PWM opportunity happens once every PWM period at the half-period, when the submodule counter matches timing value 0 (SM*n*_VAL0[VAL0]). See Half-period reload. Note that the half-period point is not necessarily half of the PWM period.

If you enable only full-period reload, the PWM opportunity happens once at the end of every PWM period, when the submodule counter matches Timing Value 1 (SM*n*_VAL1[VAL1]). See Full-period reload.

If you enable both half-period and full-period reload, you have two PWM opportunities per PWM period. See Full- and half-period reload.

When you have specified the PWM opportunities, you then specify the load frequency (SM*n*_CTRL[LDFQ]), anywhere from every opportunity to every 16 opportunities. When you specify the load frequency, it takes effect at the next PWM reload opportunity, regardless the state of load okay (MCTRL[LDOK]).

56.3.16.2.1 Half-period reload

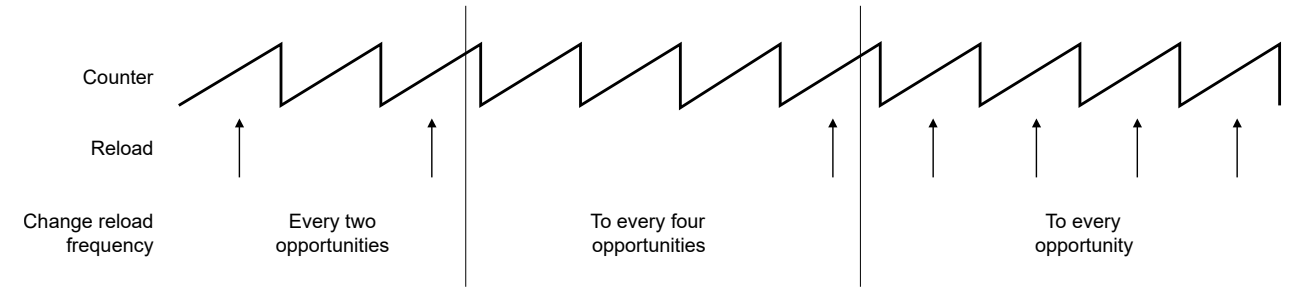

Figure 262. Half-period reload

56.3.16.2.2 Full-period reload

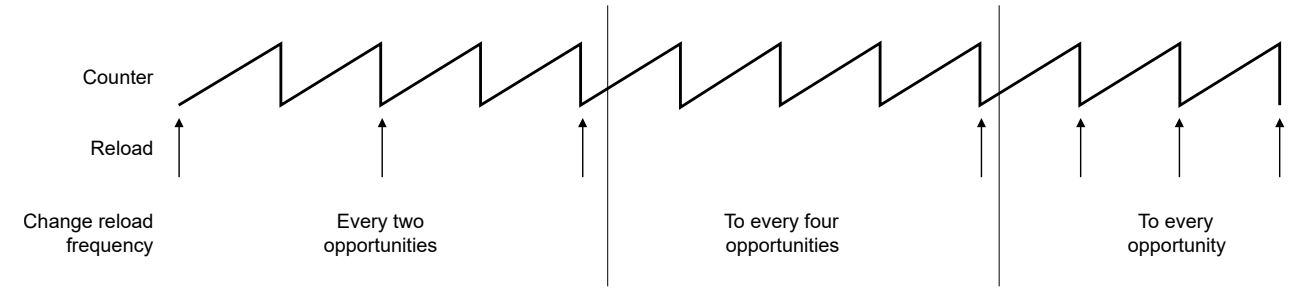

Figure 263. Full-period reload

56.3.16.2.3 Full- and half-period reload

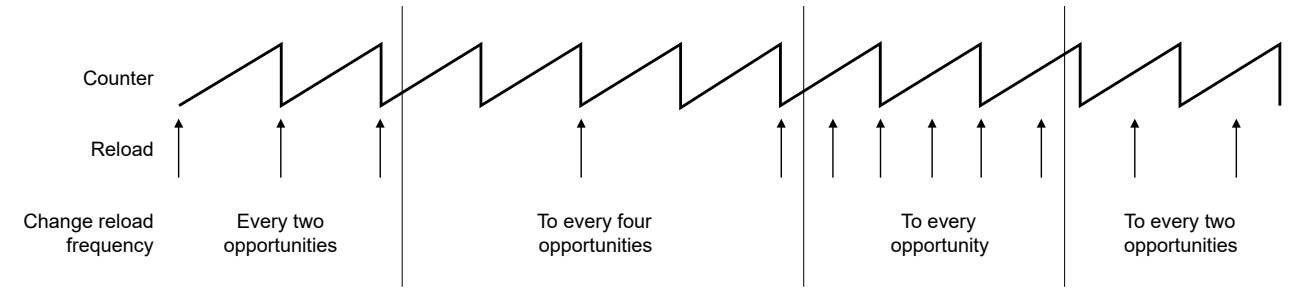

Figure 264. Full- and half-period reload

56.3.16.3 Reload interrupt requests

At every reload opportunity, the submodule sets the reload flag (SM*n*_STS[RF]), even if load okay (MCTRL[LDOK]) is zero. If reload interrupt enable (SM*n*_INTEN[RIE]) is enabled and the reload flag is set, the submodule sends reload interrupt requests to the CPU allowing software to calculate new PWM parameters in real time. If reload interrupt is not enabled, the submodule still reloads PWM parameters at the selected reload frequency without generating CPU interrupt requests, as illustrated in the following figure.

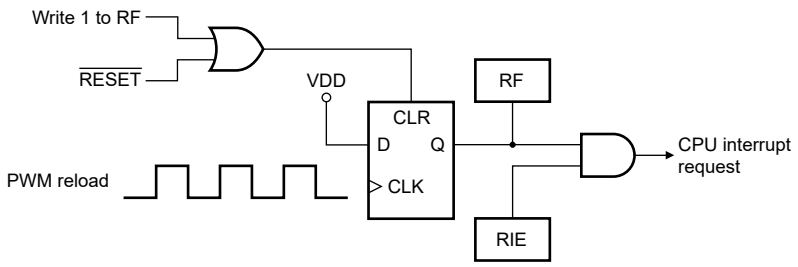

Figure 265. Reload interrupt requests

56.3.16.3.1 Reload interrupt logic

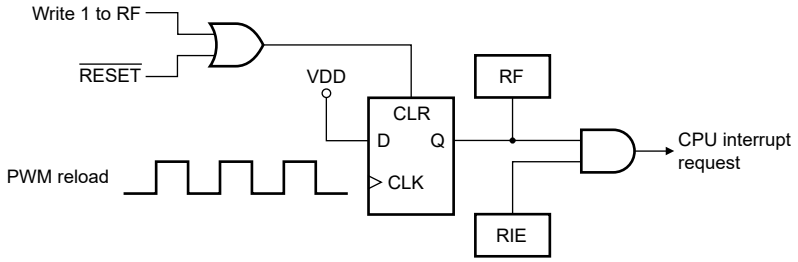

Figure 266. Reload interrupt logic

56.3.16.4 Reload errors

Whenever you update a timing value, a fractional timing value, or the prescaler divisor, the submodule sets the registers updated flag (SM*n*_STS[RUF]) to indicate that the PWM generator data is not coherent. The data is not coherent when there are values in the register buffers that have not yet been loaded into the registers. The submodule clears the registers updated flag when a successful reload occurs, that is, when the reload flag (SM*n*_STS[RF]) is set and load okay is enabled at a PWM opportunity. If the registers updated flag is set and load okay (MCTRL[LDOK]) is zero when the reload signal occurs, a reload error occurs and the submodule sets the reload error flag (SM*n*_STS[REF]). If the registers updated flag is clear when a reload signal asserts, then the data is coherent and no error occurs.

56.3.16.5 Start the PWM generator

You should initialize all of the PWM generator registers and enable load okay (MCTRL[LDOK]) before you start the PWM generator (MCTRL[RUN]).

NOTE

Even if load okay is not enabled, starting the PWM generator also sets the reload flag (SM*n*_STS[RF]). To prevent a CPU interrupt request caused by the reload flag, disable reload interrupt enable (SM*n*_INTEN[RIE]) before starting the PWM generator.

If you stop the PWM generator and then start it again while load okay is disabled, the PWM generator uses the last loaded values.

When you stop the PWM generator (write 0 to MCTRL[RUN]):

- The reload flag (SM*n*_STS[RF]) and pending CPU interrupt requests are not cleared.
- All fault circuitry remains active.
- Software and external output control remains active.
- Deadtime insertion continues during software and external output control.

56.3.17 Hardware ADC triggering

56.3.17.1 Hardware ADC triggering overview

The timing of ADC triggers is critical and therefore they must be scheduled as hardware events rather than be activated by software. eFlexPWM can generate multiple hardware triggers per PWM period or across multiple PWM periods without the need for another timer module.

56.3.17.2 Multiple triggers within a single PWM period

Multiple output triggers within a single PWM period illustrates the generation of multiple output triggers that must occur within the same PWM period. Using one submodule in complementary mode operation, you need only two timing values (VAL2 and VAL3 in the example) to generate a PWM output signal. This leaves the other timing values free to perform other functions. Software is not needed to generate triggers after the first conversion.

56.3.17.2.1 Multiple output triggers within a single PWM period

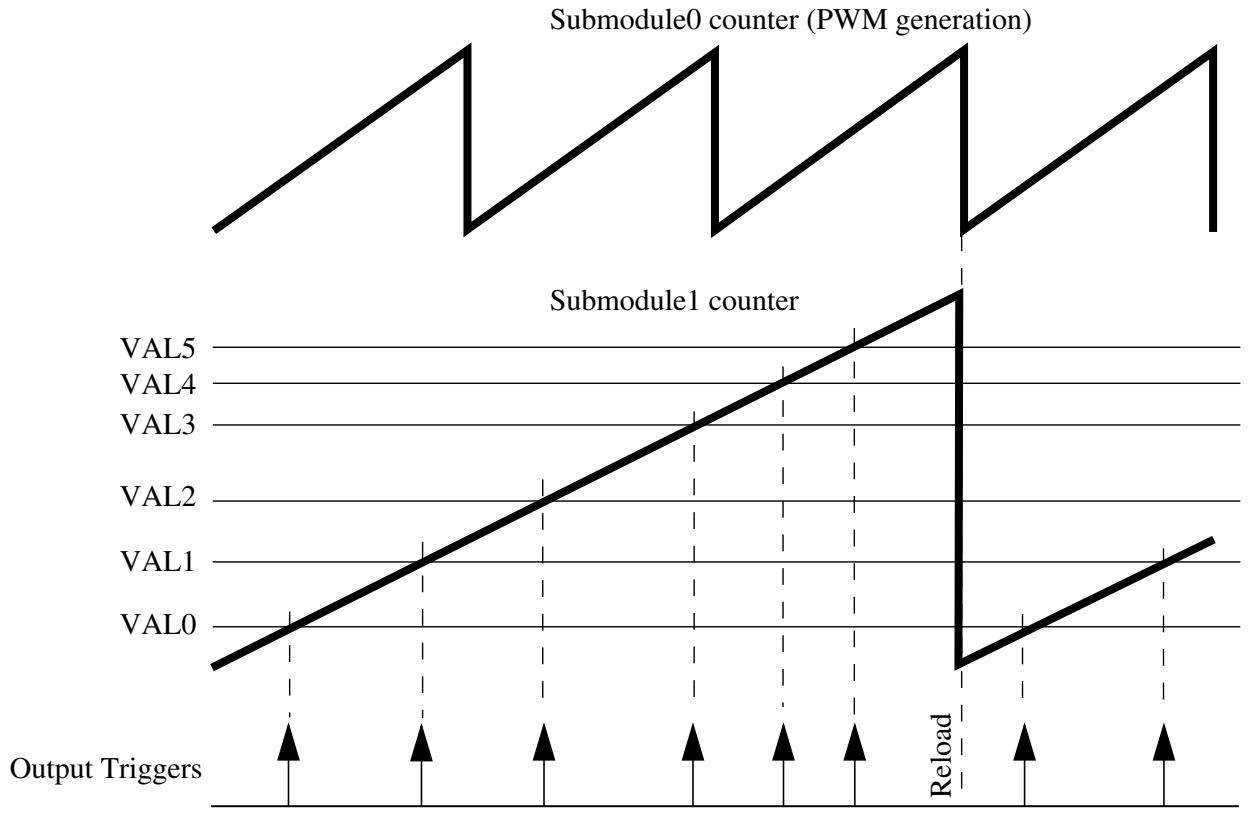

Figure 267. Multiple output triggers within a single PWM period

56.3.17.3 Multiple triggers across multiple PWM periods

Because each submodule has its own counter, it can run at a different PWM frequency from the other submodules. Therefore, one or more submodules can run at a lower frequency than submodule 0 but still be synchronized to the submodule 0 counter. Multiple output triggers over several PWM periods shows how to schedule hardware triggers over multiple PWM cycles. One application for this configuration is to use the lower-frequency submodule to control the sampling frequency of the software control algorithm and schedule multiple hardware triggers over the entire sampling period. This example uses all of the timing values of the lower-frequency submodule for ADC trigger generation.

56.3.17.3.1 Multiple output triggers over several PWM periods

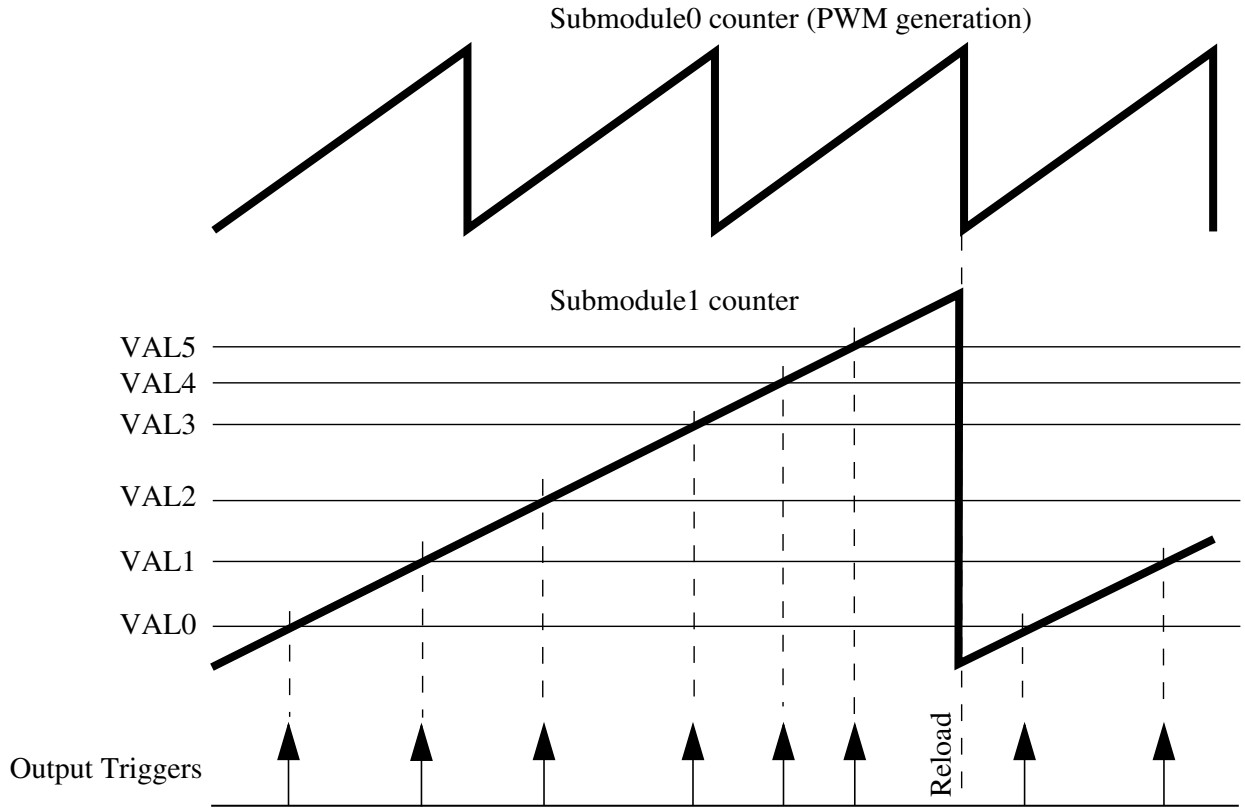

Figure 268. Multiple output triggers over several PWM periods

56.3.18 PWM clocking

56.3.18.1 PWM clocking overview

As illustrated in Clocking for each PWM submodule, you can select between three clock sources for each submodule:

- the IPBus clock
- an external clock (EXT_CLK)
- the submodule 0 counter (AUX_CLK)

The IPBus and external clocks are available to all submodules. The AUX_CLK signal is output from the submodule 0 counter and is available to the other submodules. AUX_CLK allows the submodule 0 counter (either the IPBus or the external clock divided by the submodule 0 prescaler) and submodule 0 Run (bit 0 of MCTRL[RUN]) to control the other submodules.

56.3.18.1.1 Clocking for each PWM submodule

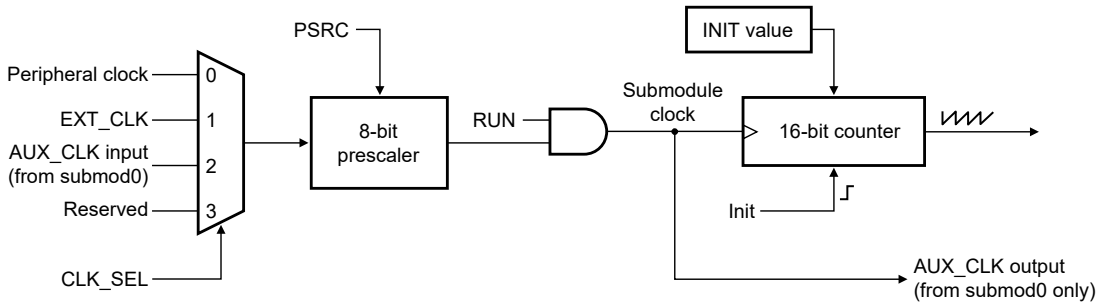

Figure 269. Clocking for each PWM submodule

56.3.18.2 Prescaler buffering

The submodule prescaler is buffered. The PWM generator does not use it until you enable load okay (MCTRL[LDOK]) for the submodule and a new PWM reload cycle begins or you assert load okay (SM*n*_CTRL[LDMOD]).

56.3.18.3 Running a submodule at a lower frequency than submodule 0

The submodule counter operates at the frequency of the selected clock source divided by the submodule prescaler (SM*n*_CTRL[PRSC]). Therefore, if you select the submodule 0 counter (AUX_CLK) as the clock source for another submodule and specify a prescaler for that submodule greater than 1, that submodule operates at a lower frequency than submodule 0.

56.3.19 Resets

All eFlexPWM registers reset to their default values upon any system reset. The reset forces all registers to their reset states and tristates the PWM outputs.

56.3.20 Interrupts

Each of the submodules within eFlexPWM module can generate an interrupt from several sources. The fault logic can also generate interrupts. The interrupt service routine (ISR) must check the related interrupt enables and interrupt flags to determine the actual cause of the interrupt.

Table 268. Interrupt Summary

Core interrupt	Interrupt flag	Interrupt enable	Name	Description
PWM_CMP0	SM0_STS[CMPF]	SM0_INTEN[CMPIE]	Submodule 0 compare interrupt	Compare event has occurred
PWM_CAP0	SM0_STS[CFA1] SM0_STS[CFA0] SM0_STS[CFB1] SM0_STS[CFB0] SM0_STS[CFX1] SM0_STS[CFX0]	SM0_INTEN[CA1IE] SM0_INTEN[CA0IE] SM0_INTEN[CB1IE] SM0_INTEN[CB0IE] SM0_INTEN[CX1IE] SM0_INTEN[CX0IE]	Submodule 0 input capture interrupt	Input capture event has occurred

56.3.21 DMA

Each submodule can request a DMA read access for its capture FIFOs and a DMA write request for its double buffered SM*n*VAL*m* registers.

Table 269. DMA Summary

DMA request	DMA enable	Name	Description
Submodule *n* read request	SM*n*_DMAEN[CX0DE]	Submodule *n* Capture FIFO X0 read request	SM*n*_CVAL0 and SM*n*_CVAL0CYC contains a value to be read
	SM*n*_DMAEN[CX1DE]	Submodule *n* Capture FIFO X1 read request	SM*n*_CVAL1 and SM*n*_CVAL1CYC contains a value to be read
	SM*n*_DMAEN[CA0DE]	Submodule *n* Capture FIFO A0 read request	SM*n*_CVAL2 and SM*n*_CVAL2CYC contains a value to be read
	SM*n*_DMAEN[CA1DE]	Submodule *n* Capture FIFO A1 read request	SM*n*_CVAL3 and SM*n*_CVAL3CYC contains a value to be read
	SM*n*_DMAEN[CB0DE]	Submodule *n* Capture FIFO B0 read request	SM*n*_CVAL4 and SM*n*_CVAL4CYC contains a value to be read
	SM*n*_DMAEN[CB1DE]	Submodule *n* Capture FIFO B1 read request	SM*n*_CVAL5 and SM*n*_CVAL5CYC contains a value to be read
	SM*n*_DMAEN[CAPTDE]	Submodule *n* Capture FIFO read request source select	Selects the source of the submodule read DMA request

Table continues on the next page...

Table 269. DMA Summary (continued)

DMA request	DMA enable	Name	Description
Submodule *n* write request	SM*n*_DMAEN[VALDE]	SM*n*_VAL*m* write request	SM*n*_VAL*m* registers need to be updated

Initialization sequence for DMA when writing on val registers.

- DMA Write Seq for LDMOD=0
  1. Configure SM*n*_INIT and SM*n*_VAL*m* then clear faults FP0_STS[FFLAG] and FP1_STS[FFLAG].
  2. Configure SM*n*_INIT and SM*n*_CTRL2 to initialize specific counter mode.

     Specify LDMOD=0 and FULL/Half reload mode.
  3. Configure MCTRL to assert MCTRL[LDOK] and MCTRL[RUN].
  4. Enable outputs from Output Enable (OUTEN) .
  5. Check DMA write request for all submodule must be disabled.
  6. Set SM*n*_DMAEN[VALDE].
  7. Wait for the corresponding submodule's DMA write request to set.
  8. Read MCTRL to verify LDOK is clear.
  9. Write on SMn_INIT and SMn_VALm using DMA bus. The new values are updated on PWM at the next reload opportunity.
  10. Wait for DMA request to disable, which indicates your request has been completed.
  11. Check corresponding PWM outputs for the changes to reflect on it.
- DMA Write Seq for LDMOD=1
  1. Configure SM*n*_INIT and SM*n*_VAL*m* then clear faults FP0_STS[FFLAG] and FP1_STS[FFLAG].
  2. Configure SM*n*_INIT and SM*n*_CTRL2 to initialize specific counter mode.

     Specify LDMOD=1.
  3. Configure MCTRL to assert MCTRL[LDOK] and MCTRL[RUN].
  4. Enable outputs from Output Enable (OUTEN) .
  5. Check DMA write request for all submodule must be disabled.
  6. Set SM*n*_DMAEN[VALDE].
  7. Wait for corresponding submodule's DMA write request to set.
  8. Read MCTRL to verify LDOK is clear.
  9. Write on SMn_INIT and SMn_VALm using DMA bus.
  10. Wait for DMA request to disable, which indicates your request has been completed.
  11. Read MCTRL to verify LDOK is set.
  12. New values are loaded on SMn_VALm at the next clock cycle when LDOK is automatically de-asserted.

56.4 Internal signals

The following table describes eFlexPWM signals.

Table 270. Internal signals

Signal	Input/Output	Function
PWM*n*_A	Input/Output	PWM channel output pair. These signals operate as independent PWM outputs or as complementary pairs (SM*n*_CTRL2[INDEP]). When not needed as outputs, they can be inputs to the input capture circuitry (SM*n*_CAPTCOMPA, SM*n*_CAPTCOMPB).
PWM*n*_B	Input/Output	
PWM*n*_X	Input/Output	Auxiliary PWM channel output. These signals operate as PWM outputs. When not needed as outputs, they can be inputs to the input capture circuitry (SM*n*_CAPTCOMPA, SM*n*_CAPTCOMPB) or they can detect the polarity of the current flowing through the complementary circuit at deadtime correction.
FAULT*n*	Input	Fault pins. Disable selected PWM outputs, as controlled by Fault Disable Mapping (Submodule a Fault Disable Mapping (SM0_DISMAP0 - SM3_DISMAP0) or Submodule a Fault Disable Mapping (SM0_DISMAP1 - SM3_DISMAP1)).
PWM*n*_OUT_TRIG0	Output	Output triggers. Allow PWM submodules to control the timing of ADC conversions. See SM*n*_TCTRL[OUT_TRIG_EN] for information about how to enable these outputs and how the compare registers match up to the output triggers.
PWM*n*_OUT_TRIG1	Output	
PWM*n*_MUX_TRIG0	Output	Multiplexed output triggers. Allow PWM submodules to control the timing of ADC conversions. See SM*n*_TCTRL[PWAOT0] and SM*n*_TCTRL[PWBOT1] for information about how to enable these outputs.
PWM*n*_MUX_TRIG1	Output	

56.5 External signals

The following table describes eFlexPWM signals.

Table 271. External signals

Signal	Input/Output	Function
PWM*n*_EXT_SYNC	Input	External synchronization. Allow an external input to initialize the submodule PWM counter. These signals support the synchronization of the PWM to external circuitry.
EXT_FORCE	Input	External output force. Allows an external input to force an update of the PWM outputs. These signals support the synchronization of the PWM to external circuitry.
PWM*n*_EXTA	Input	Alternate PWM control. Allow an alternate source to control the PWM*n*_A and PWM*n*_B outputs. Typically either PWM23 or PWM45, depending on the Current Polarity (MCTRL[IPOL]), generates the complementary pair. Examples of external control signals include ADC conversion high/low limits, TMR outputs, GPIO inputs, and comparator outputs.
PWM*n*_EXTB	Input	
EXT_CLK	Input	External clock signal. Allows an external source, typically a timer or an off-chip source, to control the PWM clocking. This input allows the PWM to be synchronized to the timer or multiple chips to be synchronized to each other. The maximum allowed external frequency should be less than the module clock frequency.

56.6 Initialization

56.6.1 Generate center-aligned PWM pulses

56.6.1.1 Center-aligned overview

A center-aligned pulse is timed relative to a center point within the PWM period, typically the mid-point, rather than from the beginning of the PWM period. In other words, the turn-on edge of the pulse occurs a specified time before the center point and the turn-off edge occurs a specified time after the center point.

56.6.1.2 Using the rollover submodule counter

To support center-aligned pulses, you can take advantage of the rollover submodule counter. See Rollover submodule counter.

To create a symmetrical center-aligned pulse aligned to the PWM period mid-point, you first specify the period with a positive integer value for the reload point (VAL1) and a two's complement negative value for the Initial Count. Then you need to calculate only one timing value, for half of the pulse width, and use that value for the pulse turn-off timing and its two's complement negative for the pulse turn-on timing. See Generate a center-aligned pulse for step-by-step instructions.

If you use this capability for both sets of PWM output edge calculations (PWM*n*_A and PWM*n*_B), then both PWM pulses are center-aligned with respect to each other.

NOTE

A side effect of this technique for center-aligned operation is that it always results in a pulse width of an odd number of counter units.

56.6.1.3 Generate a center-aligned pulse

To generate a center-aligned pulse using the PWM*n*_A output, as illustrated in Center-aligned example:

1. Select the source clock (SM0_CTRL2[CLK_SEL]).
2. Determine the desired length of the PWM period in source clock cycles.

   Example: For illustration, assume a PWM period of 288 source clock cycles.
3. Select the largest prescaler that divides evenly into the PWM period clock cycles (SM*n*_CTRL[PRSC]).

   Example: A prescaler of 32 divides into 288 clock cycles nine times with no remainder. Depending on your application, you may choose to use a smaller prescaler.
4. Calculate the total number of counter units for the desired PWM period: (clock cycles/prescaler) = counter units.

   Example: The number of counter units is nine: (288/32 = 9). See Center-aligned example.
5. Divide the calculated PWM period counter units by 2 and write the integer result to timing value 1 (SM*n*_VAL1[VAL1]).

   Example: 9/2 = 4.5. Use the integer result value of 0004h. Remember, center-aligned operation always results in a pulse width of an odd number of counter units.
6. Calculate the two's complement of the value you just wrote to VAL1 and write the result to the initial count (SM*n*_INIT[INIT]).

   Example: The two's-complement of 004h is FFFCh.
7. Determine the desired pulse period in source clock cycles. This value should be less than or equal to the PWM period. If it is equal to the PWM period, the result is a 100% duty cycle pulse.

   Example: Assume a pulse width of 160 source clock cycles.
8. Calculate the total number of counter increments for the desired pulse width.

   Example: 160/32 = 5.
9. Divide the calculated pulse width counter units by 2 and write the rounded-up integer result to timing value 3 (SM*n*_VAL3[VAL3]).

   Example: For 5/2 = 2.5, the rounded-up integer result is 0003h.

10. Calculate the two's complement of the rounded-up value you calculated in the previous step and write the result to timing value 2 (SM*n*_VAL2[VAL2]).

    Example: The two's complement of 0002h is FFFEh.

11. To synchronize half-period reload with the pulse center point, write zero to timing value 0 (SM*n*_VAL0[VAL0]).

The example values in this procedure create a five-unit (160 clock cycles) pulse aligned precisely around the center of a nine-unit (288 clock cycles) PWM period. eFlexPWM does not restrict you to symmetry around the period mid-point. By adjusting the VAL2 and VAL3 values (or VAL4 and VAL5 for a PWM*n*_B pulse), you can align the pulse anywhere within the PWM period. However, centering the pulse in the PWM period provides the greatest range for pulse width and simplifies the timing calculations.

56.6.1.4 Center-aligned example

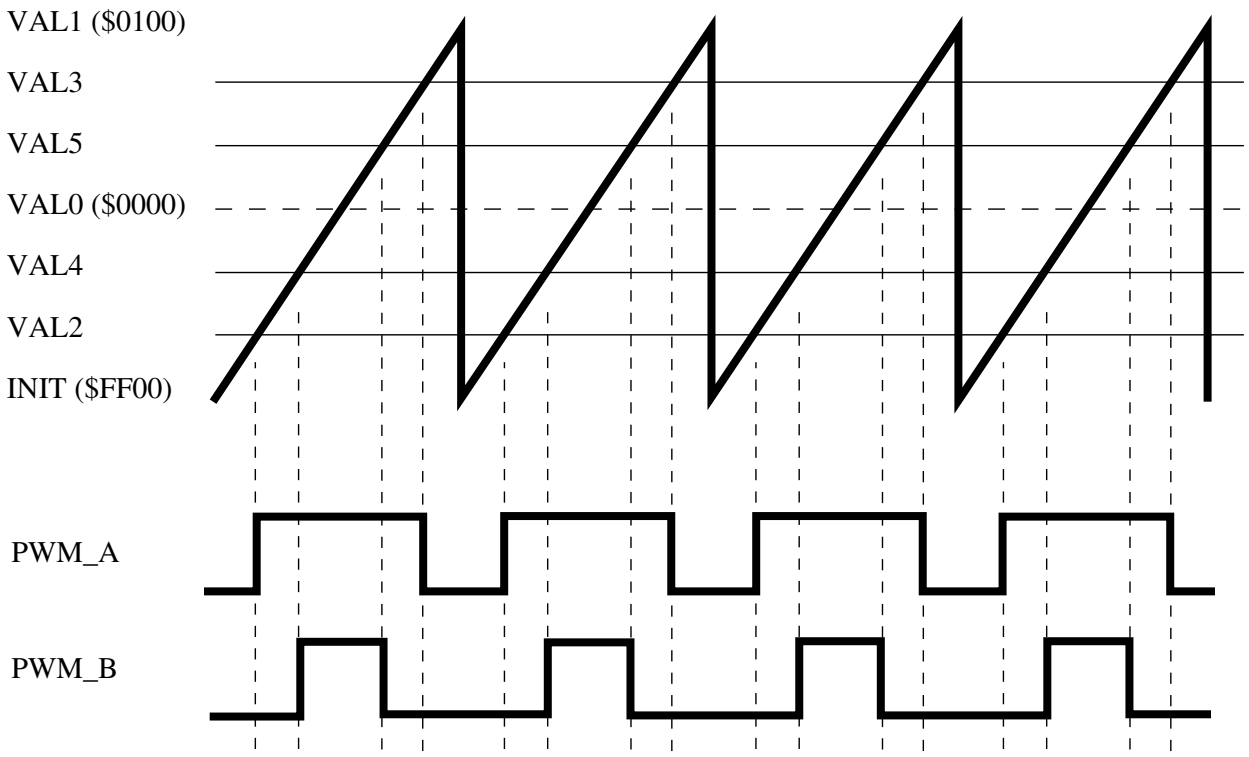

Figure 270. Center-aligned example

56.6.2 Generate edge-aligned PWM pulses

56.6.2.1 Edge-aligned overview

In edge-aligned operation, the PWM pulse turns on at the beginning of the PWM period. In other words, the timing value for the leading edge of the pulse is the same as the initial count. You change the pulse width by periodically updating the turn-off edge timing.

56.6.2.2 Edge-aligned use case: H bridge

A common technique for driving an H bridge is bipolar pulses, where a 50% duty cycle results in zero volts on the load, duty cycles less than 50% result in negative load voltages, and duty cycles greater than 50% generate positive load voltages. You use edge-aligned pulses and the rollover submodule counter to produce these bipolar pulses.

If the Initial Count (SM*n*_INIT[INIT]) is the two's-complement negative of timing value 1 (SM*n*_VAL1[VAL1]), then the turn-off timing value for a 50% duty cycle, edge-aligned pulse is 0000h. A positive integer value gives a greater than 50% duty cycle, and

a two's-complement negative value gives a less than 50% duty cycle. Therefore, when using the pulse to drive an H bridge, the turn-off edge timing is directly proportional to the motor inverter voltage, including the sign. As with center-aligned pulses, treating the submodule counter as a signed value simplifies the process because you don't need offset calculations to translate the output variable control algorithm to the voltage on an H bridge load.

Edge-aligned example illustrates edge-aligned bipolar pulses created with Generate an edge-aligned bipolar pulse.

56.6.2.3 Generate an edge-aligned bipolar pulse

To generate an edge-aligned bipolar pulse using the PWM*n*_A output, as illustrated in Edge-aligned example:

1. Select the source clock (SM0_CTRL2[CLK_SEL]).
2. Determine the desired length of the PWM period in source clock cycles.

   Example: For illustration, assume a PWM period of 320 source clock cycles.
3. Select the largest prescaler that divides evenly into the PWM period clock cycles (SM*n*_CTRL[PRSC]).

   Example: A prescaler of 32 divides into 320 clock cycles ten times with no remainder. Depending on your application, you may choose to use a smaller prescaler.
4. Calculate the total number of counter units for the desired PWM period: (clock cycles/prescaler) = counter units.

   Example: The number of counter units is ten: (320/32 = 10). See Edge-aligned example.
5. Divide the calculated PWM period counter units by 2 and write the integer result to timing value 1 (SM*n*_VAL1[VAL1]).

   Example: 10/2 = 5. Use the integer result value of 0005h. Remember, center-aligned operation always results in a pulse width of an odd number of counter units, where VAL1 = 0004h.
6. Calculate the two's complement of the value you calculated in the previous step and write the result to the initial count (SM*n*_INIT[INIT]).

   Example: The two's complement of 0005h is FFFBh.
7. To edge align the pulse with the PWM period, write the same value to timing value 2 (SM*n*_VAL2[VAL2]).
8. To start the pulse width at a 50% duty cycle, write 0000h to timing value 3 (SM*n*_VAL3[VAL3]).
9. To synchronize half-period reload with the PWM period mid-point, write zero to timing value 0 (SM*n*_VAL0[VAL0]).

The example values in this procedure create a 50% duty cycle pulse (160 clock cycles) edge-aligned to the beginning of a 10 counter unit (320 clock cycles) PWM period. By adjusting timing value 3 (VAL3), you can control the output above (positive VAL3 value) or below (negative VAL3 value) the 50% duty cycle.

56.6.2.4 Edge-aligned example

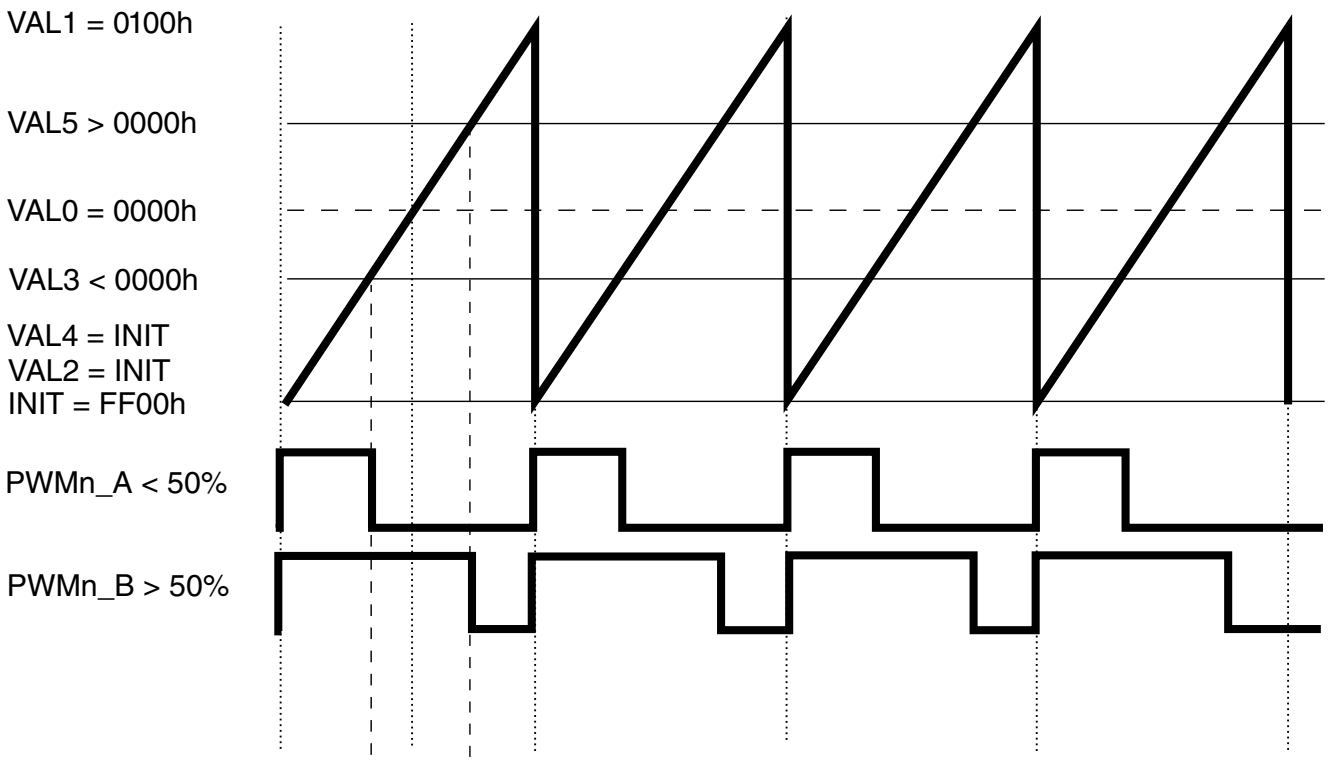

Figure 271. Edge-aligned example

56.6.3 Generate phase-shifted PWM pulses

56.6.3.1 Phase-shifted overview

Some PWM applications benefit from the ability to have one PWM pulse turn on and off at a set interval or delay from the turn on and off of another pulse. This controlled delay is called phase shifting.

Within a single submodule, you can calculate the turn-on and turn-off timing values for one pulse output, then add a bias or offset value to those timings before using them to program the other pulse output. See Phase-shifted example: within the same submodule for an illustration of this form of phase shifting. See Phase-shifted use case: multi-phase inverter for an application of this technique to operating a multi-phase inverter.

eFlexPWM also supports phase shifting across submodules. You can select the master sync from submodule 0 as the initialization source for another submodule (SM*n*_CTRL2[INIT_SEL]) and specify a non-zero phase delay value for that submodule (SM*n*_PHASEDLY[PHASEDLY]). The phase delay is the delay in counter units from assertion of master sync to submodule 0 to when the other submodule recognizes master sync. This method allows you to program all involved submodules with the same turn-on and turn-off timing values but to phase shift each subordinate submodule from submodule 0 by a submodule-specific number of counter units. See Phase-shifted example: across submodules for an illustration of this form of phase shifting.

56.6.3.1.1 Phase-shifted example: within the same submodule

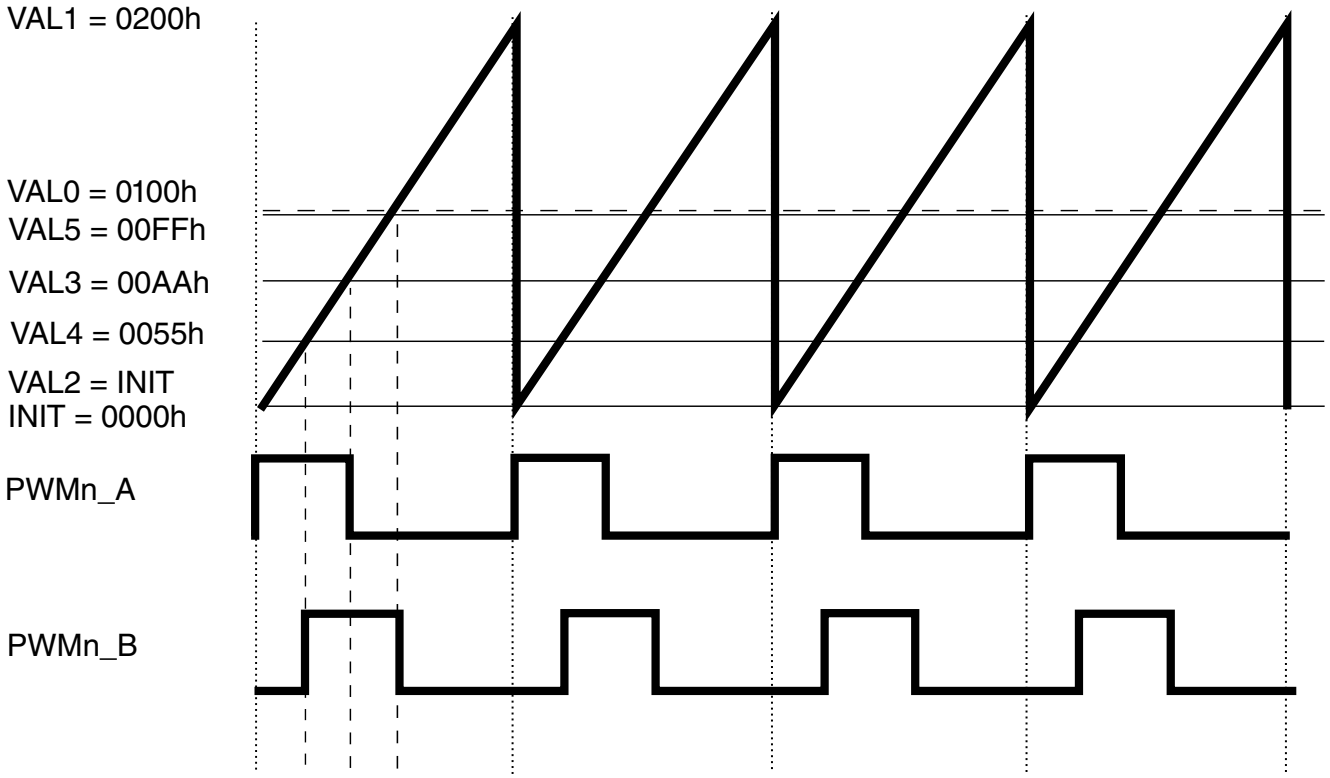

Figure 272. Phase-shifted example: within the same submodule

56.6.3.1.2 Phase-shifted example: across submodules

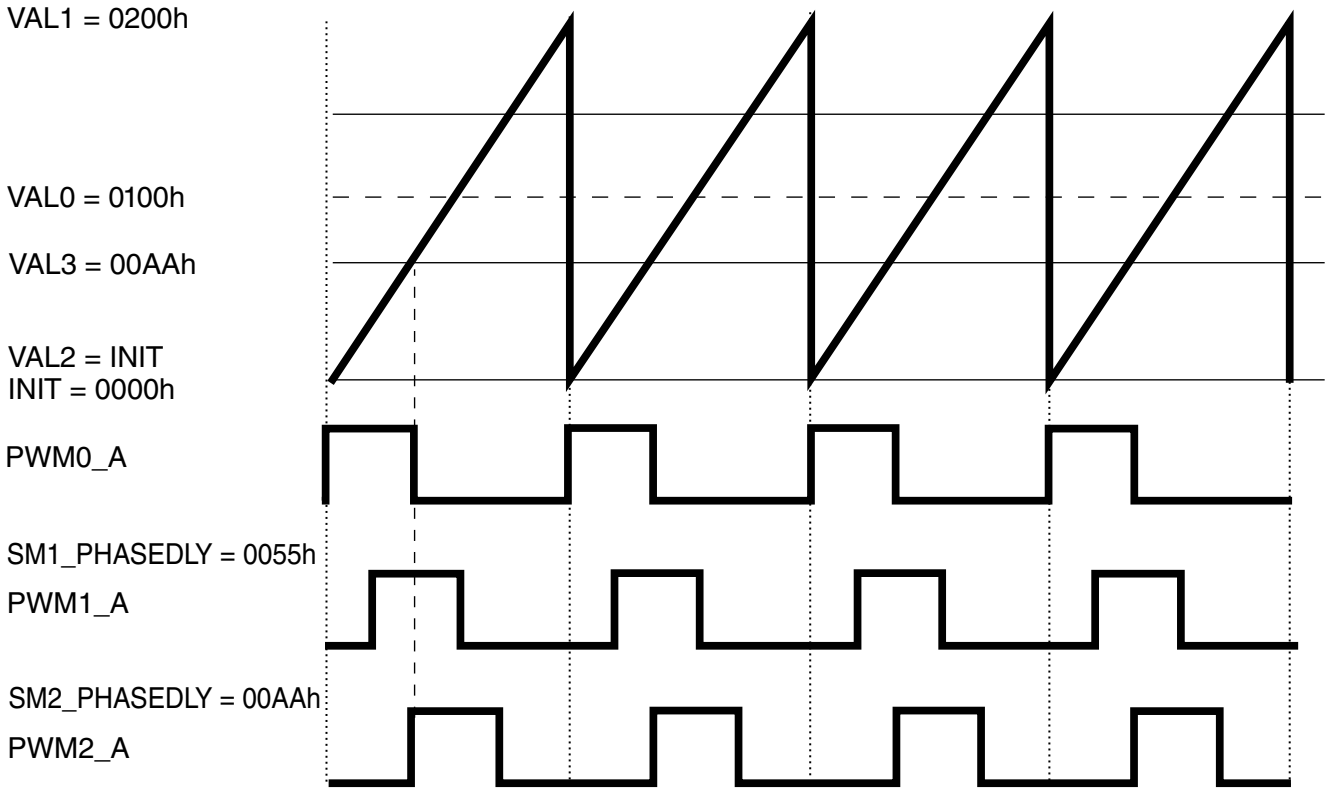

Figure 273. Phase-shifted example: across submodules

56.6.3.2 Phase-shifted use case: multi-phase inverter

When operating a multi-phase inverter at a low modulation index, all of the PWM switching edges from the different phases occur at nearly the same time. This proximity in time of the edges can be troublesome from a noise standpoint, especially if you need to schedule ADC readings near those times. Phase shifting the PWM pulses can open up timing windows between the switching edges to allow the ADC to sample a signal without noise from the other edges. However, phase shifting does not affect the duty cycle so it does not have an impact on the average load voltage.

56.6.3.3 Phase-shifted use case: transformer primary

To drive a transformer through an H bridge, you can phase shift two sets of complementary pulses. Use the complementary pulses from one submodule drive the left-side transistors of the H bridge, and the complementary pulses from another submodule to drive the right side, as illustrated in Drive a transformer primary.

56.6.3.3.1 Drive a transformer primary

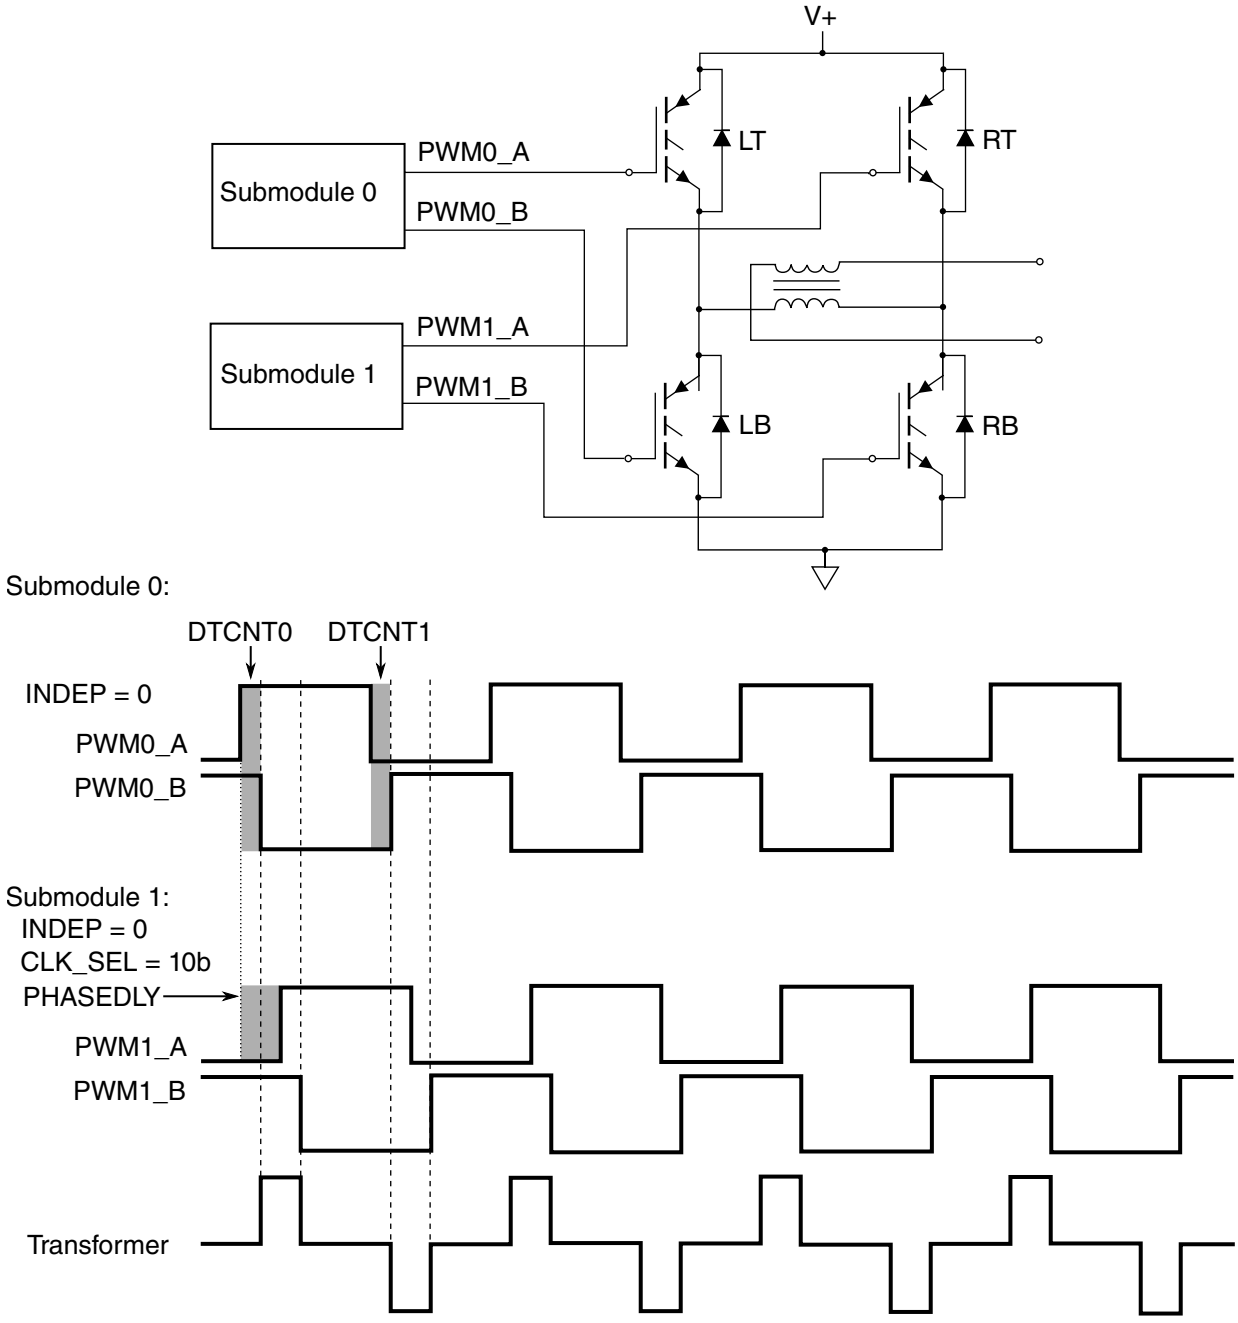

Figure 274. Drive a transformer primary

56.6.4 Generate double-switching PWM pulses

56.6.4.1 Double-switching overview

Some PWM applications require two independent serial pulses per PWM period. eFlexPWM supports double-switching pulses (SM*n*_CTRL[DBLEN]) by combining the PWM*n*_A and PWM*n*_B signals with XOR logic (force out logic) to generate the DBLPWM output. See Double-switching example.

You specify the even channel using timing values 2 and 3 (VAL2 and VAL3), and the odd channel using timing values 4 and 5 (VAL4 and VAL5). The DBLPWM output appears on PWM*n*_X. You can route the DBLPWM output through the deadtime insertion logic.

Split DBLPWM (SM*n*_CTRL[SPLIT]) causes each channel to appear on separate outputs. The pulse generated by the assertion of PWM*n*_A and deassertion of PWM*n*_B, the even channel, appears on the PWM*n*_A output. The pulse generated by the assertion of PWM*n*_B and deassertion of PWM*n*_A, the odd channel, appears on the PWM*n*_A output.

56.6.4.2 Double-switching example

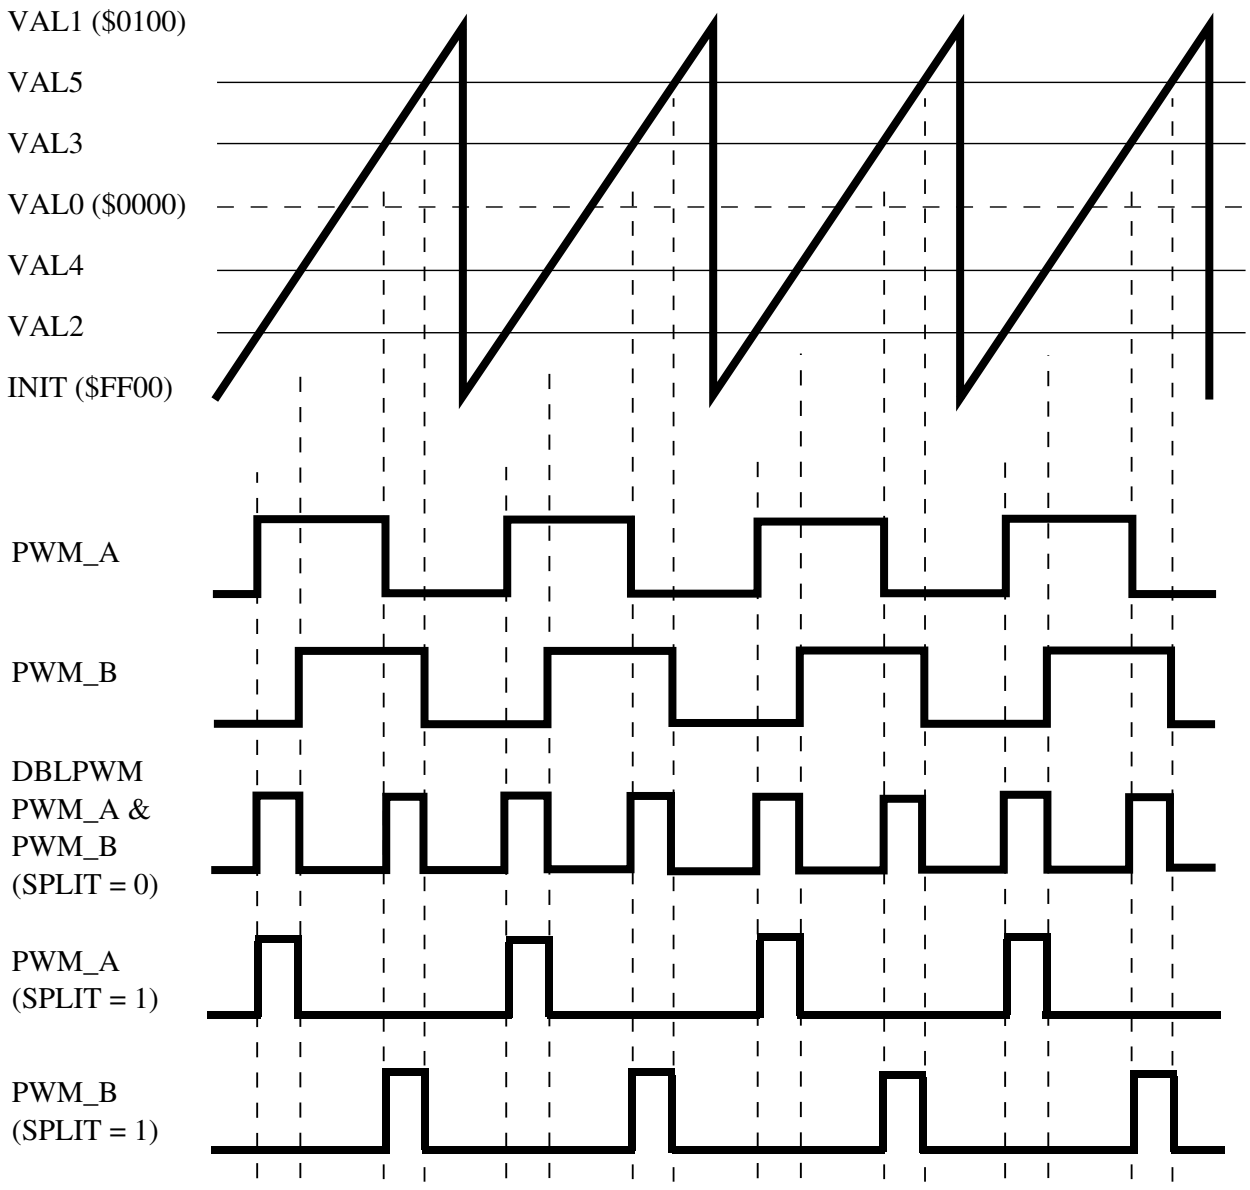

Figure 275. Double-switching example

56.7 PWM register descriptions

eFlexPWM contains a set of registers for each PWM submodule, for the configuration logic, and for each fault channel. The registers are 16-bit wide and 8-bit access is not supported.

To designate the submodule, submodule register names contain a prefix: SM0, SM1, SM2, or SM3. The base address of submodule 0 is the same as the module base address for eFlexPWM as a whole. The base address of submodule 1 is offset 60h from the module base address, and each subsequent module adds another 60h offset for its base address.

The base address of the configuration registers is offset 180h from the module base address.

To designate the fault channel, fault channel register names contain the prefix F0 or F1. The base address of fault channel 0 is equal to the module base address plus an offset of 18Ch. Fault channel 1 adds another 4h.

56.7.1 eFlexPWM memory map

eFlexPWM_0 base address: 406B_8000h

eFlexPWM_1 base address: 406B_C000h

56.7.2 Submodule a Counter (SM0_CNT - SM3_CNT)

Offset

Register	Offset
SM0_CNT	0h
SM1_CNT	60h

Table continues on the next page...

Table continued from the previous page...

Register	Offset
SM2_CNT	C0h
SM3_CNT	120h

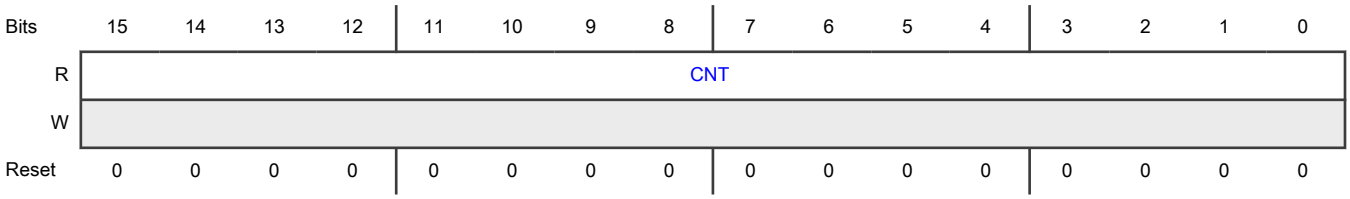
Function

Indicates the current value of the signed 16-bit submodule counter in PWM counter units. This register is not byte accessible.

NOTE

This register is buffered. The written value takes effect when software asserts submodule Load Okay (MCTRL[LDOK]) and the next PWM load cycle begins or immediately on assertion of Load Okay, depending on Load Mode Select (SM*n*_CTRL[LDMOD]). This register cannot be written when submodule Load Okay is asserted. Reading INIT returns the value in the buffer and not necessarily the value the PWM generator is currently using.

Diagram



Fields

Field	Function
15-0 CNT	Counter Value Specifies the Initial Count for the submodule in PWM counter units. This field is not byte accessible.

56.7.3 Submodule a Initial Count (SM0_INIT - SM3_INIT)

Offset

Register	Offset
SM0_INIT	2h
SM1_INIT	62h
SM2_INIT	C2h
SM3_INIT	122h

Function

Specifies the Initial Count for the submodule in PWM counter units. This register is not byte accessible.

NOTE

This register is buffered. The written value takes effect when software asserts submodule Load Okay (MCTRL[LDOK]) and the next PWM load cycle begins or immediately on assertion of Load Okay, depending on Load Mode Select (SM*n*_CTRL[LDMOD]). This register cannot be written when submodule Load Okay is asserted. Reading INIT returns the value in the buffer and not necessarily the value the PWM generator is currently using.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	INIT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-0 INIT	Initial Count The submodule loads this value into the counter at the start of every PWM period and on assertion of local sync, master sync, or master reload (SM*n*_CTRL2[INIT_SEL]), or on a forced initialization (SM*n*_CTRL2[FORCE]) with Force Init enabled (SM*n*_CTRL2[FRCEN]). This field is not byte accessible.

56.7.4 Submodule a Control 2 (SM0_CTRL2 - SM3_CTRL2)

Offset

Register	Offset
SM0_CTRL2	4h
SM1_CTRL2	64h
SM2_CTRL2	C4h
SM3_CTRL2	124h

Function

Provides control of submodule functions.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	DBGEN	WAITEN	INDEP	PWM23_I...	PWM45_I...	PWMX_IN...	INIT_SEL		FRCEN	0	FORCE_SEL			RELOAD_...	CLK_SEL	
W										FORCE						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15 DBGEN	Run In Debug Enable Specifies whether eFlexPWM continues to run while the chip is in Debug mode. If enabled, eFlexPWM continues to run in Debug mode. If disabled, when the chip enters Debug mode, eFlexPWM disables outputs. When the chip exits Debug mode, eFlexPWM resumes operation as programmed. **CAUTION** For certain types of motors (such as 3-phase AC), you must disable Run In Debug because failure to do so could result in damage to the motor or inverter. For other types of motors (example: DC motors), you may safely enable Run In Debug, but PWM parameter updates do not occur during Run In Debug. If you are using a motor that requires such updates, disable Run In Debug. If in doubt, leave it disabled. 0b - Disabled 1b - Enabled
14 WAITEN	Run In Wait Enable Specifies whether eFlexPWM continues to run while the chip is in Wait mode. If enabled, in Wait mode the peripheral clock continues to run but the CPU clock does not. If not enabled, when the chip enters Wait mode eFlexPWM disables outputs. When the chip exits Wait mode, eFlexPWM resumes operation as programmed. **CAUTION** For certain types of motors (such as 3-phase AC), you must disable Run In Wait because failure to do so could result in damage to the motor or inverter. For other types of motors (example: DC motors), you may safely enable Run In Wait, but PWM parameter updates do not occur during Run In Wait. If you are using a motor that requires such updates, disable Run In Wait. If in doubt, leave it disabled. 0b - Disabled 1b - Enabled
13 INDEP	Independent Operation Specifies whether the PWM*n*_A and PWM*n*_B channels are independent PWMs or a complementary PWM pair.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Complementary PWM pair 1b - Independent PWMs
12 PWM23_INIT	PWM23 Initial Value Specifies the initial value for PWM23 and the value it is forced to by assertion of FORCE_INIT.
11 PWM45_INIT	PWM45 Initial Value Specifies the initial value for PWM45 and the value it is forced to by assertion of FORCE_INIT.
10 PWMX_INIT	PWMn_X Initial Value Specifies the initial value for PWM*n*_X and the value it is forced to by assertion of FORCE_INIT.
9-8 INIT_SEL	Initialization Source Select Specifies the source of initialization (the INIT signal) to the counter. 00b - Local sync (PWMn_X) 01b - Master reload (from submodule 0). Master reload (from submodule 0). This setting should not be used in submodule 0 as it will force the INIT signal to logic 0. 10b - Master sync from submodule 0. Master sync from submodule 0. Do not use this source for submodule 0 because it forces the INIT signal to logic 0. 11b - External sync (EXT_SYNC)
7 FRCEN	Force Initialization Enable Enables Force Initialization (SM*n*_CTRL2[FORCE]) to initialize the counter without regard for Initialization Control Select (SM*n*_CTRL2[INIT_SEL]). This is a software controlled initialization. If the submodule Load Okay (MCTRL[LDOK]) is asserted, forced initialization also asserts the local reload. 0b - Disabled 1b - Enabled
6 FORCE	Force Initialization If the local force signal is selected (SM*n*_CTRL2[FORCE_SEL] is 000b), writing 1 to this bit triggers a FORCE_OUT event, which involves the following actions: • The PWM*n*_A and PWM*n*_B output pins assume values based on the selected sources (DTSRCSEL[SM*n*SEL23] and DTSRCSEL[SM*n*SEL45]). • If Force Initialization is enabled (SM*n*_CTRL2[FRCEN]), eFlexPWM loads the INIT value into the counter. 0b - No effect 1b - Force initialization
5-3 FORCE_SEL	Force Output Source Select

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Specifies the source of the FORCE OUTPUT signal for the submodule. Assertion of the selected signal forces an update. 000b - Local force signal (FORCE) 001b - Master force signal (from submodule 0). Master force signal (from submodule 0). Do not use this source for submodule 0 because it forces the FORCE OUTPUT signal to logic 0. 010b - Local reload signal. Local reload signal. Forces update without regard for the state of MCTRL[LDOK]. 011b - Master reload signal (from submodule 0). Master reload signal (from submodule 0). Forces updates if Load Okay (MCTRL[LDOK]) is set. Do not use this source for submodule 0 because it forces the FORCE OUTPUT signal to logic 0. 100b - Local sync signal 101b - Master sync signal (from submodule 0). Master sync signal (from submodule 0). Do not use this source for submodule 0 because it forces the FORCE OUTPUT signal to logic 0. 110b - External force signal (EXT_FORCE) 111b - External sync signal (EXT_SYNC)
2 RELOAD_SEL	Reload Source Select Specifies the source of the RELOAD signal for the submodule. Assertion of the selected signal triggers a reload. **NOTE** For submodules 1, 2, and 3: If you specify the Master RELOAD signal, you must also use the submodule 0 bit in MCTRL[LDOK] because the LDOK bits for these submodules are ignored. 0b - Local RELOAD signal 1b - Master RELOAD signal (from submodule 0). Master RELOAD signal (from submodule 0). Do not use this source for submodule 0 because it forces the RELOAD signal to logic 0.
1-0 CLK_SEL	Clock Source Select Specifies the clock signal source for the submodule prescaler and counter. 00b - IPBus clock 01b - EXT_CLK 10b - Submodule 0 clock (AUX_CLK). Submodule 0 clock (AUX_CLK). Do not use this source for submodule 0 because it forces the clock to logic 0. 11b - Reserved

56.7.5 Submodule a Control (SM0_CTRL - SM3_CTRL)

Offset

Register	Offset
SM0_CTRL	6h
SM1_CTRL	66h
SM2_CTRL	C6h
SM3_CTRL	126h

Function

Provides control of submodule functions.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	LDFQ				HALF	FULL	DT		COMP MODE	PRSC			SPLIT	LDMOD	DBLX	DBLEN
Reset	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-12 LDFQ	Load Frequency Selects the PWM load frequency. Reset clears LDFQ to the default of loading every PWM opportunity. HALF and FULL determine the PWM opportunities. **NOTE** LDFQ takes effect when the current load cycle is complete, regardless of the state of Load Okay (MCTRL[LDOK]). Reading LDFQ returns the buffered value and not necessarily the value currently in effect. 0000b - Every PWM opportunity 0001b - Every 2 PWM opportunities 0010b - Every 3 PWM opportunities 0011b - Every 4 PWM opportunities 0100b - Every 5 PWM opportunities 0101b - Every 6 PWM opportunities 0110b - Every 7 PWM opportunities 0111b - Every 8 PWM opportunities 1000b - Every 9 PWM opportunities

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1001b - Every 10 PWM opportunities 1010b - Every 11 PWM opportunities 1011b - Every 12 PWM opportunities 1100b - Every 13 PWM opportunities 1101b - Every 14 PWM opportunities 1110b - Every 15 PWM opportunities 1111b - Every 16 PWM opportunities
11 HALF	Half-Period Reload Enables half-period reloads. A half period is defined by when the submodule counter matches Timing Value 0 (SM*n*_VAL0[VAL0]) and does not have to be half-way through the PWM period. 0b - Disabled 1b - Enabled
10 FULL	Full-Period Reload Enables full-period reloads. A full period is defined as when the submodule counter matches Timing Value 1 (SM*n*_VAL1[VAL1]). You must enable either half-period (HALF) or full-period (FULL) reloads to move the buffered data into the PWM generator registers, or you must assert Load Mode (LDMOD). If you assert both half- and full-period reloads, then reloads can occur twice per period. 0b - Disabled 1b - Enabled
9-8 DT	Deadtime Indicates the sampled values of the PWM*n*_X input at the end of each deadtime. Sampling occurs at the end of deadtime 0 for DT[0] and the end of deadtime 1 for DT[1]. Reset clears these bits.
7 COMPMODE	Compare Mode Specifies how comparisons are made between the timing value (SM*n*_VAL*m*) registers and the submodule counter. **NOTE** You can write to this field only one time. After you write to it, you must reset to release the bit for writing again. 0b - Equal to. Produces PWM edges only when the counter is equal to one of the timing values. This implies that a PWM*n*_A output that is high at the end of a period maintains this state until a match with VAL3 clears the output in the following period. 1b - Equal to or greater than. Produces PWM edges only when the counter is equal to or greater than one of the timing values. This implies that a PWM*n*_A output that is high at the end of a period could go low at the start of the next period if the starting counter value is greater than (but not necessarily equal to) the new VAL3 value.
6-4	Prescaler

Table continues on the next page...

Table continued from the previous page...

Field	Function
PRSC	Selects the divide ratio of the selected PWM source clock frequency (CLK_SEL). This value determines the number of source clock cycles that occur for every increment of the submodule counter (SM*n*_CNT[CNT]). **NOTE** Reading Prescaler returns the buffered value and not necessarily the value currently in effect. The Prescaler selection takes effect at the beginning of the next PWM period and only when Load Okay (MCTRL[LDOK]) is asserted or when you select Load Okay assertion for the Load Mode (SM*n*_CTRL[LDMOD]). You cannot write to this field when Load Okay (MCTRL[LDOK]) is asserted. 000b - No divider 001b - Divide by 2 010b - Divide by 4 011b - Divide by 8 100b - Divide by 16 101b - Divide by 32 110b - Divide by 64 111b - Divide by 128
3 SPLIT	Split DBLPWM Splits the DBLPWM signal to PWMA and PWMB. Applies only if double switching is enabled. When Split DBLPMW is enabled, one PWM pulse generated by double switching appears on PWMA and the other on PWMB. PWM creates the two pulses within the same PWM period by an XOR function of the PWMA and PWMB sources. The splitting function causes PWMA to output the pulse that occurs when the PWMA source is 1 and the PWMB source is 0. The PWMB output occurs when the PWMB source is 1 and the PWMA source is 0. (See Generate double-switching PWM pulses.) 0b - Not split. PWMA and PWMB each have double pulses. 1b - Split to PWMA and PWMB.
2 LDMOD	Load Mode Select Selects the timing for loading the buffered registers in the submodule. 0b - Next PWM reload, if submodule Load Okay is asserted. Next PWM reload, if submodule Load Okay is asserted (MCTRL[LDOK]). 1b - Load Okay assertion. Load Okay assertion (MCTRL[LDOK]). This case ignores FULL or HALF.
1 DBLX	PWMX Double Switching Enable Enables double switching behavior on PWMX. When enabled, the PWMX output is the exclusive-OR combination of PWMA and PWMB before polarity and masking considerations. 0b - Disabled 1b - Enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 DBLEN	Double Switching Enable Enables double switching PWM behavior (see Generate double-switching PWM pulses). **NOTE** Double switching is not compatible with fractional PWM clock generation. If you enable any fractional cycle capability (SM*n*_FRCTRL[FRAC23_EN], SM*n*_FRCTRL[FRAC45_EN], or SM*n*_FRCTRL[FRAC1_EN]), you must also disable double switching. 0b - Disabled 1b - Enabled

56.7.6 Submodule a Value 0 (SM0_VAL0 - SM3_VAL0)

Offset

Register	Offset
SM0_VAL0	Ah
SM1_VAL0	6Ah
SM2_VAL0	CAh
SM3_VAL0	12Ah

Function

See SM*n*_VAL0[VAL0].

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	VAL0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-0 VAL0	Timing Value 0 Specifies the mid-period reload point for the PWM submodule in PWM counter units. This value also specifies when to assert the PWM*n*_X signal and reset the local sync signal. This field is not byte accessible.

Table continues on the next page...

Field	Function
	NOTE This register is buffered. The written value takes effect when software asserts submodule Load Okay (MCTRL[LDOK]) and the next PWM load cycle begins or immediately on assertion of Load Okay, depending on Load Mode Select (LDMOD). You cannot write this register when submodule Load Okay (MCTRL[LDOK]) is asserted. Reading VAL0 returns the value in the buffer and not necessarily the value the PWM generator is currently using.

56.7.7 Submodule a Fractional Value 1 (SM0_FRACVAL1 - SM3_FRACVAL1)

Offset

Register	Offset
SM0_FRACVAL1	Ch
SM1_FRACVAL1	6Ch
SM2_FRACVAL1	CCh
SM3_FRACVAL1	12Ch

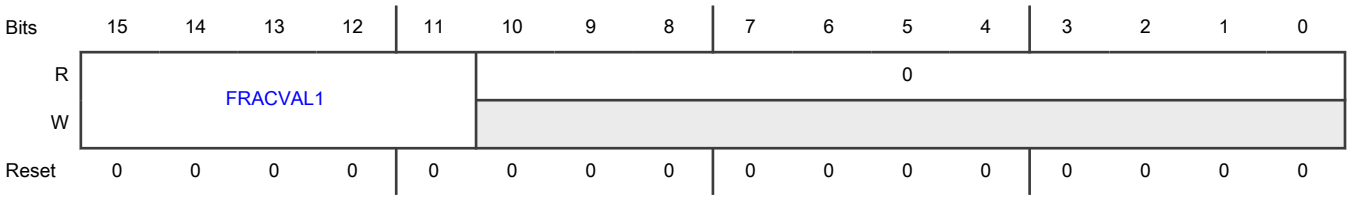
Function

Specifies the fractional addition to Submodule a Value 1 (SM0_VAL1 - SM3_VAL1) value for the submodule counter.

NOTE

This register is buffered. The written value takes effect when software asserts submodule Load Okay (MCTRL[LDOK]) and the next PWM load cycle begins or immediately on assertion of Load Okay, depending on Load Mode Select (SM*n*_CTRL[LDMOD]). You cannot write this register when submodule Load Okay (MCTRL[LDOK]) is asserted. Reading this register returns the values in the buffer and not necessarily the values the PWM generator is currently using.

Diagram



Fields

Field	Function
15-11 FRACVAL1	Fractional Timing Value 1 Specifies a fractional addition to Timing Value 1 (VAL1), in source clock cycles, that controls the PWM period width.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The PWM period is computed in source clock cycles divided by the selected prescaler. For example, if the prescaler is Divide by 16 (SM*n*_CTRL[PRSC] is 100b), the submodule counter, initial value, and all timing values represent multiples of 16 clock cycles. The submodule accumulates the fractional portion specified in FRACVAL1 at the end of every PWM period until the accumulated value is equal to or greater than the prescaler. Then, for one period, the PWM period is one counter unit longer to compensate for the accumulated fractional values. After that period, the submodule resets the fractional accumulator to zero.
10-0 —	Reserved

56.7.8 Submodule a Value 1 (SM0_VAL1 - SM3_VAL1)

Offset

Register	Offset
SM0_VAL1	Eh
SM1_VAL1	6Eh
SM2_VAL1	CEh
SM3_VAL1	12Eh

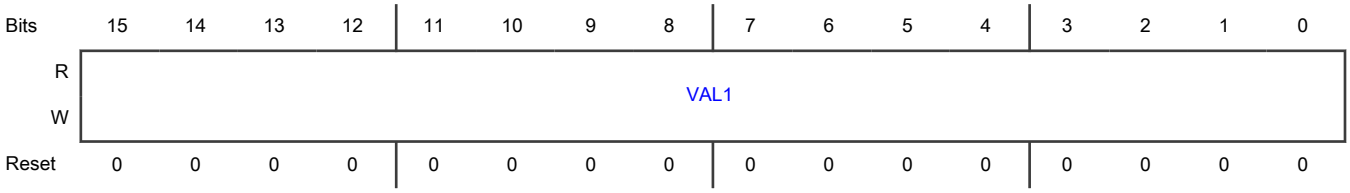
Function

Specifies the modulo count value 1 (maximum count) for the submodule counter.

NOTE

This register is buffered. The written value takes effect when software asserts submodule Load Okay (MCTRL[LDOK]) and the next PWM load cycle begins or immediately on assertion of Load Okay, depending on Load Mode Select (SM*n*_CTRL[LDMOD]). You cannot write this register when submodule Load Okay (MCTRL[LDOK]) is asserted. Reading this register returns the values in the buffer and not necessarily the values the PWM generator is currently using.

Diagram



Fields

Field	Function
15-0 VAL1	Timing Value 1 Specifies the modulo count value (maximum count) for the submodule counter. Upon reaching this count value, the counter reloads itself with the Initial Count (SM*n*_INIT[INIT]), asserts the local sync signal, and resets PWM*n*_X. This field is not byte accessible. **NOTE** When using SM*n*_FRACVAL1[FRACVAL1], limit the maximum value of VAL1 to 0xFFFE for unsigned operation (INIT is a positive integer) or to 0x7FFE for signed operation (INIT is a two's-complement negative integer) to avoid counter rollovers caused by accumulating the fractional period defined by SM*n*_FRACVAL1[FRACVAL1]. If VAL1 defines the counter period (Local Sync is selected as the counter initialization signal), you cannot achieve a 100% duty cycle on the PWM*n*_X output. After the count reaches VAL1, the PWM*n*_X output is low for a minimum of one count every cycle. When you use the Master Sync signal (only originated by the Local Sync from sub-module 0) to control the counter period, VAL1 is free for other functions such as PWM generation without the duty cycle limitation.

56.7.9 Submodule a Fractional Value 2 (SM0_FRACVAL2 - SM3_FRACVAL2)

Offset

Register	Offset
SM0_FRACVAL2	10h
SM1_FRACVAL2	70h
SM2_FRACVAL2	D0h
SM3_FRACVAL2	130h

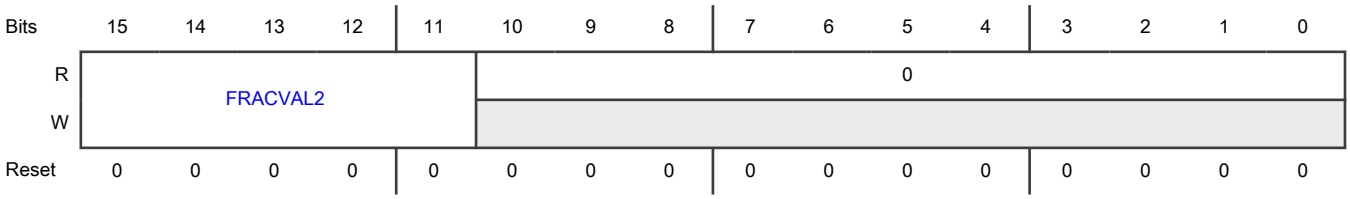
Function

Specifies the fractional addition to Submodule a Value 2 (SM0_VAL2 - SM3_VAL2) value for the submodule counter.

NOTE

This register is buffered. The written value takes effect when software asserts submodule Load Okay (MCTRL[LDOK]) and the next PWM load cycle begins or immediately on assertion of Load Okay, depending on Load Mode Select (LDMOD). You cannot write this register when submodule Load Okay (MCTRL[LDOK]) is asserted. Reading this register returns the values in the buffer and not necessarily the values the PWM generator is currently using.

Diagram



Fields

Field	Function
15-11 FRACVAL2	Fractional Timing Value 2 Specifies a fractional addition to Timing Value 2 (VAL2), in source clock cycles, that controls the PWM*n*_A turn-on timing. In complementary mode (SM*n*_CTRL2[INDEP] equal to 0) using PWM23 (submodule bit of MCTRL[IPOL] equal to 0), the submodule also adds the fractional value to the turn-off delay of PWM*n*_B. **NOTE** When the values of VAL2 and SM*n*_VAL3[VAL3] cause the high or low time of the PWM output to be three counter units or less, you should disable fractional edge placement of PWM*n*_A using SM*n*_FRACVAL2[FRACVAL2] and SM*n*_FRACVAL3[FRACVAL3] (SM*n*_FRCTRL[FRAC23_EN]).
10-0 —	Reserved

56.7.10 Submodule a Value 2 (SM0_VAL2 - SM3_VAL2)

Offset

Register	Offset
SM0_VAL2	12h
SM1_VAL2	72h
SM2_VAL2	D2h
SM3_VAL2	132h

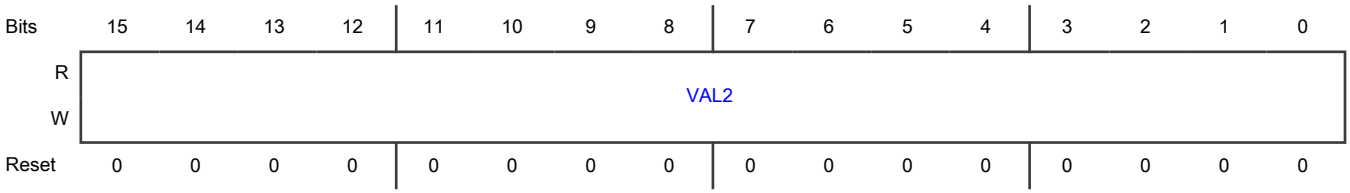
Function

Specifies the modulo count value 2 (maximum count) for the submodule counter.

NOTE

This register is buffered. The written value takes effect when software asserts submodule Load Okay (MCTRL[LDOK]) and the next PWM load cycle begins or immediately on assertion of Load Okay, depending on Load Mode Select (LDMOD). You cannot write this register when submodule Load Okay (MCTRL[LDOK]) is asserted. Reading this register returns the values in the buffer and not necessarily the values the PWM generator is currently using.

Diagram



Fields

Field	Function
15-0 VAL2	Timing Value 2 Specifies the count value to set PWM23 high. This field is not byte accessible.

56.7.11 Submodule a Fractional Value 3 (SM0_FRACVAL3 - SM3_FRACVAL3)

Offset

Register	Offset
SM0_FRACVAL3	14h
SM1_FRACVAL3	74h
SM2_FRACVAL3	D4h
SM3_FRACVAL3	134h

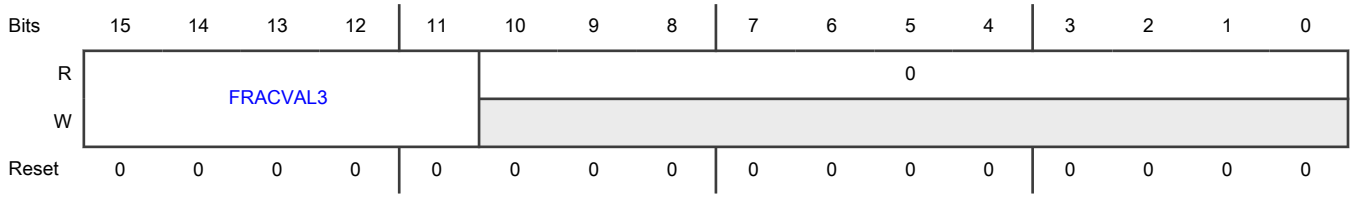
Function

Specifies the fractional addition to Submodule a Value 3 (SM0_VAL3 - SM3_VAL3) value for the submodule counter.

NOTE

This register is buffered. The written value takes effect when software asserts submodule Load Okay (MCTRL[LDOK]) and the next PWM load cycle begins or immediately on assertion of Load Okay, depending on Load Mode Select (LDMOD). You cannot write this register when submodule Load Okay (MCTRL[LDOK]) is asserted. Reading this register returns the values in the buffer and not necessarily the values the PWM generator is currently using.

Diagram



Fields

Field	Function
15-11 FRACVAL3	Fractional Timing Value 3 Specifies a fractional addition to Timing Value 3 (VAL3) that controls the PWM*n*_A turn-off timing. In complementary mode (SM*n*_CTRL2[INDEP] equal to 0) and using PWM23 (MCTRL[IPOL] equal to 0), the submodule also adds the fractional value to the turn-on delay of PWM*n*_B. **NOTE** When the values of SM*n*_VAL2[VAL2] and VAL3 cause the high or low time of the PWM output to be three counter units or less, you should disable fractional edge placement of PWM*n*_A using SM*n*_FRACVAL2[FRACVAL2] and FRACVAL3 (SM*n*_FRCTRL[FRAC23_EN]).
10-0 —	Reserved

Offset

Register	Offset
SM0_VAL3	16h
SM1_VAL3	76h
SM2_VAL3	D6h
SM3_VAL3	136h

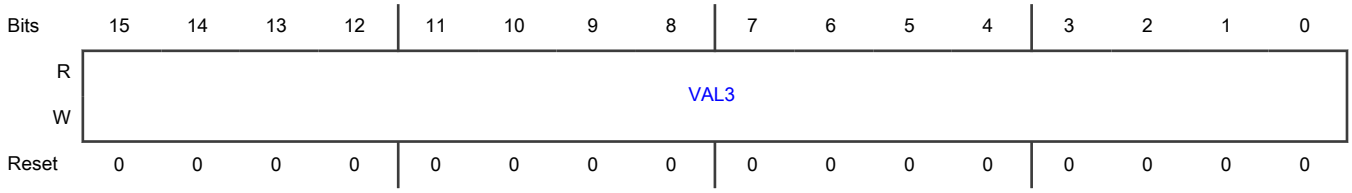
Function

Specifies the modulo count value 3 (maximum count) for the submodule counter.

NOTE

This register is buffered. The written value takes effect when software asserts submodule Load Okay (MCTRL[LDOK]) and the next PWM load cycle begins or immediately on assertion of Load Okay, depending on Load Mode Select (LDMOD). You cannot write this register when submodule Load Okay (MCTRL[LDOK]) is asserted. Reading this register returns the values in the buffer and not necessarily the values the PWM generator is currently using.

Diagram



Fields

Field	Function
15-0 VAL3	Timing Value 3 Specifies the count value to set PWM23 low. This field is not byte accessible.

56.7.13 Submodule a Fractional Value 4 (SM0_FRACVAL4 - SM3_FRACVAL4)

Offset

Register	Offset
SM0_FRACVAL4	18h
SM1_FRACVAL4	78h
SM2_FRACVAL4	D8h
SM3_FRACVAL4	138h

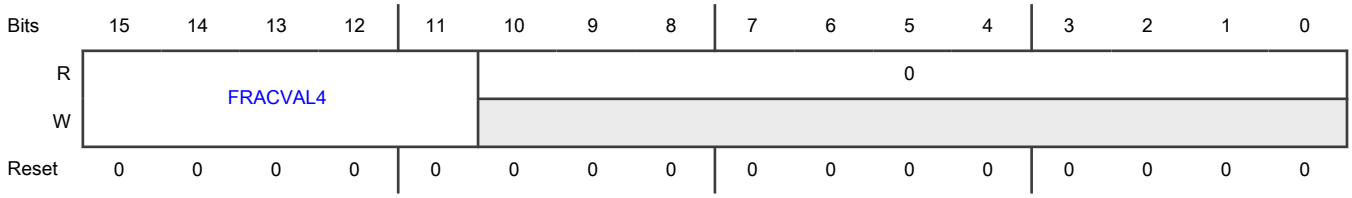
Function

Specifies the fractional addition to Submodule a Value 4 (SM0_VAL4 - SM3_VAL4) value for the submodule counter.

NOTE

This register is buffered. The written value takes effect when software asserts submodule Load Okay (MCTRL[LDOK]) and the next PWM load cycle begins or immediately on assertion of Load Okay, depending on Load Mode Select (LDMOD). You cannot write this register when submodule Load Okay (MCTRL[LDOK]) is asserted. Reading this register returns the values in the buffer and not necessarily the values the PWM generator is currently using.

Diagram



Fields

Field	Function
15-11 FRACVAL4	Fractional Timing Value 4 Specifies a fractional addition to Timing Value 4 (VAL4) that controls the PWM*n*_B turn-on timing. In complementary mode (SM*n*_CTRL2[INDEP] equal to 0) and using PWM45 (MCTRL[IPOL] equal to 1), the submodule also adds the fractional value to the turn-off delay of PWM*n*_A. **NOTE** When the values of VAL4 and SM*n*_VAL5[VAL5] cause the high or low time of the PWM output to be 3 counter units or less, you should disable fractional edge placement of PWM*n*_A using SM*n*_FRACVAL4[FRACVAL4] and SM*n*_FRACVAL5[FRACVAL5] (SM*n*_FRCTRL[FRAC45_EN]).

Field	Function
15-9 —	Reserved
8	Fractional Delay Power Up

Table continues on the next page...

Table continued from the previous page...

Field	Function
FRAC_PU	Powers up the fractional delay analog block to support fractional placement. The fractional delay block takes 25 µs to power up after writing the first FRAC_PU bit in any submodule. The fractional delay block powers down only when all submodule FRAC_PU fields are 0. The fractional delay logic can operate only when the IPBus clock runs at 100 MHz. When you turn off the fractional delay analog block, fractional placement is disabled. Before using fractional delay, you must clear the state of the analog block. 1. Power up the fractional delay analog block. 2. Wait 25 µs. 3. Load the PWM timing values to create a PWM output with greater than 0% duty cycle. 4. Run the PWM for at least one PWM period. You can do this without enabling outputs. 0b - Off 1b - On
7-5 —	Reserved
4 FRAC45_EN	Fractional Cycle Placement Enable for PWMn_B Enables fractional cycle edge placement for PWM*n*_B period using Fractional Value 4 and 5 (SM*n*_FRACVAL4[FRACVAL4] and SM*n*_FRACVAL5[FRACVAL5]). When disabled, the submodule bypasses the fractional cycle edge placement of PWM*n*_B. **NOTE** This register is buffered. The written value takes effect when software asserts submodule Load Okay (MCTRL[LDOK]) and the next PWM load cycle begins or immediately on assertion of Load Okay, depending on Load Mode Select (LDMOD). You cannot write this register when submodule Load Okay (MCTRL[LDOK]) is asserted. Reading FRAC45_EN returns the value in the buffer and not necessarily the value the PWM generator is currently using. 0b - Disable 1b - Enable
3 —	Reserved
2 FRAC23_EN	Fractional Cycle Placement Enable for PWMn_A Enables fractional cycle edge placement for PWM*n*_A period using Fractional Value 2 and 3 (SM*n*_FRACVAL2[FRACVAL2] and SM*n*_FRACVAL3[FRACVAL3]). When disabled, the submodule bypasses the fractional cycle edge placement of PWM*n*_A.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This register is buffered. The written value takes effect when software asserts submodule Load Okay (MCTRL[LDOK]) and the next PWM load cycle begins or immediately on assertion of Load Okay, depending on Load Mode Select (LDMOD). You cannot write this register when submodule Load Okay (MCTRL[LDOK]) is asserted. Reading FRAC23_EN returns the value in the buffer and not necessarily the value the PWM generator is currently using. 0b - Disable 1b - Enable
1 FRAC1_EN	Fractional Cycle PWM Period Enable Enables fractional cycle length for the PWM period using Fractional Value 1 (SM*n*_FRACVAL1[FRACVAL1]). When disabled, the submodule bypasses the fractional cycle length of the PWM period. **NOTE** This register is buffered. The written value takes effect when software asserts submodule Load Okay (MCTRL[LDOK]) and the next PWM load cycle begins or immediately on assertion of Load Okay, depending on Load Mode Select (LDMOD). You cannot write this register when submodule Load Okay (MCTRL[LDOK]) is asserted. Reading FRAC1_EN returns the value in the buffer and not necessarily the value the PWM generator is currently using. 0b - Disable 1b - Enable
0 —	Reserved

56.7.18 Submodule a Output Control (SM0_OCTRL - SM3_OCTRL)

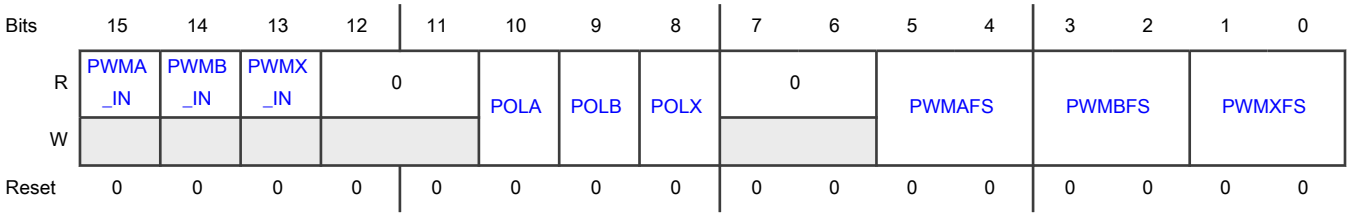
Offset

Register	Offset
SM0_OCTRL	22h
SM1_OCTRL	82h
SM2_OCTRL	E2h
SM3_OCTRL	142h

Function

Provides control of PWM output functioning.

Diagram



Fields

Field	Function
15 PWMA_IN	PWMn_A Input Indicates the logic value currently being driven into the PWM*n*_A input. The field reset state is undefined.
14 PWMB_IN	PWMn_B Input Indicates the logic value currently being driven into the PWMn_B input. The field reset state is undefined.
13 PWMX_IN	PWMn_X Input Indicates the logic value currently being driven into the PWM*n*_X input. The field reset state is undefined.
12-11 —	Reserved
10 POLA	PWMn_A Output Polarity Inverts the PWM*n*_A output polarity. 0b - Not inverted. PWMn_A is active high. 1b - Inverted. PWMn_A is active low.
9 POLB	PWMn_B Output Polarity Inverts the PWM*n*_B output polarity. 0b - Not inverted. PWMn_B is active high. 1b - Inverted. PWMn_B is active low.
8 POLX	PWMn_X Output Polarity Inverts the PWM*n*_X output polarity. 0b - Not inverted. PWMn_X is active high. 1b - Inverted. PWMn_X is active low.
7-6 —	Reserved
5-4 PWMAFS	PWMn_A Fault State

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Specifies the fault state for the PWM*n*_A output during fault conditions and STOP mode. It may also specify the output state during Wait and Debug modes depending on Wait Enable (SM*n*_CTRL2[WAITEN]) and Debug Enable (SM*n*_CTRL2[DBGEN]). 00b - Forced to logic 0 before consideration of output polarity control 01b - Forced to logic 1 before consideration of output polarity control 10b - Tristated 11b - Tristated
3-2 PWMBFS	PWMn_B Fault State Specifies the fault state for the PWM*n*_B output during fault conditions and STOP mode. It may also specify the output state during Wait and Debug modes depending on Wait Enable (SM*n*_CTRL2[WAITEN]) and Debug Enable (SM*n*_CTRL2[DBGEN]). 00b - Forced to logic 0 before consideration of output polarity control 01b - Forced to logic 1 before consideration of output polarity control 10b - Tristated 11b - Tristated
1-0 PWMXFS	PWMn_X Fault State Specifies the fault state for the PWM*n*_X output during fault conditions and Stop mode. It may also specify the output state during Wait and Debug modes depending on Wait Enable (SM*n*_CTRL2[WAITEN]) and Debug Enable (SM*n*_CTRL2[DBGEN]). 00b - Forced to logic 0 before consideration of output polarity control 01b - Forced to logic 1 before consideration of output polarity control 10b - Tristated 11b - Tristated

56.7.19 Submodule a Status (SM0_STS - SM3_STS)

Offset

Register	Offset
SM0_STS	24h
SM1_STS	84h
SM2_STS	E4h
SM3_STS	144h

Function

Provides access to several status flags of compare, capture, and reload error interrupts.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	RUF	REF	RF	CFA1	CFA0	CFB1	CFB0	CFX1	CFX0	CMPF					
W			W1C	W1C	W1C	W1C	W1C	W1C	W1C	W1C	W1C					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15 —	Reserved
14 RUF	Registers Updated Flag Indicates that the Initial Count, one of the timing values, one of the fractional timing values, or the prescaler has been written, which indicates potentially non-coherent data in the set of double-buffered registers. Clear this bit by a proper reload sequence consisting of a reload signal with Load Okay enabled (MCTRL[LDOK]). 0b - No register update since last reload 1b - At least one double-buffered register updated since last reload
13 REF	Reload Error Flag Indicates a reload occurred while Load Okay is disabled (MCTRL[LDOK]) and the double-buffered registers are in a non-coherent state (SM*n*_STS[RUF] = 1). Clear this field by writing one to it. 0b - No reload error 1b - Reload error
12 RF	Reload Flag Indicates a reload has occurred since the last time the field was cleared. The submodule sets this flag at the beginning of every reload regardless of the state of Load Okay (MCTRL[LDOK]). If Value Registers DMA (SM*n*_DMAEN[VALDE]) is disabled, clear this flag by writing one to it. Otherwise, the DMA done signal clears this bit.. 0b - No new reload since last clearing 1b - New reload since last clearing
11 CFA1	Capture A1 Flag Indicates a capture event has occurred on the Capture A1 circuit. If Capture A1 FIFO DMA (SM*n*_DMAEN[CA1DE]) is not enabled, clear the field by writing one to it. Otherwise, the DMA done signal clears this field.
10 CFA0	Capture A0 Flag Indicates a capture event has occurred on the Capture A0 circuit. If Capture A0 FIFO DMA (SM*n*_DMAEN[CA0DE]) is not enabled, clear the field by writing one to it. Otherwise, the DMA done signal clears this field.
9	Capture B1 Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
CFB1	Indicates a capture event has occurred on the Capture B1 circuit. If Capture B1 FIFO DMA (SM*n*_DMAEN[CB1DE]) is not enabled, clear the field by writing one to it. Otherwise, the DMA done signal clears this field.
8 CFB0	Capture B0 Flag Indicates a capture event has occurred on the Capture B0 circuit. If Capture B0 FIFO DMA (SM*n*_DMAEN[CB0DE]) is not enabled, clear the field by writing one to it. Otherwise, the DMA done signal clears this field.
7 CFX1	Capture X1 Flag Indicates a capture event has occurred on the Capture X1 circuit. If Capture X1 FIFO DMA (SM*n*_DMAEN[CX1DE]) is not enabled, clear the field by writing one to it. Otherwise, the DMA done signal clears this field.
6 CFX0	Capture X0 Flag Indicates a capture event has occurred on the Capture X0 circuit. If Capture X0 FIFO DMA (SM*n*_DMAEN[CX0DE]) is not enabled, clear the field by writing one to it. Otherwise, the DMA done signal clears this field.
5-0 CMPF	Compare Flags Indicate when the submodule counter value matches the value of one of the timing values. Each bit position of the field corresponds to the like-numbered timing value (SM*n*_VAL*m*) register. Clear a bit by writing a 1 to the bit position. 00_0000b - No compare event has occurred. 00_0001b - A compare event has occurred.

56.7.20 Submodule a Interrupt Enable (SM0_INTEN - SM3_INTEN)

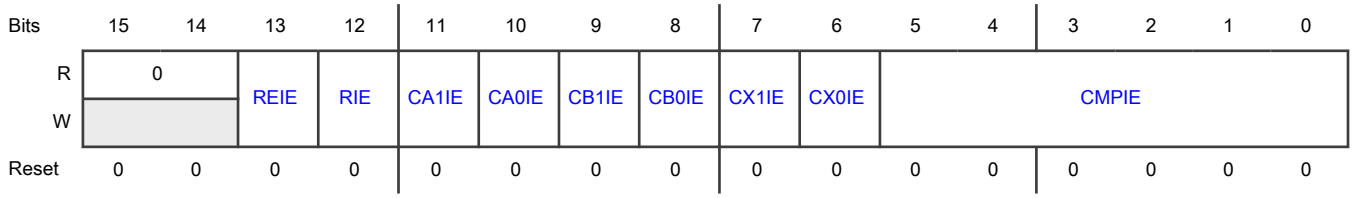
Offset

Register	Offset
SM0_INTEN	26h
SM1_INTEN	86h
SM2_INTEN	E6h
SM3_INTEN	146h

Function

Provides access to enabling of compare, capture, and reload error interrupts.

Diagram



Fields

Field	Function
15-14 —	Reserved
13 REIE	Reload Error Interrupt Enable Enables the reload error flag (SM*n*_STS[REF]) to trigger an IRQ to the CPU. 0b - Disable 1b - Enable
12 RIE	Reload Interrupt Enable Enables the reload flag (SM*n*_STS[RF]) to trigger an IRQ to the CPU. 0b - Disable 1b - Enable
11 CA1IE	Capture A1 Interrupt Enable Enables Capture A1 Flag (SM*n*_STS[CFA1]) to trigger an IRQ to the CPU. **NOTE** Do not enable both Capture A1 Interrupt and Capture A1 FIFO DMA (SM*n*_DMAEN[CA1DE]) at the same time. 0b - Disable 1b - Enable
10 CA0IE	Capture A0 Interrupt Enable Enables Capture A0 Flag (SM*n*_STS[CFA0]) to trigger an IRQ to the CPU. **NOTE** Do not enable both Capture A0 Interrupt and Capture A0 FIFO DMA (SM*n*_DMAEN[CA0DE]) at the same time. 0b - Disable 1b - Enable
9 CB1IE	Capture B1 Interrupt Enable Enables Capture B1 Flag (SM*n*_STS[CFB1]) to trigger an IRQ to the CPU.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE Do not enable both Capture B1 Interrupt and Capture B1 FIFO DMA (SM*n*_DMAEN[CB1DE]) at the same time. 0b - Disable 1b - Enable
8 CB0IE	Capture B0 Interrupt Enable Enables Capture B0 Flag (SM*n*_STS[CFB0]) to trigger an IRQ to the CPU. **NOTE** Do not enable both Capture B0 Interrupt and Capture B0 FIFO DMA (SM*n*_DMAEN[CB0DE]) at the same time. 0b - Disable 1b - Enable
7 CX1IE	Capture X1 Interrupt Enable Enables Capture X1 Flag (SM*n*_STS[CFX1]) to trigger an IRQ to the CPU. **NOTE** Do not enable both Capture X1 Interrupt and Capture X1 FIFO DMA (SM*n*_DMAEN[CX1DE]) at the same time. 0b - Disable 1b - Enable
6 CX0IE	Capture X0 Interrupt Enable Enables Capture X0 Flag (SM*n*_STS[CFX0]) to trigger an IRQ to the CPU. **NOTE** Do not enable both Capture X0 Interrupt and Capture X0 FIFO DMA (SM*n*_DMAEN[CX0DE]) at the same time. 0b - Disable 1b - Enable
5-0 CMPIE	Compare Interrupt Enables Enables the Compare Flags (SM*n*_STS[CMPF]) to trigger a compare IRQ to the CPU. Each bit position in the field corresponds to the like-numbered timing value register (SM*n*VAL*m*). 00_0000b - Disable 00_0001b - Enable

56.7.21 Submodule a DMA Enable (SM0_DMAEN - SM3_DMAEN)

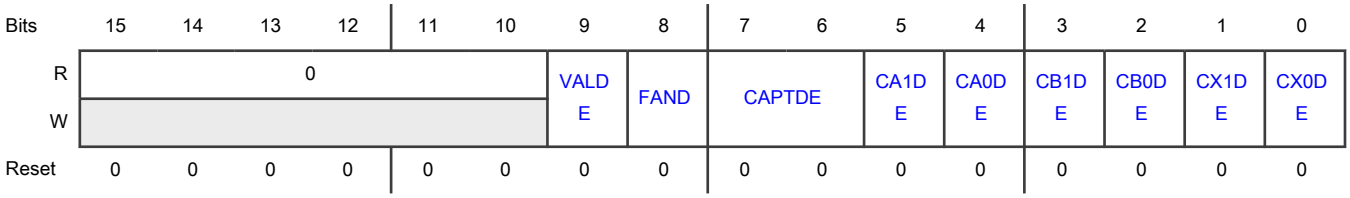
Offset

Register	Offset
SM0_DMAEN	28h
SM1_DMAEN	88h
SM2_DMAEN	E8h
SM3_DMAEN	148h

Function

Provides enabling of DMA interrupts.

Diagram



Fields

Field	Function
15-10 —	Reserved
9 VALDE	Value Registers DMA Enable Enables DMA write requests for the timing and fractional timing value (SM*n*_VAL*m*) registers when the Reload Flag (SM*n*_STS[RF]) is set. 0b - Disable 1b - Enable
8 FAND	FIFO Watermark AND Control Specifies the logic operation applied to the capture FIFO DMA enables to set the DMA request when the capture DMA source is watermark mode (SM*n*_DMAEN[CAPTDE] equal to 01b). 0b - OR: Any enabled FIFO watermark exceeded sets the DMA request 1b - AND: All enabled FIFO watermarks must be exceeded to set the DMA request
7-6 CAPTDE	Capture DMA Enable Source Select Selects the source for enabling DMA read requests for the capture FIFOs. 00b - Disable read DMA requests

Table continues on the next page...

Table continued from the previous page...

Field	Function
	01b - Exceeding a FIFO watermark. Exceeding a FIFO watermark. At least one of SM*n*_DMAEN[CA1DE], SM*n*_DMAEN[CA0DE], SM*n*_DMAEN[CB1DE], SM*n*_DMAEN[CB0DE], SM*n*_DMAEN[CX1DE], or SM*n*_DMAEN[CX0DE] must also be enabled to determine which watermarks set the DMA request. 10b - Local sync. Local sync occurs when the counter matches SM*n*_VAL1[VAL1]). 11b - Local reload. Local reload is signaled by the reload flag (SM*n*_STS[RF]).
5 CA1DE	Capture A1 FIFO DMA Enable Enables DMA read requests for the Capture A1 FIFO data when the Capture A1 flag (SM*n*_STS[CFA1]) is set. **NOTE** Do not enable both Capture A1 Interrupt (SM*n*_INTEN[CA1IE]) and Capture A1 FIFO DMA at the same time. 0b - Disable 1b - Enable
4 CA0DE	Capture A0 FIFO DMA Enable Enables DMA read requests for the Capture A0 FIFO data when the Capture A0 flag (SM*n*_STS[CFA0]) is set. **NOTE** Do not enable both Capture A0 Interrupt (SM*n*_INTEN[CA0IE]) and Capture A0 FIFO DMA at the same time. 0b - Disable 1b - Enable
3 CB1DE	Capture B1 FIFO DMA Enable Enables DMA read requests for the Capture B1 FIFO data when the Capture B1 flag (SM*n*_STS[CFB1]) is set. **NOTE** Do not enable both Capture B1 Interrupt (SM*n*_INTEN[CB1IE]) and Capture B1 FIFO DMA at the same time. 0b - Disable 1b - Enable
2 CB0DE	Capture B0 FIFO DMA Enable Enables DMA read requests for the Capture B0 FIFO data when the Capture B0 flag (SM*n*_STS[CFB0]) is set.

0 CX0DE	Capture X0 FIFO DMA Enable Enables DMA read requests for the Capture X0 FIFO data when the Capture X0 flag (SM*n*_STS[CFX0]) is set. **NOTE** Do not enable both Capture X0 Interrupt (SM*n*_INTEN[CX0IE]) and Capture X0 FIFO DMA at the same time. 0b - Disable 1b - Enable

56.7.22 Submodule a Output Trigger Control (SM0_TCTRL - SM3_TCTRL)

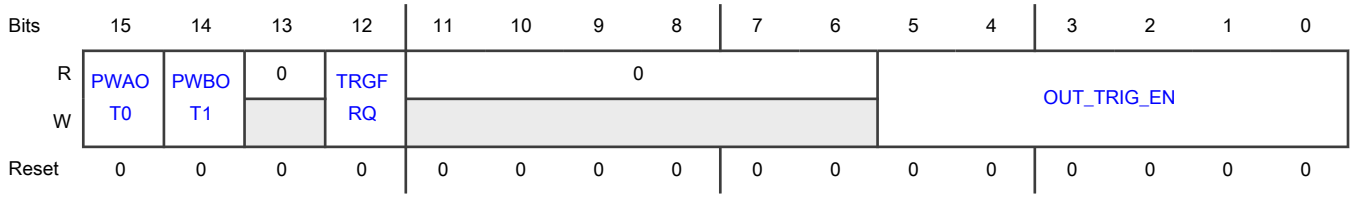
Offset

Register	Offset
SM0_TCTRL	2Ah
SM1_TCTRL	8Ah
SM2_TCTRL	EAh
SM3_TCTRL	14Ah

Function

Specifies the behavior of the output triggers.

Diagram



Fields

Field	Function
15 PWAOT0	Mux Output Trigger 0 Source Select Selects which signal to route to the PWM*n*_MUX_TRIG0 port. 0b - Route PWMn_OUT_TRIG0 signal to PWMn_MUX_TRIG0 port. 1b - Route PWMn_A output to PWMn_MUX_TRIG0 port.
14 PWBOT1	Mux Output Trigger 1 Source Select Selects which signal to route to the PWM*n*_MUX_TRIG1 port. 0b - Route PWMn_OUT_TRIG1 signal to PWMn_MUX_TRIG1 port. 1b - Route PWMn_B output to PWMn_MUX_TRIG1 port.
13 —	Reserved
12 TRGFRQ	Trigger Frequency Enables control of the frequency of the trigger outputs when using non-zero load frequency (SM*n*_CTRL[LDFQ]) values. 0b - Every period. Trigger outputs generated during every PWM period, even if the PWM is not reloaded every period due to non-zero load frequency (SM*n*_CTRL[LDFQ]). 1b - Final period. Trigger outputs generated only during the final PWM period before a reload opportunity when the PWM is not reloaded every period due to non-zero load frequency (SM*n*_CTRL[LDFQ]).
11-6 —	Reserved
5-0 OUT_TRIG_EN	Output Trigger Enables Enables the generation of the PWM*n*_OUT_TRIG0 and PWM*n*_OUT_TRIG1 outputs when the counter value matches one or more of the timing values (SM*n*_VAL*m*). **NOTE** Due to delays in creating the PWM outputs, the output trigger signals lead the PWM output edges by 2-3 clock cycles depending on the fractional cycle value. 1x_xxxxb - PWMn_OUT_TRIG1 set by Timing Value 5. PWMn_OUT_TRIG1 set by Timing Value 5 (SM*n*_VAL5[VAL5])

Table continued from the previous page...

Field	Function
11-8 DIS1X	PWMn_X Fault Disable Mask 1 Selects which fault inputs on fault channel 1 turn off the PWM*n*_X output. Each bit position in the field corresponds to the like-numbered FAULTn input on fault channel 1. If you write 1 to one of these bits, then assertion of the corresponding FAULTn input turns off the PWM*n*_X output. Reset sets all bits in this field.
7-4 DIS1B	PWMn_B Fault Disable Mask 1 Selects which fault inputs on fault channel 1 turn off the PWM*n*_B output. Each bit position in the field corresponds to the like-numbered FAULTn input on fault channel 1. If you write 1 to one of these bits, then assertion of the corresponding FAULTn input turns off the PWM*n*_B output. Reset sets all bits in this field.
3-0 DIS1A	PWMn_A Fault Disable Mask 1 Selects which fault inputs on fault channel 1 turn off the PWM*n*_A output. Each bit position in the field corresponds to the like-numbered FAULTn input on fault channel 1. If you write 1 to one of these bits, then assertion of the corresponding FAULTn input turns off the PWM*n*_A output. Reset sets all bits in this field.

56.7.25 Submodule a Deadtime Count 0 (SM0_DTCNT0 - SM3_DTCNT0)

Offset

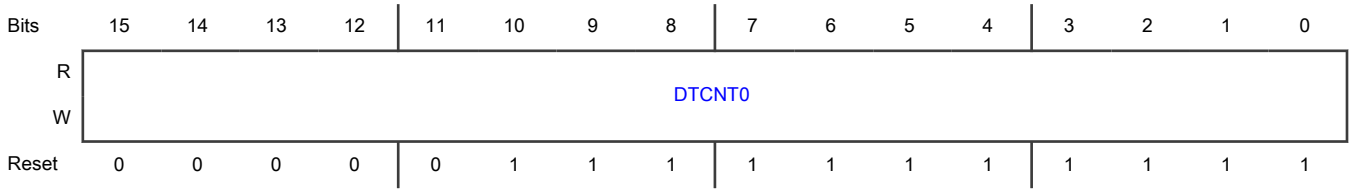
Register	Offset
SM0_DTCNT0	30h
SM1_DTCNT0	90h
SM2_DTCNT0	F0h
SM3_DTCNT0	150h

Function

Specifies the deadtime in IPBus clock cycles during the transition from deassertion to assertion of the PWM*n*_A output (assuming normal polarity).

Deadtime operation applies only to complementary channel operation. The deadtime value represents IPBus clock cycles regardless of the prescaler value (SM*n*_CTRL[PRSC]) or the selected clock source (SM0_CTRL2[CLK_SEL]). Reset sets the deadtime count for each output to a default value of 07FFh, or 2047 IPBus clock cycles.

Diagram



Fields

Field	Function
15-0 DTCNT0	Deadtime Count 0 Specifies the deadtime in IPBus clock cycles during the transition from deassertion to assertion of the PWM*n*_A output (assuming normal polarity). If you disable fractional delays (SM*n*_FRCTRL[FRAC23_EN]), then the submodule ignores the upper 5 bits and uses the lower 11 bits to specify the number of cycles of deadtime. In this case, the maximum value is 07FFh, which indicates 2047 cycles of deadtime. If you enable fractional delays, then the upper 11 bits represent the number of whole cycles of deadtime and the lower 5 bits represent the fractional cycle added to the whole number. In this case, the maximum value is 0xFFFF, which represents 2047 31/32 cycles of deadtime. This field is not byte accessible.

56.7.26 Submodule a Deadtime Count 1 (SM0_DTCNT1 - SM3_DTCNT1)

Offset

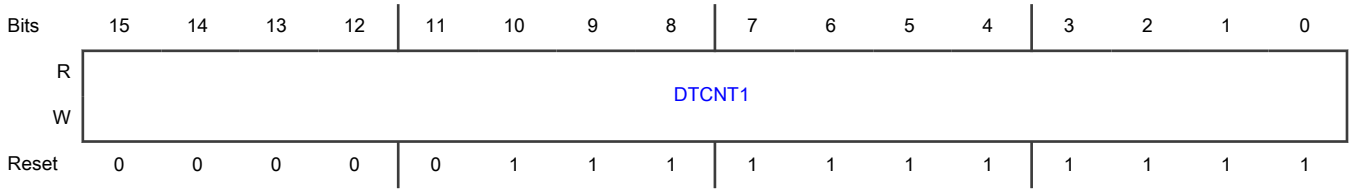
Register	Offset
SM0_DTCNT1	32h
SM1_DTCNT1	92h
SM2_DTCNT1	F2h
SM3_DTCNT1	152h

Function

Specifies the deadtime in IPBus clock cycles during the transition from deassertion to assertion of the PWM*n*_B output (assuming normal polarity).

Deadtime operation applies only to complementary channel operation. The deadtime value represents IPBus clock cycles regardless of the prescaler value (SM*n*_CTRL[PRSC]) or the selected clock source (SM0_CTRL2[CLK_SEL]). Reset sets the deadtime count for each output to a default value of 07FFh, or 2047 IPBus clock cycles.

Diagram



Fields

Field	Function
15-0 DTCNT1	Deadtime Count 1 Specifies the deadtime in IPBus clock cycles during the transition from deassertion to assertion of the PWM*n*_B output (assuming normal polarity). If you disable fractional delays (SM*n*_FRCTRL[FRAC45_EN]), then the submodule ignores the upper 5 bits and uses the lower 11 bits to specify the number of cycles of deadtime. In this case, the maximum value is 07FFh, which indicates 2047 cycles of deadtime. If you enable fractional delays, then the upper 11 bits represent the number of whole cycles of deadtime and the lower 5 bits represent the fractional cycle added to the whole number. In this case, the maximum value is 0xFFFF, which represents 2047 31/32 cycles of deadtime. This field is not byte accessible.

56.7.27 Submodule a Capture Control A (SM0_CAPTCTRLA - SM3_CAPTCTRLA)

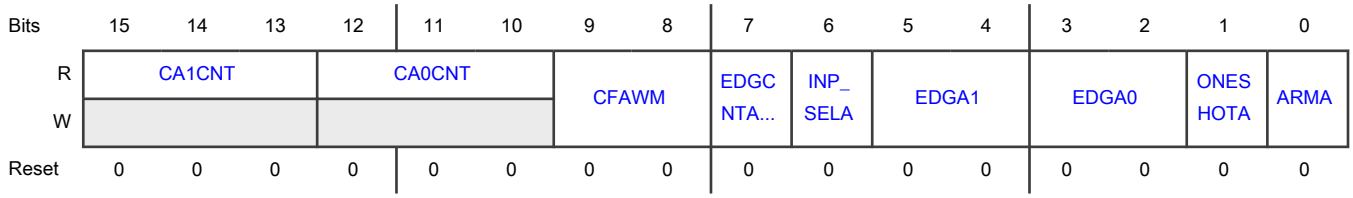
Offset

Register	Offset
SM0_CAPTCTRLA	34h
SM1_CAPTCTRLA	94h
SM2_CAPTCTRLA	F4h
SM3_CAPTCTRLA	154h

Function

Controls the input capture process for PWM*n*_A.

Diagram



Fields

Field	Function
15-13 CA1CNT	Capture A1 FIFO Word Count Indicates the number of words in the Capture A1 FIFO (FIFO depth is 1).
12-10 CA0CNT	Capture A0 FIFO Word Count Indicates the number of words in the Capture A0 FIFO (FIFO depth is 1).
9-8 CFAWM	Capture A FIFOs Watermark Specifies the watermark level for capture A FIFOs. The submodule sets the capture flags (SM*n*_STS[CFA1] and SM*n*_STS[CFA0]) when the word count of the corresponding FIFO is greater than this value (FIFO depth is 1).
7 EDGCNTA_EN	Edge Counter A Enable Enables the edge counter that counts rising and falling edges on the PWM*n*_A input signal. 0b - Disable and hold in reset 1b - Enable
6 INP_SELA	Input Select A Selects between the raw PWM*n*_A input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit. 0b - Raw PWMn_A input signal 1b - Output of edge counter/compare. Output of edge counter/compare. Enables the internal edge counter and ignores the rising or falling edges specified by SM*n*_CAPTCTRLA[EDGA0] and SM*n*_CAPTCTRLA[EDGA1]. To enable one or both of the capture registers, you must still place a non-zero value in either or both EDGA0 and EDGA1.
5-4 EDGA1	Edge A 1 Specifies which input edges cause a capture event for the input capture 1 circuit. 00b - Disable 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
3-2	Edge A 0 Specifies which input edges cause a capture event for the input capture 0 circuit.

Table continues on the next page...

Table continued from the previous page...

Field	Function
EDGA0	00b - Disable 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
1 ONESHOTA	One Shot Mode A Selects free-running or one-shot mode for the input capture circuits. If you enable both capture circuits (SM*n*_CAPTCTRLA[EDGA0] and SM*n*_CAPTCTRLA[EDGA1]) and arm input capture (SM*n*_CAPTCTRLA[ARMA]), the submodule arms capture circuit 0 first. When capture circuit 0 performs a capture, the submodule disarms capture circuit 0 and arms capture circuit 1. In free-running mode, when capture circuit 1 performs a capture, the submodule disarms capture circuit 1 and rearms capture circuit 0. The process continues indefinitely. If you enable only one capture circuit, then captures continue indefinitely on the enabled capture circuit. In one-shot mode, when capture circuit 1 performs a capture, the submodule disarms capture circuit 1 and disarms input capture (SM*n*_CAPTCTRLA[ARMA]). The submodule performs no more captures until you rearm input capture (SM*n*_CAPTCTRLA[ARMA]). If you enable only one of the capture circuits, the submodule performs a single capture on the enabled capture circuit and then disarms input capture (ARMA). 0b - Free-running 1b - One-shot
0 ARMA	Arm A Arms or disarms the input capture process. In one-shot mode, the submodule terminates input capture when either capture circuit detects a capture event. 0b - Disarm input capture 1b - Arm input capture as specified by the input edges. Arm input capture as specified by the input edges (SM*n*_CAPTCTRLA[EDGA0] and SM*n*_CAPTCTRL*m*[EDGA1]).

56.7.28 Submodule a Capture Compare A (SM0_CAPTCOMPA - SM3_CAPTCOMPA)

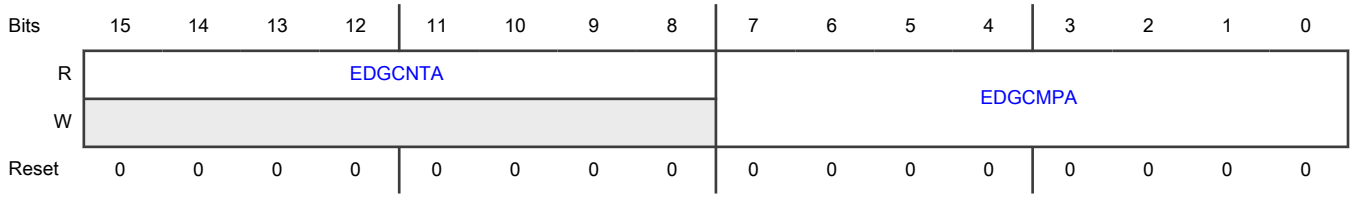
Offset

Register	Offset
SM0_CAPTCOMPA	36h
SM1_CAPTCOMPA	96h
SM2_CAPTCOMPA	F6h
SM3_CAPTCOMPA	156h

Function

Specifies the behavior of capture compare A.

Diagram



Fields

Field	Function
15-8 EDGCNTA	Edge Counter A Indicates the edge counter value for the PWM*n*_A input capture circuitry.
7-0 EDGCMPA	Edge Compare A Specifies the compare value associated with the edge counter for the PWM*n*_A input capture circuitry.

56.7.29 Submodule a Capture Control B (SM0_CAPTCTRLB - SM3_CAPTCTRLB)

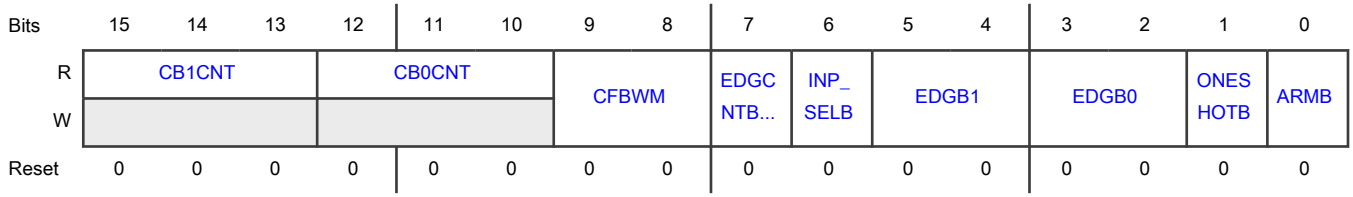
Offset

Register	Offset
SM0_CAPTCTRLB	38h
SM1_CAPTCTRLB	98h
SM2_CAPTCTRLB	F8h
SM3_CAPTCTRLB	158h

Function

Controls the input capture process for PWM*n*_B.

Diagram



Fields

Field	Function
15-13 CB1CNT	Capture B1 FIFO Word Count Indicates the number of words in the Capture B1 FIFO (FIFO depth is 1).

Table continues on the next page...

Table continued from the previous page...

Field	Function
12-10 CB0CNT	Capture B0 FIFO Word Count Indicates the number of words in the Capture B0 FIFO (FIFO depth is 1).
9-8 CFBWM	Capture B FIFOs Watermark Specifies the watermark level for capture B FIFOs. The submodule sets the capture flags (SM*n*_STS[CFB1] and SM*n*_STS[CFB0]) when the word count of the corresponding FIFO is greater than this value (FIFO depth is 1).
7 EDGCNTB_EN	Edge Counter B Enable Enables the edge counter that counts rising and falling edges on the PWM*n*_B input signal. 0b - Disable and hold in reset 1b - Enable
6 INP_SELB	Input Select B Selects between the raw PWM*n*_B input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit. 0b - Raw PWMn_B input signal 1b - Output of edge counter/compare. Output of edge counter/compare. Enables the internal edge counter and ignores the rising or falling edges specified by SM*n*_CAPTCTRLB[EDGB0] and SM*n*_CAPTCTRLB[EDGB1]. To enable one or both of the capture registers, you must still place a non-zero value in either or both SM*n*_CAPTCTRLB[EDGB0] and SM*n*_CAPTCTRLB[EDGB1].
5-4 EDGB1	Edge B 1 Specifies which input edges cause a capture event for the input capture 1 circuit. 00b - Disable 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
3-2 EDGB0	Edge B 0 Specifies which input edges cause a capture event for the input capture 0 circuit. 00b - Disable 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
1 ONESHOTB	One Shot Mode B Selects free-running or one-shot mode for the input capture circuits.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If you enable both capture circuits (SM*n*_CAPTCTRLB[EDGB0] and SM*n*_CAPTCTRLB[EDGB1]) and arm input capture (ARMB), the submodule arms capture circuit 0 first. When capture circuit 0 performs a capture, the submodule disarms capture circuit 0 and arms capture circuit 1. In free-running mode, when capture circuit 1 performs a capture, the submodule disarms capture circuit 1 and rearms capture circuit 0. The process continues indefinitely. If you enable only one capture circuit, then captures continue indefinitely on the enabled capture circuit. In one-shot mode, when capture circuit 1 performs a capture, the submodule disarms capture circuit 1 and disarms input capture (SM*n*_CAPTCTRLB[ARMB]). The submodule performs no more captures until you rearm input capture (SM*n*_CAPTCTRLB[ARMB]). If you enable only one of the capture circuits, the submodule performs a single capture on the enabled capture circuit and then disarms input capture (ARMB). 0b - Free-running 1b - One-shot
0 ARMB	Arm B Arms or disarms the input capture process. In one-shot mode, the submodule terminates input capture when either capture circuit detects a capture event. 0b - Disarm input capture 1b - Arm input capture as specified by EDGBn

56.7.30 Submodule a Capture Compare B (SM0_CAPTCOMPB - SM3_CAPTCOMPB)

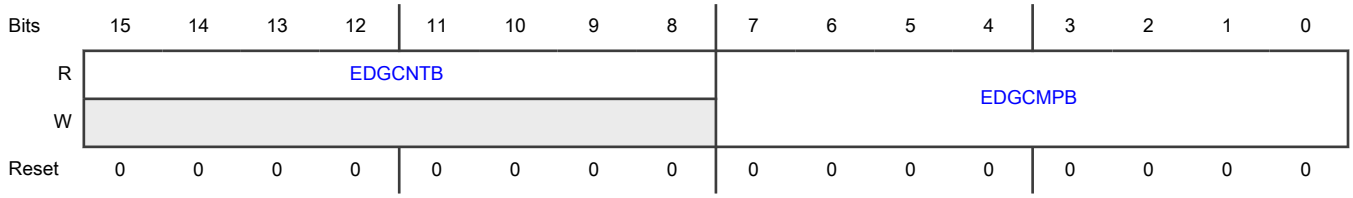
Offset

Register	Offset
SM0_CAPTCOMPB	3Ah
SM1_CAPTCOMPB	9Ah
SM2_CAPTCOMPB	FAh
SM3_CAPTCOMPB	15Ah

Function

Specifies the behavior of capture compare B.

Diagram



Fields

Field	Function
15-8 EDGCNTB	Edge Counter B Indicates the edge counter value for the PWM*n*_B input capture circuitry.
7-0 EDGCMPB	Edge Compare B Specifies the compare value associated with the edge counter for the PWM*n*_B input capture circuitry.

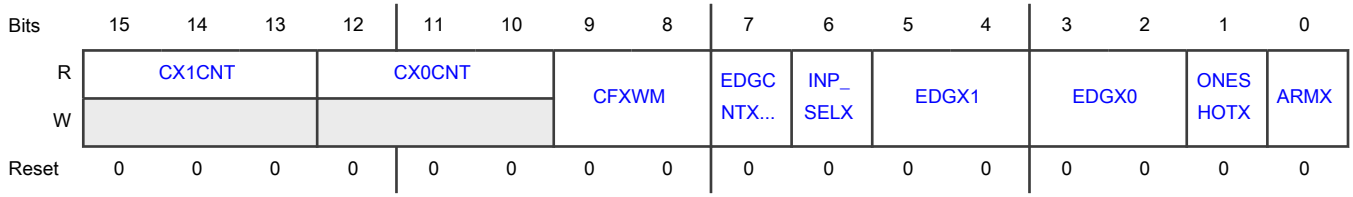
56.7.31 Submodule a Capture Control X (SM0_CAPTCTRLX - SM3_CAPTCTRLX)

Offset

Register	Offset
SM0_CAPTCTRLX	3Ch
SM1_CAPTCTRLX	9Ch
SM2_CAPTCTRLX	FCh
SM3_CAPTCTRLX	15Ch

Function
Controls the input capture process for PWM*n*_X.

Diagram



Fields

Field	Function
15-13 CX1CNT	Capture X1 FIFO Word Count Indicates the number of words in the Capture X1 FIFO (FIFO depth is 1).

Table continues on the next page...

Table continued from the previous page...

Field	Function
12-10 CX0CNT	Capture X0 FIFO Word Count Indicates the number of words in the Capture X0 FIFO (FIFO depth is 1).
9-8 CFXWM	Capture X FIFOs Watermark Specifies the watermark level for capture X FIFOs. The submodule sets the capture flags (SM*n*_STS[CFX1] and SM*n*_STS[CFX0]) when the word count of the corresponding FIFO is greater than this value (FIFO depth is 1).
7 EDGCNTX_EN	Edge Counter X Enable Enables the edge counter that counts rising and falling edges on the PWM*n*_X input signal. 0b - Disable and hold in reset 1b - Enable
6 INP_SELX	Input Select X Selects between the raw PWM*n*_X input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit. 0b - Raw PWMn_X input signal 1b - Output of edge counter/compare. Output of edge counter/compare. Enables the internal edge counter and ignores the rising or falling edges specified by SM*n*_CAPTCTRLX[EDGX0] and SM*n*_CAPTCTRLX[EDGX1]. To enable one or both of the capture registers, you must still place a non-zero value in either or both SM*n*_CAPTCTRLX[EDGX0] and SM*n*_CAPTCTRLX[EDGX1].
5-4 EDGX1	Edge X 1 Specifies which input edges cause a capture event for the input capture 1 circuit. 00b - Disable 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
3-2 EDGX0	Edge X 0 Specifies which input edges cause a capture event for the input capture 0 circuit. 00b - Disable 01b - Capture falling edges 10b - Capture rising edges 11b - Capture any edge
1 ONESHOTX	One Shot Mode X Selects free-running or one-shot mode for the input capture circuits.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If you enable both capture circuits (SM*n*_CAPTCTRLX[EDGX0] and SM*n*_CAPTCTRLX[EDGX1]) and arm input capture (SM*n*_CAPTCTRLX[ARMX]), the submodule arms capture circuit 0 first. When capture circuit 0 performs a capture, the submodule disarms capture circuit 0 and arms capture circuit 1. In free-running mode, when capture circuit 1 performs a capture, the submodule disarms capture circuit 1 and rearms capture circuit 0. The process continues indefinitely. If you enable only one capture circuit, then captures continue indefinitely on the enabled capture circuit. In one-shot mode, when capture circuit 1 performs a capture, the submodule disarms capture circuit 1 and disarms input capture (SM*n*_CAPTCTRLX[ARMX]). The submodule performs no more captures until you rearm input capture (SM*n*_CAPTCTRLX[ARMX]). If you enable only one of the capture circuits, the submodule performs a single capture on the enabled capture circuit and then disarms input capture (ARMX). 0b - Free-running 1b - One-shot
0 ARMX	Arm X Arms or disarms the input capture process. In one-shot mode, the submodule terminates input capture when either capture circuit detects a capture event. 0b - Disarm input capture 1b - Arm input capture as specified by EDGAn

56.7.32 Submodule a Capture Compare X (SM0_CAPTCOMPX - SM3_CAPTCOMPX)

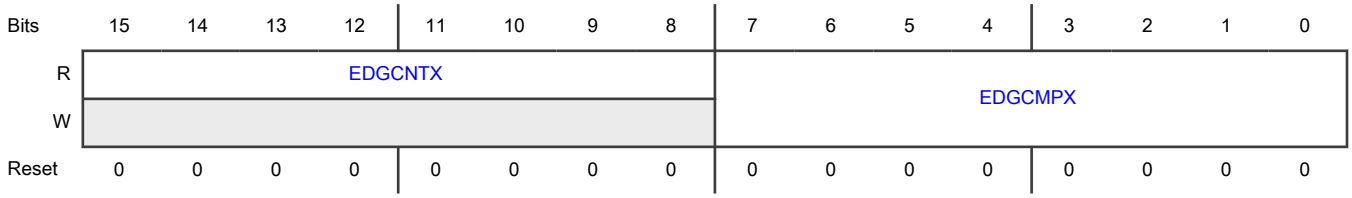
Offset

Register	Offset
SM0_CAPTCOMPX	3Eh
SM1_CAPTCOMPX	9Eh
SM2_CAPTCOMPX	FEh
SM3_CAPTCOMPX	15Eh

Function

Specifies the behavior of capture compare X.

Diagram



Fields

Field	Function
15-8 EDGCNTX	Edge Counter X Indicates the edge counter value for the PWM*n*_X input capture circuitry.
7-0 EDGCMPX	Edge Compare X Specifies the compare value associated with the edge counter for the PWM*n*_X input capture circuitry.

56.7.33 Submodule a Capture Value 0 (SM0_CVAL0 - SM3_CVAL0)

Offset

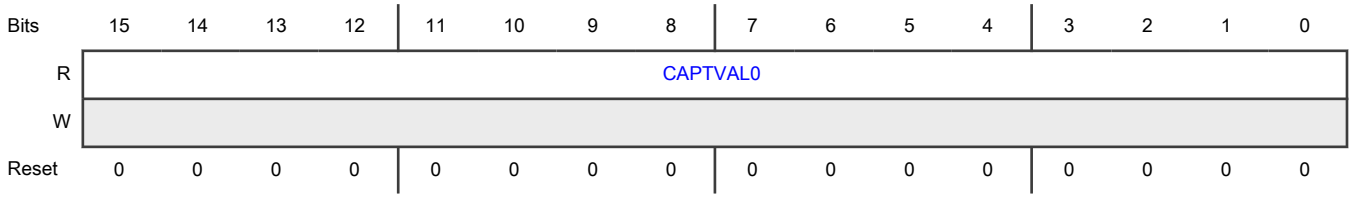
Register	Offset
SM0_CVAL0	40h
SM1_CVAL0	A0h
SM2_CVAL0	100h
SM3_CVAL0	160h

Function

Stores the value captured from the submodule counter. Edge X 0 (SM*n*_CAPTCTRLX[EDGX0]) specifies when this capture occurs. Each capture increments the capture count (SM*n*_CAPTCTRLX[CX0CNT]) until it reaches the maximum value. Each read of this register decrements the capture count until it reaches 0.

Attempting to write this register generates a transfer error.

Diagram



Fields

Field	Function
15-0 CAPTVAL0	Capture Value 0 Stores the value captured from the submodule counter. This field is not byte accessible.

56.7.34 Submodule a Capture Value 0 Cycle (SM0_CVAL0CYC - SM3_CVAL0CYC)

Offset

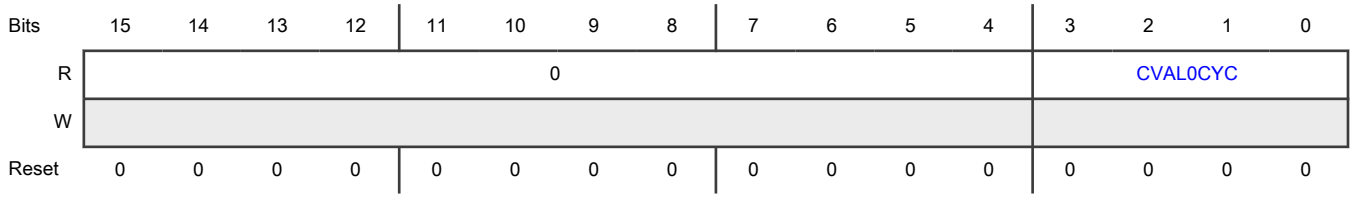
Register	Offset
SM0_CVAL0CYC	42h
SM1_CVAL0CYC	A2h
SM2_CVAL0CYC	102h
SM3_CVAL0CYC	162h

Function

Stores the value of the cycle number corresponding to the value captured. Edge X 0 (SM*n*_CAPTCTRLX[EDGX0]) specifies when this capture occurs. Each capture increments the capture count (SM*n*_CAPTCTRLX[CX0CNT]) until it reaches the maximum value. Each read of this register decrements the capture count until it reaches 0.

Attempting to write this register generates a transfer error.

Diagram



Fields

Field	Function
15-4 —	Reserved
3-0 CVAL0CYC	Capture Value 0 Cycle Stores the cycle number corresponding to the value captured in SM0_CVAL0[CAPTVAL0]. Each load of INIT into the counter at the end of a PWM modulo cycle increments this field. This field is not byte accessible.

56.7.35 Submodule a Capture Value 1 (SM0_CVAL1 - SM3_CVAL1)

Offset

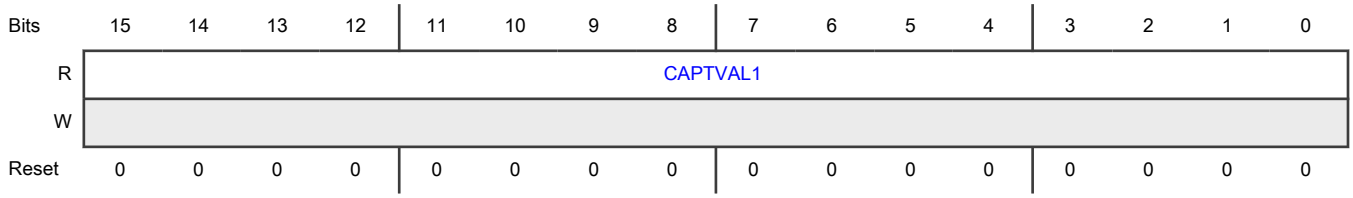
Register	Offset
SM0_CVAL1	44h
SM1_CVAL1	A4h
SM2_CVAL1	104h
SM3_CVAL1	164h

Function

Stores the value captured from the submodule counter. Edge X 1 (SM*n*_CAPTCTRLX[EDGX1]) specifies when this capture occurs. Each capture increments the capture count (SM*n*_CAPTCTRLX[CX1CNT]) until it reaches the maximum value. Each read of this register decrements the capture count until it reaches 0.

Attempting to write this register generates a transfer error.

Diagram



Fields

Field	Function
15-0 CAPTVAL1	Capture Value 1 Stores the value captured from the submodule counter. This field is not byte accessible.

56.7.36 Submodule a Capture Value 1 Cycle (SM0_CVAL1CYC - SM3_CVAL1CYC)

Offset

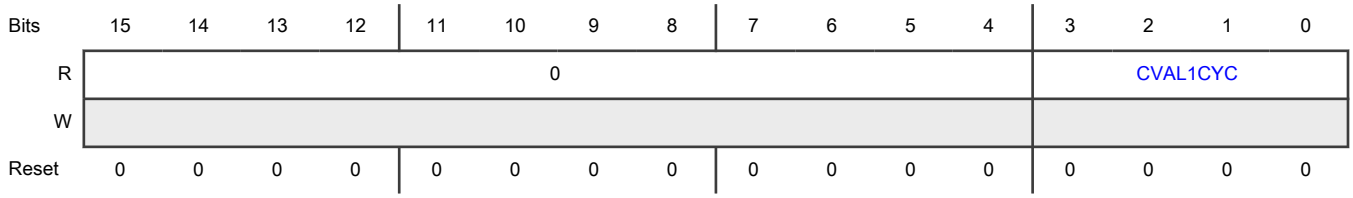
Register	Offset
SM0_CVAL1CYC	46h
SM1_CVAL1CYC	A6h
SM2_CVAL1CYC	106h
SM3_CVAL1CYC	166h

Function

Stores the value of the cycle number corresponding to the value captured. Edge X 1 (SM*n*_CAPTCTRLX[EDGX1]) specifies when this capture occurs. Each capture increments the capture count (SM*n*_CAPTCTRLX[CX1CNT]) until it reaches the maximum value. Each read of this register decrements the capture count until it reaches 0.

Attempting to write this register generates a transfer error.

Diagram



Fields

Field	Function
15-4 —	Reserved
3-0 CVAL1CYC	Capture Value 1 Cycle Stores the cycle number corresponding to the value captured in SM0_CVAL1[CAPTVAL1]. Each load of INIT into the counter at the end of a PWM modulo cycle increments this field. This field is not byte accessible.

56.7.37 Submodule a Capture Value 2 (SM0_CVAL2 - SM3_CVAL2)

Offset

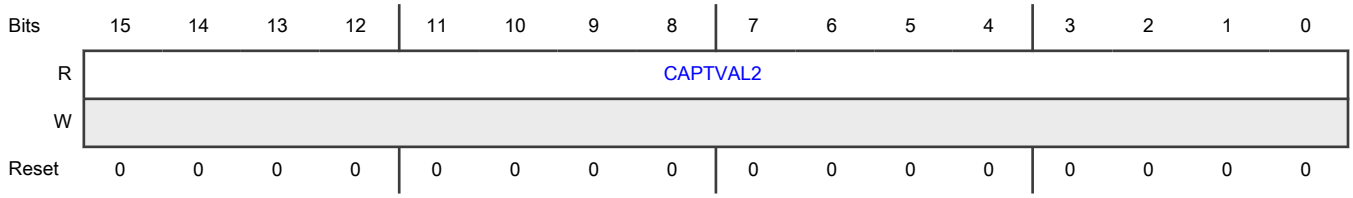
Register	Offset
SM0_CVAL2	48h
SM1_CVAL2	A8h
SM2_CVAL2	108h
SM3_CVAL2	168h

Function

Stores the value captured from the submodule counter. Edge A 0 (SM*n*_CAPTCTRL*m*[EDGA0]) specifies when this capture occurs. Each capture increments the capture count (SM*n*_CAPTCTRL*m*[CA0CNT]) until it reaches the maximum value. Each read of this register decrements the capture count until it reaches 0.

Attempting to write this register generates a transfer error.

Diagram



Fields

Field	Function
15-0 CAPTVAL2	Capture Value 2 Stores the value captured from the submodule counter. This field is not byte accessible.

56.7.38 Submodule a Capture Value 2 Cycle (SM0_CVAL2CYC - SM3_CVAL2CYC)

Offset

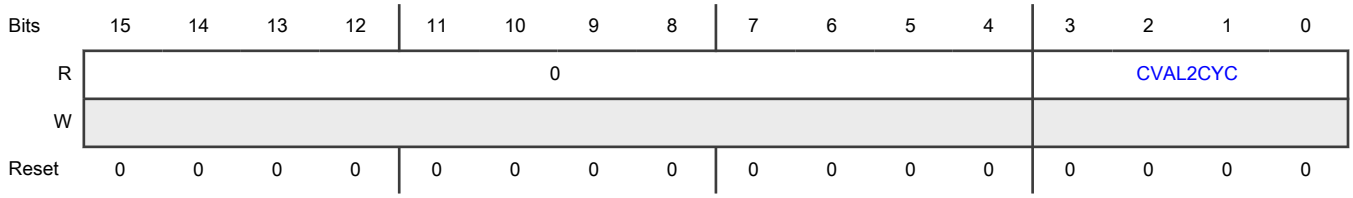
Register	Offset
SM0_CVAL2CYC	4Ah
SM1_CVAL2CYC	AAh
SM2_CVAL2CYC	10Ah
SM3_CVAL2CYC	16Ah

Function

Stores the value of the cycle number corresponding to the value captured. Edge A 0 (SM*n*_CAPTCTRL*m*[EDGA0]) specifies when this capture occurs. Each capture increments the capture count (SM*n*_CAPTCTRL*m*[CA0CNT]) until it reaches the maximum value. Each read of this register decrements the capture count until it reaches 0.

Attempting to write this register generates a transfer error.

Diagram



Fields

Field	Function
15-4 —	Reserved
3-0 CVAL2CYC	Capture Value 2 Cycle Stores the cycle number corresponding to the value captured in SM*n*_CVAL2[CAPTVAL2]. Each load of INIT into the counter at the end of a PWM modulo cycle increments this field. This field is not byte accessible.

56.7.39 Submodule a Capture Value 3 (SM0_CVAL3 - SM3_CVAL3)

Offset

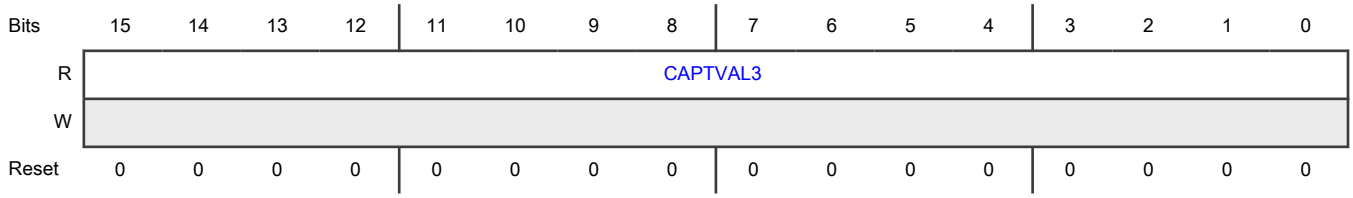
Register	Offset
SM0_CVAL3	4Ch
SM1_CVAL3	ACh
SM2_CVAL3	10Ch
SM3_CVAL3	16Ch

Function

Stores the value captured from the submodule counter. Edge A 1 (SM*n*_CAPTCTRLA[EDGA1]) specifies when this capture occurs. Each capture increments the capture count (SM*n*_CAPTCTRLA[CA1CNT]) until it reaches the maximum value. Each read of this register decrements the capture count until it reaches 0.

Attempting to write this register generates a transfer error.

Diagram



Fields

Field	Function
15-0 CAPTVAL3	Capture Value 3 Stores the value captured from the submodule counter. This field is not byte accessible.

56.7.40 Submodule a Capture Value 3 Cycle (SM0_CVAL3CYC - SM3_CVAL3CYC)

Offset

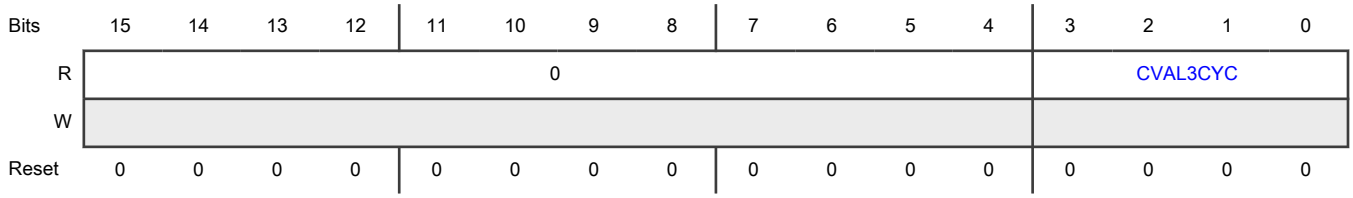
Register	Offset
SM0_CVAL3CYC	4Eh
SM1_CVAL3CYC	AEh
SM2_CVAL3CYC	10Eh
SM3_CVAL3CYC	16Eh

Function

Stores the value of the cycle number corresponding to the value captured. Edge A 1 (SM*n*_CAPTCTRLA[EDGA1]) specifies when this capture occurs. Each capture increments the capture count (SM*n*_CAPTCTRLA[CA1CNT]) until it reaches the maximum value. Each read of this register decrements the capture count until it reaches 0.

Attempting to write this register generates a transfer error.

Diagram



Fields

Field	Function
15-4 —	Reserved
3-0 CVAL3CYC	Capture Value 3 Cycle Stores the cycle number corresponding to the value captured in SM*n*_CVAL3[CAPTVAL3]. Each load of INIT into the counter at the end of a PWM modulo cycle increments this field. This field is not byte accessible.

56.7.41 Submodule a Capture Value 4 (SM0_CVAL4 - SM3_CVAL4)

Offset

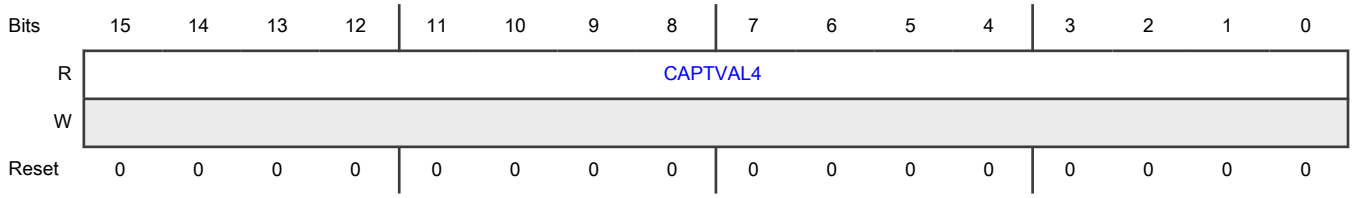
Register	Offset
SM0_CVAL4	50h
SM1_CVAL4	B0h
SM2_CVAL4	110h
SM3_CVAL4	170h

Function

Stores the value captured from the submodule counter. Edge B 0 (SM*n*_CAPTCTRLB[EDGB0]) specifies when this capture occurs. Each capture increments the capture count (SM*n*_CAPTCTRLB[CB0CNT]) until it reaches the maximum value. Each read of this register decrements the capture count until it reaches 0.

Attempting to write this register generates a transfer error.

Diagram



Fields

Field	Function
15-0 CAPTVAL4	Capture Value 4 Stores the value captured from the submodule counter. This field is not byte accessible.

56.7.42 Submodule a Capture Value 4 Cycle (SM0_CVAL4CYC - SM3_CVAL4CYC)

Offset

Register	Offset
SM0_CVAL4CYC	52h
SM1_CVAL4CYC	B2h
SM2_CVAL4CYC	112h
SM3_CVAL4CYC	172h

Function

Stores the value of the cycle number corresponding to the value captured. Edge B 0 (SM*n*_CAPTCTRLB[EDGB0]) specifies when this capture occurs. Each capture increments the capture count (SM*n*_CAPTCTRLB[CB0CNT]) until it reaches the maximum value. Each read of this register decrements the capture count until it reaches 0.

Attempting to write this register generates a transfer error.

Diagram

Field	Function
15-0 CAPTVAL5	Capture Value 5 Stores the value captured from the submodule counter. This field is not byte accessible.

56.7.44 Submodule a Capture Value 5 Cycle (SM0_CVAL5CYC - SM3_CVAL5CYC)

Offset

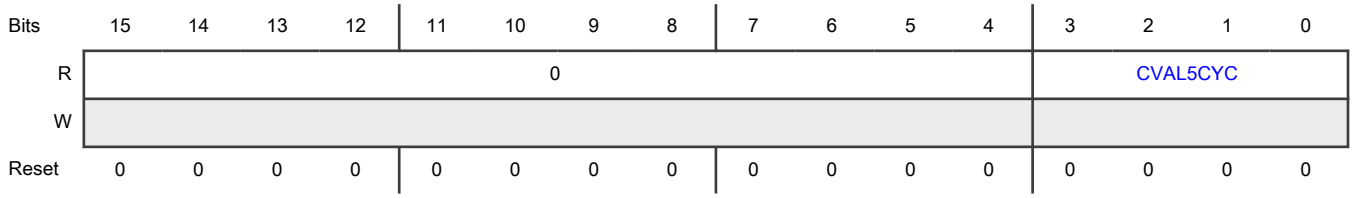
Register	Offset
SM0_CVAL5CYC	56h
SM1_CVAL5CYC	B6h
SM2_CVAL5CYC	116h
SM3_CVAL5CYC	176h

Function

Stores the value of the cycle number corresponding to the value captured. Edge B 1 (SM*n*_CAPTCTRLB[EDGB1]) specifies when this capture occurs. Each capture increments the capture count (SM*n*_CAPTCTRLB[CB1CNT]) until it reaches the maximum value. Each read of this register decrements the capture count until it reaches 0.

Attempting to write this register generates a transfer error.

Diagram



Fields

Field	Function
15-4 —	Reserved
3-0 CVAL5CYC	Capture Value 5 Cycle Stores the cycle number corresponding to the value captured in SM*n*_CVAL5[CAPTVAL5]. Each load of INIT into the counter at the end of a PWM modulo cycle increments this field. This field is not byte accessible.

56.7.45 Submodule a Phase Delay (SM1_PHASEDLY - SM3_PHASEDLY)

Offset

Register	Offset
SM1_PHASEDLY	B8h
SM2_PHASEDLY	118h
SM3_PHASEDLY	178h

Function

Specifies the delay from the master sync signal of submodule 0 to the time that this submodule recognizes the master sync in PWM counter cycles. You must select master sync as the source for initialization (SM*n*_CTRL2[INIT_SEL]) when using this register. Setting this register with a non-zero value and using the master sync signal as the initialization source allows the output of this submodule to be a fixed number of cycles delayed from submodule 0. For PWM operation, the submodule updates this register at the start of every PWM period.

NOTE

This register is buffered. The written value takes effect when software asserts submodule Load Okay (MCTRL[LDOK]) and the next PWM load cycle begins or immediately on assertion of Load Okay, depending on Load Mode Select (LDMOD). You cannot write this register when submodule Load Okay (MCTRL[LDOK]) is asserted. Reading PHASEDLY returns the value in the buffer and not necessarily the value the PWM generator is currently using.

Diagram

Fields

Field	Function
15-0 PHASEDLY	Phase Delay This field is not byte accessible. **NOTE** You should not specify a value larger than the period specified for submodule 0.

56.7.46 Output Enable (OUTEN)

Offset

Register	Offset
OUTEN	180h

Function

Enables and masks the PWM outputs.

NOTE

The mask fields in this register are buffered. The written value takes effect when a FORCE_OUT event occurs within the appropriate submodule. Reading the mask fields returns the value in the buffer and not necessarily the value currently in effect. You can override the buffering using the UPDATE_MASK field.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0				PWMA_EN				PWMB_EN				PWMX_EN			
W

Fields

Field	Function
15-12	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
11-8 PWMA_EN	PWMn_A Output Enables Enables the PWM*n*_A outputs. Each bit position in the field corresponds to the like-numbered submodule. **NOTE** If you use a PWM*n*_A pin for input capture or deadtime correction, you must disable PWM*n*_A output for that submodule (write 0 to the corresponding bit in this field). 0000b - Disable 0001b - Enable
7-4 PWMB_EN	PWMn_B Output Enables Enables the PWM*n*_B outputs. Each bit position in the field corresponds to the like-numbered submodule. **NOTE** If you use a PWM*n*_B pin for input capture or deadtime correction, you must disable PWM*n*_B output for that submodule (write 0 to the corresponding bit in this field). 0000b - Disable 0001b - Enable
3-0 PWMX_EN	PWMn_X Output Enables Enables the PWM*n*_X outputs. Each bit position in the field corresponds to the like-numbered submodule. **NOTE** If you use a PWM*n*_X pin for input capture or deadtime correction, you must disable PWM*n*_X output for that submodule (write 0 to the corresponding bit in this field). 0000b - Disable 0001b - Enable

56.7.47 Mask (MASK)

Offset

Register	Offset
MASK	182h

Function

Enables and masks the PWM outputs.

NOTE

The mask fields in this register are buffered. The written value takes effect when a FORCE_OUT event occurs within the appropriate submodule. Reading the mask fields returns the value in the buffer and not necessarily the value currently in effect. You can override the buffering using the UPDATE_MASK field.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R					MASKA				MASKB				MASKX			
W	UPDATE_MASK															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-12 UPDATE_MASK	Update Mask Bits Immediately Forces the mask bits to be updated immediately (on the following clock edge) without waiting for a FORCE_OUT event. Each bit position in the field corresponds to the like-numbered submodule. These self-clearing bits always read as zero. Software may write to any or all of these bits and may do so in the same write operation that updates MASK[MASKA], MASK[MASKB], or MASK[MASKX]. 0000b - Buffered operation 0001b - Immediate update
11-8 MASKA	PWMn_A Masks Masks the PWM*n*_A outputs. Each bit position in the field corresponds to the like-numbered submodule. Masking an output forces the output to logic 0 before consideration of the output polarity. 0000b - Output normal 0001b - Output masked
7-4 MASKB	PWMn_B Masks Masks the PWM*n*_B outputs. Each bit position in the field corresponds to the like-numbered submodule. Masking an output forces the output to logic 0 before consideration of the output polarity. 0000b - Output normal 0001b - Output masked
3-0 MASKX	PWMn_X Masks Masks the PWM*n*_X outputs. Each bit position in the field corresponds to the like-numbered submodule. Masking an output forces the output to logic 0 before consideration of the output polarity. 0000b - Output normal 0001b - Output masked

56.7.48 Software Controlled Output (SWCOUT)

Offset

Register	Offset
SWCOUT	184h

Function

Enables software control of output signals to the submodules deadtime generators.

NOTE

This register is buffered. The written value takes effect when a FORCE_OUT event occurs within the appropriate submodule. Reading SWCOUT returns the value in the buffer and not necessarily the value currently in effect.

Diagram

56.7.50 Master Control (MCTRL)

Offset

Register	Offset
MCTRL	188h

Function

Controls various aspects of eFlexPWM operation.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	IPOL				RUN				0				LDOK			
W									CLDOK							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-12 IPOL	Current Polarity Selects between PWM23 and PWM45 as the source for the generation of the complementary PWM pair output for the corresponding submodule. This does not apply in independent mode. Each bit position corresponds to the like-numbered submodule. Therefore, the description refers to the effect of an individual bit. **NOTE** This register is buffered. The written value takes effect when a FORCE_OUT event occurs within the appropriate submodule. Reading IPOL returns the value in the buffer and not necessarily the value currently in effect. 0000b - PWM23 0001b - PWM45
11-8 RUN	Run Starts the PWM generator by enabling its clock. If you enable input capture for a submodule or select local reload as the reload source for a submodule, you must write 1 to the corresponding RUN bit for that submodule. Writing 0 to the Run bit resets the submodule counter. Each bit position corresponds to the like-numbered submodule. Therefore, the description refers to the effect of an individual bit. 0000b - Stop PWM generator 0001b - Start PWM generator
7-4	Clear Load Okay

Table continues on the next page...

Table continued from the previous page...

Field	Function
CLDOK	Turns off (clears) Load Okay for a particular submodule by clearing the corresponding LDOK bit. If a reload occurs in a submodule with Load Okay enabled at the same time software writes 1 to the corresponding bit in CLDOK, then the submodule does not perform the reload and clears Load Okay. The CLDOK field is self-clearing and always reads 0. Each bit position corresponds to the like-numbered submodule. Therefore, the description refers to the effect of an individual bit. 0000b - No effect 0001b - Turn off Load Okay. Turn off Load Okay. Clears the corresponding bit in LDOK.
3-0 LDOK	Load Okay Loads the prescaler (SM*n*_CTRL[PRSC]), Initial Count (SM*n*_INIT[INIT]), fractional timing values, and timing values (SM*n*_VAL*m*) of the corresponding submodule into a set of buffers. The buffered prescaler divisor, submodule counter modulus value, and PWM pulse width take effect at the next PWM reload or immediately, depending on the Load Mode setting (LDMOD). Set the corresponding LDOK bit by reading it when it is zero and then writing one to it. You cannot write the prescaler, initial count, fractional values, or values for the corresponding submodule when LDOK equals one. Each bit position corresponds to the like-numbered submodule. Therefore, the description refers to the effect of an individual bit. In Master Reload Mode (SM*n*_CTRL2[RELOAD_SEL]), you only need to write the LDOK bit for submodule 0. However, you should also write the LDOK bits for the slave submodules to prevent unwanted writes to the slave submodule registers. You cannot write zero to LDOK bits. The submodule automatically writes zero to its corresponding LDOK bit after loading the new values, or you can manually clear an LDOK bit before a reload by writing one to the corresponding CLDOK bit. You can write one to LDOK in DMA mode when the DMA indicates that it has completed updating all the prescaler, Initial Count, fractional values, and values for the corresponding submodule. 0000b - Do not load new values 0001b - Load new values

56.7.51 Master Control 2 (MCTRL2)

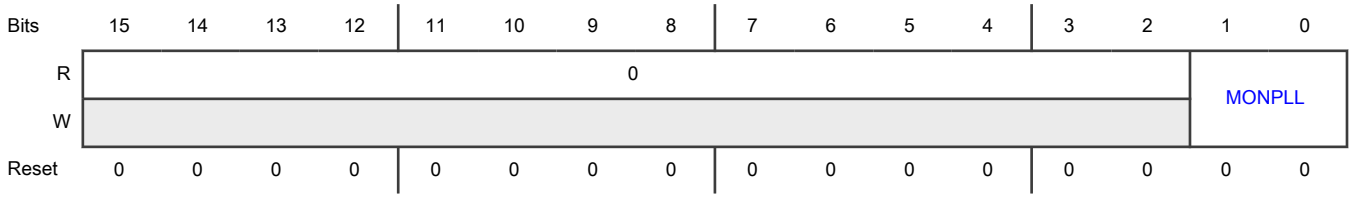
Offset

Register	Offset
MCTRL2	18Ah

Function

Controls various aspects of eFlexPWM operation.

Diagram



Fields

Field	Function
15-2 —	Reserved
1-0 MONPLL	Monitor PLL State Enables disabling of the fractional delay block when the chip PLL is unlocked or missing its input reference. The fractional delay block requires a continuous 200 MHz clock from the PLL. If this clock turns off while the fractional delay block is in use, then the output of the fractional delay block can be stuck high or low even if the PLL restarts. When you enable Monitor PLL State, PLL problems disable the fractional delay block until the PLL returns to a locked state. When the PLL is again receiving a proper reference and is locked, the fractional delay block requires 25 µs startup time just as if fractional cycle had been disabled and re-enabled (SM*n*_FRCTRL[FRAC23_EN] or SM*n*_FRCTRL[FRAC45_EN]). If you disable PLL monitoring, then when the PLL loses its reference or loses lock, software should manually disable and re-enable fractional cycle to properly restart the functional delay block. This field does not apply if you are not using the fractional delay block. 00b - PLL not locked, do not monitor PLL operation. If the PLL loses lock, software must restart the fractional delay block. 01b - PLL not locked, monitor PLL operation. If the PLL encounters problems, disable the fractional delay block automatically. 10b - PLL locked, do not monitor PLL operation. If the PLL loses lock, software must restart the fractional delay block. This field is write-protected until the next reset. 11b - PLL locked, monitor PLL operation. If the PLL encounters problems, disable the fractional delay block automatically. This field is write-protected until the next reset.

56.7.52 Fault Protection 0 Control (FP0_CTRL)

Offset

Register	Offset
FP0_CTRL	18Ch

Function

Controls fault channel operation.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	FLVL				FAUTO				FSAFE				FIE			
Reset	1	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-12 FLVL	Fault Level Specifies the level of the fault input that indicates a fault condition. Each bit position corresponds to the like-numbered fault input. Therefore, the description refers to the effect of an individual bit. 0000b - Logic 0 0001b - Logic 1
11-8 FAUTO	Automatic Fault Clearing Enables automatic fault clearing. Each bit position corresponds to the like-numbered fault input. Therefore, the description refers to the effect of an individual bit. 0000b - Manual fault clearing. Manual fault clearing. The fault channel does not re-enable PWM outputs disabled by this fault until the corresponding fault flag (FP*n*_STS[FFLAG]) is clear at the start of a half period or full period, depending on the state of half-period recovery (FP*n*_STS[FHALF]) and full-period recovery (FP*n*_STS[FFULL]). If neither full- nor half-period recovery is enabled, then the fault channel cannot clear the fault condition. Software must also take Safe mode selection (FP*n*_CTRL[FSAFE]) into account. 0001b - Automatic fault clearing. Automatic fault clearing. The fault channel re-enables PWM outputs disabled by this fault when the fault filter pin (FP*n*_STS[FFPIN]) is clear at the start of a half period or full period depending on the state of half-period recovery (FP*n*_STS[FHALF]) and full-period recovery (FP*n*_STS[FFULL]), without regard for the fault status flag (FP*n*_STS[FFLAG]). If you enable neither full- nor half-period recovery, then the fault channel cannot clear the fault condition.
7-4 FSAFE	Fault Safety Mode Selects the safety mode during manual fault clearing. Each bit position corresponds to the like-numbered fault input. Therefore, the description refers to the effect of an individual bit. In normal mode, the fault channel does not re-enable PWM outputs disabled by this fault until the corresponding fault flag (FP*n*_STS[FFLAG]) is clear at the start of a half period or full period, depending on the state of half-period recovery FP*n*_STS[FHALF]) and full-period recovery (FP*n*_STS[FFULL]), without regard to fault filtering (FP*n*_STS[FFPIN]). If you enable neither full- nor half-period recovery, then the fault channel cannot clear the fault condition.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE The fault channel does not re-enable PWM outputs disabled by this fault input until the actual FAULTn input signal de-asserts because the fault input combinationally disables the PWM outputs as programmed by fault disable mapping (SM*n*_DISMAP*n*). In safe mode, the fault channel does not re-enable PWM outputs disabled by this fault until the corresponding fault flag (FP*n*_STS[FFLAG]) and filtered fault pin (FP*n*_STS[FFPIN]) are both clear at the start of a half period or full period, depending on the state of half-period recovery (FP*n*_STS[FHALF]) and full-period recovery (FP*n*_STS[FFLAG]). If you enable neither full- nor half-period recovery, then the fault channel cannot clear the fault condition. **NOTE** Because of fault filter latency, the Filtered Fault Pin bit (FP*n*_STS[FFPIN]) may indicate that a fault condition still exists even though the actual fault signal is clear. 0000b - Normal mode 0001b - Safe mode
3-0 FIE	Fault Interrupt Enables Enables CPU interrupt requests generated by the FAULT*n* inputs. Each bit position corresponds to the like-numbered fault input. Therefore, the description refers to the effect of an individual bit. **NOTE** The fault protection circuit is independent of FP*n*_CTRL[FIE] and is always active. If the fault channel detects a fault, it disables the PWM outputs according to the Fault Disable Mapping (SM*n*_DISMAP*n*) registers. 0000b - Disable 0001b - Enable

56.7.53 Fault Protection 0 Status (FP0_STS)

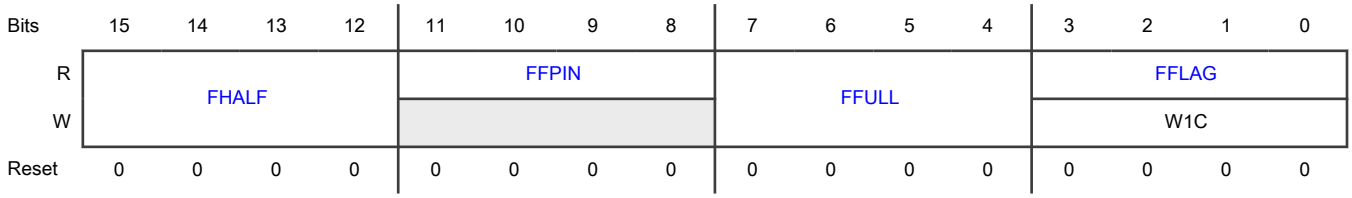
Offset

Register	Offset
FP0_STS	18Eh

Function

Provides fault status and additional fault behavior control.

Diagram



Fields

Field	Function
15-12 FHALF	Half-Period Fault Recovery Specifies the timing for re-enabling the PWM outputs after a fault condition. These bits apply to both automatic and manual clearing of a fault condition. **NOTE** You can enable both half-period (FP*n*_STS[FHALF]) and full-period fault recovery (FP*n*_STS[FFULL]) so that fault recovery occurs at the start of a full period and at the half-period point, as defined by Timing Value 0 (SM*n*_VAL0[VAL0]). If you enable neither full- nor half-period recovery, then the fault channel cannot clear the fault condition. 0000b - Not re-enabled at the start of a half period 0001b - Re-enabled at the start of a half period
11-8 FFPIN	Filtered Fault Pins Indicates the current state of the filtered FAULTn pin converted to high polarity. Reset has no effect on this field. 0000b - No fault condition 0001b - Fault condition
7-4 FFULL	Full-Period Fault Recovery Specifies the timing for re-enabling the PWM outputs after a fault condition. These bits apply to both automatic and manual clearing of a fault condition. **NOTE** You can enable both half-period (FP*n*_STS[FHALF]) and full-period fault recovery (FP*n*_STS[FFULL]) so that fault recovery occurs at the start of a full period and at the half-period point, as defined by Timing Value 0 (SM*n*_VAL0[VAL0]). If you enable neither full- nor half-period recovery, then the fault channel cannot clear the fault condition. 0000b - Not re-enabled at the start of a full period 0001b - Re-enabled at the start of a full period
3-0 FFLAG	Fault Flags Indicates a fault on the corresponding fault input. Each bit position corresponds to the like-numbered fault. The fault channel sets the flag within two CPU cycles after a transition to active on the FAULTn pin. Clear this bit by writing one to it. The reset value is 0, but these bits may be 1 by the time software can read them depending on the state of the fault input signals.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0000b - No fault present 0001b - Fault is present

56.7.54 Fault Protection 0 Filter (FP0_FILT)

Offset

Register	Offset
FP0_FILT	190h

Function

Controls fault filter operation.

The settings in fields are shared among each of the fault input filters within the fault channel.

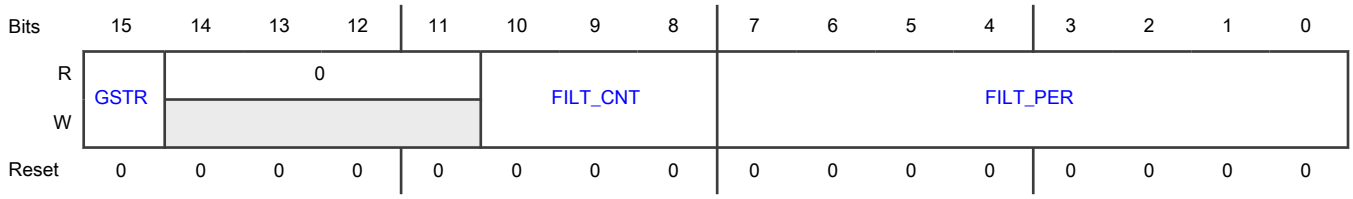
When setting these values, take the following considerations into account:

- To ensure a noise spike corrupts only one sample, you should define the fault filter period (FILT_PER) to be longer than the period of the expected noise. You should choose a fault filter count (FP*n*_FILT[FILT_CNT]) that reduces the probability of noisy samples causing detection of an incorrect transition. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the (FILT_CNT + 3) power.
- The fault filter period (FILT_PER) and fault filter count (FILT_CNT) both affect input latency for recognizing input transitions. Turning on the input filter (setting FILT_PER to a non-zero value) introduces a latency of ((FILT_CNT + 4) x FILT_PER x IPBus clock period). Note that even when the filter is enabled, there is a combinational path to disable the PWM outputs. This path ensures rapid response to fault conditions and also to ensure fault response if the PWM module loses its clock. The latency induced by the filter is seen in the time to set the fault flags (FP*n*_STS[FFLAG]) and filtered fault pins (FP*n*_STS[FFPIN]).

NOTE

When FILT_PER is small, the fault can be filtered one period earlier, hence, introduces a latency of ((FILT_CNT + 3) x FILT_PER x IPBus clock period).

Diagram



Fields

Field	Function
15	Fault Glitch Stretch Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
GSTR	Enables the fault glitch stretching logic, which stretches narrow fault glitches to ensure they are at least 2 IPBus clock cycles wide. In some cases, a narrow fault input can cause problems due to the short PWM output shutdown and re-activation time. The stretching logic ensures that when the fault filter is disabled, a glitch on the fault input registers in the fault flags. 0b - Disable 1b - Enable
14-11 —	Reserved
10-8 FILT_CNT	Fault Filter Count Specifies the number of consecutive samples minus three that must agree before the input filter accepts an input transition. In other words, a FILT_CNT value of 0 means 3 samples, and a value of 7 means 10 samples. This value affects the input latency.
7-0 FILT_PER	Fault Filter Period Specifies the sampling period, in IPBus clock cycles, of the fault pin input filter. The fault channel samples each input multiple times at this rate. If FILT_PER is 00h (default), then the fault channel bypasses the input filter. This value affects the input latency. This field applies universally to all fault inputs. **NOTE** When changing values for FILT_PER from one non-zero value to another non-zero value, you must first write zero to clear the filter.

56.7.55 Fault Protection 0 Test (FP0_TST)

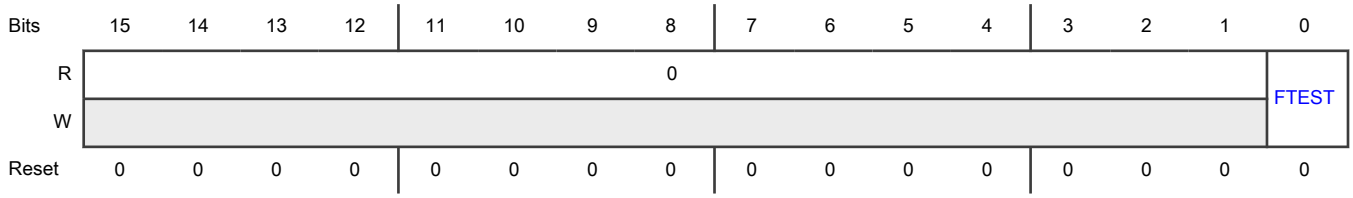
Offset

Register	Offset
FP0_TST	192h

Function

Simulates a fault condition by sending a simulated fault into all of the fault filters.

Diagram



Fields

Field	Function
15-1 —	Reserved
0 FTEST	Fault Test Simulates a fault condition by sending a simulated fault into all of the fault filters. The condition propagates to the fault flags and possibly the PWM outputs depending on the fault channel mapping (SM*n*_DISMAP*n*). Clearing this bit removes the simulated fault condition. 0b - No fault 1b - Cause a simulated fault

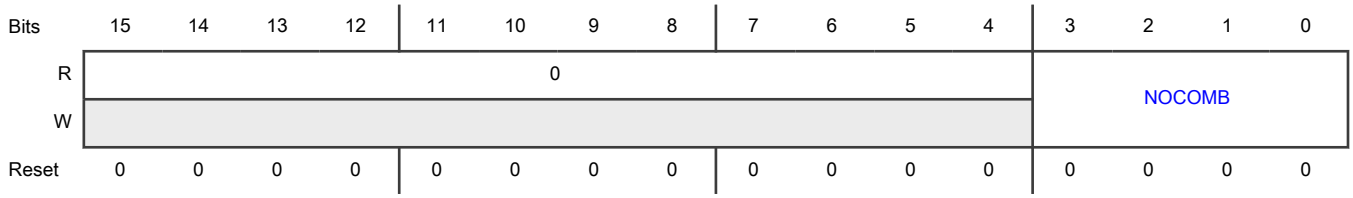
56.7.56 Fault Protection 0 Control 2 (FP0_CTRL2)

Offset

Register	Offset
FP0_CTRL2	194h

Function
See NOCOMB.

Diagram



Fields

Field	Function
15-4	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
3-0 NOCOMB	No Combinational Path Disables the combinational path from the fault inputs to the PWM outputs. When you turn off No Combinational Path (default), the corresponding fault inputs have a combinational path to the PWM outputs that is sensitive to these fault inputs as defined by the fault channel mapping (SM*n*_DISMAP*n*). This combinational path is a safety feature that ensures the output is disabled even if the SOC clocking system fails. The combinational path also means that a pulse on the fault input can cause brief disabling of the PWM output even if the fault pulse is not wide enough to pass through the input filter and be latched in the fault logic. Turning on No Combinational Path removes the combinational path and uses the filtered and latched fault signals as the fault source for disabling the PWM outputs, which eliminate fault glitches from creating PWM output glitches but also increases the latency to respond to a real fault. 0000b - Combinational path 0001b - No combinational path

56.7.57 DLL Status (DLLSR)

Offset

Register	Offset
DLLSR	1B0h

Function
Indicates the DLL status.

1. Channels indicating "—" are reserved, and access to any reserved channel may result in inappropriate data.
2. Use DCM_GPR.DCMRWF1[SUPPLY_MON_SEL] to select the value of ANAMUX_OUT.
3. Use DCM_GPR.DCMRWF2[SUPPLY2_MON_EN] to select the value of ANAMUX_OUT1.
4. The decoding signals for the selection of external ADC channels (ADC_X) use Gray encoding.

57.1.3 ANAMUX for internal supply monitoring

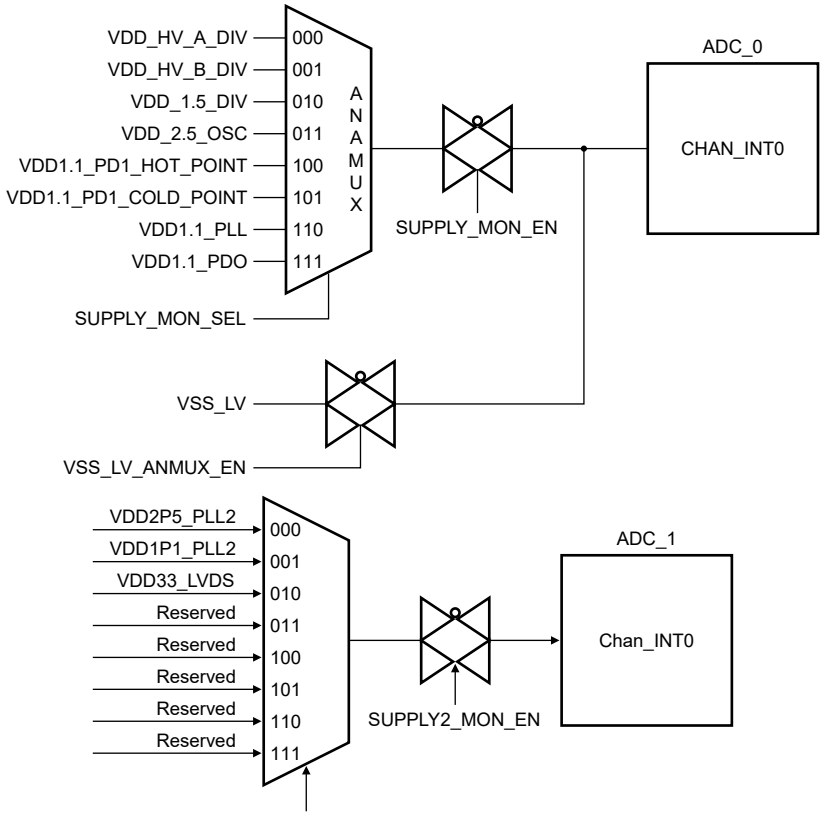

Figure 276. ANAMUX for internal supply monitoring

57.1.4 BCTU interface

ADC instances shown in the following figure are triggered from BCTU, which provides channel-conversion commands, including channel number information, to ADC. Next, ADC provides the conversion result back to BCTU.

BCTU provides a trigger pulse to all 72 channels of ADC to initiate a conversion based on the BCTU channel number.

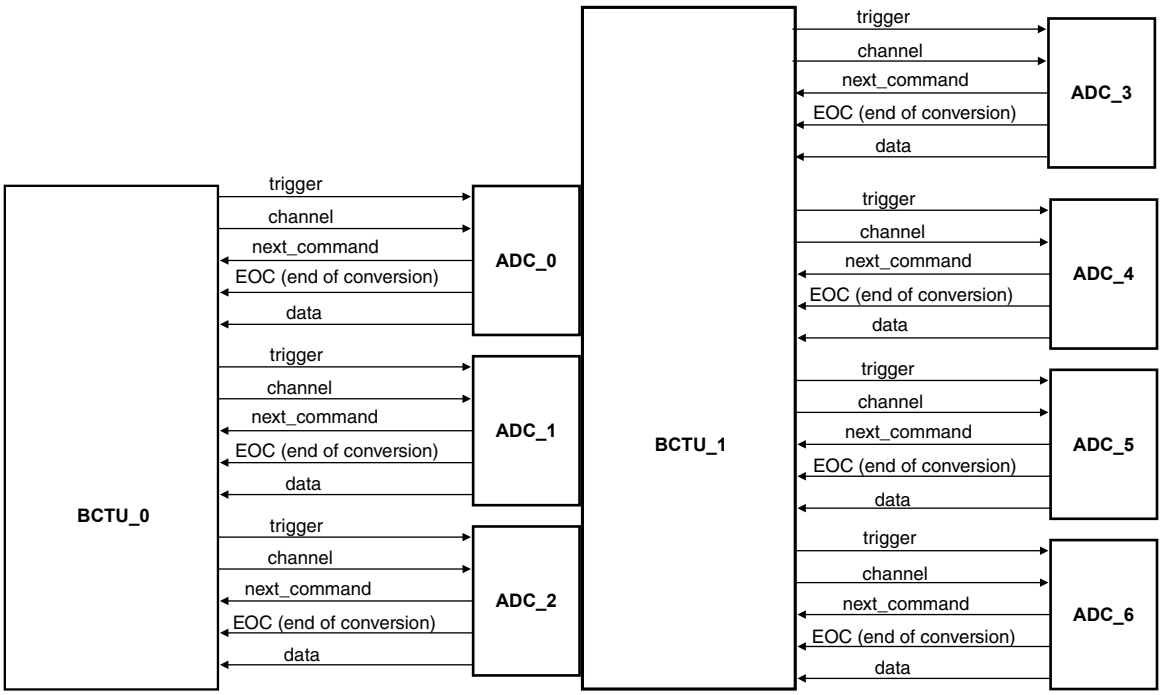

Figure 277. BCTU interface

57.1.5 Registers storing conversion data

The following ADC registers store 15-bit conversion data:

- PCDR*n*[CDATA]
- ICDR*n*[CDATA]
- ECDR*n*[CDATA]

Within BCTU, the ADC*n*DR[ADC_DATA] fields store 15-bit conversion data.

57.1.6 DMA interface

Each ADC supports a single DMA request that can occur after the conversion of every channel. The conversion result is stored in the DMAR registers and is transferred via DMA or host access.

NOTE

The final ongoing conversion is aborted as soon as ADC receives a STOP request from you. ADC then moves to Stop mode.

57.1.7 Hardware triggers

In this chip, TRGMUX outputs can provide hardware trigger signals. The normal conversion synchronization pulse is used with the normal conversion trigger to synchronize the start timing of normal conversion between multiple ADC instances.

Table 274. Hardware triggers

57.1.8 Self-test feature

You must, at regular intervals, check whether ADC is operating correctly. For this purpose, the chip provides a self-test feature. After self-test is enabled, ADC runs an automatic check on its own components and flags any errors.

57.1.9 Mux_mode GPR

Multiple pads drive some ADC channels. For this, DCM_GPR fields define which pad is connected to a particular ADC channel.

The following table shows the DCM_GPR configuration that is used for this purpose.

Table 275. DCM_GPR configuration

ADC channel	DCM_GPR register and field	Connected pad
ADC_1 standard channel 15 (ADC_1 S15)	DCMRWF4[MUX_MODE_EN_ADC1_S15]	0: GPIO PAD4 (default) 1: GPIO PAD33

57.2 Overview

ADC produces a digital value from an input analog voltage using the SAR algorithm. It features various methods to trigger a conversion and offers flexibility in the selection of input channels. ADC is useful for a wide range of applications.

A configurable self-test capability supports use cases with increased requirements for functional safety.

57.2.1 Block diagram

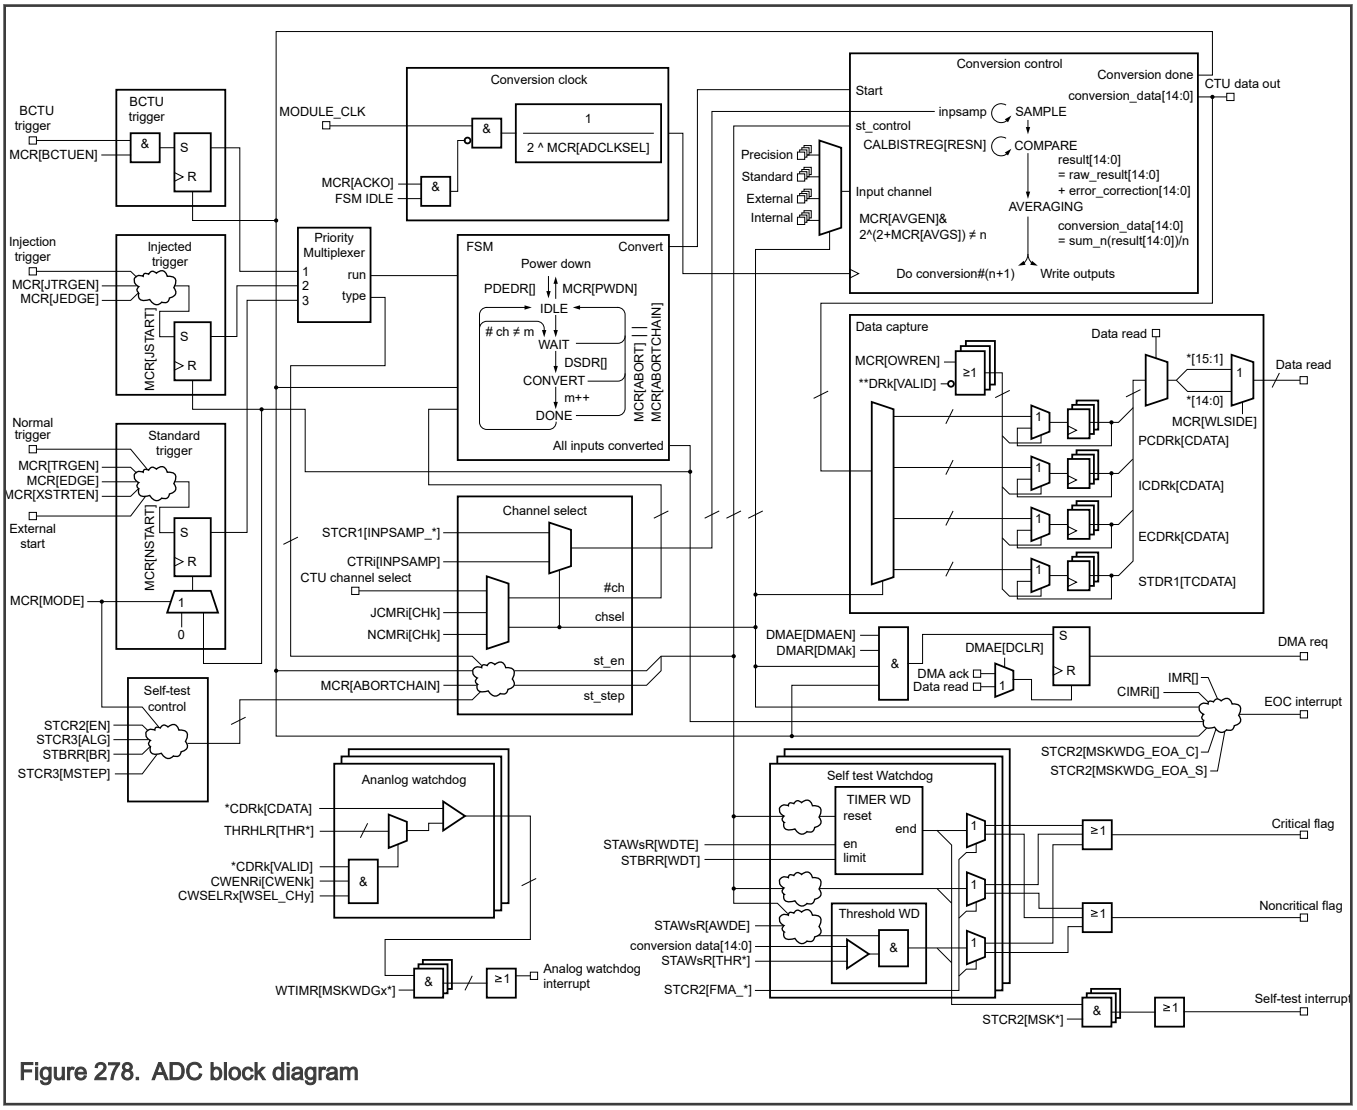

Figure 278. ADC block diagram

Guide to the diagram:

- The signal flow through the diagram is from left to right: inputs to blocks are on the left side, outputs are on the right.
- Block names have the first letters in uppercase and the other letters in lowercase—"Conversion Control," for example).
- Register names are in uppercase followed by a field name in brackets ("MCR[NSTART]," for example). Letters in lowercase are indexes. Asterisks are placeholders for letters (wildcards). Register names in the block diagram map to the names in ADC register descriptions.
- Signal names are in lowercase ("conversion done," for example).
- All digital signals shown are synchronous signals. Asynchronous inputs to the ADC are internally synchronized (synchronizers not shown).

The block diagram shows the signal flow through ADC from the left to the right and from the top to the bottom:

1. When ADC receives one of the three different types of triggers (BCTU, injected, or normal), the priority multiplexer initiates the conversion.
2. The input to be converted is selected in the Channel Select subblock, based on the type of trigger and on the self-test configuration.
3. The state machine (FSM) transitions from Idle state to Convert state. In case the channel to convert changed since the last conversion and this new channel is an external channel, the conversion starts after a delay configured by DSDR[DSD].
4. After a conversion begins, the Conversion Control block holds the internal capacitance network CDAC in the sample phase for a time defined by CTRi[INPSAMP].
5. During the compare phase, CALBISTREG[RESN] defines the number of steps used to execute the successive approximation algorithm. The error_correction values, determined during calibration, are added to the raw result. If averaging is enabled (MCR[AVGEN] = 1), up to 32 (specified via MCR[AVGS]) conversion results are averaged to obtain the result.
6. When the conversion completes and all averaging steps have completed:
    a. The conversion done signal indicates completion.
    b. Conversion_data[14:0] is written to the result registers in the Data Capture subblock.
    c. The FSM transitions into Done state.
7. The next input in the Channel Select block is selected and the next conversion is started by the transition of the FSM to Convert state. This continues until all selected inputs have been converted.
8. If an analog watchdog is enabled, the conversion result is compared to the configured threshold. If the limits are exceeded, an interrupt can be triggered.
9. Self-test can check the integrity of ADC, either interleaved with normal conversions or as a standalone check.
10. If an ongoing conversion is aborted (by writing 1 to MCR[ABORT]) or an ongoing conversion of a set of input channels is aborted (by writing 1 to MCR[ABORTCHAIN]), the FSM transitions into Idle state. The Conversion Control block stops the current conversion if MCR[ABORT] was written with 1, or finishes the current conversion if MCR[ABORTCHAIN] was written with 1. In both cases, the conversion done output signal of the Conversion Control block is set to 1.

Some details are not shown in the block diagram:

- Calibration must be performed to determine the error_correction values (see Calibration) before ADC can do meaningful conversions.
- An input can presample the internal low or high reference voltages to avoid a memory effect that may be present in the comparison due to a previous conversion (see Presampling).
- Monitor ADC status via status flags.
    - See Main Status (MSR) for the FSM state.
    - See Interrupt Status (ISR) to monitor interrupts.
    - See Channel End Of Conversion Flag For Precision Inputs (CEOCFR0) for conversion phase per input.
    - See the following registers to monitor analog watchdogs:
        - Analog Watchdog Out Of Range For Precision Inputs (AWORR0)
        - Analog Watchdog Out Of Range For Standard Inputs (AWORR1)
        - Analog Watchdog Out Of Range For External Inputs (AWORR2)

      See Analog Watchdog Threshold Interrupt Status (WTISR) to monitor analog watchdog interrupts.
    - See Self-Test Status 1 (STSR1) – Self-Test Status 4 (STSR4) to monitor self-test.

57.2.2 Features

- Selectable resolution (8-, 10-, 12-, 14-bit). Note that the conversion result is always 15 bits wide, even though the selected resolution is smaller (see CALBISTREG[RESN])
- Conversion data captured in a separate register for each input channel.
- Option to improve accuracy via averaging, which calculates conversion data by averaging the data of up to 32 conversions.
- Conversion triggers:
  - Normal conversion trigger converts a number of input channels, either once per trigger or continuously.
  - Injected conversion trigger interrupts an ongoing normal conversion and converts another set of input channels.
  - BCTU conversion trigger interrupts an ongoing conversion and converts an input channel, in which the input is selected and the conversion is started via the BCTU.
- An analog watchdog optionally monitors conversion data for each input channel and issues an interrupt if the converted data is below or above configurable limits.
- DMA functionality transfers conversion data to other modules.
- Programmable interrupts optionally issue an interrupt when conversion of one or of a set of input channels is finished.
- Self-test functions validate ADC structural integrity during functional operation and generate events with different severities on any finding.
- Conversion clock (AD_clk) control enables the use of ADC in systems with a higher clock frequency by using internal clock dividers.
- Auto turn-off of the conversion clock when ADC is idle.

57.3 Functional description

57.3.1 Clock

ADC is controlled by one clock signal, the module clock. Internally, the conversion circuit is controlled by the conversion clock, which is derived from the module clock.

The frequency of the conversion clock has to be within the limits defined in the data sheet. If the module clock frequency is higher than the maximum frequency of the conversion clock allowed during the functional conversion or during the calibration (see the chip data sheet), then you must configure the ADC conversion clock divider (MCR[ADCLKSEL]) so that the frequency of the conversion clock is within allowed limits. See Table 276.

Table 276. Clock configuration for highest conversion speeds

Module Clock Frequency f_mc[1]	Configuration during calibration	Configuration during functional conversion
40 MHz < f_mc ≤ 80 MHz	MCR[ADCLKSEL] = 1h AMSIO[HSEN] = 0h AMSIO[CMPCTRL0] = 0b	MCR[ADCLKSEL] = 0h AMSIO[HSEN] = 0h AMSIO[CMPCTRL0] = 0b
80 MHz < f_mc ≤ 120 MHz	MCR[ADCLKSEL] = 1h AMSIO[HSEN] = 1h AMSIO[CMPCTRL0] = 1b	MCR[ADCLKSEL] = 0h AMSIO[HSEN] = 1h AMSIO[CMPCTRL0] = 1b
120 MHz < f_mc ≤ 160 MHz	MCR[ADCLKSEL] = 2h	MCR[ADCLKSEL] = 1h

Table continues on the next page...

Table 276. Clock configuration for highest conversion speeds (continued)

Module Clock Frequency f_mc[1]	Configuration during calibration	Configuration during functional conversion
	AMSIO[HSEN] = 0h AMSIO[CMPCTRL0] = 0b	AMSIO[HSEN] = 0h AMSIO[CMPCTRL0] = 0b
160 MHz < f_mc ≤ 240 MHz	MCR[ADCLKSEL] = 2h AMSIO[HSEN] = 1h AMSIO[CMPCTRL0] = 1b	MCR[ADCLKSEL] = 1h AMSIO[HSEN] = 1h AMSIO[CMPCTRL0] = 1b
240 MHz < f_mc ≤ 320 MHz	MCR[ADCLKSEL] = 3h AMSIO[HSEN] = 0h AMSIO[CMPCTRL0] = 0b	MCR[ADCLKSEL] = 2h AMSIO[HSEN] = 0h AMSIO[CMPCTRL0] = 0b
320 MHz < f_mc ≤ 480 MHz	MCR[ADCLKSEL] = 3h AMSIO[HSEN] = 1h AMSIO[CMPCTRL0] = 1b	MCR[ADCLKSEL] = 2h AMSIO[HSEN] = 1h AMSIO[CMPCTRL0] = 1b

1. Lower resulting frequencies are allowed—see the chip data sheet.

When ADC is not converting (state machine is in Idle state), the conversion clock can be turned off (MCR[ACKO]).

57.3.2 Modes of operation

ADC is always in Functional mode. No other mode selection exists.

- Put ADC into Power Down state by writing 1 to MCR[PWDN] to reduce power consumption.
- Gate the clock signal by writing 1 to MCR[ACKO] when ADC is in Idle state.

57.3.3 Conversion

ADC measures the voltage of a signal—it converts an analog input value into a digital representation. When you read the conversion result, you must divide this conversion result by the number of codes (defined by selected conversion resolution in CALBISTREG[RESN]), and multiply it with the reference voltage value. This calculation provides the voltage value of the converted signal.

To convert an analog input voltage into its digital representation, ADC:

1. Receives a signal, referred to as a trigger, indicating it is to perform a conversion.
2. Captures the voltage of a signal via internal capacitances in a process referred to as sampling.
3. Compares the voltage to the reference voltage, using the SAR algorithm.

Before a conversion can be performed, you must select:

- The trigger source(s) to use (on the chip level)
- The input channel(s) to convert (NCMR0–2, JCMR0–2)

Additionally, you can tailor the conversion to meet your needs by changing the default configuration. For example, you can:

- Configure ADC to convert the selected input channel(s) only once or continuously in a loop (MCR[MODE]).
- Specify the duration that ADC samples the input signal (CTR0/1/2).
- Specify the resolution of the conversion result by selecting the number of bits (CALBISTREG[RESN]).

- Enable an analog watchdog to generate an interrupt when a conversion result falls outside a specified range (see Analog watchdog functions).
- Enable the DMA interface to send requests and receive acknowledgments (see DMA functionality).
- Check the operational integrity of ADC by running a self-test (see Self-test).

After power-up or a functional reset, ADC remains in Power Down state until enabled by writing 0 to MCR[PWDN]. After the system is powered on, you must run the calibration (see Calibration), before you can do a meaningful conversion with ADC.

Some configuration fields (listed below) are writeable only in Power Down state. If you intend to write to them, you must do so before exiting Power Down state.

- Select the conversion clock frequency to be within the allowed limits for a conversion.

57.3.4 Normal trigger

Select the input channels to convert by configuring the fields in NCMR0, NCMR1, and NCMR2.

These registers must be programmed before the start of conversion. You cannot reconfigure them until the conversion of all selected channels is complete. The sequence is always to convert the selected input channels in this order:

1. Start from the lowest input channel of the precision input channels.
2. Proceed through the standard input channels in ascending order.
3. End with the highest input channel of the external input channels.

57.3.4.1 Starting conversions in normal conversion mode

After programming the required fields of the following registers, you can start a conversion by writing 1 to MCR[NSTART]:

- Normal Conversion Enable For Precision Inputs (NCMR0)
- Normal Conversion Enable For Standard Inputs (NCMR1)
- Normal Conversion Enable For External Inputs (NCMR2)
- Main Configuration (MCR)

A hardware trigger can also start a normal conversion.

- If the external trigger is enabled (MCR[TRGEN] = 1), an external trigger enable is detected to start the conversion. The enable is checked only during start of conversion.
- Detection of an active edge defined by MCR[EDGE] (rising = 1, falling = 0) on an external trigger transitions MCR[NSTART] to 1 and starts the normal conversion.
- When MCR[TRGEN] = 1 (for example, when external trigger is enabled), conversion can be started by software.
- Any external trigger or software initiated conversion in normal conversion mode is ignored during any ongoing conversion chain.

NOTE

To have reliable operation there must be a gap of 3 clock cycles between configuration of NCMRx and the start of a conversion (by writing 1 to MCR[NSTART], or arrival of an external or internal hardware start trigger). ADC calculates the number of channels to be converted during this period.

57.3.4.2 Operation modes in normal conversions

Two operational modes are available during normal conversion:

- One-Shot mode
- Scan mode

For normal conversion, select the mode via MCR[MODE]. The first phase of the conversion process involves sampling the analog channel. The next phase is the conversion phase, curing which the sampled analog value is converted to digital as shown in the following figure.

Figure 279. Normal conversion flow

In One-Shot mode (MCR[MODE] = 0), a sequential conversion specified in the NCMR*n* mask registers is performed only once. At the end of each conversion, the digital result of the conversion is stored in the corresponding data register (CDR*n*).

For example: Channels A→B→C→D→E→F→G→H are present in a device where channels B→D→E are to be converted in One-Shot mode. Conversion begins with channel B, followed by conversion of channels D and E. At the end of conversion of channel E, the scanning of channels stops.

MSR[NSTART] automatically transitions to 1 when a normal conversion starts. At the same time, MCR[NSTART] is reset to zero by hardware, enabling software to program a new start of conversion in advance. In this case, the new requested conversion starts after completion of the running/current conversion. However, for correct functioning of the device, you should program MCR[NSTART] for the new conversion only after completion of the current conversion. The application can wait for an ECH interrupt prior to writing 1 to MCR[NSTART] again.

If an external trigger starts the conversion chain, ADC does not observe the trigger input until the conversion chain is finished. After the chain is finished, the next chain can be triggered by another hardware trigger edge.

In Scan mode operation (MCR[MODE]=1), a sequential conversion of N channels specified in the NCMR*n* registers is continuously performed. At the end of each conversion, the result is stored in the corresponding data register, as in One-Shot mode.

MSR[NSTART] automatically transitions to 1 when a normal conversion starts. Unlike One-Shot mode, MCR[NSTART] is not reset to 0 in Scan mode. It can be reset by software when you must exit Scan mode. In that case, ADC completes the current chain and after the last conversion, it resets MCR[NSTART] to 0.

For example: Channels A→B→C→D→E→F→G→H are present in the device where channels B→D→E are to be converted in Scan mode. MCR[MODE] = 1 selects Scan mode operation. Conversion starts from channel B followed by conversion of channels D→E. After conversion of channel E, the scanning of channel B starts followed by conversion of the channels D→E. This sequence repeats itself until MCR[NSTART] is reset to 0 by software.

If an external trigger starts a conversion, then MCR[NSTART] does not transition to 1. This scan chain can be stopped by writing 0 to MCR[NSTART]. The conversion stops when the ongoing chain is finished. Consequently, after it starts, the only way to stop Scan mode conversion is to write 0 to MCR[MODE].

End of conversion

In both modes, at the end of each conversion, an End of Conversion (EOC) interrupt is issued if enabled by the corresponding mask fields in CIMR*n* and IMR).

After conversion of all selected channels in NCMR*n* is complete, the conversion operation is considered finished. Then ISR[ECH] transitions to 1 and the End of Chain (ECH) interrupt is issued (if enabled in IMR[MSKECH]).

The corresponding channel field in the CEOCFR*n* register(s) is updated to indicate that data is available on data register CDR*n* of the respective channel.

If there is no channel selected in NCMR*n* and there is a start-of-conversion trigger, then ISR[ECH] is set to 1 and the End of Chain (ECH) interrupt is immediately issued (if enabled).

57.3.5 Injected trigger

An injected trigger enables you to convert a set of input channels although the standard trigger has already started conversion of another set of input channels. Each channel can be individually enabled by writing 1 to the corresponding field in JCMR0, JCMR1, or JCMR2.

The set of input channels of the injected trigger is converted only once. A continuous conversion of a set of input channels in a loop is only possible when started by a standard trigger. When an injected trigger is received, an ongoing conversion started by a standard trigger is interrupted. After the set of input channels of the injected trigger is converted once, the interrupted conversion of the set of input channels of the standard trigger resumes from the input channel that was interrupted, as shown in the following figure.

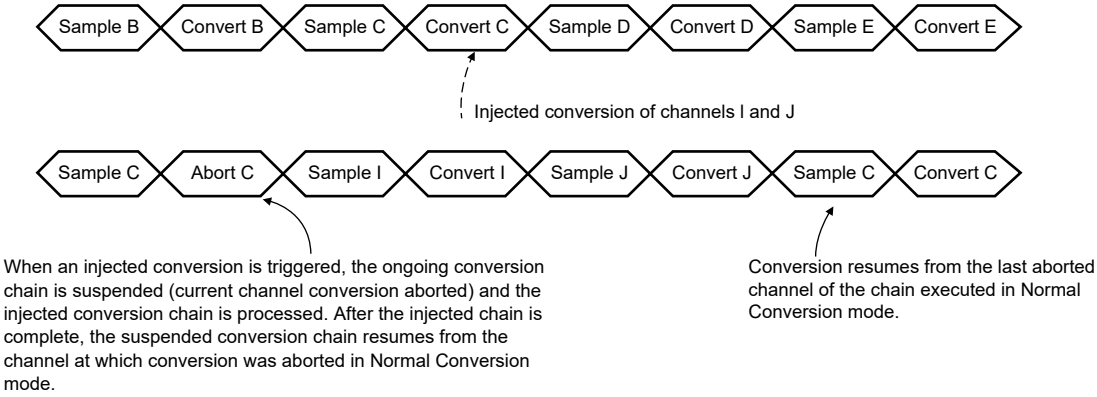

Figure 280. Injected trigger conversion sequence

57.3.5.1 Starting conversions in injected conversion mode

An injected conversion chain can be started:

- By software: When external triggering is disabled (MCR[JTRGEN] = 0), you can write 1 to MCR[JSTART], which causes the current conversion chain processed in Normal Conversion mode to be suspended and the injected chain to be processed.
- By external trigger: When external triggering is enabled (MCR[JTRGEN] = 1), a programmed event (rising/falling edge depending on the value of MCR[JEDGE]) on the injection external input starts the injected conversion.

MCR[JSTART] automatically transitions to 1 when the injected conversion chain starts. At the same time MCR[JSTART] is reset to 0, enabling software to program a new start of conversion in advance. In that case the new requested conversion starts after the running conversion completes.

At the end of each conversion, an End Of Injected Conversion (JEOC) interrupt is issued, if enabled by the corresponding mask field in Interrupt Mask (IMR). At the end of a chain, an End Of Injected Chain (JECH) interrupt is issued, if enabled by the corresponding mask field. Additionally, ADC writes 1 to ISR[JECH].

NOTE

If the content of all the Injected Conversion mask registers (JCMR*n*) is zero, that is, no channel is selected, the JECH interrupt is immediately issued after the start of conversion.

To have reliable ADC operation, there must be a gap of 3 cycles between configuration of JCMRx and starting of conversion (writing 1 to MCR[JSTART] or arrival of either an external or internal hardware start trigger). ADC calculates the total channel numbers to be converted during this period.

The corresponding channel bit in the CEOCFR*n* register is updated to indicate data is available in the channel's conversion data register, CDR*n*.

After starting, an injected chain conversion cannot be interrupted.

57.3.6 BCTU interface

The BCTU interface enhances ADC's injected conversion capability. It contains control inputs to select the channels to be converted from the appropriate event configuration register. Figure 281 shows the interface.

The BCTU generates a trigger (bctu_trigger) and a channel number (bctu_numchannel) to be converted. A single channel is converted for each request. After performing the conversion, ADC returns the result on the bctu_dataout bus together with two

output signals named bctu_nextcmd and bctu_push. The assertion of signal bctu_nextcmd means ADC is ready to accept the next trigger from BCTU. The bctu_push signal is asserted at the end of conversion, meaning that conversion is finished and the conversion result available at output bctu_dataout is valid.

The conversion result is also saved in the corresponding channel's data register and is compared with analog watchdog thresholds if requested.

The signals bctu_trigger, bctu_nextcmd and bctu_push are all of type single-cycle active-high-pulse in the ADC clock domain. The channel number provided from BCTU must be valid when bctu trigger is active-high. The result data from ADC is valid with bctu_push high.

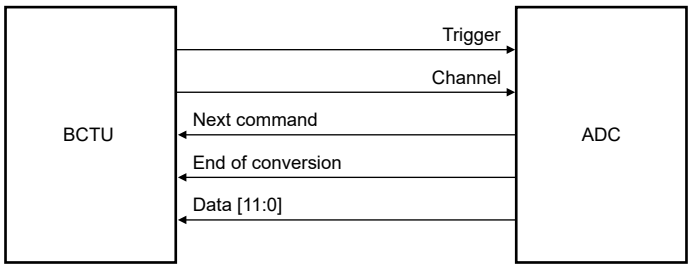

Figure 281. BCTU interface

The BCTU interface has two modes of operation:

- Trigger
- Control

To enable the BCTU interface, write 1 to MCR[BCTUEN]. The operating mode (Trigger or Control) can be fixed or programmable.

57.3.6.1 BCTU Trigger mode

In Trigger mode, normal and injected conversions can also be performed. All types of conversions can be initiated in this mode. The priorities among the three types of conversions are discussed below.

When a trigger is received, the channel number is taken as an injected channel value and the triggered injected conversion starts. MSR[BCTUSTART] transitions to 1 automatically at this point and it is also automatically reset to 0 when the triggered injected conversion is completed.

BCTU conversions must be requested only after successful ADC calibration. The application must prevent any BCTU trigger during calibration.

If a BCTU trigger is received during an ongoing injected conversion, the injected chain is aborted immediately and only the BCTU-triggered injected conversion proceeds. Additionally, MSR[JSTART] is reset to zero. The abort of an injected conversion is indicated by MSR[JABORT].

If a BCTU trigger is received during an ongoing normal conversion, the ongoing normal channel conversion is suspended and the BCTU-triggered injected conversion is processed. Normal conversion resumes from the suspended channel after completion of the BCTU-triggered conversion.

If a normal conversion is requested during BCTU conversion (MSR[BCTUSTART] = 1), the normal conversion starts after the BCTU conversion completes (MSR[BCTUSTART] is reset to zero).

Any injected conversion is discarded if requested during BCTU conversion and MCR[JSTART] is immediately reset to zero.

57.3.6.2 BCTU Control mode

In BCTU control mode (MCR[BCTU_MODE] = 0), only the BCTU can start a conversion. All other trigger sources are ignored.

Along with BCTU trigger, the information provided with signal bctu_numchannel is taken as the channel number for injected channel and BCTU triggered conversion starts. MSR[BCTUSTART] transitions to 1 automatically at the start of the conversion and it remains 1 unless BCTU is disabled by writing 0 to MCR[BCTUEN].

The conversion must be requested (generating bctu_trigger) when calibration has finished successfully. If a BCTU trigger is received during calibration execution, calibration is stopped immediately in order to satisfy the BCTU request. Calibration fails in this case.

57.3.7 Aborting a conversion

Two abort functions are provided:

- Abort of a single channel
- Abort of a chain

To abort an ongoing conversion, write 1 to MCR[ABORT]. The current conversion aborts and conversion of the next channel of the chain begins immediately.

Depending on the current state of a conversion, an Abort action may take 1 to 4 cycles of the bus clock. At the start of any conversion, and at the end of a particular conversion when internal state counters are changing, an abort action is delayed by a maximum of 3 cycles to put all states in a stable condition.

To ensure that the abort action completes, do not change MCR[ABORT] for the next 3 cycles.

Avoid writing 1 to MCR[ABORT] along with, and within 3 cycles of, writing 1 to MCR[NSTART] or MCR[JSTART].

During an abort:

- MCR[NSTART] and MCR[JSTART] remain 1, if not in the last channel of the chain.
- MCR[ABORT] is reset to 0 when the channel is aborted.
- The EOC interrupt corresponding to the aborted channel is not generated. This behavior applies to normal and injected conversions. If the last channel of a chain is aborted, the end of chain is reported by generating an ECH interrupt.

It is possible to abort the current chain of conversions by writing 1 to MCR[ABORTCHAIN]. In this case, the behavior of ADC depends on the value of MCR[MODE] (One-Shot/Scan operation modes). If Scan operation mode is disabled, MCR[NSTART] is automatically reset to 0 along with MCR[ABORTCHAIN]. Otherwise, in Scan Operation mode, a new chain is started. The EOC interrupt of the current aborted conversion is not generated but an ECH interrupt is generated to signal the end of the chain.

NOTE

For a single channel chain, an ECH interrupt is not generated for an abort or abort chain.

When an abort chain is requested while an injected chain is running over a suspended normal chain, both the injected and normal chains are aborted, and both MCR[NSTART] and MCR[JSTART] are reset to 0.

57.3.8 Configuring ADC clock divider and sample time settings

You can scale the AD_clk frequency via MCR[ADCLKSEL]. ADCLKSEL can only be written in Power Down state (MCR[PWDN] = 1). Depending on the frequency of the module clock, there might be different settings necessary for functional conversion and for calibration. See the chip data sheet for ADC electrical characteristics.

Three conversion timing registers are used (CTR*n*) to support different sampling times for the different types of channels. An exception exists for the temperature sensor channel, which always uses the Conversion Timing For Standard Inputs (CTR1) value. See the register description for details.

57.3.9 Presampling

The presampling feature enables pre-charge or discharge of the ADC internal sample capacitor node to a defined level before sampling of the selected analog input channel starts. This is useful for resetting information (history effect/offset) from the most recent conversion. During presampling, ADC samples the internally generated voltage. During the sampling phase, ADC samples analog input coming from pads.

Enable presampling on a per-channel basis by setting the corresponding fields in the PSR*n* registers to one.

After enabling presampling for a channel, the normal sequence of operation for the channel is:

1. Presampling
2. Sampling
3. Evaluation

You can bypass sampling of all channels by writing 1 to PSCR[PRECONV]. When sampling of a channel is bypassed, the sampled and stored internal voltage applied during the presampling phase is converted (Figure 282). See Conversion time for the timing equation for conversion.

Presampling does not apply for self-test channels.

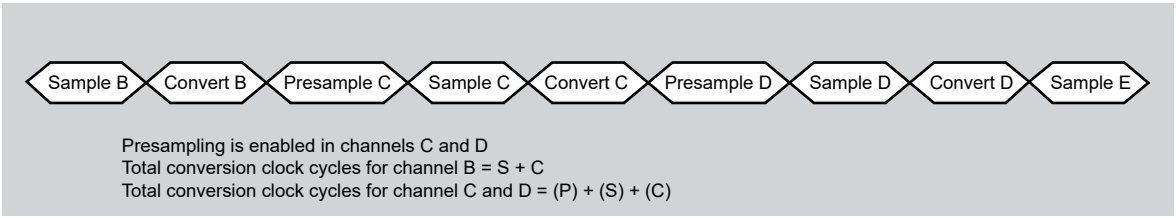

Figure 282. Presampling sequence

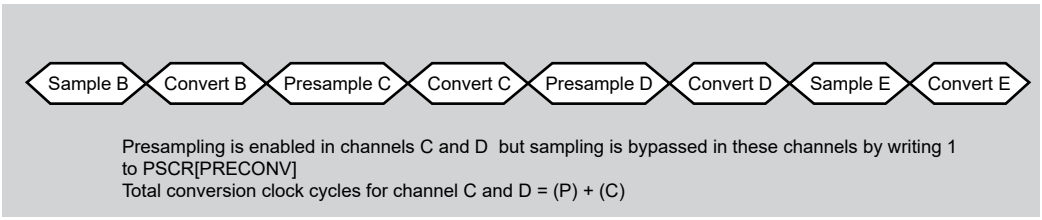

Figure 283. Presampling sequence with PRECONV=1

57.3.9.1 Enabling presampling per channel

Enable presampling for specific channels by programming Presampling Control (PSCR). You can select between two internally generated voltages by configuring the PREVAL*n* fields in Presampling Control (PSCR) to the appropriate values, as given in the following table.

Table 277. Presampling voltage selection via PREVAL*n*

PREVAL*n*	Presampling voltage
0	Presample voltage – 0: VREFL
1	Presample voltage – 1: VREFH

The presampling configuration field(s) (PSCR[PREVAL0], PSCR[PREVAL1], PSCR[PREVAL2]) are located in Presampling Control (PSCR). These fields enable selection of the presampling channel.

The temperature sensor channel has an exception. This channel is mapped with a fixed channel depending on device configuration, but it uses the presampling configuration defined for channel group 2. So, when the temperature sensor channel is selected, the presampling voltage defined by PSCR[PREVAL1] is selected. This voltage might be different from the one selected for channel group 1 via PSCR[PREVAL0].

57.3.10 Analog watchdog functions

When enabled, an analog watchdog monitors conversion results for an associated channel and reports an issue if it determines a result is outside customer-defined limits (as shown in Analog watchdog configuration (up to 16 watchdogs)). These limits are specified by an upper and a lower threshold value named THRH and THRL respectively.

After the conversion of the selected channel a comparison is performed between the converted value and the threshold values. If the converted value is outside that threshold value, then ADC generates a corresponding threshold violation interrupt.

The comparison result is stored as HAWIFx and LAWIFx fields in Analog Watchdog Threshold Interrupt Status (WTISR), as explained in the following table. Depending on the values of WTIMR[LAWIFENx] and WTIMR[HDWIFENx] mask fields, an interrupt is generated on a threshold violation.

Table 278. Values of HAWIFx and LAWIFx

HAWIFx	LAWIFx	Conversion result
1	0	Conversion result > THRH
0	1	Conversion result < THRL
0	0	THRH ≥ conversion result ≥ THRL

Depending on the chip's factory settings, up to 16 analog watchdogs are available. See the chip-specific configuration information for availability.

There are two types of mutually exclusive settings for analog watchdogs. Both types are described in the following sections. The availability depends on device configuration. See the chip-specific configuration information for availability.

Different capabilities are available with the two settings, as described below.

57.3.10.1 Channel analog watchdog select registers

ADC configuration includes selecting the analog watchdog threshold register (THRHLR*n*) that provides limits to monitor inputs of a given type. You select the THRHLR*n* using CWSELR*a*l*n* registers.

Table 279. CWSELR*a*l*n* register naming

Index	Description
a	ADC input type associated with a CWSELR*a*l*n* register. • P = Precision inputs • S = Standard inputs • E = External inputs
n	0-indexed register number.

57.3.10.2 Analog watchdog configuration (up to 16 watchdogs)

ADC can have up to 16 watchdogs in the factory configuration. (See the chip-specific configuration information for availability.) For each watchdog there is one threshold value register, THRHLR*n*, that contains the high and low thresholds.

You can independently enable the analog watchdog for each channel by programming the appropriate CWENR*n* register.

The threshold values for each channel can be selected independently from a maximum of 16 threshold registers (THRHLR*n*) using the corresponding WSEL_CH*n* field in the appropriate CWSELR*a*l*n*, where *a* indicates the input type:

- P = precision
- S = standard
- E = external

Each CWSELR*a*l*n* register is associated with 8 consecutive channels. CWSELR*a*l0 holds 8 WSEL_CH fields for channels 0 to 7. CWSELR*a*l1 is for channels 8 to 15 and so on. The availability of fields and registers depends on device configuration. See the chip-specific configuration information for availability.

If the conversion result of a selected channel is outside the range specified by threshold values, then the corresponding field in the Analog Watchdog Out of Range register (AWORR*n*) transitions to 1. For example, if channel 7 is to be monitored with the threshold values in THRHLR3, then CWSELR*a*l0[WSEL_CH7] must be programmed with 3. Enabling the watchdog is done by writing 1 to the corresponding field for channel 7 in CWENR0.

In this configuration, a set of threshold values (THRHLR*n*) can be linked to several ADC channels.

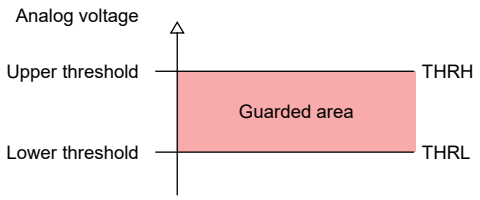

Figure 284. Guarded area

NOTE

If the higher threshold of the analog watchdog is programmed below the lower threshold and the conversion result is below the lower threshold, then the WDG*n*L interrupt for the low threshold violation transitions to 1. If the conversion result is greater than the lower threshold (and therefore also greater than the higher threshold), then the interrupt WDG*n*H for high threshold violation is generated. Thus you should take care to avoid that situation, as it could lead to misinterpretation of the watchdog interrupts.

57.3.11 DMA functionality

Conversion result data from any channel can be transferred from a register to system memory via Direct Memory Access (DMA). DMA transfers are enabled by writing 1 to DMAE[DMAEN]. After being enabled, the on-chip DMA controller can receive a DMA request after the conversion of each channel by writing 1 to the respective masking field in:

- DMA Request Enable For Precision Inputs (DMAR0)
- DMA Request Enable For Standard Inputs (DMAR1)
- DMA Request Enable For External Inputs (DMAR2)

DMA masking registers must be programmed before starting any conversion.

A DMA request to the DMA controller can be cleared at different times in two modes:

- Mode-1: Clearing of DMA request on acknowledgment from DMA controller (DMAE[DCLR] = 0)
- Mode-2: Clearing of DMA request on read to data registers (DMAE[DCLR] = 1)

The figures below show the operation of DMA in two modes (cycle counts are typical values).

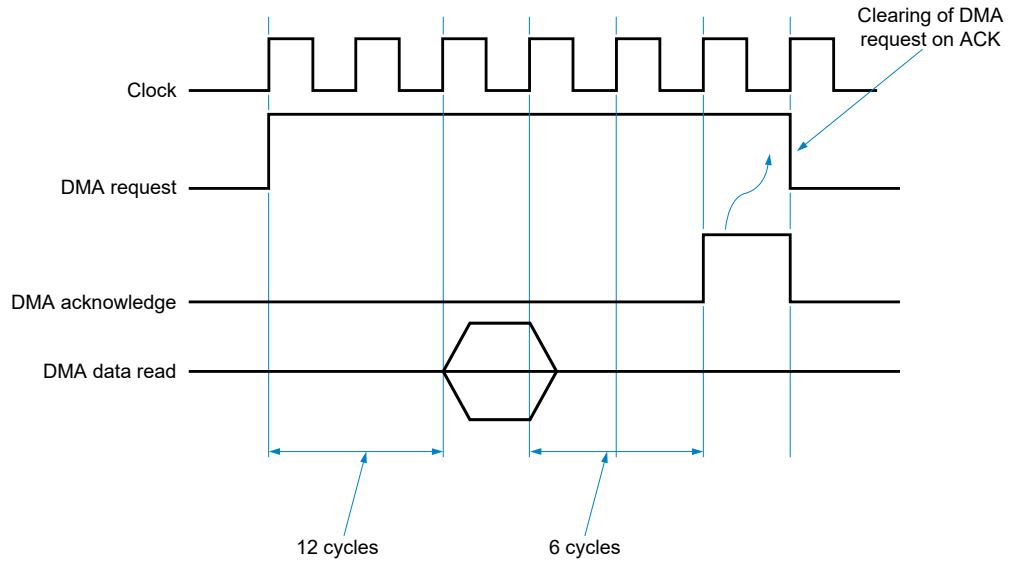

Figure 285. DMA operation Mode-1 (DMAE[DCLR] = 0)

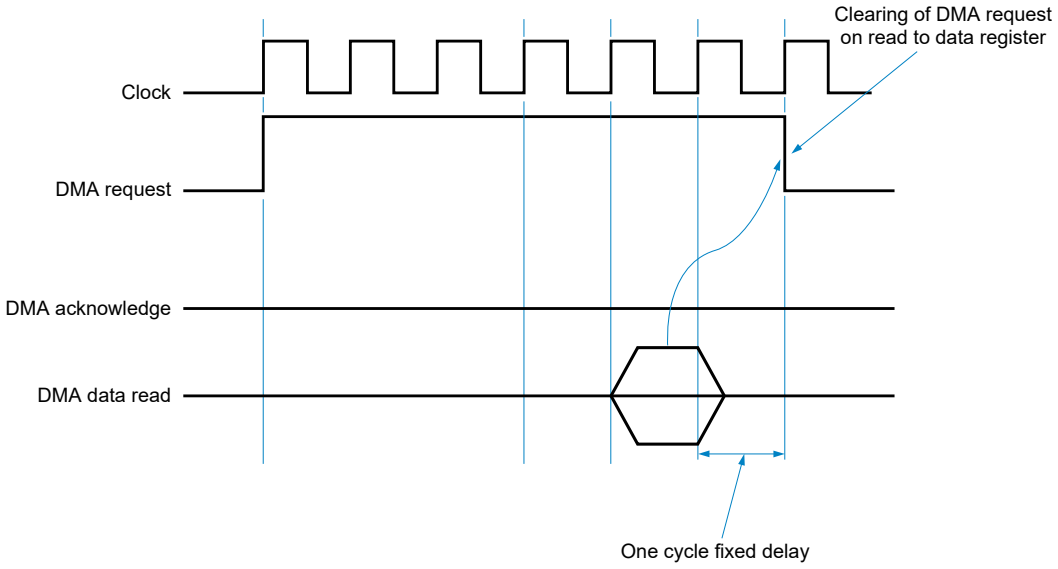

Figure 286. DMA operation Mode-2 (DMAE[DCLR] = 1)

57.3.12 Interrupts

ADC generates the following maskable interrupts:

- EOC (End of Conversion)
- ECH (End of Chain)
- JEOC (End of Injected Conversion)
- JECH (End of Injected Chain)
- EOBCTU (End of BCTU-triggered Conversion)
- LAWIFx and HDWIFx (Watchdog threshold)

- Self-testing interrupts

Interrupts are generated during the conversion process to signal events such as End Of Conversion (EOC), and so on, as described in Interrupt Status (ISR). ISR and another register, Interrupt Mask (IMR), are provided to check and enable the interrupt request to an external interrupt controller.

Interrupts can be individually enabled on a per-channel basis by programming EOC Interrupt Enable For Precision Inputs (CIMR0).

CEOCFR*n* are used for pending End of Conversion interrupts, with one field per channel to indicate completed conversions on a per-channel basis.

Interrupts generated due to the analog watchdogs are managed by two 32-bit registers, Analog Watchdog Threshold Interrupt Status (WTISR) and Analog Watchdog Threshold Interrupt Enable (WTIMR), to check and enable the interrupt request. A watchdog interrupt causes two corresponding fields to transition to 1 for each channel monitored. One field is in WTISR[WDG*n*H] and another in WTISR[WDG*n*L].

Generated events are logged into status registers and used to generate interrupts if enabled in corresponding Mask registers.

There are three different interrupt outputs. The interrupt structure is shown in Figure 287.

Each interrupt is generated by combining a group of events.

The following interrupts are combined (logic OR) into one interrupt output.

- EOC
- ECH
- EOBCTU
- JEOC
- JECH
- End of self-test algorithm (WDG_EOA_S and WDG_EOA_C)

Interrupts of all HDWIFx and LAWIFx are combined on the second interrupt output.

Interrupts of all self-test errors (watchdog threshold, sequence, and timer violations) in Self-Test Status 1 (STSR1) are combined on the third interrupt output. The errors are:

- WDSERR
- WDTERR
- ERR_S0
- ERR_S1
- ERR_S2
- ERR_C

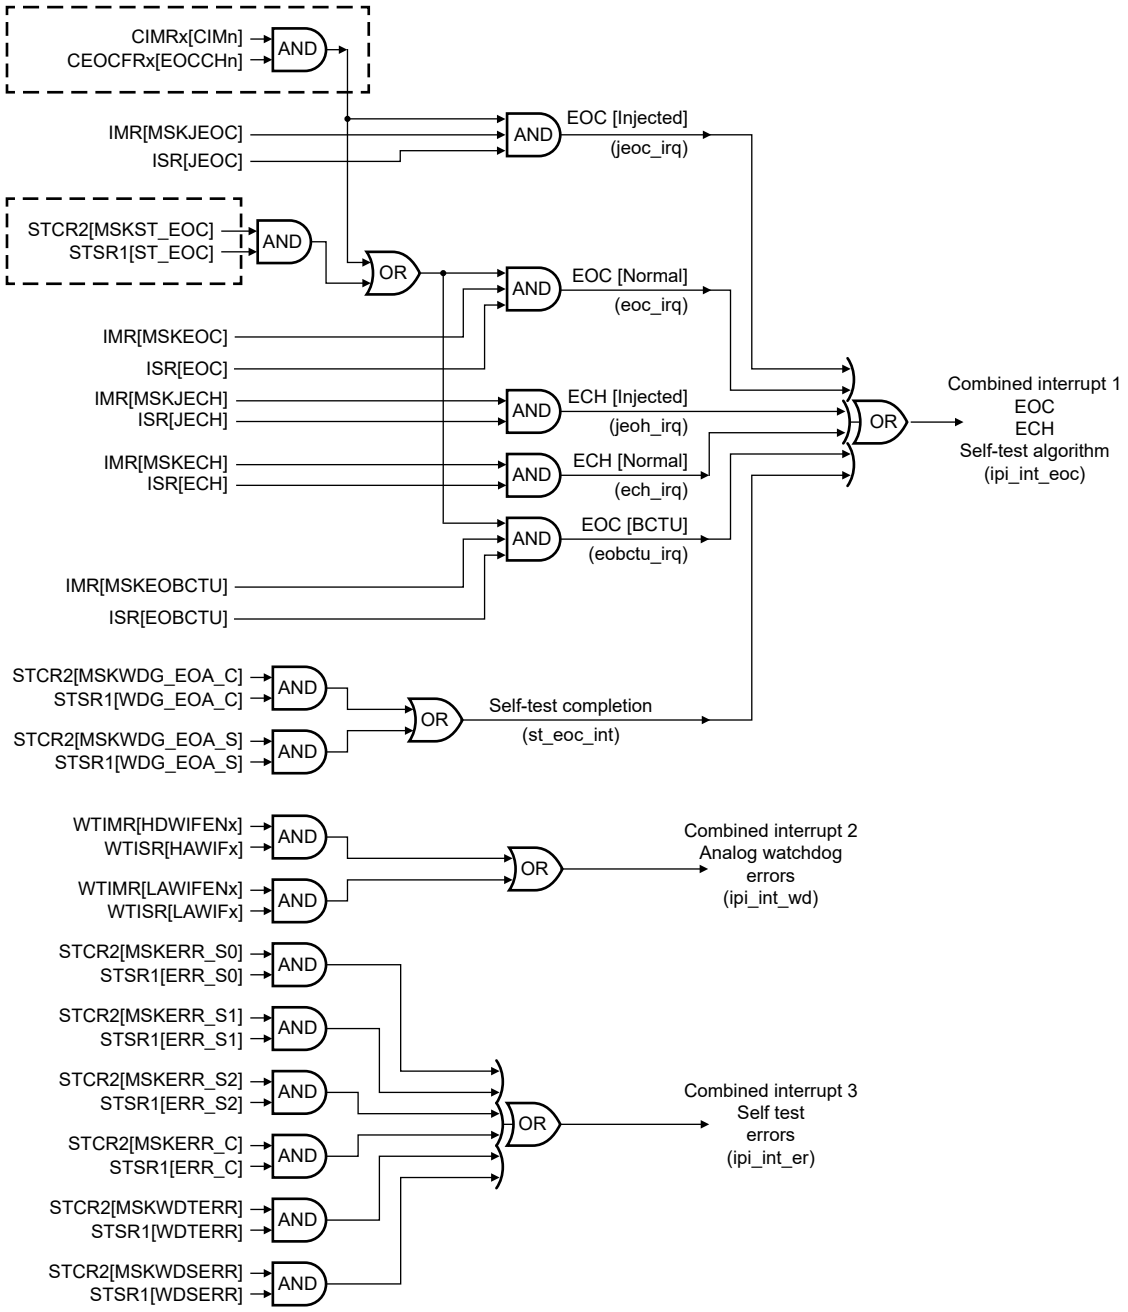

Figure 287. Interrupt structure of ADC

Interrupt Status (ISR) Indicates the interrupt pending request status. Write 1 to the corresponding status field to clear the pending interrupt flag (at this write operation all the other fields in Interrupt Status (ISR) must be maintained at 0).

ISR checks for three types of interrupts.

The first type, Interrupt 1, relates to the following:

- End of normal or injected conversion (EOC or JEOC)
- End of normal or injected conversion chain (ECH or JECH)
- End of algorithm C or algorithm S self-test (WD_EOA_C or WD_EOA_S)

Perform the following actions for this type of interrupt:

1. Read Interrupt Status (ISR) to determine whether the event is an EOC, JEOC, ECH, JECH, or EOBCTU event.
2. Read Self-Test Status 1 (STSR1) to identify the end of self-test algorithm events (WDG_EOA_S or WDG_EOA_C), if present.
3. If the interrupt is an EOC or JEOC event:
   - Clear the respective channel pending field in the appropriate CEOCFR*n* register for an EOC by writing a 1 to it.
   - Clear ISR[EOC] or ISRJEOC] by writing a 1 to it.
4. If the interrupt is an ECH or JECH, clear ISR[ECH] or ISR[JECH] by writing 1 to it.
5. If the interrupt is EOBCTU, clear ISR[EOBCTU] by writing 1 to it.
6. If the interrupt is for self-test end of algorithm, clear STSR1[WDG_EOA_S] or STSR1[WDG_EOA_C] by writing 1 to it.

The second type, Interrupt 2, relates to analog watchdog errors. Perform the following actions for this type of interrupt:

1. Read Analog Watchdog Threshold Interrupt Status (WTISR) to determine which watchdog triggered the interrupt.
2. Read the AWORRx register(s) to determine which channel's data caused the interrupt (if present).
3. Clear the respective field of the WTISR[WDG*n*H/WDG*n*L] register, where *n* = watchdog number, by writing 1 to it.
4. Clear the respective field of the AWORR*n*[AWOR_CH*n*] register, where x = register, n = channel, by writing 1 to it.

The third type, Interrupt 3, relates to self-test errors. Perform the following actions for this type of interrupt:

1. Read Self-Test Status 1 (STSR1) to determine the type of error encountered in self-test (WDSERR, WDTERR, ERR_S0, ERR_S1, ERR_S2, ERR_C, and so on) if present.
2. Clear the respective field in Self-Test Status 1 (STSR1) by writing 1 to it.

The connectivity of interrupt lines at the chip level (external to ADC) determines whether software must read all the registers for all three interrupts or any one or combination of any two.

57.3.13 External decode signals delay

The ADC provides three external decode signals which it uses to select one channel out of eight in the external analog multiplexers. There can be a maximum of four such multiplexers used to connect the 32 external channels. The ADC automatically sets the decode signals to control these external analog multiplexers, based on the current channel selected for conversion. Delay Start Of Data Conversion (DSDR) is provided to take the switching time of the external analog multiplexer into account. It enables you to program the delay between the decoding signal selection and the actual start of conversion.

If presampling is enabled, the DSD delay starts after the presample phase (presampling time is the same duration as sample time).

57.3.14 Power Down state

The analog part, along with the ADC controller, can be put in Power Down state by writing 1 to MCR[PWDN]. This shuts down ADC and stops the clock to the ADC controller. After release of reset, MCR[PWDN] remains 1, so the ADC analog module is kept in Power Down state by default. You must exit this state before starting any operation, by writing 0 to MCR[PWDN]. In Power Down state, no conversion can be started. If a BCTU trigger pulse is received during this state, it is discarded. You must ensure that a BCTU trigger is not initiated to ADC before writing 0 to MCR[PWDN], as it may cause the BCTU module to be stuck in a wait state.

You can set MCR[PWDN] by writing 1 to it at any time. If a conversion is ongoing, ADC does not move into Power Down state immediately. ADC enters Power Down state only after completion of the ongoing conversion. During scan operation, the ongoing operation should be aborted manually by writing 0 to MCR[NSTART] before or after writing 1 to MCR[PWDN].

ADC Power Down state status is indicated by MSR[ADCSTATUS] when ADC enters into Power Down state.

If the BCTU is enabled and MSR[BCTUSTART] = 1, then you cannot write 1 to PWDN. When BCTU Trigger mode is enabled, the application must wait for the end of conversion (MSR[BCTUSTART] is automatically reset to 0). When BCTU Control mode is enabled, before entering Power Down state the application must write 0 to BCTUEN also.

If Power Down state is entered by writing 1 to MCR[PWDN], the process running before entry into Power Down state must be restarted manually (by writing 1 to the appropriate START field in Main Configuration (MCR)) after exiting Power Down state.

NOTE

Writing 0 to MCR[PWDN] and writing 1 to MCR[NSTART] or MCR[JSTART] during the same cycle is not supported.

57.3.15 Low Power mode support

For low-power operation, ADC must be in Idle state and then put into Power Down state to ensure proper signal condition at the analog boundary.

From any of the states listed below, follow the sequence of steps shown to put ADC into Power Down state.

1. Idle condition
    a. Verify that ADC is in Idle state (MSR[ADCSTATUS] = 000b).
    b. Write 1 to MCR[PWDN], to shut off the clock to the hard macro with the proper state of signals required for Low Power mode.
    c. Verify that ADC is in Power Down state (MSR[ADCSTATUS] = 001b).
2. During calibration

    NOTE

    Writing 1 to MCR[PWDN] during calibration is prohibited. After calibration is started it should be allowed to finish normally. Alternatively, it can be terminated by starting a normal conversion before writing 1 to MCR[PWDN].

    a. Check the current ADC state either via MSR[ADCSTATUS] (000b = Idle, 011b = Calibration), or via CALBISTREG[C_T_BUSY] (1 = calibration is in progress).
    b. When ADC is in Idle state, write 1 to MCR[PWDN] to shut off the clock to the hard macro with the proper state of signals required for Low Power mode.
    c. Verify that ADC is in Power Down state (MSR[ADCSTATUS] = 001b).
3. During conversion (normal [one-shot]/Injected/BCTU):
    a. Write 1 to MCR[PWDN].
    b. ADC enters Power Down mode after completing the current conversion chain (for normal and injected conversions) or the conversion for conversion triggered by BCTU.
    c. Check the ADC state via MSR[ADCSTATUS] (000b = Idle state, 001b = Power Down state).
4. During Scan mode operation of normal conversion

    NOTE

    Writing 1 to MCR[PWDN] during scan mode operation has no effect other than to prevent software from starting a new normal or injected conversion. It does not stop a conversion in progress and cannot put ADC into Power Down state.

    a. Software must write 0 to MCR[NSTART] to stop the ongoing scan conversion before (or after) writing 1 to MCR[PWDN]. This stops conversion at the current chain boundary.
    b. ADC enters Power Down mode after coming to an Idle state after MCR[PWDN] is written with 1. This shuts the clock off to the hard macro and puts analog inputs in the proper state required for Low Power mode.
    c. Verify that ADC is in Power Down state (MSR[ADCSTATUS] = 001b).

57.3.16 Auto Clock Off mode

To reduce power consumption during Idle state (without going into Power Down state), an auto-clock-off feature can be enabled by writing 1 to MCR[ACKO]. When enabled, the internal ADC operating clock (AD_Clk) is automatically switched off during an idle period (for example, no conversion is programmed).

57.3.17 Calibration and self-test

57.3.17.1 Calibration

ADC must be calibrated before it can do meaningful conversions. The application must prevent any start of conversion before the ongoing calibration has finished successfully. No conversion trigger may be received during calibration.

During calibration, a known reference voltage is sampled and converted under controlled conditions to determine the correction values (calibration values) for offset, gain, and capacitor mismatch.

These calibration values (except gain calibration) are used in a post-processing step after conversion, reducing or eliminating the various error contribution effects. The gain calibration is used during sample phase to define the additional charge to be loaded to compensate for gain failure.

You must run calibration after every power-up reset (check device-specific reset connectivity for appropriate reset applied). You must also run calibration if it is indicated by the self-test (see Self-test).

Configuration and start of calibration is done by programming the Control And Calibration Status (CALBISTREG). During calibration, internal hardware averaging function should be enabled. Maximum averaging is recommended, and 16 should be the minimum.

Calibration status is captured by a status flag (CALBISTREG[TEST_FAIL]) to indicate any fault detected during calibration execution or if calibration was prematurely aborted. Calibration is aborted if any normal conversion is initiated during the calibration execution, which is called premature termination. (Flag TEST_FAIL = 1 indicates a calibration fail, for example when a calibration value is out of internally defined limits.)

To execute the calibration algorithm, perform the following steps:

1. Select the conversion clock frequency to be within the allowed limits for the calibration.
2. Bring ADC from Power Down state to active conversion (program MCR[PWDN] = 0b).
3. Configure the Control And Calibration Status (CALBISTREG). The default values are set for maximum accuracy (recommended).
4. Disable the error correction for the smaller capacitances in the CDAC of the ADC (write 0h to CAL2[ENX]).
5. Start calibration (program CALBISTREG[TEST_EN] = 1b), and calibration starts immediately.
6. Poll the status of CALBISTREG[C_T_BUSY] for 0 (wait until it transitions to 0).
7. Check CALBISTREG[TEST_FAIL] to determine the final status. If 1, then calibration failed.
8. Check the status of MSR[CALIBRTD]. If calibration was successful this field is 1.

57.3.17.2 Self-test

For safety applications, it is important to verify correct operation at regular intervals. ADC has a self-test feature for this purpose. When self-test is enabled, ADC automatically checks its components and flags errors, if any are found.

Tests can be enabled to check the reference (VrefH) and calibrated values.

The following test algorithms have been implemented:

- Supply self-test (algorithm S): It includes the conversion of the band gap and VREF voltages. It includes a sequence of num_supply_steps test conversions (steps). The supply test conversions must be an atomic operation (that is, all supply algorithm conversions must be performed one after another with no functional conversions in between).

- Capacitive self-test (algorithm C): It includes a sequence of test steps per definition of algorithm C (see Table 280) which executes the capacitive matrix of the CDAC used for sampling and conversion.

Individual steps can take up to 1 µs at 80 MHz ADC clock frequency.

Table 280. Self-test steps

STCR3[ALG]	STCR3 [step](per algorithm definition)	Description	Outcome	Comment
00 (algorithm S)	0	Supply self-test (band gap voltage)	Measures the internal band gap voltage	
	1	Supply self-test (reference voltage high)	Measures ADC high reference voltage	
	2	Supply self-test (reference voltage high)	Measures ADC high reference voltage	
01 (Reserved)	Reserved			
10 (algorithm C)	0 – 11	Capacitive self-test. One of the calibration steps is being run.	The difference/error of the individual offset value from the previously calibrated value is being returned as an ADC result that is compared with the programmed value in the self-test analog watchdog register(s) to detect any fault.	The ideal result value is expected to be 0. If the returned value is higher, it indicates a runtime fault or accuracy shift. The error is indicated in the status register and can be used to generate an interrupt also. It that indicates ADC should be recalibrated to check whether the reported error can be managed by calibration or that permanent damage occurred to ADC.
11 (algorithm S + C)	0 – 2 (S), 0 – 11 (C)	Supply for One-Shot mode and (supply + capacitive) for Scan mode only.	Same as above.	

ADC:

- Schedules self-testing algorithms using configuration registers.
- Monitors the converted data using analog watchdog registers.
- Flags any errors to a fault control unit (FCCU), if one exists.

Self-test steps can be activated from software (CPU) or BCTU.

ADC mode	TEST algorithm (CPU)	TEST algorithm/step (BCTU)
CPU mode (MCR[BCTUEN] = 0)	Yes	No

Table continues on the next page...

Table continued from the previous page...

ADC mode	TEST algorithm (CPU)	TEST algorithm/step (BCTU)
	• One-Shot operation mode • Scan operation mode	
BCTU mode	No	Yes

57.3.17.2.1 CPU mode

In this mode, self-test conversion is similar to normal conversion. You enable self-test by writing 1 to STCR2[EN].

Self-test conversions execute along with the functional conversions. The sequencing of steps of the selected algorithm depends on the operating mode of normal conversions (selected by MCR[MODE]).

In One-Shot operation mode, if self-test is enabled, only one step of the selected self-testing algorithm is executed at the end of the chain. The step number and algorithm to be executed are programmed in Self-Test Status 3 (STSR3). In One-Shot operation mode the sequence is:

1. Program NCMR*n* to select channels to be converted for normal conversion.
2. Write 0 to MCR[MODE] to select one-shot operation.
3. Configure the self-test algorithm threshold values (see Table 281).
4. Program sampling duration values in STCR1[INPSAMP*m*] (*m* = S, C).
5. Select the self-testing algorithm (in STCR3[ALG]), and step (in STCR3[MSTEP]). The default is algorithm S, step 0.
6. Enable self-testing by writing 1 to STCR2[EN].
7. Start the normal conversion by writing 1 to MCR[NSTART].
8. All normal conversions are executed as usual.
9. At the end of all normal conversions in the chain, the step number (programmed in STCR3[MSTEP]) of the self-testing algorithm (selected by STCR3[ALG]), is executed similar to a normal functional channel.
10. At the end of the conversion for the self-test channel:
    - The result is written to STDR1[TCDATA].
    - STDR1[VALID] transitions to 1.
    - ISR[EOC], ISR[ECH], and STSR1[ST_EOC] transition to 1.
11. ADC returns to Idle state.

For example: Channels A→B→C→D→E→F→G→H are present in the device where channels B→D→E are to be converted in One-Shot operation mode. At the end of conversion for channels B→D→E, self-test conversion is performed and ISR[ECH] and ISR[EOC] transition to 1. The sequence is B→D→E→self-test step.

MSR[NSTART] transitions to 1 when the normal conversion starts and transitions to 0 at the end of conversion for the test channel.

In Scan operation mode, consecutive steps of the selected self-test algorithm are converted continuously at the end of each chain of normal conversions. The number of channels converted at the end of each chain is 1 (except for algorithm S, in which all the steps are performed sequentially without any functional conversion interleaved). So, in Scan operation mode the sequence is:

1. Program NCMR*n* to select the channels to be converted for normal conversion.
2. Write 1 to MCR[MODE] to select Scan operation mode.
3. Configure the self-test algorithm threshold values (see Table 281).
4. Program sampling duration values in STCR1[INPSAMP*m*] field (*m* = S, C).

5. Select the self-testing algorithm in STCR3[ALG]. By default, all algorithms (supply and capacitive) are selected, that is, all algorithms are executed step-by-step, one after the other.
6. Enable self-testing by writing 1 to STCR2[EN].
7. Start the normal conversion by writing 1 to MCR[NSTART].
8. All normal conversions are executed as usual.
9. At the end of the chain of normal conversions (assuming the default value of STCR3[ALG]), all steps of algorithm S are performed (as algorithm S is always atomic). MSR[SELF_TEST_S] transitions to 1.
10. At the end of the conversion of the self-test channel for the last step of algorithm S, the result is written to STDR1[TCDATA] and STDR1[VALID] transitions to 1. At the same time, MSR[SELF_TEST_S] transitions to 0. The following registers also transition to 1:
    - ISR[EOC]
    - ISR[ECH]
    - STSR1[ST_EOC]
11. The next chain of normal conversions then starts.
12. At end of the chain of normal conversions, ADC executes step 0 of algorithm C.
13. At the end of the conversion of the test channel for step 0 of algorithm C, the result is stored in STDR1[TCDATA] and STDR1[VALID] transitions to 1 (if STSR1[OVERWR] is 1). Also, ISR[EOC] and ISR[ECH] transition to 1. STSR1[ST_EOC] also transitions to 1.
14. The next chain of normal conversion then starts.
15. At the end of the normal conversion chain, ADC executes step1 of algorithm C.

This process continues for all steps of all three algorithms. The state machine returns to Idle state when MCR[NSTART] transitions to 0.

For example: channels A→B→C→D→E→F→G→H are present in the device where channels B→D→E are to be converted in Scan operation mode. At the end of every conversion chain for channels B→D→E, one step of the self-test conversion is performed and ISR[ECH] and ISR[EOC] transition to 1.

The sequence is:

B→D→E→ST-S0→ST-S1→ST-S2→B→D→E→ST-C0→B→D→E→ST-C1→B→D→E→ST-C2→ . . . B→D→E→ST-C11→B→D→E→ST-S0 . . .

ST-Sx - Self-test supply step x (x = 0, 1, 2)

ST-Cx - Self-test capacitive step x (x = 0 to 11)

MSR[NSTART] transitions to 1 when normal conversion starts.

NOTE

- If instead of starting normal conversion by software (by writing 1 to MCR[NSTART]), it is started by an external trigger, the self-test behavior remains the same.
- Self-test channel conversion is not performed for injected conversions. It is performed only during normal conversions.
- If, during a test channel conversion, an injected conversion arrives, the test conversion is aborted (just as a normal functional channel) and the injected conversion is performed. After the injected conversion is complete, the test conversion resumes from the step at which it was aborted. In this case, MSR[SELF_TEST_S] remains 1 during the injected conversion.
- For self-test, MCR[MODE] should be programmed (at least one cycle) before writing 1 MCR[NSTART] and should not be changed until the conversion is finished or terminated.

Table 281. Recommended self-test threshold values

Register field	Hex value	Decimal value	Comment
STAW0R[THRH]	3669h	13929	The threshold values depend on the stability of the supply and the reference voltage. When you see voltage variations, widen the limits.
STAW0R[THRL]	5 V reference: 1A7Fh 3 V reference: 2B27h	5 V reference: 6784 3 V reference: 11047	
STAW1R[THRL]	3FF9h	16377	
STAW2R[THRL]	3FF9h	16377	
STAW4R[THRH]	20h	32	
STAW4R[THRL]	7FE0h	–32	
STAW5R[THRH]	20h	32	
STAW5R[THRL]	7FE0h	–32	

57.3.17.2.2 BCTU mode

BCTU mode is enabled by writing 1 to MCR[BCTUEN].

Self-test conversion behaves in the same way for all BCTU operating modes (Trigger mode and Control mode). In both cases, if MCR[BCTUEN] = 1, the self-test conversion can be started only by BCTU—software cannot start it. MCR[BCTUEN] must not be changed during normal conversion. The interface between BCTU and ADC (for self-test) is shown in the following figure.

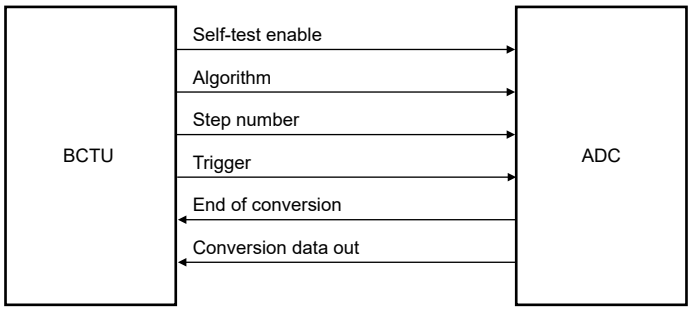

Figure 288. Self-test interface between ADC and BCTU

For self-test conversions in BCTU mode, BCTU asserts self-test enable along with the Trigger command. The algorithm and the step number to be executed is put on algorithm and step number, respectively. The other commands (Trigger, End Of Conversion, and Conversion Data Out) have the same meaning, like normal BCTU functional conversion.

As already mentioned for algorithm S, the three steps must be atomic. In BCTU mode, this is managed by BCTU, that is, BCTU sends three triggers (one for each step) asserting self-test enable and updating test_step for each step.

57.3.17.2.3 Abort and abort chain for self-testing channel

Writing 1 to MCR[ABORT] during self-test channel conversion has no effect.

In One-Shot operation mode, if you write 1 to MCR[ABORTCHAIN] during the self-test channel conversion, the self-test channel is aborted and ISR[ECH] transitions to 1. In this case, ISR[EOC] for the self-test channel is not generated.

In Scan operation mode, if MCR[ABORTCHAIN] = 1 when self-test channel step *n* is ongoing, self-test channel step *n* is aborted and the next chain conversion begins. At the end of the chain, the step *n* conversion is performed again. (For algorithm S, the full algorithm is executed again).

57.3.17.2.4 Self-test analog watchdog

ADC provides monitoring options for conversion data generated by self-test algorithms. Analog watchdogs determine whether the conversion results for self-test algorithms are in the range of a particular guard area. ADC provides separate self-test analog watchdog registers for each algorithm.

After the conversion of each step of a self-test algorithm, ADC compares the converted value and the threshold values if the analog watchdog feature has been enabled by writing 1 to STAW*n*R[AWDE] (for example, STAW0R[AWDE]). If the converted value is not between the upper and lower threshold values specified by the Self-Test Analog Watchdog Register for the particular algorithm, the corresponding error flag, STSR1[ERR_x], transitions to 1 and the step number in which error occurred is captured in STSR1[STEP_x] (for algorithm C). Erroneous data is written to STSR4[DATA*n*]. The STSR1[ERR_x] flags generate an interrupt if enabled by the corresponding mask bit in Self-Test Configuration 2 (STCR2). The fault indication is also forwarded to the fault control unit, if present, so that necessary action can be taken at the chip level. The fault type (critical or noncritical) is specified by the configuration in Self-Test Configuration 2 (STCR2).

The analog watchdog feature works differently for algorithm S. Algorithm S is always an atomic operation. Self-Test Status 1 (STSR1) has a separate error field for each step of algorithm S to avoid overwrite in case an error occurs in more than one step. Therefore, there are separate mask bits for each step in STCR1. For the same reason, the status registers (Self-Test Status 2 (STSR2) and Self-Test Status 3 (STSR3)) have separate fields for each step to store erroneous data.

In step 0 of the supply algorithm, ADC measures the band gap voltage (1.2 V), which is assumed to be stable. The conversion result of step 0 is compared against high (THRH) and low (THRL) thresholds as defined in Self-Test Analog Watchdog S0 (STAW0R), if enabled (STAW0R[AWDE] = 1). The STSR1[ERR_S0] flag transitions to 1 if any of the thresholds are violated. STSR1[ERR_S0] is cleared by writing 1 to it. The conversion result of ADC can be calculated with the following formula:

- ADC data (decimal) = (Vin × 2^{15} ÷ (Vrh - Vrl))

Where:

- Vin: input voltage (band gap voltage in this case)
- Vrh: ADC reference high voltage
- Vrl: ADC reference low voltage

The upper and lower threshold value can be calculated with the above formula using maximum and minimum values of Vin, Vrh, Vrl (Vin is the band gap supply voltage in this case):

- Upper threshold (THRH, decimal) = (Vin[max] × 2^{15}) ÷ (Vrh[min] - Vrl[max])
- Lower threshold (THRL, decimal) = (Vin[min] × 2^{15}) ÷ (Vrh[max] - Vrl[min])

The minimum and maximum voltages can be obtained from the chip data sheet. The band gap voltage tolerance, as well as the actual reference voltage used and its tolerances, must be considered when calculating high and low thresholds.

For algorithm S steps 1 and 2, (VREF/VREF) is measured in order to check the integrity of the sampling signal. For these particular conversions, no higher threshold value is required as the ideal value is FFFh. Only the lower threshold value is programmed in Self-Test Analog Watchdog S1 (STAW1R) and Self-Test Analog Watchdog S2 (STAW2R).

For algorithm C, a separate register is provided for step 0. In step 0 an offset for other steps is measured. The converted data is compared with the threshold values in Self-Test Analog Watchdog C (STAW5R) if STAW4R[AWDE] = 1. For other steps, this offset is subtracted from converted data before performing watchdog checks.

57.3.17.2.5 Watchdog timer

The watchdog timer is an additional check that monitors the sequence of the self-testing algorithm that has been implemented, and also checks whether the algorithm is completed within a safe time period. The watchdog timers are enabled for CPU as well as BCTU conversions. Each algorithm has an independent watchdog timer. The watchdog timer for a particular algorithm is enabled by writing 1 to STAWxR[WDTE]. The safe time value is programmed in STBRR[WDT] (the default value is 10 ms, assuming an 80 MHz clock).

The safe time is measured starting from step 0 of the algorithm (including all normal chain conversions in between) to the point where step 0 of the same algorithm starts again.

The programming sequence is:

1. Program NCMR*n* to select the channels for normal conversion in Scan operation mode (MCR[MODE] = 1).
2. Select the self-test algorithm in STCR3[ALG]. By default, all algorithms (supply and capacitive) are selected (all algorithms are executed step-by-step, one after the other).
3. Enable the self-test channel by writing 1 to STCR2[EN].
4. Program the safe period value in STBRR[WDT].
5. Enable the watchdog timer by writing 1 to STAWxR[WDTE]. Assume writing 1 to STAWxR[WDTE] occurs at time *t*0. It is important to do all configuration programming before writing 1 to STAWxR[WDTE], because the safe time check is also performed between writing 1 to STAWxR[WDTE] and the start of step 0. This is to verify that the algorithm has started within the safe time.
6. Start the normal conversion by writing 1 to MCR[NSTART].
7. At the end of the first conversion chain, three steps (steps 0, 1, and 2) of algorithm S are executed in sequence. Assume the start of Step 0 occurs at time *t*1.
8. After completion of algorithm S, ADC performs conversion of the next chain.
9. At the end of the conversion chain, the first step (step 0) of algorithm C is performed.
10. In this way, one step of algorithm C is performed after completion of one conversion chain until all steps are finished. Steps are executed in sequence (steps 0–11)
11. After the last step of algorithm C, another chain conversion is executed. At the end of this chain conversion, step 0 of algorithm S is started again, repeating the whole sequence. Assume this time (starting of step 0 of the supply algorithm) to be at time *t*2.
12. For algorithm S, if (*t*1 - *t*0) > safe period or (*t*2 - *t*1) > safe period, the watchdog timer flags an error and STSR1[WDTERR] transitions to 1. ADC asserts a fault signal per the criticality configuration (critical or noncritical) and an interrupt is generated, if enabled (STCR2[MSKWDTERR] = 1). Otherwise, the watchdog timer counter is reset and starts again to monitor the next sequence.
13. A similar sequence is followed for watchdog timers for algorithm C.

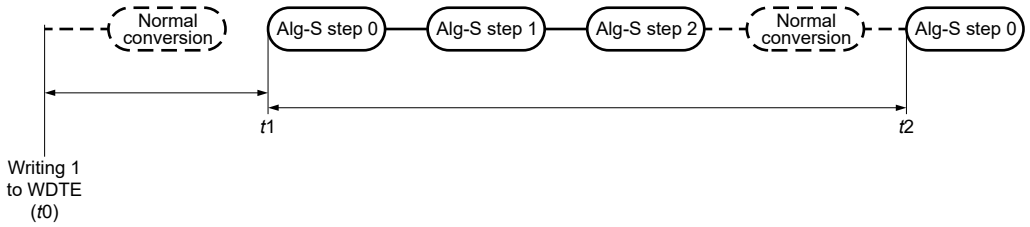

Figure 289. Watchdog timer monitor for algorithm S

NOTE

1. Because BCTU may not incorporate any safe period checking mechanism, the watchdog timers can also be enabled for BCTU conversions.
2. You must disable watchdog timers for self-test algorithms that are not executed.

57.3.17.2.5.1 Watchdog sequence checking

The self-test watchdog timer incorporates sequence checking features to verify that the steps of each algorithm are executed in the correct order. If the steps are not in the correct order, STSR1[WDSERR] transitions to 1 to indicate the error. A fault is indicated by an interrupt flag if STCR2[MSKWDSERR] = 1. A fault is also asserted as per criticality configuration (critical or noncritical) and an interrupt generated if STCR2[MSKWDSERR] = 1.

A watchdog sequence error is flagged in the following cases:

- The steps of any algorithm are not executed in proper order.
- The step numbers provided by BCTU for a BCTU conversion are not in order. Watchdog sequence checking is significant only for BCTU burst mode.
- When an abort chain occurs during a self-test channel conversion, that step must be repeated at the end of the next chain. This generates a sequence error as soon as the self-test channel conversion resumes. There is an exception, however. If an abort chain occurs during the last step of algorithm S, the sequence error is not flagged because the whole algorithm must be repeated.

If an injected conversion occurs during self-test channel conversion, a watchdog sequence error is not flagged, although the ongoing step number is aborted and is repeated.

NOTE

The watchdog timer feature is applicable for Scan operation mode but not for One-Shot operation mode.

57.3.17.2.6 Baud rate control for test channel

The baud rate control feature controls the scheduling of self-test channel conversions between normal conversion chains. The scheduling rate is specified by STBRR[BR].

By default, if the self-test channel is enabled, one step of the selected algorithm is executed after each normal conversion chain. The bandwidth consumed by the self-test channel depends on the number of channels in the normal chain. For example, if you have 50 normal conversions in a chain, then the self-test channel consumes only 2% of the total bandwidth, which is very small. If the number decreases to just 3 channels, the bandwidth consumed by the self-test channel is 25%, which is significant (and may not be desirable because it slows down the normal conversion rate).

STBRR[BR] provides flexibility by scheduling the self-test channel conversion to be performed not at the end of every chain, but at the end of BR + 1 chains. For example, if STBRR[BR] = 5, a single step of the selected algorithm for the test channel is performed after 6 chain conversions. The next step is performed at the end of the next six chain conversions, and so on. By default, STBRR[BR] = 0.

NOTE

This feature is applicable only for Scan operation mode and not for One-Shot operation mode. STBRR[BR] should be written with 0 for One-Shot operation mode.

To use the baud rate control feature in Scan operation mode, NCMR*n* should have a nonzero value.

57.3.17.2.6.1 Abort chain when baud rate is nonzero

As already described, for a nonzero value of STBRR[BR], the self-test channel conversion is performed at the end of BR + 1 chains. If an abort chain occurs during the chain in which a self-test channel conversion is scheduled to be performed, the self-test channel conversion is performed after the next BR + 1 chains.

For example, if STBRR[BR] = 2, the sequence is two normal chains (without any self-test channel conversion), followed by a chain with the self-test channel converted at the end. If an abort chain occurs during the first two chains, it is treated as a normal chain abort and the self-test channel is converted at the end of the third chain only (as in the case without any abort chain). However, if an abort chain occurs during the third chain in which the self-test channel is scheduled to be converted, the self-test channel is converted after the next three chains (for example, at the end of the sixth chain, counting from the beginning).

57.3.18 Conversion time

Total conversion time depends on the conversion clock frequency, which is configured by programming MCR[ADCLKSEL].

The components of conversion time and affecting configurations are:

- PST
- ST
- CT

- DP
- TPT

Presample phase time is equal to the sample time with a one AD_clk cycle delay for phase transition from presample phase to sample phase. CTR*n*[INPSAMP] controls sample time for different types of channels and is specified in terms of AD_clk cycles, so the presampling time is sample time plus one cycle of AD_clk. The minimum value of sample time is 8. If the value programmed is less than 8, it has no effect on sample time and the sample time is 8 AD_clk cycles.

Compare phase time is controlled by:

- The evaluation time of a single bit
- The number of bits converted

For *n*-bit conversions, the value of CT is *n* multiplied by the evaluation time of a single bit in terms of AD_clk cycles.

The evaluation time of a single bit is 4 AD_clk cycles if AMSIO[HSEN] = 0h and AMSIO[CMPCTRL0] = 0b. The evaluation time of a single bit is 6 AD_clk cycles if AMSIO[HSEN] = 1h and AMSIO[CMPCTRL0] = 1b.

The data processing time is 2 cycles of AD_clk. During these cycles raw converted data is corrected for offset, gain, capacitor mismatch, and so on.

Trigger processing time consists of:

- One module_clock cycle, which is required to prepare the channel and calculate the initial gain value used by ADC for the first conversion.
- BCTU triggering time:
  - Triggers from the synchronous BCTU interface require 1 cycle of the module clock for processing. One more cycle is required to register the BCTU trigger in synchronous mode.

The total conversion time, in terms of the module clock cycles, is calculated using the following equation for normal and injected conversions:

Total_conversion_time = ([(PST + ST + CT + DP) × chain_length] + TPT) × TAD_clk

Example:

The ADC controller clock is equal to the module clock (80 MHz, clock cycle = 12.5 ns)

- ADC resolution 12 bit + 1 bit for a special capacitor (CS)
- Three channels are programmed in NCMR*n*, so a chain of three is to be converted
- Default sample time (22 cycles) is specified
- No presampling
- Conversion time (4 cycles per bit)

The total time for the three conversions = [(0 + 22 + (4×13) + 2) × 3] + 1 = 229 cycles ~= 2.862 µs

Conversion timing in Calibration for full test:

- Single conversion time = [sample time (CALBISTREG[TSAMP]) + compare time (11 × 4) + data proc(2)]
- Inter-conversion gap = 1 cycle
- Total number of tests = 12
- Averaging = 32

One test duration = (single conversion time + inter-conversion gap) × averaging samples

Total test duration = ((one test duration) × total number of tests).

Example: sample time = 22

Total test time = ((((22 + (11×4) +2)+1) × 32) × 12) = 26496 cycles × 12.5 ns (80 MHz) = 331200 ns

Conversion time in self-test:

Self-test conversion time equals one test period multiplied by the number of consecutive (atomic) steps. For supply self-test, the atomic step is 3 and for other tests it is 1.

One test period for self-test is as below.

- For supply tests: ([sample_time + (13 × 4) + 2])
- For other algorithms: ([sample_time + (11 × 4) + 2])

NOTE

Algorithm S steps (conversions) always run in atomic operation, required for an algorithmic procedure. In Scan operation mode, when all algorithms are selected, three steps of algorithm S run together after the end of the conversion chain. algorithm C steps are not required to be run together, so after each conversion chain one step is executed serially. Conversion time with self-test must also be calculated accordingly.

Example.

- Channels in chain A→B→C.
- Scan operation mode.
- All self-test algorithms are selected.

So, the resulting conversion order is:

[A→B→C→AS_step0→AS_step1→AS_step2→A→B→C→AC_step0→A→B→C→AC_step1→A→B→C→AC_step2→.....→A→B→C→AC_step11]→[same sequence repeats]

NOTE

- AS = Algorithm S (supply self-test)
- AC = Algorithm C (capacitive self-test)

57.3.19 Conversion data processing

Raw converted data contains many types of errors, such as offset, gain, and so on. ADC processes raw conversion data before writing the result to a data register, to reduce or eliminate error contributions. The process of error correction happens in parallel with bit-by-bit evaluation, using the correction values generated during the offset determination and calibration process.

The error correction value is subtracted from the raw conversion result whenever the comparator output for one of the calibrated capacitors evaluates high during the conversion period.

To reduce data processing time, error correction is done in parallel during each bit evaluation of a conversion. Lower-weighted capacitors (smaller than C9) are not calibrated, so no error correction is performed for these capacitors. However, they are self-tested to guarantee that the error contribution is below specified accuracy limits.

The final result is checked for any overflow or underflow. When the processed data is above the maximum value that can be represented by ADC resolution, the output data is forced to all 1s (FFFh for 12-bit resolution). Similarly, if the processed data is negative then output data is forced to all 0s (000h for 12-bit resolution).

57.3.20 User-defined offset and gain values

In addition to the ADC-calculated offset value and gain value, ADC enables you to specify another set of offset and gain values in Offset And Gain User (OFSGNUSR). These values must be stored in two's complement format, where the leftmost bit (the most significant bit) is the sign bit.

ADC subtracts these values from the final processed conversion result. The values are used to removed fixed DC bias or any other known errors—for instance those caused by board design, sensors, and so on.

57.4 External signals

This module has no external signals.

57.5 Clock frequency

ADC's internal blocks are designed for an input clock frequency up to the Fin (Input Signal Bandwidth) maximum (see the ADC electrical specification section in the chip data sheet). The specified speed can be achieved with this clock frequency. If the input clock frequency exceeds the specified maximum frequency, ADC accuracy degrades and, in the worst case scenario, ADC malfunctions. ADC accuracy also degrades if the input clock frequency is below the specified minimum frequency. Sampling time has an absolute maximum value to guarantee the specified parameters and accuracy. For slower clocks, the sampling clock count must be programmed accordingly.

57.6 Memory map and register definition

ADC has a wide range of configurations to tailor its operation to application requirements. This comes with the drawback of possible corner cases. To avoid unintended behavior, configure ADC before starting a conversion and change any configuration only when ADC is idle, in other words when MSR[ADCSTATUS] = 0.

57.6.1 Transfer error description

The following register accesses cause a transfer error and do not change register content:

- Any access to an unused address.
- Any write access to a read-only register.

Fields

Field	Function
31 OWREN	Overwrite Enable Specifies whether a conversion data register accepts new data before the current conversion data has been read. When enabled, the new conversion result overwrites the older data, regardless of the validity of the older conversion data. When PCDR*n*[VALID] = 1, the conversion data has not been read. 0b - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enable
30 WLSIDE	Write Left-Aligned Specifies whether conversion data is right-aligned or left-aligned when written to one of the conversion data registers: • PCDR*n* • ICDR0*n* • ECDR*n* Right-aligned data occupies *CDR[14:0]. Left-aligned data occupies *CDR[15:1], 0b - Right aligned 1b - Left-aligned
29 MODE	Normal Conversion Mode Specifies whether the set of input channels selected for a normal conversion are converted only once per start event or continuously after a start event. If a conversion is done only once, ADC enters an idle state after conversion is complete. For continuous conversion, all input channels selected for the normal conversion are converted continuously in a loop. Stop the loop by writing 0 to NSTART. 0b - Single conversion 1b - Continuous conversion
28 —	Reserved
27 TRGEN	External Trigger Enable Specifies whether the normal trigger input starts a conversion. 0b - Normal trigger input does not start a conversion 1b - Normal trigger input starts a conversion
26 EDGE	External Trigger Edge Selection Selects which edge of the normal trigger input starts a conversion. 0b - Falling edge 1b - Rising edge
25 XSTRTEN	Auxiliary External Start Enable Enables the auxiliary normal trigger source to start a conversion. You can use this field to synchronize the start of a conversion of two ADC instances. 0b - Disable 1b - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
24 NSTART	Start Normal Conversion Starts a normal conversion. If the continuous mode is selected (MODE = 1), the value of this field remains 1. Write 0 to this field to stop the in-progress conversion loop after conversion of the last input channel of the selected set of input channels is complete. If continuous mode is not selected (MODE = 0), this field automatically resets to 0 after writing 1. 0b - No effect 1b - Starts conversion
23 —	Reserved
22 JTRGEN	Injection Trigger Enable Enables the injected trigger input as a source to start a conversion. 0b - Disable 1b - Enable
21 JEDGE	Injected Trigger Edge Selection Selects which edge of the injected trigger input starts an injected conversion. 0b - Falling edge 1b - Rising edge
20 JSTART	Injected Start Interrupts any ongoing normal conversion and starts an injected conversion. This field automatically resets to 0. If an injected conversion is already ongoing, the field value remains 1 until the next injected conversion starts. This field can only be written with 1. 0b - Injected conversion can be started 1b - Starts an injected conversion
19-18 —	Reserved
17 BCTUEN	Body Cross Trigger Unit Enable Enables BCTU as a trigger source. 0b - Disable 1b - Enable
16 BCTU_MODE	Body Cross Trigger Unit Mode Select Specifies whether sources other than BCTU can start a conversion when the BCTU is enabled as a trigger source (BCTUEN = 1). This field is writeable only when ADC is in Power Down state (PWDN = 1).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Only BCTU can trigger conversion 1b - All trigger sources can trigger conversion
15 STCL	Self-Test Configuration Lock Protects the following registers from writing: • STCR1 • STCR2 • STCR3 • STBRR • STAW0R • STAW1R • STAW2R • STAW4R • STAW5R 0b - Registers are writeable 1b - Registers are read-only
14-12 —	Reserved
11 AVGEN	Averaging Enable Enables conversion averaging. 0b - Disable 1b - Enable
10-9 AVGS	Averaging Select Specifies the number of conversions ADC uses to calculate the conversion result. 00b - 4 conversions 01b - 8 conversions 10b - 16 conversions 11b - 32 conversions
8 —	Reserved
7 ABORTCHAIN	Abort Chain Aborts the conversion of the selected set of input channels (chain of input channels). The currently ongoing conversion completes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field always reads 0. This field cannot be programmed during BCTU conversion. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Undefined When writing 0b - Conversion continues 1b - Conversion aborted
6 ABORT	Abort Conversion Aborts an ongoing conversion. This field always reads 0 and cannot be written during BCTU conversion. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Undefined When writing 0b - Conversion continues 1b - Conversion aborted
5 ACKO	Auto Clock Off Reduces power consumption by turning off the clock of the analog part of ADC when it is in Idle state. 0b - Clock always active 1b - Clock gated
4-3 —	Reserved
2-1 ADCLKSEL	Conversion Clock (AD_clk) Frequency Selection Selects the frequency for the clock signal of the conversion circuit (AD_clk = module clock ÷ ($2^{ADCLKSEL}$)). This field can be written only when ADC is in Power Down state (PWDN = 1). 00b - Module clock frequency 01b - Module clock frequency ÷ 2 10b - Module clock frequency ÷ 4 11b - Module clock frequency ÷ 8
0	Power Down

Table continues on the next page...

Table continued from the previous page...

Field	Function
PWDN	Reduces power consumption by turning off power to the analog portion of ADC. 0b - ADC enters a functional state 1b - ADC enters Power Down state

57.6.2.3 Main Status (MSR)

Offset

Register	Offset
MSR	4h

Function

Contains flags that indicate the current ADC state.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31 CALIBRTD	Calibration Status Indicates ADC calibration status. 0b - Uncalibrated or calibration unsuccessful 1b - Calibrated
30-25 —	Reserved
24	Normal Conversion Started

Table continues on the next page...

Table continued from the previous page...

Field	Function
NSTART	Shows whether a normal conversion is in progress. 0b - Not in progress 1b - In progress
23 JABORT	Injected Conversion Aborted Indicates whether the conversion of a set of inputs selected for injected conversion has been aborted. This field resets to 0 when a new injected conversion is started. 0b - Not aborted 1b - Aborted
22-21 —	Reserved
20 JSTART	Injected Conversion Started Indicates whether an ongoing conversion was started by the injection trigger. 0b - Not an injected conversion 1b - Injected conversion
19 —	Reserved
18 SELF_TEST_S	Indicates whether an ongoing conversion is for self-test. 0b - Not self-test 1b - Self-test
17 —	Reserved
16 BCTUSTART	BCTU Conversion Started Indicates whether a BCTU conversion is ongoing. This field is 1 when a BCTU trigger event is received and the BCTU conversion starts. When the BCTU trigger mode is selected, this field is automatically reset to 0 when conversion is completed. Otherwise, if BCTU control mode is selected, this field resets to 0 when the BCTU is disabled (BCTUEN = 0). 0b - Conversion was not triggered by BCTU 1b - Ongoing conversion was triggered by BCTU
15-9 CHADDR	Input Under Measure Contains the number of the input that is currently converted. 000_0000b-011_1111b - Input number
8-6	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
5 ACKO	Auto Clock-Off On Indicates whether the auto clock-off feature is active, and the conversion circuit is not receiving a clock signal. When auto clock-off is inactive, the conversion circuit is clocked. 0b - Inactive 1b - Active
4-3 —	Reserved
2-0 ADCSTATUS	ADC State Indicates the current state of the ADC Finite State Machine (FSM). 000b - Idle 001b - Power Down 010b - Wait 011b - Calibrate 100b - Convert 110b - Done

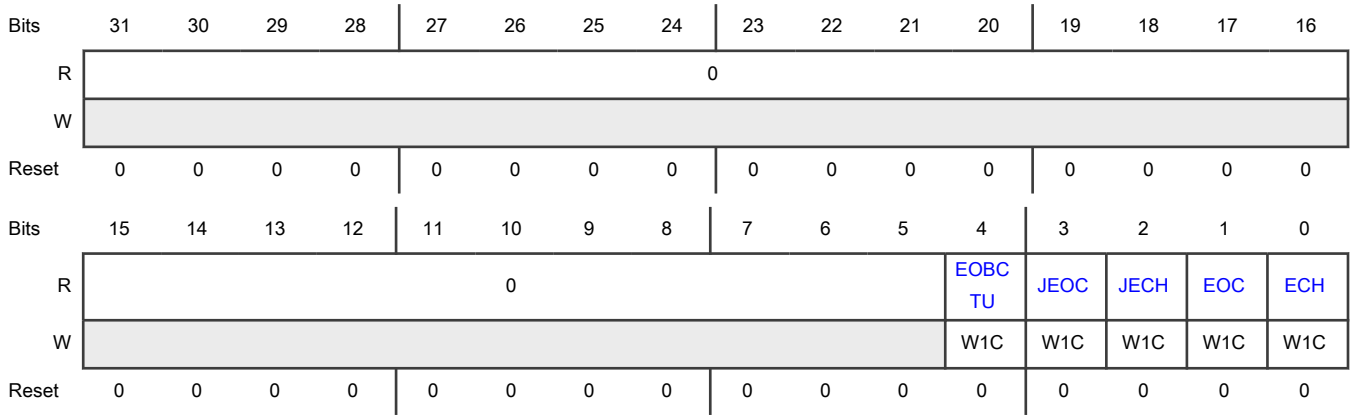
57.6.2.4 Interrupt Status (ISR)

Offset

Register	Offset
ISR	10h

Function
Contains flags that indicate whether an interrupt has been generated.

Diagram



Fields

Field	Function
31-5 —	Reserved
4 EOBCTU	End Of BCTU Conversion Indicates the status of the End of BCTU Conversion (EOBCTU) interrupt, which is generated after a BCTU conversion completes. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No EOBCTU interrupt generated 1b - EOBCTU interrupt generated When writing 0b - No effect 1b - Clears flag
3 JEOC	End Of Injected Conversion Indicates the status of the End of Injected Conversion (JEOC) interrupt, which is generated after an injected conversion completes. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No JEOC interrupt generated 1b - JEOC interrupt generated When writing

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No effect 1b - Clears flag
2 JECH	End Of Injected Chain Conversion Indicates the status of the End of Injected Chain (JECH) interrupt, which is generated after injected conversion of a set of inputs completes. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No JECH interrupt generated 1b - JECH interrupt generated When writing 0b - No effect 1b - Clears flag
1 EOC	End Of Conversion Indicates the status of the End of Conversion (EOC) interrupt, which is generated after a normal conversion completes. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No EOC interrupt generated 1b - Interrupt generated When writing 0b - No effect 1b - Clears flag
0 ECH	End Of Chain Conversion Indicates the status of the End of Chain (ECH) conversion interrupt, which is generated after a set of inputs has been converted normally. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Indicates no ECH interrupt generated 1b - Indicates an ECH interrupt has been generated When writing

Fields

Field	Function
31-0 EIEOCIENn	External Input EOC Interrupt Enable Specifies whether a completed conversion of external input *n* flags an EOC interrupt. 0b - Interrupt is not flagged 1b - Interrupt is flagged

57.6.2.12 Analog Watchdog Threshold Interrupt Status (WTISR)

Offset

Register	Offset
WTISR	30h

Function

Contains flags that indicate the result of a comparison between the conversion result and the threshold value defined in the analog watchdog.

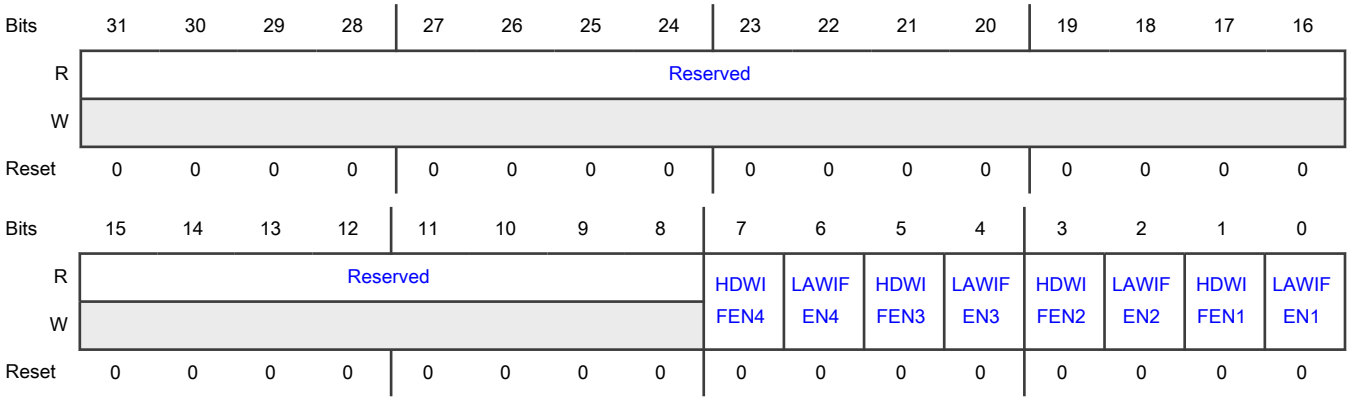
57.6.2.13 Analog Watchdog Threshold Interrupt Enable (WTIMR)

Offset

Register	Offset
WTIMR	34h

Function
Enables the interrupt for each analog watchdog threshold value.

Diagram



Fields

Field	Function
31-8 —	Reserved
7 HDWIFEN4	High Data Watchdog Interrupt Flag Enable n Enables flagging of an interrupt when a conversion result is higher than the high threshold value of the analog watchdog *n*. 0b - Interrupt is not flagged 1b - Interrupt is flagged
6 LAWIFEN4	Low Analog Watchdog Interrupt Flag Enable n Enables flagging of an interrupt when a conversion result is lower than the low threshold value of analog watchdog *n*. 0b - Interrupt is not flagged 1b - Interrupt is flagged
5 HDWIFEN3	High Data Watchdog Interrupt Flag Enable n Enables flagging of an interrupt when a conversion result is higher than the high threshold value of the analog watchdog *n*. 0b - Interrupt is not flagged 1b - Interrupt is flagged
4 LAWIFEN3	Low Analog Watchdog Interrupt Flag Enable n Enables flagging of an interrupt when a conversion result is lower than the low threshold value of analog watchdog *n*. 0b - Interrupt is not flagged 1b - Interrupt is flagged
3	High Data Watchdog Interrupt Flag Enable n

Table continues on the next page...

Table continued from the previous page...

Field	Function
HDWIFEN2	Enables flagging of an interrupt when a conversion result is higher than the high threshold value of the analog watchdog *n*. 0b - Interrupt is not flagged 1b - Interrupt is flagged
2 LAWIFEN2	Low Analog Watchdog Interrupt Flag Enable n Enables flagging of an interrupt when a conversion result is lower than the low threshold value of analog watchdog *n*. 0b - Interrupt is not flagged 1b - Interrupt is flagged
1 HDWIFEN1	High Data Watchdog Interrupt Flag Enable n Enables flagging of an interrupt when a conversion result is higher than the high threshold value of the analog watchdog *n*. 0b - Interrupt is not flagged 1b - Interrupt is flagged
0 LAWIFEN1	Low Analog Watchdog Interrupt Flag Enable n Enables flagging of an interrupt when a conversion result is lower than the low threshold value of analog watchdog *n*. 0b - Interrupt is not flagged 1b - Interrupt is flagged

57.6.2.14 Direct Memory Access Configuration (DMAE)

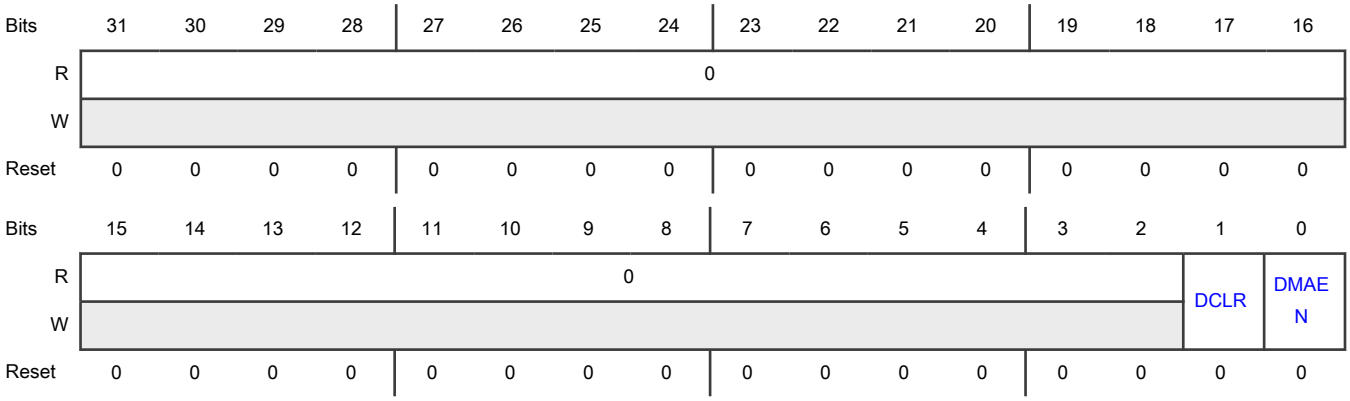
Offset

Register	Offset
DMAE	40h

Function

Configures the DMA feature.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 DCLR	DMA Clear Request Selects one of the following events to clear a DMA request: • DMA controller acknowledges the request. • Application reads the conversion data register. 0b - DMA controller acknowledges the request 1b - Conversion data register is read
0 DMAEN	DMA Enable Enables DMA. 0b - Disable 1b - Enable

57.6.2.15 DMA Request Enable For Precision Inputs (DMAR0)

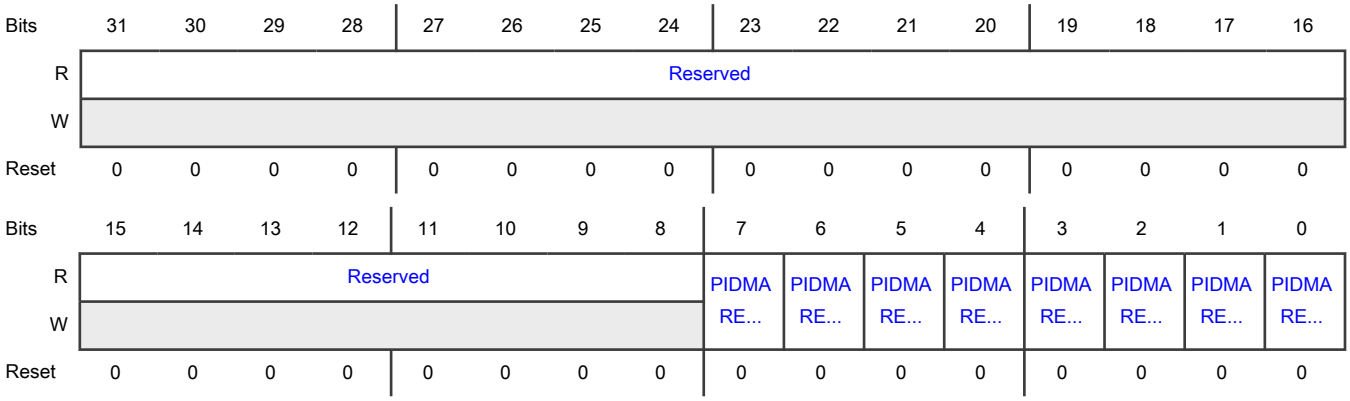
Offset

Register	Offset
DMAR0	44h

Function

Selects the precision inputs that trigger a DMA request after conversion is complete.

Diagram



Fields

Field	Function
31-8 —	Reserved
7 PIDMAREN7	Precision Input DMA Request Enable 7 Specifies whether a DMA request is triggered after conversion is complete for precision input 7. 0b - Not triggered 1b - Triggered
6 PIDMAREN6	Precision Input DMA Request Enable 6 Specifies whether a DMA request is triggered after conversion is complete for precision input 6. 0b - Not triggered 1b - Triggered
5 PIDMAREN5	Precision Input DMA Request Enable 5 Specifies whether a DMA request is triggered after conversion is complete for precision input 5. 0b - Not triggered 1b - Triggered
4 PIDMAREN4	Precision Input DMA Request Enable 4 Specifies whether a DMA request is triggered after conversion is complete for precision input 4. 0b - Not triggered 1b - Triggered
3 PIDMAREN3	Precision Input DMA Request Enable 3 Specifies whether a DMA request is triggered after conversion is complete for precision input 3. 0b - Not triggered 1b - Triggered

Table continues on the next page...

Table continued from the previous page...

Field	Function
2 PIDMAREN2	Precision Input DMA Request Enable 2 Specifies whether a DMA request is triggered after conversion is complete for precision input 2. 0b - Not triggered 1b - Triggered
1 PIDMAREN1	Precision Input DMA Request Enable 1 Specifies whether a DMA request is triggered after conversion is complete for precision input 1. 0b - Not triggered 1b - Triggered
0 PIDMAREN0	Precision Input DMA Request Enable 0 Specifies whether a DMA request is triggered after conversion is complete for precision input 0. 0b - Not triggered 1b - Triggered

57.6.2.16 DMA Request Enable For Standard Inputs (DMAR1)

Offset

Register	Offset
DMAR1	48h

Function

Selects the standard inputs that trigger a DMA request after conversion is complete.

57.6.2.18 Analog Watchdog Threshold Values (THRHLR0 - THRHLR3)

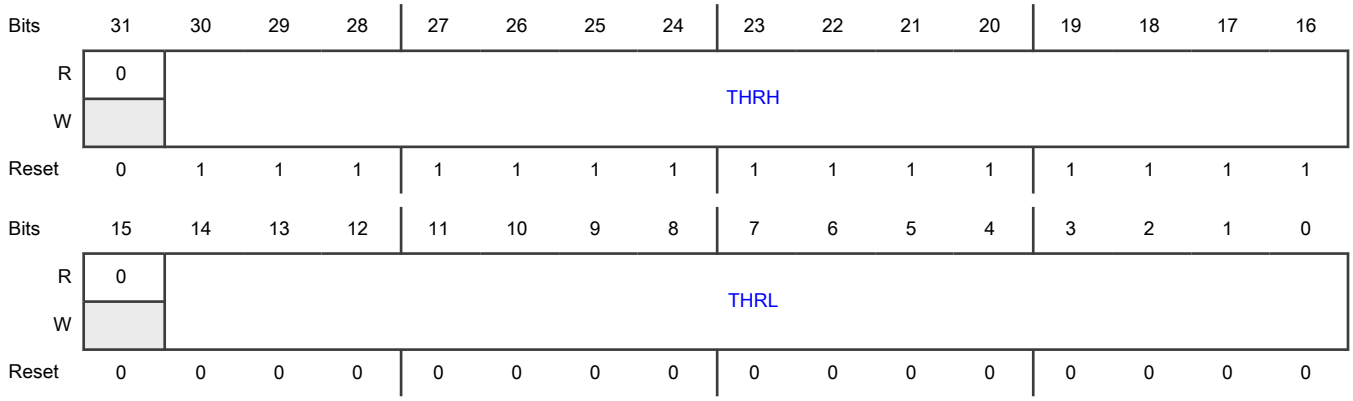
Offset

Register	Offset
THRHLR0	60h
THRHLR1	64h
THRHLR2	68h
THRHLR3	6Ch

Function

Specifies limits for the valid operating range of a monitored input.

Diagram



Fields

Field	Function
31 —	Reserved
30-16 THRH	High Threshold Value If enabled, flags an interrupt when the converted data of the input is higher than this value.
15 —	Reserved
14-0 THRL	Low Threshold Value If enabled, flags an interrupt when the converted data of the input is lower than this value.

57.6.2.19 Presampling Control (PSCR)

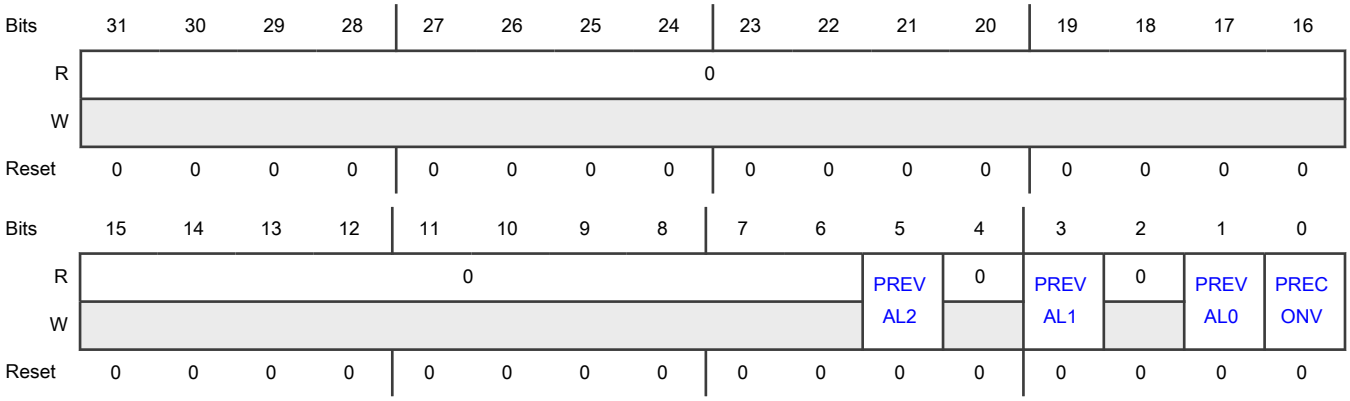
Offset

Register	Offset
PSCR	80h

Function

Configures ADC to presample an internal voltage before the actual input is converted.

Diagram



Fields

Field	Function
31-6 —	Reserved
5 PREVAL2	Presampling Voltage Select For External Inputs Selects the internal voltage that is presampled for external inputs. **NOTE** This field is not supported in every instance. The following table includes only supported registers. 0b - VREFL 1b - VREFH
4 —	Reserved

Instance	Field supported in	Field not supported in

57.6.2.23 Conversion Timing For Precision Inputs (CTR0)

Offset

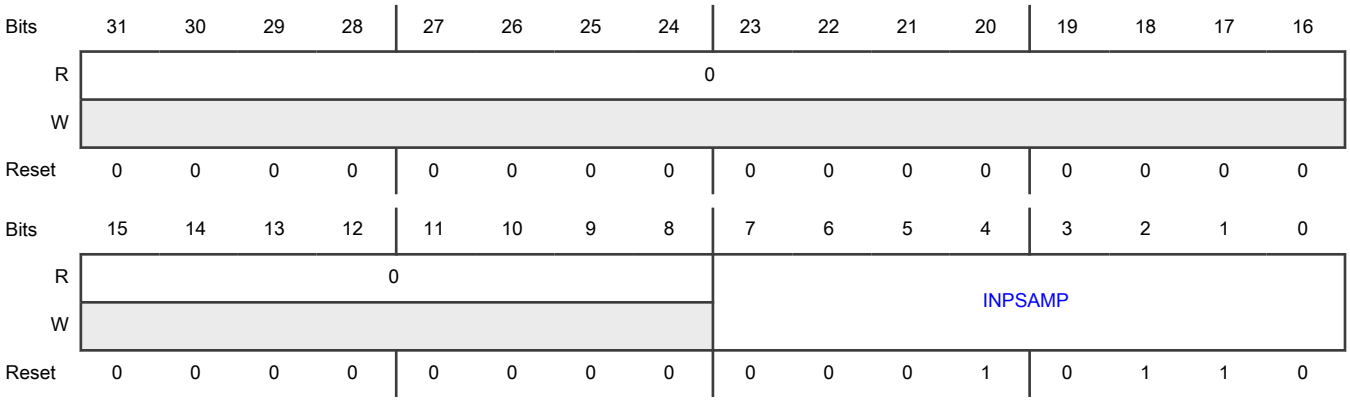
Register	Offset
CTR0	94h

Function

Specifies duration, in terms of the number of conversion clock cycles, of the sampling of precision inputs.

The conversion clock frequency depends on the configuration of MCR[ADCLKSEL].

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 INPSAMP	Input Sample Cycles Specifies the sample duration in terms of conversion clock cycles. The minimum value is 8. Specifying a lower value automatically forces a value of 8.

57.6.2.24 Conversion Timing For Standard Inputs (CTR1)

Offset

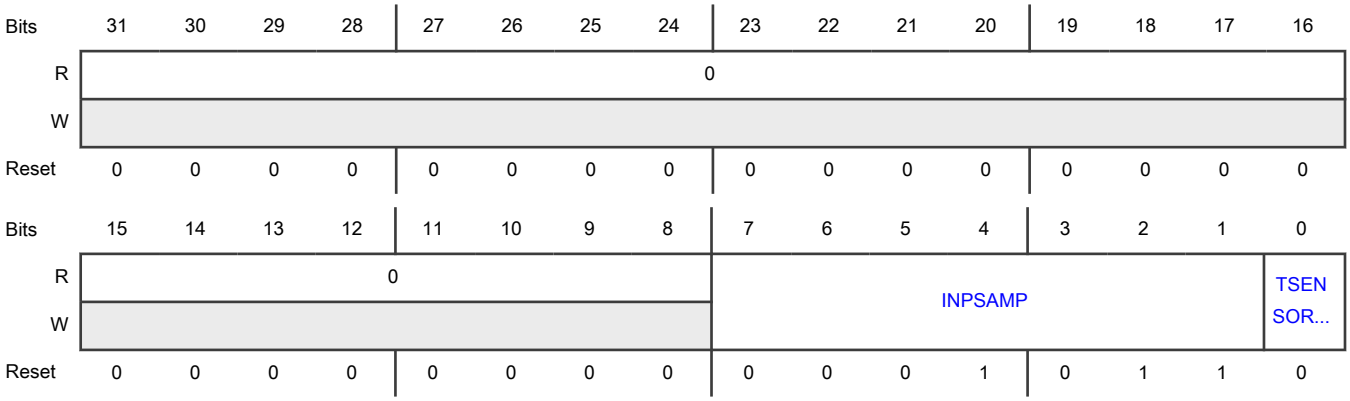
Register	Offset
CTR1	98h

Function

Specifies the duration, in terms of the number of conversion clock cycles, of the sampling of standard inputs or the temperature sensor.

The conversion clock frequency depends on the configuration of MCR[ADCLKSEL].

Diagram



Fields

Field	Function
31-8 —	Reserved
7-1 INPSAMP	Specifies the sample duration in terms of conversion clock cycles. The minimum value is 8. Specifying a lower value automatically forces a value of 8. This field uses the TSENSOR_SEL bit as its low-order bit. In other words, INPSAMP is effectively an 8-bit field, but the low-order bit has a dual function.
0 TSENSOR_SEL	Temperature Sensor Voltage Select Selects the voltage for external temperature sensors (if available). If a temperature sensor is available, this field may be used as the selector for the mux between two temperature sensors. **NOTE** This field is applicable only when there is more than one temperature sensor. 0b - Selects temperature sensor source 0 1b - Selects temperature sensor source 1

57.6.2.25 Conversion Timing For External Inputs (CTR2)

Offset

Register	Offset
CTR2	9Ch

Function

Specifies the number of conversion clock cycles when the external inputs are sampled.

The conversion clock frequency depends on the configuration of MCR[ADCLKSEL].

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
ADC_0	CTR2	—

15-0 DSD	Delay Specifies the delay in terms of the number of module clock cycles.

57.6.2.33 Power Down Exit Delay (PDEDR)

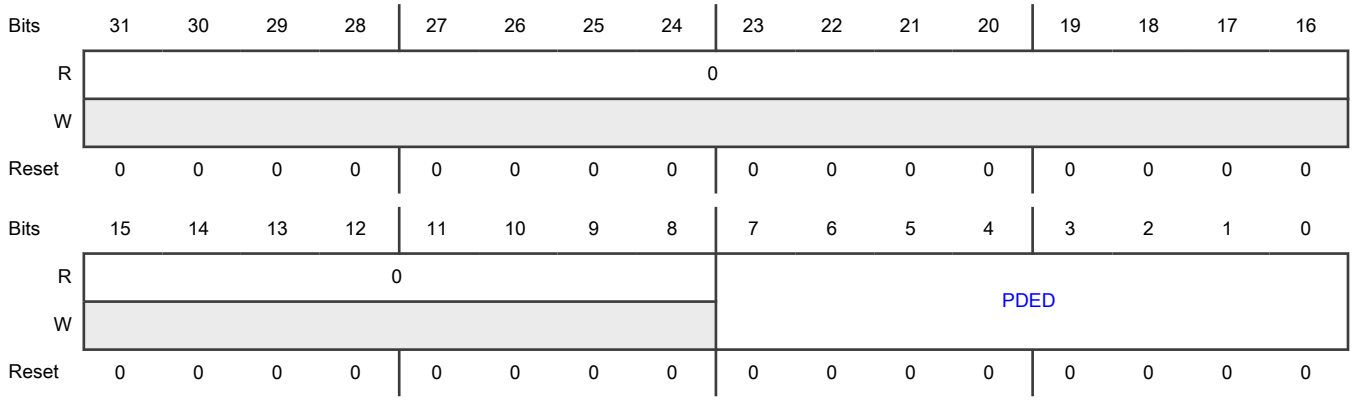
Offset

Register	Offset
PDEDR	C8h

Function

Delays the transition out of Power Down into Idle state to wait for necessary settling times. See the device data sheet for the minimal time between the power-down exit request and when ADC can start a conversion.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 PDED	Delay Specifies a delay in terms of the number of conversion clock cycles.

57.6.2.34 Precision Input n Conversion Data (PCDR0 - PCDR7)

Offset

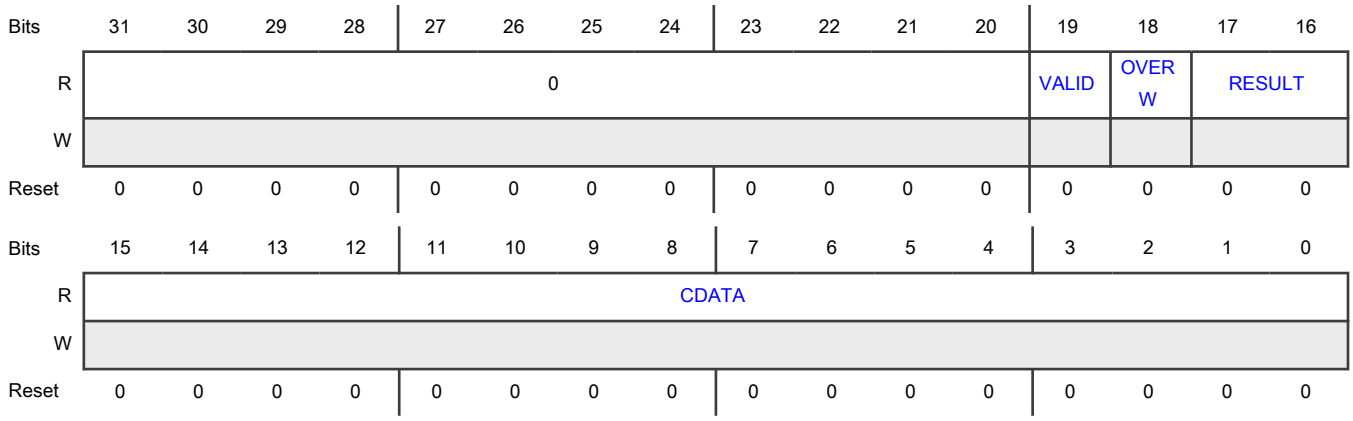
For n = 0 to 7:

Register	Offset
PCDRn	100h + (n × 4h)

Function

Contains conversion data from precision input *n*.

Diagram



Fields

Field	Function
31-20 —	Reserved
19 VALID	Conversion Data Available Indicates whether new conversion data is available. This field is automatically reset to 0 when the data is read. 0b - No unread conversion data 1b - Unread conversion data is available
18 OVERW	Overwrite Status Flag Indicates whether the previous conversion data was overwritten without having been read, in which case the overwritten data is lost. The ability to overwrite conversion data is controlled by MCR[OWREN]. 0b - No unread data is overwritten 1b - Unread data is overwritten
17-16 RESULT	Conversion Data Type Indicates the type of trigger that started the conversion for this conversion data. 00b - Normal trigger 01b - Injected trigger 10b - BCTU trigger
15-0 CDATA	Conversion Data Contains conversion data from precision input *n*, determined by the successive approximation algorithm. The conversion data is always 15 bits wide, regardless of the conversion resolution selected (CALBISTREG[RESN]). Depending on the value of MCR[WLSIDE], the conversion data can be in bits [14:0] (MCR[WLSIDE] = 0), or in bits [15:1] (MCR[WLSIDE] = 1).

57.6.2.35 Standard Input n Conversion Data (ICDR0 - ICDR25)

Offset

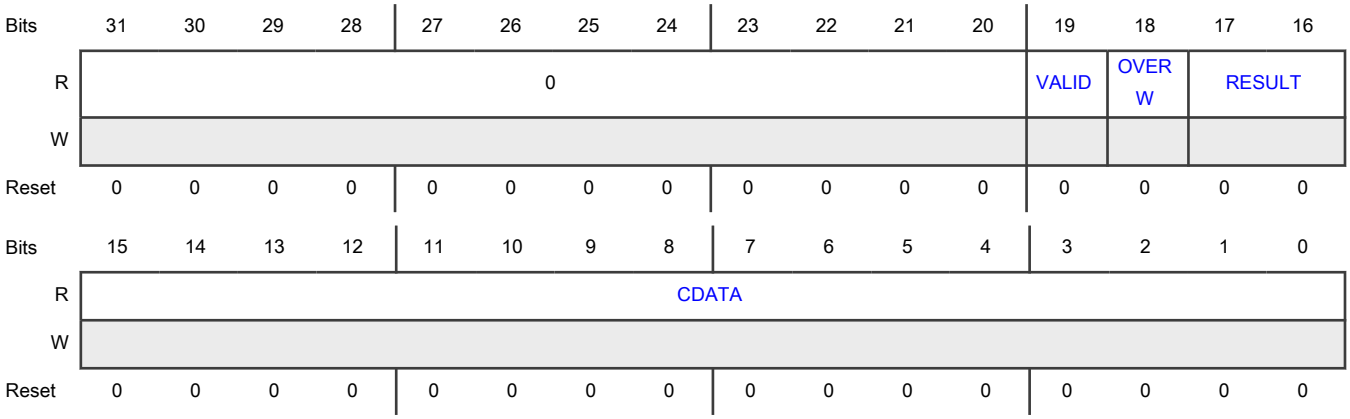
For a = 0 to 25:

Register	Offset
ICDRa	180h + (a × 4h)

Function

Contains conversion data from standard input *n*.

Diagram



Fields

Field	Function
31-20 —	Reserved

57.6.2.52 Self-Test Configuration 1 (STCR1)

Offset

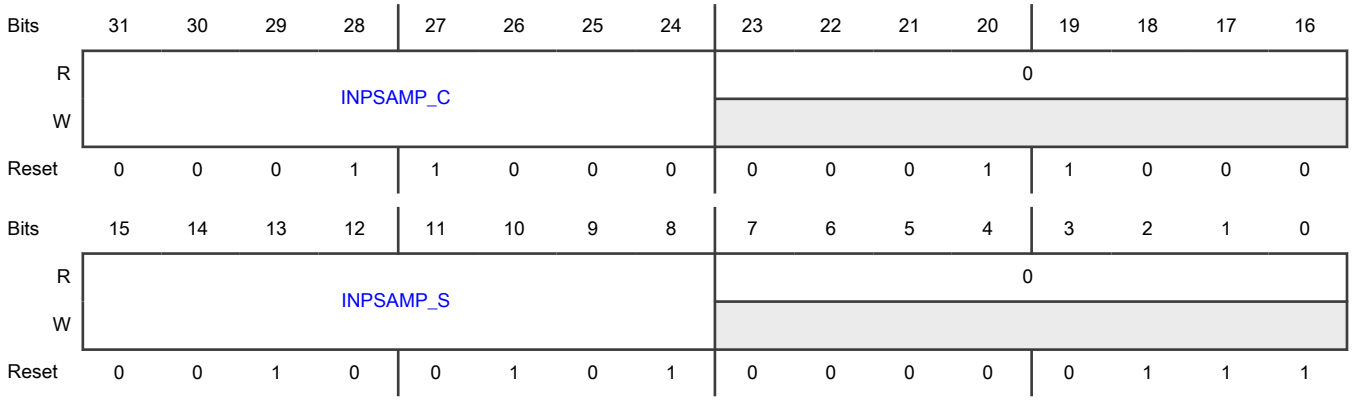
Register	Offset
STCR1	340h

Function

Specifies the input sampling duration in terms of conversion clock cycles.

Conversion clock frequency depends on the configuration of MCR[ADCLKSEL].

Diagram



Fields

Field	Function
31-24 INPSAMP_C	Input Sampling Time Algorithm C Specifies the sample duration for test conversions related to algorithm C. The minimum acceptable value is 8. Specifying a lower value automatically forces a value of 8.
23-16 —	Reserved
15-8 INPSAMP_S	Input Sampling Time Algorithm S Specifies sample duration for test conversions related to algorithm S. The minimum value is 8. Specifying a lower value automatically forces a value of 8.
7-0 —	Reserved

57.6.2.53 Self-Test Configuration 2 (STCR2)

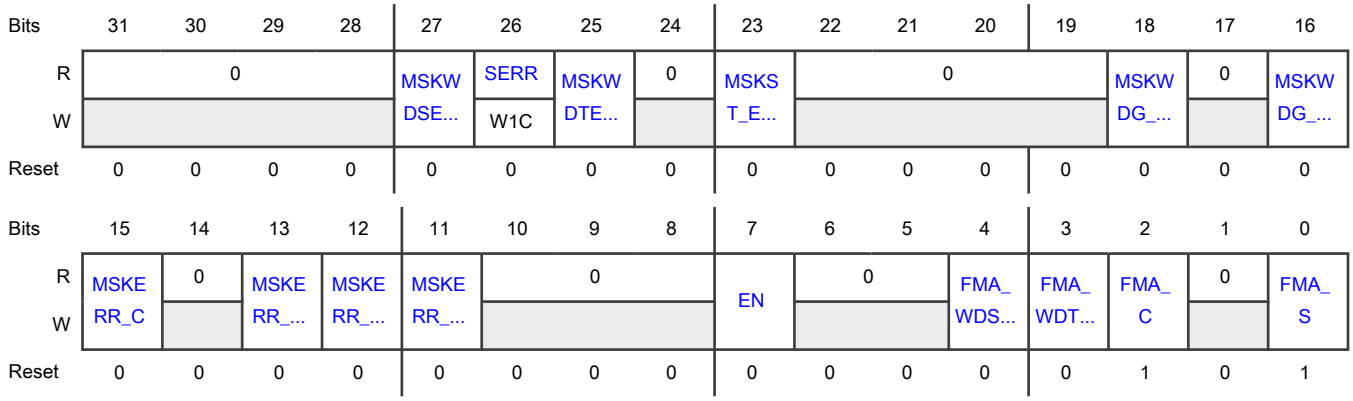
Offset

Register	Offset
STCR2	344h

Function

Configures ADC self-test functions.

Diagram



Fields

Field	Function
31-28 —	Reserved
27 MSKWDSERR	Mask Interrupt Self-Test Watchdog Sequence Error Generates an interrupt when the WDSERR flag transitions to 1. 0b - No interrupt is generated 1b - Interrupt is generated
26 SERR	Self-Test Error Injection Writes 1 to the STSR1[ERR_C], STSR1[ERR_S0], STSR1[ERR_S1], and STSR1[ERR_S2] status fields, causing an error. This field is reset to 0 immediately after writing. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Error can be injected 1b - Error is being injected When writing 0b - No effect 1b - Injects a self-test error
25 MSKWDTERR	Mask Interrupt Self-Test Watchdog Timer Error Generates an interrupt when the WDTERR flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
24	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
23 MSKST_EOC	Mask Interrupt Self-Test End Of Conversion Generates an interrupt when the ST_EOC flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
22-19 —	Reserved
18 MSKWDG_EOA_C	Mask Error Interrupt End Of Algorithm C Generates an interrupt when the WDG_EOA_C flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
17 —	Reserved
16 MSKWDG_EOA_S	Mask Error Interrupt End Of Algorithm S Generates an interrupt when the WDG_EOA_S flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
15 MSKERR_C	Mask Error Interrupt Algorithm C Generates an interrupt when the ERR_C flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
14 —	Reserved
13 MSKERR_S2	Mask Error Interrupt Algorithm S2 Generates an interrupt when the ERR_S2 flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
12 MSKERR_S1	Mask Error Interrupt Algorithm S1 Generates an interrupt when the ERR_S1 flag is set. 0b - No interrupt is generated

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Interrupt is generated
11 MSKERR_S0	Mask Error Interrupt Algorithm S0 Generates an interrupt when the ERR_S0 flag is set. 0b - No interrupt is generated 1b - Interrupt is generated
10-8 —	Reserved
7 EN	Self-Test Enable Enables ADC structural self-test. When BCTU is enabled, this field has no effect. This field must be 1 before starting normal conversion and must not be changed during conversion. This field must be reset to 0 only after end of conversion for the last self-test channel has been received. 0b - Disable 1b - Enable
6-5 —	Reserved
4 FMA_WDSERR	Fault Mapping Self-Test Watchdog Sequence Error Specifies whether a self-test watchdog sequence error sets the flag on the critical or noncritical fault line. 0b - Noncritical fault line 1b - Critical fault line
3 FMA_WDTERR	Fault Mapping Self-Test Watchdog Timer Error Specifies whether a self-test watchdog timer error sets the flag on the critical or noncritical fault line. 0b - Noncritical fault line 1b - Critical fault line
2 FMA_C	Fault Mapping Algorithm C Specifies whether a fault in algorithm C sets the flag on the critical or noncritical fault line. 0b - Noncritical fault line 1b - Critical fault line
1 —	Reserved
0 FMA_S	Fault Mapping Algorithm S Specifies whether a fault in algorithm S sets the flag on the critical or noncritical fault line.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Noncritical fault line 1b - Critical fault line

57.6.2.54 Self-Test Configuration 3 (STCR3)

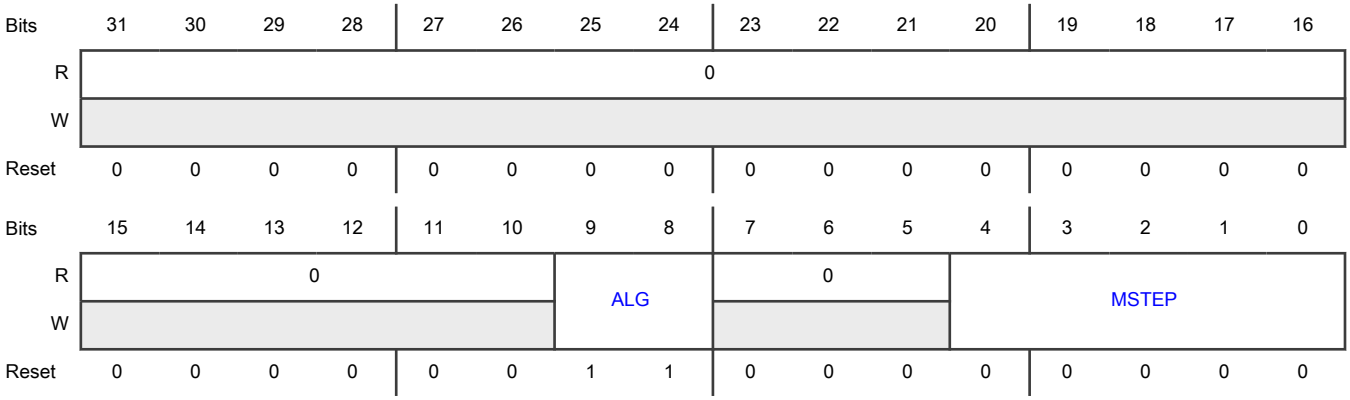
Offset

Register	Offset
STCR3	348h

Function

Configures ADC self-test functions. When BCTU is enabled, writes to the fields registers have no effect. This register must be programmed before starting a conversion and must not be changed when conversion is ongoing.

Diagram



Fields

Field	Function
31-10 —	Reserved
9-8 ALG	Algorithm Selection One-Shot operation mode: • 00 Algorithm S (single step = MSTEP) • 01 Reserved • 10 Algorithm C (single step = MSTEP)

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• 11 Algorithm S (default) (use for test/debug purposes) Continuous conversion mode: • 00 Algorithm S • 01 Reserved • 10 Algorithm C • 11 Algorithm S + algorithm C (default)
7-5 —	Reserved
4-0 MSTEP	Algorithm Step For One-Shot operation mode: • MSTEP = 0 to 2 for algorithm S • MSTEP = 0 to 11 for algorithm C Unused codes are reserved and must not be used. For Scan operation mode: This field is not used in Scan operation mode because single-step execution (interleaved mode) is always performed. This field must be programmed to zero in Scan operation mode.

57.6.2.55 Self-Test Baud Rate (STBRR)

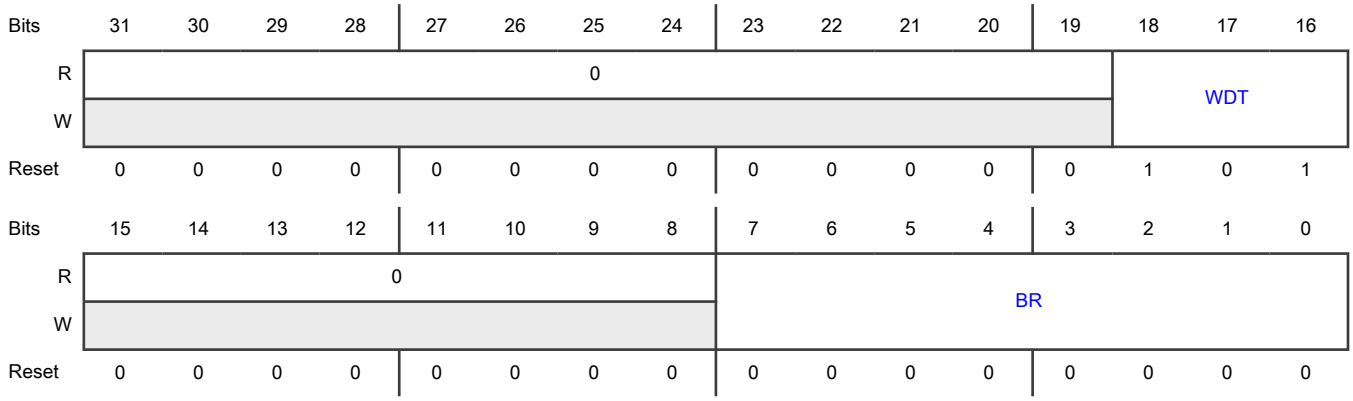
Offset

Register	Offset
STBRR	34Ch

Function

Specifies when the self-test algorithm steps are executed and the maximum time allowed for self-test to finish.

Diagram



Fields

Field	Function
31-19 —	Reserved
18-16 WDT	Self-Test Watchdog Timer Specifies the safe time period in terms of conversion clock cycles. The safe time period is the maximum duration until the running self-test is expected to finish. 000b - 8192 conversion clock cycles (~0.1 ms at 80 MHz) 001b - 39,936 conversion clock cycles (~0.5 ms at 80 MHz) 010b - 79,872 conversion clock cycles (~1 ms at 80 MHz) 011b - 159,744 conversion clock cycles (~2 ms at 80 MHz) 100b - 400,384 conversion clock cycles (~5 ms at 80 MHz) 101b - 799,744 conversion clock cycles (~10 ms at 80 MHz) 110b - 1,599,488 conversion clock cycles (~20 ms at 80 MHz) 111b - 3,999,744 conversion clock cycles (~50 ms at 80 MHz)
15-8 —	Reserved
7-0 BR	Baud Rate Selects the number of conversions of the selected inputs, after which the next self-test algorithm step executes. This field must be programmed when STCR2[EN] is zero, that is, before enabling self-test. 0000_0000b - A step of the selected self-test algorithm is executed every time after the set of selected inputs has been converted. 1111_1111b - A step of the selected self-test algorithm is executed after the set of selected inputs has been converted 256 times.

57.6.2.56 Self-Test Status 1 (STSR1)

Offset

Register	Offset
STSR1	350h

Function
Indicates self-test status.

Fields

Field	Function
31-28 —	Reserved
27 WDSERR	Self-Test Watchdog Sequence Error Indicates whether the selected self-test algorithm has executed in the correct sequence. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Algorithm executed in correct sequence 1b - Algorithm did not execute in correct sequence When writing 0b - No effect 1b - Clears flag
26	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
25 WDTERR	Self-Test Watchdog Timer Error Indicates whether the self-test algorithm has finished within the defined safe time period. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Algorithm finished within the safe time period (or safe time period not yet elapsed). 1b - Algorithm did not finish within safe time period. When writing 0b - No effect 1b - Clears flag
24 OVERWR	Self-Test Error Status Overwrite Indicates whether an error occurred when the respective error status flag (ERR_S0, ERR_S1, ERR_S2, or ERR_C) was set. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No self-test error status flag overwritten 1b - Self-test error status flag overwritten When writing 0b - No effect 1b - Clears flag
23 ST_EOC	Self-Test End Of Conversion Indicates whether a self-test conversion has completed. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clears flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
22-19 —	Reserved
18 WDG_EOA_C	Self-Test Watchdog End Of Algorithm C Indicates whether self-test algorithm C has completed. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clears flag
17 —	Reserved
16 WDG_EOA_S	Self-Test Watchdog End Of Algorithm S Indicates whether self-test algorithm S has completed. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clears flag
15 ERR_C	Error Algorithm C Indicates whether an error occurred during execution of algorithm C. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No effect 1b - Clears flag
14 —	Reserved
13 ERR_S2	Error Algorithm S Step 2 Indicates whether an error occurred during execution of step 2 of algorithm S. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clears flag
12 ERR_S1	Error Algorithm S Step 1 Indicates whether an error occurred during execution of step 1 of algorithm S. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clears flag
11 ERR_S0	Error Algorithm S Step 0 Indicates whether an error occurred during execution of step 0 of algorithm S. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No effect 1b - Clears flag
10 —	Reserved
9-5 STEP_C	Step Of Algorithm C Indicates the step of self-test algorithm C in which an error occurred. Although this register field is read-only, no transfer error is generated when writing to it.
4-0 —	Reserved

57.6.2.57 Self-Test Status 2 (STSR2)

Offset

Register	Offset
STSR2	354h

Function

Contains the conversion result when an error in step 1 of algorithm S has occurred.

31 AWDE	Self-Test Watchdog Enable Enables the self-test watchdog for step 0 of algorithm S. 0b - Disable 1b - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
30 WDTE	Self-Test Watchdog Timer Enable Enables the self-test watchdog timer for algorithm S. The self-test watchdog timer verifies: • Correct sequence of execution of the steps of the algorithm • Execution of the algorithm within the safe time period as defined by STBRR[WDT] This field must be 1 only in continuous conversion mode (MCR[MODE]=1). The safe time period starts when this field is written with 1. If the safe time period has elapsed before algorithm S starts, the WDTERR flag is set. The safe time period is restarted each time algorithm S starts. 0b - Disable 1b - Enable
29-16 THRH	Higher Threshold Value Sets the ERR_S0 flag when a self-test conversion value is greater than this value.
15 —	Reserved
14-0 THRL	Lower Threshold Value Sets the ERR_S0 flag when a self-test conversion value is less than this value.

57.6.2.62 Self-Test Analog Watchdog S1 (STAW1R)

Offset

Register	Offset
STAW1R	388h

57.6.2.67 Control And Calibration Status (CALBISTREG)

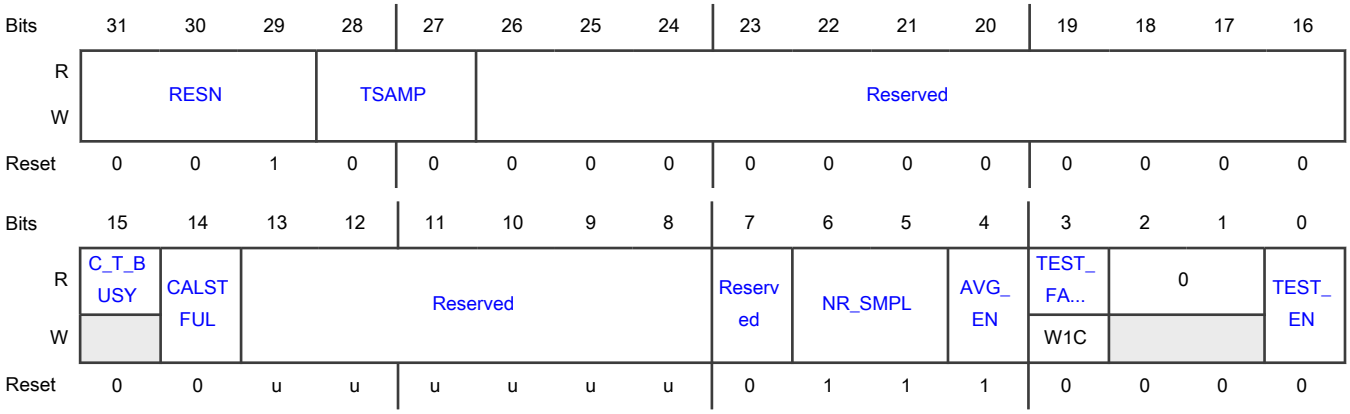
Offset

Register	Offset
CALBISTREG	3A0h

Function

Controls several ADC functions for data conversion, calibration, and calibration status.

Diagram



Fields

Field	Function
31-29 RESN	Conversion Resolution Specifies the number of significant bits per conversion data (functional conversion only, not for calibration or self-test). Reducing this number speeds up the conversion because the SAR algorithm executes fewer steps. This field must be modified only when ADC is idle. 000b - 14-bit resolution 001b - 12-bit resolution 010b - 10-bit resolution 011b - 8-bit resolution
28-27 TSAMP	Sample Period In Calibration Specifies the number of conversion clock cycles during which the reference voltage is sampled. 00b - 22 conversion clock cycles 01b - 8 conversion clock cycles 10b - 16 conversion clock cycles 11b - 32 conversion clock cycles
26-16 —	Reserved The value of this field must not be modified.
15 C_T_BUSY	Calibration Busy Indicates whether calibration is running. 0b - Calibration can be started 1b - Calibration is in progress
14 CALSTFUL	Calibration And Self-Test Full Range Comparison Specifies the range of conversion data bits compared when ADC is calibrated or running self-test. Because the results from calibration and self-test are so low that the significant bits are in the lower 11 bits only, the comparison cycles for the upper 4 bits can be skipped to reduce the execution duration of the calibration and of the self-test. 0b - Lowest 11 bits are compared. 1b - All 15 bits are compared.
13-8 —	Reserved **CAUTION** This field contains a value that ADC uses internally. Writing to this field can cause ADC to operate unreliably.
7 —	Reserved This field is reserved and always has the value 0. Only the reset value can be written to this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
6-5 NR_SMPL	Calibration Averaging Number Specifies the number of data conversions per result (averaging) during calibration. 00b - 4 samples 01b - 8 samples 10b - 16 samples 11b - 32 samples
4 AVG_EN	Calibration Averaging Enable Enables averaging of the calibration results over several conversion iterations to improve accuracy. This field only affects the calibration process. 0b - Disable 1b - Enable
3 TEST_FAIL	Calibration Status Indicates calibration status. This field reads 0 when calibration is in progress. This field is reset to 0 when calibration starts. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Calibration finished successfully or has not been run since the last reset 1b - Calibration did not finish successfully When writing 0b - No effect 1b - Clears flag
2-1 —	Reserved
0 TEST_EN	Calibration Enable Calibrates ADC. This field automatically resets to 0 after the calibration is complete or is interrupted. 0b - Wait to start a calibration 1b - Start calibration

57.6.2.68 Offset And Gain User (OFSGNUSR)

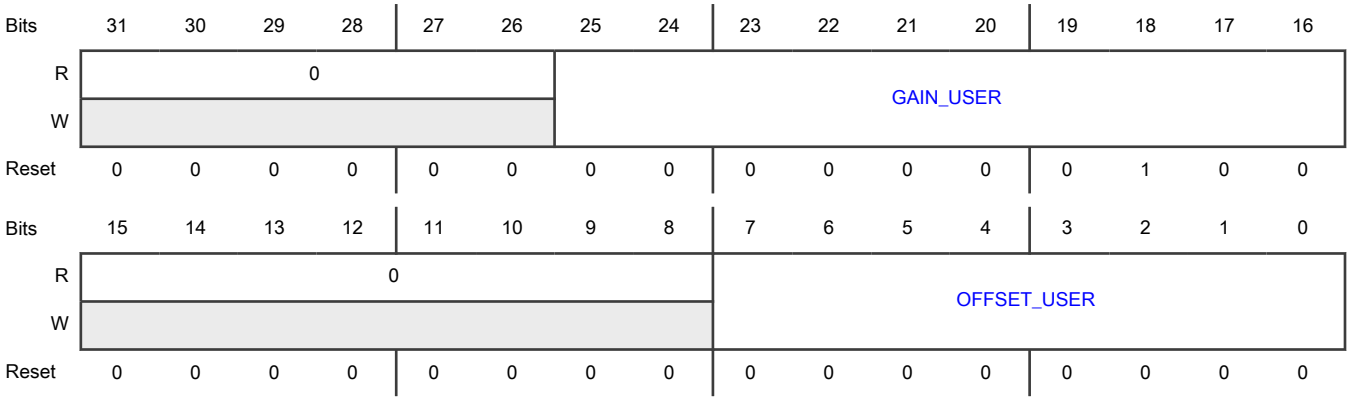
Offset

Register	Offset
OFSGNUSR	3A8h

Function

Specifies the user-configured offset and gain values used by the SAR algorithm. The values must be written in two's complement format and can be either positive or negative.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-16 GAIN_USER	Gain User Adds extra gain to the gain calculated during calibration. The value must be in two's complement format.
15-8 —	Reserved
7-0 OFFSET_USER	Offset User Adds extra offset to the offset calculated by calibration. The value is must be in two's complement format.

57.6.2.69 Calibration Value 2 (CAL2)

Offset

Chapter 58
SIGMA DELTA ANALOG TO DIGITAL CONVERTER (SDADC)

58.1 Chip-specific SDADC information

58.1.1 SDADC instances

This chip has 4 instances of SDADC:

- SDADC_0
- SDADC_1
- SDADC_2
- SDADC_3

NOTE

On die, vcom0_hv is shorted to VREFH and vcom1_hv to VREFL. Vcom2_hv is generated by BIASGEN as (VREFH+VREFL)/2.

58.1.2 Hardware Trigger interface

Table describes the mapping of trigger sources from different motor control IP instances to SDADC hardware trigger interface.

Table 282. Hardware Trigger interface of SDADC

58.2 Overview

SDADC digital interface block controls the on-chip SDADC and holds control and status registers accessible for application.

SDADC provides the output data at a rate of 4fs ÷ OSR and FIR compensation filter performs the decimation of 4 in DSP Core.

Figure 290 depicts the block diagram of SDADC and its digital control block. SDADC digital interface block provides all control information for operating mode selection (single-ended or differential), analog input gain, decimation rate, etc. It also generates the bias controls for common mode voltage selection, to bias the positive and negative terminals to different voltage levels (for example, half scale bias, reference ground, reference supply) for diagnostics. It generates the analog multiplexer control signals for the selected channels. It also provides external modulator support and keeps the internal modulator in low consumption mode. To assist synchronous operation across multiple ADC blocks, hardware trigger support is implemented to start data conversion.

58.2.1 Block diagram

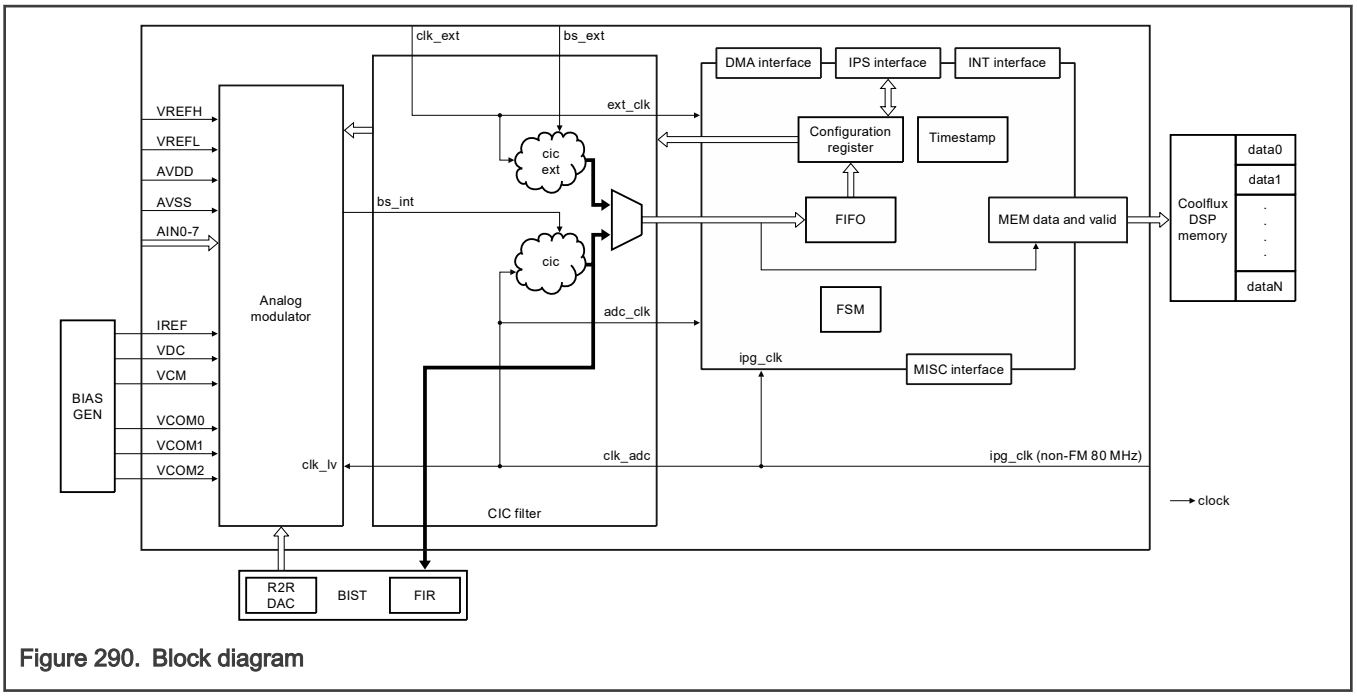

Figure 290. Block diagram

58.2.2 Features

- Sampling frequency (fs) is 40 MHz.
- 16-bit data resolution output.
- Single-ended input or differential input mode of operation.
- Programmable wraparound mechanism for both modes of operation:
  - Configurable trigger sources:hardware or software
  - Configurable initial entry and wraparound values for the loop
- Configurable biasing for negative input terminal in single ended mode.
- Gain and offset calibration support using fixed bias for input terminals.
- Programmable decimation rate.
- Programmable gain for analog inputs.
- External modulator support.
- Hardware trigger support for synchronous operation of multiple SDADC blocks.
- Trigger event output generation by software.
- Signed/Unsigned format of converted data output.
- Interrupt/DMA request generation based on various conditions:
  - Data buffer above the threshold
  - Data buffer overrun for interrupt only
  - WDG crossover event
- Programmable threshold range WDG support.
- Low power consumption mode.
- Optional conversion process halt mechanism on SoC debug request.

58.3 Functional description

58.3.1 Modes of operation

SDADC describes the different modes of operation. When exiting reset, the mode of operation is determined by Module Configuration Register (MCR).

- Low power consumption mode
- Differential input mode
- Single-ended input mode
- Input channel bias support mode (AC coupling mode)
- External modulator mode
- Wraparound mode
- 20 MHz sampling rate mode

58.3.2 Description of Modes

SDADC supports many modes. The description of each mode is given below.

58.3.2.1 Low power consumption mode

This is the default mode after exiting from reset. This mode is exited by asserting MCR[BIASGEN_EN] first then asserting MCR[EN] to enable SDADC block. The software should wait after enabling biasgen to stabilized bias supply to SDADC. When data conversion is not required, SDADC internal modulator can be put in low consumption mode by deasserting MCR[EN] to disable to reduce power consumption. Then deassert MCR[BIASGEN_EN] to disable. Since biasgen supports multiple SDADC, it is only disabled when MCR[BIASGEN_EN] is disabled in all SDADCs.

58.3.2.2 Differential input mode

After system reset exit, this is the default mode of operation if SDADC is enabled by asserting MCR[EN]. This mode is entered by negating MCR[MODE]. In differential input mode, a pair of analog inputs among AN[0:7] is connected to the input terminals of SDADC modulator block. The module supports four differential pairs: AN[0,1], AN[2,3], AN[4,5], and AN[6,7].

The modulator block has two input terminals, positive (INP) and negative (INM). The selection of input pair depends on CSR[ANCHSEL]. The connectivity of each analog input in a given differential pair, whether it is connected to positive or negative terminal, is determined according to Table 283.

The differential input mode can also be used to perform gain and offset calibration, where the input terminals are biased with fixed voltages coming from the bias block.

58.3.2.3 Single-ended input mode

Single-ended input mode is entered by asserting MCR[MODE]. In this mode, one of the analog inputs among AN[0:7] is selected by CSR[ANCHSEL], and is connected to the positive terminal. The negative input terminal is biased with a fixed internal voltage. There are three internal bias voltages available: vcom0, vcom1 and vcom2. The selection of this common mode voltage is controlled by MCR[VCOMSEL].

58.3.2.4 Input channel bias support mode (AC coupling mode)

The complete selection and connectivity of analog inputs AN[7:0] is based on CSR[ANCHSEL], MCR[MODE] and MCR[VCOMSEL], see Table 283. Each analog input can be biased to half scale (AVDD/2) via on-chip 100 kohm resistance. This allows simple AC coupling to the external analog inputs through a capacitor. This biasing is applicable irrespective of whether analog channel is selected through multiplexer or not. This mode should be enabled by asserting MCR.ENBIAS[7:0] corresponding to each channel. By default, the IP is in DC coupling mode (i.e. no biasing to the input channel).

58.3.2.5 External modulator mode

This mode is selected by asserting MCR[EMSEL]. In this mode, the data stream and clock outputs from the external modulator available on EMDATA/EMCLK input pins are multiplexed with internal modulator data output and input sampling clock. External modulator data must be synchronized with respect to the falling edge of EMCLK. In this mode, hardware trigger input is ignored even if it is enabled by asserting MCR[TRIGEN]. All other configuration settings (for example gain, decimation rate, filter, etc.) programmed in MCR have no effect on the conversion.

58.3.2.6 Wraparound mode

Incremented channel is converted upon receiving of trigger and it wraparounds to 0th channel after channel specified in CSR[ANCHSEL_WRAP]. Initial entry value for the first loop is selected by CSR[ANCHSEL]. Thereafter loop starts from '0'.

NOTE

Any conversion on non-existing/unconnected channel due to wraparound mode/any trigger may result into unknown data. Ignore data corresponding to non-existing/unconnected channel. See chip-specific SDADC chapter for the list of non-existing/unconnected channels.

In wraparound control mode, hardware and software triggers are equally valid. The hardware trigger source should be selected before enabling the wraparound mode.

Wraparound Control Mechanism: Wrap-around logic shall include all analog channels of the input multiplexer from 000") to CSR[ANCHSEL_WRAP] in both single ended and differential ended mode in wraparound sequence triggered by hardware or software source:

- MCR[WRMODE] would enable or disable the wraparound mechanism. Clearing MCR[WRMODE] automatically switches FSM back to software control mode.
- Every valid trigger advances the wraparound counter to next channel to be converted.
- Wraparound Counter: An internal wraparound counter which points to analog channel to be converted takes the initial entry value for the first loop of execution from CSR[ANCHSEL] while entering wraparound mode. From next loop onwards the counter wraparounds to default initial value '000'. Maximum value of the counter (wraparound value) should be programmed in CSR[ANCHSEL_WRAP] before entering wraparound mode, definition of CSR[ANCHSEL] and CSR[ANCHSEL_WRAP] is provided in Table 283, Analog input AN[0:7] selection.
- Upon entering or during wraparound mode user should take care to program CSR[ANCHSEL] value is less than CSR[ANCHSEL_WRAP] value.
- Possible trigger sources:
  - SOURCE1 (Software Bit): writing to RKR[RESET_KEY] at any time during the wraparound mode (irrespective of MCR[TRIGEN] or MCR[TRIGSEL] setting) generates a trigger pulse, each such trigger initiates a fresh conversion and advances the wraparound counter by one.

    NOTE

    Care should be taken while programming the TRIGEN/TRIGSEL of each SDADC instance that no unintended simultaneous SW triggering of multiple instances happen.

  - SOURCE2 (Hardware Trigger): Here external trigger output (for e.g., mux_advance of GTM) enabled by MCR[TRIGEN] or MCR[TRIGEDSEL] or MCR[TRIGSEL] before entering wraparound mode for selective or all SDADC instances provides trigger, each such valid trigger initiates a fresh conversion and advances the wraparound counter by one. One of the hw_trig_in ports can be used to connect the external trigger output.
- Next channel number to be converted can be updated by software even in the middle of wraparound sequence execution, this can be done by rewriting CSR[ANCHSEL]. After CSR[ANCHSEL] is rewritten, the next trigger takes updated value (wraparound counter would increment from the updated value).
- Current wraparound counter value can be read from SFR[ANCHSEL_CNT].

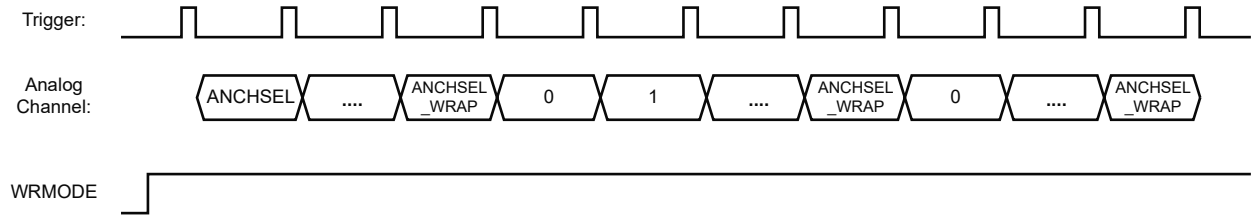

Figure 291. Wraparound Mode

58.3.2.7 20 MHz sampling rate mode

SDADC modulator can be run with 20 MHz sampling rate. For 20 MHz sampling rate mode, set CCR[CCR_B1_IPS_EN] = 1, then program CCR[OSR_HALF] = 1 and CCR[EN_CLK_RATE_HALF] = 1 in initialization sequence.

58.3.3 SDADC Channel Selection

This is analog channel selection table of SDADC.

Table 283. SDADC channel selection

MCR[MODE]	MCR[VCOMSEL]	CSR[ANCHSEL]	INP (positive terminal)	INM (negative terminal)

		111	AN[7]	vcom0_hv

58.3.4 Programmable decimation rate

SDADC is provided with a fixed input sampling clock of frequency fs. The input signal is grossly oversampled by the modulator in order to reduce quantization noise. To support different passbands with a fixed sampling clock, a programmable decimation rate is implemented. The process of decimation, to eliminate redundant data at the output while retaining the necessary information, is controlled by MCR[PDR].

58.3.5 Programmable gain

All analog inputs can be configured to have a selectable input gain as defined in MCR[PGAN]. This means that the input signal is sampled and the result is amplified by the factor determined by PGAN before providing the same to modulator.

58.3.6 Data conversion

Software Control Mechanism: SDADC block is in continuous conversion mode as soon as it is enabled. The conversion data is not accurate enough for some time, depending on the latency and output settling time specifications. This is true even when there is any change in the configuration settings provided by MCR, change in the analog channel selection due to mux switching time. To account for these delays, an internal timer is implemented which counts down from a start value determined by OSDR[OSD]. This timer is reloaded whenever RKR[RESET_KEY] is written with 5AF0h, which is required to start SDADC conversion from a fresh state with a changed configuration. The timer is stalled on reaching count '0' and asserts SFR[CDVF]. Once this flag is asserted, converted data is loaded into data FIFO at output data rate (fd).

Any write access to Module Configuration Register (MCR) and Channel Selection Register (CSR) deasserts SFR[CDVF] to indicate that the data coming from SDADC is not valid or corrupted. If SFR[CDVF] is reset, SFR[DFFF] and SFR[DFORF] are blocked from becoming asserted, i.e. transitioning from inactive state to active state. If SFR[DFFF] is already set, this means that the data FIFO is already full before SFR[CDVF] deassertion.

SFR[DFFF] (which not conditioned by the interrupt or DMA selection) is provided outside which can be routed to timer module at SoC level.

FIFO Flush Option: This option allows to clear FIFO content and re-initialize FIFO pointers before carrying out next set of conversion after reconfiguring the channel and conversion configuration parameters (Gain, Channel no. e.t.c). This can be done by providing a functional reset by setting FCR[FRST].

This allows to clear the stale unread data corresponding to previous conversion and starting afresh from new channel configuration.

58.3.7 Hardware triggering

Software Control Mechanism: SDADC conversion can be triggered by various hardware events coming from either external pins or internal timers. MCR[TRIGSEL] selects which hardware event is to be used for triggering conversions. This trigger event, which is synchronous to the peripheral clock, is enabled by asserting MCR[TRIGEN]. As soon as a trigger event is detected, reset input of SDADC block is asserted synchronously for four cycles. This ensures that SDADC starts from a fresh state when reacting to the input trigger event. SDADC internal modulator must be enabled before enabling the trigger event otherwise the trigger event is ignored. A hardware trigger event is also ignored when external modulator is selected (MCR[EMSEL] = 1).

If the same trigger event is provided to multiple SDADC digital interface modules and the respective enable controls (MCR[TRIGEN]) are asserted, synchronous operation of multiple SDADC blocks can be achieved with output results being updated at the same time. Once the reset input is deasserted, the first valid conversion output is stored in data FIFO after a configurable delay determined by OSDR[OSD].

It is also possible to generate a software trigger event output by a write access of Software Trigger Key Register (STKR) with a predefined key. This event output can be used as a trigger to achieve synchronous software start of multiple SDADC blocks.

In case of a hardware trigger, It should be synchronous to ADC clock. It is more than one ADC clock cycle due to synchronization. In case of a software trigger, all SDADCs start synchronous sampling.

58.3.8 Interrupt/DMA request support

SDADC has one condition that generates interrupts only and another that generates interrupts or DMA request.

SFR[DFFF] is asserted when the data FIFO full condition is detected, indicating that the number of converted datawords stored in data FIFO is greater than the value indicated by threshold determined by FCR[FTHLD]. The interrupt or DMA request is generated only when RSER[DFFDIRE] is asserted. RSER[DFFDIRS] selects whether a DMA request or an interrupt request is generated.

SFR[DFORF] indicates FIFO overflow condition. Further converted datawords cannot be received and data is lost. The interrupt request is generated only when RSER[DFORIE] is asserted.

Apart from above, a WDG threshold crossover event can also generate an interrupt or DMA request.

58.3.9 Gain and offset calibration

SoC/software should perform gain and offset calibration on final data using following methods:

NOTE

Offset and gain calibration needs to be performed at every power cycle.

58.3.9.1 Gain calculation

- Write 1 to MCR[BIASGEN_EN] to enable BIASGEN and 1 to MCR[VCOM2EN] to enable common mode output.
- Write 0 to MCR[MODE] to enable differential mode.
- Write 1 to MCR[ODF].
- Program channel ANCHSEL = b110.
- Configure OSDR[OSD] > 4.
- Write 1 to MCR[EN] to enable SDADC.
- Write 5AF0h to RKR[RESET_KEY] to generate a reset event.
- Read CDR. Take multiple readings and calculate the average output.
  - Average output is Dmax.
- Write 0 to MCR[EN] to disable SDADC.
- Program channel ANCHSEL = b111.
- Write 1 to MCR[EN] to enable SDADC.
- Write 5AF0h to RKR[RESET_KEY] to generate a trigger event.
- Read CDR. Take multiple readings and calculate the average output.
  - Average output is Dmin.
- Gain = (Dmax-Dmin)/65536.

NOTE

Data output from SDADC is in 2'complement form. So this calculation should take care of signed arithmetic.

58.3.9.2 Offset error calculation

- Write 1 to MCR[BIASGEN_EN] to enable BIASGEN and 1 to MCR[VCOM2EN] to enable common mode output.
- Write 0 to MCR[MODE] to enable differential mode.
- Write 1 to MCR[ODF].
- Program channel ANCHSEL = b100 or b101.
- Configure OSDR[OSD] > 4.
- Write 1 to MCR[EN] to enable SDADC.
- Write 5AF0h to RKR[RESET_KEY] to generate a trigger event.

- Read CDR. Take multiple readings and calculate the average output.
  - Average output is Doffset.
- Offset Error (OFS) is Doffset.

58.3.9.3 Data calculation after gain and offset calibration

Calculate the final data:

- Dadj = (Dout-OFS)/Gain

58.3.10 Clocking

SDADC has the following clock.

Clock	Description
MODULE_CLK	This clock is used for system bus, CIC filter, SD modulator. This should be kept at 80 MHz non-FM clock. This clock is also known as IPG_CLK.

58.3.11 Reset

SDADC has the following reset signal.

Reset Signal	Description
MODULE_RESETB (ipg_hard_async_reset_b)	This is active low reset with asynchronous assertion and synchronous de-assertion. It is used to reset all digital content in SDADC.

58.4 Initialization information

To initialize SDADC for data conversion, the following sequence is required.

1. Configure MCR to select the required mode, polarity, common mode voltage, input gain, and decimation rate.
   - Write 1 to MCR[BIASGEN_EN] to enable biasgen before SDADC enables MCR[EN].
2. Select the required analog channel for data conversion. It is possible to select the bias for each channel for AC coupling applications.
3. Configure OSD delay according to SDADC startup time or latency from reset exit.
4. Program FIFO threshold FCR[FTHLD] and enable FIFO FCR[FE].
5. Program Request Select and Enable Register (RSER) for DMA/Interrupt request.
6. Enable SDADC by asserting MCR[EN].
7. Write 5AF0h to RKR[RESET_KEY] to generate a trigger event. Otherwise, if data conversion need to be triggered by a hardware event, assert MCR[TRIGEN].
8. DFFF interrupt or DMA request is generated after the data FIFO has reached threshold to indicate that data can be transferred or Wait until SFR[DFFF] is clear.
9. Read data by CDR[CDATA].

Follow the sequence when external modulator mode of SDADC is selected for data conversions.

1. Configure and program MCR to select the external modulator mode.
2. Program FIFO threshold FCR[FTHLD] and enable FIFO FCR[FE].
3. Program Request Select and Enable Register (RSER) for DMA/Interrupt request.
4. Enable SDADC using MCR[EN].
5. Select the required external pins EMDATA/EMCLK in the system integration logic (SIUL) of the device.
   - Start EMCLK clock only after above steps are complete.
6. Configure OSD delay according to external modulator startup time or latency from reset exit.
7. External modulator clock should get enabled only when external modulator selection is done.
8. Write 5AF0h to RKR[RESET_KEY] to generate a reset event.
9. DFFF interrupt or DMA request is generated after the data FIFO has reached threshold to indicate that data can be transferred or wait until SFR[DFFF] is clear.
10. Read data by CDR[CDATA].

58.5 SDADC register descriptions

This section provides the descriptions of all registers used for configuring SDADC.

NOTE

Write to read-only register does not generate a transfer error.

58.5.1 SDADC memory map

Calculates register addresses by adding register offset plus SDADC base address. Use 8-bit, 16-bit, or 32-bit addressing to access registers.

SDADC_0 base address: 406F_4000h

SDADC_1 base address: 406F_8000h

SDADC_2 base address: 406F_C000h

SDADC_3 base address: 4070_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Module Configuration Register (MCR)	32	RW	0000_0000h
4h	Channel Selection Register (CSR)	32	RW	0000_0000h
8h	Reset Key Register (RKR)	32	RW	0000_A50Fh

30-29 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
28-24 PDR	Programmable Decimation Rate Selects the over-sampling ratio to be applied to support different passbands with a fixed input sampling clock. The final output data rate (fd) of SDADC is equal to fs/(OSR), where fs is the input sampling clock frequency. The decimation of OSR/4 is done by CIC filter and the decimation of 4 is done by FIR compensation filter. When external modulator is selected, the output data rate is independent of this field and is fixed to fs_ext/128. 0_0000b - OSR = 120 0_0001b - OSR = 140 0_0010b - OSR = 160 0_0011b - OSR = 180 0_0100b - OSR = 200 0_0101b - OSR = 220 0_0110b - OSR = 240 0_0111b - OSR = 280 0_1000b - OSR = 320 0_1001b - OSR = 360 0_1010b - OSR = 376 0_1011b - OSR = 400 0_1100b - OSR = 440 0_1101b - OSR = 480 0_1110b - OSR = 560 0_1111b - OSR = 640 1_0000b - OSR = 720 1_0001b - OSR = 800 1_0010b - OSR = 880 1_0011b - OSR = 960 1_0100b - OSR = 1120 1_0101b - OSR = 1280 1_0110b - OSR = 125. This is special case. Here CIC decimation rate is 25 and FIR is suppose to do decimation by 5. 1_0111b - Reserved 1_1111b - Reserved
23 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
22 —	Reserved
21-20 PGAN	Programmable Gain Selects the gain to be applied to the analog input stage of SDADC. The effective analog input becomes the input voltage level multiplied by the gain factor. 00b - Gain = 1 01b - Gain = 2 10b - Gain = 4 11b - Gain = 8
19 ODF	Output Data Format Controls the output data in CDR. 0b - Output data is unsigned. Data in CDR represents magnitude only i.e. 16th bit (MSB) is always 0. 1b - Output data is signed and sign extended to 16 bits
18 —	Reserved
17 EMSEL	External Modulator Selection Selects data and clock from external modulator. 0b - External modulator data and clock inputs are ignored 1b - External modulator data stream and clock inputs are provided to SDADC
16 —	Reserved
15 WDGEN	Watchdog Enable Enables the WDG monitor. 0b - Disable 1b - Enable
14-13 TRIGEDSEL	Trigger Edge Selection Selects the edge of hardware trigger. 00b - Falling edge of trigger input is selected 01b - Rising edge of trigger input is selected 10b - Both edges of trigger input are selected 11b - Both edges of trigger input are selected

Table continues on the next page...

Table continued from the previous page...

Field	Function
12 TRIGEN	Trigger Enable Enables the hardware trigger input to initiate a fresh conversion. Upon receiving a trigger event, SDADC reset input is asserted and deasserted synchronously with respect to the peripheral clock. The reset pulse width is fixed to four peripheral clock cycles. The trigger event is ignored if SDADC internal modulator is not enabled (MCR[EN] = 0) or the external modulator is selected (MCR[EMSEL] = 1). 0b - Disable 1b - Enable
11-8 TRIGSEL	Trigger Input Selection Selects which input is used for hardware-triggered conversions. 0000b - Input trigger 0 is selected 0001b - Input trigger 1 is selected 0010b - Input trigger 2 is selected 0011b - Input trigger 3 is selected 0100b - Input trigger 4 is selected 0101b - Input trigger 5 is selected 0110b - Input trigger 6 is selected 0111b - Input trigger 7 is selected 1000b - Input trigger 8 is selected 1001b - Reserved 1010b - Reserved 1011b - Reserved 1100b - Reserved 1101b - Reserved 1110b - Reserved 1111b - Reserved
7 FRZ	Freeze Enables stopping SDADC conversions at the end of the current channel conversion when the SoC enters debug mode. When the SoC enters debug mode, further conversions by SDADC analog block is stopped, and converted data output from SDADC analog block are ignored. The ongoing channel conversion is completed and the converted data is stored. When the SoC exits debug mode, user must resume the conversion by writing in to RKR register. 0b - Conversions are not stopped. 1b - Conversions are stopped.
6 VCOM2EN	Common Mode Voltage Enable Enables/ disables common mode voltage output in BIASGEN.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
5-4 VCOMSEL	Common Voltage Bias Selection Selects the common voltage bias for the negative input terminal of SDADC during single-ended mode (MCR[MODE] = 1). 00b - Negative input terminal is biased with vcom0_hv 01b - Negative input terminal is biased with vcom1_hv 10b - Negative input terminal is biased with vcom2_hv 11b - Negative input terminal is biased with vcom0_hv
3 WRMODE	Wrap-Around Mode Selects the wraparound mechanism for conversion of programmed sequence of channels. 0b - Disable 1b - Enable
2 —	Reserved
1 MODE	Mode Selection Selects between differential input mode and single-ended input mode of SDADC. 0b - Differential input mode selected 1b - Single-ended input mode selected
0 EN	Enable for SDADC Block (PDR, PGAN, ODF, ODA, EMSEL, VCOMSEL, MODE, BIASEN and ANCHSEL) should be changed only when EN = 0. 0b - SDADC internal modulator placed in low consumption mode 1b - SDADC internal modulator enabled

58.5.3 Channel Selection Register (CSR)

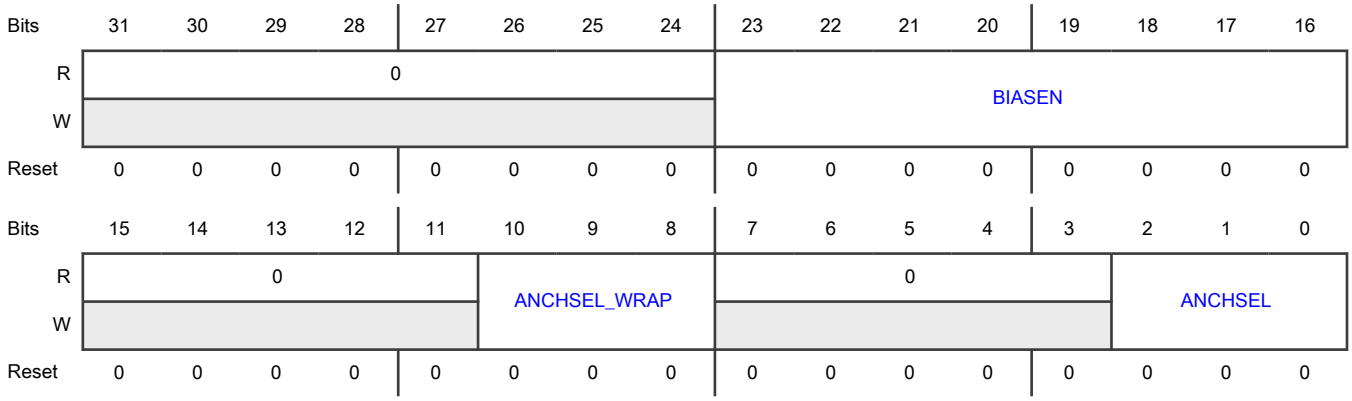
Offset

Register	Offset
CSR	4h

Function

Selects analog inputs AN[0:7] to be connected to positive and negative terminals of SDADC and controls the biasing of analog inputs to half-scale bias through 100 kohm resistance.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 BIASEN	Bias Enable If BIASEN[i] = 0, AN[i] channel is not biased. If BIASEN[i] = 1, analog input AN[i] (could be single-ended input or differential analog input) is connected to half-scale bias through a 100 Kohm resistor.
15-11 —	Reserved
10-8 ANCHSEL_WRAP	Analog Channel Selection Wraparound Value Indicates the maximum value of the wraparound counter when in wraparound mode, after which it is wrap around back to initial value 000. This value should be programmed before enabling wraparound mechanism (MCR[WRMODE] = 1)
7-3 —	Reserved
2-0 ANCHSEL	Analog Channel Selection Based on single-ended or differential mode of operation (MCR[MODE]), common mode voltage selection (MCR[VCOMSEL]), this field defines the connectivity of analog inputs to either positive or negative polarity terminals of SDADC. Wraparound Mode: 1. This field also indicates the initial entry value for the first loop of the wraparound sequence from where the wraparound counter starts incrementing when wraparound mode is entered (when wraparound mechanism enabled (MCR[MODE] = 1). 2. If this field is written any time during wraparound mode (when MCR[WRMODE]= 1), the present value of the wraparound counter is updated with the value of ANCHSEL - the next trigger acts on the updated channel, and the next increment is on the updated channel. Here, the value of ANCHSEL chosen should be less than CSR[ANCHSEL_WRAP]; otherwise it is ignored by hardware.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	3. Wraparound is always from initial counter value 000. **NOTE** For wraparound mode, see Wraparound mode.

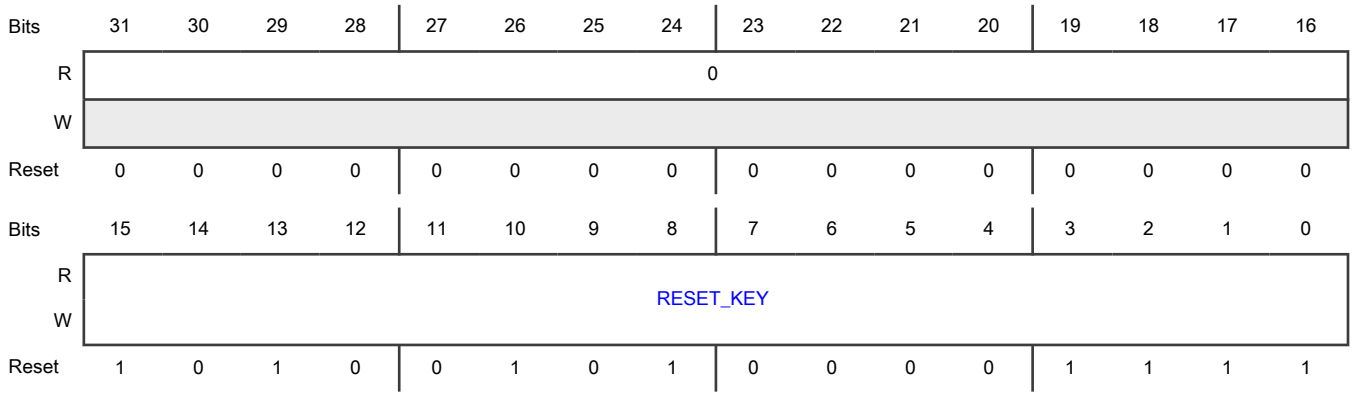
58.5.4 Reset Key Register (RKR)

Offset

Register	Offset
RKR	8h

Function
Specifies a predefined key write operation to reset SDADC to start a fresh conversion.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 RESET_KEY	Reset Key Generates the reset for the SDADC block, when written with 5AF0h and reloads the internal counter with the start value programmed in OSDR. Any write access to this register which is different from the predefined key is ignored. Read access always returns the inverted key.

58.5.5 Status Flag Register (SFR)

Offset

Register	Offset
SFR	Ch

Function

Contains status and flag bits. These bits are set by hardware and reflect the status of SDADC and indicate the occurrence of events that may generate an interrupt or a DMA request. Software can clear some flags by writing '1' to those bits. Writing '0' to a flag has no effect.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0													ANCHSEL_CNT		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-19 —	Reserved
18-16 ANCHSEL_CNT	Analog Channel Selection Counter Reflects the current value of the internal analog channel selection counter. It indicates the present number of the channel selected through the analog multiplexer.
15-9 —	Reserved
8 DFEF	Data FIFO Empty Flag Asserts when there is no dataword in FIFO. 0b - Not empty 1b - Empty
7-5	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
4 WTHH	Watchdog Upper Threshold Cross Over Event Sets when Converted Data crosses upper threshold of WDG. 0b - Did not occur 1b - Occurred
3 WTHL	Watchdog Lower Threshold Cross Over Event Sets when Converted Data crosses Lower Threshold of WDG. 0b - Did not occur 1b - Occurred
2 CDVF	Converted Data Valid Flag Specifies the actual status of data coming from SDADC block. The converted data is not valid or becomes corrupted whenever there is a change in configuration settings determined by Module Configuration Register (MCR), channel selection programmed in Channel Selection Register (CSR). Any write access to Module Configuration Register (MCR) and Channel Selection Register (CSR) resets this flag. This flag is set automatically after triggering SDADC and internal timer counts OSD cycles of output clock fd. **NOTE** If SDADC triggered in freeze mode, CDVF bit can get set automatically. Ignore CDVF bit in freeze mode. 0b - Data is not valid 1b - Data is valid
1 DFORF	Data FIFO Overrun Flag Indicates that software or DMA failed to prevent FIFO from overflowing with converted datawords. Software can clear this bit by writing '1' to it after reading FIFO contents through CDR. This flag remains set if software or DMA failed to clear the condition that caused this flag setting. If DFORF is set, further datawords are not received into FIFO even if sufficient room exists. 0b - No overrun has occurred since the last time the flag was cleared 1b - Overrun has occurred or DFORF has not been cleared since the last overrun occurred
0 DFFF	Data FIFO Full Flag Sets when the number of converted datawords in FIFO is more than the number indicated by FCR[FTHLD]. Software can clear this bit by writing '1' to it. This bit is also cleared by an acknowledgement from the DMA controller when DMA request generation is selected. This bit remains set if software or DMA failed to clear the condition that caused this flag setting. Even if DFFF is set, datawords continues to be received until an overrun condition occurs. Datawords are not received if the converted data is not valid (CDVF = 0). 0b -The number of datawords in FIFO is less than or equal to the number indicated by FCR[FTHLD]

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b -The number of datawords in FIFO is greater than the number indicated by FCR[FTHLD] at some point in time since this flag was last cleared **NOTE** Whenever (MCR[EN]) is cleared in order to stop SDADC or change the channel configuration, it is necessary to also clear RSER[DFFDIRE] alongwith. Similarly if DMA or software is too slow in not reading FIFO datawords resulting in DFFF condition it is advisable to stop SDADC by clearing (MCR[EN]) followed by clearing of RSER[DFFDIRE]. Both these actions ensure safe operation.

58.5.6 Request Select and Enable Register (RSER)

Offset

Register	Offset
RSER	10h

Function

Serves two purposes:

1. Enables the flag bits in SFR to generate DMA requests or interrupt requests.
2. Selects the type of request to generate.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table continued from the previous page...

Field	Function
23-18 —	Reserved
17 WTHDIRS	WDG Threshold Cross Over Event DMA/Interrupt Request Select When (SFR[WTHH])/ (SFR[WTHL]) and RSER[WTHDIRE] are set, this field selects between generating a DMA request or an interrupt request. 0b - Interrupt request is selected 1b - DMA request is selected
16 DFFDIRS	Data FIFO Full DMA/Interrupt Request Select When (SFR[DFFF]) and (RSER[DFFDIRE]) are set, this field selects between generating a DMA request or an interrupt request 0b - Interrupt request is selected 1b - DMA request is selected
15 —	Reserved
14-4 —	Reserved
3 WTHDIRE	WDG Threshold Cross Over Event DMA/Interrupt Request Enable Enables (SFR[WTHH]) or (SFR[WTHL]) to generate a request. (SFR[WTHDIRS]) determines which is selected, a DMA request or an interrupt request. 0b - Interrupt/DMA request is disabled on WDG threshold cross over event 1b - Interrupt/DMA request is enabled on WDG threshold cross over event
2 —	Reserved
1 DFORIE	Data FIFO Overrun Interrupt Enable Enables (SFR[DFORF]) to generate an interrupt request. 0b - Interrupt request is disabled when data FIFO overrun condition occurs 1b - Interrupt request is enabled when data FIFO overrun condition occurs
0 DFFDIRE	Data FIFO Full DMA/Interrupt Request Enable Enables (SFR[DFFF]) to generate a request. (RSER[DFFDIRS]) determines which is selected, a DMA request or an interrupt request. To have safe operation this bit should not be set when (MCR[EN] = 1) Whenever (MCR[EN]) is cleared this bit should also be cleared if already set and FCR[FRST] can be set to clear the previous FIFO content.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Interrupt/DMA request is disabled when data FIFO full condition occurs 1b - Interrupt/DMA request is enabled when data FIFO full condition occurs

58.5.7 Output Settling Delay Register (OSDR)

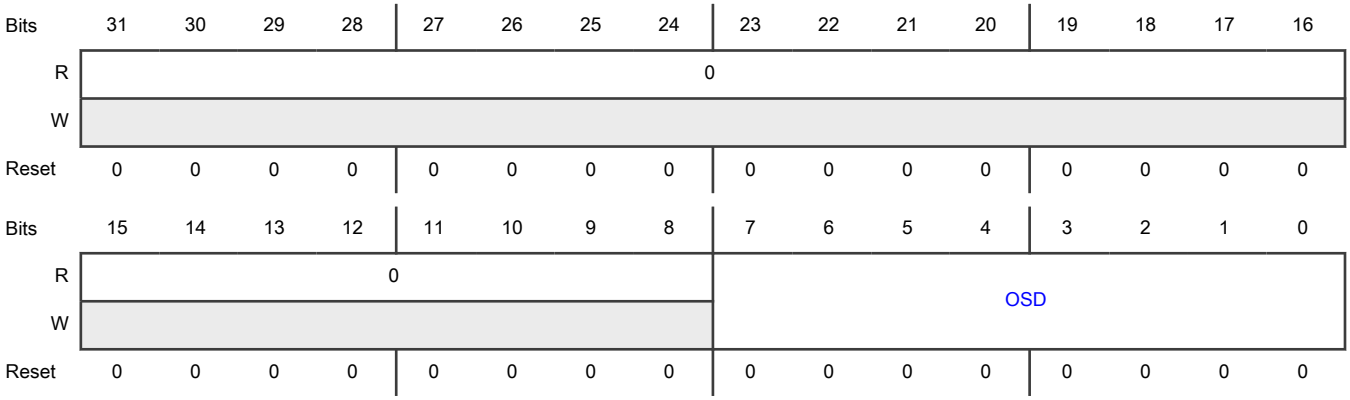
Offset

Register	Offset
OSDR	14h

Function

Provides a delay value to qualify the converted output data coming from SDADC.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 OSD	Output Settling Delay Defines the delay to qualify the conversion data stored in CDR. Whenever SDADC block is reset in order to start the conversion from a fresh state, an internal timer is loaded with this start value. The counter counts down with output data valid rate fd until it reaches zero, and then it generates a flag which qualifies the converted data. The output data valid rate fd is equal to fs/(OSR/4), where fs is the input sampling clock frequency. When external modulator is selected, the output valid data rate is fixed to fs/128.

58.5.8 FIFO Control Register (FCR)

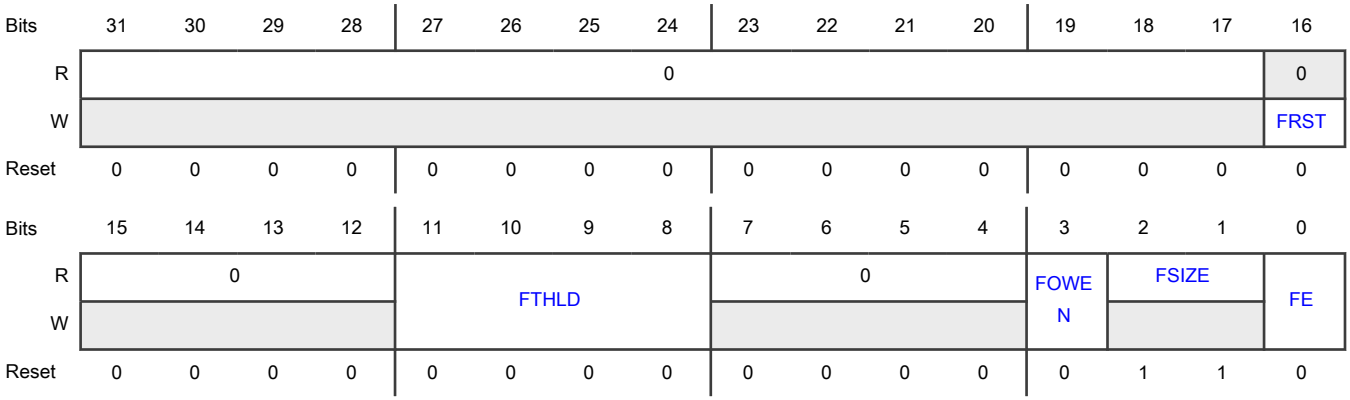
Offset

Register	Offset
FCR	18h

Function

Provides the ability to turn on and off FIFO functionality, and to select the size of FIFO depth. This register also provides the ability to set the programmable threshold for notification of dataword removal from FIFO. This register may be read at any time, but should only be written when SDADC is disabled (MCR[EN] = 0).

Diagram



Fields

Field	Function
31-17 —	Reserved
16 FRST	FIFO Flush Reset This is functional soft reset to flush the current FIFO content and initialize the internal FIFO pointers. This is W1S (write one shot) bit which can be written as '1' but always read as '0'. Use this option only after disabling ADC i.e. (MCR[EN] = 0). 0b - No effect. 1b - Generate a single cycle reset event to flush FIFO.
15-12 —	Reserved
11-8 FTHLD	FIFO Threshold When the number of datawords in the data FIFO is greater than the value in FTHLD, FIFO full event is flagged. An interrupt or a DMA request is generated as determined by RSER[DFFDIRE] and

Table continues on the next page...

Table continued from the previous page...

Field	Function
	RSER[DFFDIRS]. For proper operation, the value in FTHLD must be set to be less than FIFO size as indicated by FCR[FSIZE].
7-4 —	Reserved
3 FOWEN	FIFO Over Write Enable When set the built-in FIFO structure allows the overwriting of new converted data over older converted data after FIFO has number of entries equal to FCR[FSIZE]. 0b - Disable 1b - Enable
2-1 FSIZE	FIFO Size Specifies the maximum number of converted datawords that can be stored in the data FIFO before an overrun occurs. This field is read-only. The reset value of this field depends on the implementation parameter to define FIFO size. 00b - FIFO depth = 1 dataword 01b - FIFO depth = 4 datawords 10b - FIFO depth = 8 datawords 11b - FIFO depth = 16 datawords
0 FE	FIFO Enable Enables the built-in FIFO structure after this field is set. The size of FIFO structure is indicated by FCR[FSIZE]. If this field is not set then FIFO depth is set to one dataword regardless of the value in FCR[FSIZE]. 0b - Data FIFO is not enabled for multiple datawords; FIFO depth is one dataword 1b - Data FIFO is enabled; FIFO depth is indicated by FSIZE

58.5.9 Software Trigger Key Register (STKR)

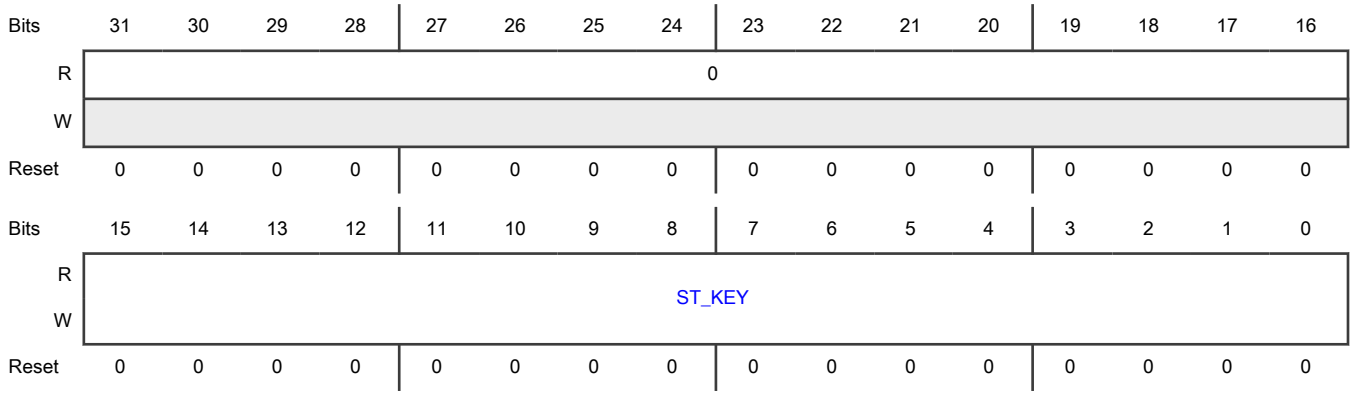
Offset

Register	Offset
STKR	1Ch

Function

Generates the trigger event output by a software write operation.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 ST_KEY	Software Trigger Key Generates the trigger event output, when written with FFFFh, which can be used to trigger conversions of multiple SDADC blocks synchronously depending on the SoC implementation. Any write access to this register which is different from the predefined key is ignored. Read access always returns 0000h.

58.5.10 Converted Data Register (CDR)

Offset

Register	Offset
CDR	20h

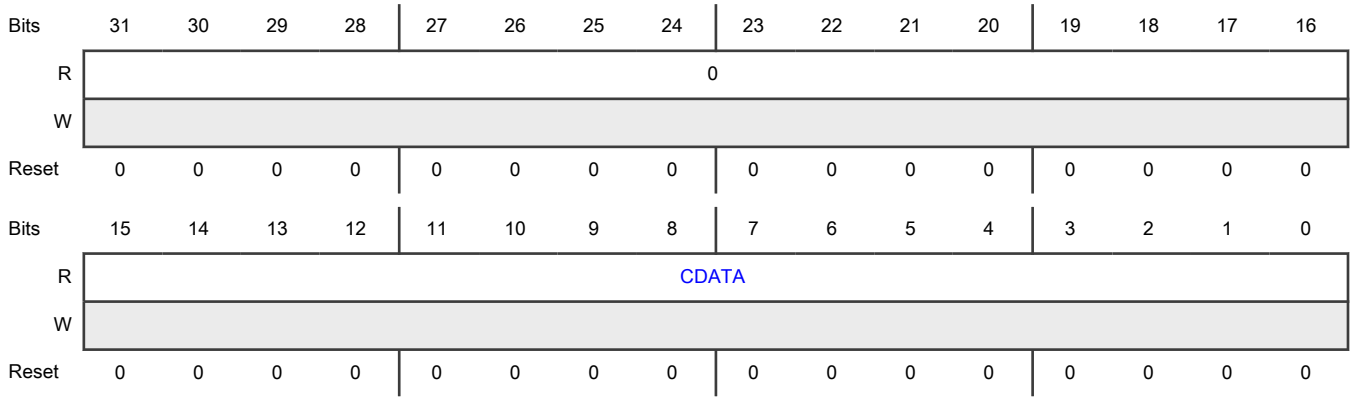
Function

Stores the converted data in the data FIFO.

NOTE

CDR read is not allowed in FIFO empty condition otherwise it may lead to invalid data read.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 CDATA	Converted Data The converted datawords can be read from FIFO by reading this register. The data width is 16 bits which has actual 16-bit data (bits 15 down to 0) coming from ADC.

58.5.11 WDG Threshold Register (WTHHLR)

Offset

Register	Offset
WTHHLR	24h

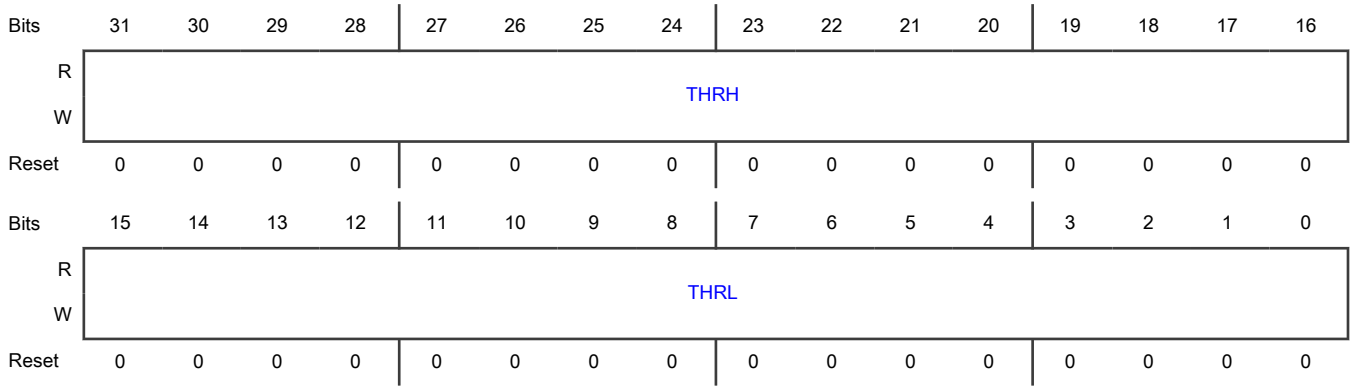
Function

This is the Converted Data Range WDG Threshold register.

NOTE

A single WDG monitor checks for lower and upper threshold crossover events.

Diagram



Fields

Field	Function
31-16 THRH	WDG Upper Threshold Value Indicates the upper threshold for the converted data on any channel, above which threshold a crossover event would be flagged through SFR[WTHH].
15-0 THRL	WDG Lower Threshold Value Indicates the lower threshold for the converted data on any channel, below which threshold cross over event would be flagged through SFR[WTHL].

58.5.12 CIC Configuration Register (CCR)

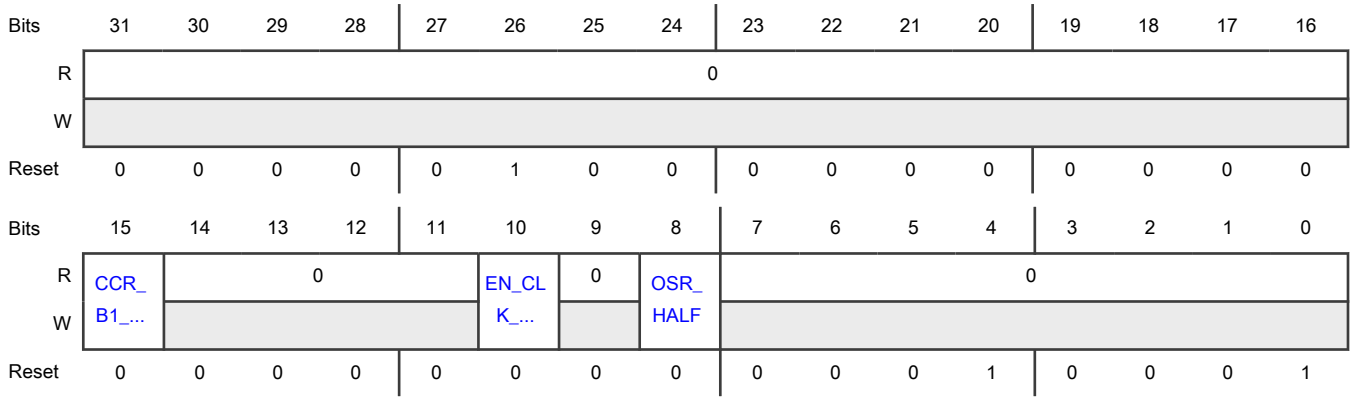
Offset

Register	Offset
CCR	28h

Function

This is the CIC FILTER's control register. This register should be programmed when SDADC is disabled (i.e. MCR[EN] = 0).

Diagram



Fields

Field	Function
31-16 —	Reserved
15 CCR_B1_IPS_EN	Enable or Disable CCR Byte 1 IPS programmability Enables or disables IPS programmability for CCR[OSR_HALF] and CCR[EN_CLK_RATE_HALF]. 0b - Disable IPS programmability 1b - Enable IPS programmability

Chapter 59
ADCBIST

59.1 Introduction

ADCBIST creates a sine wave, which the SDADC being tested then measures. This measured data is sent from SDADC via DMA to the system.

59.1.1 Features

- A BIST to stimulate SDADC instances serially, where the conversion data of SDADC is filtered and sent on request via DMA to the system for further processing.
- R2RDAC to generate test stimuli for the ADC.

59.1.2 Block diagram

The following figure shows the general functional blocks of the module.

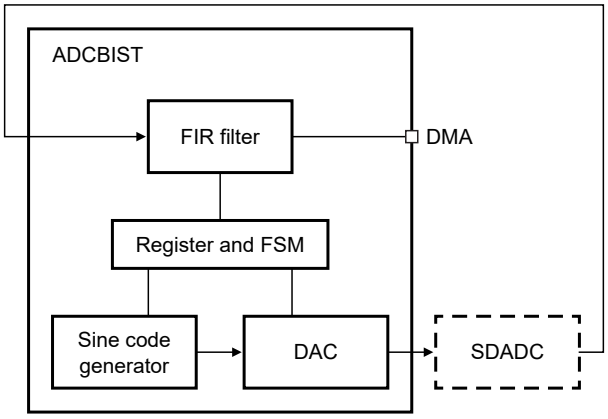

Figure 292. Block diagram

59.1.3 Detailed functioning

The following figure represents the detailed functioning of ADCBIST (for a top-level view, see Block diagram):

- Signals flow from left to right: inputs to blocks are shown on the left side, and outputs are shown on the right side of the figure.
- FIR filter, symbol rate counter, sine angle counter, and CORDIC algorithm are the names of functional blocks.
- Register and field mnemonics, for example, BISTCTL[TESTRUN], map to the mnemonics in ADCBIST register descriptions.
- Conversion control and conversion data are signal names.
- All shown digital signals are synchronous. Asynchronous inputs to ADCBIST are internally synchronized (synchronizers are not shown).

This figure also shows the data flow through ADCBIST and how you can use the registers provided in ADCBIST register descriptions to configure and control ADCBIST. The legend included with the figure explains the symbols used in the figure. You must:

- Configure SDCFG[SDSEL] to select SDADC under test.
- Configure BISTCFG[TESTSEL] to select the test to run.
- Write 1 to BISTCTL[TESTRUN] to run a test.

After you enable the SDADC test, the CORDIC algorithm is enabled, and that generates codes for the R-2R DAC to output a sine wave. You must configure SDCFG[DACSR] and SDSINECFG[SINESTEP] to set the frequency of the generated sine wave. SDADC measures the sine wave—you can observe the conversion data. You can read ADCBIST Status (BISTSTAT) to see the status of ADCBIST.

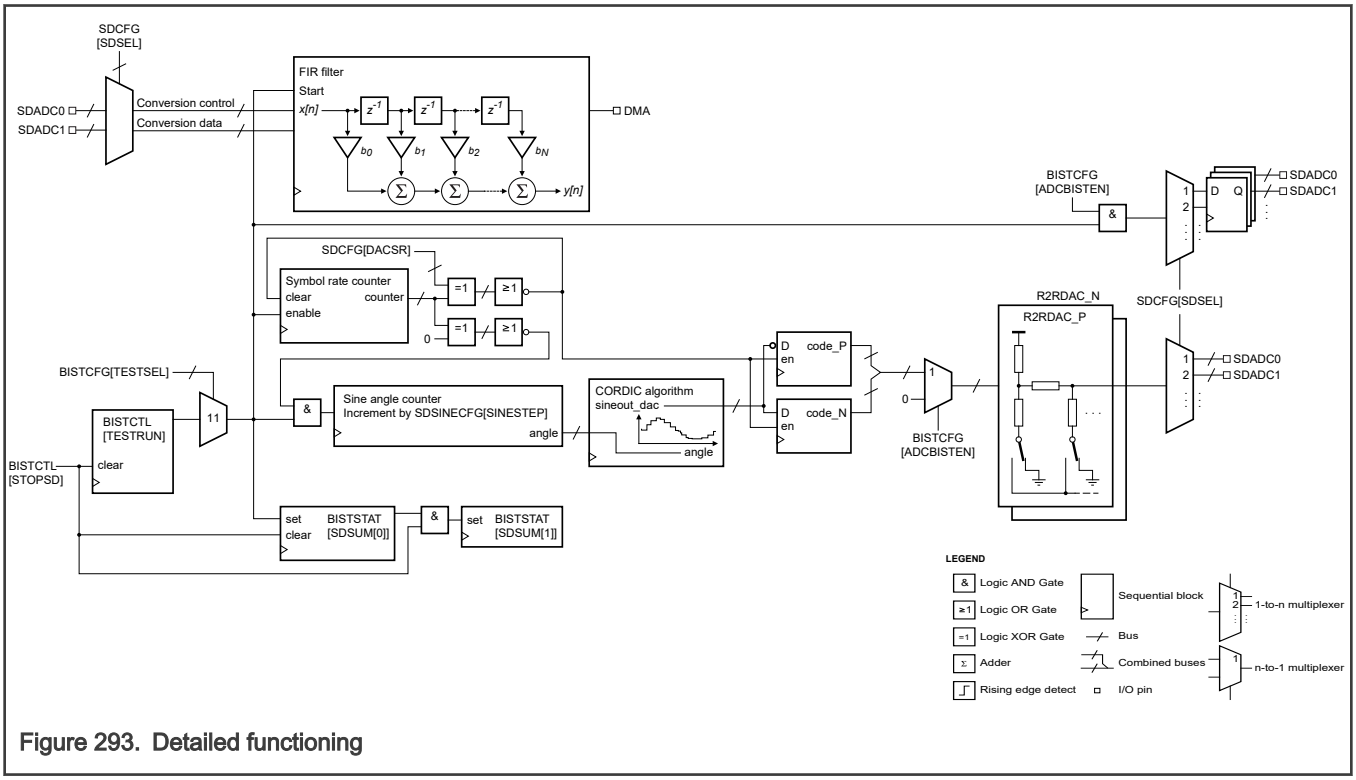

Figure 293. Detailed functioning

59.2 ADCBIST register descriptions

59.2.1 ADCBIST memory map

ADCBIST supports 32-bit write accesses and 32-bit, 16-bit, and 8-bit read accesses. ADCBIST generates a transfer error in these cases:

- Access to an address that does not map to a register
- Write access to a read-only register
- Non-32-bit write access

59.2.6 SDADC Test Configuration (SDCFG)

Offset

Register	Offset
SDCFG	200h

Function

Configures the tests where SDADC is used or tested.

You can:

- Write to this register only when no test is running, that is, when BISTCTL[TESTRUN] = 0.
- Use this register to define the number of module clock edges. After you do this, a new symbol (code) is given to R2RDAC. The resulting symbol rate is f_symbol = (module clock frequency) ÷ (DACSR + 1). The period to send a new code to R-2R DAC is constant only if the resulting symbol rate is an even value. Otherwise, the period differs by one clock cycle.
- Use this register to select the SDADC to be tested.

Diagram

59.2.7 SDADC Sine Wave Configuration (SDSINECFG)

Offset

Register	Offset
SDSINECFG	204h

Function

Configures the step size to generate the sine wave.

The value that you write to this register is $2^{32} \div N$, where N is the desired number of samples per period of the sine wave. This value must be equal to or larger than 2^{14}; smaller step sizes cannot be resolved.

You can write to this register only when no test is running, that is, if BISTCTL[TESTRUN] = 0.

NOTE

To program SDSINECFG[SINESTEP] with values mentioned against Configuration1 and Configuration2, refer to Table 284.

59.2.8 Finite Impulse Response Filter (FIRF)

Offset

Register	Offset
FIRF	800h

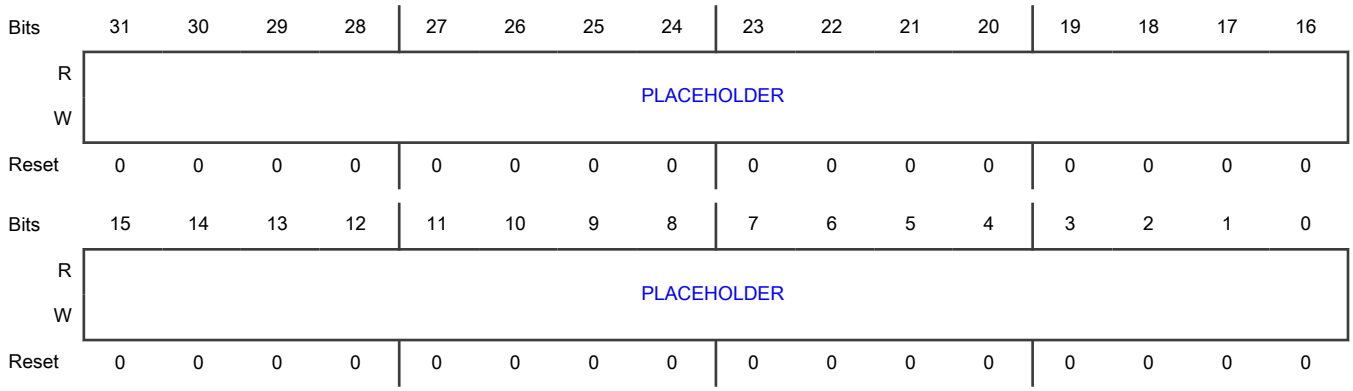
Function

Provides the address to access the FIRF.

You can write to this register only when no test is running, that is, if BISTCTL[TESTRUN] = 0.

See the "FIR Filter" chapter for details on accessible registers.

Diagram



Fields

Field	Function
31-0 PLACEHOLDER	Finite Impulse Response Filter

59.3 Functional description

59.3.1 Operating mode

ADCBIST includes only one operating mode. To enable this operating mode, you must write 1 to BISTCFG[ADCBISTEN].

59.3.2 SDADC test

You must test SDADC by stimulating the SDADC being tested with a sine wave and analyzing the conversion results outside ADCBIST.

Perform this procedure to run the SDADC test, configure ADCBIST, and start the SDADC test:

1. Select the SDADC being tested by configuring SDCFG[SDSEL].
2. Configure SDADC to achieve coherent sampling (see Table 284).

3. Ignore the conversion data received during test startup (write 14h to FIR Filter.OSDR[OSD]).
4. Select the SDADC test (write 11b to BISTCFG[TESTSEL]).
5. Start the SDADC test (write 1 to BISTCTL[TESTRUN]).

Perform this procedure to configure SDADC:

1. Enable the bias generator (write 1 to SDADC.MCR[BIASGEN_EN]).
2. Enable the SDADC being tested (write 1 to SDADC.TCR[TEST_SDADC_EN]).
3. Disable the inmux override (write 0 to SDADC.TCR[INMUX_EN]).
4. Enable the R2RDAC mux override (write 1 to SDADC.TCR[TESTMUX_EN]).
5. Enable the SDADC test mode (write 1 to SDADC.TCR[TEST_EN]).
6. Wait until SDADC is ready to use (check in SDADC if a delay is needed here).

The SDADC test starts running.

Observe the conversion data via DMA and perform post-processing (through FFT) outside ADCBIST.

After enough conversion data is received, perform this procedure to disable SDADC:

1. Disable the SDADC test mode (write 0 to SDADC.TCR[TEST_EN]).
2. Disable the R2RDAC mux override (write 0 to SDADC.TCR[TESTMUX_EN]).
3. Enable the inmux override (write 1 to SDADC.TCR[INMUX_EN]).
4. Disable the SDADC under test (write 0 to SDADC.TCR[TEST_SDADC_EN]).

Perform this procedure to stop the SDADC test:

1. Write 1 to BISTCTL[STOPSD].
2. Read BISTSTAT[SDSUM] to ensure that the SDADC test is complete.

You must repeat the aforementioned steps for all SDADC instances. Write 1 to BISTCTL[CLEAR] to clear ADCBIST before each test.

You can control the sine wave, which is used to stimulate SDADC, by configuring SDCFG[DACSR] (sets the limit for the symbol_rate_counter) and SDSINECFG[SINESTEP] (sets the angle for the CORDIC algorithm).

Together with the settings in the SDADC under test, you must configure the SDADC test to achieve coherent sampling, which is needed for running an FFT analysis on the conversion data: f_s ÷ f_r = N ÷ M, where:

- f_s is the sampling frequency of the generated sine wave.
- f_r is the frequency of the sine wave that SDADC converts.
- N is the number of samples taken (must be a power of 2).
- M is the number of cycles of the sine wave (must be mutually prime to the number of samples).

NOTE

SDADC BIST runs at the startup phase. While ADCBIST is running, both SDADC and DSPSS are unavailable for use. Only after ADCBIST completes, DSPSS is enabled. Therefore, ADCBIST cannot use PMEM in any use case when operating in this mode.

Table 284. Example settings for coherent sampling

Configuration	SDSINECFG[SINESTEP]	SDCFG[DACSR] @ 80 MHz module clock frequency	f_s	f_r	N (read samples via DMA)	M
1	028C_0000h	4Fh	1 MHz	10 kHz	16384	163

FIR	Finite impulse response
R-2R DAC	Resistor-2 resistor digital-to-analog converter

Chapter 60
FIR filter

60.1 Overview

Finite Impulse Response filter (FIR) is compensation filter for the SDADC devices.

It is implemented inside ADCBIST.

The basic implementation of an FIR requires three basic building blocks

- Multiplication
- Addition
- Signal delay
- Memory to store filter coefficient

The FIR filters has equation of the form the output.

$$y[n] = \sum_{k=0}^{3} b_k x[n-k]$$

Figure 294. Equation

Using the building blocks described above, we can construct a block diagram as below:

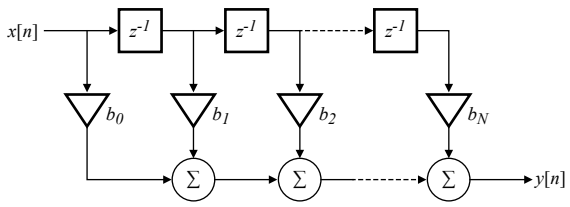

Figure 295. Functional block diagram

60.1.1 Block diagram

The following figure shows the block diagram of FIR filter.

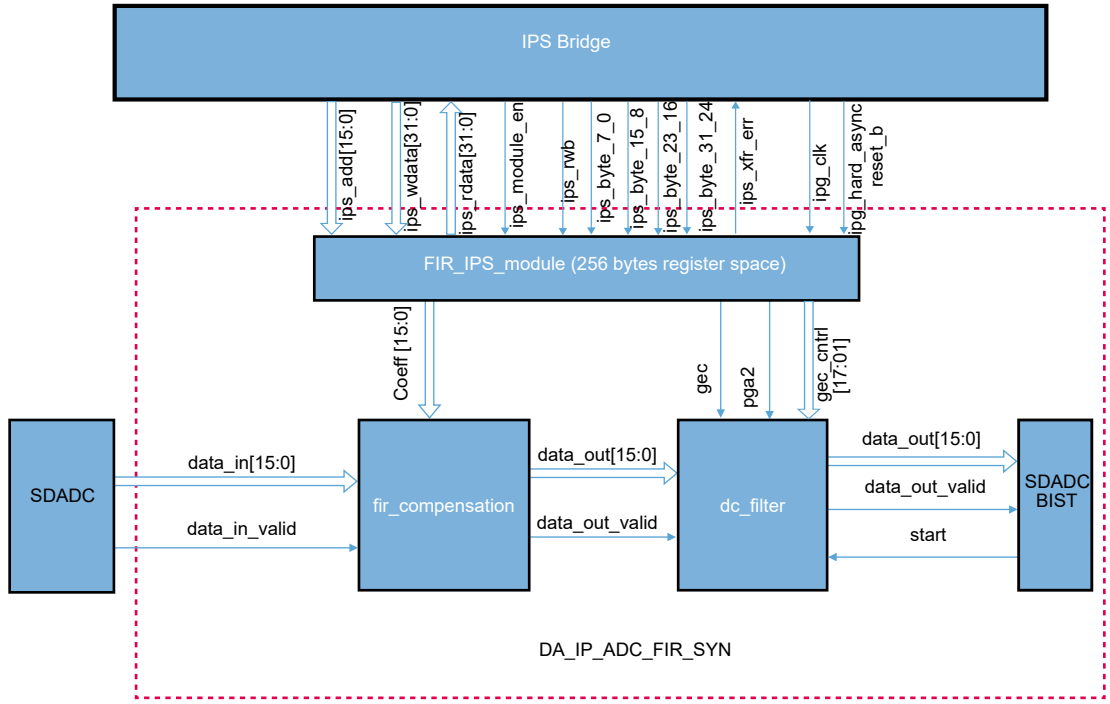

Figure 296. Block diagram

60.1.2 Features

FIR features include:

- 51 tap filter
- Support Gain Error Correction (GEC) enable/disable
- Support programmable gain by 2 enable/disable feature
- Support programmable gain error factor

60.2 Functional description

The HW FIR compensation filter for the SDADC is implemented in the ADCBIST IP. FIR compensation filter that uses down-sampling filter output (CIC filter) and provides an output at the final SDADC conversion rate. The output of the FIR filter is decimated by four before the final output.

The FIR compensation filter is a linear phase filter and have a symmetrical impulse response (symmetrical coefficients). FIR filter digital block has fir compensation and post processing blocks.

GEC (Gain Error Correction) and PGA2(programmable gain by 2) features are implemented in post processing block. The FIR compensation filter have 51 filter taps .

The FIR compensation filter shall receive a 16-bit sign extended input from the Sigma-Delta CIC filter and gives output SDADC BIST FFT.

60.2.1 FIR compensation

This is core FIR filter module. It takes coefficient and data as input and it gives filtered output. It is also do the decimation of data rate by 4.

60.2.2 Post processing module

This module does the post processing of data like gain error correction and programmable gain of 2.

60.2.3 Clocking

This clock is used for FIR compensation and postprocessing. This should be 80MHz non-FM clock.

60.2.4 Reset

The active low reset is [MODULE_RESETB/ipg_hard_async_reset_b] with asynchronous assertion and synchronous de-assertion. It is used to reset all digital content in FIR.

60.2.5 Interrupt/DMA request support

The following condition that generates interrupts or DMA request in FIR.

The DFFF field is asserted when the data FIFO full condition is detected, indicating that the number of converted datawords stored in data FIFO is equal to or greater than the value indicated by threshold determined by FCR[FTHLD]. The interrupt or DMA request is generated only when RSER[DFFDIRE] is asserted. RSER[DFFDIRS] selects whether a DMA request or an interrupt request is generated.

The data FIFO overrun flag (DFORF) indicates the FIFO overflow condition. Further converted datawords cannot be received and data is lost. The interrupt request is generated only when RSER[DFORIE] is asserted.

The following is an example of DMA transfer waveform.

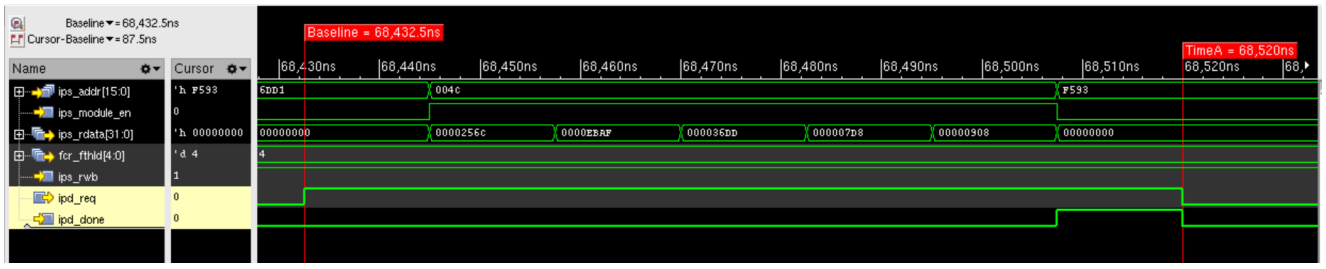

Figure 297. DMA waveform

60.3 External signals

This module has no external signals.

60.4 Initialization

1. Program FIR_CNTRL[PGA2] and FIR_CNTRL[GEC] (if required).
   - Program GEC_PRGRM_FACTOR accordingly.
2. Program FCR to enable fifo and fifo threshold.
3. Program RSER to select interrupt/DMA mode.
4. Generate a trigger event by writing 0x5AF0 to RESET_KEY of RKR.
5. Read CDR to read the FIR output data.

60.5.4 Status Flag Register (SFR)

Offset

Register	Offset
SFR	3Ch

Function

The Status Flag Register (SFR) contains status and flag bits. These bits are set by hardware and reflect the status of the FIR and indicate the occurrence of events that may generate an interrupt or a DMA request. Software can clear some flags by writing '1' to those bits. Writing a '0' to a flag has no effect.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-19 —	Reserved
18-9 —	Reserved
8	Data FIFO Empty Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
DFEF	This field is asserted when there is no dataword in the FIFO. 0b - Data FIFO is not empty 1b - Data FIFO is empty
7-3 —	Reserved
2 CDVF	Converted Data Valid Flag This field gives the actual status of data coming from the FIR block. The converted data is not valid or becomes corrupted whenever there is a change in configuration settings determined by(FIR_CNTRL), FIR_COEFF0-13. Any write access to the registers(FIR_CNTRL) and FIR_COEFF0-13 will reset this flag. This flag is set automatically after generating FIR reset and internal timer counts OSD cycles of output clock fd. If OSD is 0 then, this flag will set at start itself. 0b - Data output from FIR is not valid 1b - Data output from FIR is valid
1 DFORF	Data FIFO Overrun Flag This field indicates that software or DMA failed to prevent FIFO from overflowing with converted datawords. Software can clear this bit by writing '1' to it after reading the FIFO contents through CDR. This flag remains set if software or DMA failed to clear the condition that caused this flag setting. If DFORF is set, further datawords will not be received into FIFO even if sufficient room exists. 0b - No overrun has occurred since the last time the flag was cleared 1b - Overrun has occurred or the DFORF has not been cleared since the last overrun occurred
0 DFFF	Data FIFO Full Flag This bit is set when the number of converted datawords in the FIFO is more than the number indicated by FCR[FTHLD]. Software can clear this bit by writing '1' to it. This bit is also cleared by an acknowledgement from the DMA controller when DMA request generation is selected. This bit remains set if software or DMA failed to clear the condition that caused this flag setting. Even if DFFF is set, datawords will continue to be received until an overrun condition occurs. Datawords will not be received if the converted data is not valid (CDVF = 0). 0b -The number of datawords in FIFO is equal to or less than the number indicated byFCR[FTHLD] 1b -The number of datawords in FIFO is greater than the number indicated by FCR[FTHLD] at some point in time since this flag was last cleared **NOTE** Whenever the FIR is stopped or change the configuration, it is necessary to also clear the RSER[DFFDIRE] bit along with. Similarly if DMA or software is too slow in not reading the FIFO datawords resulting in DFFF condition it is advisable to stop the FIR followed by clearing of RSER[DFFDIRE] bit. Both these action will ensure safe operation.

60.5.5 Request Select and Enable Register (RSER)

Offset

Register	Offset
RSER	40h

Function

The Request Select and Enable Register (RSER) serves two purposes:

1. Enables the flag bits in SFR to generate DMA requests or interrupt requests.

2. Selects the type of request to generate.

Refer to the field descriptions for the type of requests that are supported

Diagram

Table continued from the previous page...

Field	Function
1 DFORIE	Data FIFO Overrun Interrupt Enable This bit enables the (SFR[DFORF]) field to generate an interrupt request. The final interrupt request also depends on the gating signal if enabled by the GDIGE field. 0b - Interrupt request is disabled when data FIFO overrun condition occurs 1b - Interrupt request is enabled when data FIFO overrun condition occurs
0 DFFDIRE	Data FIFO Full DMA/Interrupt Request Enable This field enables the (SFR[DFFF]) field to generate a request. The DFFDIRS field determines which is selected, a DMA request or an interrupt request. The final DMA/interrupt request also depends on the gating signal if enabled by the GDIGE field. To have safe operation this bit should not be set when FIR is running. FCR[FRST] can be set to clear the previous FIFO content 0b - Interrupt/DMA request is disabled when data FIFO full condition occurs 1b - Interrupt/DMA request is enabled when data FIFO full condition occurs

60.5.6 Output Settling Delay Register (OSDR)

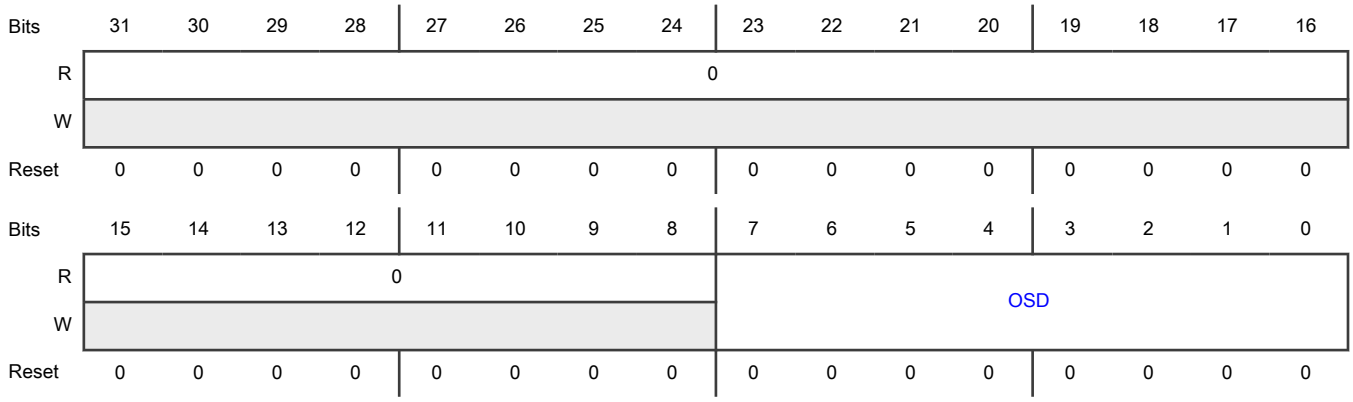
Offset

Register	Offset
OSDR	44h

Function

The Output Settling Delay Register (OSDR) provides a delay value to qualify the converted output data coming from the FIR.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 OSD	Output Settling Delay This field defines the delay to qualify the conversion data stored in CDR. Whenever the FIR block is reset in order to start the conversion from a fresh state, an internal timer is loaded with this start value.

60.5.7 FIFO Control Register (FCR)

Offset

Register	Offset
FCR	48h

Function

The FIFO Control Register (FCR) provides the ability to turn on and off the FIFO functionality, and to select the size of FIFO depth. This register also provides the ability to set the programmable threshold for notification of dataword removal from the FIFO. This register may be read at any time, but should only be written when FIR is disabled (FCR[FOWEN]=0).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															0
W																FRST
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0				FTHLD				0				FOWEN	FSIZE		FE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

Fields

Field	Function
31-17 —	Reserved
16 FRST	FIFO Flush Reset

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This is functional soft reset to flush the current FIFO content and initialize the internal FIFO pointers. This is W1S(write one shot) bit which can be written as '1' but always read as '0'. Use this option only when FIR is not running. 0b - No effect. 1b - Generate a single cycle reset event to flush the FIFO.
15-12 —	Reserved
11-8 FTHLD	FIFO Threshold When the number of datawords in the data FIFO is greater than the value in FTHLD field, the FIFO full event is flagged. An interrupt or a DMA request will be generated as determined by DFFDIRE and DFFDIRS fields of RSER. For proper operation, the value in the FTHLD field must be set to be less than the FIFO size as indicated by FSIZE
7-4 —	Reserved
3 FOWEN	FIFO Over Write Enable When set the built-in FIFO structure allows the overwritting of new converted data over older converted data after the FIFO has number of entries equal to the FSIZE. 0b - Data FIFO OW option disabled. 1b - Data FIFO OW option enabled.
2-1 FSIZE	FIFO Size The maximum number of converted datawords that can be stored in the data FIFO before an overrun occurs. This field is read-only. The reset value of this field depends on the implementation parameter to define the FIFO size. 00b - FIFO depth = 1 dataword 01b - FIFO depth = 4 datawords 10b - FIFO depth = 8 datawords 11b - FIFO depth = 16 datawords
0 FE	FIFO Enable When this field is set the built-in FIFO structure is enabled. The size of the FIFO structure is indicated by the FSIZE field. If this field is not set then the FIFO depth is set to one dataword regardless of the value in the FSIZE field. 0b - Data FIFO is not enabled for multiple datawords; FIFO depth is one dataword 1b - Data FIFO is enabled; FIFO depth is indicated by FSIZE

60.5.8 Converted Data Register (CDR)

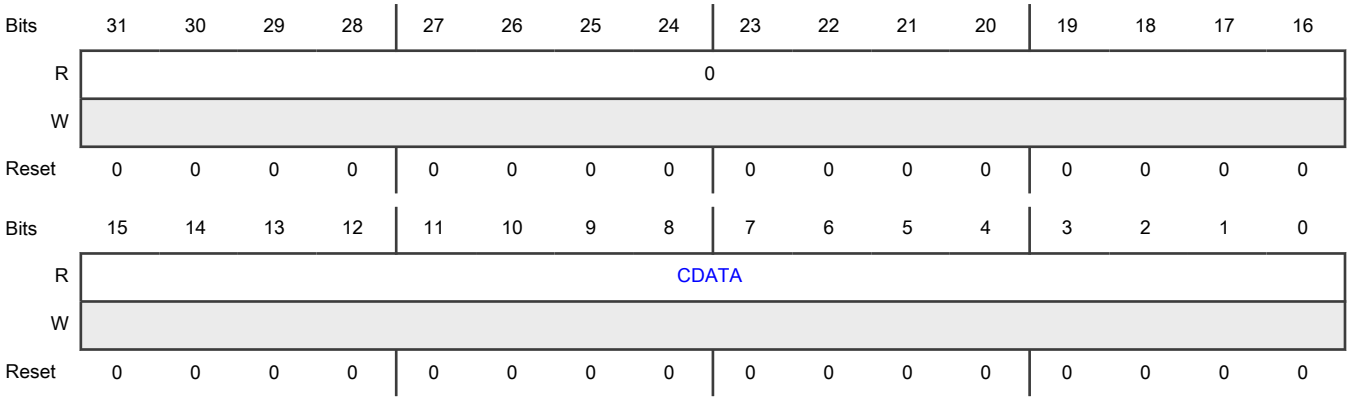
Offset

Register	Offset
CDR	4Ch

Function

The Converted Data Register (CDR) stores the converted data in the data FIFO.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 CDATA	Converted Data Register The converted datawords can be read from FIFO by reading this register. The data width is 16 bits which has actual 16-bit data (bits 15 down to 0) coming from ADC.

Chapter 61
Low Power Comparator (LPCMP)

61.1 Chip-specific LPCMP information

61.1.1 Instantiation information

Table 285. LPCMP instances

Chip	Instance	No. of external inputs
S32K396	LPCMP_0	8
	LPCMP_1	4

61.1.2 LPCMP input output connections

See the IOMUX file attached to this document for pin/pad assignments corresponding to CMP pins.

The LPCMP channels can be used as a wakeup source in trigger mode to wakeup the device from standby mode.

61.1.3 LPCMP-DAC "vrefh0" and "vrefh1" references

The 8-bit DAC sub-block supports selection of "vrefh0" and "vrefh1" by CMPx_DCR[VRSEL]. For this device, the references are connected as follows:

- vrefh0 (External Reference): VDD_HV_A
- vrefh1 (Internal Reference): 1.2 V PMC bandgap reference

NOTE

1.2 V internal reference voltage is not available in Standby mode.

61.1.4 LPCMP Window control

The window mode operation of all the comparator instances in the chip can be enabled/disabled by the TRGMUX. See the TRGMUX connectivity file attached to this document for details.

NOTE

Window/Sample signal must be of minimum 4 cycle pulse for Window mode/Sample mode to function.

61.1.5 Comparator Trigger Mode

The comparator modules in the device support trigger mode operation as described in 'Trigger Mode' section. Device can operate in trigger mode in both standby and run mode to continuously scan the input channels. The main features of the device trigger mode operation are:

- Round robin clock: RTC_CLK
- Round robin trigger source: RTC_API

NOTE

It must be ensured that the RTC_CLK period is greater than the comparison time corresponding to the value of C0[PMODE]. It is also required to **not** select the internal reserved channels, if available on the package, for trigger mode operation by INPSEL and INNSEL. See the IOMUX file attached to this document for the pins available in various packages supported for the device.

NOTE

Only SIRC is supported as RTC_CLK for trigger mode operation. The LPCMP initialization delay is not supported by RRCR0[RR_INITMOD] with FXOSC or FIRC as RTC_CLK.

NOTE

In run mode, the generated trigger is delayed by 3 RTC_CLK cycles before being given to comparator trigger input.

61.1.6 Interaction with RTC API to cause wakeup

LPCMP can be used for waking up the chip from standby. For this, RTC-API and LPCMP must be configured before entering into standby mode as per below shown figure.

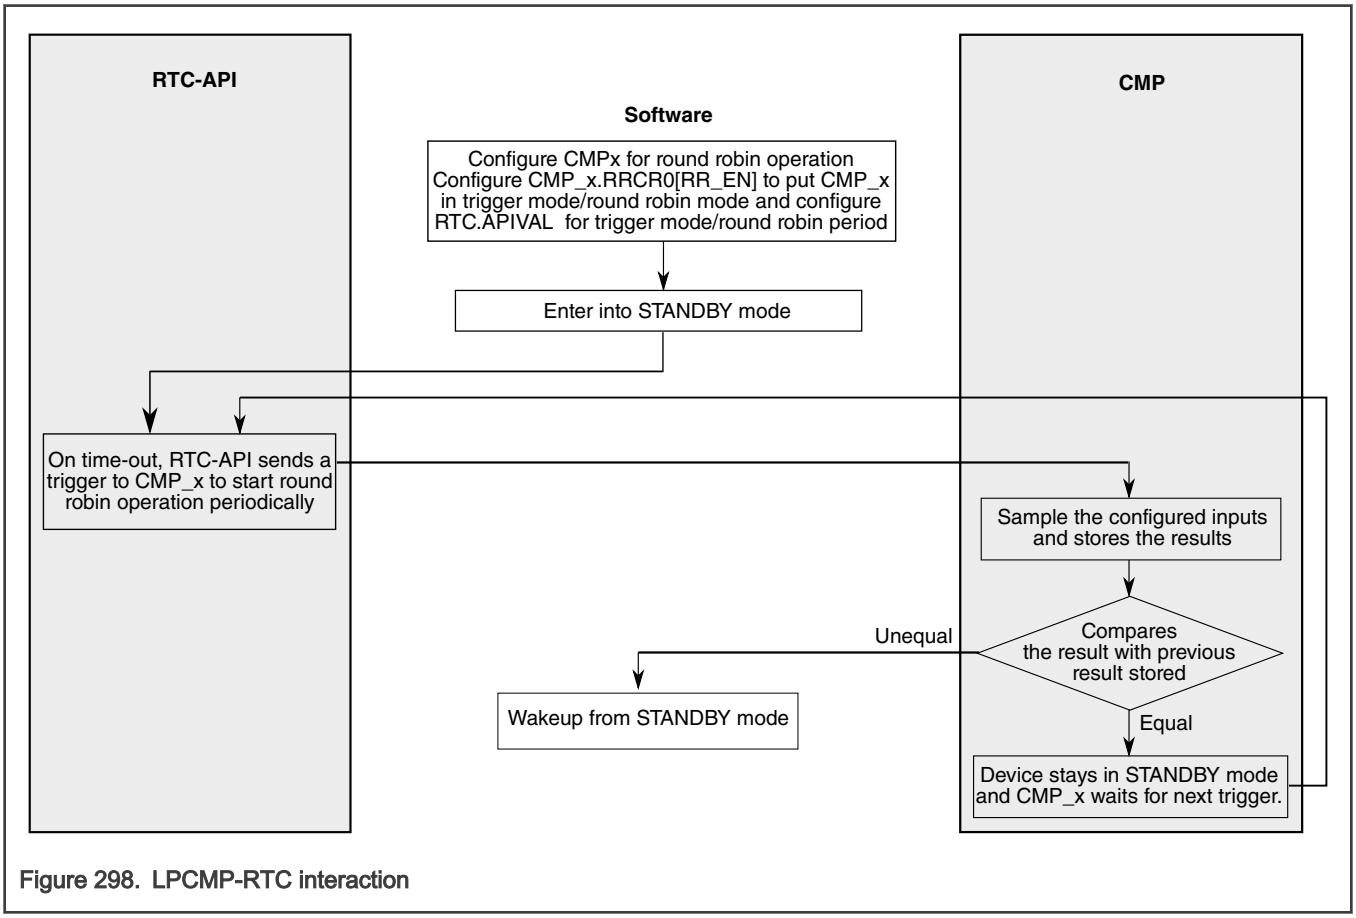


Figure 298. LPCMP-RTC interaction

In the trigger mode operation, only the continuous mode is supported. None of the window/filter/sample functions should be used. Refer to the "Functional Modes" section for details on comparator modes of operation.

Register configurations before entering Standby mode for LPCMP trigger mode operation:

1. Configure RTC.APIVAL to set the period of the round robin operation.
2. Execute standby mode entry.

61.2 Overview

The LPCMP module provides a circuit to compare two analog input voltages. It includes the following:

- A low power comparator (CMP)
- A DAC

- An analog mux (ANMUX)

See Block diagram for more information.

LPCMP can operate across the full range of the supply voltage, known as rail-to-rail operation.

DAC is a 256-tap resistor ladder network that provides a selectable voltage reference for applications requiring a voltage reference. DAC divides the supply reference V_{in} into 256 voltage levels. An 8-bit digital signal input selects the output voltage level, which varies from V_{in} to $V_{in}/256$.

You can select V_{in} from the following voltage sources:

- VREFH0
- VREFH1

See the Chip-specific LPCMP information for more information on source of VREFH0 and VREFH1.

NOTE

The LPCMP's internal DAC output is available as an on-chip internal signal only and is not available for an external chip pin.

ANMUX allows you to select an analog input signal from among eight channel options. One channel option is the DAC output. Other chip resources are connected to the other channels. See the Chip-specific LPCMP information section for more information. ANMUX can operate across the full range of the supply voltage.

61.2.1 Block diagram

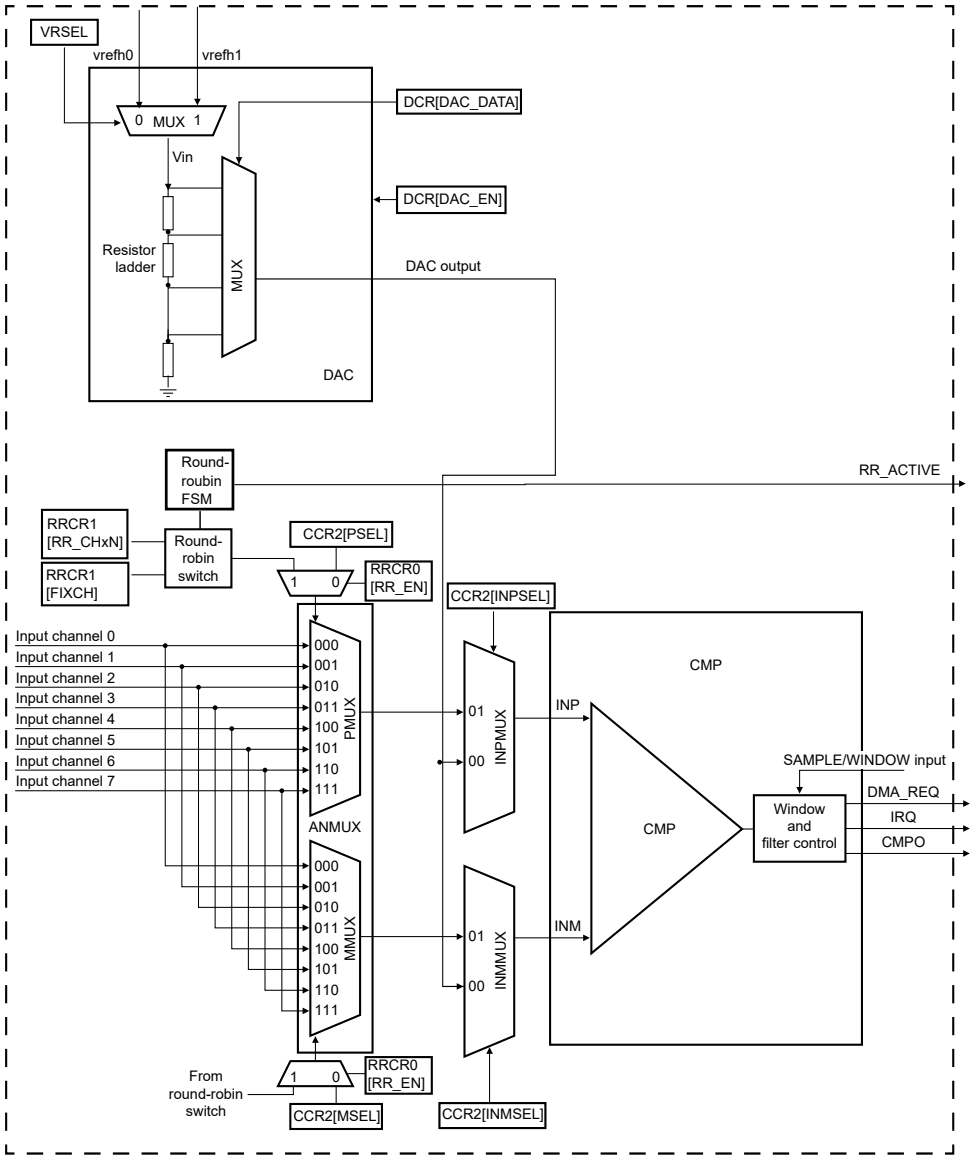

Figure 299. Block diagram

61.2.2 Features

The features of the LPCMP module include：

- Includes two 8-to-1 channel MUXes to select input signal from eight channels
- Supports multiple operation modes to produce a wide range of outputs such as:
  - Sampled
  - Windowed, which is ideal for certain PWM zero-crossing-detection applications
  - Digitally filtered
- Provides the following advance features for window and sample:

- Window and sample signals can be inverted.
- CMPO rising, falling or both edges closes the window.
- CMPO level can be defined when window is closed.

- Provides selectable performance levels:
  - Low-Power (speed) mode
  - High-Power (speed) mode
- Supports programmable hysteresis control
- Provides a selectable inversion on comparator output
- Uses an external hysteresis at the same time the output filter is used for internal functions
- Provides interrupt and DMA support
- Supports Round Robin Trigger mode
- Includes an 8-bit resolution DAC
- Provides a selectable supply reference source for DAC
- Provides a configurable Low-Power (speed) mode or High-Power (speed) mode for DAC

61.3 Functional description

61.3.1 Functional block diagram

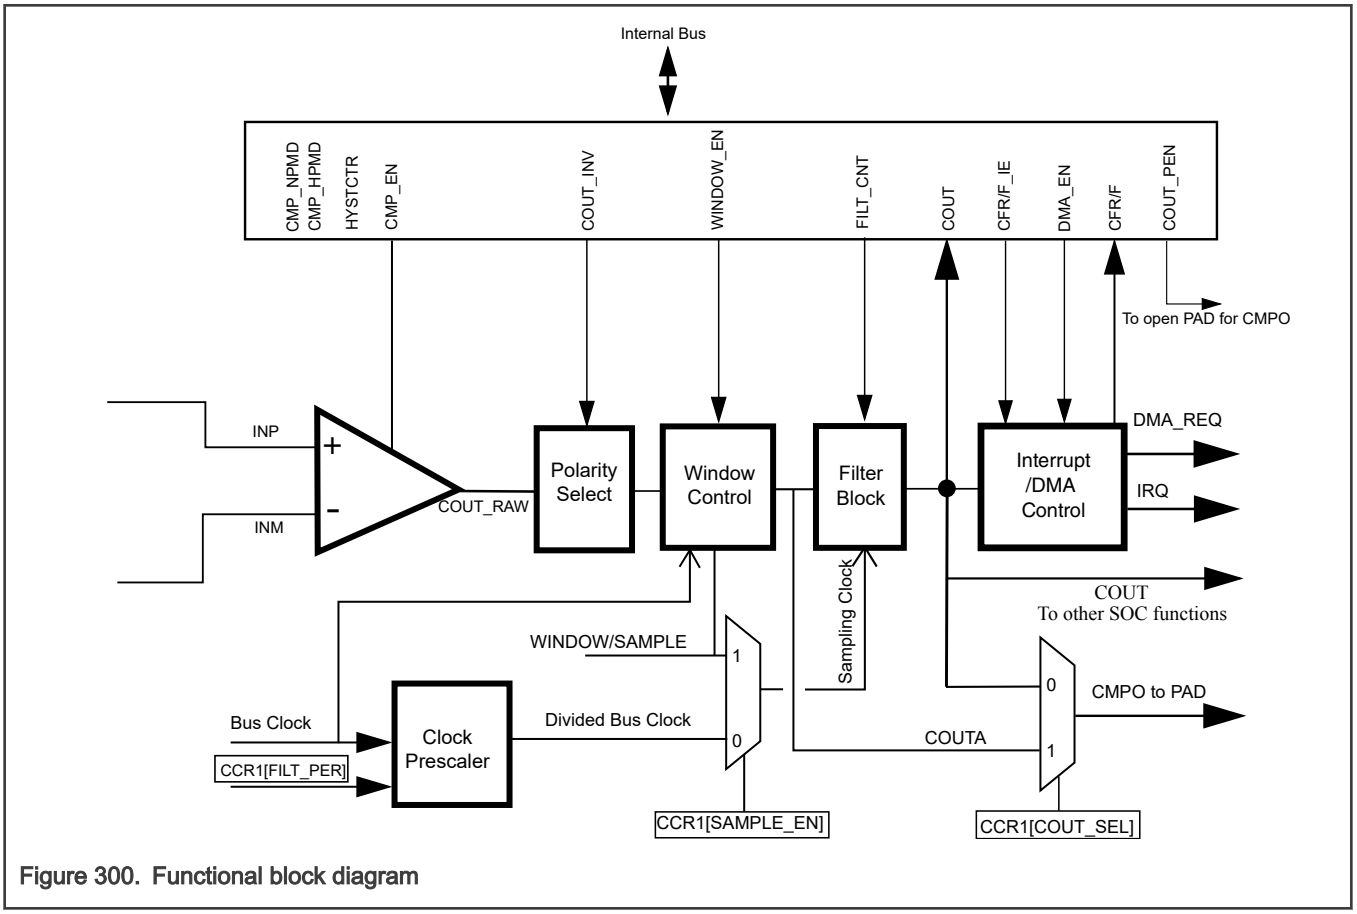

Figure 300. Functional block diagram

As shown in the block diagram, the functions are:

- Compared two analog input voltages applied to INP and INM, COUT_RAW is high when the INP input voltage is greater than the INM input voltage, and COUT_RAW is low when the INP input voltage is less than the INM input voltage.
- The COUT_RAW signal can be inverted by enabling CCR1[COUT_INV].
- The optionally inverted comparator output COUT_RAW is sampled on every bus clock when you enable the CCR1[WINDOW_EN] to generate COUTA. In this case, the comparator output is ignored during time periods when the input voltages are not valid. This is useful when you implement zero-crossing-detection for certain PWM applications.
- The window control block is bypassed when CCR1[WINDOW_EN] is disabled.
- The filter block acts as a simple sampler when CCR1[FILT_CNT] is set to 01h.
- The filter block acts as a filter based on multiple samples when CCR1[FILT_CNT] is set to be greater than 01h.
  - If CCR1[SAMPLE_EN] is set to 1, use the external SAMPLE input as the sampling clock.
  - If CCR1[SAMPLE_EN] is set to 0, use the divided bus clock as the sampling clock.
- Bypasses the filter block when it is not in use.

```
Bypass_Filter_Block = (FILT_CNT == 0x00) |  (~SAMPLE_EN & (FILT_PER == 0x00))
```

- Both COUTA and COUT can be configured as module output CMPO by configuring CCR1[COUT_SEL], and are used for different purposes within the system.
- The optionally filtered COUT can be read directly in CSR[COUT].
- The SAMPLE/WINDOW signal can be inverted by setting CCR1[WINDOW_INV].
- The SAMPLE/WINDOW signal can be closed by CMPO's falling edge and/or rising edge by setting CCR1[WINDOW_CLS] in Window mode.
- In Window mode, when window is closed, define the COUTA value as CCR1[COUTA_OW] by setting CCR1[COUTA_OWEN]. If CCR1[COUTA_OWEN] is not set, COUTA holds the last sampled value.

NOTE

See the chip configuration section for the source of SAMPLE/WINDOW input.

61.3.2 Round-robin trigger mode

You can enable Round-Robin Trigger mode by setting RRCR0[RR_EN] and CCR0[CMP_EN] to 1. A trigger event initiates a comparison sequence. The next trigger event should not occur before the current sequence completes.

RRCR1[FIXP] and RRCR1[FIXCH] select the reference channel for the plus side mux or the minus side mux. RRCR1[RR_CHnEN] selects active channels.

When a trigger comes, the analog comparator enables. After the comparison sequence completes, the analog comparator disables again. RRCR0[RR_INITMOD] controls the analog stabilization time. Note that RR_INITMOD*round robin clock period must be longer than the initialization delay specified in the Comparator and 8-bit DAC electrical specifications section of LPCMP datasheet.

After the stabilization process completes, the round robin manner comparison sequence begins. Sample the comparison result for the selected active channel after RRCR0[RR_NSAM] defines the configurable number of operation clocks.

After all the active channels are sampled/compared, if the comparison result changes from its pre-programmed state, the corresponding flag in RRSR[RR_CHnF] is set. Write to RRCSR[RR_CHnOUT] to configure the pre-programmed state for each channel. Update RRCSR[RR_CHnOUT] to store the last comparison result for each channel. If any flag in RRSR[RR_CHnF] sets, CSR[RRF] also sets. If IER[RRF_IE] sets, an asynchronous interrupt asserts. Note that these flags do not support generating a DMA transfer event.

The following diagram shows the basic flow of this mode. In the diagram, RRCR1[RR_CH1EN], RRCR1[RR_CH3EN], and RRCR1[RR_CH4EN] are 1, so channels #1, #3, and #4 are selected for round-robin depending on their priority setting. RRCR0[RR_NSAM] sets to 2'b01, so you can sample one clock later the comparison result of the selected channel. After you

compare the channel #4, the result is sampled, and round-robin ends. If any of the comparison results from channel #1, #3, or #4 changed from their programmed value (written to RRCSR[RR_CH1OUT], RRCSR[RR_CH3OUT], and RRCSR[RR_CH4OUT]), generates an interrupt . Software can then poll RRSR[RR_CHnF] to see which channel input(s) changed value.

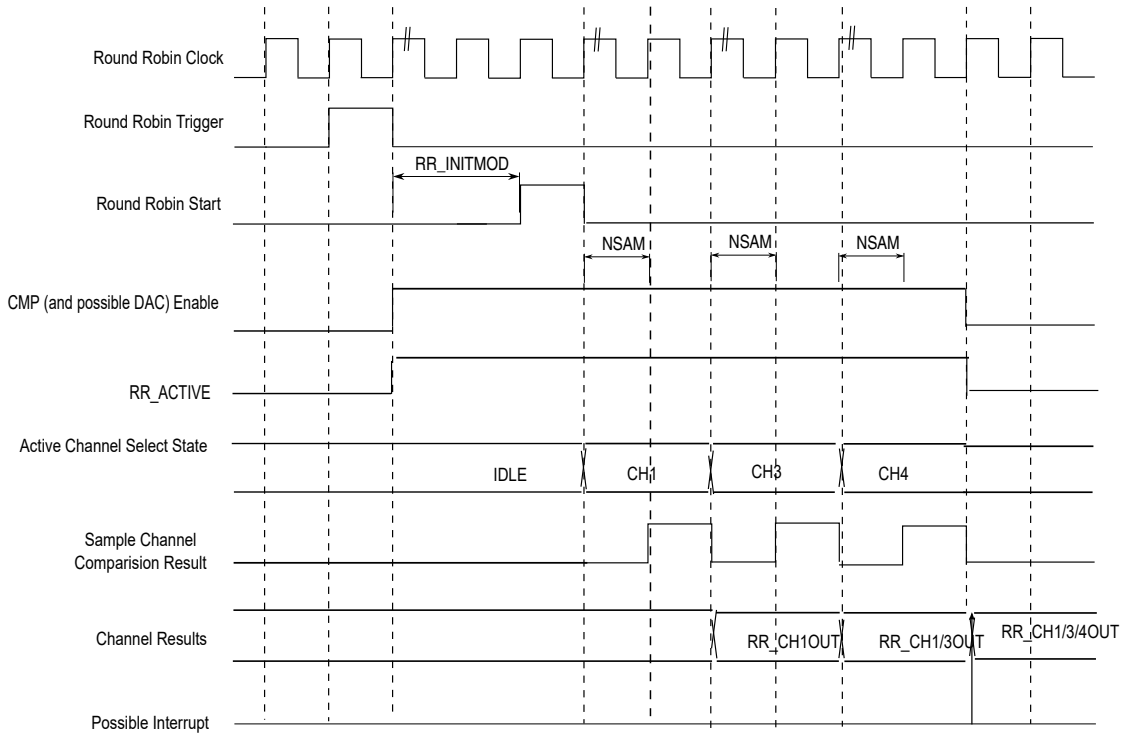

Figure 301. Trigger mode

The table below shows the channel decode in both Functional mode and Trigger mode. Other cases not in the table are illegal.

Table 286. CMP channel decode in functional mode and round-robin trigger mode

Mode	RR_EN	PSEL[2:0]	MSEL[2:0]	INPSEL[1:0]	INMSEL[1:0]	FIXP	FIXCH[2:0]	RR_CHxN	INP	INM	CMP Behavior
Functional mode	0	x[1]	0 to 7	0	1	x	x	x	DAC	Channel decoded from MSEL[2:0]	Channel 0 to 7 can be compared with DAC
		0 to 7	x	1	0	x	x	x	Channel decoded from	DAC	Channel 0 to 7 can be compared with DAC

Table continues on the next page...

Table 286. CMP channel decode in functional mode and round-robin trigger mode (continued)

Mode	RR_EN	PSEL[2:0]	MSEL[2:0]	INPSEL[1:0]	INMSEL[1:0]	FIXP	FIXCH[2:0]	RR_CHxN	INP	INM	CMP Behavior
									PSEL[2:0]		
		0 to 7	0 to 7	1	1	x	x	x	Channel decoded from PSEL[2:0]	Channel decoded from MSEL[2:0]	Channel 0 to 7 can be compared with channel 0 to 7[2]
Trigger mode	1	x	x	0	1	0	x	0 to 7	DAC	Channel sweep (RR_CHxN)	Channel 0 to 7 can be swept with DAC
		x	x	1	0	1	x	0 to 7	Channel sweep (RR_CHxN)	DAC	Channel 0 to 7 can be swept with DAC
		x	x	1	1	0	0 to 7	0 to 7	Channel fixed by FIXCH[2:0]	Channel sweep (RR_CHxN)	Channel 0 to 7 can be swept with a fixed channel(0 to 7)[3]
		x	x	1	1	1	0 to 7	0 to 7	Channel sweep (RR_CHxN)	Channel fixed by FIXCH[2:0]	Channel 0 to 7 can be swept with a fixed channel(0 to 7)[3]

1. "x" means "don't care"
2. PSEL should not be same as MSEL.
3. Channel in the sweep side should not be same as the fixed side.

61.3.3 Low-pass filter mode

The low-pass filter mode operates on an unfiltered, optionally inverted comparator output COUTA, and generates the filtered and synchronized output COUT. You can configure both COUTA and COUT as module outputs and use for different purposes within the system.

Synchronization and edge detection determine the bit values of status register. They also apply to COUT for all sampling and windowed modes. You can perform filtering using an internal timebase defined by CCR1[FILT_PER], or use an external sample input to determine sample time.

The need for digital filtering and the amount of filtering depends on your requirements. Filtering can become more useful in the absence of an external hysteresis circuit. Without external hysteresis, generate a high-frequency oscillations at COUTA when the selected INM and INP input voltages differ by less than the offset voltage of the differential comparator.

61.3.3.1 Enabling low-pass filter mode

You can enable low-pass filter mode by setting the following:

- CCR1[FILT_CNT] > 01h
- CCR1[FILT_PER] to a nonzero value or writing 1 to CCR1[SAMPLE_EN].

If you use the divided bus clock to drive the low-pass filter, it samples COUTA every CCR1[FILT_PER] bus clock cycle.

If CCR1[SAMPLE_EN] is set to 1, the low-pass filter samples COUTA on each positive transition of the sample input. The output state of the filter changes when all the consecutive CCR1[FILT_CNT] samples agree that the output value has changed.

61.3.3.2 Latency issues

Program the value of CCR1[FILT_PER] or sample period such that the sampling period is longer than the period of the expected noise, ensuring that a given noise spike corrupts only one sample. You must choose the value of CCR1[FILT_CNT] to reduce the probability of noisy samples causing an incorrect transition to recognize. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of CCR1[FILT_CNT].

You must trade off the values of CCR1[FILT_PER] or sample period and CCR1[FILT_CNT] against the need for minimal latency in recognizing actual comparator output transitions. The probability of detecting an actual output change within the nominal latency is the probability of a correct sample raised to the power of CCR1[FILT_CNT].

Table 288 summarizes maximum latency values for the various modes of operation in the absence of noise. Filtering latency restarts each time the noise masks an actual output transition.

61.3.4 Low power mode operation

Below table introduces the mode of operation of lower power.

Table 287. Low power mode operation

Mode of operation	Description
STANDBY	LPCMP can operate only in Continuous mode or Round-robin trigger mode.

61.3.5 Functional modes

You can combine the comparator window and filter features as shown in the following table.

Table 288. Functional modes

Mode #	CMP_EN	WINDOW_EN	SAMPLE_EN	FILT_CNT	FILT_PER	Operation	Maximum latency[1]
1	0	X	X	X	X	See the Disabled mode (#1).	N/A
2A	1	0	X	0x00	X	See the Continuous mode (#2A and #2B).	T_{PD}
2B	1	0	0	X	0x00		
3A	1	0	1	0x01	X	See the Sampled, non-filtered mode (#3A and #3B).	$T_{PD} + T_{SAMPLE} + 3T_{per}$
3B	1	0	0	0x01	> 0x00		$T_{PD} + (FILT_PER * T_{per}) + 3T_{per}$

Table continues on the next page...

Table 288. Functional modes (continued)

Mode #	CMP_EN	WINDOW_EN	SAMPLE_EN	FILT_CNT	FILT_PER	Operation	Maximum latency[1]
4A	1	0	1	> 0x01	X	See the Sampled, filtered mode (#4A and #4B).	T_{PD} + (FILT_CNT * T_{SAMPLE}) + $3T_{per}$
4B	1	0	0	> 0x01	> 0x00		T_{PD} + (FILT_CNT * FILT_PER x T_{per}) + $3T_{per}$
5A	1	1	0	0x00	X	See the Windowed mode (#5A and #5B).	T_{PD} + $2T_{per}$
5B	1	1	0	X	0x00		
6	1	1	0	0x01	> 0x00	See the Windowed/ Resampled mode (#6).	T_{PD} + (FILT_PER * T_{per}) + $3T_{per}$
7	1	1	0	> 0x01	> 0x00	See the Windowed/ Filtered mode (#7).	T_{PD} + (FILT_CNT * FILT_PER x T_{per}) + $3T_{per}$
All other combinations of CMP_EN, WINDOW_EN, SAMPLE_EN, FILT_CNT, and FILT_PER are illegal.							

1. T_{PD} represents the intrinsic delay of the analog component plus the polarity select logic. T_{SAMPLE} is the clock period of the external sample clock. T_{per} is the period of the bus clock.

61.3.5.1 Disabled mode (#1)

In this mode:

- The analog comparator is non-functional and consumes no power.
- CSR[COUT] and CMPO are the same as CCR1[COUT_INV].

61.3.5.2 Continuous mode (#2A and #2B)

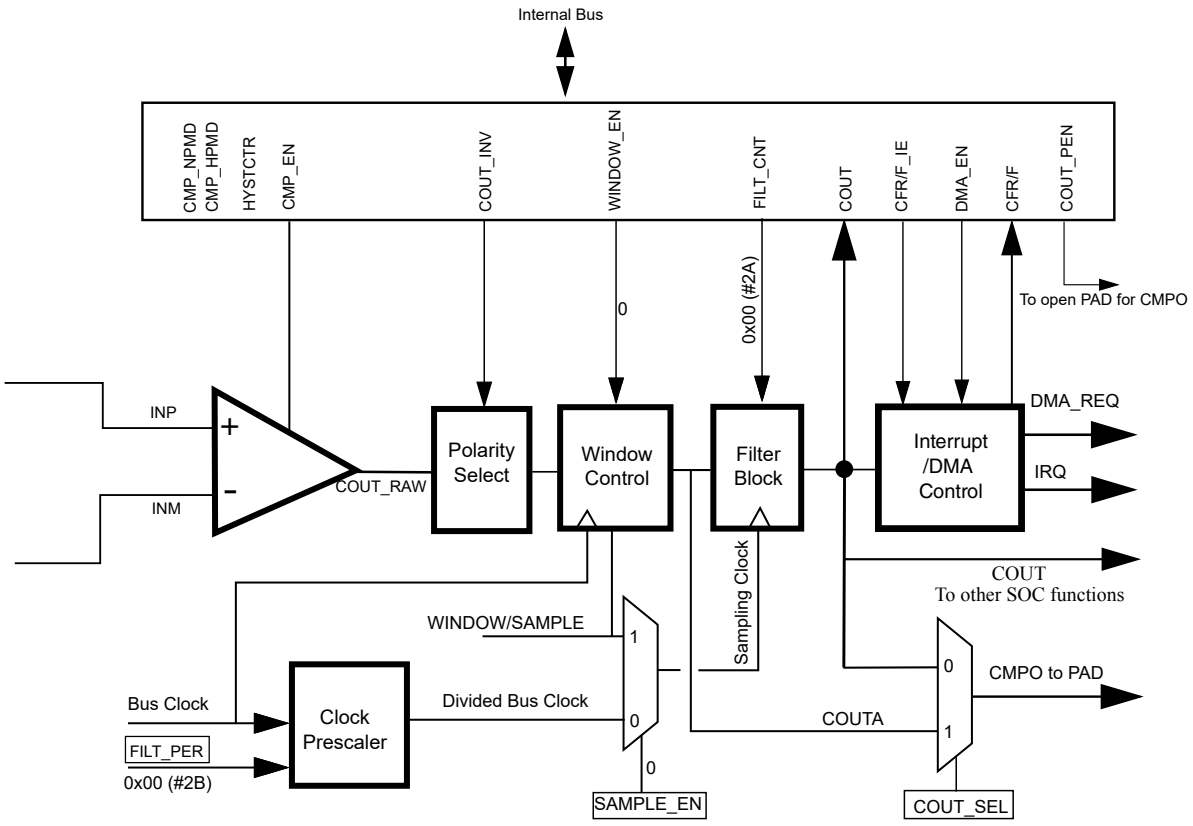

Figure 302. Comparator operation in continuous mode

COUT_RAW is optionally inverted in this mode but is not subject to external sampling or filtering. Both window control and filter blocks bypass completely, and CSR[COUT] updates continuously. The path from comparator input pins to output pins operates in a combinational (unclocked) mode. COUT and COUTA are identical in this mode.

For cases where a comparator drives a fault input, you must configure it to operate in Continuous mode so that an external fault can immediately pass to the target fault circuitry through the comparator.

61.3.5.3 Sampled, non-filtered mode (#3A and #3B)

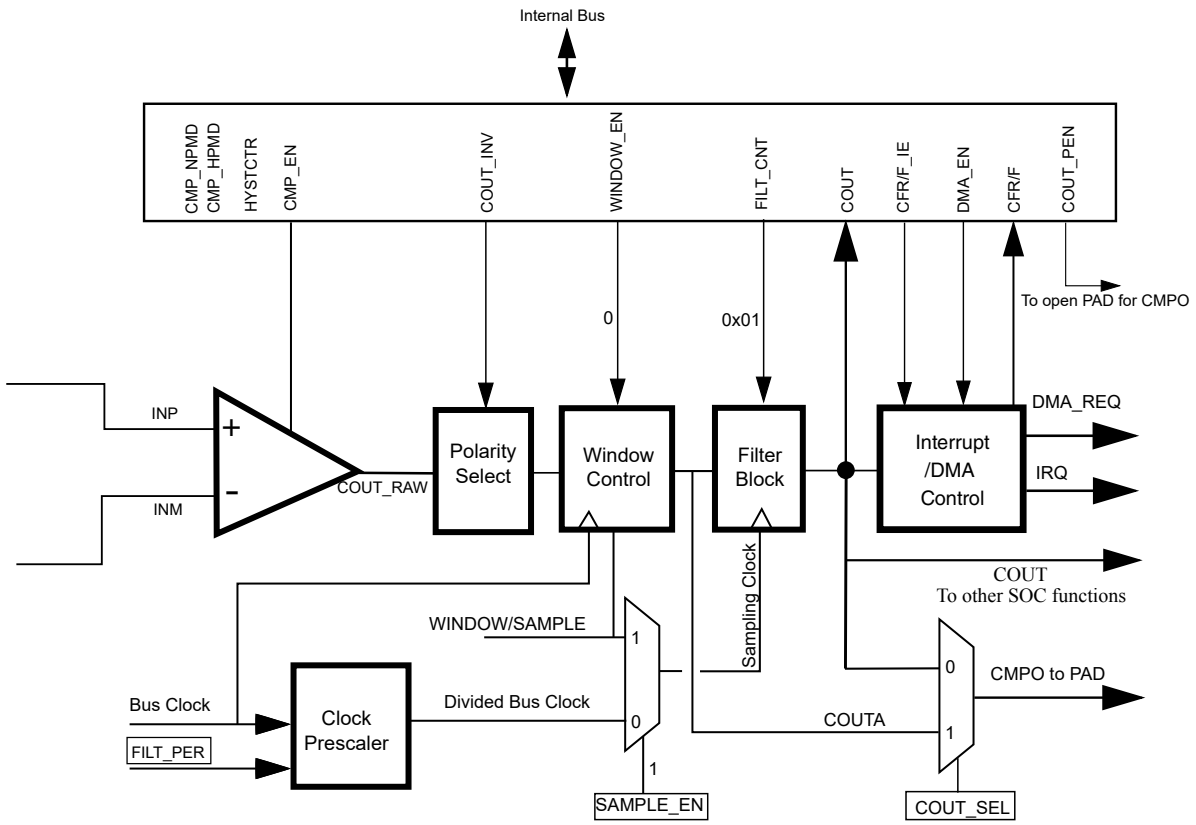

Figure 303. Sampled, non-filtered (#3A): sampling point externally driven

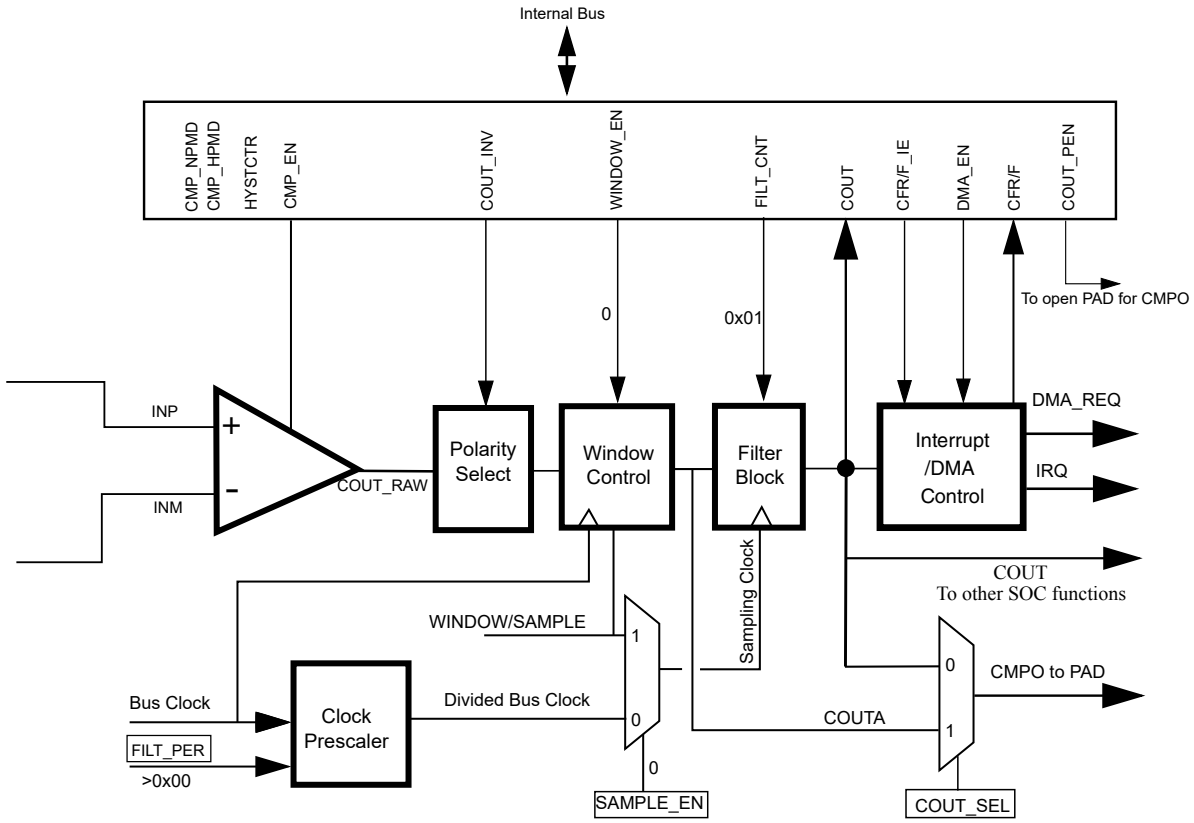

Figure 304. Sampled, Non-Filtered (#3B): sampling interval internally derived

In this mode, the path from analog inputs to COUTA is combinational (unclocked). Windowing control bypasses completely. You can sample COUTA whenever you detect a rising edge on the sampling clock.

The difference in two operation modes (#3A and #3B) of sampled, non-filtered mode is that how you drive the clock to the filter block. In #3A, the clock to filter block drives externally, and in #3B, the clock to filter block drives internally.

The filter block has no other function than sample or hold of the comparator output in this mode.

The following figure shows the comparator operation in this mode, assuming that the polarity select sets to a non-inverting state.

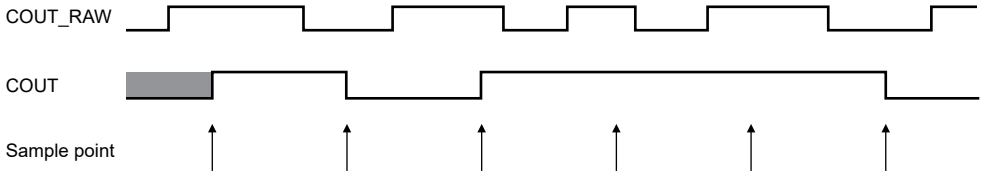

Figure 305. Sampled, Non-Filtered mode timing diagram

61.3.5.4 Sampled, filtered mode (#4A and #4B)

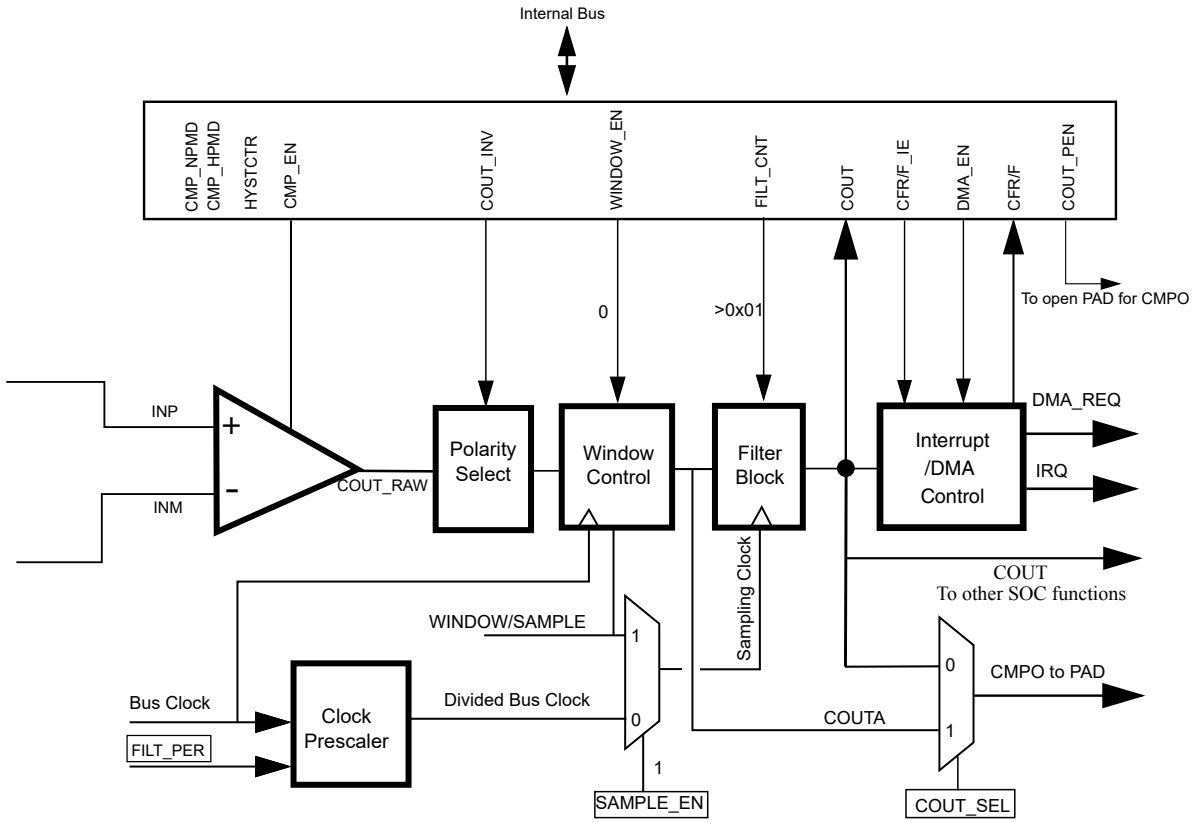

Figure 306. Sampled, filtered (#4A): sampling point externally driven

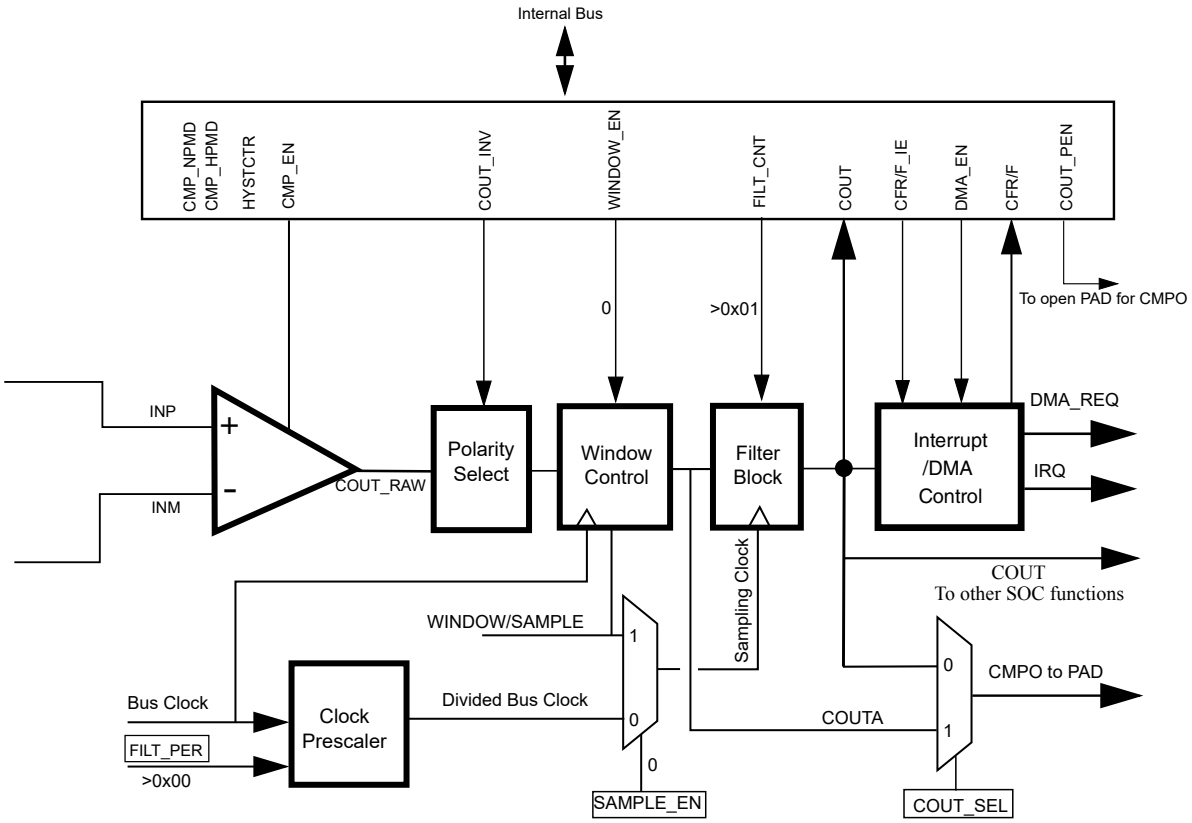

Figure 307. Sampled, filtered (#4B): sampling point internally derived

In this mode, the path from the analog inputs to COUTA is combinational(unclocked). Windowing control bypasses completely. You can sample COUTA whenever you detect a rising edge on the sampling clock.

The only difference in operation between sampled, non-filtered (#3A) mode and sampled, filtered (#4A) mode is that CCR1[FILT_CNT] is larger than 1, which activates filter operation.

The only difference in operation between sampled, non-filtered (#3B) mode and sampled, filtered (#4B) mode is that CCR1[FILT_CNT] is larger than 1, which activates filter operation.

61.3.5.5 Windowed mode (#5A and #5B)

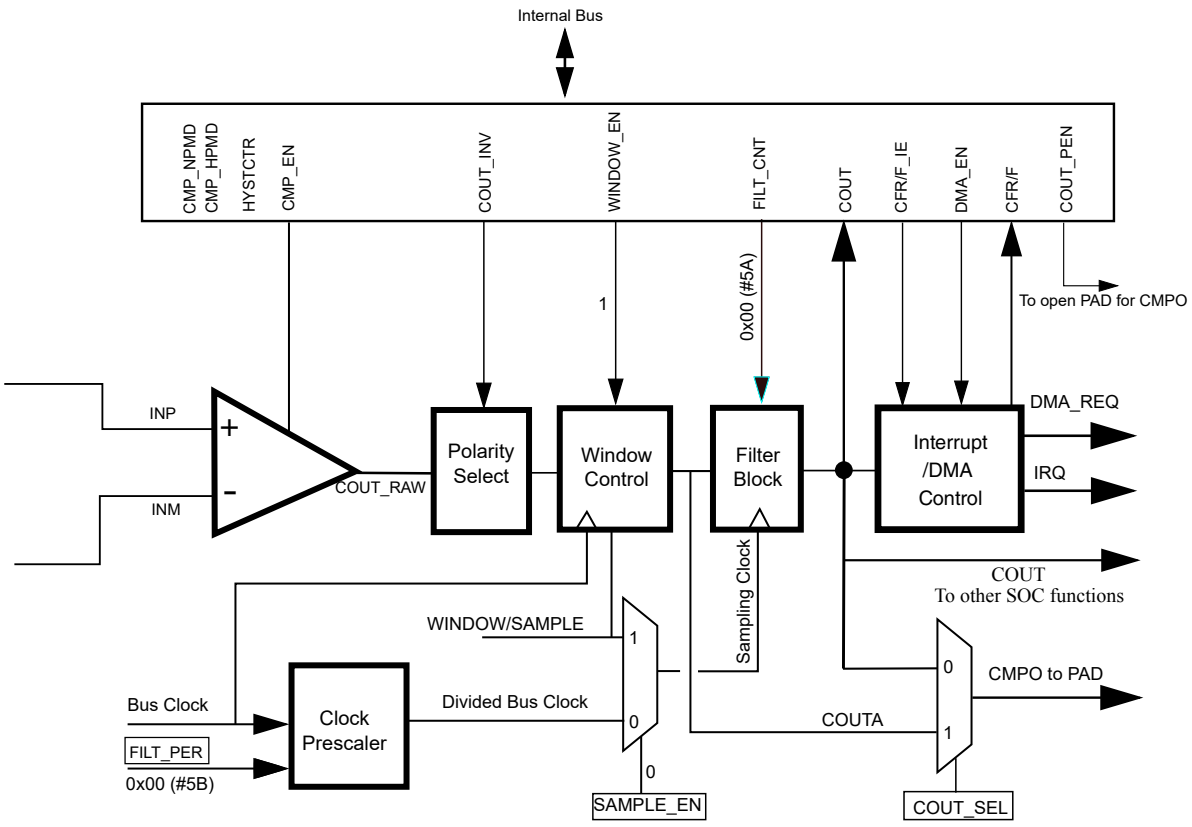

Figure 308. Windowed mode

The bus clock clocks COUTA whenever you enable the window in this mode. The last latched value holds after you disable the window and the filter block is bypassed.

The following figure shows the comparator operation in this mode, ignoring the latency of the analog comparator, polarity select, and window control block. The polarity select sets to a non-inverting state.

COUTA may lag the analog inputs by up to two functional clock cycles plus the combinational path delay through the comparator and polarity select logic in the actual operation.

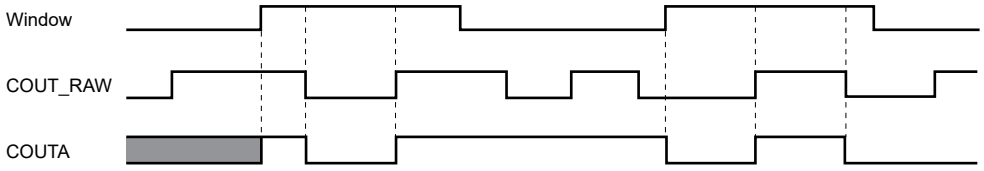

Figure 309. Windowed mode timing diagram

The following figure shows that if CCR1[COUTA_OWEN] becomes 1, you can define COUTA level as CCR1[COUTA_OW], after you closes the window.

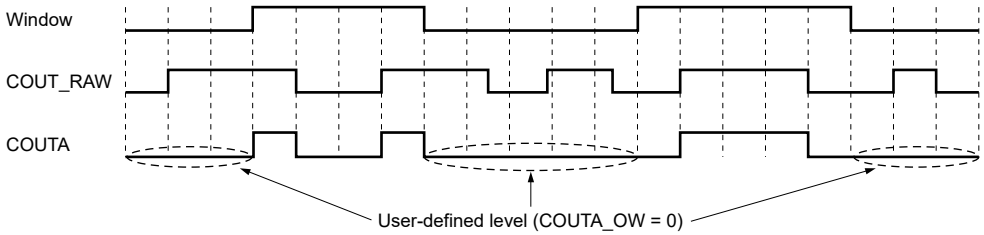

Figure 310. Windowed mode timing diagram with user defined value 0 outside window

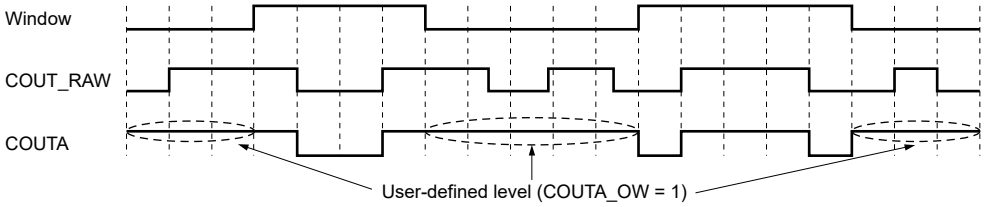

Figure 311. Windowed mode timing diagram with user defined value 1 outside window

NOTE

When the window is open, COUT_A will switch from COUTA_OW to COUT_RAW. When the window is closed, COUT_A will switch from COUT_RAW to COUTA_OW. This may generate unnecessary transition flags, for instance, CFR or CFF. User needs to choose COUTA_OW carefully according to the actual application, and select the appropriate flag CFR or CFF to generate interrupt.

If CCR1[WINDOW_CLS] becomes 1, you can define the CMPO event (rising edge, falling edge or both edges that CCR1[EVT_SEL] selects) to close the window. The external window signal has to go to zero and back to one to enable the internal window again. The following figure shows an example that CMPO rising edge closes the internal window.

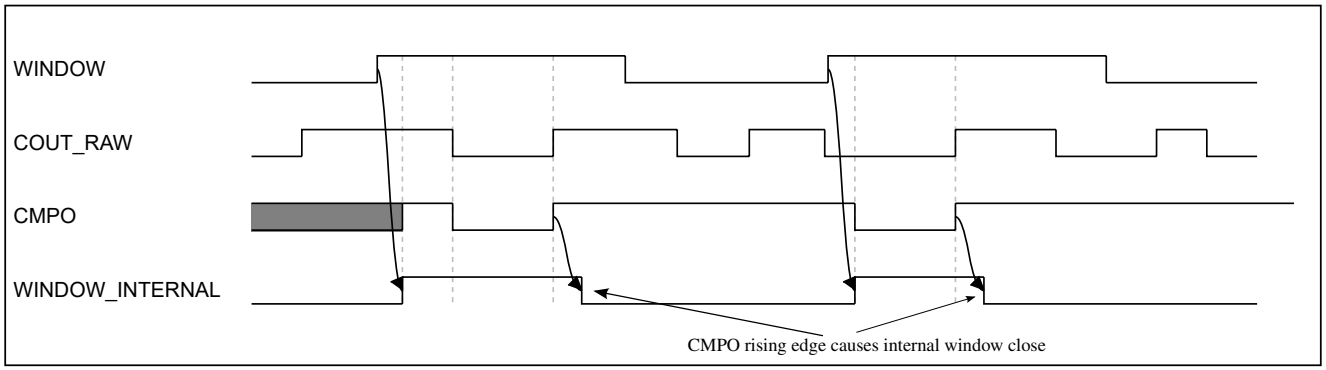

Figure 312. Windowed mode timing diagram with CMPO rising edge close window

The following figure shows that if CCR1[WINDOW_INV] becomes 1, you can invert the window signal before you use it.

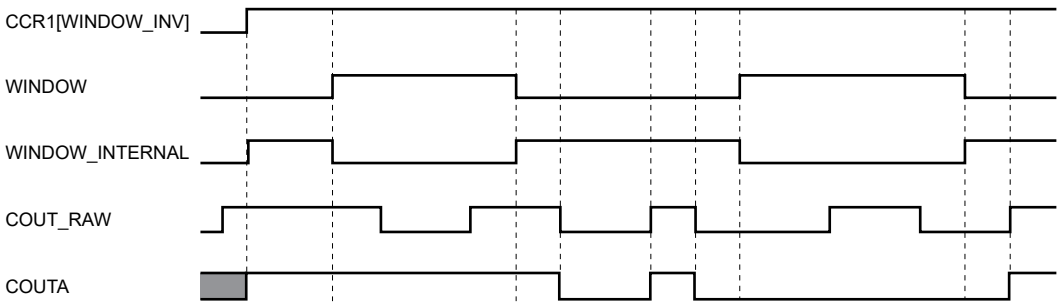

Figure 313. Windowed mode timing diagram with window signal inverted

61.3.5.6 Windowed/Resampled mode (#6)

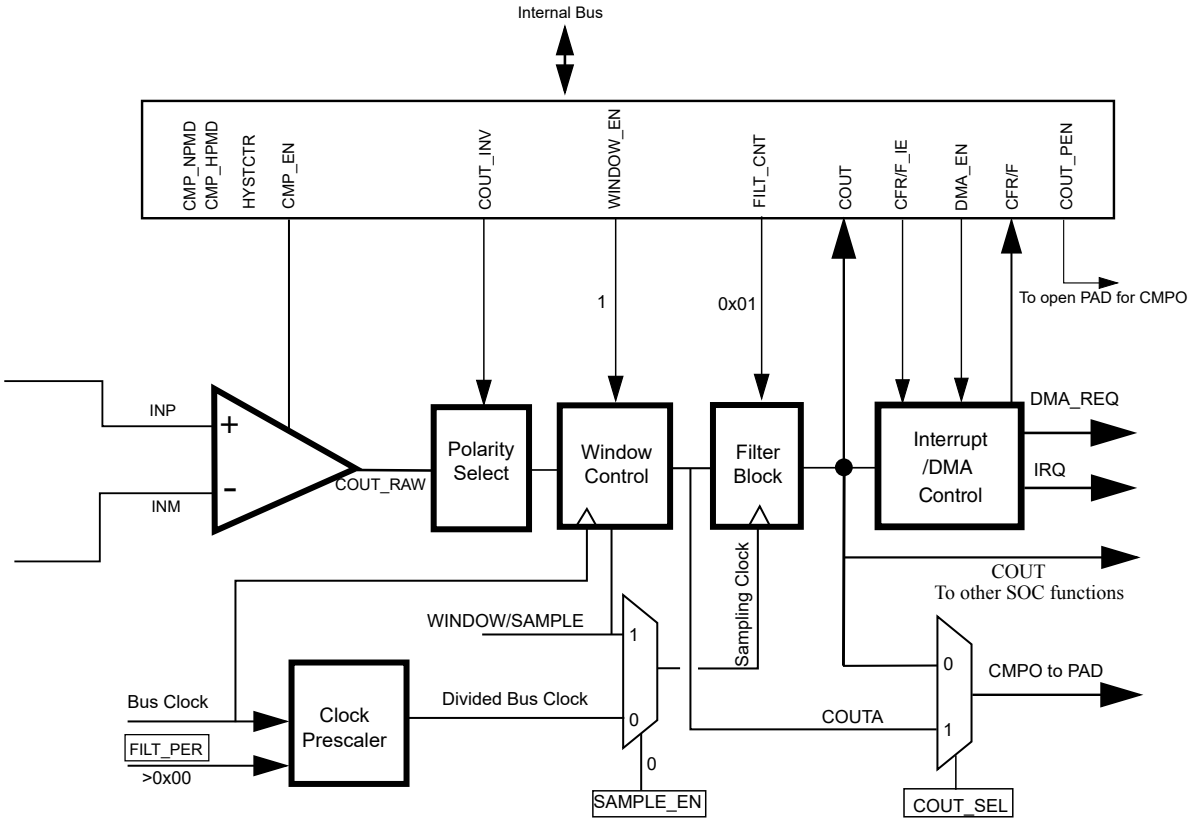

Figure 314. Windowed/Resampled mode

This mode of operation results in an unfiltered string of comparator samples where CCR1[FILT_PER] and the bus clock rate determines the interval between the samples. The following section shows that the configuration for this mode is virtually identical to that for the Windowed/Filtered mode. The only difference is that the value of CCR1[FILT_CNT] must be 1 in this mode.

The following figure uses the same input stimulus shown in Figure 309, and adds resampling of COUTA to generate COUT. The arrows in the figure indicate the time points at which the samples are taken. You can ignore prop delays and latency for clarity.

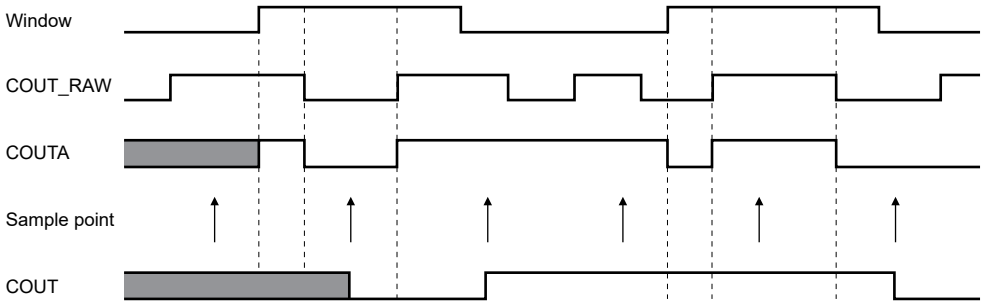

Figure 315. Windowed/Resampled mode operation

This example demonstrates the operation of the comparator in Windowed/Resampled mode, and does not reflect any specific application. Based on the sampling rate and window placement, COUT may not see zero-crossing events that the analog comparator detects. You must carefully consider the sampling period and/or window placement for a given application.

61.3.5.7 Windowed/Filtered mode (#7)

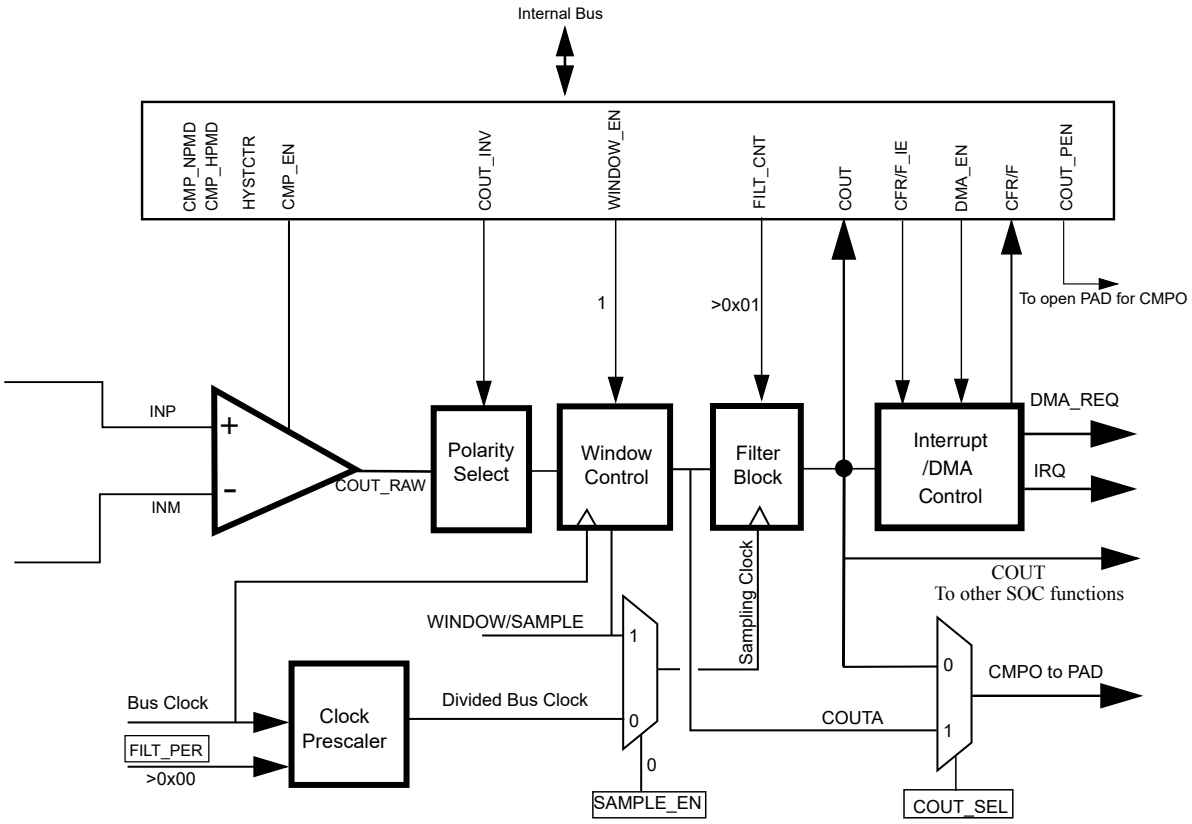

Figure 316. Windowed/Filtered mode

The only difference in operation between Windowed/Resampled mode (#6) and Windowed/Filtered mode (#7) is that CCR1[FILT_CNT] is >1, which activates filter operation.

This mode is the most complex mode of operation for the comparator block, as it utilizes both windowing and filtering features. It also has the highest latency of any of the modes. This is approximately: up to 2 peripheral clock synchronization in the window function + ((CCR1[FILT_CNT] x CCR1[FILT_PER]) + 1) x peripheral clock for the filter function.

61.3.6 DMA

After DMA is enabled by writing 1 to CCR1[DMA_EN] and interrupt is enabled by writing 1 to IER[CFR_IE], IER[CFF_IE], or both, the corresponding change on COUT forces a DMA transfer request rather than a CPU interrupt. After the DMA completes the transfer, it sends a transfer completing indicator signal that deasserts the DMA transfer request and clears the flags (both CSR[CFR] and CSR[CFF]) to allow a subsequent change on comparator output to occur and forces another DMA request.

61.3.7 Clocking

LPCMP requires the following clocks to operate:

Table 289. LPCMP clocks

Type of clock	Description
Bus	Controls the access to LPCMP registers and window/ filter function.
Round-robin clock (RCLK)	Controls Round-robin trigger mode.

61.3.8 Resets

The global chip reset signal resets LPCMP.

61.3.9 Interrupts

After the corresponding IER becomes 1, CSR[CFR], CSR[CFF], and CSR[RRF] can generate an interrupt, assuming that CCR1[DMA_EN] is not 1. You can clear either the flag or IER to deassert the interrupt.

61.4 External signal descriptions

Below table introduces external signals.

Table 290. External signal descriptions

Signal	Description	I/O
CMPO	Filtered or unfiltered comparator output	O
Input_Analog_Channels	Analog input channels (see the chip-specific information for more on the connections).	I
VREFH_EXT	External reference voltage for the CMP-DAC (see the chip-specific information for more on the connections).	I
RR_ACTIVE	Round-robin trigger mode enabled.	O

61.5 Initialization

You can enable LPCMP by writing 1 to CCR0[CMP_EN], and then configuring the control registers (CCR1, CCR2, DCR, and so on).

To disable LPCMP, write 0 to CCR0[CMP_EN]. Switching operation modes or changing control register fields on-the-fly (when CCR0[CMP_EN] is set to 1) may cause noise on the COUT or COUTA signals. To avoid unwanted signal noise, you must ensure to disable the module before switching modes or changing control fields.

The time required to stabilize COUT is the power-on delay of the comparators plus the largest propagation delay from a selected analog source through the analog comparator, windowing function, and filter (see the Comparator and 8-bit DAC electrical specifications section of LPCMP datasheet for more information on propagation delay and power-up delay). Table 288 specifies the delay that the windowing and filter function causes.

During operation, you must always consider the propagation delay of the selected data paths. It can take many bus clock cycles for COUT and CSR[CFR]/CSR[CFF] to reflect an input change or a configuration change to one of the components involved in the data path.

61.6 Application information

61.6.1 Round-robin trigger mode programing recommendation

Configure the Round-robin trigger mode as follows:

1. Configure the comparison cycles by RRCR0[RR_NSAM]. Note: It is a mandatory request that the round robin cycling period must set longer than the time that all the active channels complete the specified comparison cycles set by RRCR0[RR_NSAM].
2. Configure CMP initialization delay by RRCR0[RR_INITMOD]. Note: In programming RRCR0[RR_INITMOD], the RR_INITMOD x round robin clock period must be longer than the initialization delay, see the LPCMP datasheet for more information.
3. Configure RRCR1[FIXP] to select the fixed port of CMP and
    a. If you use one input channel to compare with other channels, configure RRCR1[FIXCH] to select the fixed channel.
    b. If you use DAC output to compare with input channels, configure CCR2[INPSEL] or CCR2[INMSEL] (according to RRCR1[FIXP]) to select the DAC output.
4. Configure channels for comparison by RRCR1[RR_CHnEN].
5. Write RRCSR[RR_CHnOUT] to define the pre-set state of channel n.
6. Clear channel flags RRSR[RR_CHnF].
7. Enable round robin interrupt by IER[RRF_IE] (disable IER[CFR_IE] and IER[CFF_IE]).
8. Enable round-robin trigger mode by setting RRCR0[RR_EN] to 1.
9. Enable comparator by setting CCR0[CMP_EN] to 1.

61.6.2 Round-robin clock (RCLK) frequency requirement

(1) RCLK high frequency limit

RCLK high frequency limit depends on two facts:

1. The analog CMP and DAC initialization time (see the chip data sheet for more information on the initialization time.)
    - RRCR0[RR_INITMOD] provides a maximum 63 RCLK cycles for the analog CMP and DAC initialization.
    - RCLK must be slow to assure: $63 * (1/f_{RCLK}) > T_{initialization}$, where f_{RCLK} is in MHz, and $T_{initialization}$ is in microsecond.
    - so $f_{RCLK} < 63 / T_{initialization}$
    - Example: $T_{initialization}$ = 40 µs, then f_{RCLK} should be smaller than 1.575 MHz.
2. The analog CMP propagation delay (see the Comparator and 8-bit DAC electrical specifications section of LPCMP datasheet for more information on the CMP propagation delay.)
    - RRCR0[RR_NSAM] provides a maximum 4 RCLK cycles for the analog CMP propagation delay.
    - RCLK must be slow to assure: $4 * (1/f_{RCLK}) > T_{propagation}$, where f_{RCLK} is in MHz, and $T_{propagation}$ is in microsecond.
    - $f_{RCLK} < 4 / T_{propagation}$
    - Example: $T_{propagation}$ = 0.1 µs, then f_{RCLK} must be smaller than 40 MHz.

(2) RCLK low frequency limit

In theory, RCLK frequency has no low limit. But the lower the RCLK frequency, the longer the scan time. Therefore, the lower limit of the RCLK frequency depends on the system application.

61.7 LPCMP register descriptions

The memory map comprises of 32-bit aligned registers, which you can access via 8-, 16- or 32-bit reads and 32-bit write. Attempted accesses using unsupported write data sizes, writes to read-only resources, or to reserved spaces terminate with an error. Read access to reserved address generates a transfer error and the read data bus shows all 0s.

61.7.1 LPCMP memory map

LPCMP_0 base address: 4037_0000h

LPCMP_1 base address: 4037_4000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Version ID (VERID)	32	R	0100_0001h
4h	Parameter (PARAM)	32	R	0000_0002h

30h	Round Robin Status (RRSR)	32	RW	0000_0000h

61.7.2 Version ID (VERID)

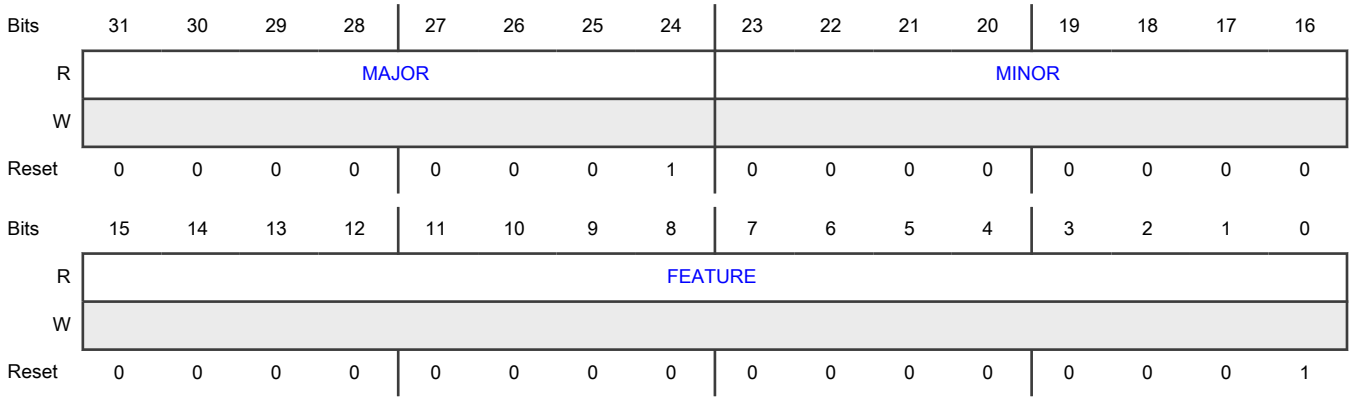
Offset

Register	Offset
VERID	0h

Function

Contains version numbers for the module design and feature set.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number Returns the major version number for the module design.
23-16 MINOR	Minor Version Number Returns the minor version number for the module design.
15-0 FEATURE	Feature Specification Number Returns the feature set number. 0000_0000_0000_0001b - Round robin feature

61.7.3 Parameter (PARAM)

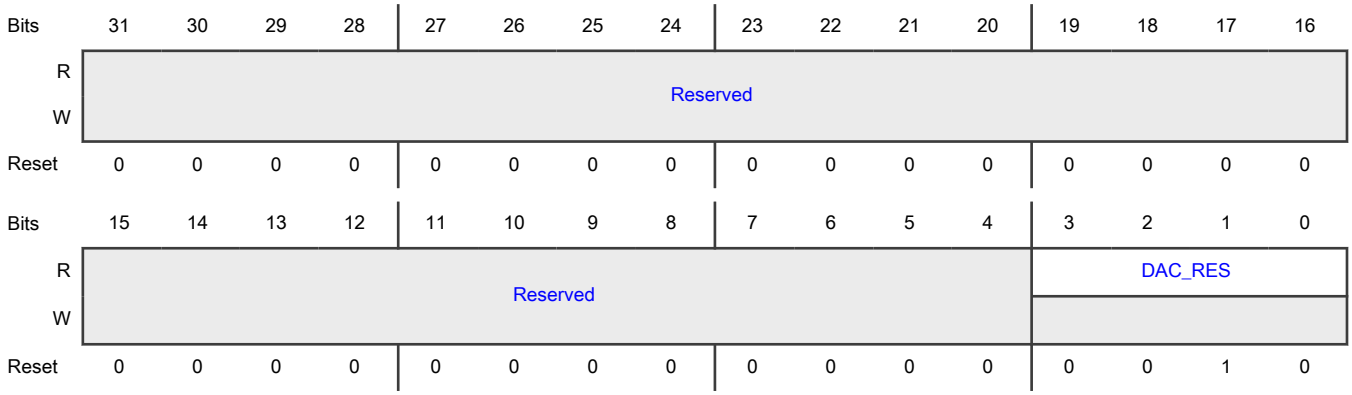
Offset

Register	Offset
PARAM	4h

Function

Contains parameter values that are implemented in the module.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 DAC_RES	DAC Resolution Indicates supported DAC resolutions. **NOTE** All other bit field values are reserved. 0000b - 4-bit DAC 0001b - 6-bit DAC 0010b - 8-bit DAC 0011b - 10-bit DAC 0100b - 12-bit DAC 0101b - 14-bit DAC 0110b - 16-bit DAC

61.7.4 Comparator Control Register 0 (CCR0)

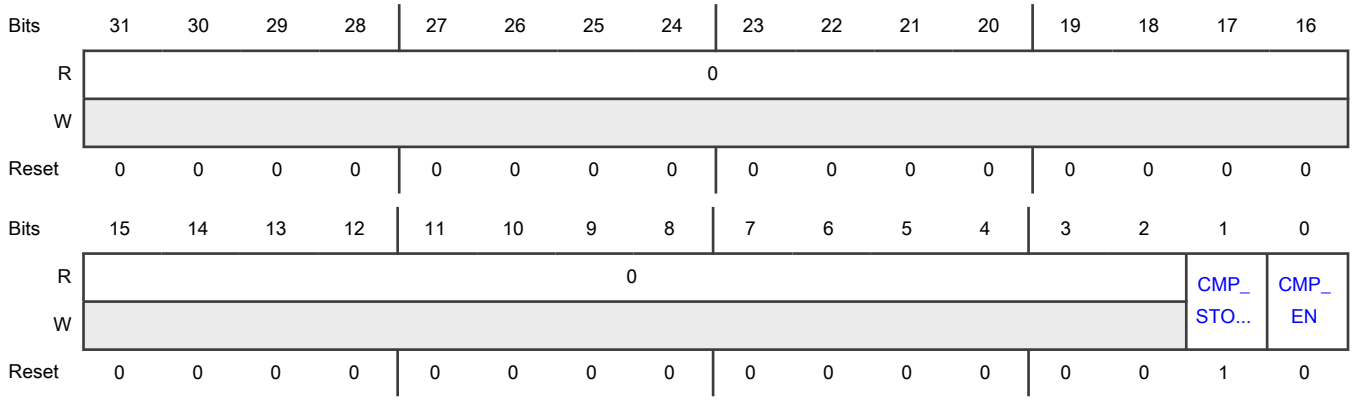
Offset

Register	Offset
CCR0	8h

Function

Contains configuration options for enabling the analog comparator.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 CMP_STOP_EN	Comparator STANDBY Mode Enable Enables the analog comparator or the DAC when the module is in STANDBY mode. **NOTE** This field has no effect in Round-robin Trigger mode. 0b - Disables the analog comparator regardless of CMP_EN. 1b - Allows CMP_EN to enable the analog comparator.
0 CMP_EN	Comparator Enable Enables the analog comparator. 0b - Disable (The analog logic remains off and consumes no power.) 1b - Enable

61.7.5 Comparator Control Register 1 (CCR1)

Offset

Register	Offset
CCR1	Ch

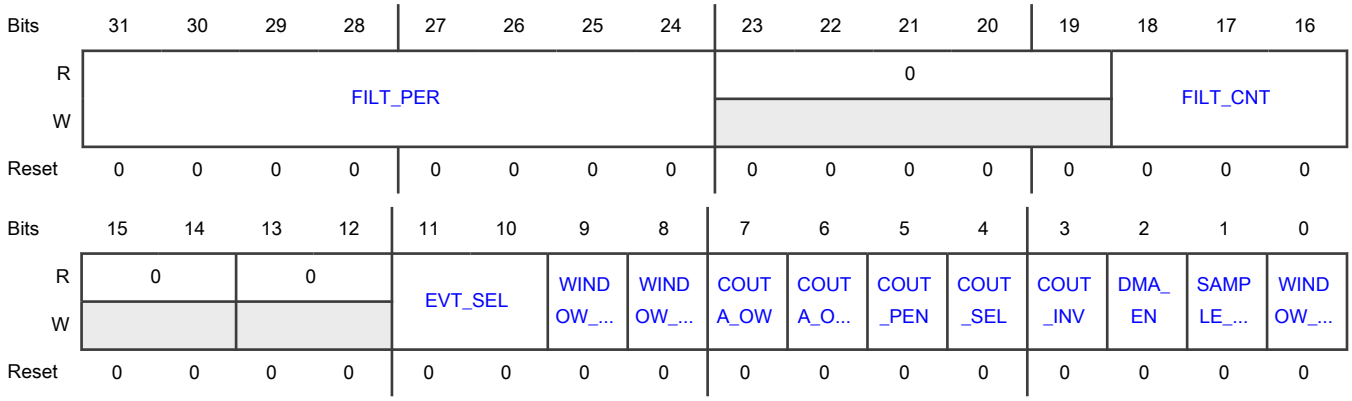
Function

Contains configuration options for the comparator operation, such as enabling Sampling or Windowing mode.

NOTE

You cannot enable Sampling and Windowing modes both at the same time. Sampling mode takes precedence over Windowing mode. If you write 1 to both SAMPLE_EN and WINDOW_EN, only SAMPLE_EN becomes 1.

Diagram



Fields

Field	Function
31-24 FILT_PER	Filter Sample Period Specifies the sampling period (in bus clock cycles) of the comparator output filter. Programming this field to 00h bypasses the filter. See Functional description for more information on filter programming and latency. **NOTE** FILT_PER has no effect in Sampling mode (CCR1[SAMPLE_EN] = 1).
23-19 —	Reserved
18-16 FILT_CNT	Filter Sample Count Specifies the number of consecutive samples that must agree before the comparator output filter accepts the sample as a new valid output state. See Functional description for more information on filter programming and latency. 000b - Filter is bypassed: COUT = COUTA 001b - 1 consecutive sample (Comparator output is simply sampled.) 010b - 2 consecutive samples 011b - 3 consecutive samples 100b - 4 consecutive samples 101b - 5 consecutive samples 110b - 6 consecutive samples 111b - 7 consecutive samples
15-14 —	Reserved
13-12 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
11-10 EVT_SEL	CMPO Event Select Selects which CMPO signal edge (rising, falling, or both) defines a CMPO event. **NOTE** Valid only in Windowing mode. 00b - Rising edge 01b - Falling edge 1xb - Both edges
9 WINDOW_CLS	CMPO Event Window Close Enables a CMPO event (defined as a CMPO rising edge, falling edge, or both) to close an active window. See EVT_SEL to configure the CMPO event. **NOTE** The WINDOW signal has to go to zero and back to one again to re-activate the window. Valid only in Windowing mode. 0b - CMPO event cannot close the window 1b - CMPO event can close the window
8 WINDOW_INV	WINDOW/SAMPLE Signal Invert Inverts the window/sample signal. 0b - Do not invert 1b - Invert
7 COUTA_OW	COUTA Output Level for Closed Window Defines the COUTA signal value when the window is closed. **NOTE** Valid only in Windowing mode and when COUTA_OWEN=1. 0b - COUTA is 0 1b - COUTA is 1
6 COUTA_OWEN	COUTA_OW Enable Enables the COUTA signal value to be defined by COUTA_OW when the window is closed. **NOTE** Valid only in Windowing mode. 0b - COUTA holds the last sampled value. 1b - Enables the COUTA signal value to be defined by COUTA_OW.
5	Comparator Output Pin Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
COUT_PEN	Enables the comparator output to become an available signal option for a selected package pin. 0b - Not available 1b - Available
4 COUT_SEL	Comparator Output Select Selects which comparator output option, COUT or COUTA, to use for CMPO. 0b - Use COUT (filtered) 1b - Use COUTA (unfiltered)
3 COUT_INV	Comparator Invert Selects the polarity of the analog comparator function, affecting the value driven to the COUT output (on both the chip pin and as CSR[COUT]) when CCR0[CMP_EN] is 0. **NOTE** COUT_INV has no effect in Trigger mode. 0b - Do not invert 1b - Invert
2 DMA_EN	DMA Enable Enables DMA transfers triggered from the LPCMP module. After this field and the corresponding interrupt enable field becomes 1, a DMA request is asserted when CFR or CFF becomes 1. 0b - Disable 1b - Enable
1 SAMPLE_EN	Sampling Enable Enables Sampling mode. 0b - Disable 1b - Enable
0 WINDOW_EN	Windowing Enable Enables Windowing mode. **NOTE** Valid only when SAMPLE_EN = 0. 0b - Disable 1b - Enable

61.7.6 Comparator Control Register 2 (CCR2)

Offset

Register	Offset
CCR2	10h

Function

Contains the configuration options for the comparator operation, such as selecting the plus and minus comparator inputs and the hysteresis levels.

NOTE

When an inappropriate operation selects the same signal for both the plus and minus comparator inputs, the analog comparator automatically shuts down (regardless of CMP_EN) to prevent itself from becoming a noise generator.

61.7.7 DAC Control (DCR)

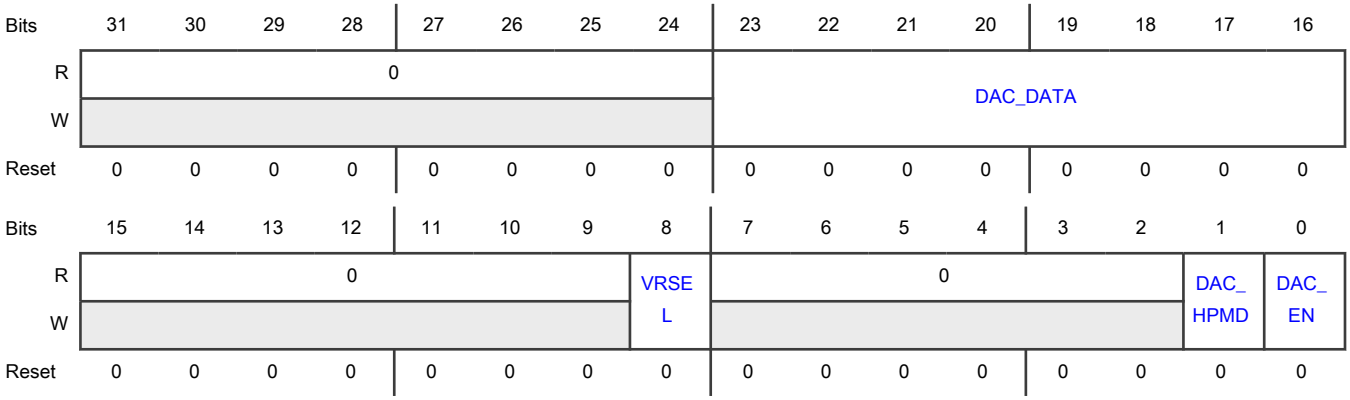
Offset

Register	Offset
DCR	18h

Function

Contains the configuration options to enable the DAC.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 DAC_DATA	DAC Output Voltage Select Selects the DAC output (DACO) voltage from one of 256 distinct levels by configuring the value of DAC_DATA. The DACO ranges from Vin/256 to Vin. **NOTE** DACO = (Vin/256) * (DAC_DATA + 1)
15-9 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
8 VRSEL	DAC Reference High Voltage Source Select Selects the high voltage reference source for the Vin supply of the DAC's resistor ladder network. See the chip-specific LPCMP information for the source of vrefh0 and vrefh1. 0b - VREFH0 1b - VREFH1
7-2 —	Reserved
1 DAC_HPMD	DAC High Power Mode Enables the DAC high power mode. 0b - Disable 1b - Enable
0 DAC_EN	DAC Enable Enables the DAC. When disabled, power-down the DAC to conserve power. 0b - Disable 1b - Enable

61.7.8 Interrupt Enable (IER)

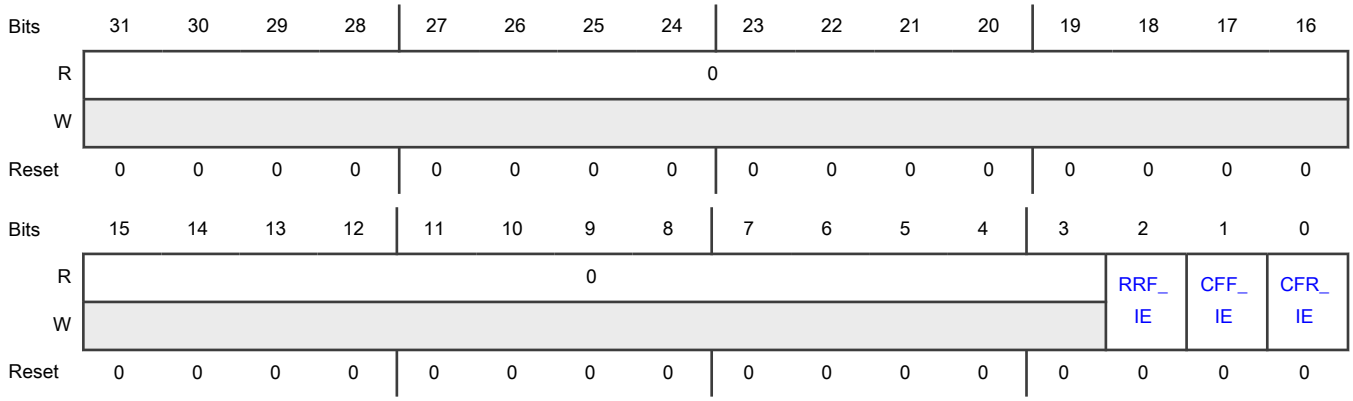
Offset

Register	Offset
IER	1Ch

Function

Provides enable fields for the comparator and round-robin flag interrupts.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 RRF_IE	Round-Robin Flag Interrupt Enable Enables or disables the round-robin flag interrupt. 0b - Disables the round-robin flag interrupt. 1b - Enables the round-robin flag interrupt when the comparison result changes for a given channel.
1 CFF_IE	Comparator Flag Falling Interrupt Enable Enables or disables the comparator flag falling interrupt. 0b - Disables the comparator flag falling interrupt. 1b - Enables the comparator flag falling interrupt when CFF is set.
0 CFR_IE	Comparator Flag Rising Interrupt Enable Enables or disables the comparator flag rising interrupt. 0b - Disables the comparator flag rising interrupt. 1b - Enables the comparator flag rising interrupt when CFR is set.

61.7.9 Comparator Status (CSR)

Offset

Register	Offset
CSR	20h

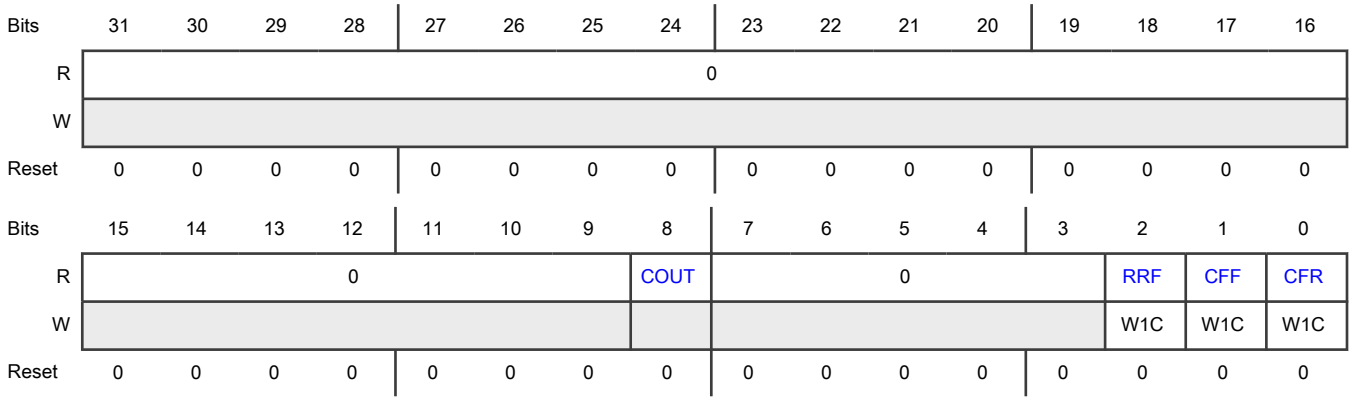
Function

Indicates comparator status, including COUT, CFF, CFR, and RRF.

NOTE

LPCMP may output a glitch and affect the value of CSR[CFF] and CSR[CFR] at the moment of enabling CMP. In order to ensure correctness, it is recommended to write one to clear (W1C) CSR[CFF] and CSR[CFR] before further configuring CMP.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 COUT	Analog Comparator Output Returns the current value of the analog comparator output when read. This field resets to 0 and reads as CCR1[COUT_INV] after the analog comparator module disables when CCR0[CMP_EN] = 0. Writing to this field is ignored.
7-3 —	Reserved
2 RRF	Round-Robin Flag Detects when any channel's last comparison result is different from the pre-set value in Trigger mode. Write 1 to clear this field. This field clears when CCR0[CMP_EN] or RRCR0[RR_EN] is not 1. 0b - Not detected 1b - Detected
1 CFF	Analog Comparator Flag Falling Detects when a falling edge on COUT occurs. Write 1 to clear this field when CCR1[DMA_EN] is disabled. If CCR1[DMA_EN] is enabled, the flag automatically clears after DMA is done. This field clears when CCR0[CMP_EN] is not 1. 0b - Not detected 1b - Detected
0 CFR	Analog Comparator Flag Rising Detects when a rising edge on COUT occurs. Write 1 to clear this field when CCR1[DMA_EN] is disabled. If CCR1[DMA_EN] is enabled, the flag automatically clears after DMA is done. This field clears when CCR0[CMP_EN] is not 1. 0b - Not detected 1b - Detected

61.7.10 Round Robin Control Register 0 (RRCR0)

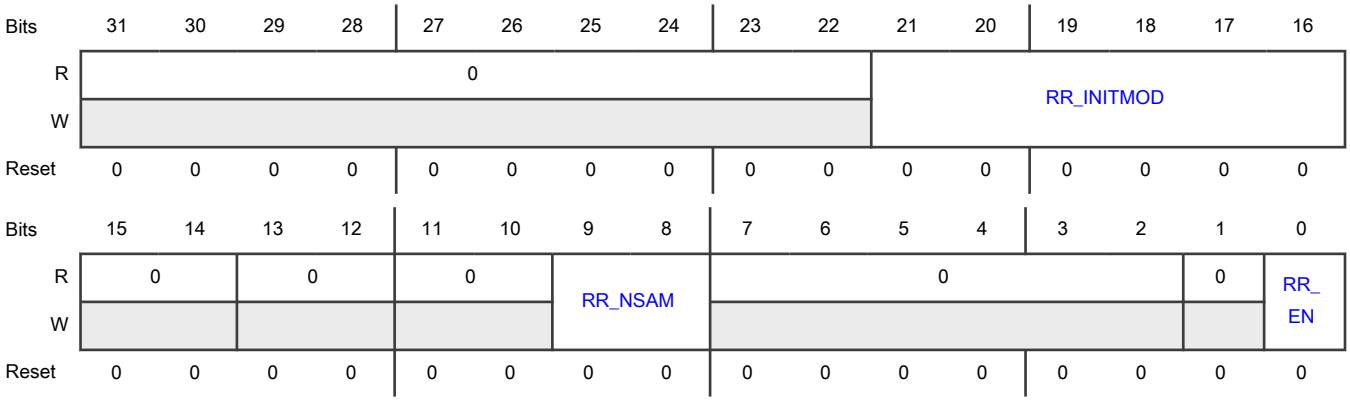
Offset

Register	Offset
RRCR0	24h

Function

Contains configuration options for the round-robin operation, such as enabling it and specifying the initialization delay.

Diagram



Fields

Field	Function
31-22 —	Reserved
21-16 RR_INITMOD	Initialization Delay Modulus Specifies the number of round-robin clock cycles that determines the comparator and DAC initialization delay specified in the chip datasheet. Calculate the initialization delay as RR_INITMOD * (round-robin clock period). For example, if the initialization delay is 80us and the round-robin clock is 100kHz, program RR_INITMOD to be 80us/10us = 8. 00_0000b - 63 cycles (same as 111111b) 00_0001b-11_1111b - 1 to 63 cycles
15-14 —	Reserved
13-12 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
11-10 —	Reserved
9-8 RR_NSAM	Number of Sample Clocks Specifies the number of the round-robin clock cycles to wait after scanning the active channel before sampling the channel's comparison result. After the next cycle of the round-robin clock, the sampling takes place RR_NSAM clocks later. 00b - 0 clock 01b - 1 clock 10b - 2 clocks 11b - 3 clocks
7-2 —	Reserved
1 —	Reserved
0 RR_EN	Round-Robin Enable Enables the round-robin operation. 0b - Disable 1b - Enable

61.7.11 Round Robin Control Register 1 (RRCR1)

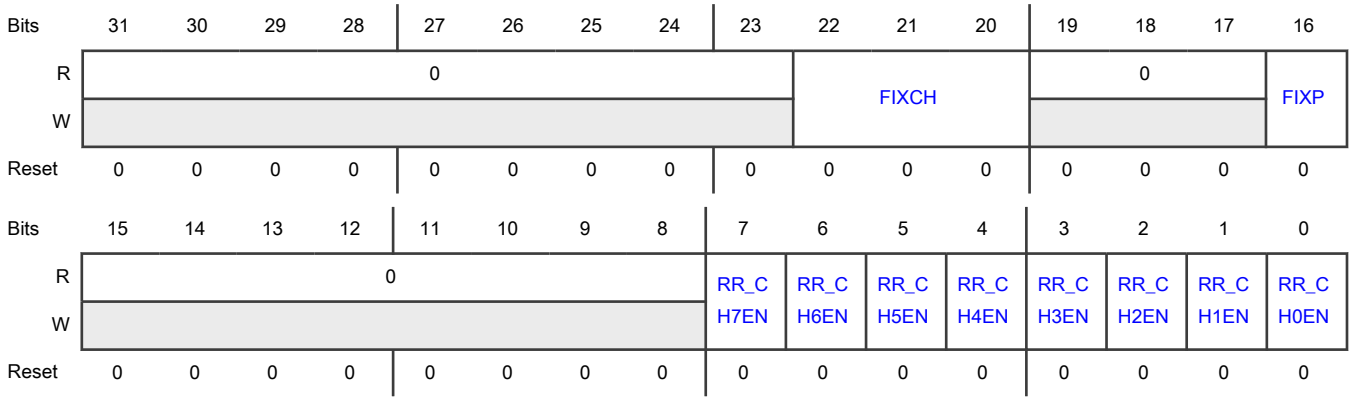
Offset

Register	Offset
RRCR1	28h

Function

Contains configuration options for the round-robin operation, such as enabling individual channels to participate.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-20 FIXCH	Fixed Channel Select Selects which channel in the mux port to fix for a given round-robin trigger mode application. 000b - Channel 0 001b - Channel 1 010b - Channel 2 011b - Channel 3 100b - Channel 4 101b - Channel 5 110b - Channel 6 111b - Channel 7
19-17 —	Reserved
16 FIXP	Fixed Port Fixes an analog mux port (plus or minus) for round-robin trigger mode. The inputs to the non-fixed port sweep during each round. 0b - Fix the plus port. Sweep only the inputs to the minus port. 1b - Fix the minus port. Sweep only the inputs to the plus port.
15-8 —	Reserved
7-0	Channel n Input Enable in Trigger Mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
RR_CHnEN	Enables channel n of the non-fixed mux port to check its voltage value when in Trigger mode. **NOTE** RR_CHnEN has no effect when the same channel is selected as the reference voltage. 0b - Disable 1b - Enable

61.7.12 Round Robin Control and Status (RRCSR)

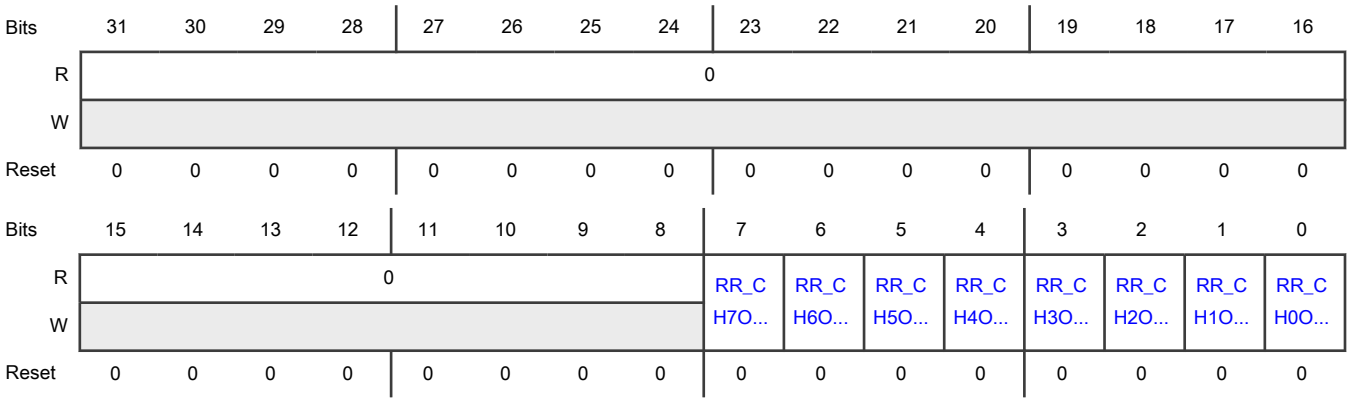
Offset

Register	Offset
RRCSR	2Ch

Function

Contains the latest comparison results of the individual channels with the fixed mux port. It also allows you to define the pre-set state for each channel.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 RR_CHnOUT	Comparison Result for Channel n Returns the latest comparison result for channel n when read and defines the pre-set state for channel n when written to.

61.7.13 Round Robin Status (RRSR)

Offset

Register	Offset
RRSR	30h

Function

Contains individual channel flags that indicates when a channel's last comparison result is different from its pre-set value.

Chapter 62
Logic Control Unit (LCU)

62.1 Chip-specific LCU information

62.1.1 LCU instances

This chip has 2 instances of LCU:

- LCU_0
- LCU_1

62.2 Overview

LCU selects multiple inputs from timers, Pulse Width Modulation (PWM) signals, and Input/Output (I/O) pads, and combines them using a programmable logic function to create output waveforms.

62.2.1 Block diagram

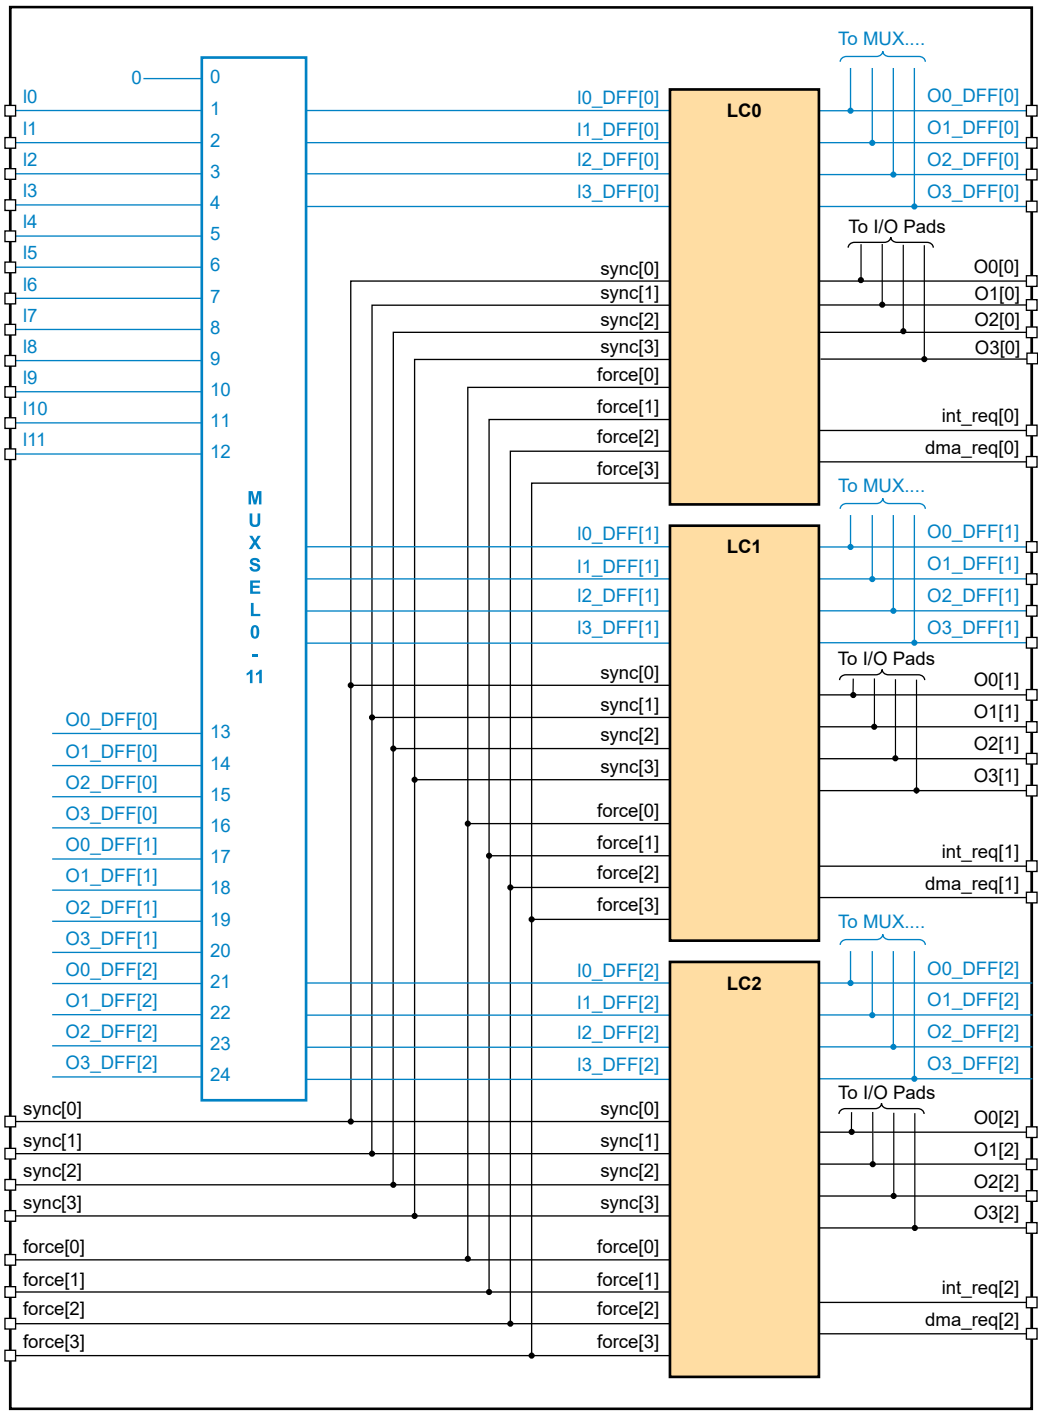

Figure 317. Block diagram

NOTE

3 LCs are shown in this block diagram.

62.2.2 Features

- 3 LCs with programmable logic function for generating output results
- 12 inputs to and 12 outputs from each LC
- Muxing to map any input to any LC
- Independent filters for the rising and falling output states of each LC
- Software override logic for inputs using multiple modes
- 4 force inputs with programmable edge filtering to force output states using multiple modes
- 2 sync inputs to control transition timing
- Lock bit to block writes to configuration registers
- Interrupt request generation based on output change or force event
- DMA transfer request generation based on output change or force event

62.3 Functional description

62.3.1 LC operation

62.3.1.1 Overview

An LC performs logic operations based on the LUT principle, as described in Logic operations.

Each LC supports the following features:

- Independent filter thresholds for the rising and falling output states support different transition delays.
- Bypass of the output state filter by setting the filter threshold to zero. Bypassing the filter causes the asynchronous signal to propagate to the output of the LC.
- Force logic that instantly switches an LC output to the inactive state upon external fault signal assertion. The return from the inactive state to the output state is either:
  - Instantaneous: when LCU deasserts the force signal.
  - Instantaneous synchronized: when LCU deasserts the force signal and then the sync input asserts.
  - Manual: when you write 1 to the force status bit and then the LCU deasserts the force input.
  - Manual synchronized: when you write 1 to the force status bit and LCU deasserts the force input, and then the sync input asserts.
- Input software override logic to override external inputs by writing to the following registers:
  - LC*n* Sync Control (LC*n*_SCTRL[SW_MODE])
  - Software Override Value (SWVALUE[SWVALUE])
  - Software Override Enable (SWEN[SWEN])
- Generation of interrupt requests or DMA transfer requests.

62.3.1.2 LC diagram

This figure illustrates an example LC implementation with:

- One LC
- Four force inputs
- Four sync inputs

For the number of each resource in this chip, see Features.

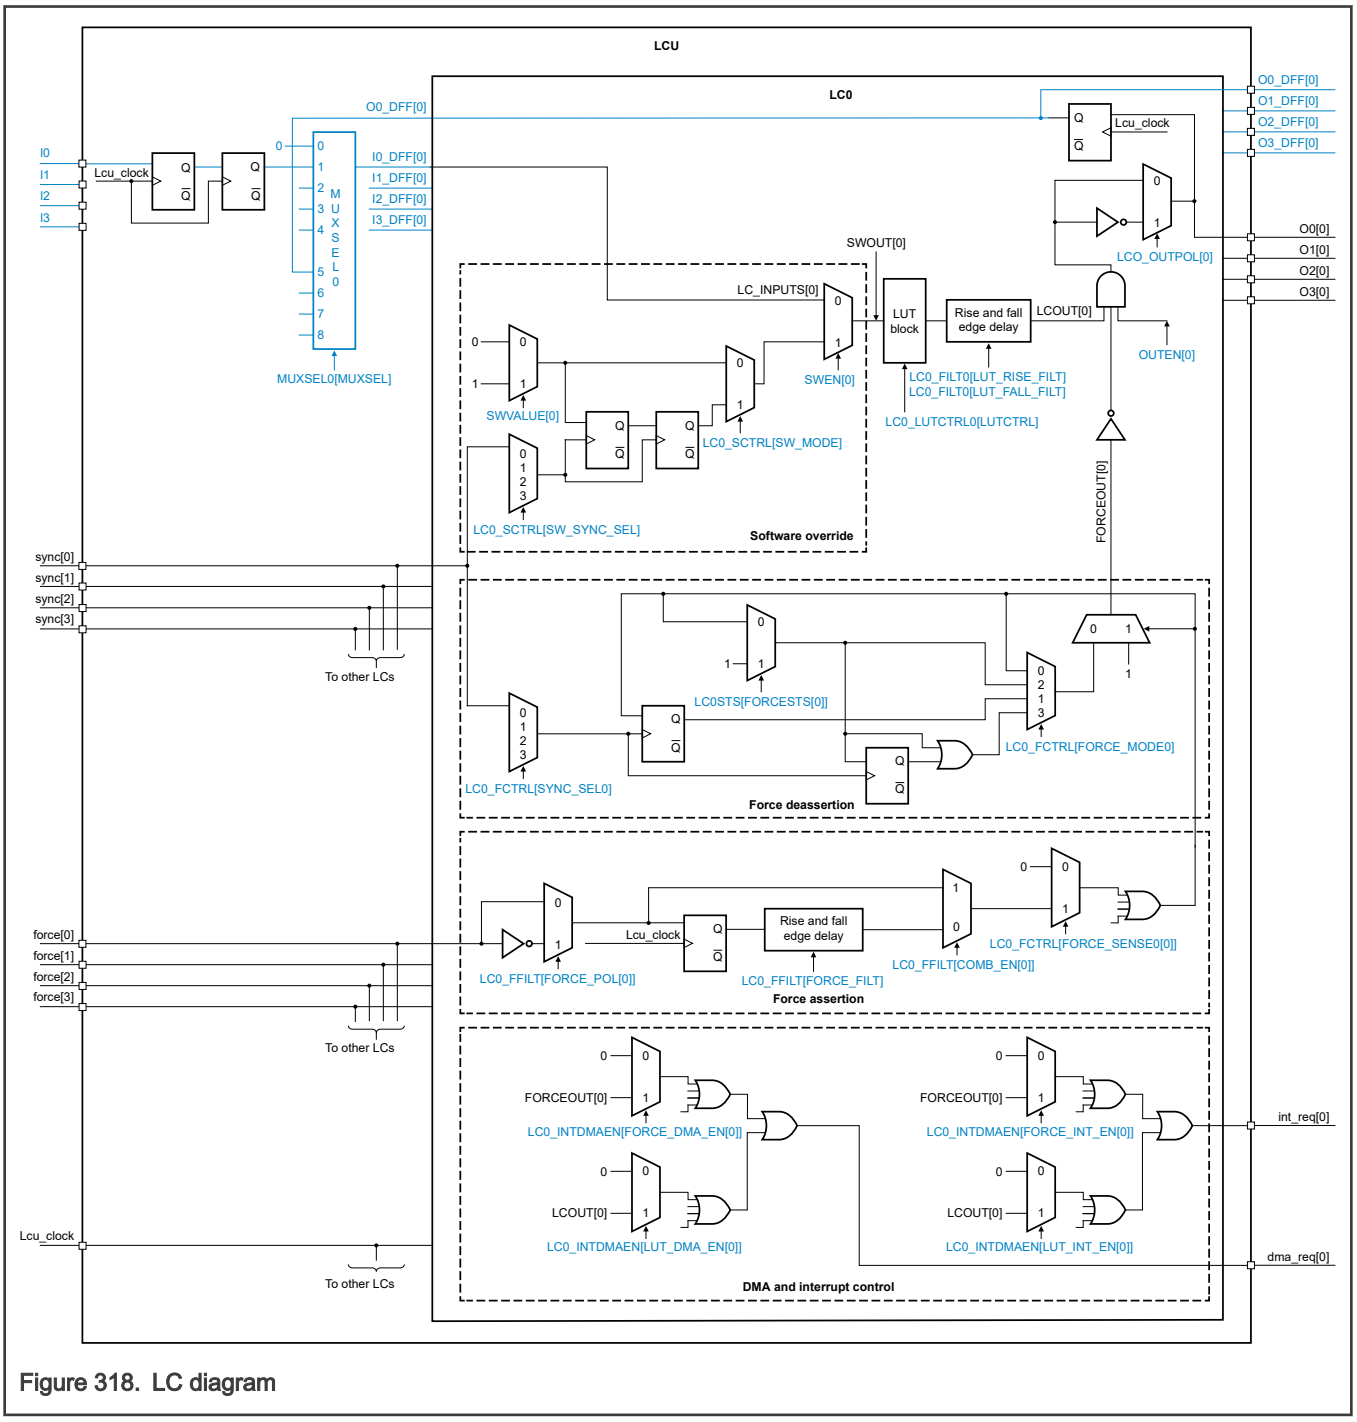

Figure 318. LC diagram

62.3.1.3 Logic operations

An LC reads its set of inputs (inputs 3, 2, 1, and 0) as a four-bit binary value, with Input 3 as the most-significant bit and Input 0 as the least-significant bit. For example, if:

Input 0 = 0

Input 1 = 1

Input 2 = 0

Input 3 = 1

then the combined input value is 1010b (10 decimal).

Each possible four-bit input value corresponds to a bit position in the LUT Control (LCn_LUTCTRLm[LUTCTRL]), as illustrated in LC LUT. For a given LC output, if the combined LC input value corresponds to a bit position in that output's LUTCTRL value that equals 1, then the LC asserts that output.

For example, if you write 35h to LUTCTRL (shown in the Example column of the LC LUT), then the combined input values 0 (0000b), 2 (0010b), 4 (0100b), and 5 (0101b) cause assertion of the output. All other input values cause deassertion of the output.

LCU processes each look-up table asynchronously.

62.3.1.4 LC LUT

The LUT maps the combined LC input value to a bit position in LC*n*_LUTCTRL*m*.

Table 291. LC LUT

Input 3	Input 2	Input 1	Input 0	LUTCTRL bit position	Example LUTCTRL value: 35h
0	0	0	0	0	1
0	0	0	1	1	0
0	0	1	0	2	1
0	0	1	1	3	0
0	1	0	0	4	1
0	1	0	1	5	1
0	1	1	0	6	0
0	1	1	1	7	0
1	0	0	0	8	0
1	0	0	1	9	0
1	0	1	0	10	0
1	0	1	1	11	0
1	1	0	0	12	0
1	1	0	1	13	0
1	1	1	0	14	0
1	1	1	1	15	0

62.3.1.5 LC output filters

Each LC supports two optional digital filters, a Rise Filter (LC*n*_FLIT*m*[LUT_RISE_FILT]) and a Fall Filter (LC*n*_FLIT*m*[LUT_FALL_FILT]), to post-process the LUT output and delay the output signal change.

Each filter starts accumulating clock cycles on the occurrence of the associated LUT event. The Rise Filter counts from an output assertion, and the Fall Filter counts from an output deassertion. When the number of clock cycles reaches the filter threshold (matches the specified filter value), the output flips to the new state. For example, if you specify a Rise Filter value of 100h, and the LUT event triggers an output assertion, the output signal does not assert until the 256th clock cycle after the event.

A filter value of 0 bypasses the filter.

NOTE

LCU usecase (intercell/feedback loop path along with TRGMUX Path) does not work with default RISE/FALL filter time. You must configure RISE/FALL Filter delay at least for 1 cycle to avoid such glitches/failures.

62.3.2 Behavior in different chip modes of operation

Table 292. Modes of operation

Operation mode	Status of outputs
Normal	• Controlled by LC*n*_LUTCTRL*m* and MUXSEL*n* • Toggled based on the states of the selected inputs
Debug	Inactive or normal operation controlled by Debug Mode Enable (DBGEN)

62.3.3 Clocking

This module has no clocking considerations.

62.3.4 Interrupts

Each LC has a single interrupt request output int_req[n]. Interrupt request enables bits for all the 4 outputs in each LC defined in LC*n*_INTDMAEN with LC*n*_INTDMAEN[FORCE_INT_EN] for interrupt request generation when a force event occurs and LC*n*_INTDMAEN[LUT_INT_EN] for interrupt request generation when a LUT event occurs.

When user enables interrupt for a force event on an output and the force event occurs on that output, LCU generates an interrupt request if LC*n*_STS[FORCESTS] and LC*n*_INTDMAEN[FORCE_INT_EN] for that output is 1. Similarly when user enables interrupt for a LUT event on an output and a LUT event occurs on that output, LCU generates an interrupt request if LC*n*_STS[LUT_STS] and LC*n*_INTDMAEN[LUT_INT_EN] for that output is 1.

62.3.5 DMA

Each LC has a single DMA request output dma_req[n]. DMA request enables bits for all the 4 outputs in each LC defined in LC*n*_INTDMAEN with LC*n*_INTDMAEN[FORCE_DMA_EN] for DMA request generation when a force event occurs and LC*n*_INTDMAEN[LUT_DMA_EN] for DMA request generation when a LUT event occurs.

When user enables DMA for a force event on an output and the force event occurs on that output, LCU generates a DMA request if LC*n*_STS[FORCESTS] and LC*n*_INTDMAEN[FORCE_DMA_EN] for that output is 1. Similarly when user enables DMA for a LUT event on an output and a LUT event occurs on that output, LCU generates a DMA request if LC*n*_STS[LUT_STS] and LC*n*_INTDMAEN[LUT_DMA_EN] for that output is 1.

62.4 External signals

This module has no external signals.

62.5 Initialization

This module does not require initialization.

62.6 Application information

62.6.1 Use-case examples

62.6.1.1 Two-channel multiplexer

62.6.1.1.1 Overview

A multiplexer (or mux) takes multiple inputs and, based on some control mechanism, passes only one of those inputs to the output. You can implement a two-channel multiplexer controlled by an external signal or a software override using three inputs and one output of a single LC, as illustrated in Logic diagram and Implementation.

This example implementation controls the multiplexer with the SEL input signal and a software override. The software override controls the multiplexer output regardless of the SEL signal state. To use software override, you must enable it for the corresponding output (SWEN[SWEN]). You assert software override by writing 1 to the corresponding bit of the Software Override Value (SWVALUE[SWVALUE]).

62.6.1.1.7 Waveforms

In this figure, the SWEN and SWVALUE signals represent the states of the software override control registers. Writes to SWEN and SWVALUE have immediate impact on LC outputs, whereas LC inputs require input synchronization to prevent metastability.

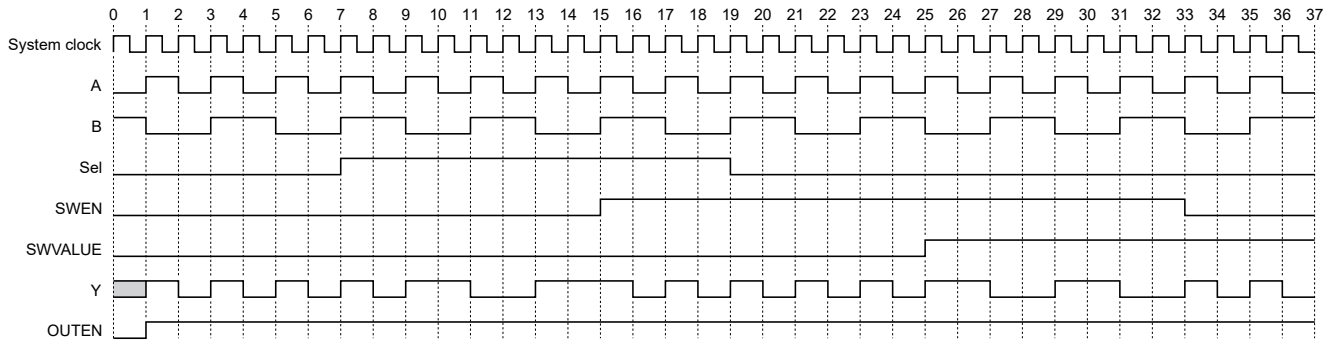

Figure 321. Waveforms

62.6.1.2 Binary to Gray code converter

62.6.1.2.1 Overview

Gray code, also known as reflected binary code (RBC), is a non-weighted, minimum change code. In this code, any two adjacent code numbers differ by only one bit. This code solves the problem of physical switch transitions by changing only one switch at a time, so there is never any ambiguity of position.

You can implement binary to Gray code conversion using a single LC, as illustrated in Logic diagram and Implementation.

In this example, the LC also generates a DMA request on each rising edge of output 3, which is bit 0 of the Gray code (G0).

62.6.1.2.2 Conversion table

Table 296. Conversion table

Decimal	Binary	Gray

The LC outputs are delayed by two clock cycles because of the two-stage input synchronizers.

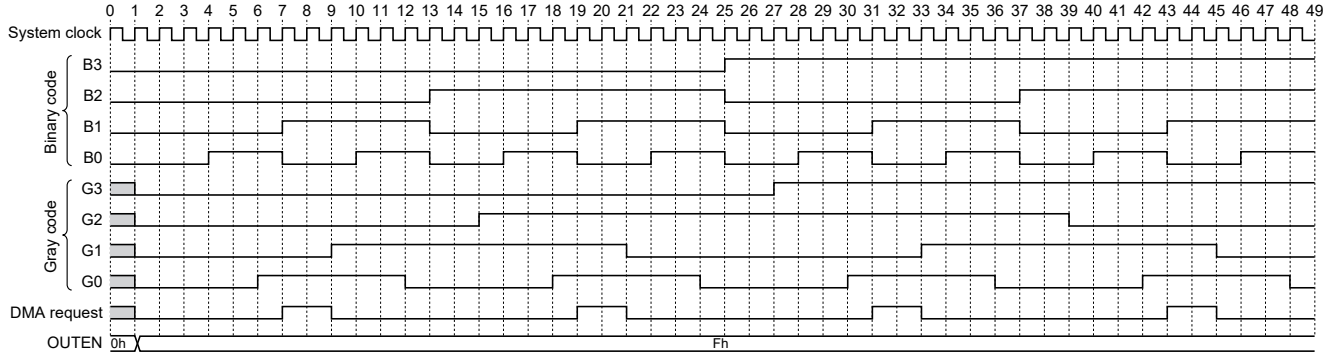

Figure 324. Waveforms

62.6.1.3 Manchester encoder and decoder

62.6.1.3.1 Overview

Manchester encoding (also known as phase encoding) is a data-modulation technique for binary data transfer based one of these signals:

- Analog
- RF
- Optical
- High-speed-digital
- Long-distance-digital

The fundamental idea behind Manchester encoding is to use voltage transitions, instead of voltage levels, to represent 1s and 0s. It performs an exclusive OR of data and clock signals to encode and decode data. A high-to-low transition on the falling clock edge indicates 0. A low-to-high transition on the rising clock edge indicates 1.

62.6.1.3.8 Waveforms for encoder

This figure includes the Manchester-encoded waveform (labeled PE) of the input waveform (labeled "Data in"). The PE waveform is delayed by two clock cycles because of two-stage input synchronization.

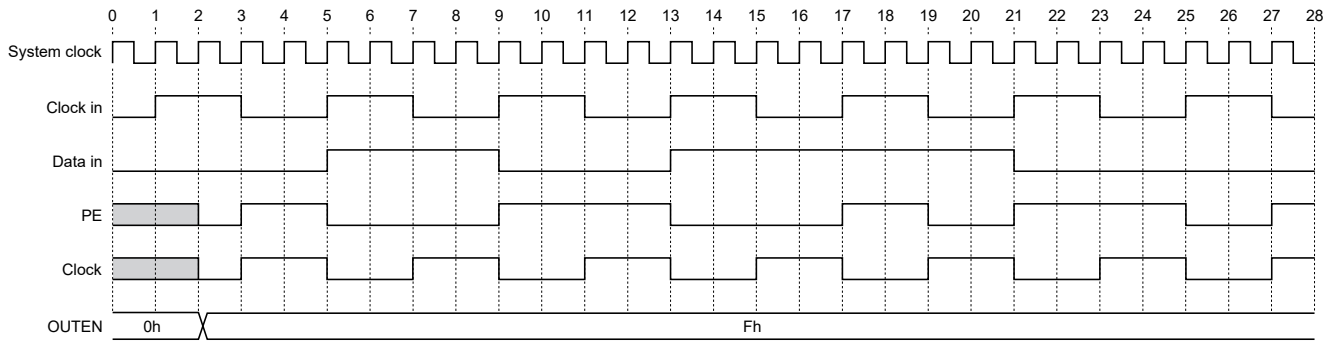

Figure 327. Waveforms for encoder

62.6.1.3.9 Waveforms for decoder

The output waveform (labeled "Data out") is delayed by four clock cycles from the input waveform (labeled "Data in") because of two-stage input synchronization. In this example, the Manchester encoder also propagates the Clock waveform that the decoder uses to reconstruct the "Data in" waveform from the Manchester-decoded waveform (labeled PE).

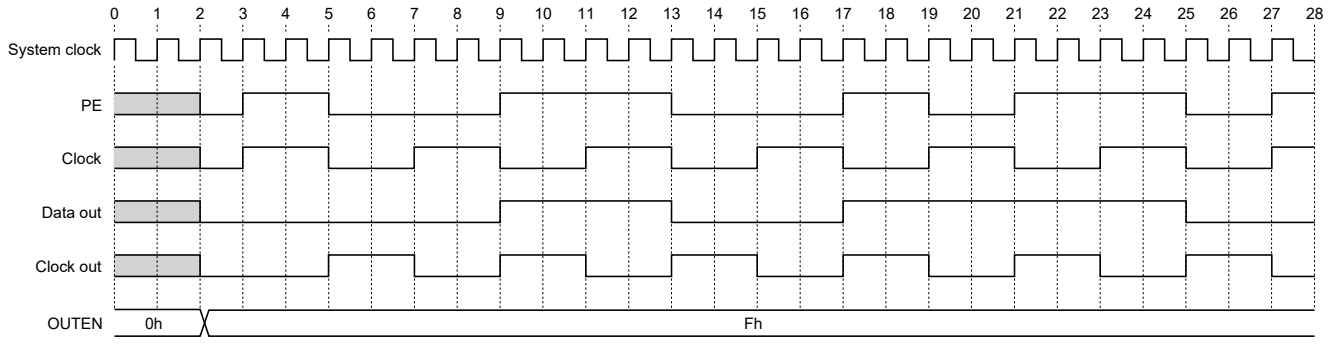

Figure 328. Waveforms for decoder

62.6.1.4 Adjustable PWM/FM generator

62.6.1.4.1 Overview

In many cases, it is useful to route an LC output back to one of its inputs, as illustrated in Implementation. In addition, you can delay outputs with a digital filter with different time constants for delaying rising and falling edges. Combining these capabilities, you can use an LC to generate output waveforms with adjustable pulse width and frequency.

In addition to waveform generation, the software-override feature forces the generator output low or high by software. You control the override via Software Override Enable (SWEN) and Software Override Value (SWVALUE).

62.6.1.4.2 Implementation

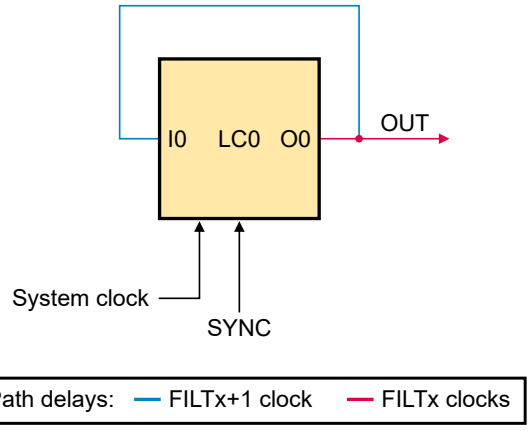

Figure 329. Implementation

62.6.1.4.3 Connections and controls

Table 304. Connections and controls

Name	Description
I0	Delayed output routed back to LC input
O0 and OUT	Delayed output
System clock	Clock frequency supplied to LC
SYNC	Software override synchronization signal

62.6.1.4.4 Truth table

This example generates an adjustable PWM/FM waveform according to the following table. In the table:

- OUT is the LC output signal that is also routed to the LC input using an internal multiplexer.
- TdH is the digital filter value to delay the rising edge of the output signal.
- TdL is the digital filter value to delay the falling edge of the output signal.

Table 305. Truth table

I0	OUT
0	1 delayed by TdH (see Output edge delays)
1	0 delayed by TdL (see Output edge delays)

In this figure, the SWEN and SWVALUE signals represent the states of the software override control registers. Writes to Software Override Enable (SWEN) and Software Override Value (SWVALUE) have immediate impact on LC outputs, whereas LC inputs require input synchronization to prevent metastability.

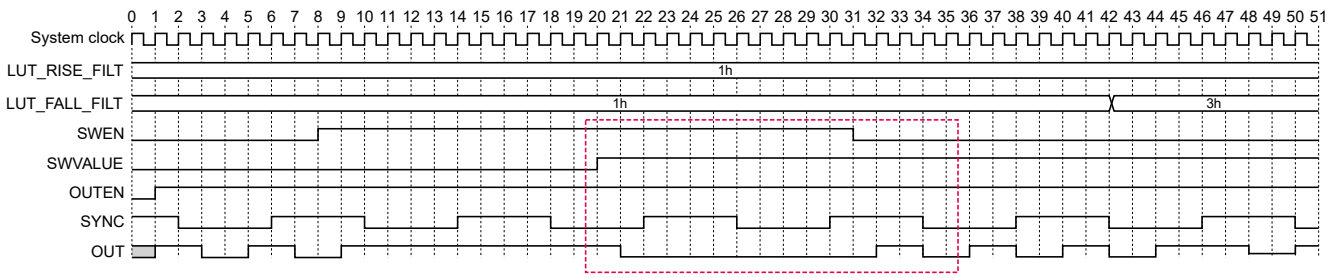

Figure 331. Waveforms for immediate software override

62.6.1.4.8 Waveforms for synced software override

In this example, software override control is synced with the rising edges of the SYNC waveform.

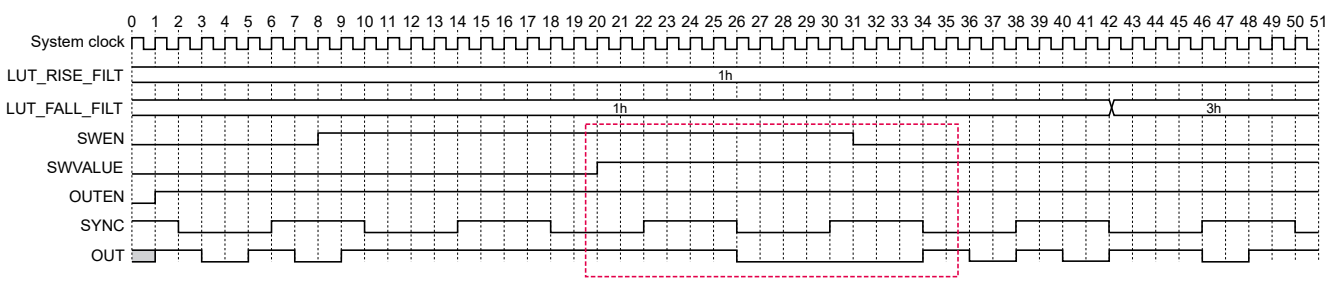

Figure 332. Waveforms for synced software override

62.6.1.5 SR latch

62.6.1.5.1 Overview

An SR latch is the simplest bistable device and a fundamental component of data storage.

This example implementation uses one LC that includes an internal feedback path configured by the internal multiplexer, as illustrated in Implementation. Output Q responds to inputs S (set) and R (reset). It changes with a delay of two clock cycles—the time required for the S and R signal inputs to pass through the internal two-stage synchronizers. This example implementation bypasses the Q digital filter; therefore, the loop of Q back to the input experiences a delay of one clock cycle." See Waveforms.

62.6.1.6 D flip-flop

62.6.1.6.1 Overview

A D flip-flop stores and outputs whatever logic level is applied to its data terminal at the time its clock input goes high.

You can implement a D flip-flop element using an LC as illustrated in Implementation. On a clock rising edge, the LC either asserts or deasserts the Q output based on the D input.

The Q output and CLKO digital filters are bypassed. Therefore, the states of these variables are fed to inputs with a delay of one clock cycle. See Waveforms.

62.6.1.7 JK flip-flop

62.6.1.7.1 Overview

A JK flip-flop is a gated SR latch (see SR latch) with an added clock input circuit that prevents the illegal or invalid output condition that can occur when both SR-latch inputs (S and R) are asserted.

Truth table for JK flip-flop presents the four possible input combinations for a JK flip-flop. All output changes occur at the clock rising edge.

You can create a JK flip-flop using two LCs, as illustrated in Implementation. The first LC detects rising edges of the CLK clock input (see Truth table for LC0). The second LC processes J and K inputs at every rising clock edge (see Truth table for LC1).

Output Q and CLKO digital filters are bypassed. Therefore, the states of these variables are fed to inputs with a delay of one clock cycle (see Waveforms).

62.6.1.8 Incremental encoder

62.6.1.8.1 Overview

An incremental encoder provides A and B pulse outputs in the form of 90-degree shifted waveforms (see Outputs). The decoding circuit processes these waveforms to detect the rotor position and the direction of rotation.

This example implementation requires two LCs (see Implementation):

- LC0 provides pulse streams on CW or CCW output at every A and B signal edge. If the encoder rotation is CW (A signal leading), then pulses appear at the CW output. If the encoder rotation is CCW (B signal leading), then pulses appear at the CCW output. Two pulse counters accumulate these pulse streams to provide the actual absolute encoder position in the respective direction of rotation.
- LC1 then uses the LC0 outputs to detect the direction of the rotation.

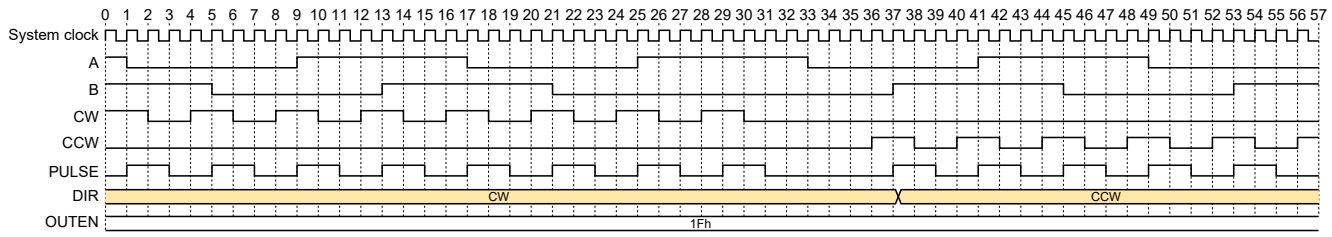

Figure 341. Waveforms

62.6.1.9 AC motor PWM controller

62.6.1.9.1 Overview

Driving a three-phase AC motor requires dedicated PWMs to perform:

- Complementary signal generation
- Dead time insertion
- Fault-state assertion
- Manual or automatic fault recovery

LCU enhances basic timer functionality with the necessary complementary features available only on dedicated motor control PWMs.

Implementation for AC motor controller shows all input and output signals of LCU in a typical three-phase motor control application.

TdH is the time delay preceding each rising edge of the complementary PWM output signals. See Truth table for details.

Fault signals are routed from analog comparators or external protection circuits to protect power switches against damage caused by overcurrent. Any active fault must immediately change all PWM outputs to the inactive state. Force logic causes PWM outputs to transition to the inactive state upon an external fault event. See Truth table for details.

The dead time is one clock cycle. On a fault event, both PWM outputs transition to the inactive state (logic 0). When the fault event deasserts, both PWM signals start operating according to FORCE_MODE = 00 (cleared on force deassertion). See Waveforms for force cleared on force deassertion for details.

62.6.1.9.7 Waveforms for force cleared on force deassertion

This example shows two behaviors, depending on the Force Clearing mode (LC0_FCTRL[FORCE_MODE0]).

00b - Both PWM signals start normal operation when the fault event deasserts. See Waveforms for force cleared on force deassertion for details.

01b - Both PWM signals start normal operation on rising sync after the fault event deasserts. See Waveforms for force cleared on rising sync after force deassertion for details.

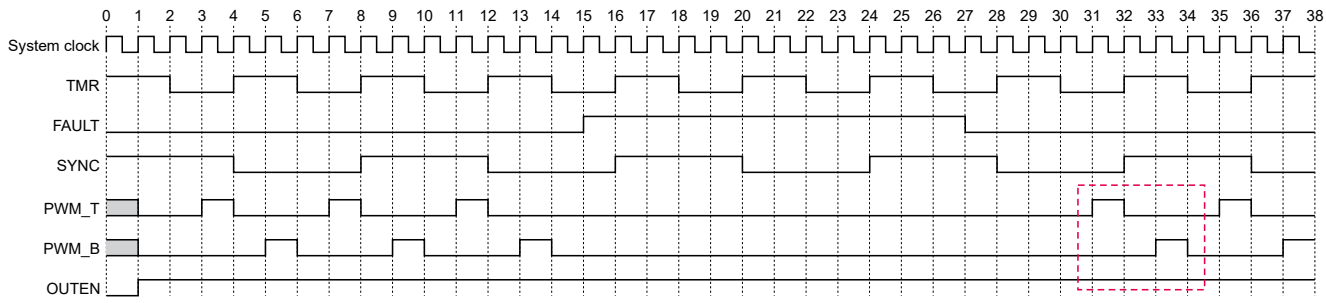

Figure 344. Waveforms for force cleared on force deassertion

62.6.1.9.8 Waveforms for force cleared on rising sync after force deassertion

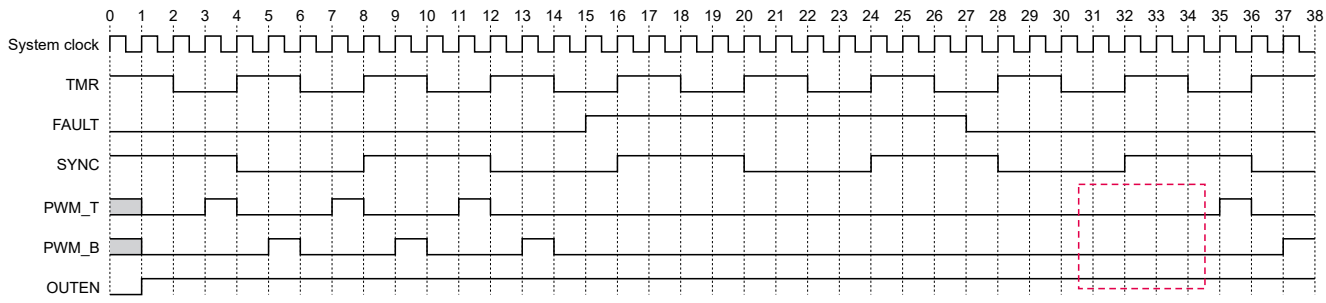

Figure 345. Waveforms for force cleared on rising sync after force deassertion

62.6.1.10 AC motor double-switching controller

62.6.1.10.1 Overview

The simplest method of obtaining motor winding currents is to measure the current in each phase by placing a shunt resistor in two or three inverter legs (phases).

This example implementation of an AC motor drive for low-cost and high-volume applications uses a single shunt on the DC bus return path, as illustrated in AC motor power stage schematic. LCU supports double-switching by XORing two timer channel outputs. The implementation uses two LCs arranged to perform double switching, dead time generation, and the processing of three external fault signals.

62.6.1.10.2 Double-switching

The double-switching technique requires:

- Six synchronized timer pulses
- Three fault signals
- Six PWM outputs for controlling top and bottom power switches
- A sync signal for automatic fault recovery

Waveforms for double-switching technique example applies the PWM switching cycle to an AC motor to reconstruct currents in three phases using a single DC bus shunt resistor (RSH). It applies the non-zero switching vectors 100, 110, and 101 to the power switches, which sample currents IA[0], -IC[0], -IC[1], and IA[1]. Because the durations (T1) of active vectors 110 and 101 are the same, it also applies the zero switching vector (000) with durations T2 and T3 in the middle of the switching cycle to allow phase current reconstruction. This technique can only be used by PWM modules targeted at motor control and power conversion applications.

62.6.1.10.3 Fault inputs and deadtime insertion

Fault signals are routed from analog comparators or external protection circuits to protect power switches against damage caused by overcurrent. You must program the Combinational Force Path (LCn_FFILT[COMB_EN]) to enable an active fault input to immediately force all PWM outputs to the inactive state.

62.6.1.10.4 Deadtime insertion

In Waveforms for generation of PWM complementary signals using an LC, the PWMA_T output is generated by XORing timer outputs TMR0 and TMR1. The PWMA_B output is complementary to PWMA_T. Digital filters insert a dead time of one system clock cycle to delay the rising edges of both PWM signals.

62.6.1.10.5 Fault events

Waveforms for force cleared on force deassertion shows the reaction to the fault event. On a fault event, both the PWM outputs transition to the inactive state (logic 0). When fault event deasserts, both the PWM signals start operating according to FORCE_MODE = 00 (cleared on force deassertion).

Alternatively, after the fault event deasserts, fault clearing can be performed according to FORCE_MODE = 01 (cleared on rising sync force deassertion). See Waveforms for force cleared on rising sync after force deassertion for details.

62.6.1.11 Brushless DC (BLDC) motor PWM controller

62.6.1.11.1 Overview

You can use LCU to replace the mechanical commutator in the BLDC motor control application with Hall-sensor position measurement.

In this example implementation, LC0 receives the direction (DIR) and Hall A, Hall B, and Hall C sensor output states, and from those inputs generates the switching states S1, S2, and S3. LC1 and LC2 convert the switching states to PWM or on-off signals for controlling power switches, as illustrated in Waveforms for BLDC motor control technique.

BLDC motor power stage schematic and BLDC motor electrical arrangement illustrate a three-phase BLDC motor power stage with switching pulses and phase currents controlling motor rotation in the CCW direction. The state of the Hall sensors is 010. As the rotor shaft rotates, Hall sensors track the motor position. You accelerate or decelerate the motor by controlling the width of the PWM signal. You can include one or more faults (force inputs) to force power switches instantaneously into the inactive state if there is an overcurrent.

62.6.1.11.13 Waveforms for reversing BLDC motor

This figure illustrates the waveforms for controlling a reversing BLDC motor. The DIR input indicates the direction of rotation:

- Logic 0 for CW rotation
- Logic 1 for CCW rotation

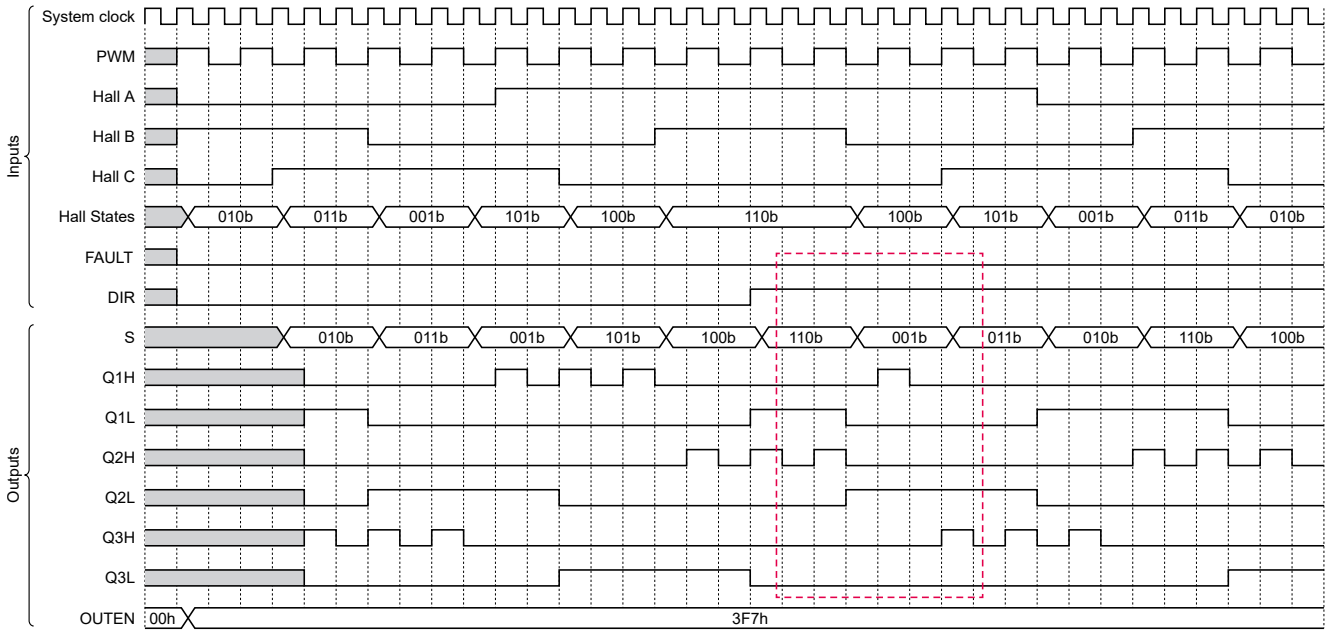

Figure 357. Waveforms for reversing BLDC motor

62.6.1.11.14 Waveforms for reversing BLDC motor with fault assertion

This figure illustrates the waveforms for the reaction to an external fault in addition to reversing the BLDC motor. On the occurrence of an external fault event, the power switches transition to the inactive state (logic 0). Two clock cycles after external fault deassertion, the power switches start operating normally.

Switching state outputs S1, S2, and S3, generated by LC0, receive an additional delay of one clock cycle on their way to the inputs of other LCs (digital filters bypassed).

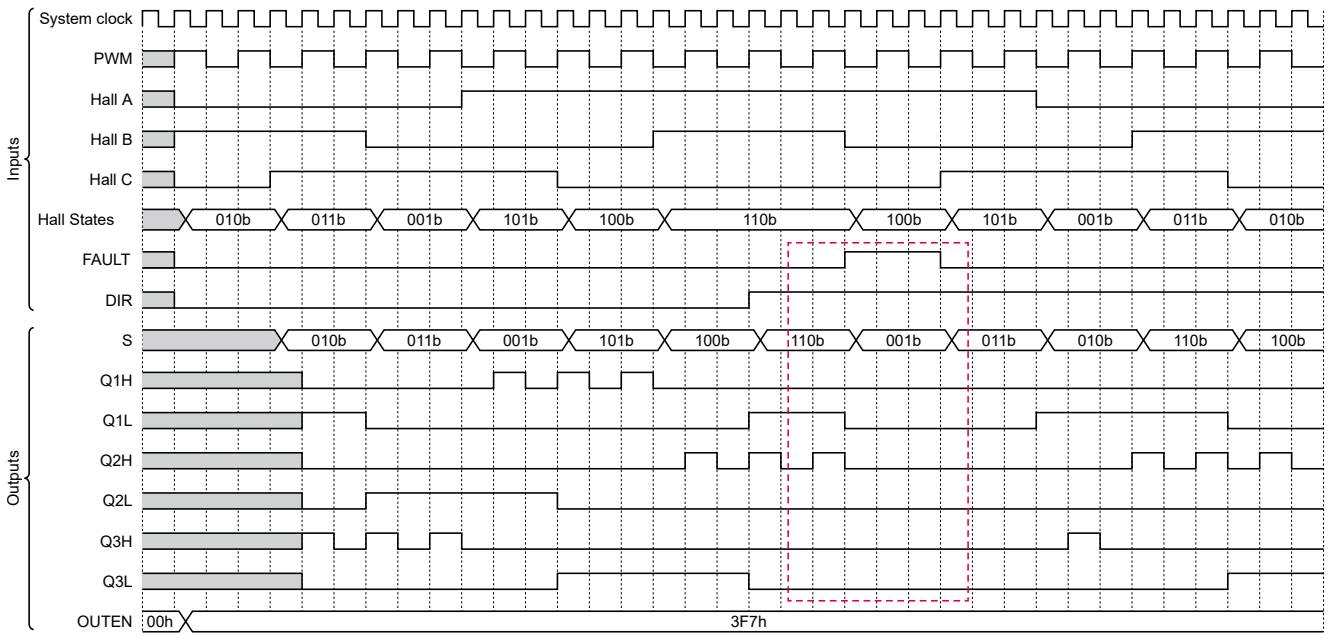

Figure 358. Waveforms for reversing BLDC motor with fault assertion

62.7 Mapping of 12-bit input, output, and state fields

This table maps inputs, outputs, or states to the bit positions in the following 12-bit fields:

- SWEN[SWEN]
- SWVALUE[SWVALUE]
- OUTEN[OUTEN]
- LCIN[LC_INPUTS]
- SWOUT[SWOUT]
- LCOUT[LCOUT]
- FORCEOUT[FORCEOUT]
- FORCESTS[FORCESTS]
- DBGEN[DBGEN]

62.8.2 LC n Output m LUT Control (LC0_LUTCTRL0 - LC2_LUTCTRL3)

Offset

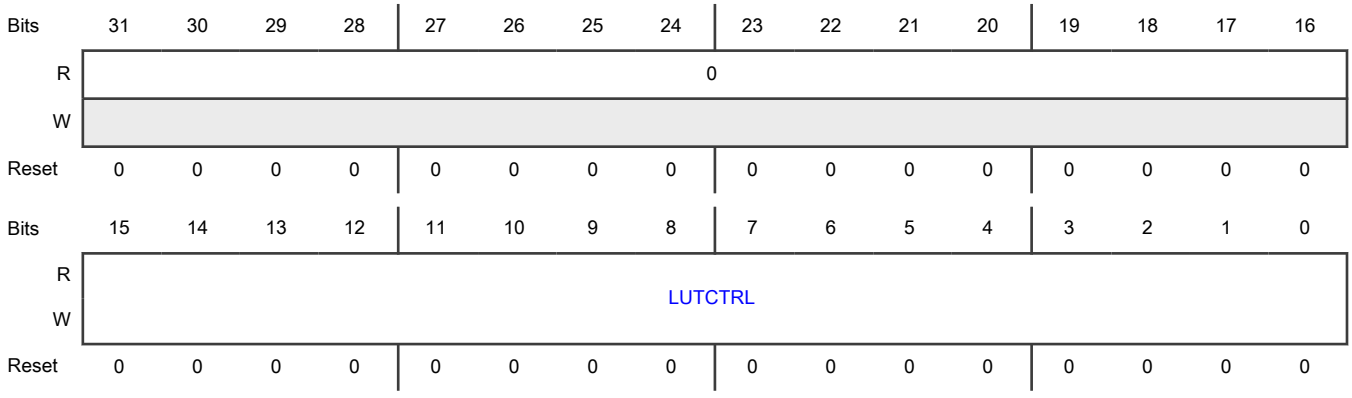
For n = 0 to 2; m = 0 to 3:

Register	Offset
LCn_LUTCTRLm	0h + (n × 40h) + (m × 4h)

Function

See LUTCTRL.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 LUTCTRL	LUT Control Specifies the LUT positions, based on the combined LC input value, that result in assertion of this output. For more information, see Logic operations.

62.8.3 LC n Output m Filter (LC0_FILT0 - LC2_FILT3)

Offset

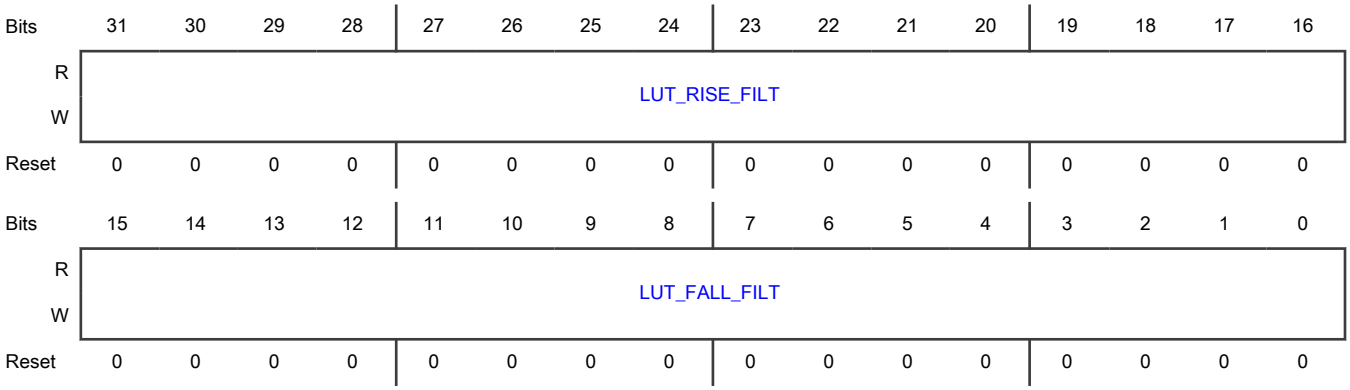
For n = 0 to 2; m = 0 to 3:

Register	Offset
LCn_FILTm	10h + (n × 40h) + (m × 4h)

Function

Specifies the rising- and falling-edge thresholds for the LC output filters.

Diagram



Fields

Field	Function
31-16 LUT_RISE_FILT	Rise Filter Specifies the number of consecutive clock cycles the filter output must be logic 1 before the output signal goes high. 0000_0000_0000_0000b - Bypass filter All other values - Filter threshold

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-0 LUT_FALL_FILT	Fall Filter Specifies the number of consecutive clock cycles the filter output must be logic 0 before the output signal goes low. 0000_0000_0000_0000b - Bypass filter All other values - Filter threshold

62.8.4 LC n Interrupt and DMA Enable (LC0_INTDMAEN - LC2_INTDMAEN)

Offset

Register	Offset
LC0_INTDMAEN	20h
LC1_INTDMAEN	60h
LC2_INTDMAEN	A0h

Function
Enables interrupt and DMA requests for LUT and force events.

Diagram

Fields

Field	Function
31-12 —	Reserved
11-8 FORCESTS	Force Event Indicates that a force event has occurred on the associated output. For each bit: 0b - No event 1b - Event occurred Mapping of bits:

Output	Register bit
0	8
1	9
2	10
3	11

When you enable DMA for a force output (LC*n*_INTDMAEN[FORCE_DMA_EN]) and a force event occurs on that output, LCU generates a DMA request. The resulting DMA done signal causes LCU to change the bit to 0, or you can write 1 to the bit.

You can also change these bits to 0 by writing to the corresponding Force Status bits (FORCESTS[FORCESTS]).

The timing of status clearing depends on the selected Force Mode (LC*n*_FCTRL[FORCE_MODEm]).

7-4 —	Reserved
3-0	LUT Event

Table continued from the previous page...

<table>

Fields

Field	Function
31-28 COMB_FORCE	Combined Sensed Force Input Indicates the combined value of force inputs to each output. For each bit: 0b - Logic low 1b - Logic high Mapping of bits:
27-24 COMB_EN	Combinational Force Path (CFP) Enable Enables an active force input to combinationally affect the LC outputs. When CFP is not enabled, force inputs must be synchronized and then optionally filtered. When you enable CFP (write 1 to one of these bits), the corresponding force input bypasses synchronization and filtering and immediately affects the LC output. The Force Filter (FORCE_FILT) is still in effect. Force inputs that do not meet the pulse width requirements for synchronization and filtering are not registered in Force Status (FORCESTS) and you do not need to write 1 to change the bit to 0. CFP provides a safety factor when the LC outputs drive a motor and immediate response is required. In some topologies, an oscillation can result if the assertion of the force input causes the LC output to turn off. This situation in turn leads to deassertion of the force input and the output turning back on. In general, you

7-0 MUXSEL	Mux Select Selects the source of the LC input. All LU_IN inputs go through a two-stage synchronizer, but the LU_OUT signals fed back to this mux do not have this two-stage delay because they are already synchronous to LCU clock. 0000_0000b - Logic 0 0000_0001b-0000_1100b - LU_IN0 to LU_IN11 0000_1101b-0001_1000b - LU_OUT0 to LU_OUT11 All other values are reserved.

62.8.11 Configuration (CFG)

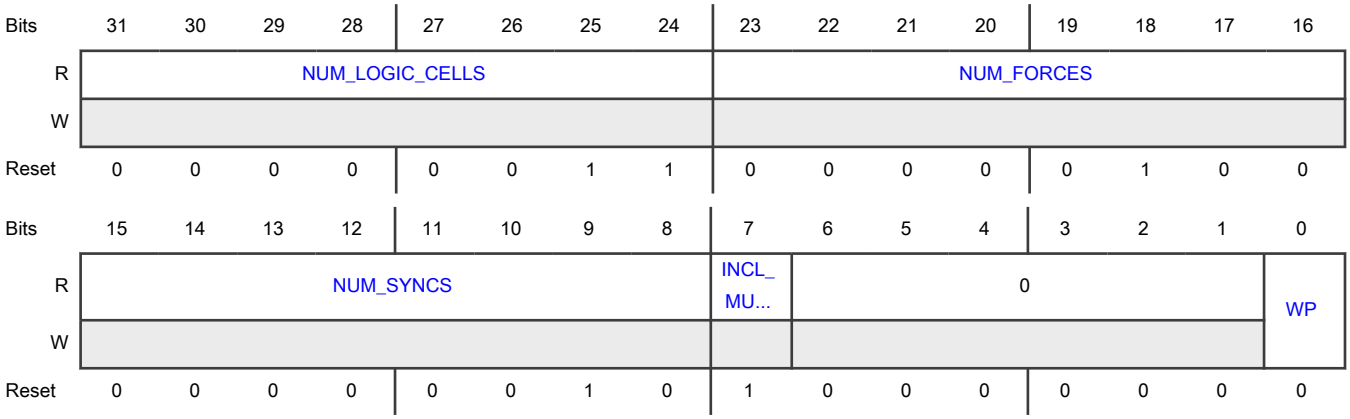
Offset

Register	Offset
CFG	280h

Function

Indicates the LCU configuration, and provides write protection.

Diagram



Fields

Field	Function
31-24 NUM_LOGIC_CELLS	LCs Indicates the number of LCs.
23-16 NUM_FORCES	Force Inputs Indicates the number of force inputs for each LC.
15-8 NUM_SYNCS	Sync Inputs Indicates the number of sync inputs for each LC.
7 INCL_MUXES	Input Muxing Indicates whether LCU supports input muxing. 0b - Not supported 1b - Supported
6-1 —	Reserved
0 WP	Write Protect Turns on write protection for all LCU registers except SWVALUE, LC*n*_STS, and FORCESTS. 0b - No effect 1b - Turn on write protection

62.8.12 Software Override Enable (SWEN)

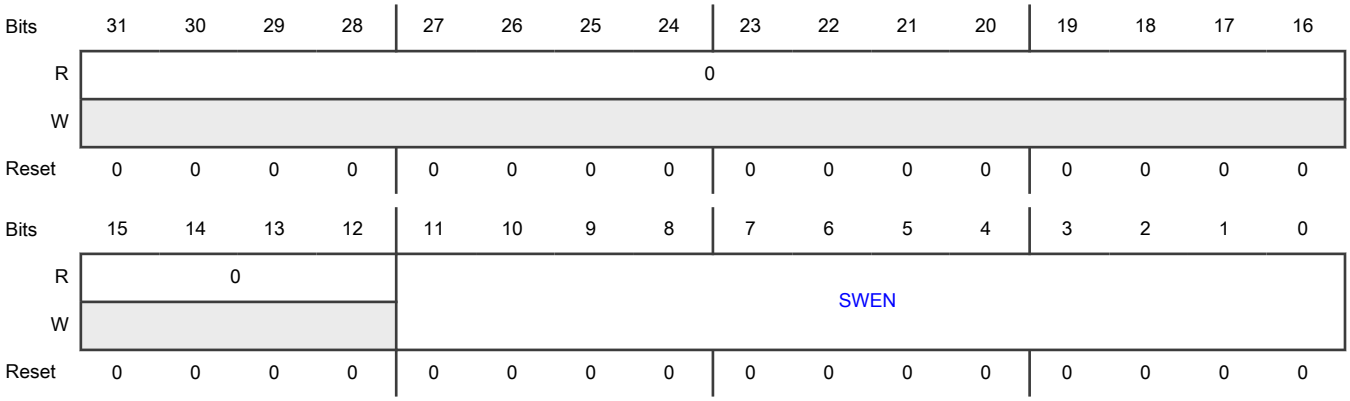
Offset

Register	Offset
SWEN	284h

Function

Enables overrides for LC inputs.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-0 SWEN	Software Override Enable Enables software override of LC inputs. For each bit: 0b - Disable 1b - Enable Mapping of bits: See Mapping of 12-bit input, output, and state fields.

62.8.13 Software Override Value (SWVALUE)

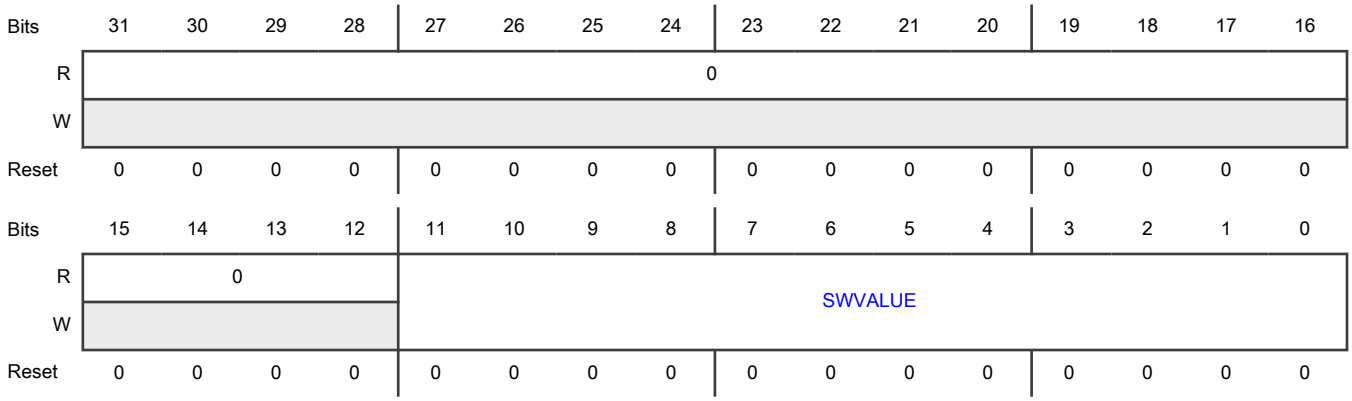
Offset

Register	Offset
SWVALUE	288h

Function

Specifies the software override value for each LC input.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-0 SWVALUE	Software Override Value Specifies the software override value for each LC input. For each bit: 0b - 0 1b - 1 Mapping of bits: See Mapping of 12-bit input, output, and state fields.

62.8.14 Output Enable (OUTEN)

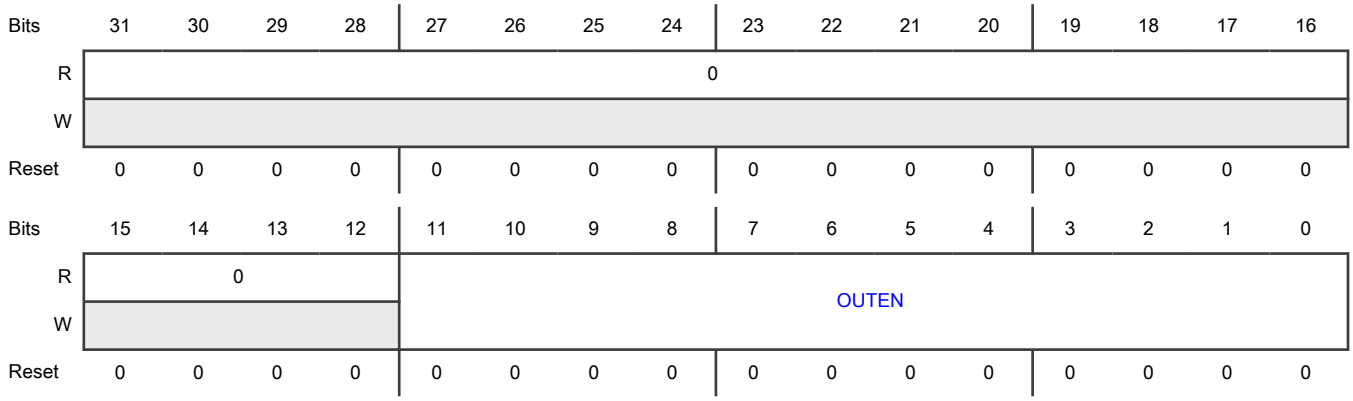
Offset

Register	Offset
OUTEN	28Ch

Function

Enables LC outputs.

Diagram



Fields

Field	Function

Enhanced Modular IO Subsystem (eMIOS)

63.1 Chip-specific eMIOS information

63.1.1 eMIOS configuration

This chip has only 1 instances of eMIOS as shown in the table below:

Table 335. eMIOS instances

Instance	eMIOS_0

Table 336. eMIOS configuration

Parameter	eMIOS_0
Timer width	24 bits
Number of channels	24
Channels configuration	See EMIOS channel configuration figure below
Local Channel prescaler width	4
Number of global counter buses	2
Number of global prescaler	1
Global channel prescaler width	8

NOTE

eMIOS is clocked by CORE_CLK.

EMIOS shall have an option for each channel to support the reload of updated PWM values after 2, 3 or 4 PWM periods.

63.1.2 Channel types

eMIOS contains the following TypeZ channels, which is listed below.

Table 337. eMIOS channel types

Mode Description	Name	Ch TypeZ
General Purpose Input / Output	GPIO	X
Single Action Input Capture	SAIC	X
Single Action Output Compare	SAOC	X
Modulus Counter	MC	X
Modulus Counter Buffered (Up / Down)	MCB	X
Input Pulse Width Measurement	IPWM	X
Input Period Measurement	IPM	X
Double Action Output Compare	DAOC	X

63.1.3 Channel configuration

The eMIOS channel configuration with respect to Type and Counter_bus is shown below.

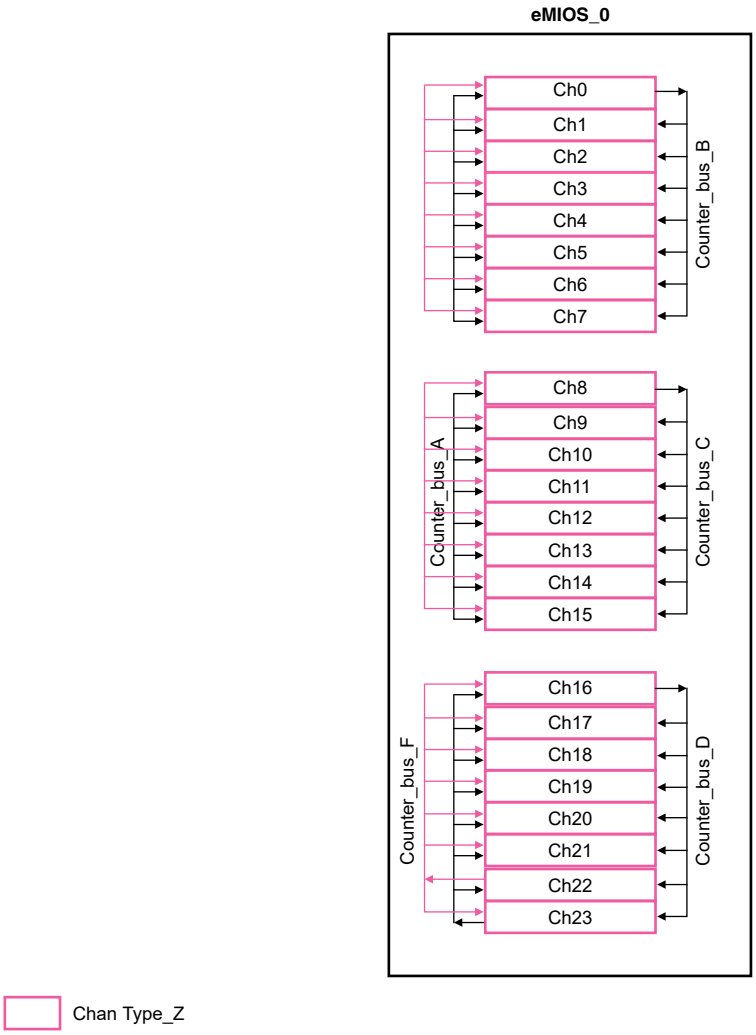

Figure 359. EMIOS channel types

63.1.4 eMIOS disabling

eMIOS can disable it's output using it's disable inputs. Disable inputs[3:0] are driven from the flag out bits[11:8].

Disable inputs	
eMIOS0 Output disable input[3:0]	trgmux_output[71:68]

For details, see the TRGMUX connectivity file attached to this document.

63.1.5 BCTU Interface

Each eMIOS channel, with the exception of the main counterbus channel (ch[23]) is capable of triggering the BCTU. See BCTU chapter for mapping. BCTU allows triggering from as many eMIOS modes as possible.

63.2 Introduction

eMIOS provides independent channels, UCs, that you configure to generate or measure time events for different functions in different chip applications.

eMIOS distributes these channels across a number of global and local counter buses. Each local bus is dedicated to a group of eight contiguous channels. Each channel can generate its own timebase, and each counter bus has its timebase provided by a dedicated channel. For a list of counter buses with their assigned channels and timebase sources, see Counter buses, channels, and timebase sources.

63.3 Block diagram

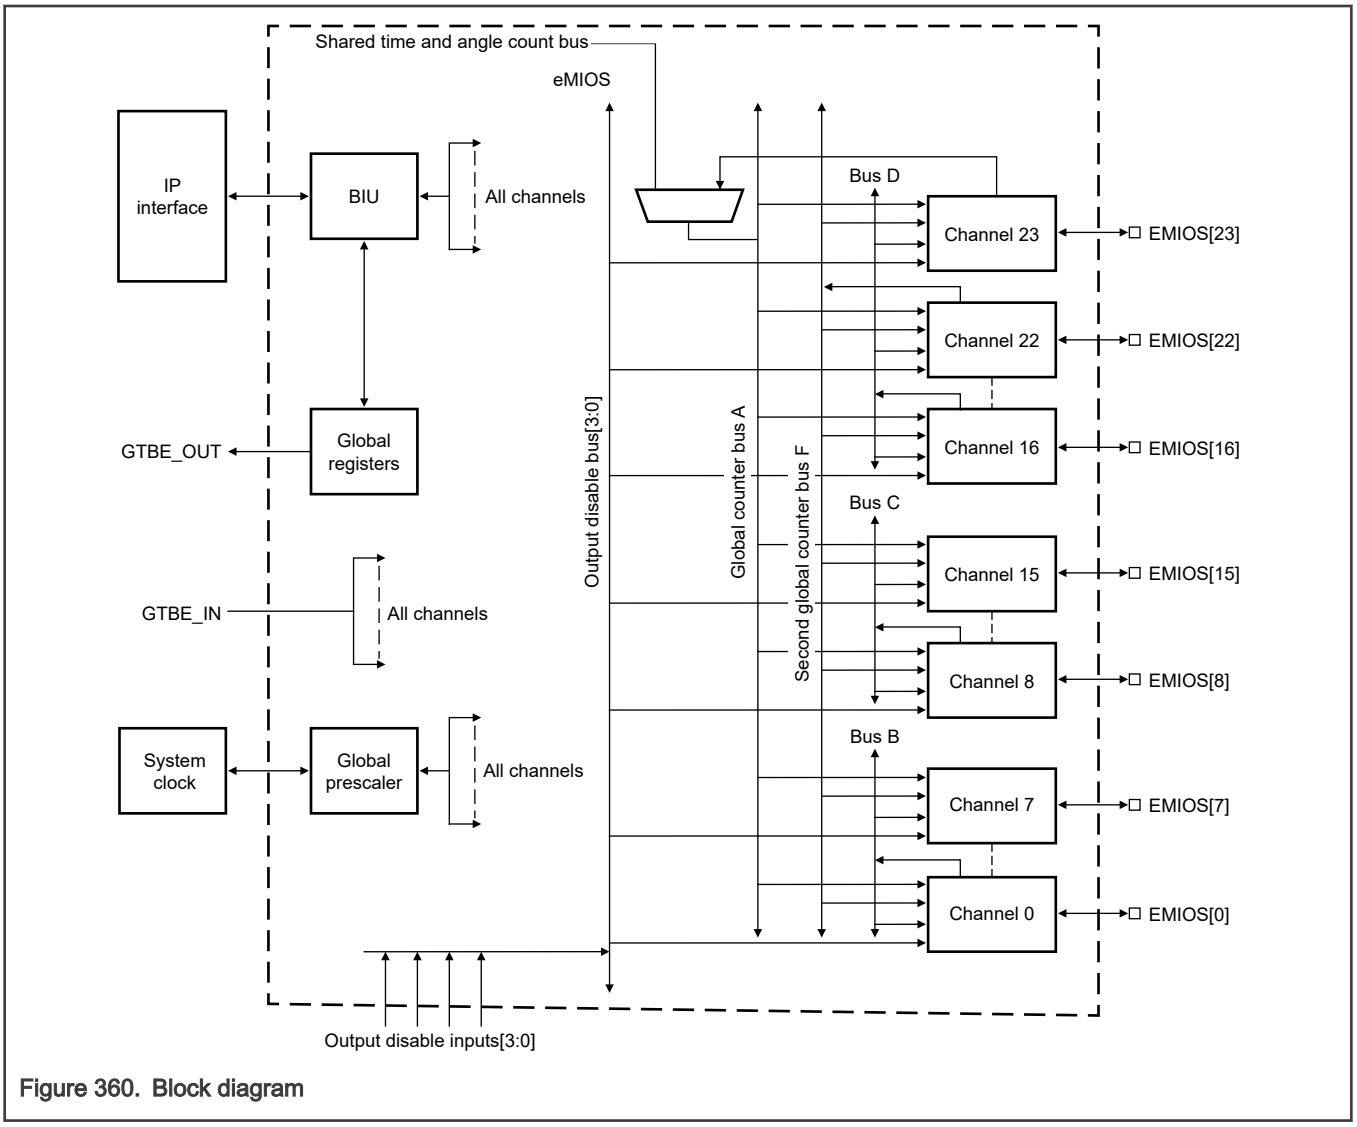

Figure 360. Block diagram

63.4 Features

- 24 UCs distributed across local counter buses as shown in Counter buses, channels, and timebase sources

- Global counter bus A driven by UC23 or by the external shared timer bus (STAC client)
- Global counter bus F driven by UC22
- Synchronized timebases shared through the counter buses
- Dedicated timebase for each channel, distinct from the counter buses
- Global clock prescaler (GCP)
- One CP per channel
- STAC client
- Dedicated set of control and status registers for each UC
- 24-bit–wide data registers
- Shadow flag register (GFLAG) to access all channel flags with one read access
- Ability to freeze the UC state for debug purposes
- Motor control capability

63.5 Functional description

63.5.1 Reset

eMIOS resets asynchronously. Reset affects all registers.

On reset, UCs enter GPIO input mode.

63.5.2 Counter buses, channels, and timebase sources

Table 339. Counter buses, channels, and timebase sources

Counter bus	Channels	Timebase channel
Global bus A	All UCs	23 or the external shared timer bus (STAC client)
Local bus B	• UC0 • UC1 • UC2 • UC3 • UC4 • UC5 • UC6 • UC7	0
Local bus C	• UC8 • UC9 • UC10 • UC11 • UC12	8

Table continues on the next page...

Table 339. Counter buses, channels, and timebase sources (continued)

	• UC13 • UC14 • UC15	
Local bus D	• UC16 • UC17 • UC18 • UC19 • UC10 • UC21 • UC22 • UC23	16
Global bus F	All UCs	22

63.5.3 Unified channels (UC)

63.5.3.1 Overview

Each UC contains the following:

- Two double-buffered data registers, A*n* and B*n*, that allow up to two events—input capture, output compare, or both—to occur before software intervention is needed
- Two comparators, A and B, that indicate when the selected counter bus is equal to the value in A*n* and B*n*
- An internal counter (CNT*n*[C]) that runs in all modes except GPIO.

  You can use this counter as a local timebase or to count input events. You can use it as a timebase if CNT*n*[C] is not used in the current mode.
- An output flip-flop that holds the logic level to be applied to the output pin
- A status register, UC Status n (S0 - S23), that flags input capture and match events, indicates flag overruns and overflows, and shows the input and output pin states
- A control register, UC Control n (C0 - C23), that controls UC operation

You control the following operational characteristics for each UC:

- The logic (C*n*[MODE]) that specifies the behavior of the UC (see UC modes)
- The counter bus (C*n*[BSL]) that provides the timebase for all timing functions
- The CP (C*n*[UCPRE] and C2_*n*[UCEXTPRE])
- The minimum input pulse width (C*n*[IF]) for the input filter that determines valid pin transitions
- Which input edges to detect (C*n*[EDSEL])
- Which of four output disable input signals (C*n*[ODISSL]) to use for disabling outputs
- For all output modes except GPIO, whether to disable the output flip-flop (C*n*[ODIS])

UC block diagram illustrates the basic UC architecture.

For a list of counter buses and their assigned channels and timebase sources, see Counter buses, channels, and timebase sources.

63.5.3.2 UC block diagram

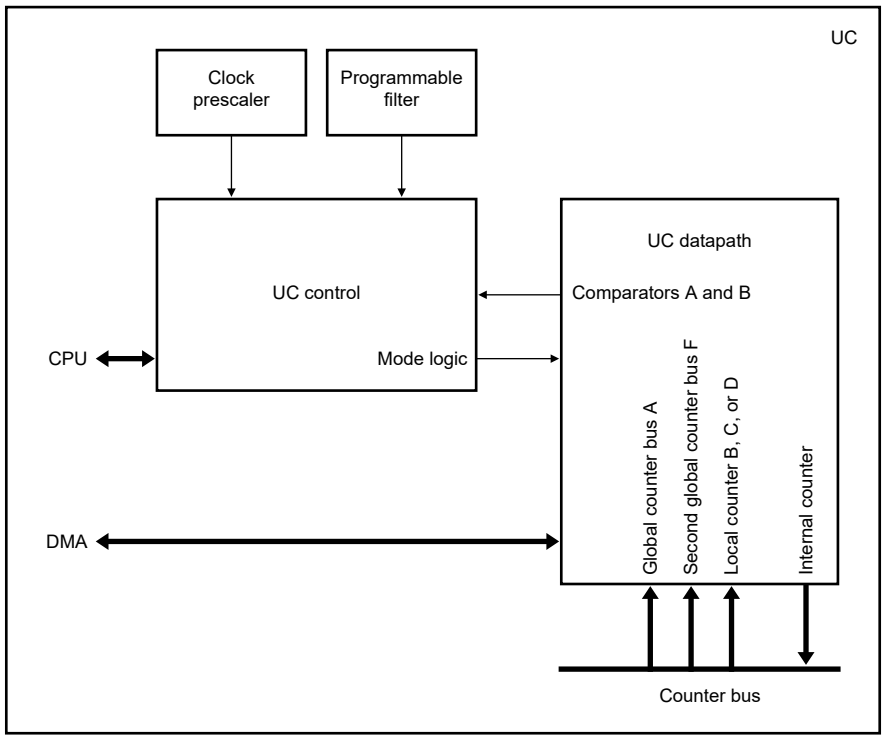

Figure 361. UC block diagram

63.5.3.3 Buffered modes

To provide smooth waveform generation even when A*n*[A] and B*n*[B] are changing, the following modes double buffer the A*n* and B*n* registers:

- Modulus Counter Buffered (MCB) mode
- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Output PWM Buffered (OPWMB) mode

These modes appear in separate sections because there are several basic differences in UC operation between them and their corresponding nonbuffered modes.

63.5.3.4 UC control and datapath

As illustrated in UC control and datapath diagram, the UC contains control and datapath sub-blocks.

The control sub-block generates signals to control the multiplexers in the datapath sub-block. eMIOS implements each UC mode in dedicated logic independent from the other modes. The UC modes share a set of registers allowing the storing of sequential events.

The datapath block contains the channel A and B registers, the internal timebase, and the comparators. Multiplexers receive inputs from the control sub-block to configure the datapath for the specific channel modes. This configuration consists of selecting the input of comparators and data for the register inputs. The outputs of the A and B comparators connect to the control block.

63.5.3.5 UC control and datapath diagram

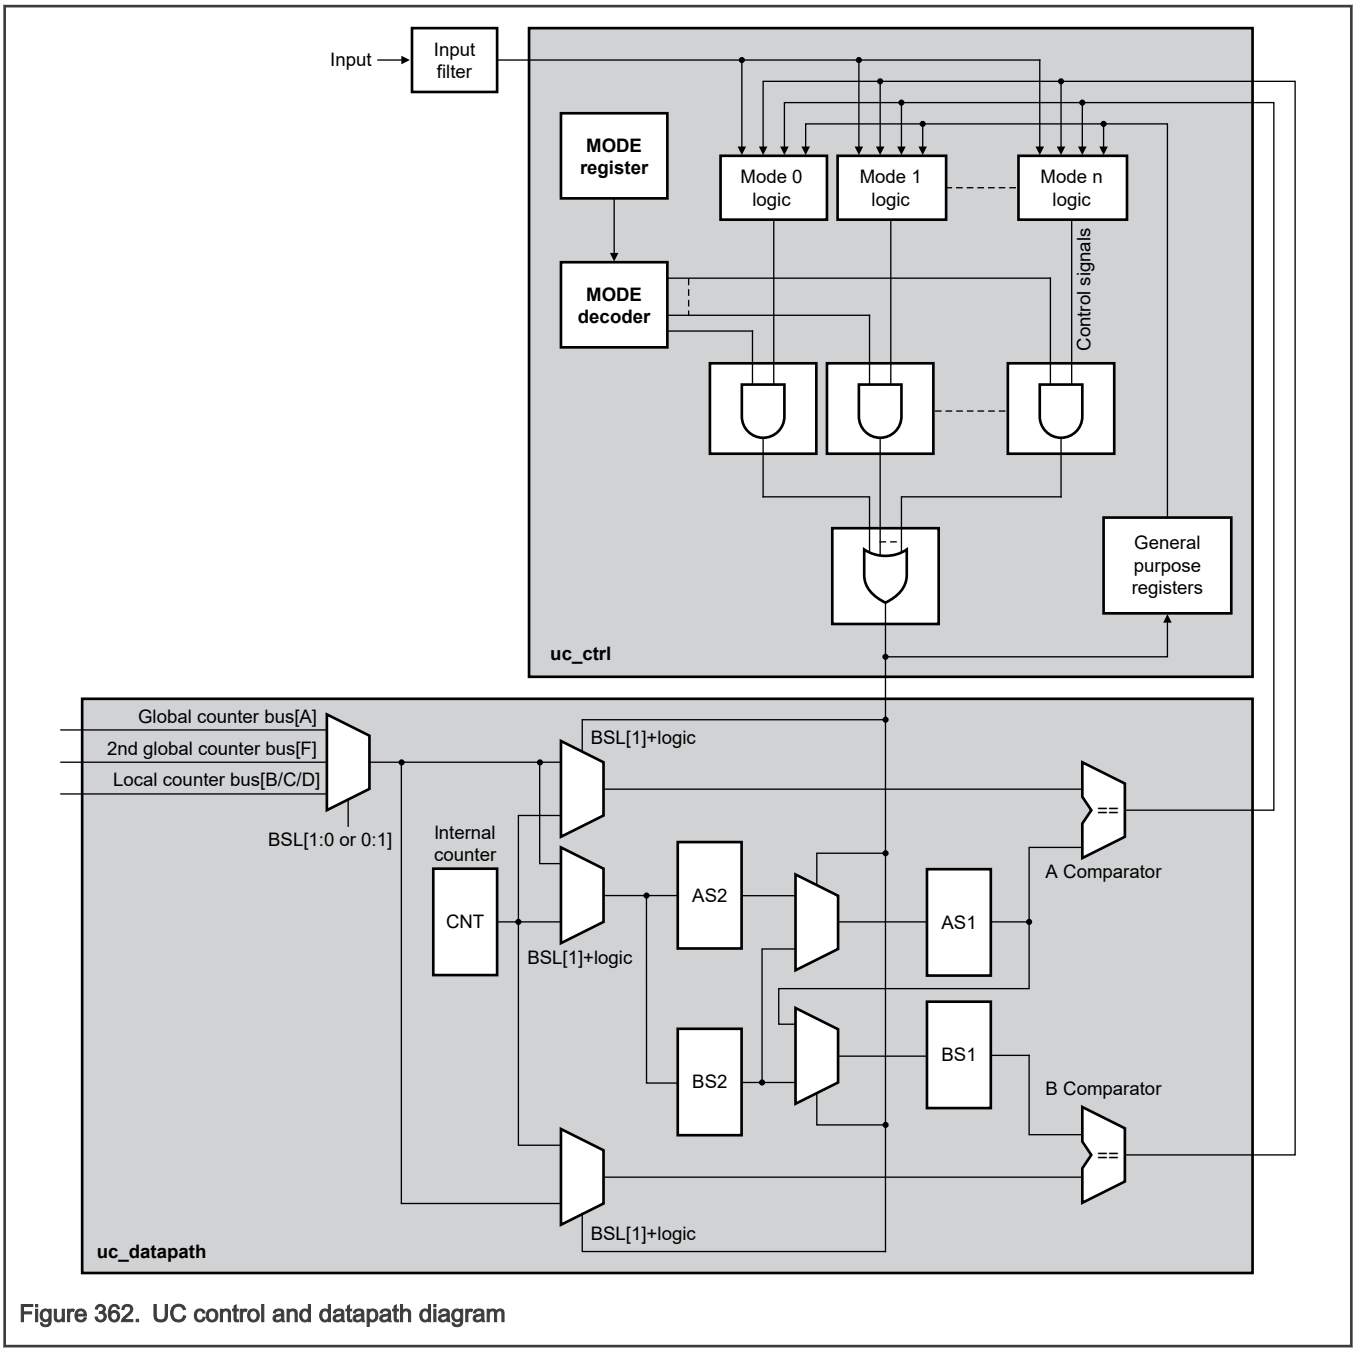

Figure 362. UC control and datapath diagram

63.5.3.6 UC modes

You can configure UCs to operate in the following modes:

- General-Purpose Input and Output (GPIO) mode
- Single Action Input Capture (SAIC) mode
- Single Action Output Capture (SAOC) mode
- Input Pulse Width Measurement (IPWM) mode
- Input Period Measurement (IPM) Mode

- Double Action Output Compare (DAOC) mode
- Pulse or Edge Accumulation (PEA) mode
- Pulse Edge Counting (PEC) mode
- Quadrature Decode (QDEC) mode
- Windowed Programmable Time Accumulation (WPTA) mode
- Modulus Counter (MC) mode
- Modulus Counter Buffered (MCB) mode
- Output Pulse Width and Frequency Modulation (OPWFM) mode
- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Center Aligned Output PWM with Dead Time Insertion (OPWMC) mode
- Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode
- Output PWM (OPWM) mode
- Output PWM Buffered (OPWMB) mode
- Output PWM with Trigger (OPWMT) mode

Each channel supports a specific subset of these modes. See the chip-configuration information to see which modes each channel supports.

63.5.3.7 General-Purpose Input and Output (GPIO) mode

63.5.3.7.1 Overview

This mode disables all UC input-capture and output-compare functions, and resets and disables the internal counter (C*n*[C]). All control fields remain accessible.

To change the UC from one operation mode to another, you must first change to GPIO mode and then change to the desired final mode. To prepare the UC for a new operation mode, you must configure AS1, BS1, AS2, and BS2 before exiting GPIO mode and entering the desired final mode (see AS1, AS2, BS1, and BS2 shadow registers). Specifically:

- Writing to A*n*[A] stores the same value in AS1 and AS2.
- Writing to B*n*[B] stores the same value in BS1 and BS2.
- Writing to ALTA*n*[ALTA] stores a value only in AS2.

As its name implies, GPIO mode supports both input and output submodes. See Differences for input and output submodes.

63.5.3.7.2 Differences for input and output submodes

Table 340. Differences for input and output submodes

Submode	To enter submode, write this value to C*n*[MODE]	Characteristics
Input	0	• You control the generation of input-capture flags with C*n*[EDPOL] and C*n*[EDSEL]. • You can determine the input pin status by reading S*n*[UCIN].
Output	1	• The UC performs as a single output port pin. • The value of C*n*[EDPOL] permanently drives the output flip-flop.

63.5.3.8 Single Action Input Capture (SAIC) mode

63.5.3.8.1 Overview

In this mode, when a triggering event occurs on the input pin, eMIOS:

- Captures the selected timebase into AS2
- Changes S*n*[FLAG] to 1 to indicate that an input capture has occurred

A*n*[A] returns the value of AS2. As soon as the UC enters SAIC mode after exiting GPIO mode, the channel is ready to capture events.

eMIOS captures the events as soon as they occur. Therefore, reading A*n*[A] always returns the value of the latest captured event. Subsequent capture events occur regardless of whether you read the previous event from A*n*[A]. Each new capture event sets the input capture flag (writes 1 to S*n*[FLAG]).

The input capture is triggered by an edge transition on the input pin as configured by C*n*[EDPOL] and C*n*[EDSEL].

SAIC with rising edge triggering and SAIC with both edges triggering show how to use the UC for input capture.

63.5.3.8.2 SAIC submodes and MODE field values

Table 341. SAIC submodes and MODE field values

Capture behavior	C*n*[MODE] (binary)
The UC only captures the timestamp.	000_0010
• The UC captures a timestamp. • AS2 bit 31 indicates the input signal level.	100_0010

63.5.3.8.3 Effect of C*n*[EDPOL] on edge capturing

Table 342. Effect of C*n*[EDPOL] on edge capturing

C*n*[EDPOL]	Input signal transition	Resulting value of AS2 bit 31
0	0→1	0
	1→0	1
1	0→1	1
	1→0	0

63.5.3.8.4 SAIC with rising edge triggering

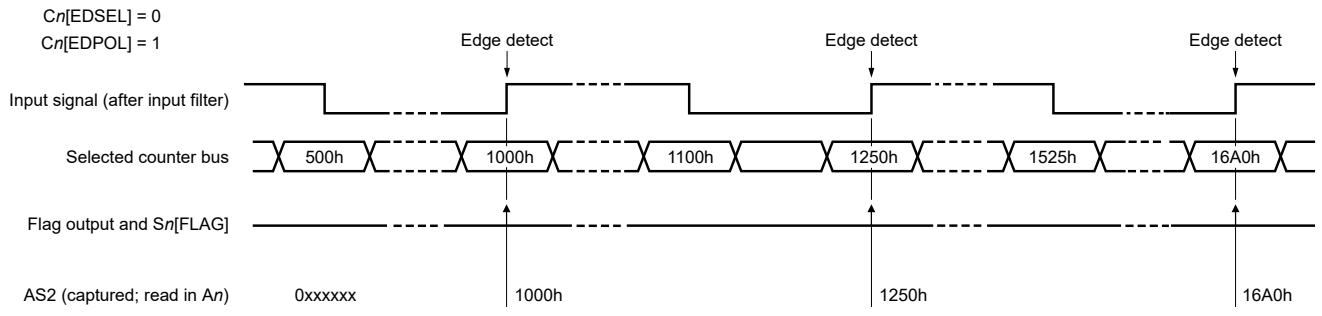

Figure 363. SAIC with rising edge triggering

63.5.3.8.5 SAIC with both edges triggering

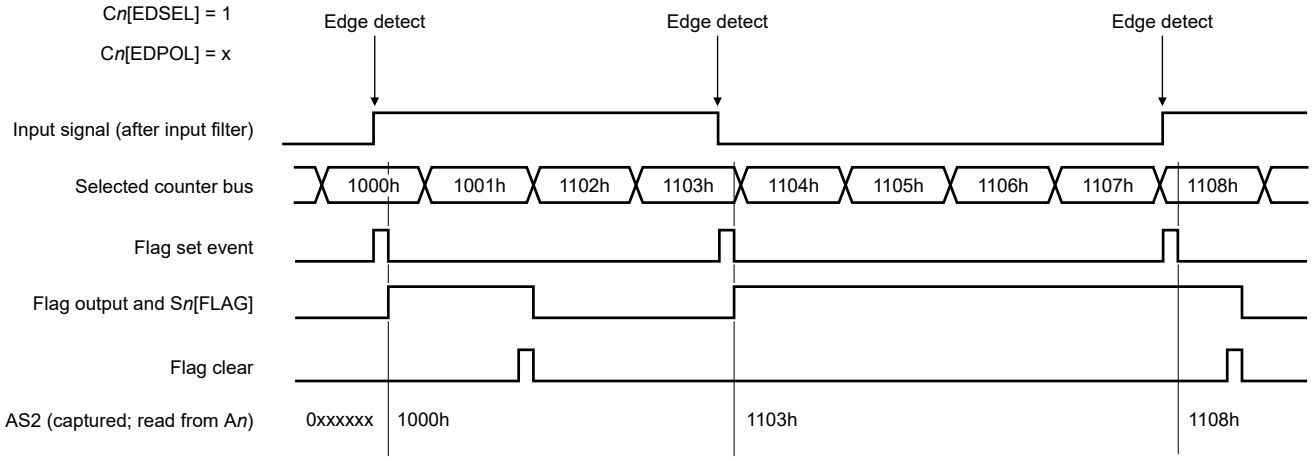

Figure 364. SAIC with both edges triggering

63.5.3.9 Single Action Output Capture (SAOC) mode

63.5.3.9.1 Overview

In this mode, eMIOS loads a match value into AS2 and then immediately transfers it to AS1 for comparison with the selected timebase. When an output-compare match occurs, eMIOS:

- Either toggles the output flip-flop or transfers C*n*[EDPOL] to the output flip-flop, as determined by C*n*[EDSEL].
- Sets the input capture flag (changes S*n*[FLAG] to 1).

Along with the match, S*n*[FLAG] becomes 1 to indicate that the output-compare match has occurred. Writing to A*n*[A] stores the value in AS2, and reading A*n*[A] returns the AS1 value.

The channel internal counter in SAOC mode is free-running. It starts counting as soon as the UC enters SAOC mode.

You can force an output-compare match by writing 1 to C*n*[FORCMA]. A forced output-compare match does not set the input capture flag (S*n*[FLAG]).

When the UC enters SAOC mode after exiting GPIO mode, the output flip-flop value becomes the complement of C*n*[EDPOL].

You select the internal or external counter bus with C*n*[BSL].

SAOC with C*n*[EDPOL] transferred to the output flip-flop shows how to perform a single output compare and transfer C*n*[EDPOL] to the output flip-flop.

SAOC toggling the output flip-flop shows how to perform a single output compare and toggle the output flip-flop at each match.

63.5.3.9.2 Preload the desired match value

eMIOS enables matches immediately after the UC enters SAOC mode. Therefore, you must write the desired match value to AS1 before the UC enters SAOC mode. You can update AS1 at any time. This modifies the match value reflected in the channel-generated output signal. Subsequent capture events occur regardless of whether you write to A*n*[A] again. Each new capture event sets the input capture flag (S*n*[FLAG]). See SAOC with flag behavior.

63.5.3.9.3 SAOC with C*n*[EDPOL] transferred to the output flip-flop

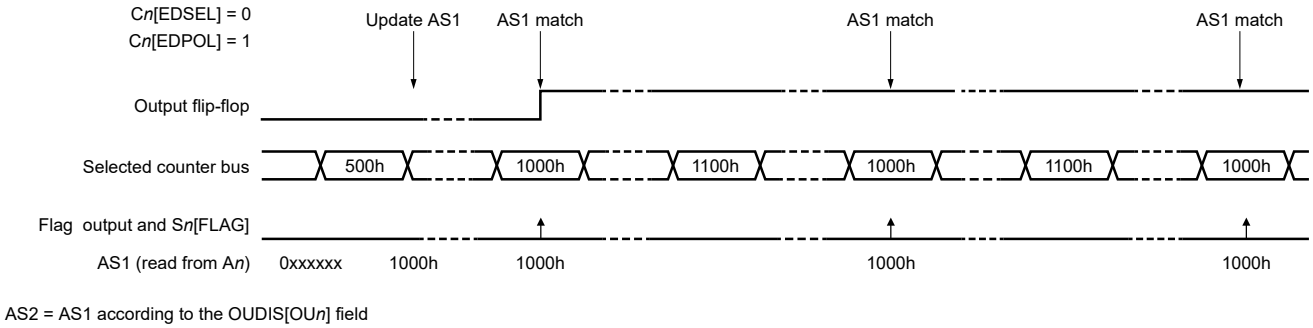

Figure 365. SAOC with C*n*[EDPOL] transferred to the output flip-flop

63.5.3.9.4 SAOC toggling the output flip-flop

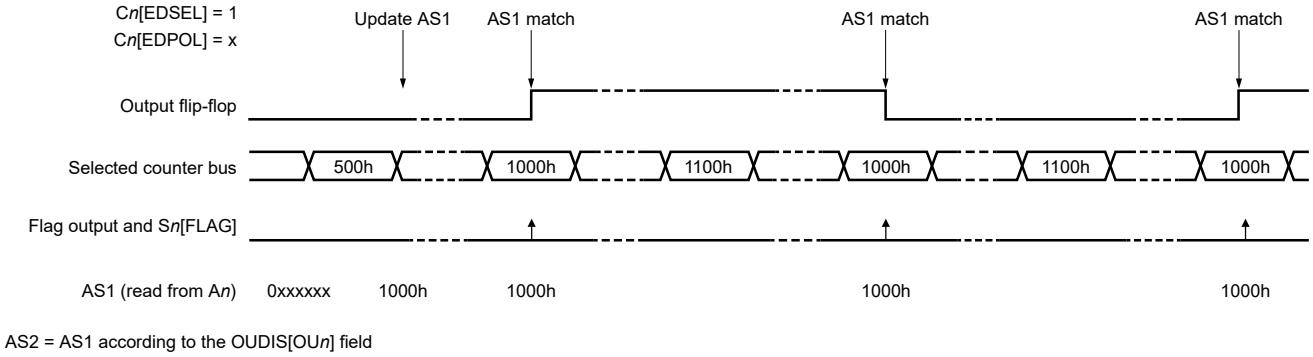

Figure 366. SAOC toggling the output flip-flop

63.5.3.9.5 SAOC with flag behavior

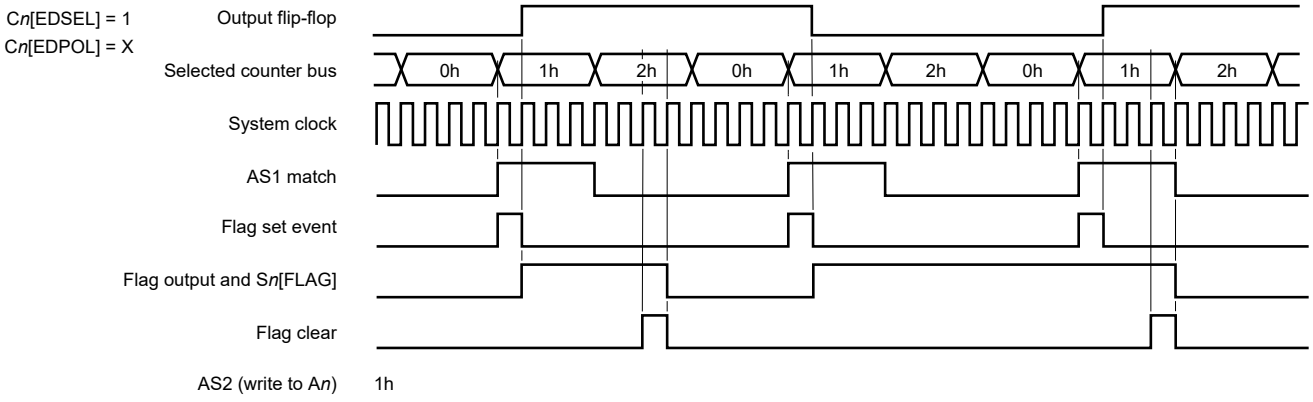

Figure 367. SAOC with flag behavior

63.5.3.10 Input Pulse Width Measurement (IPWM) mode

63.5.3.10.1 Overview

This mode allows you to measure the width of a positive or negative pulse. Select whether to measure from the rising or falling edge with Edge Polarity (Cn[EDPOL]).

The first leading edge:

- Triggers the first input capture, which latches the count value of the selected timebase into BS2 (see AS1, AS2, BS1, and BS2 shadow registers)
- Does not set the input-capture flag (Sn[FLAG])
- Enables AS2 capture

The next trailing edge:

- Latches the selected timebase into AS2
- Sets the input-capture flag (Sn[FLAG])
- Transfers BS2 to BS1 and AS1

eMIOS captures successive values on consecutive edges of opposite polarity. If you initiate subsequent input capture events while the input-capture flag (Sn[FLAG]) is set, eMIOS updates AS2, BS1, and AS1 with the latest captured values and keeps the flag set.

63.5.3.10.2 Coherency

Reading A*n*[A] updates BS1 with AS1. It also disables transfers from BS2 and BS1 until the next read of B*n*[B].

Reading Bn updates BS1 with AS1. It also re-enables transfers from BS2 to BS1, which takes effect at the next trailing edge capture.

Because transfers from BS2 to AS1 are never blocked, to guarantee data coherency you must read An, then read Bn.

If you do not require coherent data, you should read Bn before you read An, although doing so requires a second read of Bn to unblock BS1 updates.

63.5.3.10.3 Timing example: measure pulse width

This figure shows how to measure the input pulse width by subtracting BS1 from AS2.

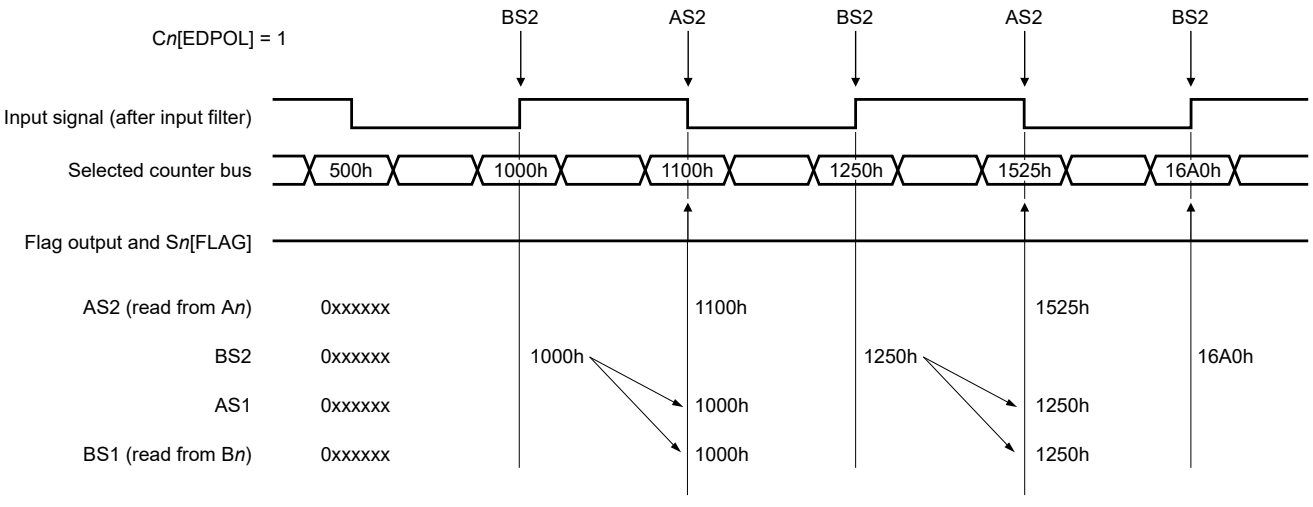

Figure 368. Timing example: measure pulse width

63.5.3.10.4 Timing example: AS1 and BS1 updates on channel reads

This example illustrates AS1 and BS1 updates when you read A*n*[A] and B*n*[B]. AS1 always has coherent data related to AS2 (see Coherency).

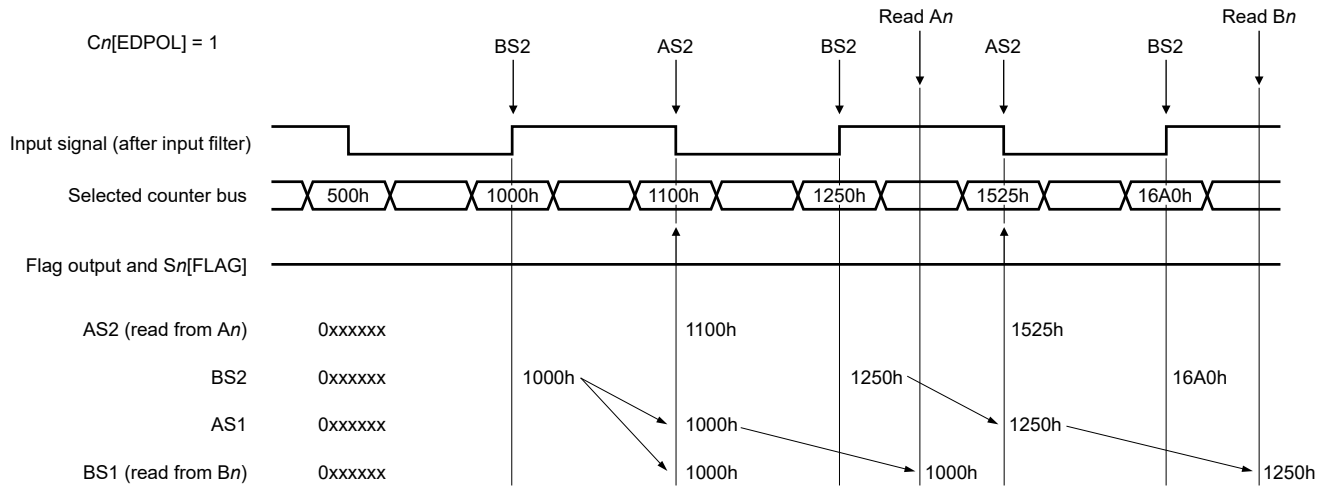

Figure 369. Timing example: BS1 and AS1 updates on channel reads

63.5.3.11 Input Period Measurement (IPM) Mode

63.5.3.11.1 Overview

This mode allows you to measure the period of an input signal. Select whether to measure from the rising or falling edges with Edge Polarity (C*n*[EDPOL]).

The first edge of selected polarity:

- Latches the selected timebase into AS2 and BS2 (see AS1, AS2, BS1, and BS2 shadow registers)
- Transfers BS2 to BS1
- Does not set the input-capture flag (S*n*[FLAG])

The second edge of the same polarity:

- Latches the counter bus value into AS2 and BS2
- Transfers BS2 to BS1 and AS1
- Sets the input-capture flag (S*n*[FLAG])

eMIOS repeats this process for each subsequent capture.

eMIOS captures successive values on two consecutive edges of the same polarity. The measured input signal must have a period of at least four system clock cycles to be properly captured by the synchronization logic at the channel input, even if the input filter is in bypass mode.

63.5.3.11.2 Coherency

Reading A*n*[A] updates BS1 with AS1, which provides coherent data in AS2 and BS1 (see Timing example: AS1 and BS1 updates on channel reads). It also disables transfers from BS2 and BS1 until the next read of B*n*[B].

Reading B*n*[B] updates BS1 with AS1. It also re-enables transfers from BS2 to BS1, which takes effect at the next edge capture.

63.5.3.11.3 Timing example: measure input period

This example illustrates how to measure the input period by subtracting BS1 from AS2.

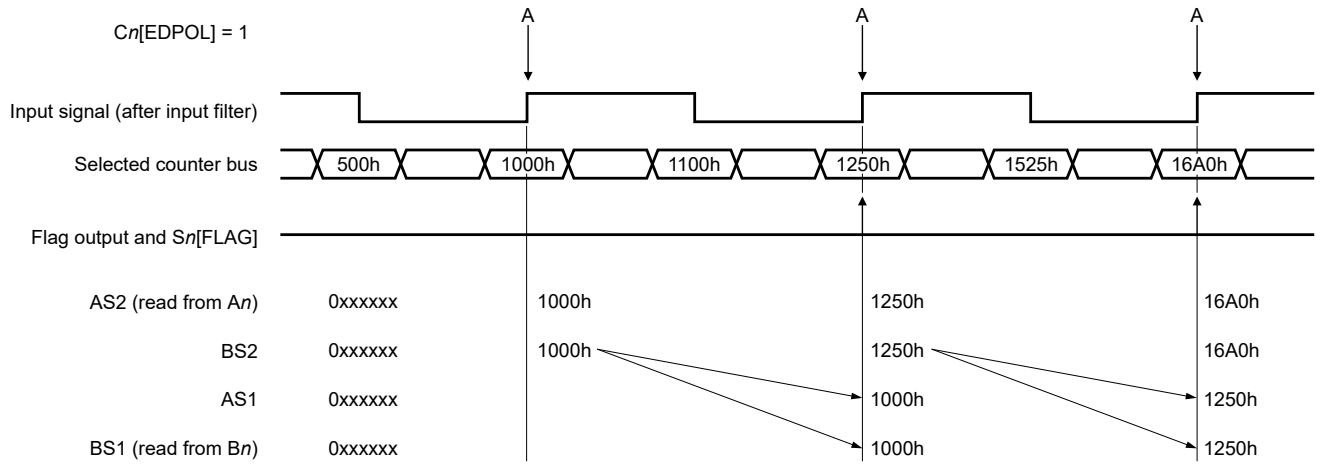

Figure 370. Timing example: measure input period

63.5.3.11.4 Timing example: AS1 and BS1 updates on channel reads

This diagram illustrates AS1 and BS1 updates when you read A*n*[A] and B*n*[B].

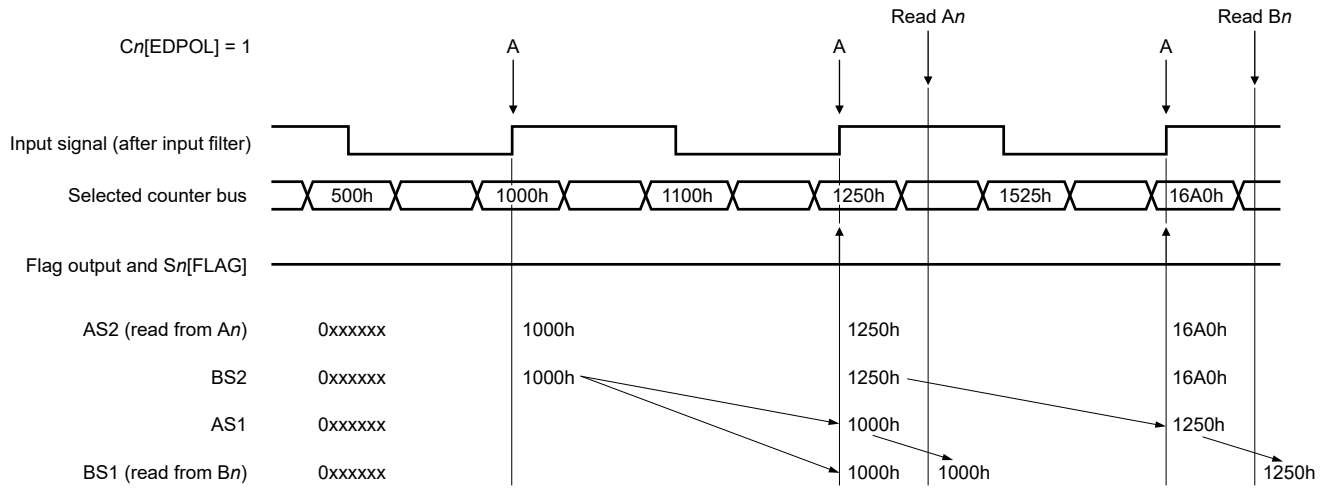

Figure 371. Timing example: AS1 and BS1 updates on channel reads

63.5.3.12 Double Action Output Compare (DAOC) mode

63.5.3.12.1 Overview

In this mode, matches on comparators A and B cause the UC to generate the leading and trailing edges of the variable pulse width output. See DAOC submodes and MODE field values. There is no restriction on the order in which A and B matches occur.

When the UC enters DAOC mode from GPIO mode, eMIOS disables both comparators and drives the complement of Edge Polarity (C*n*[EDPOL]) onto the output flip-flop.

63.5.3.12.2 DAOC submodes and MODE field values

Table 343. DAOC submodes and MODE field values

When set flag event occurs	C*n*[MODE] (binary)
Only on B matches	000_0110
On A or B matches	000_0111

63.5.3.12.3 Data transfer and compare

If you enable output (write 0 to OUDIS[OU*n*]), on the next clock cycle the UC transfers AS2 and BS2 to AS1 and BS1 respectively (see Timing example: leading dead time insertion). If you disable output (write 1 to OUDIS[OU*n*]), no transfer occurs.

eMIOS enables and disables the A and B comparators independently. It enables comparator A only after the transfer to AS1 completes, and disables comparator A on the next A match. Similarly, eMIOS enables comparator B only after the transfer to BS1 completes, and disables comparator B on the next B match.

When a match occurs on comparator A, the output flip-flop acquires the value of Edge Polarity (C*n*[EDPOL]). When a match occurs on comparator B, the output flip-flop acquires the complement of Edge Polarity (C*n*[EDPOL]).

63.5.3.12.4 Differences between flag on A match and flag on A and B matches

In the flag on B match submode (see DAOC submodes and MODE field values), the UC sets the input-capture flag (S*n*[FLAG]) only for matches on the B comparator. In the flag on both A and B matches submode, it sets the flag for matches on either comparator.

If subsequent enabled output compares occur on AS1 or BS1, the UC continues generating pulses regardless of the flag state.

If you load both AS1 and BS1 with the same value, the B match takes precedence and the UC drives the complement of Edge Polarity (C*n*[EDPOL]) onto the output flip-flop.

63.5.3.12.5 Forced operation by Cn[FORCMA] and Cn[FORCMB]

Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to the comparator, Edge Polarity (C*n*[EDPOL]) for an A match, or the complement of Edge Polarity for a B match. The force-match operations do not set the input-capture flag (S*n*[FLAG]).

63.5.3.12.6 Timing example: flag on both matches

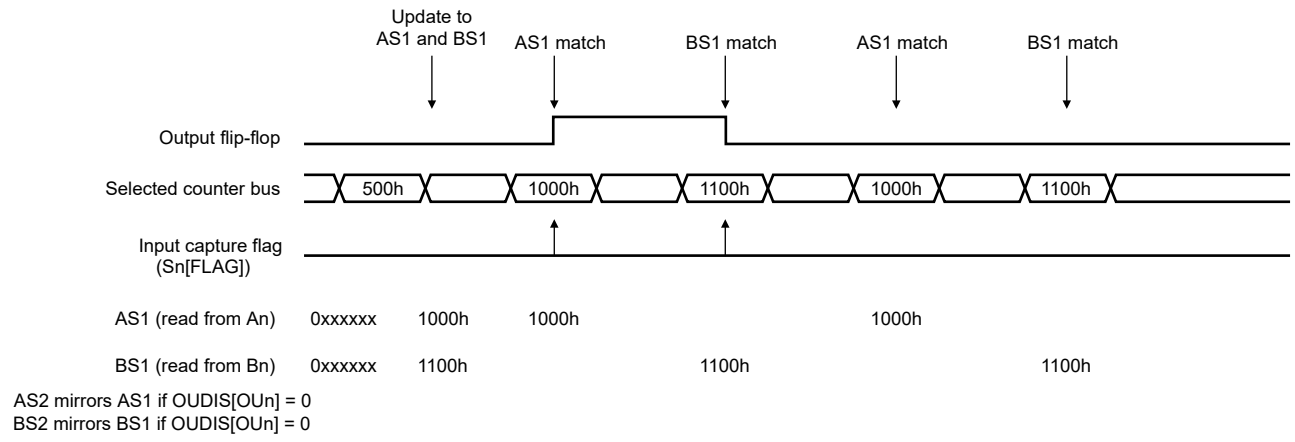

Figure 372. Timing example: flag on both matches

63.5.3.12.7 Timing example: flag on second match

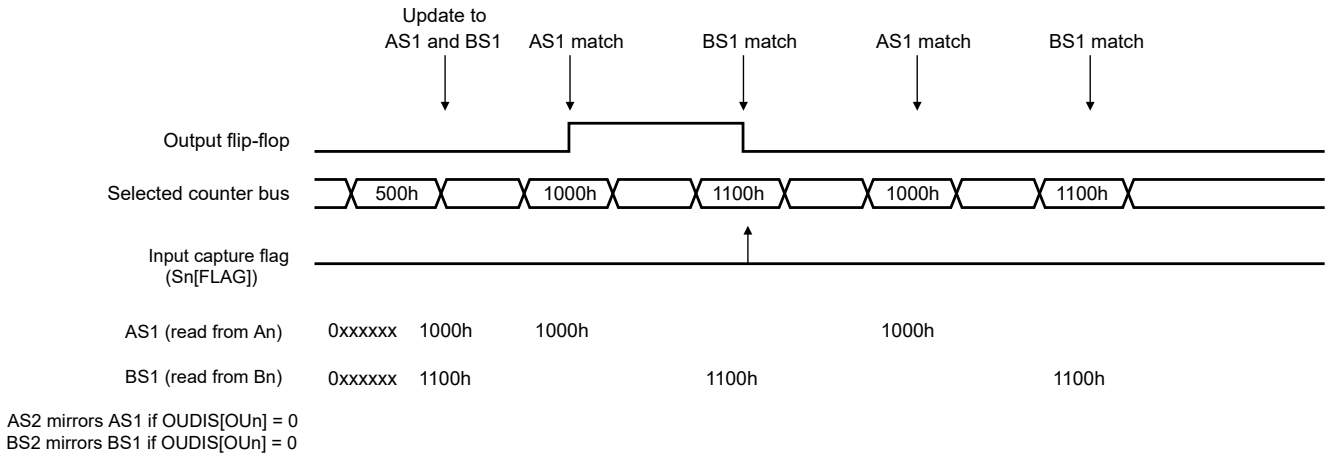

Figure 373. Timing example: flag on second match

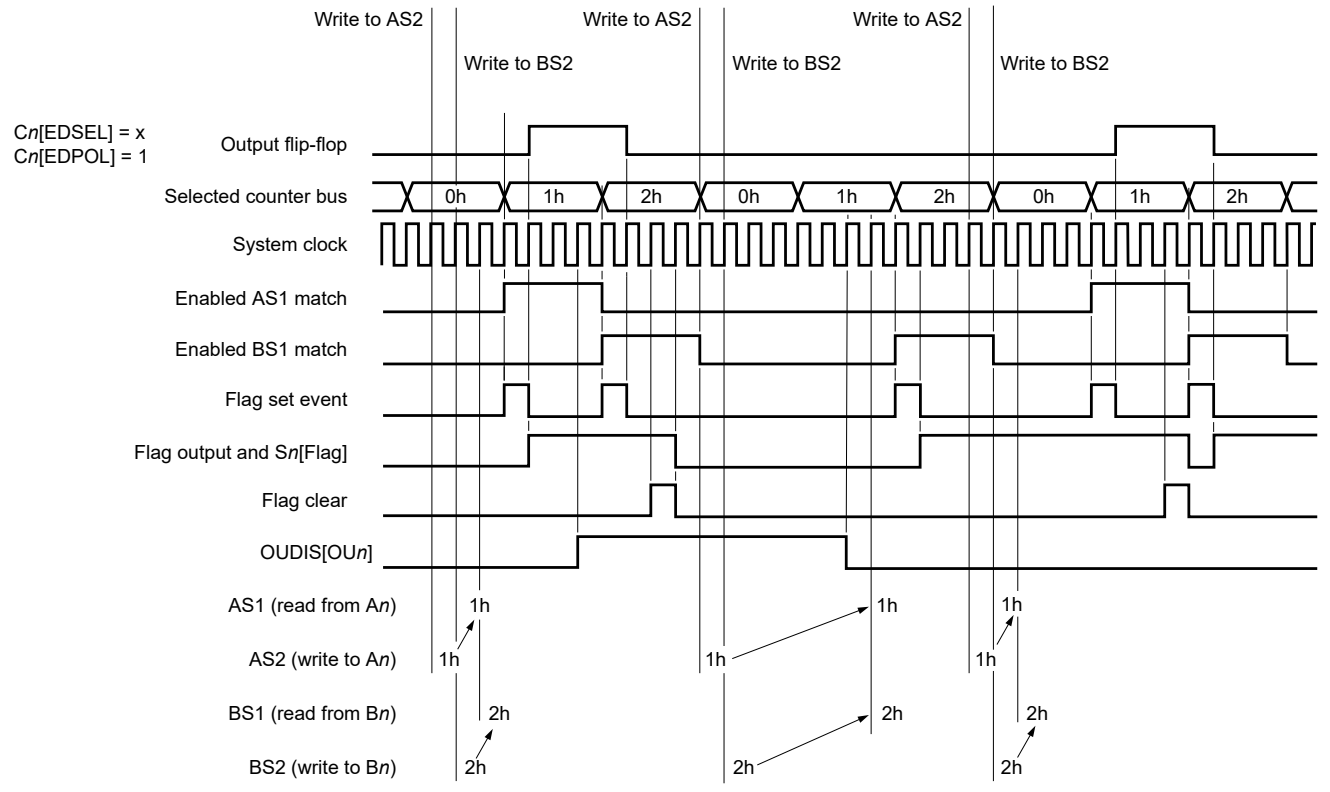

Figure 374. Timing example: transfer disabling

63.5.3.13 Pulse or Edge Accumulation (PEA) mode

63.5.3.13.1 Overview

This mode returns the time taken to detect a desired number of input events.

See PEA submodes and MODE field values for the values that you must write to C*n*[MODE] to enter this mode.

You begin timing by writing the target number of input events to AS1. After you write to AS1, eMIOS:

- Resets the internal counter after the first input event.
- Prepares to start counting input events.
- Stores the selected timebase in BS2.

When the internal counter (CNT*n*[C])matches AS1, eMIOS:

- Captures the counter bus value and stores it in AS2 and BS2.
- Transfers the data previously held in BS2 to BS1.
- Sets the input-capture flag (S*n*[FLAG]) to indicate that an event has occurred.

You determine the desired time interval by subtracting BS1 (read from B*n*[B]) from AS2 (read from A*n*[A]).

Accumulation cycles may be lost if you do not read the data registers in a timely manner. If the input-capture flag is set (S*n*[FLAG] = 1), one or more cycles have been lost.

An edge transition on the input pin—rising, falling, or both—triggers the counter clock (input event). C*n*[EDSEL] and C*n*[EDPOL] select the polarity of the triggering edge.

Timing example continuous and Timing example single-shot show how to use the UC in continuous and single-shot operation.

63.5.3.13.2 PEA submodes and MODE field values

Table 344. PEA submodes and MODE field values

Operation	C*n*[MODE] (binary)
Continuous; eMIOS resets the counter on the next input event after a set-flag event and continues to operate as described in Overview.	000_1000
Single-shot; eMIOS does not reset or increment the counter after a set-flag event until you write to A*n*[A] again.	000_1001

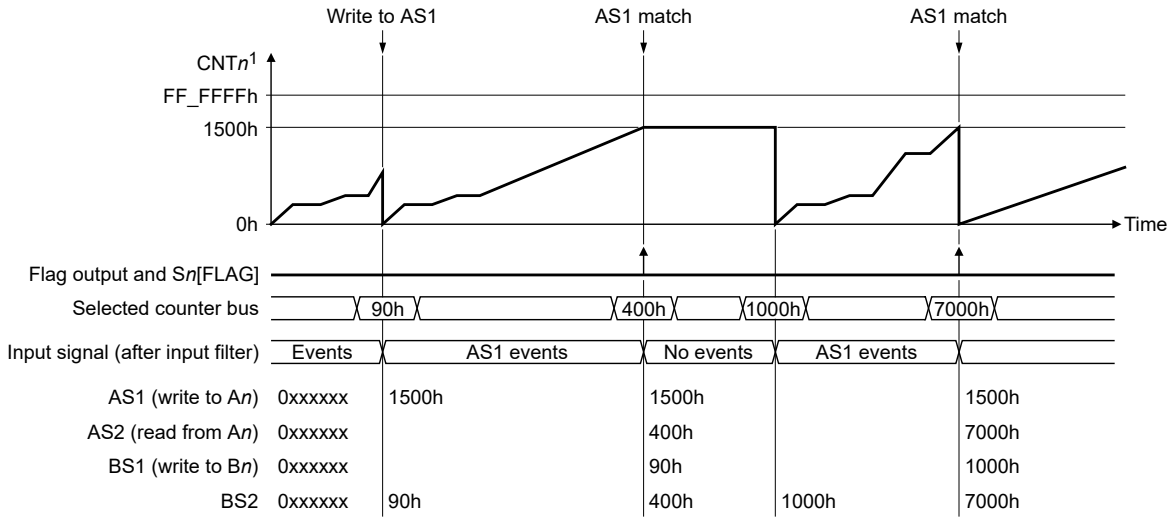
63.5.3.13.3 Data coherency in PEA mode

As part of the coherency mechanism, reading A*n* disables BS2→BS1 transfers. These transfers remain disabled until the next read of B*n*. Reading B*n* re-enables BS2→BS1 transfers, to take effect at the next transfer event, as described above. If BS1 was not updated because you disabled a BS2→BS1 transfer by reading A*n*, further reads of A*n* and B*n* do not return coherent data until a new bus capture is triggered to AS2 and BS2. This capture event is indicated by the set input-capture flag (S*n*[FLAG] = 1). If you enable interrupts (write 0 to C*n*[DMA] and 1 to C*n*[FEN]), the setting of the input-capture flag (S*n*[FLAG]) also generates an interrupt.

To ensure coherent data in continuous operation, perform the following steps. This procedure assumes that S*n*[FLAG] is initially 0.

1. Wait for S*n*[FLAG] to become 1.
2. Read A*n*.
3. Read B*n*.
4. Write 1 to S*n*[FLAG] to clear it.
5. Return to step 1.

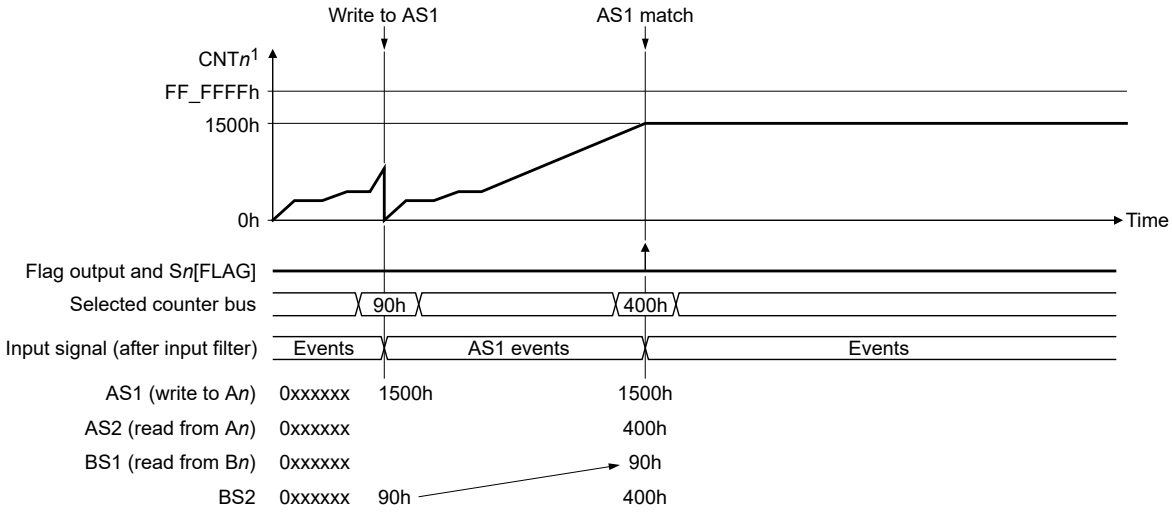
63.5.3.13.4 Timing example continuous



Note: 1. Cleared on the first input event after writing to AS1.

Figure 375. Timing example continuous

63.5.3.13.5 Timing example single-shot



Note: 1. Cleared on the first input event after writing to AS1.

Figure 376. Timing example single-shot

63.5.3.14 Pulse Edge Counting (PEC) mode

63.5.3.14.1 Overview

This mode counts the number of pulses or edges detected on the input for a desired time window. C*n*[EDSEL] and C*n*[EDPOL] determine which edges the UC counts.

Specify the window start time in AS1 and the end time in BS1. After you write to AS1, when the selected timebase matches comparator A, eMIOS resets the internal counter and starts counting input events. When the timebase matches comparator B, eMIOS:

- Disables the internal counter.
- Transfers the counter's content to AS2.
- Sets the input-capture flag (changes S*n*[FLAG] to 1).

You obtain the number of detected pulses by reading C*n*[C] or AS2.

Timing example continuous and Timing example single-shot show how to use the UC in continuous or single-shot operation.

63.5.3.14.2 PEC submodes and MODE field values

Table 345. PEC submodes and MODE field values

Operation	C*n*[MODE] (binary)
Continuous; the next match between comparator A and the selected timebase resets the internal counter and enables counting again. To guarantee coherent measurements when you read C*n*[C] after S*n*[FLAG] becomes 1, you must check if the timebase value is out of the time interval defined by AS1 and BS1. Alternately, AS2 (available in ALTA*n*[ALTA]) always holds the latest available measurement, providing coherent data at any time after the first set-flag event.	000_1010
Single-shot; The next match between comparator A and the selected timebase has no effect until you write to A*n*[A]. eMIOS also transfers the C*n*[C] value to AS2 when a match in the B comparator occurs.	000_1011

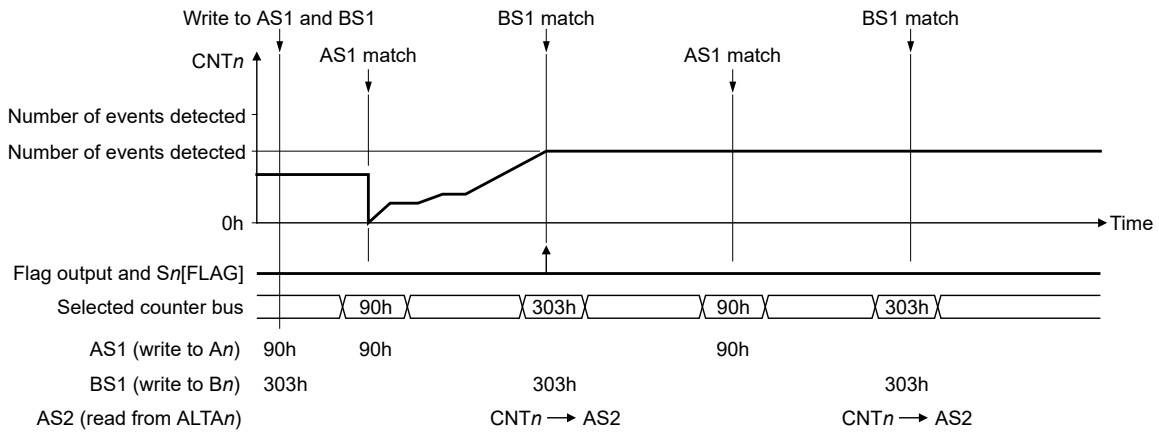

Figure 378. Timing example single-shot

63.5.3.15 Quadrature Decode (QDEC) mode

63.5.3.15.1 Overview

This mode implements a quadrature decoder on input signals corresponding to the current UC and its preceding UC. See QDEC submodes and MODE field values.

Entering QDEC mode automatically selects but does not reset the internal counter. You need to write a target counter value to AS1. The UC sets the input-capture flag (S*n*[FLAG]) when the internal counter matches the target value in AS1.

In QDEC mode, the UC uses the PIF from the next lower numbered UC. This arrangement is circular: the lowest numbered UC uses the PIF from the highest numbered UC.

You can use UC*n*–1 in an operation mode that does not use I/O pins, such as MC mode.

63.5.3.15.2 QDEC submodes and MODE field values

Table 346. QDEC submodes and MODE field values

Type of encoder	C*n*[MODE] (binary)
Count and direction	000_1100
Phase_A and phase_B	000_1101

63.5.3.15.3 Count and direction encoder

When you select the count and direction encoder submode (C*n*[MODE] = 000_1100b), illustrated in Timing example: count and direction encoder:

- Ensure the UC input pin is connected to the direction signal (see the SIUL2 chapter).
- Ensure the next lower numbered UC input pin is connected to the count signal of the quadrature encoder (see the SIUL2 chapter).
- Select the count direction (increment or decrement) according to the direction signal using Edge Polarity (C*n*[EDPOL]).
- Select whether the internal counter is clocked on the rising or falling edge of the count signal using the Edge Polarity of the next lower UC (C*n-1*[EDPOL]).

63.5.3.15.4 Timing example: count and direction encoder

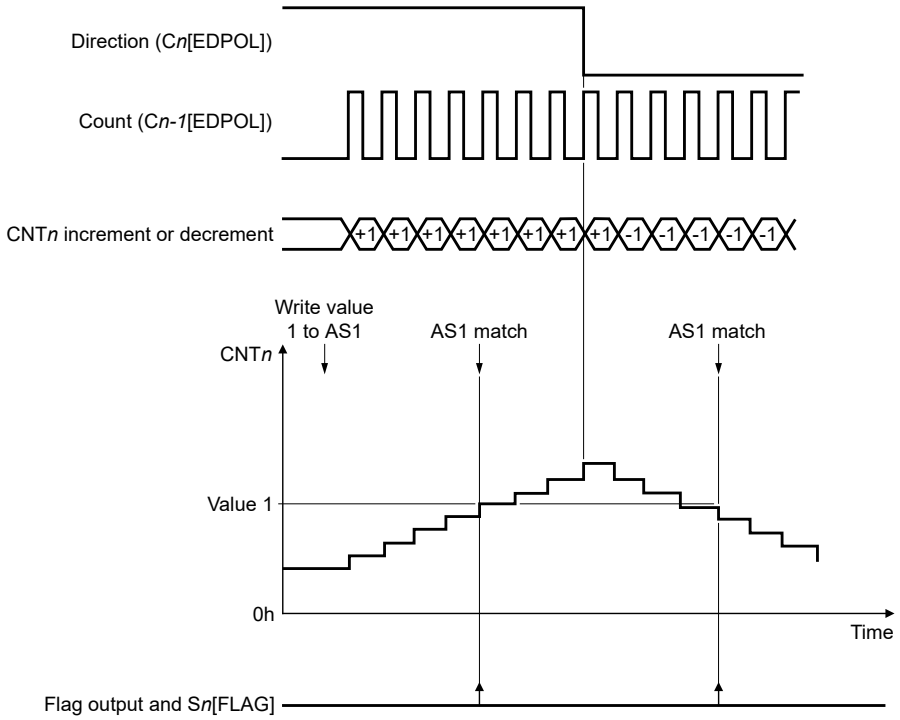

Figure 379. Timing example: count and direction encoder

63.5.3.15.5 Phase_A and phase_B encoder

When you select the phase_A and phase_B encoder submode (C*n*[MODE] = 000_1101b), illustrated in Timing example: phase_A and phase_B encoder:

- Ensure the UC input pin is connected to the phase_A signal
- Ensure the next lower numbered UC input pin is connected to the phase_B signal of the quadrature encoder
- Select the count direction according to the phase difference between the phase_A and phase_B signals using Edge Polarity (C*n*[EDPOL]):
  - If phase_A leads phase_B, count direction is up (increments)
  - If phase_A lags phase_B, count direction is down (decrements)

63.5.3.15.6 Timing example: phase_A and phase_B encoder

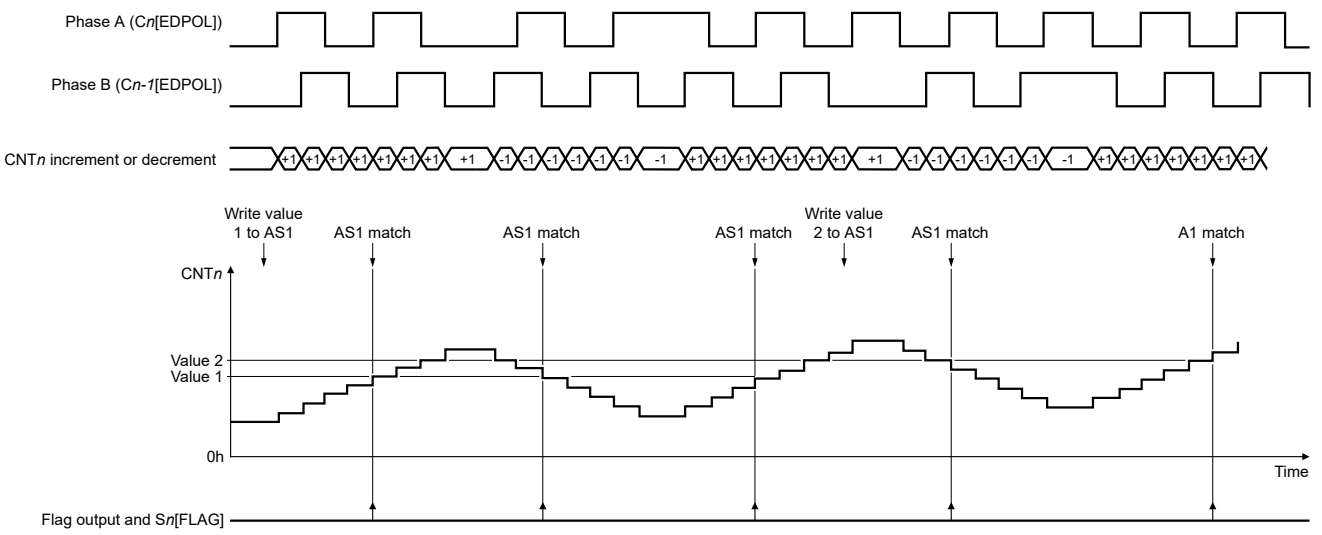

Figure 380. Timing example: phase_A and phase_B encoder

63.5.3.16 Windowed Programmable Time Accumulation (WPTA) mode

63.5.3.16.1 Overview

In this mode (C*n*[MODE] = 000_1110b), eMIOS accumulates the sum of an input signal's total high or low time over a programmable time window.

You control the increment rate of the internal counter by specifying the CP (C*n*[UCPRE]). Specify the window start time in AS1 and the end time in BS1.

When a match occurs between A*n*[A] and the selected timebase, eMIOS resets CNT*n*[C] and starts counting. The internal counter serves as a time accumulator—it counts up when the input-signal polarity matches C*n*[EDPOL], and does not count otherwise. When a match occurs in comparator B, eMIOS:

- Disables the internal counter regardless of the input signal polarity.
- Sets the input-capture flag (changes S*n*[FLAG] to 1).
- Transfers the count (CNT*n*[C]) to AS2.

Reading CNT*n*[C] or AS2 (available in ALTA*n*[ALTA]) returns the high or low time of the input signal.

Timing example illustrates how you can use the UC to accumulate high time.

63.5.3.16.2 Counter and AS2 stability

The internal counter (CNT*n*[C]) is stable only outside the time window defined by AS1 and BS1. Inside the time window, CNT*n*[C] is actively counting and does not reflect the final value. In contrast, AS2 returns the latest available measurement. Because eMIOS updates AS2 only when a comparator B match occurs, AS2 always contains stable and up-to-date data.

63.5.3.16.3 Timing example

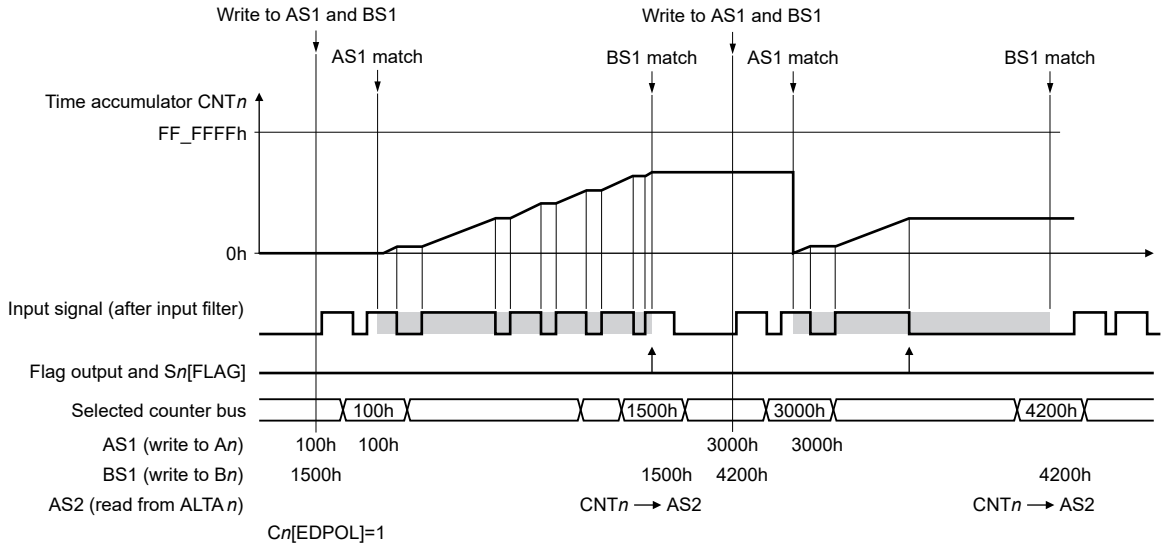

Figure 381. Timing example

63.5.3.17 Modulus Counter (MC) mode

63.5.3.17.1 Overview

In this mode, the UC produces a timebase for a counter bus or as a general purpose timer. The internal counter (C*n*[C]) counts up from the current value until it matches AS1.

Selecting external clock source (see MC submodes and MODE field values) causes the UC to uses the input signal pin as the source. You select the triggering polarity edge using Edge Polarity (C*n*[EDPOL]) and Edge Select (C*n*[EDSEL]).

You must write only non-zero values to A*n*[A]. Writing to A*n*[A] or the internal counter may cause a match to be missed and the counter to roll over and resume operation in the next cycle. The channel writes 0 to BS1, which is not accessible by the MCU. You can read and write BS2, but it is not used in this mode.

63.5.3.17.2 MC submodes and MODE field values

Table 347. MC submodes and MODE field values

Submode or function	C*n*[MODE] (binary)
Internal clock source	001_0pp0[1]
External clock source	001_0pp1[1]
Internal counter reset on match start	001_0p0p[1]
Internal counter reset on match end	001_0p1p[1]
Up Count	001_00pp[1]
Up Count-Down Count	001_01pp[1]

1. *p* = Adjust parameters for submodes and options. See Unified channels (UC).

63.5.3.17.3 Up Count submode

Table 348. Up Count submode operation

Counter reset timing[1]	C*n*[MODE]		
	Bit 1	External clock (Bit 0 = 1)	Internal clock (Bit 0 = 0)
Reset on match start	0	When the AS1 match occurs, the UC: • Writes 0 to the internal counter. • Sets the input-capture flag (S*n*[FLAG]). • Increments the internal counter at the next input event, resulting in a short zero count.	When the AS1 match occurs, the UC: • Writes 0 to the internal counter. • Sets the input-capture flag (S*n*[FLAG]). • Maintains the internal counter at 0 on the next prescaler tick after the match. • Resumes counting on the next prescaler tick.
		See Timebase with the fastest prescaler ratio and Timebase generation with clear on match start and internal clock.	
Clear on match end	1	When the next input event after the AS1 match occurs, the UC: • Writes 0 to the internal counter. • Sets the input-capture flag (S*n*[FLAG]).	When the next internal counter tick after the AS1 match occurs, the UC: • Writes 0 to the internal counter. • Sets the input-capture flag (S*n*[FLAG]).
		See Timebase with the fastest prescaler ratio and Timebase generation with clear on match end.	

1. If you select internal clock source and a prescaler value of 1 for the internal counter, the behavior is the same for both submodes.

See Timing example: Up Count submode.

63.5.3.17.4 Timing example: Up Count submode

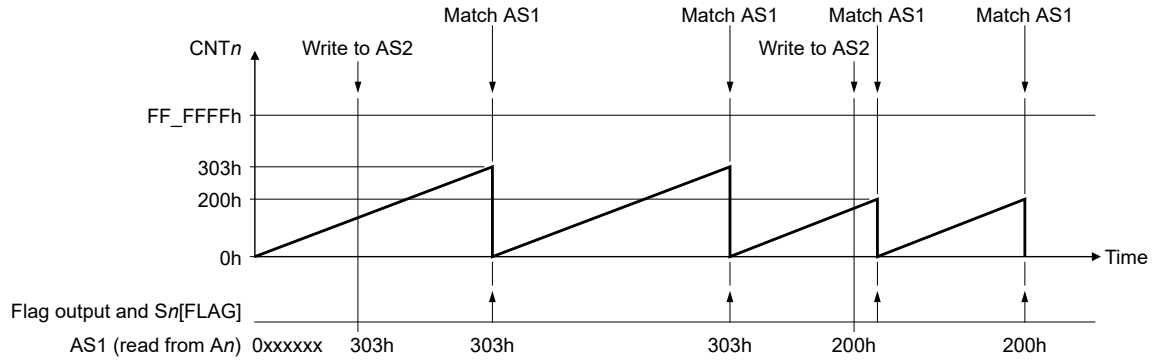

Figure 382. Timing example: Up Count submode

63.5.3.17.5 Up Count-Down Count submode operation

In Up Count-Down Count submode:

- When the internal counter matches AS1, the counter begins decrementing and the UC sets the input-capture flag (S*n*[FLAG]).
- When the internal counter matches BS1, the counter begins incrementing and, if in clear on match end operation (C*n*[1] = 1), the UC sets the input-capture flag (S*n*[FLAG]).

See Timing example: Up Count-Down Count submode.

63.5.3.17.6 Timing example: Up Count-Down Count submode

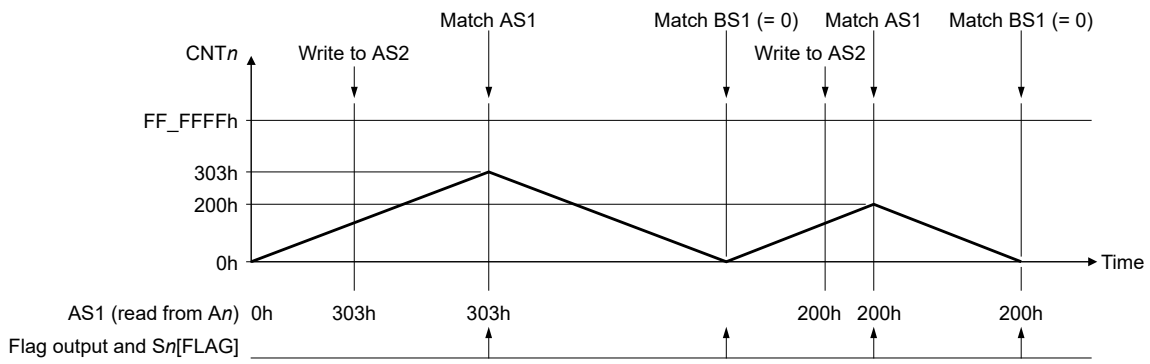

Figure 383. Timing example: Up Count-Down Count submode

63.5.3.17.7 Up Count with delayed reload operation

When the internal counter matches AS1 in the Up Count submode or BS1 in the Up Count-Down Count submode, the UC asserts the counter bus reload signal. You can read the counter bus reload signal in the following modes:

- Output PWM Buffered (OPWMB) mode
- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode

You can use the Reload Signal Output Delay Interval (C2*n*[UCRELDEL_INT]) to cause the UC to assert the reload signal only after a specified number of match events (from 2 to 32).

See Timing example: Up Count mode with delayed reload.

63.5.3.17.8 Timing example: Up Count mode with delayed reload

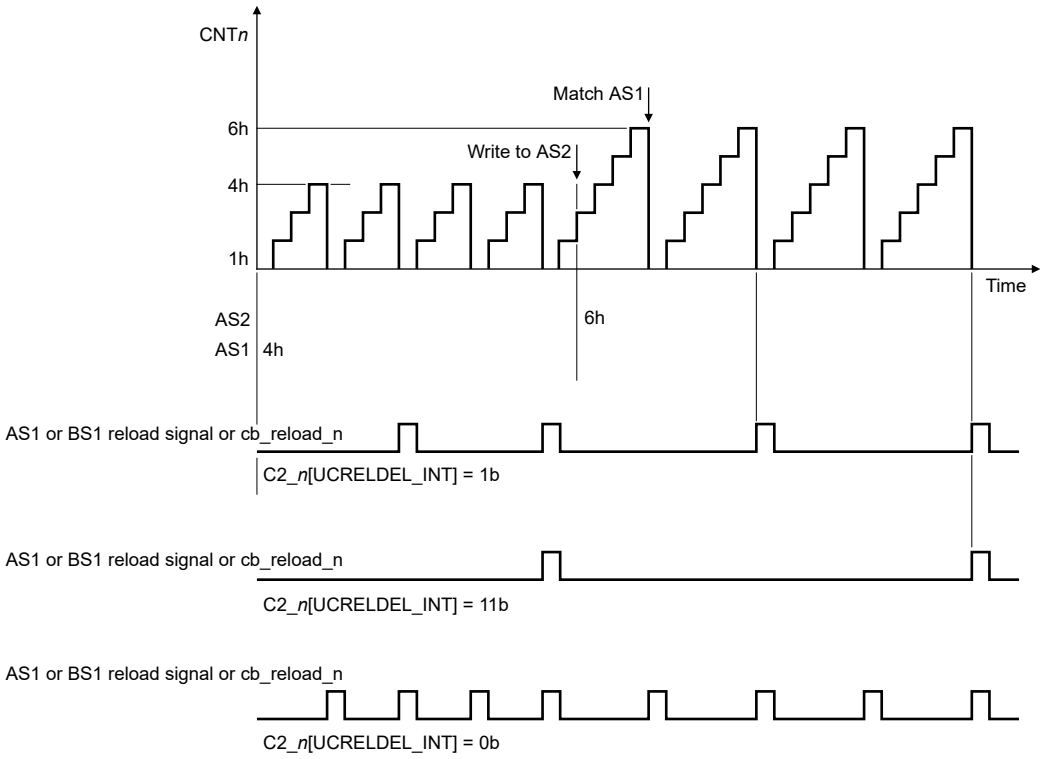

Figure 384. Timing example: Up Count mode with delayed reload

63.5.3.18 Modulus Counter Buffered (MCB) mode

63.5.3.18.1 Overview

In this mode, the UC generates a timebase that can be shared with other channels through the internal counter buses. AS1 is double-buffered, so you can change AS2 at any time with smooth transitions. The UC updates AS1 at the counter period boundary, which is when the internal counter (CNT*n*[C]) transitions to 1h.

Selecting external clock (see MCB submodes and MODE field values) causes the UC to use the input signal as the source. You select the triggering edge with Edge Polarity (C*n*[EDPOL]) and Edge Select (C*n*[EDSEL]).

You must ensure the internal counter is in the range from 1h to the AS1 value; otherwise, the A*n*[A] match does not occur and this causes the internal counter to wrap at the maximum counter value (FF_FFFFh for a 24-bit counter). After a counter wrap occurs, the UC resets the counter to 1h and resumes normal operation.

NOTE

Do not write 1h to the internal counter when the UC is in Freeze state. Doing so can cause the match to be missed and the counter to overflow.

63.5.3.18.2 Changing to MCB mode

To avoid causing an unexpected interrupt or DMA request, you must use the following procedure to change to MCB mode:

1. Put the UC in GPIO mode (write 0b or 1b to C*n*[MODE]).
2. Disable the UC input capture flag (write 0 to C*n*[FEN]).
3. Write the correct values for MCB mode to A*n* and B*n*.

4. Put the UC in MCB mode (write the appropriate value to C*n*[MODE], as described in MCB submodes and MODE field values).
5. Clear the UC input capture flag (write 1 to S*n*[FLAG]).
6. Enable the UC input capture flag (write 1 to C*n*[FEN]).

63.5.3.18.3 MCB submodes and MODE field values

Table 349. MCB submodes and MODE field values

Submode or function	C*n*[MODE] (binary)
Internal clock source	101_0pp0b[1]
External clock source	101_0pp1b[1]
Up Count	101_000p[1]
Reserved	101_001p[1]
Up Count-Down Count	101_01pp[1]
Flag set only on match start	101_010p[1]
Flags also set at counter period boundary	101_011p[1]

1. *p* = Adjust parameters for submodes and options. See Unified channels (UC).

63.5.3.18.4 Up Count submode

In the Up Count submode:

- The internal counter (CNT*n*[C]) starts counting up (incrementing) from its current value.
- When the internal counter matches AS1 and a clock tick occurs (either prescaled clock or input pin event), the UC resets the internal counter to 1h.
- The UC sets the input-capture flag (S*n*[FLAG]) one system clock cycle after the match occurs.

You must write only values greater than 1h to AS1.

The boundary between counter period *n* and period *n*+1 occurs when the UC changes the internal counter from the AS1 value in period *n* to 1h in period *n*+1. AS1 defines the counter period.

The UC asserts the AS1 load signal (which has a duration of one system clock cycle) at the last system clock cycle of a counter period. This causes the UC to update AS1 with AS2 at the period boundary, at the same time that it resets the counter to 1h. Therefore, any value you write to AS2 during period *n* updates AS1 at the next period boundary and the UC uses it in period *n*+1. See Timing example: Up Count submode.

You can use Output Update Disable (OUDIS) to delay the update of AS1 for synchronization.

The UC sets the input-capture flag (S*n*[FLAG]) at the period boundary. See Timing example: Up Count submode flag assertion.

63.5.3.18.5 Timing example: Up Count submode

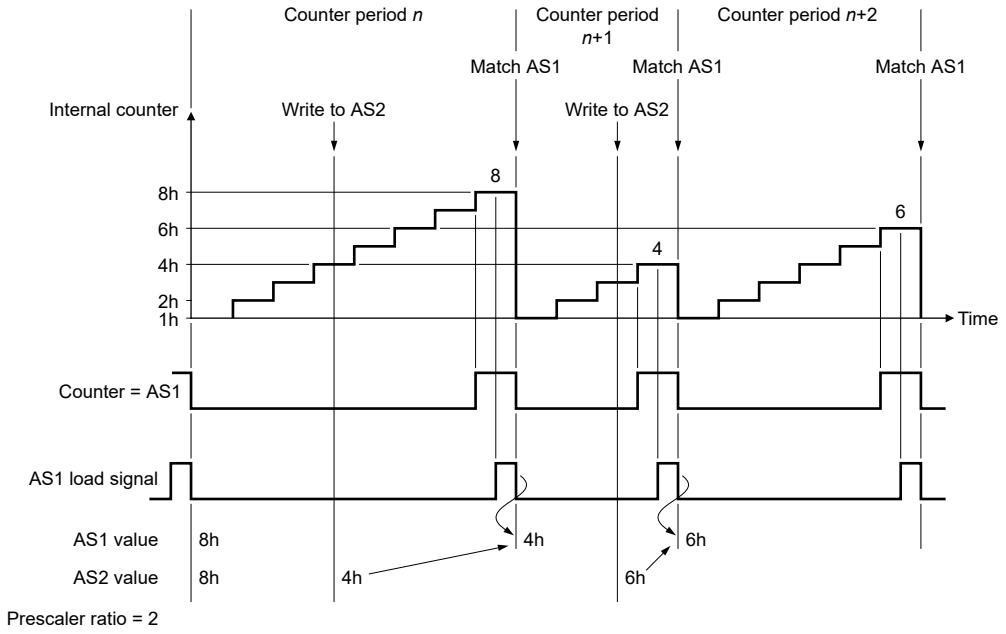

Figure 385. Timing example: Up Count submode

63.5.3.18.6 Timing example: Up Count submode flag assertion

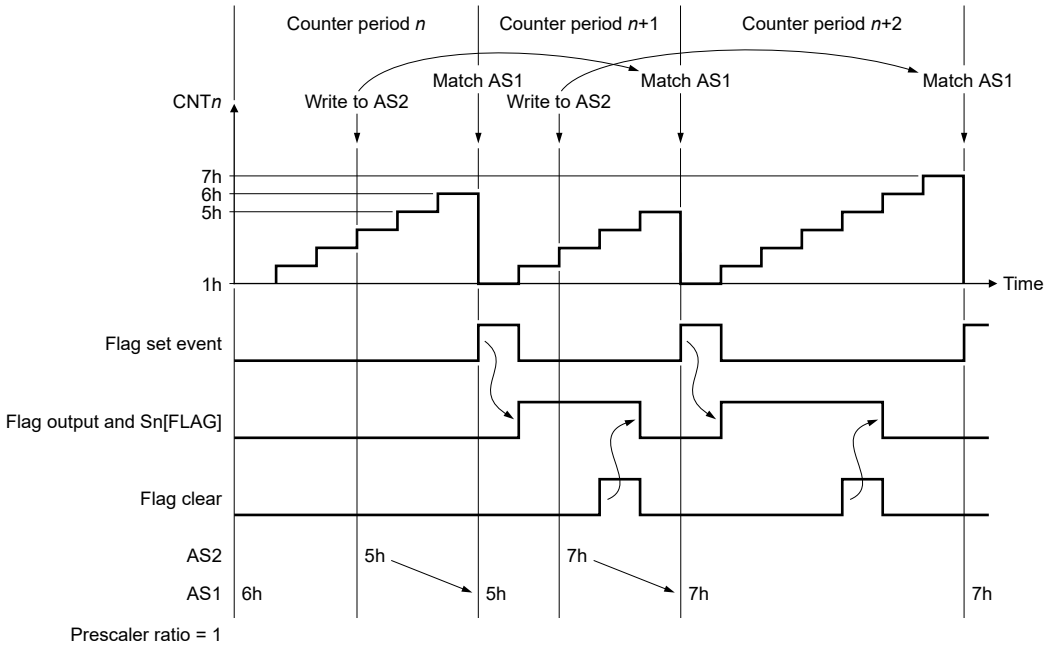

Figure 386. Timing example: Up Count submode flag assertion

63.5.3.18.7 Up Count-Down Count submode

In Up Count-Down Count submode:

- The counter period is: (2 x AS1) – 2. The counter changes direction at AS1 match and counts down (decrements) until it reaches 1h, then counts up (increments) again.
- BS1 generates a match to start the internal counter incrementing, and BS1 cannot be changed in this submode.

The UC updates AS1 at the counter period boundary. If you write AS2 (write A*n*[A]) during period *n*, the UC uses this new value in period *n*+1 for AS1 match. You can disable updates of AS1 (OUDIS[OU*n*]). See Timing example: Up Count-Down Count submode.

The UC sets the input-capture flag (S*n*[FLAG]) at AS1 match start, and may also do so at the period boundary. See Overview and Timing example: Up Count-Down Count submode flag assertion.

63.5.3.18.8 Timing example: Up Count-Down Count submode

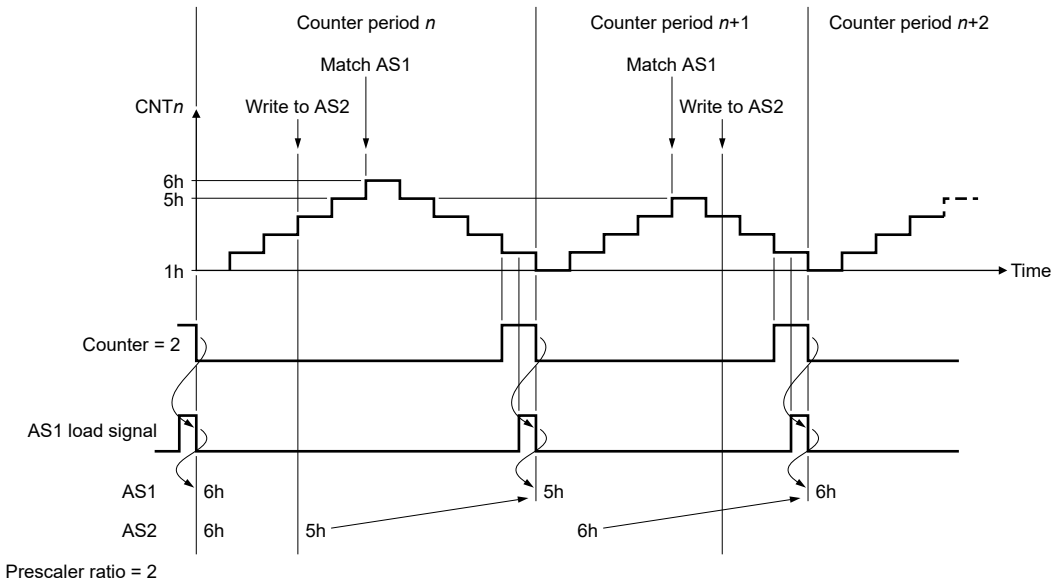

Figure 387. Timing example: Up Count-Down Count submode

63.5.3.18.9 Timing example: Up Count-Down Count submode flag assertion

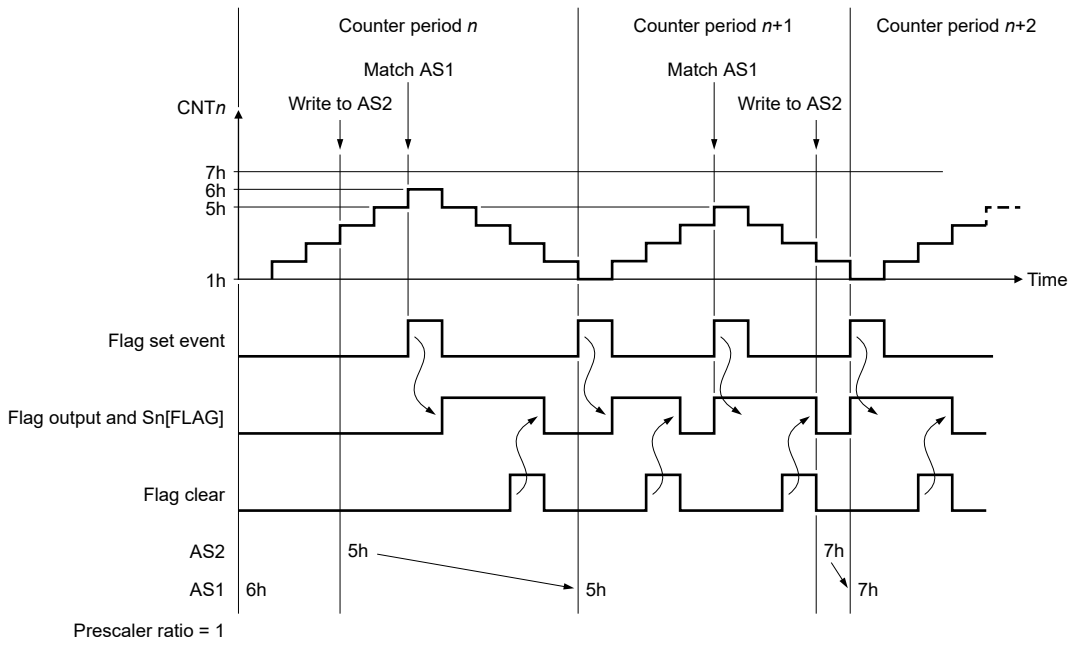

Figure 388. Timing example: Up Count-Down Count submode flag assertion

63.5.3.18.10 Up Count mode with delayed reload operation

When the internal counter matches AS1 in the Up Count submode or 1h in the Up Count-Down Count submode (see MCB submodes and MODE field values), the UC asserts the counter bus reload signal. You can read the counter bus reload signal in the following modes:

- Output PWM Buffered (OPWMB) mode
- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode

You can use the Reload Signal Output Delay Interval (C2[UCRELDEL_INT]) to cause the UC to assert the reload signal only after a specified number of match events (from 2 to 32).

See Timing example: Up Count mode with delayed reload.

63.5.3.18.11 Timing example: Up Count mode with delayed reload

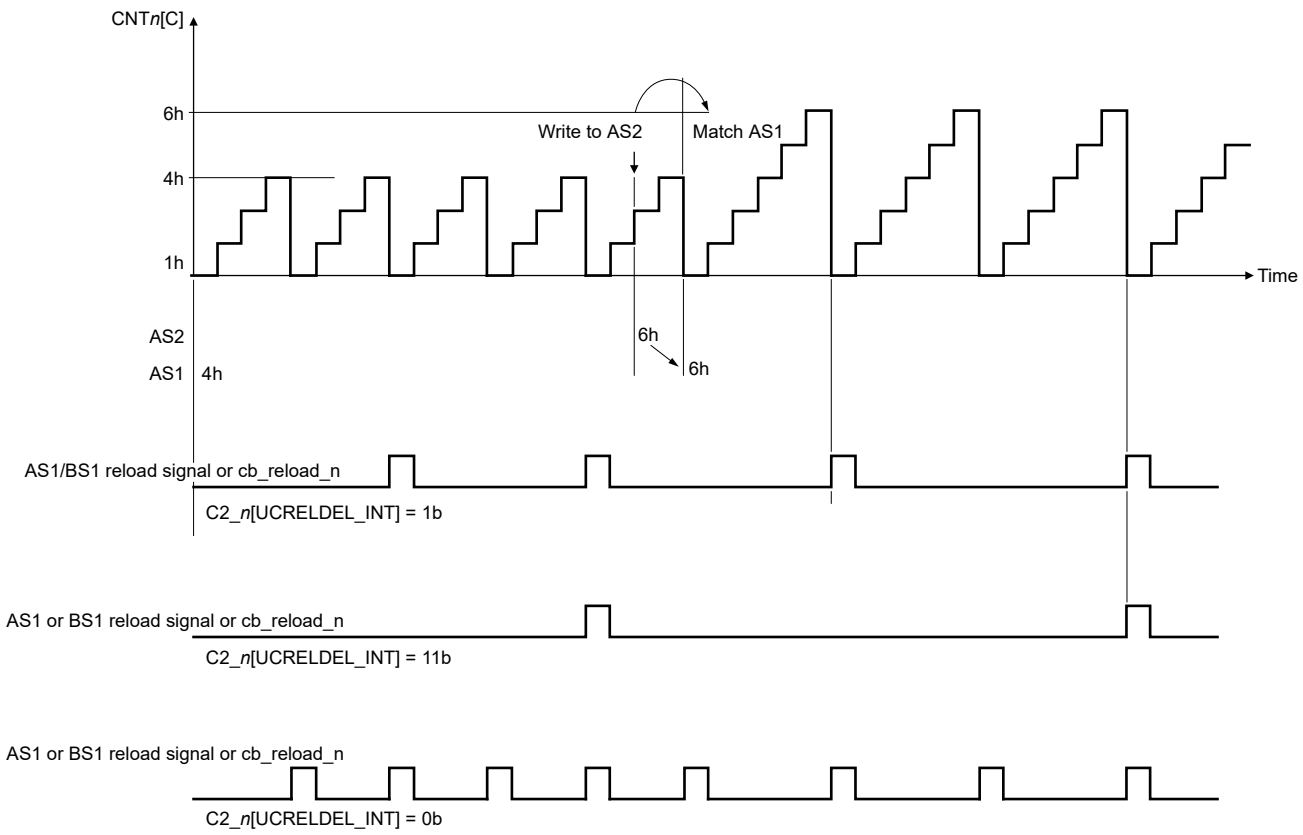

Figure 389. Timing example: Up Count mode with delayed reload

63.5.3.19 Output Pulse Width and Frequency Modulation (OPWFM) mode

63.5.3.19.1 Overview

In this mode, the UC produces an output signal that has:

- A period of (BS1 + 1) eMIOS clock cycles.
- A duty cycle as calculated by Equation for duty cycle in OPWFM mode.

See OPWFM submodes and MODE field values for the values that you must write to C*n*[MODE] to enter this mode.

You request a value for BS1 by writing to BS2. After you write to BS2, eMIOS transfers the value to BS1. This transfer can occur immediately or with a delay, as described in this section.

When the UC enters OPWFM mode from GPIO mode, the UC drives the complement of C*n*[EDPOL] onto the output flip-flop.

eMIOS automatically selects the internal counter as a timebase. Therefore, C*n*[BSL] has no meaning. When a match on comparator A occurs, the UC drives the value of C*n*[EDPOL] onto the output flip-flop. When a match on comparator B occurs, the UC drives the complement of C*n*[EDPOL] onto the output flip-flop and resets the internal counter.

Timing example: immediate update shows the UC running in OPWFM mode with immediate register update. Timing example: next period update shows the UC running in OPWFM mode with next period update.

63.5.3.19.2 Equation for duty cycle in OPWFM mode

$$Duty\ cycle\ (\%) = \frac{ASI + 1}{BSI + 1} \times 100$$

Equation 12. Equation for duty cycle in OPWFM mode

63.5.3.19.3 OPWFM submodes and MODE field values

Table 350. OPWFM submodes and MODE field values

When BS2→BS1 transfer occurs	When FLAG generation occurs	C*n*[MODE] (binary)
Immediately (resulting in the fastest change of the duty cycle); see Timing example: immediate update.	When BS1 matches the selected counter	010_0000
	When AS1 or BS1 match the selected counter	010_0010
Whenever AS1 matches the selected counter; see Timing example: next period update.	When BS1 matches the selected counter	010_0001
	When AS1 or BS1 match the selected counter	010_0011

63.5.3.19.4 Force match

Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to a match on comparators A or B, respectively. Also, writing to C*n*[FORCMB] resets the internal counter (CNT*n*[C]. If subsequent matches occur on comparators A and B, the UC continues to generate PWFM pulses regardless of the input capture flag (S*n*[FLAG]). The force-match operations do not set the input-capture flag (S*n*[FLAG]).

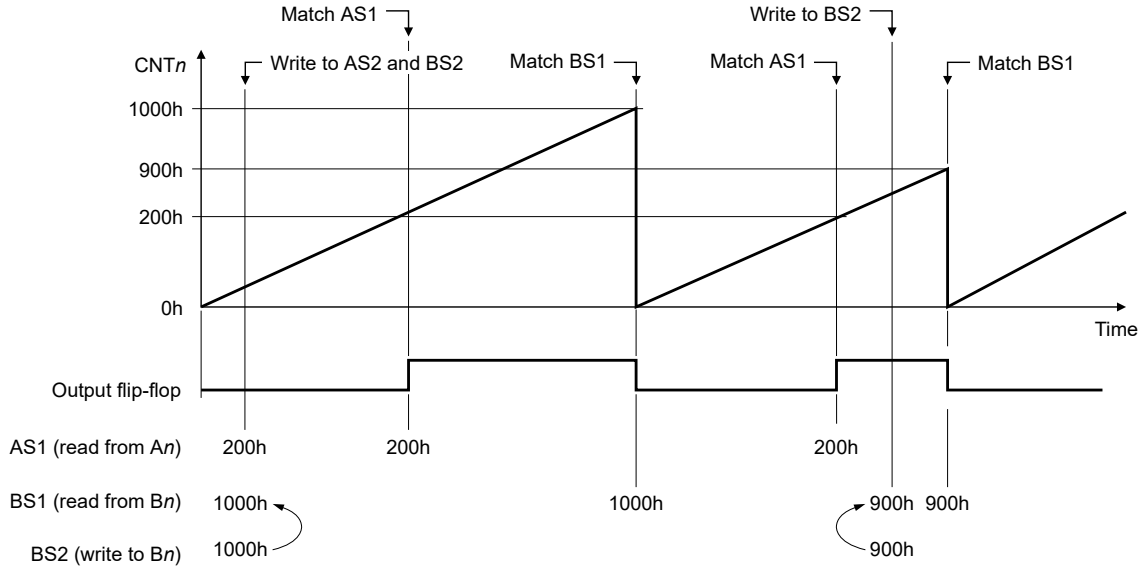
63.5.3.19.5 Duty cycle

To achieve 100% duty cycle, you must write the same value to both AS1 and BS1. When a simultaneous match occurs on comparators A and B, the output flip-flop acquires the value of C*n*[EDPOL]. To achieve 0% duty cycle, write 0 to AS1. When a match occurs, the output flip-flop changes at every period to the value of C*n*[EDPOL]. Bit 0 of C*n*[MODE] still controls the BS2→BS1 transfer as described in OPWFM submodes and MODE field values.

NOTE

Writing 0 to AS1 and BS1 produces a duty cycle of 0%.

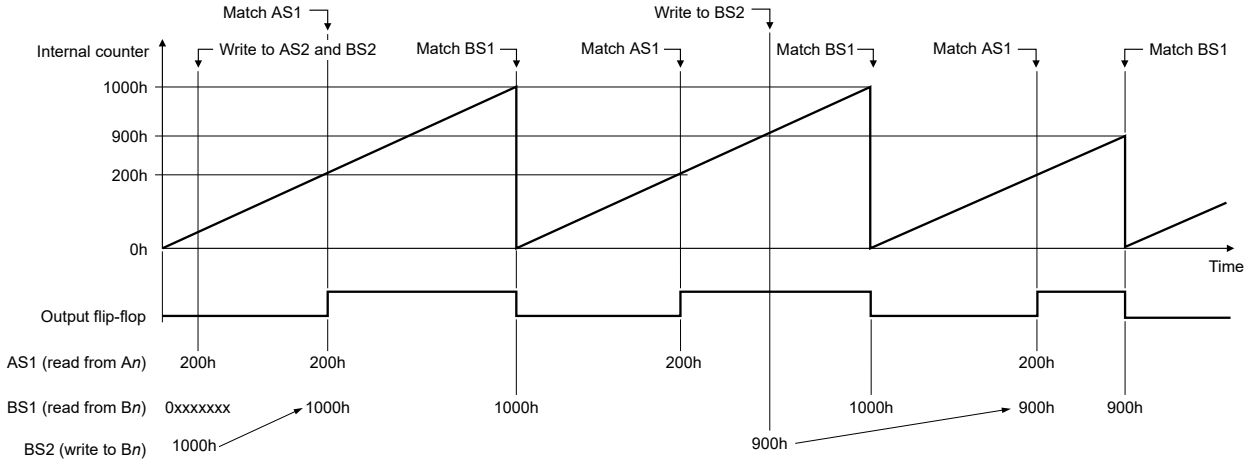
63.5.3.19.6 Timing example: immediate update



AS2 = AS1 according to the OUDIS[OU*n*] field
BS2 = BS1 according to the OUDIS[OU*n*] field

Figure 390. Timing example: immediate update

63.5.3.19.7 Timing example: next period update



AS2 = AS1 according to the OUDIS[OU*n*] field
BS2 = BS1 according to the OUDIS[OU*n*] field

Figure 391. Timing example: next period update

63.5.3.20 Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode

63.5.3.20.1 Overview

In this mode, the UC produces an output signal that has:

- A duty cycle determined by AS1.
- A period of BS1.

The double-buffered AS1 and BS1 registers produce smooth duty-cycle and period transitions when you change AS1 and BS1 during runtime.

See Table 359 for the values that you must write to C*n*[MODE] to enter this mode.

To provide smooth and consistent channel operation, this mode differs substantially from Output Pulse Width and Frequency Modulation (OPWFM) mode. In OPWFMB mode:

- AS1 and BS1 are both double-buffered to allow smooth signal generation when changing the register values.
- There is a delay from the AS1 match to the output pin transition (see AS1 and BS1 match timing).
- The internal counter ranges from 1h to BS1. When you write to BS1, you must write only values greater than 1h. Writing 0h or 1h leads to unpredictable results.

When a match on comparator A occurs, the UC drives C*n*[EDPOL] onto the output flip-flop. When a match on comparator B occurs, the UC drives the complement of C*n*[EDPOL] onto the output flip-flop. A BS1 match also causes the internal counter to transition to 1h, thus restarting the counter cycle.

The UC automatically selects the internal channel counter as the timebase when you select this mode. The mode supports duty cycles ranging from 0% to 100%.

63.5.3.20.2 OPWFMB submodes and MODE field values

Table 351. OPWFMB submodes and MODE field values

Match behavior	C*n*[MODE] (binary)
When BS1 matches the selected counter	101_1000
When AS1 or BS1 match the selected counter	101_1010

63.5.3.20.3 Avoid counter wrapping

When the UC enters OPWFMB mode, the output flip-flop acquires the value of C*n*[EDPOL]. If the UC transitions from GPIO to OPWFMB mode when the internal counter value is not within the range 1h–BS1, then the B match never occurs. Because the match never occurs, the internal counter wraps at the maximum counter value—FF_FFFFh for a 24-bit counter. When the counter wrap occurs, the counter returns to 1h and normal OPWFMB operation resumes. Therefore, to avoid this counter wrapping, ensure that the counter value is within the range 1h–BS1 before the UC enters OPWFMB mode.

63.5.3.20.4 AS1 and BS1 match timing

As illustrated in Timing example: AS1 and BS1 match, the output pin transition occurs when the AS1 or BS1 match signal deasserts, as indicated by the AS1 match negative-edge detection signal. If you write 4h to AS1, the output pin transitions 4 counter increments plus one system clock cycle after the counter period starts.

63.5.3.20.5 Timing example: AS1 and BS1 match

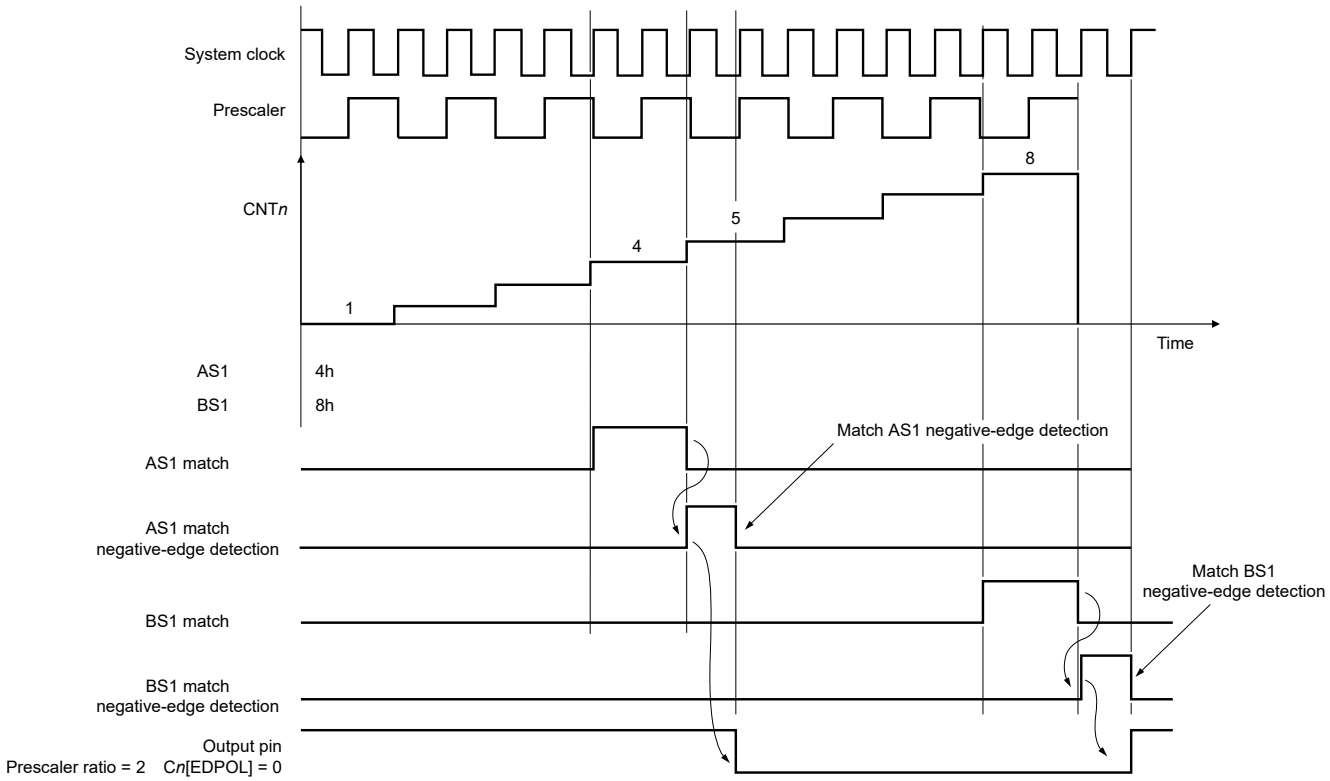


Figure 392. Timing example: AS1 and BS1 match

63.5.3.20.6 0% duty cycle

Timing example: AS1 = 0 illustrates the generated output signal when AS1 = 0, which results in a 0% duty cycle.

Because the internal counter never reaches zero in this situation, the UC infers a match as if AS1 = 1h. However, it is the positive edge of the match signal that triggers the output pin transition instead of the negative edge, which is what happens when AS1 = 1h. The AS1 positive-edge match signal from period *n*+1 occurs at the same time as the BS1 negative-edge match signal from period *n*. This timing allows the AS1 positive-edge match to mask the BS1 negative-edge match when they occur at the same time. As a result, no transition occurs on the output flip-flop and the UC generates a 0% duty cycle.

63.5.3.20.7 Timing example: AS1 = 0

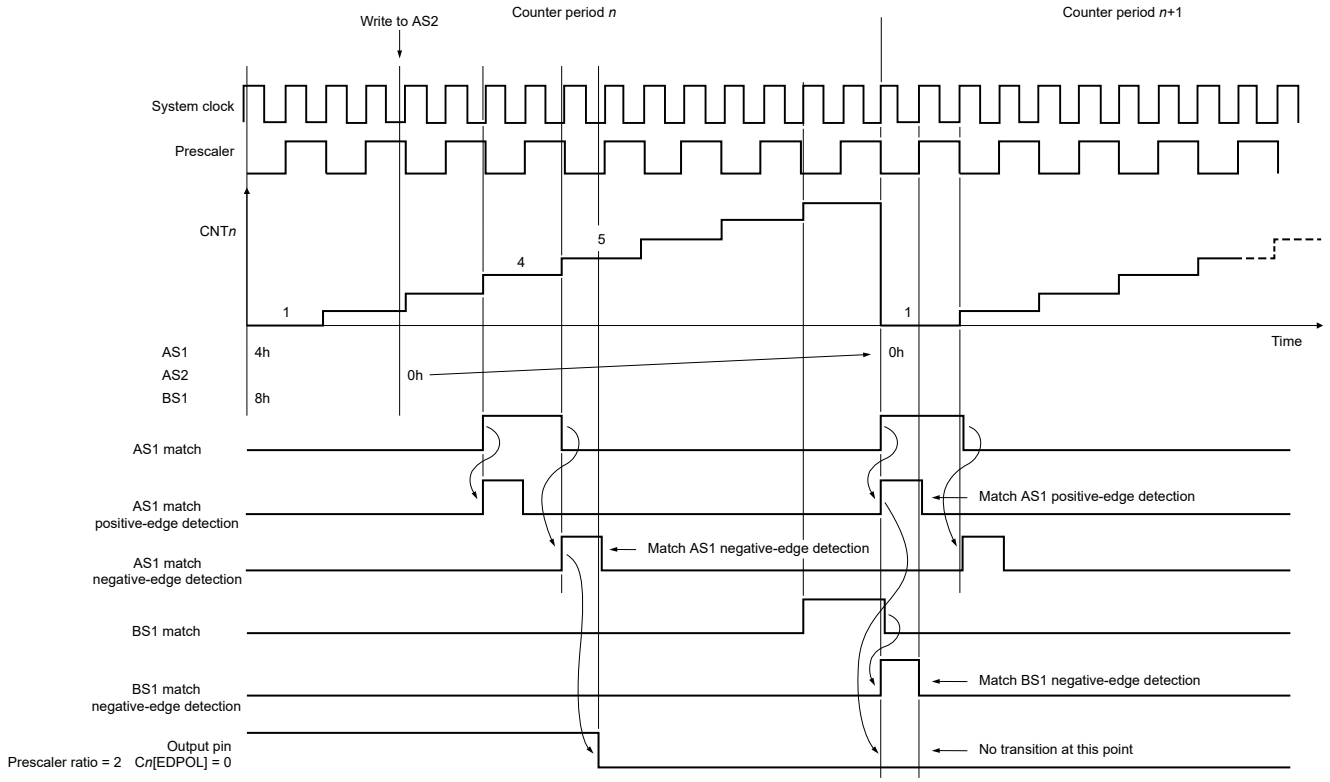

Figure 393. Timing example: AS1 = 0

63.5.3.20.8 Loading AS1 and BS1

As illustrated in Timing example: AS1 and BS1 update and FLAGs, AS1 and BS1 both use the same signal, generated at the last system clock cycle of a counter period. Therefore, eMIOS updates AS1 and BS1 with AS2 and BS2 values, respectively, at the same time that it changes the internal counter (CNT*n*[C]) to 1h. This event is the counter period boundary. The load signal pulse lasts for one system clock cycle. If you write AS2 and BS2 within counter period *n*, their values are available in AS1 and BS1, respectively, at the first clock cycle of counter period *n*+1. The UC then uses these new values for matches at counter period *n*+1. You can use Output Update Disable (OUDIS) to delay updating AS1 and BS1 for synchronization purposes.

63.5.3.20.9 Timing example: AS1 and BS1 update and FLAGs

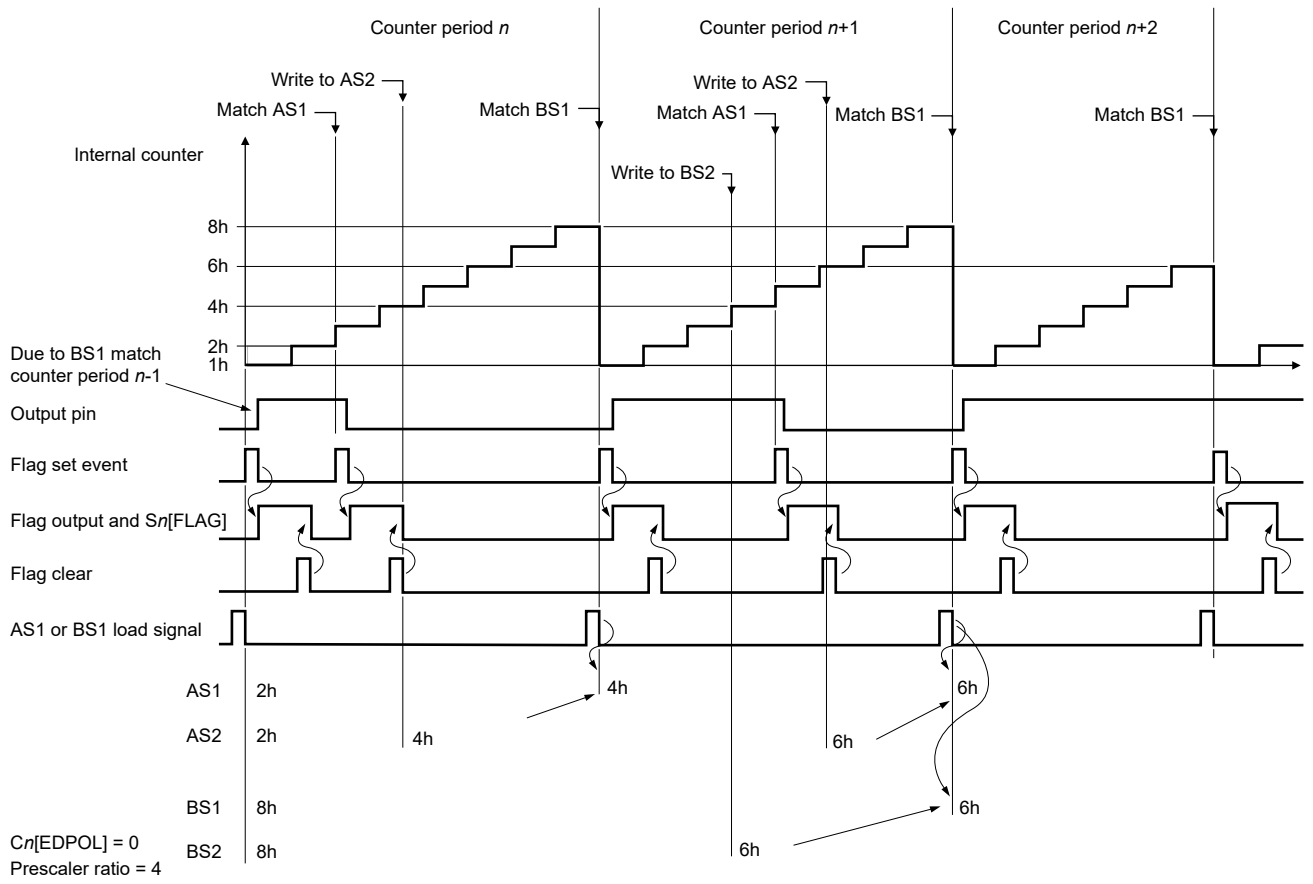

Figure 394. Timing example: AS1 and BS1 update and FLAGs

63.5.3.20.10 Flag generation

Timing example: AS1 and BS1 update and FLAGs assumes that both the channel and global prescalers are 1h (divide ratio of 2), causing the internal counter to transition every four system clock cycles. You can configure flags to be generated only on BS1 matches when bit 1 of C*n*[MODE] is 0, or on both AS1 and BS1 matches when that bit is 1. Because the BS1 flag occurs at the period boundary, you can use this flag to indicate that the AS2 or BS2 data written in period *n* has been loaded to AS1 or BS1, respectively, thereby generating matches in period *n*+1. Flag operation is synchronous, which means the flag sets one system clock cycle after the set-flag event.

63.5.3.20.11 Output disable

As illustrated in Timing example: active output disabled, the output-disable feature in OPWFMB mode forces the channel output flip-flop to the value of C*n*[EDPOL]. This functionality supports applications that use active-high signals and a high-to-low transition at an AS1 match. In this case, you must write 0 to C*n*[EDPOL]. You also must configure the internal counter to transition on every system clock cycle (write 0 to both GCP and CP).

The output-disable feature operates synchronously, meaning that the assertion of the Output Disable input signal causes the channel output flip-flop to transition to C*n*[EDPOL] at the next system clock cycle. If the Output Disable input pin deasserts, the output-signal transition occurs at the next AS1 or BS1 match.

Timing example: active output disabled assumes that the Output Disable input is enabled (using C*n*[ODIS]) and selected (using C*n*[ODISSL]). See UC Control n (C0 - C23) for a detailed description of the ODIS and ODISSL fields that enable and select the Output Disable inputs, respectively.

63.5.3.20.12 Timing example: active output disabled

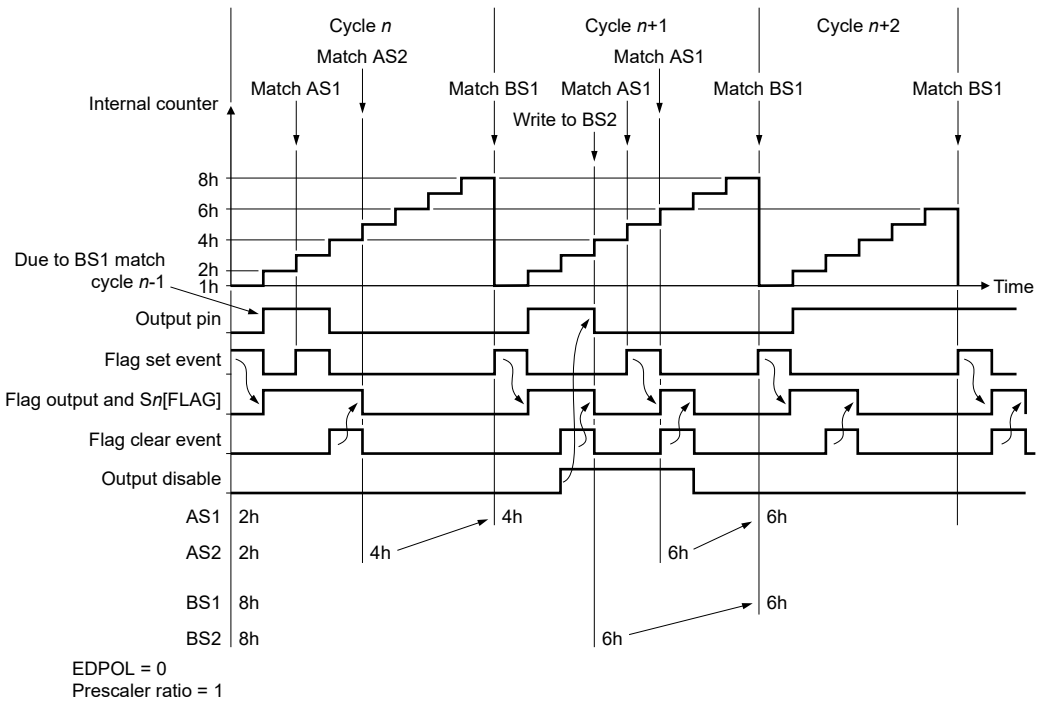

Figure 395. Timing example: active output disabled

63.5.3.20.13 Force match

Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to a match on comparators A or B, respectively. Similarly to a BS1 match, Force Match B changes the internal counter to 1h. The force-match operations do not set the input-capture flag (S*n*[FLAG]).

63.5.3.20.14 100% and 0% duty cycles

Timing example: from 100% to 0% duty cycle illustrates the generation of 100% and 0% duty-cycle signals. Initially, AS1 = 8h and BS1 = 8h. In this case, a BS1 match has precedence over an AS1 match—therefore, the output flip-flop acquires the complement of C*n*[EDPOL]. This configuration corresponds to a 100% duty-cycle signal. The same output signal can be generated for any AS1 value greater than or equal to BS1.

If AS1 is 0, the UC generates a 0% duty-cycle signal. In this case, the BS1 = 8h match from period 8 occurs at the same time as the AS1 = 0h match from period 9. See Timing example: AS1 = 0 for AS1 and BS1 match generation. In this case, an AS1 match has precedence over a BS1 match, and the output signal transitions to C*n*[EDPOL].

63.5.3.20.15 Timing example: from 100% to 0% duty cycle

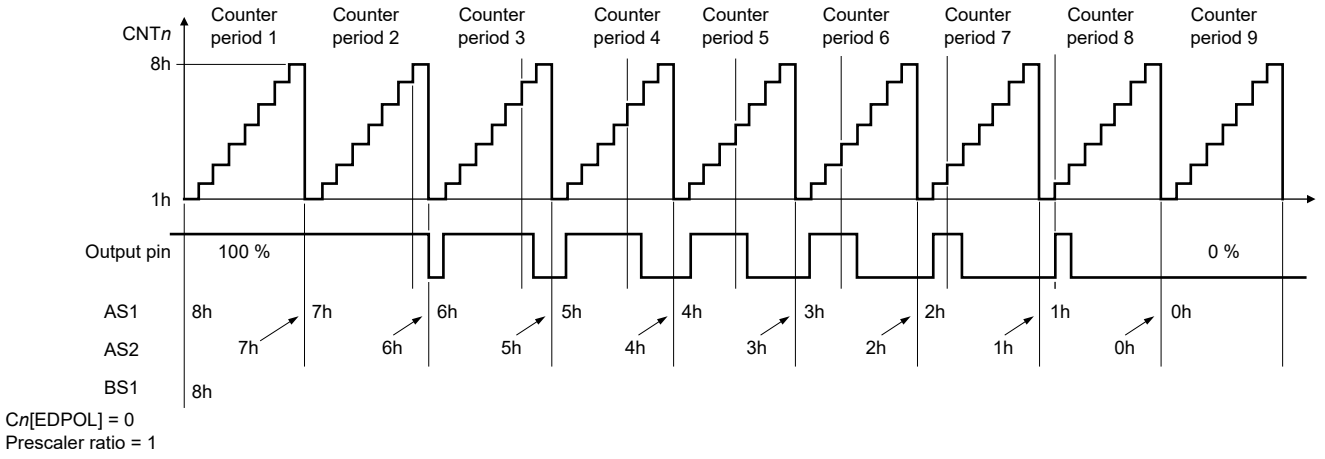

Figure 396. Timing example: from 100% to 0% duty cycle

63.5.3.21 Center Aligned Output PWM with Dead Time Insertion (OPWMC) mode

63.5.3.21.1 Overview

This mode generates a center-aligned PWM pulse with dead time insertion in the leading or trailing edge. See OPWMC functions and MODE field values.

When the UC enters OPWMC mode from GPIO mode:

- The UC drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
- Select the timebase using Bus Select (C*n*[BSL]).
- The counter bus you select must be running an Up Count-Down Count timebase. See Timing example: Up Count-Down Count submode.
- Store the ideal duty cycle for the PWM signal in AS1 (write to A*n*[A]), which the UC compares with the selected timebase.
- Store the dead time value in BS1 (write to B*n*[B]), which the UC compares with the internal counter (CNT*n*[C]).
- You must ensure that BS1 is greater than AS1.

The internal counter may use the internal prescaler ratio, while the selected timebase may use a different prescaler ratio.

See Leading edge dead time insertion and Timing example: leading dead time insertion.

See Trailing edge dead time insertion and Timing example: trailing dead time insertion.

63.5.3.21.2 OPWMC functions and MODE field values

Table 352. OPWMC functions and MODE field values

Function	C*n*[MODE] (binary)
Trailing edge dead time insertion, with duty cycle determined by BS1 + AS1	001_11p0[1]
Leading edge dead time insertion, with duty cycle determined by BS1 - AS1	001_11p1[1]
Set the input-capture flag (S*n*[FLAG]) on the trailing edge of the PWM output	001_110p[1]
Set the input-capture flag (S*n*[FLAG]) on both edges of the PWM output	001_111p[1]

1. *p* = Adjust parameters for submodes and options. See Unified channels (UC).

63.5.3.21.3 Leading edge dead time insertion

When the first match between AS1 and the selected timebase occurs:

- The UC resets the internal counter to 0.
- The UC switches the selected timebase to the internal counter.

When a match between BS1 and the selected timebase occurs:

- The UC drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
- The UC switches the timebase to the selected counter bus.

When the next match between AS1 and the selected timebase occurs, the UC drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

The UC repeats this process continuously.

See Timing example: leading dead time insertion.

63.5.3.21.4 Timing example: leading dead time insertion

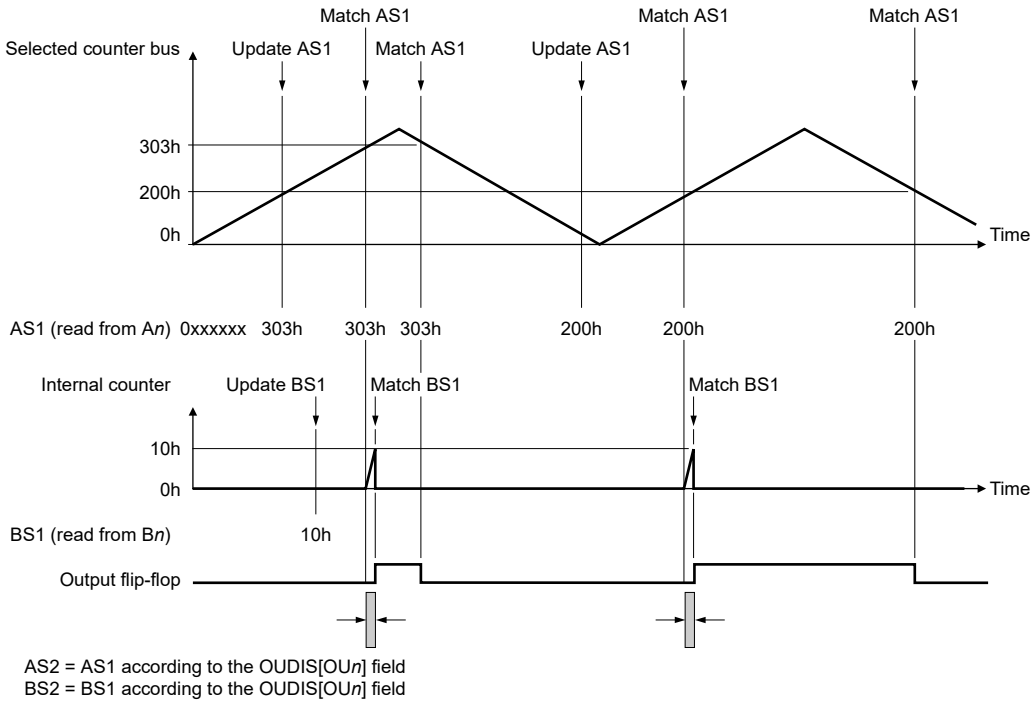

Figure 397. Timing example: leading dead time insertion

63.5.3.21.5 Trailing edge dead time insertion

When the first match between AS1 and the selected timebase occurs, the UC drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

When the next match between AS1 and the selected timebase occurs:

- The UC resets the internal counter to 0.
- The UC switches the selected timebase to the internal counter.

When a match between BS1 and the selected timebase occurs:

- The UC drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

- The UC switches the timebase to the selected counter bus.

The UC repeats this process continuously.

See Timing example: trailing dead time insertion.

63.5.3.21.6 Timing example: trailing dead time insertion

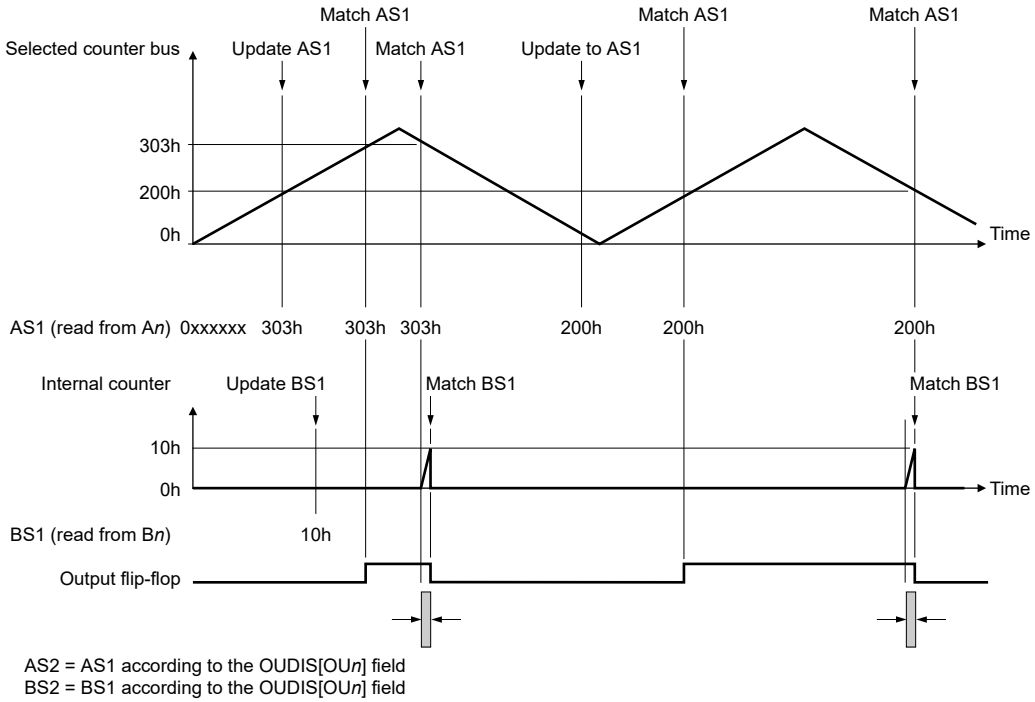

Figure 398. Timing example: trailing dead time insertion

63.5.3.21.7 Duty cycle

To generate a 100% duty cycle waveform, write the same non-zero value to both AS1 and BS1. When a simultaneous match occurs on AS1 and BS1:

- The UC drives the value of EDPOL (C*n*[EDPOL]) on the output flip-flop.
- The UC switches the selected timebase to the selected counter bus, allowing a new cycle to begin at any time.

To generate a 0% duty cycle waveform, write 0h to both AS1 and BS1. When a match occurs:

- The UC drives the complement of EDPOL (C*n*[EDPOL]) on the output flip-flop.
- The UC switches the selected timebase to the selected counter bus, allowing a new cycle to begin at any time.

Both of the above cases set the input-capture flag (S*n*[FLAG]) regardless of trailing or leading edge dead time insertion operation.

63.5.3.21.8 Force match

Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to a match on comparators A or B, respectively. If subsequent matches occur on comparators A and B, the UC continues to generate PWM pulses.

In Freeze state, comparison matches do not occur, and therefore the only way to set the output flip-flop is through a Force Match operation.

The Force Match operations do not set the input-capture flag (S*n*[FLAG]).

63.5.3.22 Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode

63.5.3.22.1 Overview

In this mode, the UC generates a center-aligned PWM pulse with dead time insertion in the leading or trailing edge. See OPWMCB functions and MODE field values. AS1 and BS1 are double-buffered to allow smooth output signal generation when you change the AS2 or BS2 values.

When the UC enters OPWMCB mode from GPIO mode:

- The UC drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
- Select the timebase using Bus Select (C*n*[BSL]). The timebase you select must be running in Up Count-Down Count mode. See Timing example: Up Count submode flag assertion. You must start the MCB timebase after the UC enters OPWMCB mode to avoid missing a match on the first duty cycle.
- Store the ideal duty cycle for the PWM signal in AS1 (write to A*n*[A]), which the UC compares with the selected timebase.
- Store the dead time value in BS1 (write to B*n*[B]), which the UC compares with the internal counter (CNT*n*[C]).

The internal counter may use the internal prescaler ratio, while the selected timebase may use a different prescaler ratio. The UC always resets the internal counter to 1h when an AS1 match occurs.

As in OPWMB and OPWFMB modes, the UC generates the match signal which compares the selected timebase with AS1 or BS1. When the UC deasserts the channel's combinational comparator output signal, it uses the match signal to assert or negate the channel's output flip-flop. See Timing example: AS1 and BS1 match for an illustration of the delay from match to output flip-flop transition in OPWFMB mode. The operation of OPWMCB mode is similar to OPWFMB mode with respect to match behavior and output pin transition.

See Entering OPWMCB mode.

63.5.3.22.2 OPWMCB functions and MODE field values

Table 353. OPWMCB functions and mode field values

Function	C*n*[MODE] (binary)
Insert trailing edge dead time with duty cycle determined by BS1 + AS1	101_11p0[1]
Insert leading edge dead time with duty cycle determined by BS1 – AS1	101_11p1[1]
Assert the input capture flag (Sn[FLAG]) on the trailing edge of the output PWM signal	101_110p[1]
Assert the input capture flag (Sn[FLAG]) on both edges of the output PWM signal	101_111p[1]

1. *p* = Adjust parameters for submodes and options. See Unified channels (UC).

63.5.3.22.3 Entering OPWMCB mode

To enter OPWMCB mode (this procedure assumes the channel is initially in GPIO mode):

1. Disable the GCP (write 0 to MCR[GPREN]).
2. For the timebase (MCB) channel:
    a. Disable the CP (write 0 to C*n*[UCPREN]).
    b. Initialize the internal counter (write 1h to CNT*n*[C]).
    c. Initialize the A data (write appropriate value to A*n*[A]).

d. Configure the UC for MCB Up Count-Down Count mode (write 101_01*xy*b to C*n*[MODE], where *x* = 0 for flag set on match start or *x* = 1 for flag set at period boundary, and *y* = 0 for internal clock source or *y* = 1 for external clock source).

e. Select the CP ratio (C*n*[UCPRE]).

f. Enable the CP (write 1 to C*n*[UCPREN]).

3. For the OPWMCB channel:

a. Disable the CP (write 0 to C*n*[UCPREN]).

b. Initialize the A data (write appropriate value to A*n*[A]).

c. Initialize the B data (write appropriate value to B*n*[B]).

d. Select the timebase input (C*n*[BSL]).

e. Configure the UC for MCB Up Count-Down Count mode (write 101_01*xy*b to C*n*[MODE], where *x* = 0 for flag set on match start or *x* = 1 for flag set at period boundary, and *y* = 0 for internal clock source or *y* = 1 for external clock source).

f. Select the CP ratio (C*n*[UCPRE]).

g. Enable the CP (write 1 to C*n*[UCPREN]).

4. Enable the GPC (write 1 to MCR[GPREN]).

63.5.3.22.4 Timing example: AS1 and BS1 load

When the selected counter bus transitions from 2h to 1h:

- The UC loads AS1 and BS1 as shown in the following figure.
- This event defines the counter period boundary.

The UC loads the values you write to AS2 or BS2 within period *n* into AS1 or BS1, respectively, and uses them to generate matches in period *n*+1.

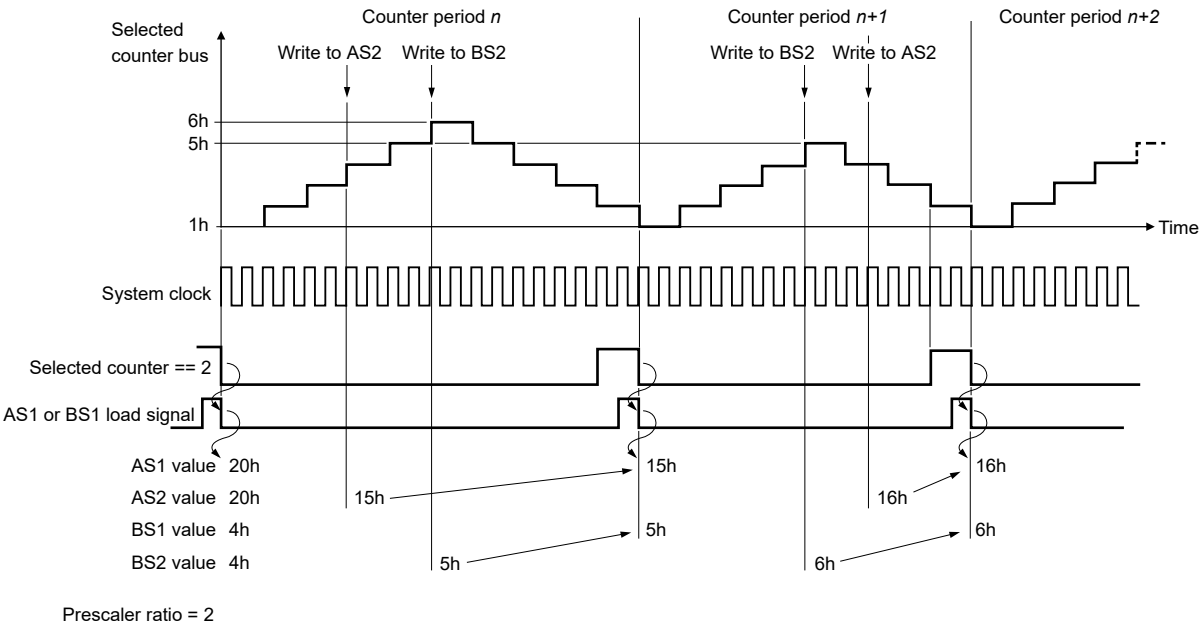

Figure 399. Timing example: AS1 and BS1 load

63.5.3.22.5 Operation sequence with leading edge dead time insertion

When operating with leading edge dead time insertion:

1. When the first AS1 match occurs, the UC writes 1h to the internal counter.
2. When a match between BS1 and the internal timebase occurs, the UC drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
3. When the next match between AS1 and the selected timebase occurs, the UC drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

The UC repeats the above sequence continuously.

You must not allow the internal counter to reach 0h as the result of a rollover. To avoid this, you must not write a value greater than

2 x ((external Count Up limit) – A*n*[A])

into B*n*[B].

See Timing example: leading dead time insertion.

63.5.3.22.6 Timing example: leading dead time insertion

This example illustrates two cycles of a center-aligned PWM signal. AS1 and BS1 values change within the same period, which allows you to change the duty cycle and dead time values at the same time.

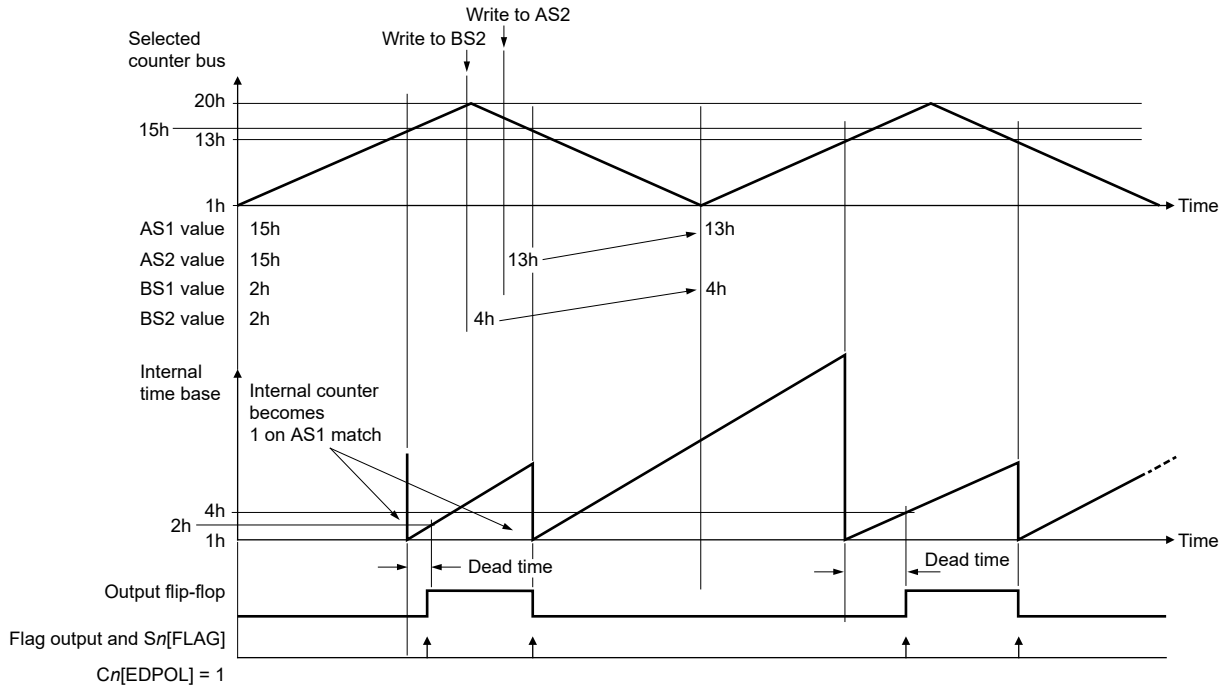

Figure 400. Timing example: leading dead time insertion

63.5.3.22.7 Operation sequence with trailing edge dead time insertion

When operating with trailing edge dead time insertion:

1. When the first match between AS1 and the selected timebase occurs, the UC:
   a. Drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
   b. Writes the internal counter (CNT*n*[C]) to 1h.
2. When the second match between AS1 and the selected timebase occurs, the UC:

a. Writes the internal counter to 1h.

b. Enables BS1 matches.

3. When a match between BS1 and the selected timebase occurs, the UC drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

The UC repeats this sequence continuously.

63.5.3.22.8 Timing example: trailing dead time insertion

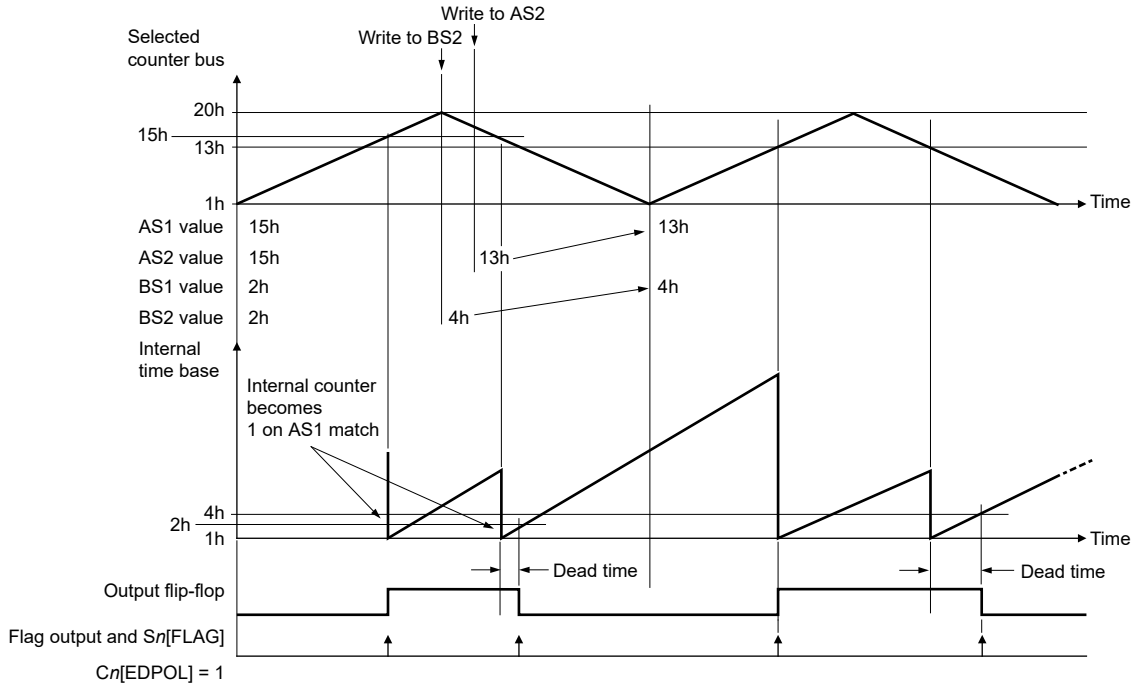

Figure 401. Timing example: trailing dead time insertion

63.5.3.22.9 Force match

Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to a match on comparators A or B, respectively. If subsequent matches occur on comparators A and B, the UC continues to generate PWM pulses regardless of the input capture flag (S*n*[FLAG]). The force-match operations do not set the input-capture flag (S*n*[FLAG]).

When you select leading edge dead time insertion:

- Force Match A drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
- Force Match B drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

When you select trailing edge dead time insertion:

- Force Match A drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.
- Force Match B drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

Force Match operation does not write 1h to the internal timebase.

Force Match operation does not set the input-capture flag.

When you assert Force Match A and Force Match B at the same time, the UC drives the complement of Edge Polarity (C*n*[EDPOL]) on the output flip-flop. This is the equivalent of saying that Force Match A has precedence over Force Match B when you select

leading edge dead time insertion, and Force Match B has precedence over Force Match A when you select trailing edge dead time insertion.

Force Match A and Force Match B have the same output transition behavior in both Freeze state and unfrozen state.

63.5.3.22.10 Duty cycle

You generate a duty cycle from 0% to 100% by writing appropriate values to AS1 and BS1 relative to the period of the external timebase.

To generate a 100% duty cycle waveform:

- Select trailing edge dead time insertion (see OPWMCB functions and MODE field values).
- Write 1h to Edge Polarity (C*n*[EDPOL]).
- The BS1 match must occur on or after the counter period boundary (external counter = 1).

You can also generate a 100% duty cycle waveform by writing 1h to AS1. However, if you do this before the UC enters OPWMCB mode, a 100% duty cycle may not occur in the first PWM period depending upon the pin state at mode entry.

To generate a 0% duty cycle waveform:

- AS1 must be greater than the maximum value of the selected counter period.
- The pin must start the current period with the complement value of Edge Polarity (C*n*[EDPOL]). If starting at 100% duty cycle, you can change Edge Polarity (C*n*[EDPOL]) to its complement by forcing the pin (see Force match).

You must write only non-zero values to AS1. If you write the maximum value of the external counter given by

(external counter period)/2

to AS1, the UC constantly drives the value of Edge Polarity (C*n*[EDPOL]) on the output flip-flop.

UC logic prevents matches from one period propagating to the next period. In trailing edge dead time insertion, the UC masks out BS1 matches that occur late in period *n*, so matches in period *n*+1 are unaffected and the output flip-flop does not transition.

63.5.3.22.11 Timing example: duty cycle

To generate a 100% duty cycle output waveform, write 4h to AS1 and 3h to BS1, as illustrated in this diagram. In this case, the trailing edge is at the boundary of counter period *n*+1, which actually belongs to period *n*+2 and therefore does not cause the output flip-flip to transition.

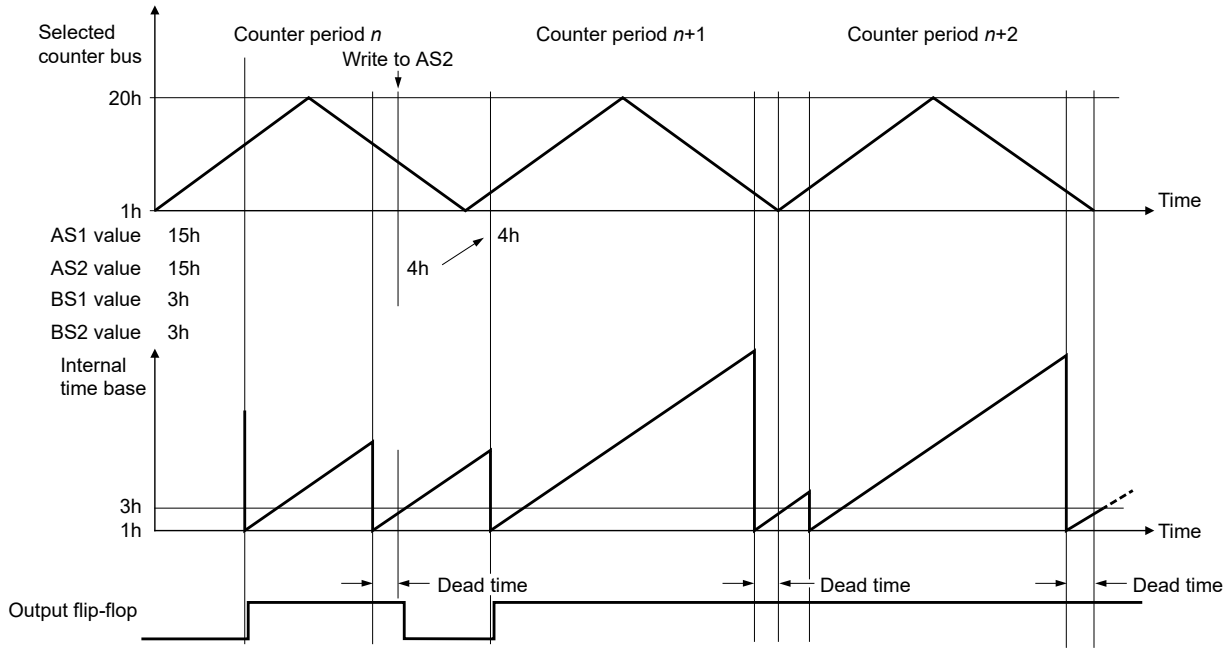

Figure 402. Timing example: duty cycle

63.5.3.22.12 Output disable

You can use Output Update Disable (write 0 to OUDIS[OU*n*]) to disable AS1 and BS1 updates. This allows you to update AS1 and BS1 in the same counter period and synchronize the loading of these registers with the loading of AS1 or BS1 in other channels.

Asserting Output Update Disable drives the complement of Edge Polarity (C*n*[EDPOL]) on output flip-flop. The internal channel matches continue to occur, and therefore the UC continues to set flags.

When you deassert Output Update Disable, the output flip-flop is again controlled by AS1 and BS1 matches. The UC transitions the output flip-flop only on system clock edges.

63.5.3.23 Output PWM (OPWM) mode

63.5.3.23.1 Overview

In this mode, the UC produces an output PWM pulse for which:

- AS1 defines the leading edge.
- BS1 defines the trailing edge.

See OPWM submodes and MODE field values for the values that you must write to C*n*[MODE] to enter this mode.

The UC compares the AS1 value with the value of the selected timebase. When a match on comparator A occurs, the output flip-flop acquires the value of C*n*[EDPOL]. When a match occurs on comparator B, the output flip-flop acquires the complement of C*n*[EDPOL].

Depending on the OPWM submode, eMIOS sets the input-capture flag on match B, or on either match A or match B. See OPWM submodes and MODE field values.

When the UC enters OPWM mode, the output flip-flop acquires the complement of C*n*[EDPOL].

Timing example: immediate update and Timing example: next-period update show the UC running in OPWM mode with immediate update and next-period update, respectively.

63.5.3.23.2 OPWM submodes and MODE field values

Table 354. OPWM submodes and MODE field values

When BS2→BS1 transfer occurs	When FLAG generation occurs	C*n*[MODE] (binary)
Immediately (resulting in the fastest change of the duty cycle); see Timing example: immediate update	When match B occurs	010_0000
	When match A or match B occur	010_0010
Whenever AS1 matches the selected counter; see Timing example: next-period update	When match B occurs	010_0001
	When match A or match B occur	010_0011

63.5.3.23.3 Force match

Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to a match on comparators A or B, respectively. If subsequent matches occur on comparators A and B, the UC continues to generate PWM pulses regardless of the input capture flag (S*n*[FLAG]). The force-match operations do not set the input-capture flag (S*n*[FLAG]).

63.5.3.23.4 Duty cycle

To generate a waveform with 100% duty cycle, write the same nonzero value to AS1 and BS1. When a simultaneous match occurs on comparators A and B, the UC drives C*n*[EDPOL] on the output flip-flop at every period.

To generate a waveform with 0% duty cycle, write 0h to AS1. When a match occurs, the UC drives the complement of C*n*[EDPOL] on the output flip-flop at every period. Bit 0 of C*n*[MODE] still controls when the BS2→BS1 transfer occurs.

NOTE

If AS1 = BS1 = 0h, the UC produces a waveform with 0% duty cycle.

63.5.3.23.5 Timing example: immediate update

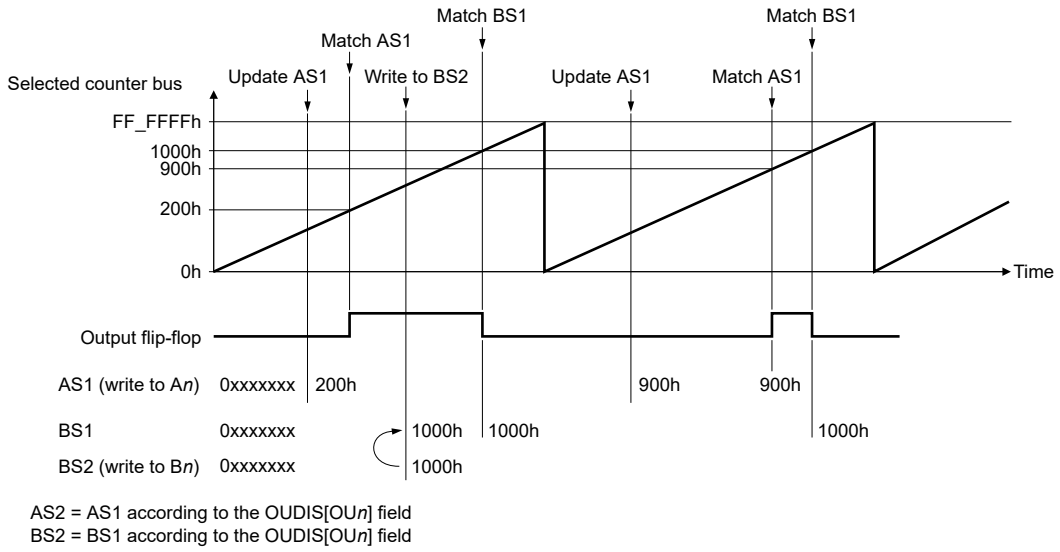

Figure 403. Timing example: immediate update

63.5.3.23.6 Timing example: next-period update

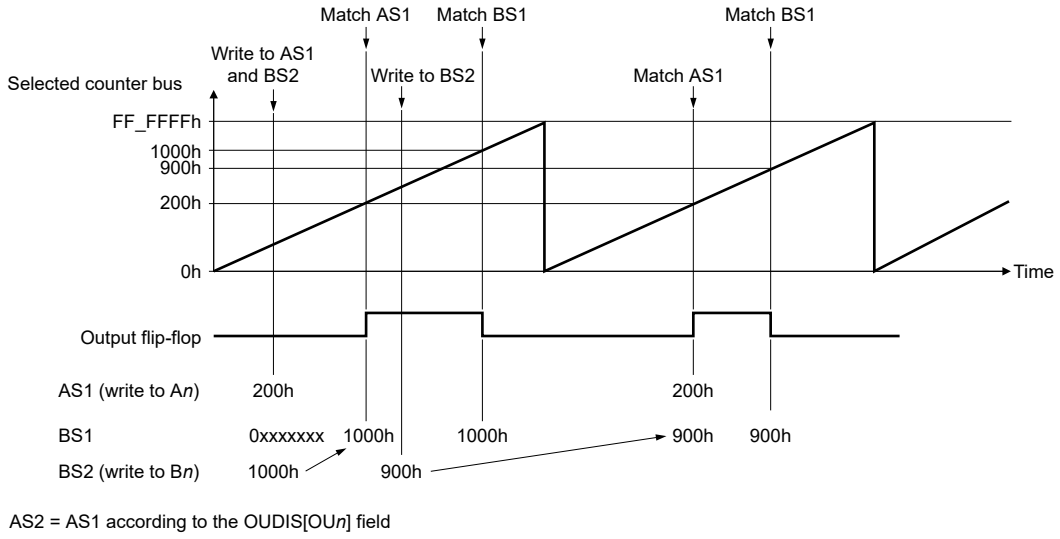

Figure 404. Timing example: next-period update

63.5.3.24 Output PWM Buffered (OPWMB) mode

63.5.3.24.1 Overview

In this mode, the UC produces PWM pulses with programmable leading and trailing edge placement. You must select an external counter driven in MCB Up mode from one of the counter buses. AS1 and BS1 define the first and second edges, respectively. C*n*[EDPOL] defines the output signal polarity. If C*n*[EDPOL] = 0, a negative edge occurs when AS1 matches the selected counter bus and a positive edge occurs when BS1 matches the selected counter bus.

See OPWMB submodes and MODE field values for the values that you must write to C*n*[MODE] to enter this mode.

AS1 and BS1 are double-buffered and updated from AS2 and BS2, respectively, at the cycle boundary. The load operation is similar to the one that occurs in OPWFMB mode. See Timing example: AS1 and BS1 update and FLAGs for more information about AS1 and BS1 updates.

When the UC enters OPWMB mode, the UC drives C*n*[EDPOL] on the output flip-flop.

These rules apply to OPWMB mode:

- If the AS1 and BS1 matches occur at the same time within the same counter period, the BS1 match has precedence over the AS1 match.
- An AS1 = 0 match in period *n* has precedence over a BS1 match in period *n*-1.
- The UC masks out AS1 matches if they occur after a BS1 match within the same period.
- The UC loads any value that you write to AS2 or BS2 in period *n* into AS1 and BS1 at the following period boundary (assuming that the corresponding OU*n* field of Output Update Disable (OUDIS) is 0). Therefore, the UC uses the new values for AS1 and BS1 matches in period *n*+1.

Timing example: 100% to 0% duty cycle illustrates a waveform changing from 100% to 0% duty cycle. In this example, BS1 is programmed to the same value as the period of the external selected timebase. If you write a value smaller than 8h to BS1, you cannot achieve a 0% duty cycle by only changing AS1. Because BS1 matches have precedence over AS1 matches, the flag output transitions to the complement of C*n*[EDPOL] at a BS1 match. For another example, if you write 9h to BS1, a BS1 match does not occur, and the UC generates a 0% duty-cycle signal.

63.5.3.24.2 OPWMB submodes and MODE field values

Table 355. OPWMB submodes and MODE field values

When FLAG generation occurs	C*n*[MODE] (binary)
At a BS1 match	110_0000
At an AS1 or BS1 match	110_0010

63.5.3.24.3 Force match

Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to a match on comparators A or B, respectively. If subsequent matches occur on comparators A and B, the UC continues to generate PWM pulses regardless of the input capture flag (S*n*[FLAG]). The force-match operations do not set the input-capture flag (S*n*[FLAG]).

63.5.3.24.4 Matches and flag operation

Timing example: matches and flags illustrates the operation of OPWMB mode with an emphasis on AS1 and BS1 matches and the transition of the channel output pin. The output pin transitions are based on the negative edges of the AS1 and BS1 match signals. AS1 becomes zero in period *n*+1. In this case, the UC uses the match positive edge instead of the negative edge to transition the output flip-flop.

63.5.3.24.5 Timing example: matches and flags

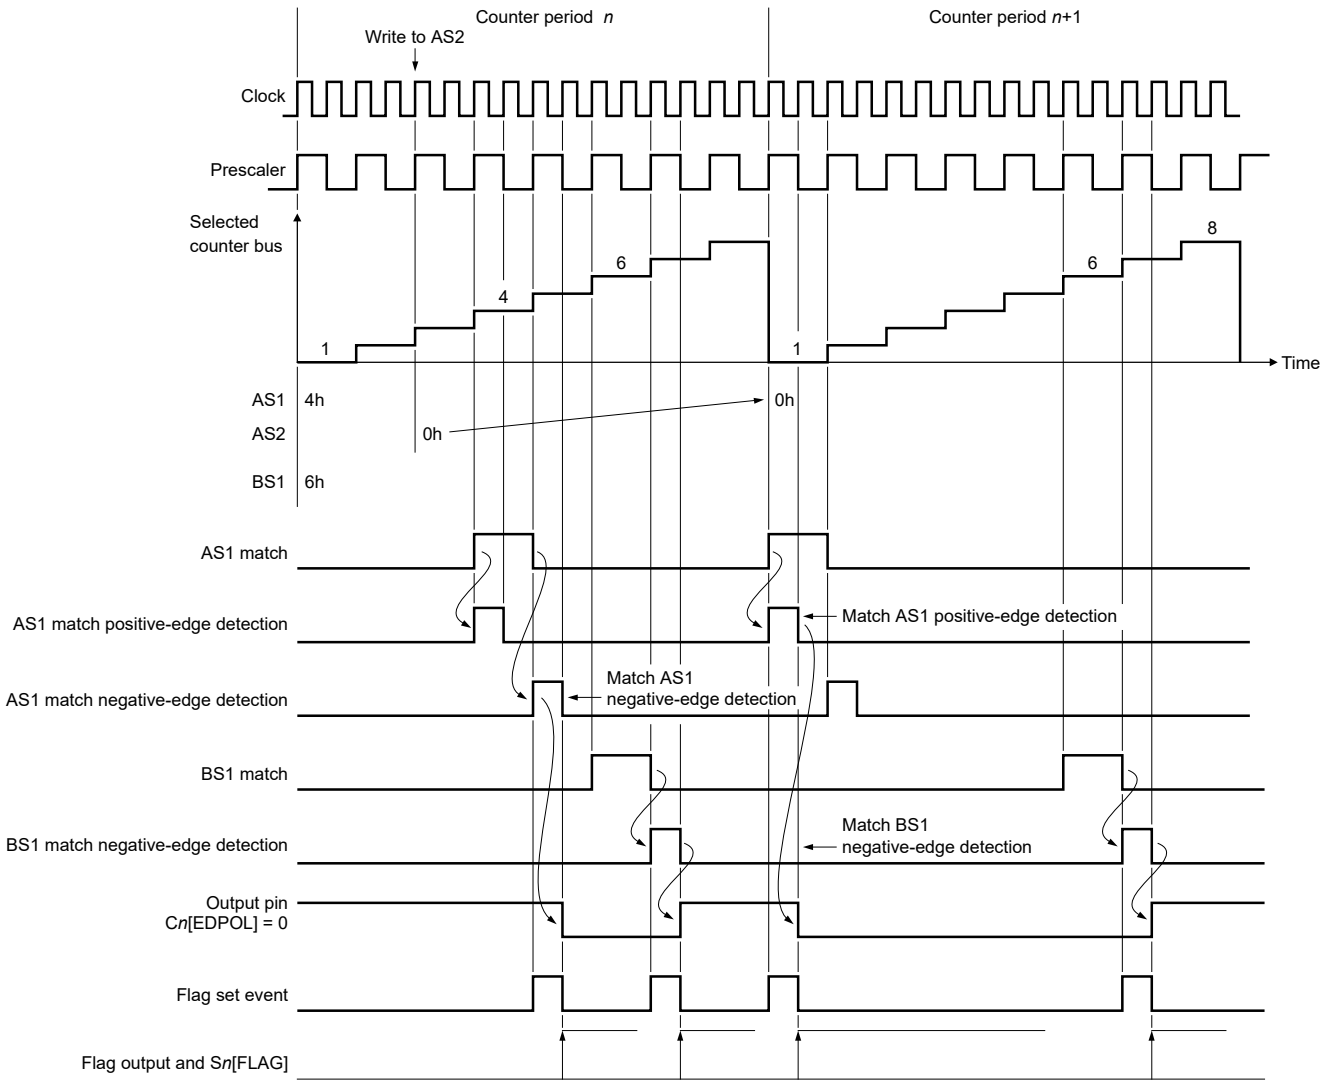

Figure 405. Timing example: matches and flags

63.5.3.24.6 0% duty cycle

Timing example: 0% duty cycle illustrates the channel operation for a 0% duty cycle. The AS1 match positive-edge signal occurs at the same time as the BS1 = 8h negative-edge signal. In this case, the AS1 match has precedence over the BS1 match, causing the output pin to remain at the value of C*n*[EDPOL] and generating a 0% duty-cycle signal.

63.5.3.24.7 Timing example: 0% duty cycle

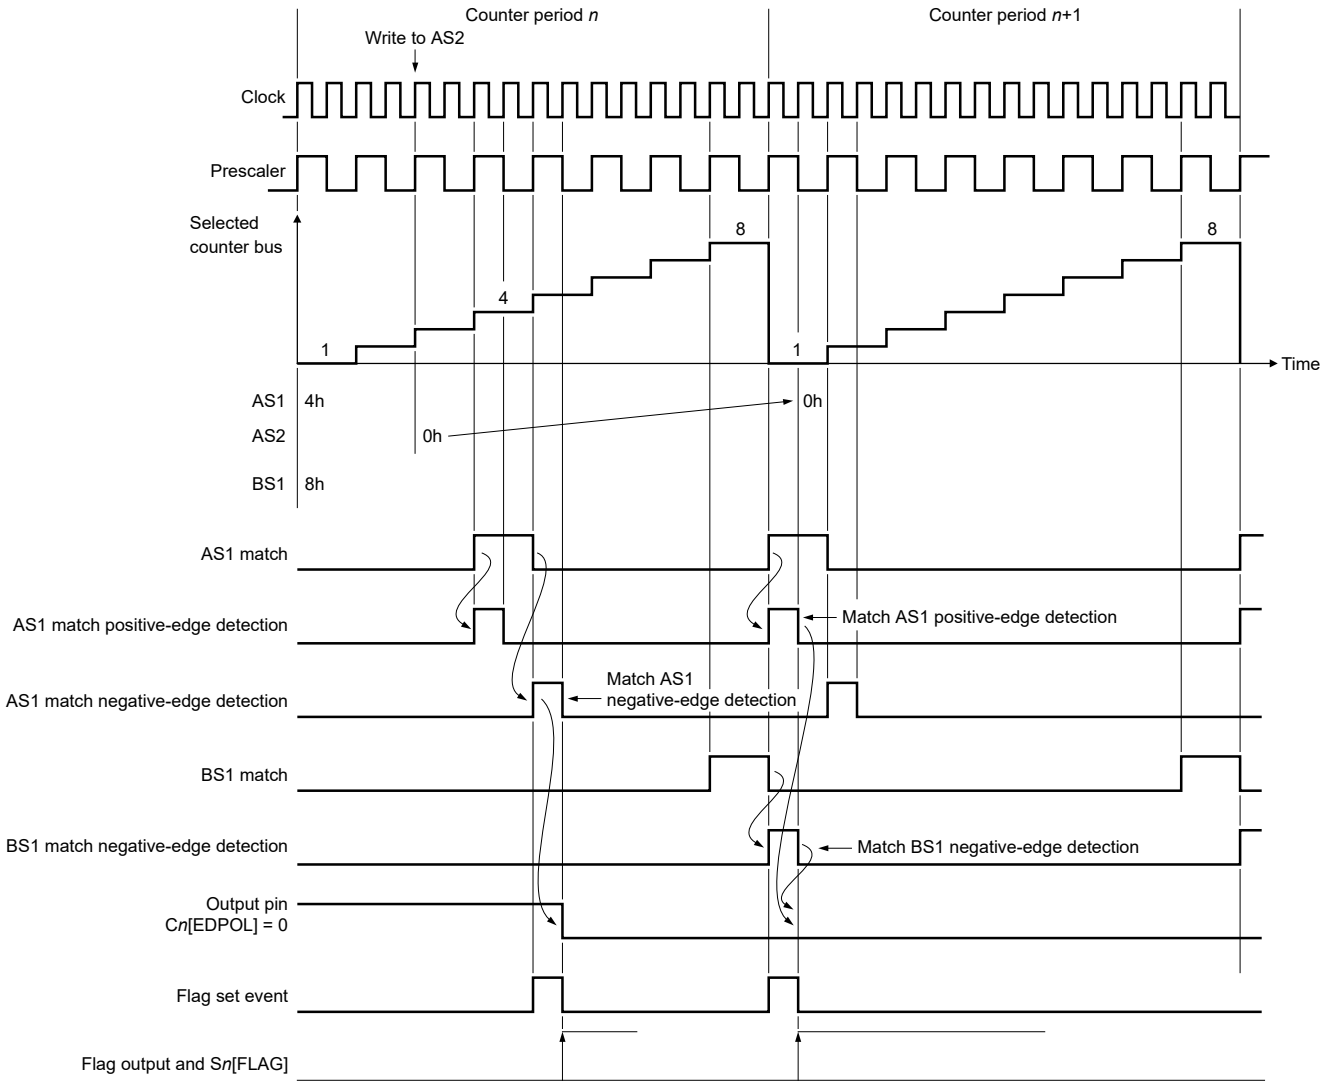

Figure 406. Timing example: 0% duty cycle

63.5.3.24.8 Active output disabled

Timing example: active output disabled illustrates the operation of the OPWMB mode with an emphasis on the assertion of the output-disable signal. The output disable forces a transition in the output pin to the value of C*n*[EDPOL]. The deassertion of the output-disable signal allows the output pin to transition at the following AS1 or BS1 match. The output disable does not modify the behavior of S*n*[FLAG]. A delay of one system clock cycle exists between the assertion of the output-disable signal and the transition of the output pin to C*n*[EDPOL].

63.5.3.24.9 Timing example: active output disabled

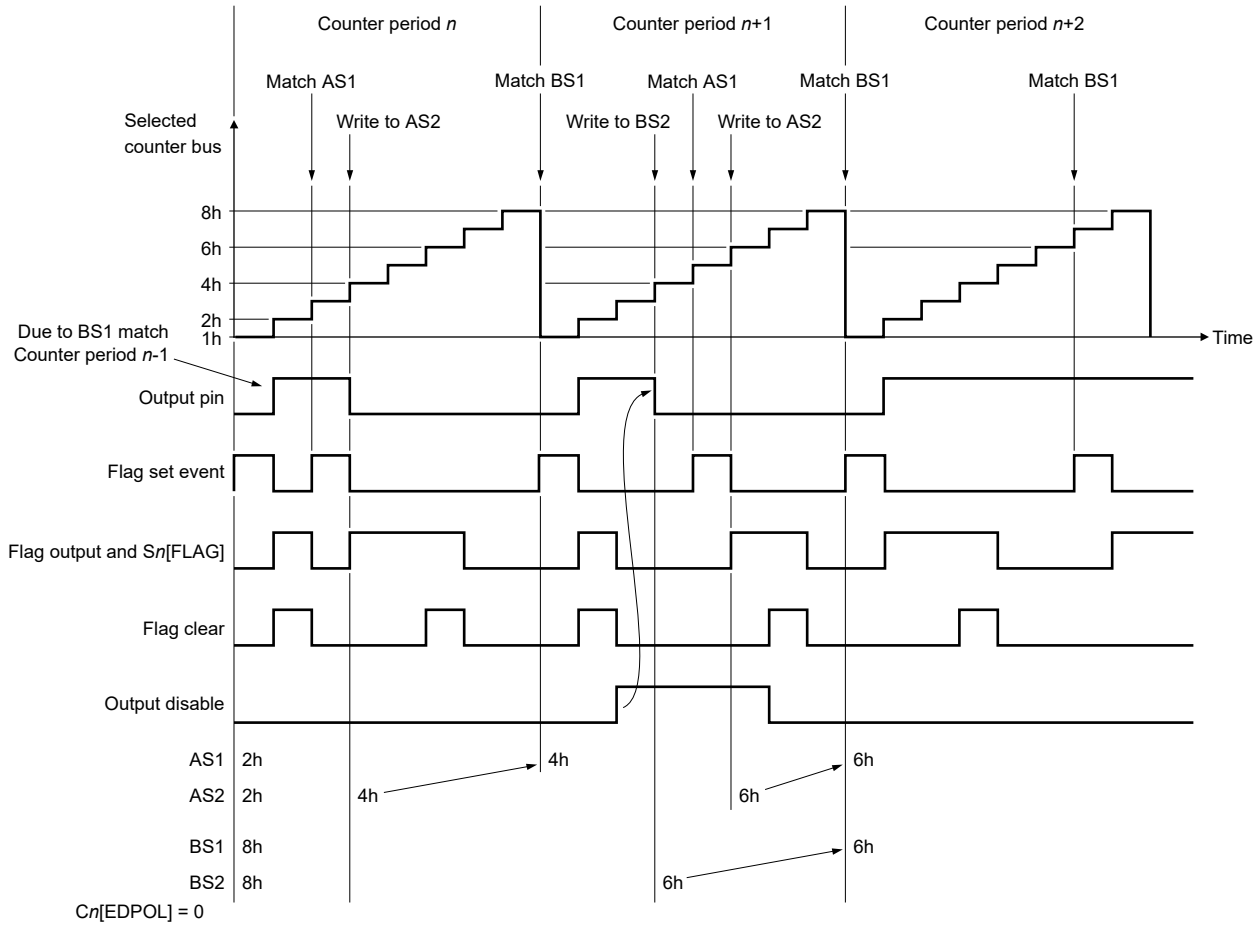

Figure 407. Timing example: active output disabled

63.5.3.24.10 Changing from 100% to 0% duty cycle

Timing example: 100% to 0% duty cycle illustrates a waveform changing from 100% to 0% duty cycle. In this example, BS1 has the same value as the period of the external selected timebase. If you write a value smaller than 8h to BS1, you cannot achieve a 0% duty cycle by only changing AS1. Because BS1 matches have precedence over AS1 matches, the output pin transitions to the complement of C*n*[EDPOL] at a BS1 match. For another example, if you write 9h to BS1, a BS1 match does not occur, and the UC generates a 0% duty-cycle signal.

63.5.3.24.11 Timing example: 100% to 0% duty cycle

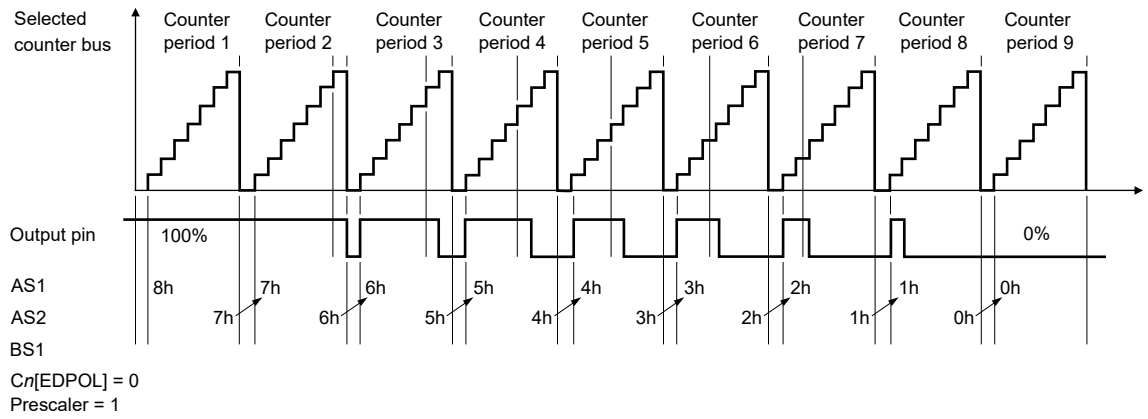

Figure 408. Timing example: 100% to 0% duty cycle

63.5.3.25 Output PWM with Trigger (OPWMT) mode

63.5.3.25.1 Overview

In this mode, the UC generates PWM pulses where the period does not change while the UC outputs the signal, but the duty cycle changes. When the duty cycle changes, it must not create glitches. The mode supports multiple UCs executing in the same mode and sharing a common timebase. Each UC can have a fixed PWM leading-edge position with respect to the other UCs. It can also generate a trigger signal at any point in the period. eMIOS can output this trigger signal to initiate activity in other parts of the chip—for example, to start ADC conversions.

You must select an external counter, driven in either MC Up or MCB Up mode (see Modulus Counter Buffered (MCB) mode), from one of the counter buses.

AS1 in OPWMT mode, AS2 in OPWMT mode, and BS1 and BS2 in OPWMT mode describe the configuration and behavior of the individual shadow registers in this mode.

To account for the shift in the AS1-defined leading edge of the waveform, the BS1-defined trailing edge may roll over into the next period. This means that a match against BS1 does not have to be qualified by a match in AS1. This also means that if you incorrectly write a value less than AS1 to BS1, the output persists over a period boundary until the UC encounters the BS1 value.

This mode provides a buffered update of the trailing edge by updating BS1 with BS2 contents only at a match of AS1.

The positive edges of the AS1, BS1, and AS2 match signals drive the output pin and flag transitions. See Timing example: matches and flags for details on positive-edge matches.

The UC sets the input capture flag (S*n*[FLAG]) only at an AS2 match. An AS1, BS1, or BS2 match has no effect on the flag.

When the UC enters OPWMT mode, it drives the complement of C*n*[EDPOL] on the output flip-flop.

Timing example: OPWMT illustrates the UC running in OPWMT mode with trigger-event generation and duty-cycle update after the next-period update.

63.5.3.25.2 Timing example: OPWMT

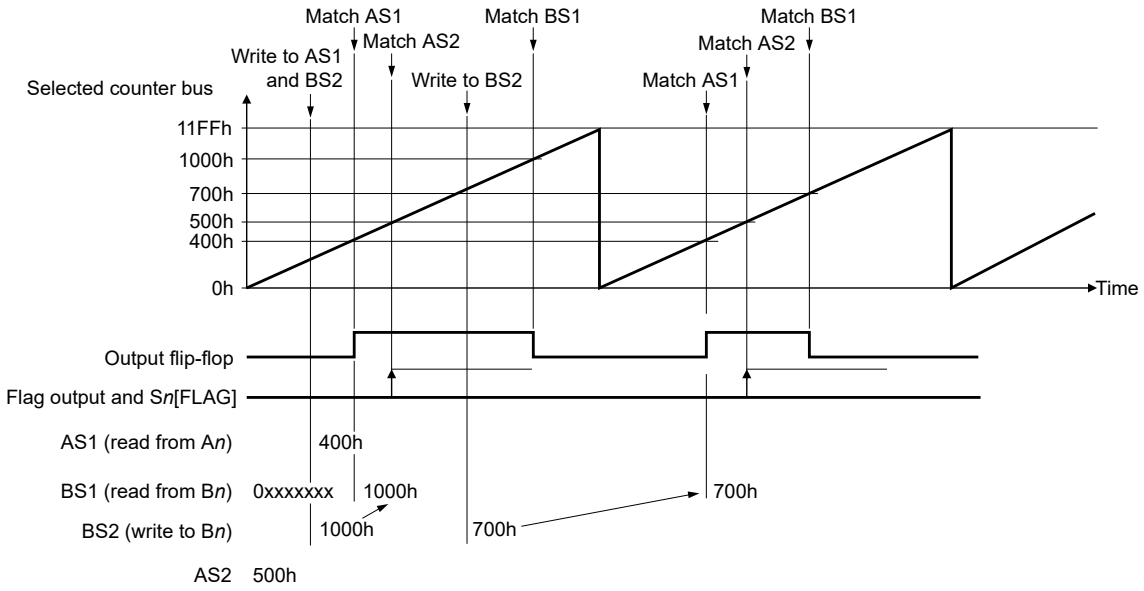

Figure 409. Timing example: OPWMT

63.5.3.25.3 AS1 in OPWMT mode

AS1 defines the leading edge of the PWM pulse output, and therefore the beginning of the PWM period. Using this fact, you can ensure that, when using a shared timebase, the leading edges of multiple UCs in OPWMT mode occur at specific times with respect to the other UCs. You can also introduce a fixed offset for each UC, which is particularly useful in the generation of lighting control signals. For this application, to reduce or eliminate noise generation, you can shift the PWM pulse of each UC with respect to the selected timebase by adjusting the AS1 value for each channel. The value you write to AS1 must be within the range of the selected timebase. Shadow registers (AS1, AS2, BS1, and BS2) loaded with 0h do not produce matches if the channel driving the timebase is in MCB mode.

AS1 is not buffered, because the shift of a PWM channel must not change while the UC generates the PWM signal. If you modify AS1, it updates immediately and one PWM pulse could be lost.

The UC compares AS1 to the selected timebase. When a match on AS1 occurs, the UC drives C*n*[EDPOL] on the output flip-flop. When a match occurs on comparator B, the UC drives the complement of C*n*[EDPOL] on the output flip-flop.

63.5.3.25.4 AS2 in OPWMT mode

AS2 defines the generation of a trigger event within the PWM period. The value you write to AS2 must be within the range of the selected timebase—otherwise the UC does not generate a trigger. A match on the comparator asserts the input-capture flag, but the match has no effect on the PWM output signal generation. The typical setup to obtain a trigger with a flag is to enable DMA and drive the DMA acknowledgement or DMA completion input high.

AS2 is not buffered, and therefore the UC updates it immediately. If the UC is running when you make a change, this could cause either of the following:

- The loss of one trigger event
- The generation of two trigger events within the same period

You access AS2 by reading or writing ALTA*n*[ALTA].

63.5.3.25.5 BS1 and BS2 in OPWMT mode

You access BS1 and BS2 using B*n*[B]:

- When you read B*n*[B], you read BS1.
- When you write to B*n*[B], you write to BS2.

BS1 defines the trailing edge of the PWM pulse output, and therefore the duty cycle of the PWM signal. To synchronize the BS1 update with the PWM signal and to ensure a correct output pulse generation, the BS2→BS1 transfer occurs at every AS1 match. This behavior is the same as in OPWM mode with next-period update.

Output Update Disable (OUDIS) affects transfers between BS2 and BS1 only.

63.5.3.25.6 Force match

At any time, Force Match A (C*n*[FORCMA]) and Force Match B (C*n*[FORCMB]) allow you to force the output flip-flop to the level corresponding to a match on AS1 or BS1, respectively. Similarly to a BS1 match, Force Match B changes the internal counter to 1h. The force-match operations do not set the input-capture flag (S*n*[FLAG]). Any match resulting from writing 1 to FORCMA or FORCMB has priority over any simultaneous match regarding output pin transitions. BS2→BS1 transfer at an A match is not inhibited by writing 1 simultaneously to both FORCMA or FORCMB. If you write 1 to both FORCMA and FORCMB simultaneously, the output pin acquires the complement of C*n*[EDPOL], as if AS1 and BS1 had the same value. FORCMA assertion causes the UC to process the BS2→BS1 transfer as a regular A match comparison and not due to FORCMA assertion, regardless of FORCMB assertion. If subsequent matches occur on comparators AS1 and B, the UC continues to generate PWM pulses, regardless of the state of S*n*[FLAG].

63.5.3.25.7 Duty cycle

To achieve 0% duty cycle, you must write the same value to AS1 and BS2. When a simultaneous match on comparators A and B occurs, the UC drives the complement of C*n*[EDPOL] on the output flip-flop at every period.

To achieve 100% duty cycle, you must write a value to BS1 that is greater than the maximum value of the selected timebase. The maximum counter value for the timebase is FF_FFFEh for a 24-bit counter and FFFEh for a 16-bit counter. When a match on comparator AS1 occurs, the UC drives C*n*[EDPOL] on the output flip-flop at every period. The match at comparator A still triggers the BS2→BS1 transfer.

Timing example: 0% duty cycle illustrates the UC running in OPWMT mode with trigger-event generation and a 0% duty cycle.

Timing example: 100% duty cycle illustrates the UC running in OPWMT mode with trigger-event generation and a 100% duty cycle.

63.5.3.25.8 Timing example: 0% duty cycle

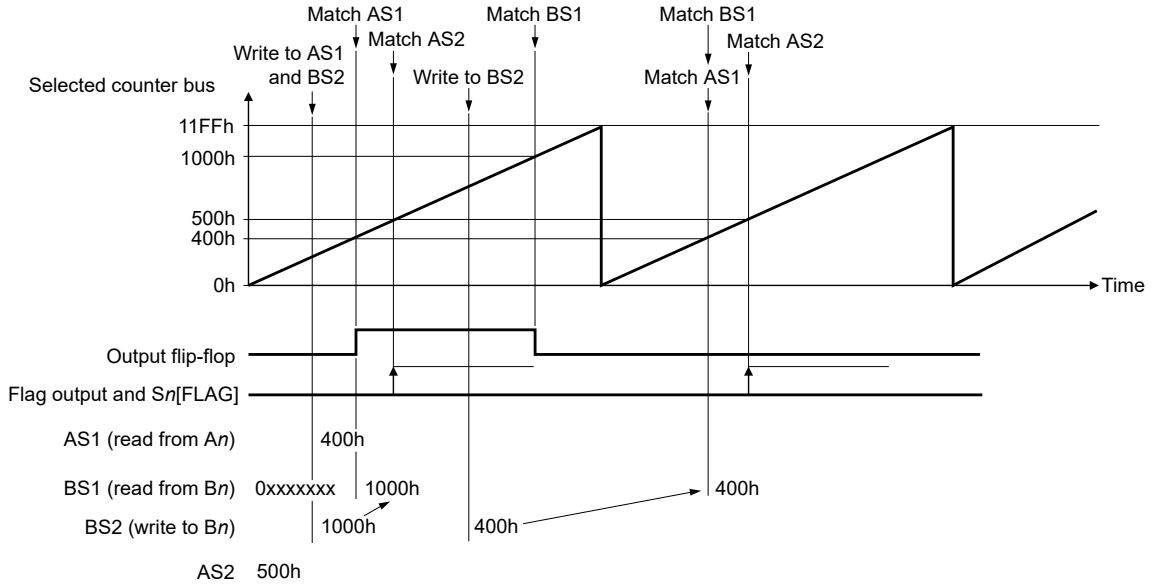

Figure 410. Timing example: 0% duty cycle

63.5.3.25.9 Timing example: 100% duty cycle

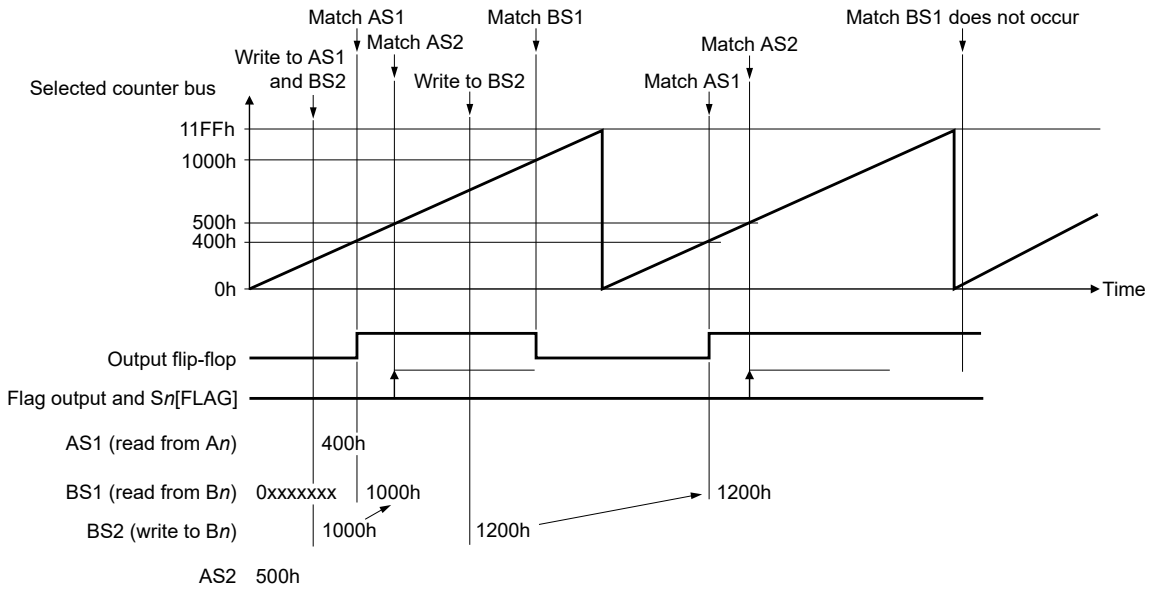

Figure 411. Timing example: 100% duty cycle

63.5.3.25.10 Output disable

As with other UC modes, OPWMT mode implements the output-disable function. When C*n*[ODIS] = 1, assertion of the output-disable input causes the UC to drive C*n*[EDPOL] on the output. Other than the fixed output, the UC continues to operate normally. When the output-disable signal deasserts, the UC returns to full normal operation.

63.5.3.26 Programmable input filter (PIF)

63.5.3.26.1 Overview

The PIF specifies the minimum input pulse width, in clock cycles, that can pass through the filter. It supports bypass operation (C*n*[IF]), with the input signal synchronized before arriving at the digital filter, or from 2 to 16 clock cycles in powers of 2.

63.5.3.26.2 Counter

The PIF is a 5-bit programmable up counter. The selected clock source increments the up counter after the number of clock cycles specified by the input filter (C*n*[IF]0.

The system clock synchronizes the input signal. When this signal changes state, the counter begins incrementing. As long as the new signal state is stable, the counter continues incrementing. If the counter overflows, eMIOS validates the new signal value. In this case, it transmits the value as a pulse edge to the edge detector. If the opposite edge appears on the signal before validation (overflow), eMIOS resets the counter. At the next transition, the counter starts incrementing again. A glitch does not occur on the edge detector for any pulse shorter than the full range of the masked counter.

Neither Freeze state nor deasserted GTBE disables the filter.

63.5.3.26.3 UC PIF logic

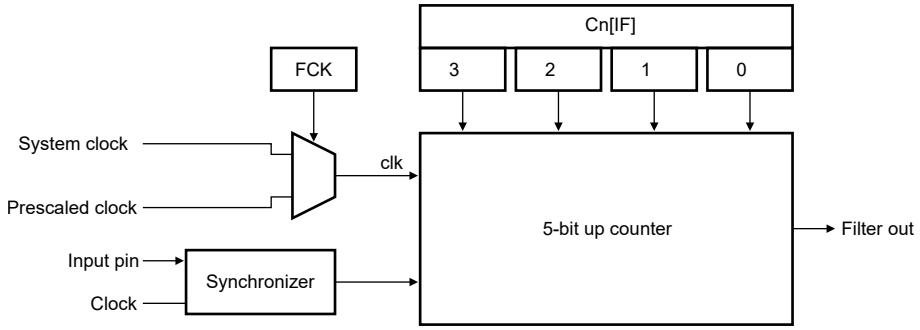

Figure 412. UC PIF logic

63.5.3.26.4 Timing example: UC PIF at 4 cycles

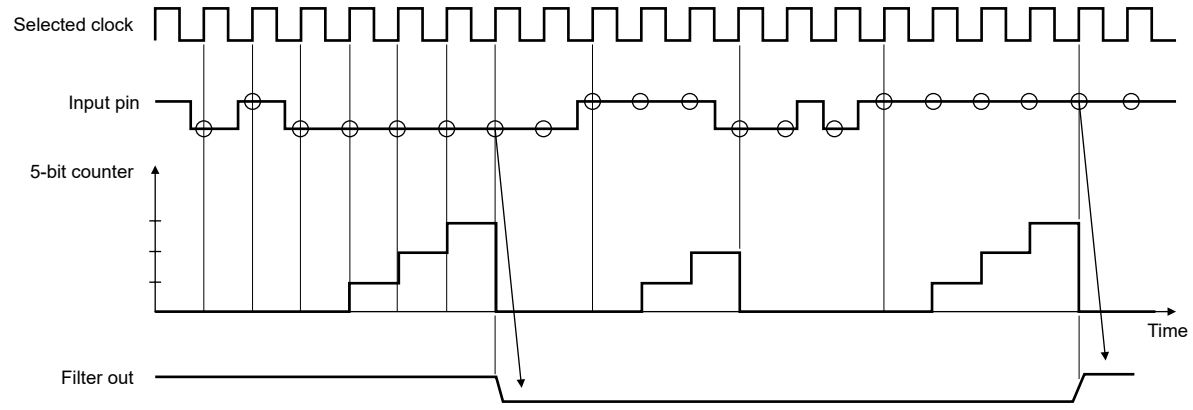

Figure 413. Timing example: UC PIF at 4 cycles

63.5.3.27 UC clock prescaler (CP)

eMIOS divides the GCP output signal by the UC CP (C*n*[UCPRE] + 1) to generate a clock enable for the UC internal counter. See Global clock prescaler (GCP). You enable the UC CP by writing 1 to C*n*[UCPREN]. If you disable the CP (write 0 to the same field), eMIOS stops the UC internal counter.

To ensure safe operation and avoid glitches, you must perform the following steps to change the UC CP:

1. Disable the GCP (write 0 to MCR[GPREN]).
2. Disable the UC CP (write 0 to C*n*[UCPREN]).
3. Specify the new prescaler value (write CP – 1 to C*n*[GPRE].
4. Enable the UC CP (write 1 to C*n*[UCPREN]).
5. Enable the GCP (write 1 to MCR[GPREN]).

63.5.4 Peripheral bus interface unit (BIU)

The BIU provides the interface between the IIB and the peripheral bus, which allows communication among all submodules and the IP interface. The BIU supports 8-, 16-, and 32-bit accesses performed over a 32-bit data bus in a single clock cycle.

63.5.5 STAC bus client

63.5.5.1 Overview

The STAC bus client provides one external timebase, imported from the STAC bus, to the UCs (see STAC block diagram). You select the Server Time Slot (MCR[SRV]) for output to the STAC bus. Every time the selected time slot occurs, eMIOS updates the STAC output (see Timing example: STAC output).

See the chip-specific information for the STAC server IDs.

63.5.5.2 STAC block diagram

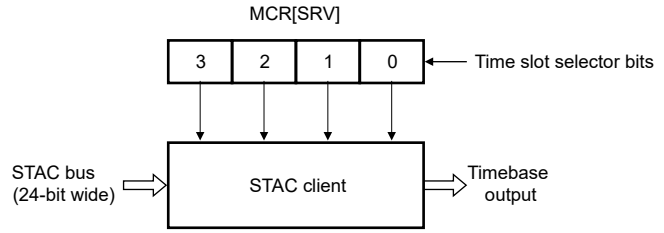

Figure 414. STAC block diagram

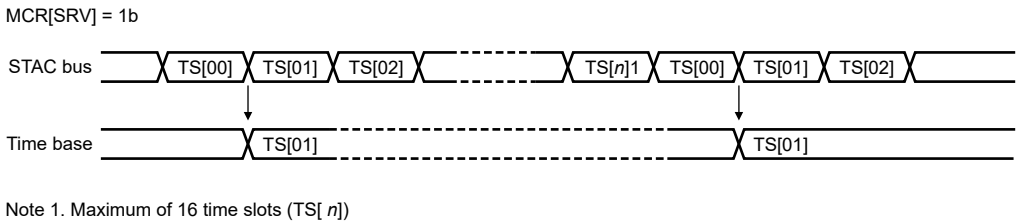
63.5.5.3 Timing example: STAC output



Note 1. Maximum of 16 time slots (TS[*n*])

Figure 415. Timing example: STAC output

63.5.6 Global clock prescaler (GCP)

eMIOS divides the system clock by the GCP (MCR[GPRE] + 1) and routes the resulting prescaled clock output to the channel CPs. You enable the GCP by writing 1 to MCR[GPREN]. If you disable the GCP (write 0 to the same field), eMIOS clears the prescaler counter and stops the prescaler clock.

To ensure safe operation and avoid glitches, you must perform the following steps to change the GCP:

1. Disable the GCP (write 0 to MCR[GPREN]).
2. Specify the new prescaler value (write GCP – 1 to MCR[GPRE].
3. Enable the GCP (write 1 to MCR[GPREN]).

63.5.7 Freeze and chip Debug mode

63.5.7.1 Enter and exit Freeze state

When the chip is in Debug mode (the chip Debug signal is asserted), you can freeze individual UCs. For the effects of Freeze state on eMIOS functions, see Freeze effects.

To put a channel in Freeze state, you must meet all of the following conditions:

- The chip must assert Debug.
- Prepare eMIOS for the Freeze state (write 1 to MCR[FRZ]).
- Enable Freeze for each channel you want to freeze:
  - Write 1 to C*n*[FREN].

A channel exits Freeze state when any of the following conditions occur:

- The chip deasserts Debug.
- You take eMIOS out of the Freeze state (write 0 to MCR[FRZ]).
- You disable Freeze for the channel:
  - write 0 to C*n*[FREN].

63.5.7.2 Freeze effects

Function	Effects of freeze
GCP	No effect
UC	• Halts counter, capture, and compare operation. • Freezes UC in its current state. • Makes all registers accessible. • In output modes, force match remains operational, allowing software to force the output to the desired level. • In input modes, the UC ignores input events. • When eMIOS exits Freeze state then UC operations resume, but they may be inconsistent until the UC reenters GPIO mode.
STAC	No effect
BIU	No effect

63.6 Initialization information

When initializing eMIOS, take the following considerations into account.

For eMIOS behavior on reset, see Reset.

Before changing the UC operating mode, you must:

1. Put the UC in GPIO mode (write 0b or 1b to C*n*[MODE]).
2. Write the correct values for the next operating mode to A*n* and B*n*.
3. Put the UC in the new operating mode (write the appropriate value to C*n*[MODE]).

If you change a UC from one mode to another without performing this procedure, the first operation cycle of the selected timebase can be random; that is, matches can occur in random time because you did not update A*n* and B*n* with correct values before the timebase matches the previous contents of either register.

NOTE

To to avoid causing an unexpected interrupt or DMA request when changing from GPIO to MCB mode, you must use the procedure described in Changing to MCB mode.

When you enable interrupts, any interrupt service routine must clear the flag before exiting.

63.7 Application information

63.7.1 Overview

All output operation modes can generate correlated output signals. You can disable updates of the output signals for each UC (OUDIS).

To guarantee that incrementing of the internal counters of correlated channels occurs in the same clock cycle, you must configure the internal CPs before enabling the GCP. If you configure the internal CPs after enabling the GCP, the internal counters may increment in the same ratio, but at different clock cycles.

You should drive the Output Disable Input signals with the flag signals of some UCs running in SAIC mode. When an output disable condition happens, the interrupt service routine must process the output channels before processing the channels running SAIC. This sequence avoids glitches in the output pins.

63.7.2 Timebase generation

In the MC and OPWFM modes with internal clock sources, you can modify the internal counter rate by configuring the CP ratio. Timebase with the fastest prescaler ratio illustrates a timebase with a prescaler ratio of one.

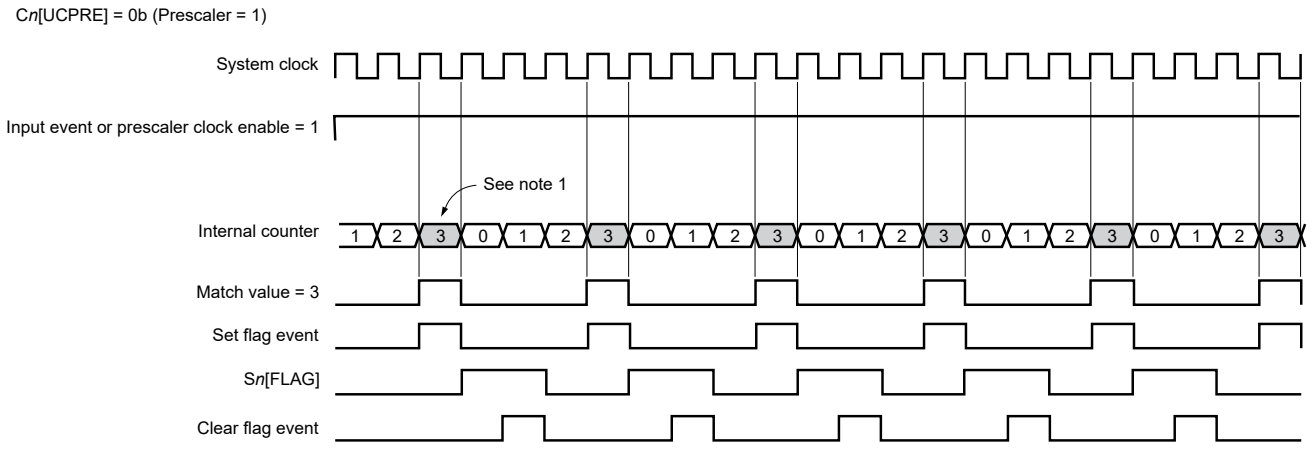
NOTE

The buffered modes, MCB and OPWFMB, behave differently.

If the prescaler ratio is greater than one or you select an external clock, the internal counter behaves in one of four different ways depending on the channel mode:

- In MC mode with Clear on Match Start and External Clock: Timebase generation with clear on match start and external clock.
- In MC mode with Clear on Match Start and Internal Clock source: Timebase generation with clear on match start and internal clock.
- In MC mode with Clear on Match End: Timebase generation with clear on match end.
- In OPWFM mode: Timebase generation with clear on match start and internal clock. The internal counter clears at the start of the match signal, skips the next prescaled clock edge, and then increments in the subsequent prescaled clock edge.

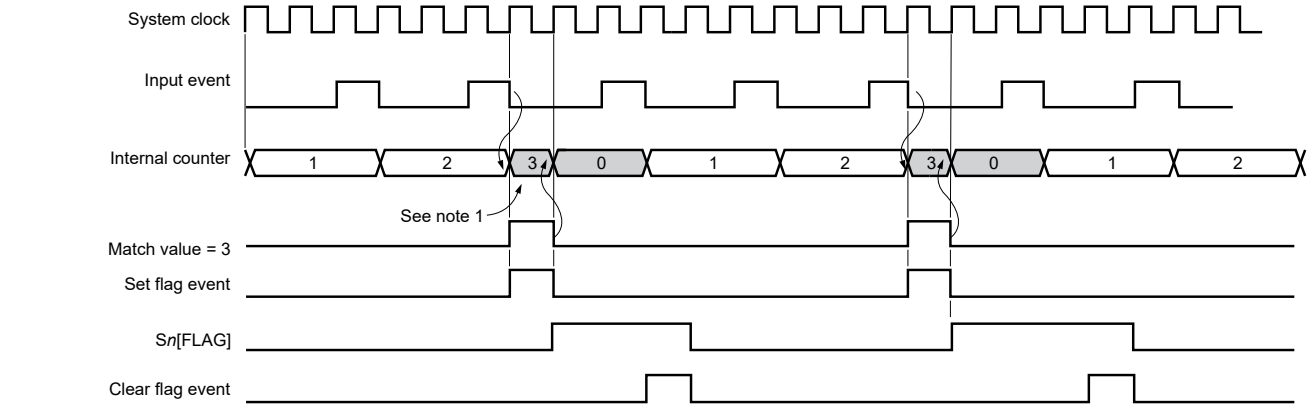
63.7.3 Timebase with the fastest prescaler ratio



Note 1: When a match occurs, eMIOS resets the internal counter in the first cycle, which starts another period.

Figure 416. Timebase with fastest prescaler ratio

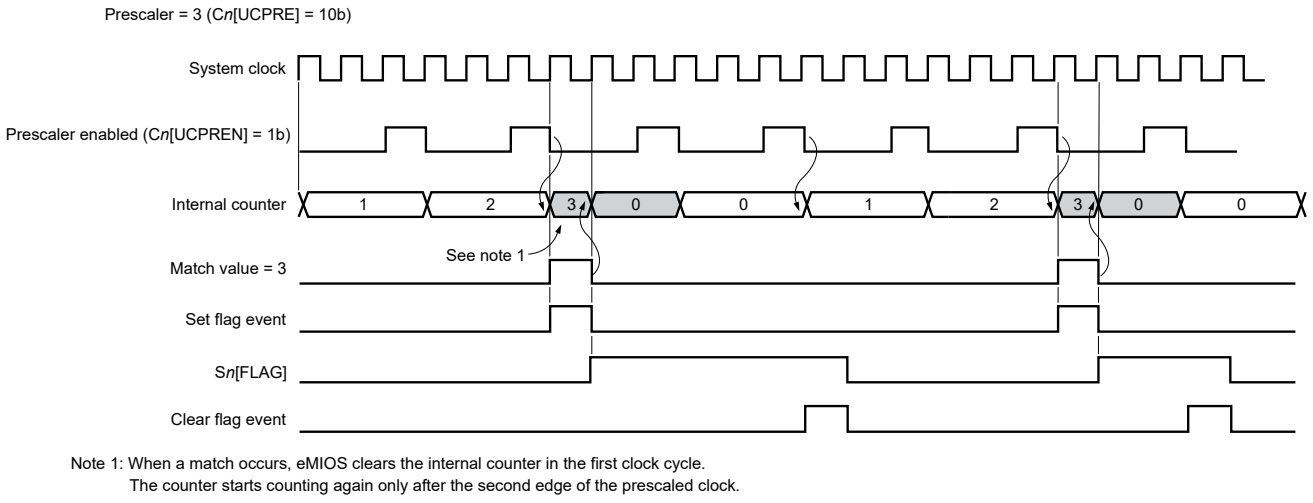
63.7.4 Timebase generation with clear on match start and external clock



Note 1: When a match occurs, eMIOS resets the internal counter in the first clock cycle. The counter starts counting at the next edge of the prescaler clock enable.

Figure 417. Timebase generation with clear on match start and external clock

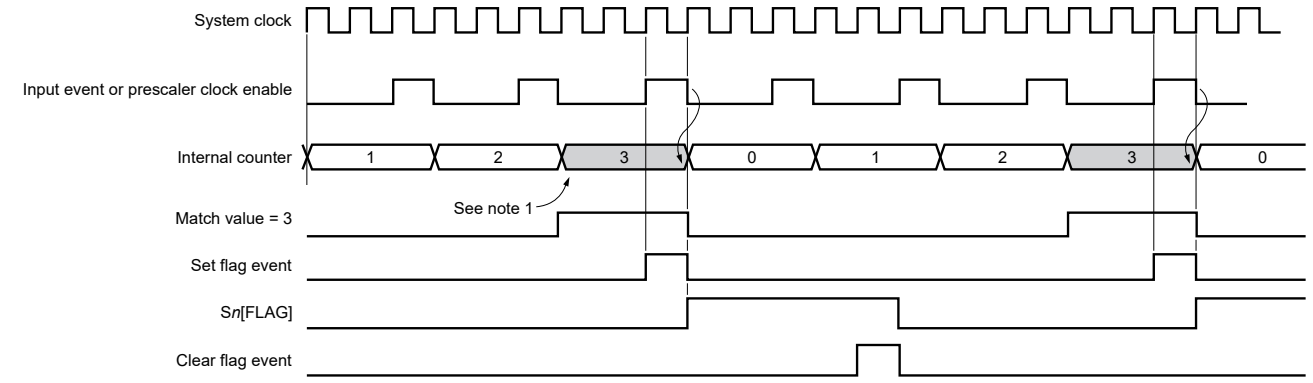
63.7.5 Timebase generation with clear on match start and internal clock



Note 1: When a match occurs, eMIOS clears the internal counter in the first clock cycle.
The counter starts counting again only after the second edge of the prescaled clock.

Figure 418. Timebase generation with clear on match start and internal clock

63.7.6 Timebase generation with clear on match end



Note 1: The match occurs only when the input event or prescaler clock enable is active.
When the match occurs, eMIOS resets the internal counter immediately.

Figure 419. Timebase generation with clear on match end

63.7.7 Coherent accesses

Reading A*n*[A] again in the same period as the last read of B*n*[B] results in incoherent results if the last read of B*n*[B] occurred after a disabled BS2→BS1 transfer.

63.7.8 Initializing channels and modes

Perform the following basic steps for output mode startup. This procedure assumes the channels are initially in GPIO mode:

1. Disable the GPC (write 0 to MCR[GPREN]).
2. For each timebase UC:
    a. Disable the CP (write 0 to C*n*[UCPREN]).
    b. Write an initial value to the internal counter (CNT*n*[C]).

c. Write initial values to A*n*[A] and B*n*[B].

d. Configure the UC for MC or MCB Up mode (write the appropriate value to C*n*[MODE]).

e. Select the CP ratio (C*n*[UCPRE]).

f. Enable the CP (write 1 to C*n*[UCPREN]).

3. For each output UC:

a. Disable the CP (write 0 to C*n*[UCPREN]).

b. Write initial values to A*n*[A] and B*n*[B].

c. Select the timebase input (C*n*[BSL]).

d. Specify the output mode (write the appropriate value to C*n*[MODE]).

e. Select the same CP ratio as the timebase UC (C*n*[UCPRE]).

f. Enable the CP (write 1 to C*n*[UCPREN]).

4. Enable the GPC (write 1 to MCR[GPREN]).

5. Enable GBTE (write 1 to MCR[GBTE]).

The timebase channel and the output channel may be the same for some applications such as in OPWFM or OPWFMB mode, or whenever the output channel drives the timebase itself.

You may configure flags at any time.

63.8 Memory maps and registers

63.8.1 Overall address map organization

All address locations not explicitly mentioned in this table are reserved. When you access an absent register, absent channel, or reserved address space, the transfer terminates with an error.

Table 356. Overall address map organization

Base address (hex)	Description
0	Module Configuration (MCR)
4	Global Flag (GFLAG)
8	Output Update Disable (OUDIS)
C	Disable Channel (UCDIS)
20	Channels 0–7
120	Channels 8–15
220	Channels 16–23

63.8.2 UC memory overview

Table 357. UC memory overview

Offset from UC *n* base address (hex)	Description
0	UC A n (A0 - A23)

Table continues on the next page...

Table 357. UC memory overview (continued)

Offset from UC *n* base address (hex)	Description
4	UC B n (B0 - B23)
8	UC Counter n (CNT0 - CNT23)
C	UC Control n (C0 - C23)
10	UC Status n (S0 - S23)
14	Alternate Address n (ALTA0 - ALTA23)
18	UC Control 2 n (C2_0 - C2_23)
1C–1F	Reserved

63.8.3 AS1, AS2, BS1, and BS2 shadow registers

When you use eMIOS UC modes, you rely heavily on four shadow registers:

- AS1
- AS2
- BS1
- BS2

You use A*n*[A], B*n*[B], and ALTA*n*[ALTA] to access these shadow registers:

- Each instance of A*n*[A] has a separate associated instance of AS1 and AS2. In some UC modes, you also use ALTA*n*[ALTA] to access AS2.
- Each instance of B*n*[B] has a separate associated instance of BS1 and BS2.

See Relationship between A*n*, B*n*, ALTA*n*, and shadow registers.

Each UC mode uses the AS1-AS2 and BS1-BS2 shadow register pairs for various match and capture functions, as described in Unified channels (UC).

A reset clears all shadow registers.

Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA] describes how you write to and read from the shadow registers for all operation modes. Values not listed are reserved. For more information, see Unified channels (UC).

63.8.4 Relationship between A*n*, B*n*, ALTA*n*, and shadow registers

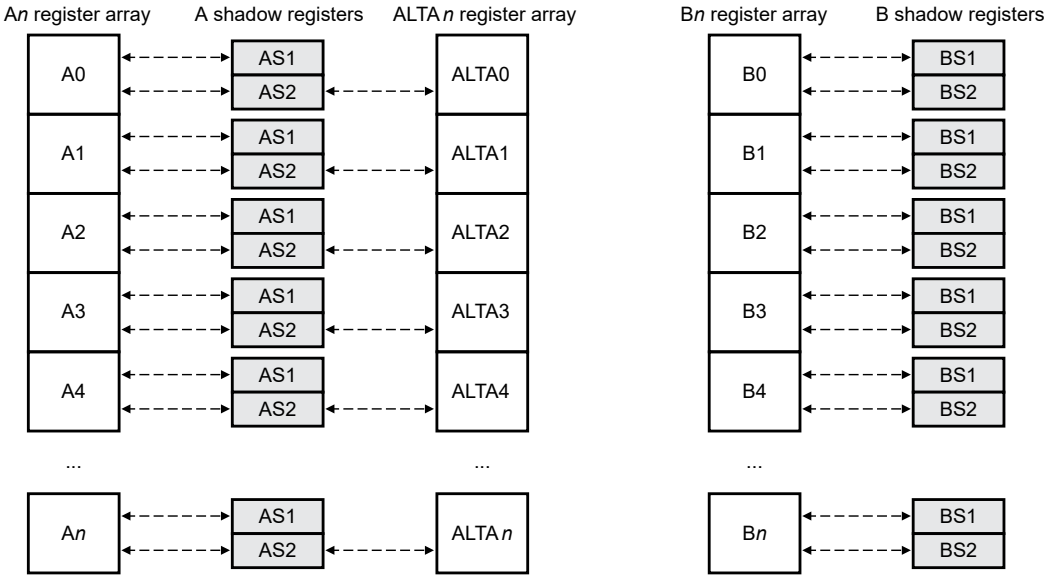


Figure 420. Relationship between A*n*, B*n*, ALTA*n*, and shadow registers

63.8.5 Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA]

This table describes how you write to and read from the following registers for all operation modes:

- UC A n (A0 - A23)
- UC B n (B0 - B23)
- Alternate Address n (ALTA0 - ALTA23)

Values not listed are reserved. For more information, see Unified channels (UC).

Table 358. Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA]

Operation mode	Register access					
	A*n*		B*n*		ALTA*n*	
	Write	Read	Write	Read	Write	Read
GPIO	AS1 and AS2[1]	AS1	BS1 and BS2[2]	BS1	AS2	AS2
SAIC[3]	—	AS2	BS2	BS2	—	—
SAOC[3]	AS2	AS1	BS2	BS2	—	—
IPWM	—	AS2	—	BS1	—	—
IPM	—	AS2	—	BS1	—	—
DAOC	AS2	AS1	BS2	BS1	—	—
PEA	AS1	AS2	—	BS1	—	—
PEC[3]	AS1	AS1	BS1	BS1	—	AS2
QDEC[3]	AS1	AS1	BS2	BS2	—	—

Table continues on the next page...

Table 358. Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA] (continued)

Operation mode	Register access					
	A*n*		B*n*		ALTA*n*	
	Write	Read	Write	Read	Write	Read
WPTA	AS1	AS1	BS1	BS1	—	AS2
MC[3]	AS2	AS1	BS2	BS2	—	—
OPWFM	AS2	AS1	BS2	BS1	—	—
OPWMC	AS2	AS1	BS2	BS1	—	—
OPWM	AS2	AS1	BS2	BS1	—	—
OPWMT	AS1	AS1	BS2	BS1	AS2	AS2
MCB[3]	AS2	AS1	BS2	BS1	—	—
OPWFMB	AS2	AS1	BS2	BS1	—	—
OPWMCB	AS2	AS1	BS2	BS1	—	—
OPWMB	AS2	AS1	BS2	BS1	—	—

1. This operation writes the same value to AS1 and AS2.
2. This operation writes the same value to BS1 and BS2.
3. These modes do not require UC B n (B0 - B23), but you can still use it to access BS2.

63.8.6 eMIOS_0 register descriptions

All control registers are 32 bits wide. Data fields are 24 bits wide. There are 24 UCs, as mapped in Counter buses, channels, and timebase sources.

63.8.6.1 eMIOS_0 memory map

eMIOS_0 base address: 4008_8000h

63.8.6.2 Module Configuration (MCR)

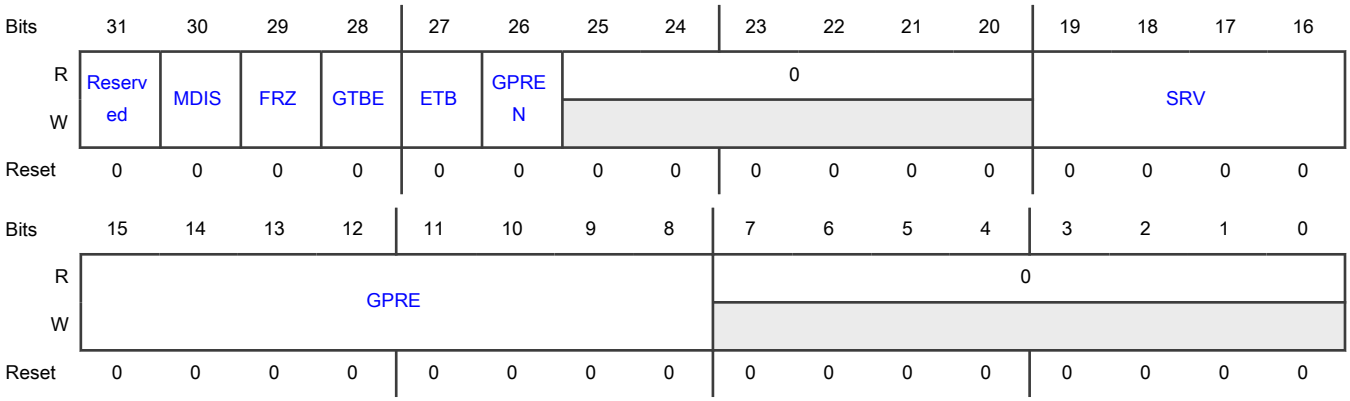
Offset

Register	Offset
MCR	0h

Function

Configures eMIOS operation.

Diagram



Fields

Field	Function
31 —	Reserved Write only the reset value to this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
30 MDIS	Module Disable Disables eMIOS by stopping the clock. When you disable eMIOS, its clock stops, it consumes less power, and you can access only the following registers: • Module Configuration (MCR) • Output Update Disable (OUDIS) • Disable Channel (UCDIS) 0b - Enable 1b - Disable
29 FRZ	Freeze Prepares eMIOS to enter Freeze state (see Freeze and chip Debug mode). eMIOS does not enter Freeze state until both of the following conditions occur: • The chip asserts Debug mode. • You enable Freeze for each UC (write 1 to C*n*[FREN]). A channel remains frozen until one or more of the following occur: • You force eMIOS to exit the Freeze state (write 0 to FRZ). • The chip deasserts Debug mode. • You disable Freeze for that UC (write 0 to C*n*[FREN]). 0b - Exit Freeze state 1b - Enter Freeze state
28 GTBE	Global Timebase Enable Asserts the GTBE_OUT signal. If GTBE_OUT is connected to the GTBE_IN input of one or more eMIOS instances, asserting the signal turns on the internal counters of those eMIOS instances simultaneously. **NOTE** The GTBE_IN input enables (asserted) or disables (deasserted) the internal counters. 0b - Deassert GTBE_OUT 1b - Assert GTBE_OUT
27 ETB	External Time Base Selects the time base source to drive counter bus A. 0b - Unified Channel 1b - STAC
26 GPREN	Global Prescaler Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Enables the global prescaler counter. Disabling the global prescaler clears the prescaler counter and stops the prescaler clock. 0b - Disable 1b - Enable
25-20 —	Reserved
19-16 SRV	Server Time Slot Selects the time slot for output of the STAC bus.
15-8 GPRE	Global Prescaler Specifies the global clock prescaler. Write the desired clock divide ratio minus 1. For example, for a divide ratio of 8, write 111b. The prescaler can range from 1 (0b) to 256 (11111111b).
7-0 —	Reserved

63.8.6.3 Global Flag (GFLAG)

Offset

Register	Offset
GFLAG	4h

Function

Groups the flag fields from all channels into one register to improve interrupt handling.

For UCs, each field mirrors the corresponding channel flag (S*n*[FLAG]).

Diagram

63.8.6.4 Output Update Disable (OUDIS)

Offset

Register	Offset
OUDIS	8h

Function

Disables transfers from AS2 to AS1 and BS2 to BS1 on a per-channel basis. This applies to any channel operating in MC, MCB, or any output mode that writes to AS2 and BS2.

When a field is 0, transfers on that channel occur immediately or in the next period, depending on the operation mode. Unless that mode's description states otherwise, the transfer occurs immediately.

63.8.6.6 UC A n (A0 - A23)

Offset

For n = 0 to 23:

Register	Offset
An	20h + (n × 20h)

Function

Accesses the AS1 and AS2 shadow registers for each UC, depending on the selected UC mode. See AS1, AS2, BS1, and BS2 shadow registers.

For information about how you write to and read from A*n*, B*n*, and ALTA*n* for all UC modes, see Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA].

For n = 0 to 23:

Register	Offset
Bn	24h + (n × 20h)

Function

Accesses the BS1 and BS2 shadow registers for each UC, depending on the selected UC mode. See AS1, AS2, BS1, and BS2 shadow registers.

For information about how you write to and read from A*n*, B*n*, and ALTA*n* for all UC modes, see Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA].

63.8.6.8 UC Counter n (CNT0 - CNT23)

Offset

For n = 0 to 23:

Register	Offset
CNTn	28h + (n × 20h)

Function

Indicates the value of the UC internal counter.

When eMIOS is in GPIO mode or the UC is frozen, this register is read-write. For all other modes, this register is read-only. When entering some UC modes, eMIOS automatically clears this register. See Unified channels (UC) for details.

The following modes use the UC counter:

- Output Pulse Width and Frequency Modulation (OPWFM) mode
- Output Pulse Width and Frequency Modulation Buffered (OPWFMB) mode
- Center Aligned Output PWM with Dead Time Insertion (OPWMC) mode
- Center Aligned Output PWM with Dead Time Insertion Buffered (OPWMCB) mode
- Pulse or Edge Accumulation (PEA) mode
- Pulse Edge Counting (PEC) mode
- Windowed Programmable Time Accumulation (WPTA) mode
- Quadrature Decode (QDEC) mode
- Modulus Counter (MC) mode
- Modulus Counter Buffered (MCB) mode

All other modes not in this list do not use the internal counter.

1. p = Adjust parameters for the mode of operation. See Unified channels (UC) for details.

Table 360. Edge Polarity (EDPOL) settings

For these modes:	EDPOL does this:	and EDPOL values mean:
Input except QDEC	Selects which edge triggers the internal counter, an input capture, or the input capture flag. If EDPOL does not appear in the UC mode description, it has no effect on UC operation.	0b - Trigger on a falling edge 1b - Trigger on a rising edge
QDEC with bit 0 in MODE = 0	Selects the count direction according to the direction signal (UC*n* input). The EDPOL value in C*n-1* selects the edge that clocks the UC*n* internal counter.	0b - Counts down (decrements) when UC*n* asserts 1b - Counts up (increments) when UC*n* asserts
QDEC with bit 0 in MODE = 1	Selects the count direction according to the phase difference. To operate properly, EDPOL must be the same for C(*n* - 1) and C*n*.	0b - Counts down (decrements) if phase_A is ahead of phase_B 1b - Counts up (increments) if phase_A is ahead of phase_B
Output	Selects the logic level on the output pin.	0b - A match on comparator A deasserts the output flip-flop, while a match on comparator B sets it 1b - A match on comparator A asserts the output flip-flop, while a match on comparator B clears it

Table 361. Edge Select (EDSEL) settings

For these modes:	EDSEL does this:	and EDSEL values mean:
Input	Selects whether the internal counter is triggered by both edges of a pulse or by a single edge as defined by EDPOL. If EDSEL does not appear in the UC mode description, it has no effect on UC operation.	0b - Single-edge triggering on edge specified in EDPOL 1b - Both-edges triggering
GPIO in	Selects whether an edge asserts the input capture flag (S*n*[FLAG]).	0b - Sets S*n*[FLAG] on the edge specified in EDPOL 1b - Does not set S*n*[FLAG]
SAOC	Selects the behavior of the output flip-flop at each match.	0b - Drive the EDPOL value on the output flip-flop 1b - Toggle output flip-flop

14-3 —	Reserved
2 UCIN	UC Input Pin Indicates the input pin state after the input pin has been filtered and synchronized. 0b - Negated 1b - Asserted
1 UCOUT	UC Output Pin Indicates the output pin state. 0b - Negated 1b - Asserted
0 FLAG	Flag Indicates that an input capture or a match event in the comparators has occurred. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No event 1b - Event has occurred When writing 0b - No event 1b - Clear the flag (FLAG returns to 0)

63.8.6.11 Alternate Address n (ALTA0 - ALTA23)

Offset

For n = 0 to 23:

Register	Offset
ALTAn	34h + (n × 20h)

Function

Provides an alternate address to access AS2 shadow registers in these restricted modes:

- General-Purpose Input and Output (GPIO) mode
- Pulse Edge Counting (PEC) mode
- Windowed Programmable Time Accumulation (WPTA) mode
- Output PWM with Trigger (OPWMT) mode

In these modes, you can use A*n*[A] together with ALTA*n*[ALTA] to access both AS1 and AS2. Assignment of values for A*n*[A], B*n*[B], and ALTA*n*[ALTA] summarizes the ALTA*n* writing and reading accesses for all ALTA*n* operation modes.

In modes that do not require this register, any write access is ignored and any read access returns unspecified data.

64.2 Overview

BCTU accepts ADC conversion-request trigger inputs and routes those requests to one or more ADCs.

BCTU accepts the following trigger sources:

- Hardware triggers (outputs from on-chip timer modules)
- Software triggers through the SFTRGRn register

BCTU maps each trigger input to a Trigger Configuration (TRGCFG_0 - TRGCFG_44) register, which specifies the target ADC channel and other control data for the requested conversion.

You can configure a list of ADC channels, the CL, that processes a sequence of conversions in response to a single trigger input. See the Conversion list (CL) section.

BCTU stores each ADC conversion result for CPU access or routing to memory through DMA.

If the same ADC is targeted by multiple triggers, priority logic selects the next trigger to process from all active trigger inputs. See Priority of simultaneous triggers.

BCTU input trigger signals are level-sensitive; thus, if a logical level 1 is detected, an event is captured by the BCTU.

64.2.1 Block diagram

The following figure shows the top-level block diagram of BCTU.

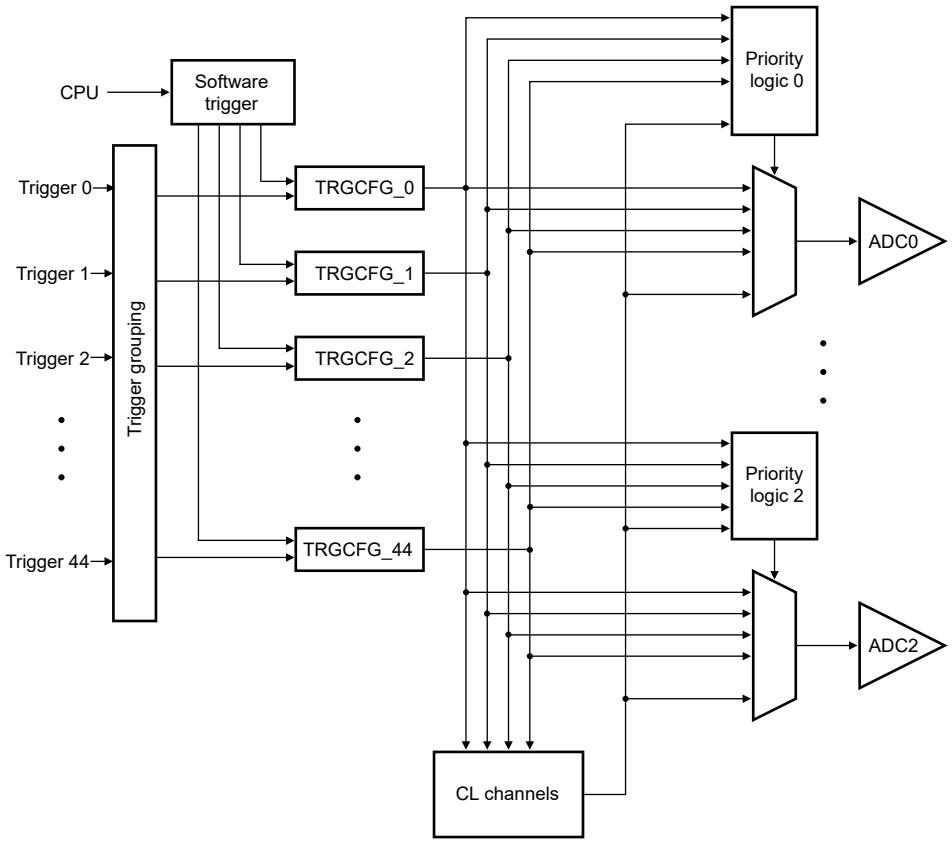

Figure 421. BCTU block diagram

64.2.2 Features

BCTU supports:

- 45 Trigger inputs, configured with the Trigger Configuration (TRGCFG_0 - TRGCFG_44) registers
- Trigger outputs to 3 ADCs
- One priority selection logic block per ADC
- Selection multiplexers to select one trigger at a time for each ADC
- A CL of 32 ADC channels
- A trigger grouping block to latch the hardware triggers. BCTU clears these triggers when the ADC sends an acknowledgement for conversion completion.

64.2.3 Interaction with other peripherals

BCTU works together with timer and ADC modules on the chip. Use the trigger configuration registers (TRGCFG_*n*) to map BCTU triggers to ADC inputs. When a timer output asserts a BCTU trigger, BCTU passes the trigger to an ADC input and stores the trigger assertion until the corresponding ADC begins the requested conversion. When the ADC completes the conversion, BCTU asserts a trigger clear signal to clear both the internally stored trigger and the external trigger source if they are still asserted. Implementation illustrates the modules that interact with BCTU.

NOTE

A timer trigger can remain active until the corresponding ADC initiates conversion. Therefore, another match may occur in the timer before the ADC conversion begins. BCTU does not detect this trigger overrun. Your application must look for and respond to such conditions.

64.2.4 Implementation

The following figure shows the implementation structure of the BCTU.

NOTE

For more details of the actual trigger sources implemented in this device, see the chip-specific information section.

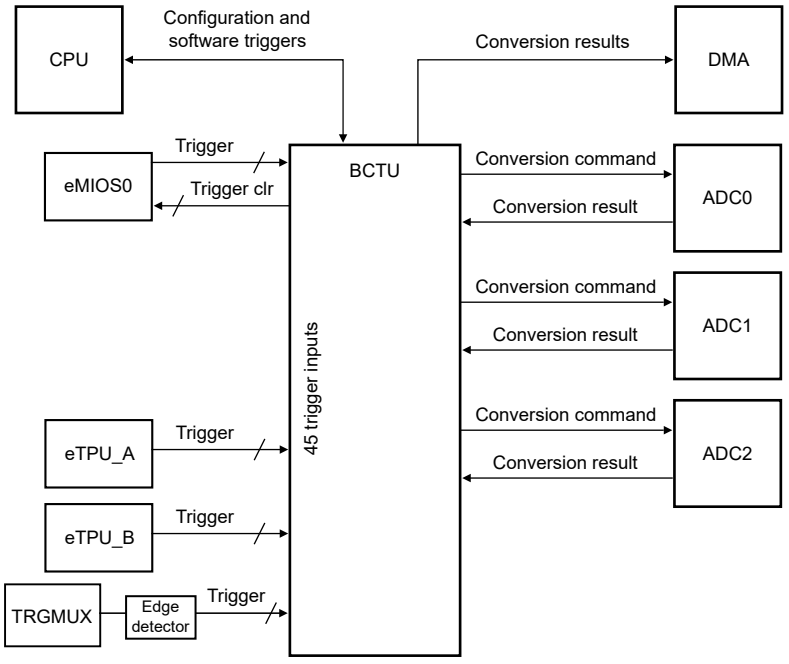

Figure 422. Implementation

64.3 Functional description

64.3.1 Triggers

64.3.1.1 Overview

BCTU prioritizes ADC trigger inputs based on the input number: the lower the number, the higher the priority associated with it. Therefore, trigger 0 is the highest priority trigger and trigger 44 is the lowest priority. The trigger input priority scheme determines which trigger takes precedence when more than one trigger occurs at the same time, or when the triggered ADC is busy with a conversion. Therefore, there are two possible scenarios for the trigger priority selection:

- When there are no ongoing conversions
- When a triggered ADC is executing a conversion

BCTU supports two types of trigger sources:

- Hardware triggers from timer modules
- Software triggers (SFTRGR*n*)

64.3.1.2 Hardware triggers

To request an ADC conversion through the BCTU, a timer module such as eMIOS asserts its output signal, which is connected to a BCTU trigger input. When BCTU detects the asserted trigger, it routes that request to the ADCs selected in the corresponding Trigger Configuration (TRGCFG_*n*[ADC_SEL*m*]). The trigger remains asserted until the requested conversion begins, at which time BCTU clears the trigger. If the timer asserts the trigger input when the trigger is already set, BCTU ignores the new trigger. If BCTU receives a new trigger input at the same time it is clearing the trigger, then the trigger remains asserted and BCTU initiates a new conversion.

If you configure the trigger for CL, trigger assertion begins a sequence of conversions controlled by the CL Channel Address (LISTCHR_0 - LISTCHR_15) registers. In this event, BCTU clears the trigger when the last conversion in the CL begins.

NOTE

Any new trigger input participates in the trigger priority selection scheme and therefore may not trigger the next conversion.

64.3.1.3 Software triggers

You assert a software trigger by writing 1 to the corresponding field of the appropriate software trigger (SFTRGR*n*) register. Similar to the hardware triggers, BCTU changes the software trigger field to 0 when the requested conversion begins. If you write 1 to the software trigger field while the conversion is still in progress, BCTU ignores the request. If you write 1 to the field at the same time BCTU is attempting to clear the trigger (change the field to 0), the trigger remains asserted and BCTU triggers a new conversion following the trigger priority criteria.

64.3.1.4 Configure all triggers

Global trigger enable (MCR[GTRGEN]) allows you to configure the BCTU trigger inputs and then activate them all at one time.

To configure and then activate all BCTU triggers:

1. Clear any currently active and asserted trigger inputs (write 0 to TRGFG_*n*[TRG_FLAG]), which also causes BCTU to assert trigger clear to the trigger sources.
2. Disable global triggers (MCR[GTRGEN]). This action deactivates all trigger inputs and prevents BCTU from generating any ADC conversion requests.
3. Configure the individual trigger inputs (see Configure individual triggers).
4. Enable global triggers (MCR[GTRGEN]). This action activates all individually enabled triggers at the same time.

64.3.1.5 Configure individual triggers

Using Trigger Configuration (TRGCFG_0 - TRGCFG_44), for each trigger:

- Enable the trigger (TRIGEN).
- Specify the target ADC (ADC_SEL*n*).
- Specify the ADC channel (CHANNEL_VALUE_OR_LADDR).
- Specify whether the trigger initiates a single conversion or a CL (TRS).
- For a CL trigger, specify a pointer to the CL element (TRGCFG_x[CHANNEL_VALUE_OR_LADDR]).

64.3.1.6 Reconfigure triggers on-the-fly

NOTE

Reconfigure BCTU triggers only when the individual trigger is not active (TRG_FLAG). If TRG_FLAG is 1, the requested conversion is still in progress and it is not safe to modify the trigger configuration.

To reconfigure a trigger on-the-fly (while BCTU is in full operation):

1. Disable the trigger (TRIGEN) to prevent it from requesting a new conversion.
2. Check the current state of the trigger (TRG_FLAG) to be sure no conversion or CL is in progress.
3. When any in-progress conversion or CL completes (TRG_FLAG == 0), clear the trigger source by writing 1 to TRG_FLAG. This action ensures that only trigger inputs that assert after you reconfigure and re-enable the trigger are able to request a new conversion or CL.
4. Reconfigure the trigger (see Configure individual triggers).
5. Enable the trigger (TRIGEN).

64.3.1.7 Enable software triggers

To allow software triggers (SFTRGRn) to request conversions, you must enable global trigger enable (MCR[GTRGEN]). If you disable global trigger enable, software triggers do not initiate a conversion but asserted triggers remain asserted. However, when you enable global trigger enable, any asserted software triggers initiate conversions following the priority scheme of lowest to highest trigger number.

Software triggers operate regardless of individual trigger enable (TRGCFG_x[TRIGEN]). That is, writing 1 to any Software Trigger (SFTRGRn) initiates a conversion (following the priority scheme) regardless of the value of trigger enable. This software trigger independence supports the elimination of conflict between software and hardware triggers.

64.3.1.8 Trigger timing

There are four clock cycles from assertion of a BCTU trigger input to assertion of the trigger output to the ADC. For single conversions, BCTU asserts trigger clear back to the trigger source simultaneous to asserting the trigger to the ADC.

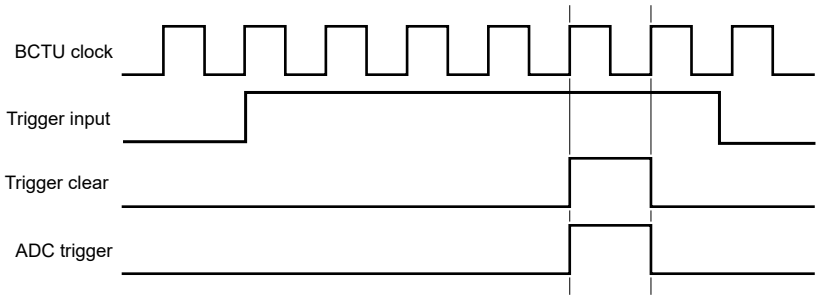

Figure 423. Trigger timing

64.3.1.9 Priority of simultaneous triggers

When more than one trigger input asserts a conversion request to the same ADC at the same time—that is, in the same BCTU clock cycle—BCTU employs a priority scheme to determine which asserted trigger to process next. BCTU prioritizes trigger inputs based on the trigger number. The lowest number, trigger 0, has the highest priority, and the highest number, trigger 44, has the lowest priority.

If two triggers assert in the same clock cycle, BCTU gives priority to the lower numbered trigger. For example, if trigger 0 and trigger 1 both assert in the same cycle, BCTU selects trigger 0 for trigger generation. Trigger 1 remains active (pending) until the conversion requested by trigger 0 completes. See Simultaneous trigger priority management.

If trigger 0 asserts again before the next trigger selection opportunity at the end of the current conversion, then BCTU selects it again and trigger 1 remains asserted (pending) during the next ADC conversion time frame.

As illustrated in Trigger timing, BCTU requires four clock cycles to transmit a conversion request to an ADC if that ADC is not already executing a conversion. However, if the ADC is busy at the time of trigger assertion, BCTU requires only three clock cycles to generate the conversion request for a subsequent conversion.

Triggers that assert in the same clock cycle but target different ADCs are not in conflict, and BCTU processes both triggers at the same time.

64.3.1.10 Simultaneous trigger priority management

The following figure shows the simultaneous triggers for priority management.

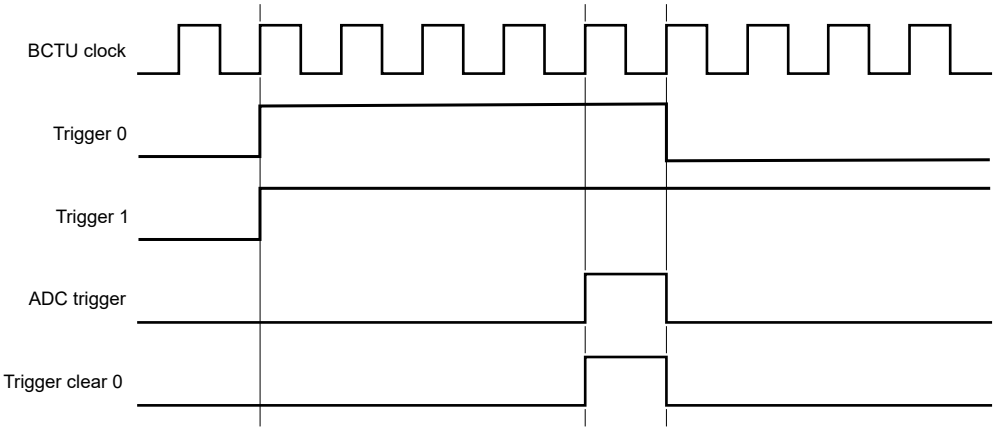

Figure 424. Simultaneous trigger priority management

64.3.1.11 Trigger management when ADC is busy

When a trigger input asserts a conversion request to an ADC that is already processing a conversion requested by a different trigger, the new trigger remains active (pending) until the conversion in progress completes. This behavior is the same as if the two triggers had been simultaneous (occurred in the same clock cycle). When the in-progress conversion completes, the pending trigger then competes for priority with any other active trigger for that ADC.

64.3.1.12 Trigger clearing mechanism

There are two sources of ADC conversion triggers: hardware trigger, from the trigger inputs and software triggers, from SFTRGRn register.

A logical level 1 is detected in the input and captured into an input trigger register. This register remains set until the related conversion starts. At this time, the input trigger register is cleared. If another logical level 1 is detected while the trigger register is already set, the new level is not considered by the BCTU hardware. If a new logical level 1 occurs at the same time the trigger register is being cleared, then the register remains set and a new conversion is triggered by this input.

NOTE

The new triggered conversion will participate in the trigger priority selection thus may not trigger the next conversion.

The software trigger behaves similarly to the hardware trigger. The difference is that the trigger register is set by a CPU write operation. The trigger register is cleared by the BCTU hardware when the related conversion starts. If the CPU tries to set the trigger register by writing to the SFTRGR register corresponding bit, while the register is already set, the new attempt to set the register is not considered by the BCTU hardware. If a set occurs at the same time the hardware is attempting to clear the same trigger register, then the set has precedence and the register remains set. A new conversion will be triggered following the trigger priority criteria implemented in the hardware.

In case a LIST of conversions is triggered, instead of a single conversion, the trigger register is cleared at the start of the last conversion in the LIST.

64.3.2 Conversion list (CL)

64.3.2.1 CL overview

A CL executes a sequence of conversions on one or more target ADCs. See CL architecture and operation. It also stores information from the last conversion executed in a sequence except for the target ADC, which is stored in ADC select n (TRGCFG_*m*[ADC_SEL*n*]).

If the channel or CL address (TRGCFG_x[CHANNEL_VALUE_OR_LADDR]) points to a CL element containing one or more entries:

1. The trigger initiates a sequence of conversions starting with the target CL element.
2. The sequence executes until the LAST channel (LISTCHR_*n*[LAST_y] is 1), and stops after that channel is converted.

When you configure the CL element for next channel wait for trigger (write 1 to LISTCHR_*n*[NEXT_CH_WAIT_ON_TRIG_y]):

1. BCTU clears the trigger source.
2. CL execution pauses after the current conversion is completed.
3. CL execution resumes when the same trigger asserts again.

BCTU determines trigger priority before executing any CL. See Priority of simultaneous triggers.

64.3.2.2 CL architecture and operation

The following figure shows the CL architecture and operation.

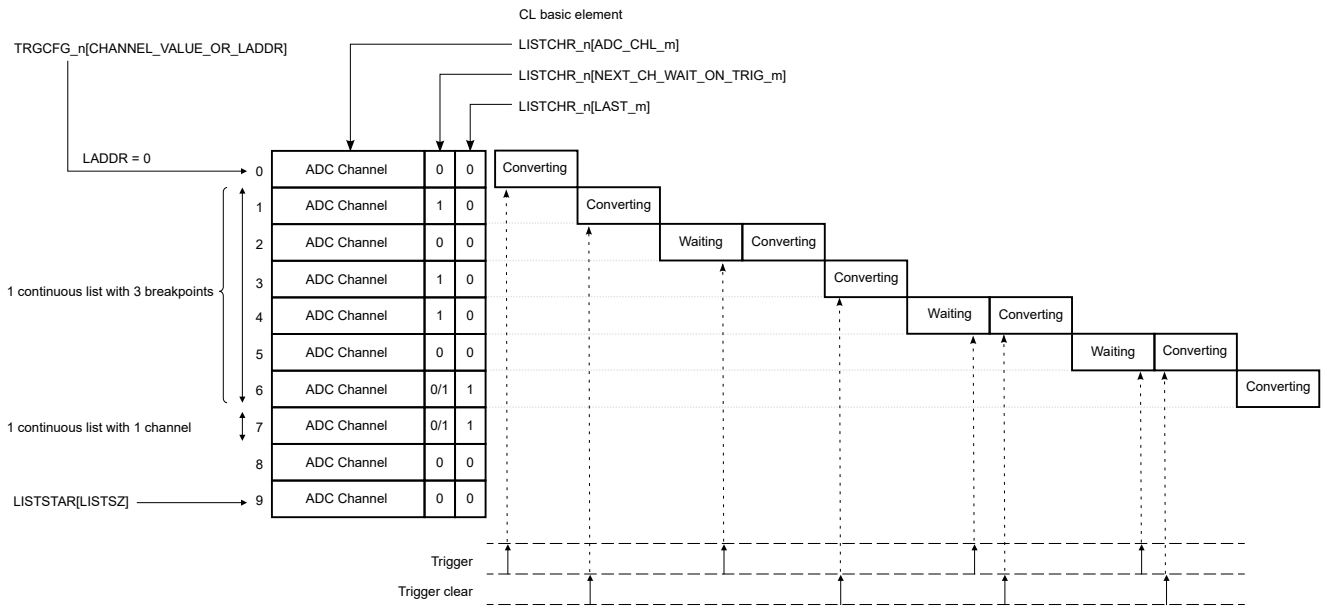

Figure 425. CL architecture and operation

64.3.2.3 CL channel rules

CL conversion obeys the following rules:

- The sequence of conversions executes until the Last Channel (LISTCHR_*n*[LAST_y] is 1).
- A CL conversion sequence precludes other conversions on the same ADC. If the CL is waiting (LISTCHR_*n*[NEXT_CH_WAIT_ON_TRIG_y] is 1), BCTU cannot route a non-CL conversion to that ADC (although that ADC remains available for normal and injected conversions).
- Two or more triggers for different ADCs may point to the same CL. This CL can drive parallel execution on the selected ADCs.

- If the Channel or CL Address (TRGCFG_x[CHANNEL_VALUE_OR_LADDR]) does not point to a valid list address, BCTU uses address 0 by default.
- When the CL pointer reaches the last available list address (LISTSTAR[LISTSZ] minus 1), the pointer wraps to list address 0.
- You can select more than one ADC per trigger using the ADC Select n (TRGCFG_x[ADC_SELn]) fields, but selecting more than one ADC is valid only for multiple parallel CL operation. If you select more than one ADC for a single-conversion trigger, BCTU ignores the trigger.

64.3.3 ADC conversion results access

64.3.3.1 Overview

The value of DATA_DEST determines access to ADC results.

- DATA_DEST = 000: ADC results are available in the ADC data registers.
- DATA_DEST = 001: ADC results are available in FIFO 1 Result Data (FIFO Result Data (FIFO1DR - FIFO3DR)). See Route conversion data to FIFO.
- DATA_DEST = 010: ADC results are available in FIFO 2 Result Data (FIFO Result Data (FIFO1DR - FIFO3DR)). See Route conversion data to FIFO.
- DATA_DEST = 011: ADC results are available in FIFO 3 Result Data (FIFO Result Data (FIFO1DR - FIFO3DR)). See Route conversion data to FIFO.

You can access ADC results using flags and interrupt requests (see Access on interrupt request) or DMA (see Access on DMA request). Interrupt requests are based on Module Status (MSR) flags. ADC*n*DR provides the following information, with one register used for each ADC:

- The conversion results
- The channel that was used for the conversion
- The trigger input that initiated the conversion
- Whether a CL element generated the conversion
- Whether the data was the last conversion of a CL

64.3.3.2 Access on interrupt request

If interrupts are enabled for ADC*n* Result Data (MCR[IEN*n*] is 1) and DMAs are disabled for ADC*n* Result Data (MCR[DMA*n*] is 0), BCTU generates an interrupt request for each available conversion data in ADC*n*DR. Because BCTU executes conversions on different ADCs in parallel, conversion results may be available on multiple ADCs at the same time. New Data (MSR[NDATAn] is 1) indicates that new conversion data is available in the corresponding ADC Data Result (ADC*n*DR). To clear the New Data flag, write 1 to MSR[NDATAn_CLR].

64.3.3.3 Access on DMA request

If you enable DMA requests (MCR[DMA*n*]):

- You must select one channel for DMA per ADC.
- New conversion result data (ADC*n*DR) generates a DMA request.
- The DMA controller deasserts the DMA request and writes 1 to MSR[NDATAn_CLR] to clear the flag.

When an ADC generates new data (MSR[NDATAn]), BCTU processes the DMA request. See Clear a DMA request.

64.3.3.4 Clear an interrupt request

BCTU clears an interrupt request when:

- The number of valid entries is less than or equal to the FIFOn watermark level (FIFOWM[WM_FIFO*n*]).

- You write 1 to FIFO watermark interrupt status (FIFOERR[WM_INT_FIFO*n*]).

64.3.3.5 Clear a DMA request

BCTU clears a DMA request when:

- The number of valid entries is less than or equal to the FIFOn watermark level (FIFOWM[WM_FIFO*n*]).
- The DMA controller sends acknowledgment to BCTU.

64.3.3.6 Clear an error-generated interrupt request

Clear an interrupt generated because of an error condition by writing 1 to the appropriate error flag:

- FIFOERR[OVR_ERR_FIFO1]
- FIFOERR[UNDR_ERR_FIFO1]
- FIFOERR[OVR_ERR_FIFO2]
- FIFOERR[UNDR_ERR_FIFO2]
- FIFOERR[OVR_ERR_FIFO3]
- FIFOERR[UNDR_ERR_FIFO3]

64.3.3.7 Conversion data overrun

If new ADC conversion data becomes available before you read the previous data (ADC*n*DR), then BCTU indicates a data overrun (MSR[DATAOVRn] is 1).

If you enable interrupts for the ADC (MCR[IEN*n*]), a data overrun also generates an interrupt request, regardless of the DMA request configuration.

To clear a data overrun (MSR[DATAOVRn]), write 1 to data overrun clear (MSR[DATAOVRn_CLR]). See Clear an error-generated interrupt request.

64.3.3.8 Route conversion data to FIFO

BCTU allows you to route multiple ADC conversion results to one of 3 internal data FIFOs. Any trigger source can route results to an available FIFO based on the trigger index. Each FIFO has a dedicated counter (FIFOCNTR[CNTR_FIFO*n*]) to indicate the number of entries in the FIFO.

Each FIFO also has its own result data register (FIFO*n*DR) that contains the following information about the last conversion result routed to the FIFO.

- ADC result data
- Trigger source index
- ADC number
- ADC channel number

64.3.3.9 Read ADC result from FIFO

Each FIFO has DMA and interrupt interfaces. The DMA interface reads data. The interrupt interface indicates watermark and error conditions:

- An overrun error (FIFOERR[OVR_ERR_FIFO*n*]) occurs when you attempt to write data to an already full FIFO.
- An underrun error (FIFOERR[UNDR_ERR_FIFO*n*]) occurs when you attempt to read data from an empty FIFO.
- BCTU asserts a watermark interrupt request if the number of valid FIFO entries exceeds the watermark level (FIFOWM[WM_FIFO*n*]).

You can read a FIFO:

- by enabling DMA requests (FIFOCR[DMA_EN_FIFO*n*])
- by polling the FIFO full status (FIFOSR[FULL_FIFO*n*])

See Configuration of DMA and interrupt behavior.

64.3.3.10 Configuration of DMA and interrupt behavior

Table 364. Configuration of DMA and interrupt behavior

FIFOCR[DMA_EN_FIFO*n*]	FIFOCR[IEN_FIFO*n*]	Condition
0	0	No DMA request; no interrupt request
0	1	Interrupt request when FIFO exceeds watermark level; interrupt request on error
1	0	DMA request when FIFO exceeds watermark level
1	1	DMA request when FIFO exceeds watermark level; interrupt request on error

64.3.4 Multiple parallel conversions (MPC)

64.3.4.1 Overview

The MPC mechanism allows you to execute a series of simultaneous ADC conversions by selecting more than one ADC for any CL-configured trigger.

64.3.4.2 Configure MPC

To configure a CL to perform MPC:

1. Select CL for the trigger resolution (write 1 to TRGCFG_*m*[TRS]).
2. Select more than one ADC for the trigger (TRGCFG_*m*[ADC_SEL*n*]).
3. Specify the CL address for the first CL element (TRGCFG_*m*[CHANNEL_VALUE_OR_LADDR]).

64.3.4.3 CL address selection for MPC

When the trigger input for the CL asserts, BCTU uses the channel or list address (CHANNEL_VALUE_OR_LADDR) as an index into the CL for the lowest numbered ADC selected (ADC_SEL*n*), and each subsequent element of the CL for each remaining selected ADC. The set of selected ADC channels perform their conversions in parallel. When that set of conversions is complete, the next set of CL elements determine the next set of ADC channels to perform parallel conversions, as illustrated in:

- Example: MPC with two ADCs
- Example: MPC with three ADCs

64.3.4.4 Example: MPC with two ADCs

The following figure shows the example of MPC with two ADCs.

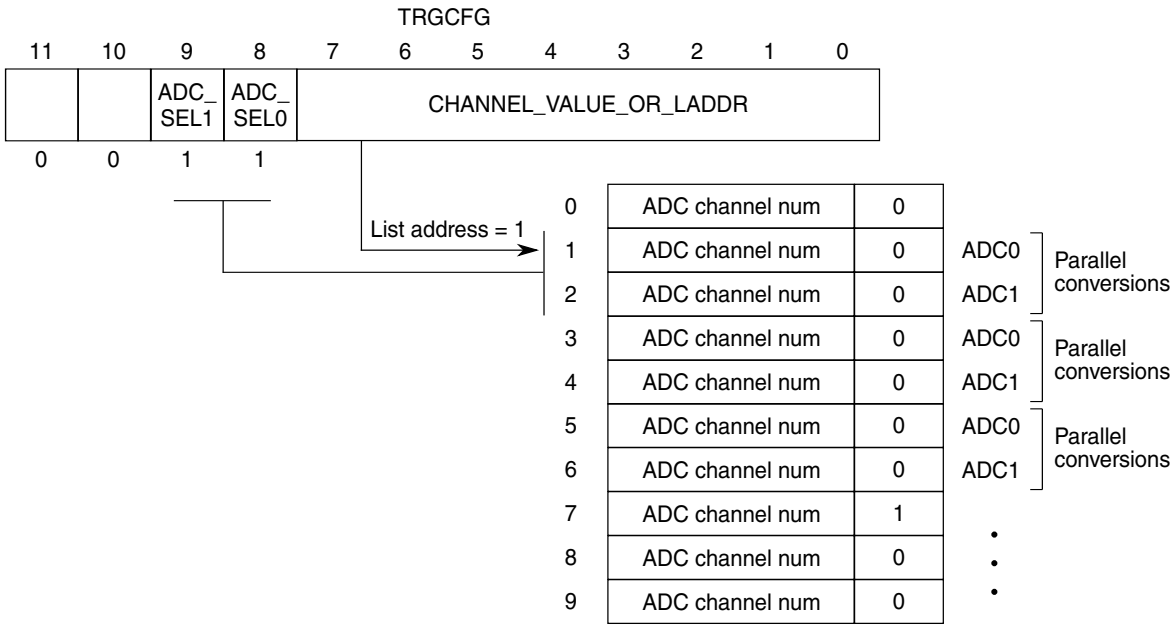

Figure 426. Example: MPC with two ADCs

64.3.4.5 Example: MPC with three ADCs

The following figure shows the example of MPC with three ADCs.

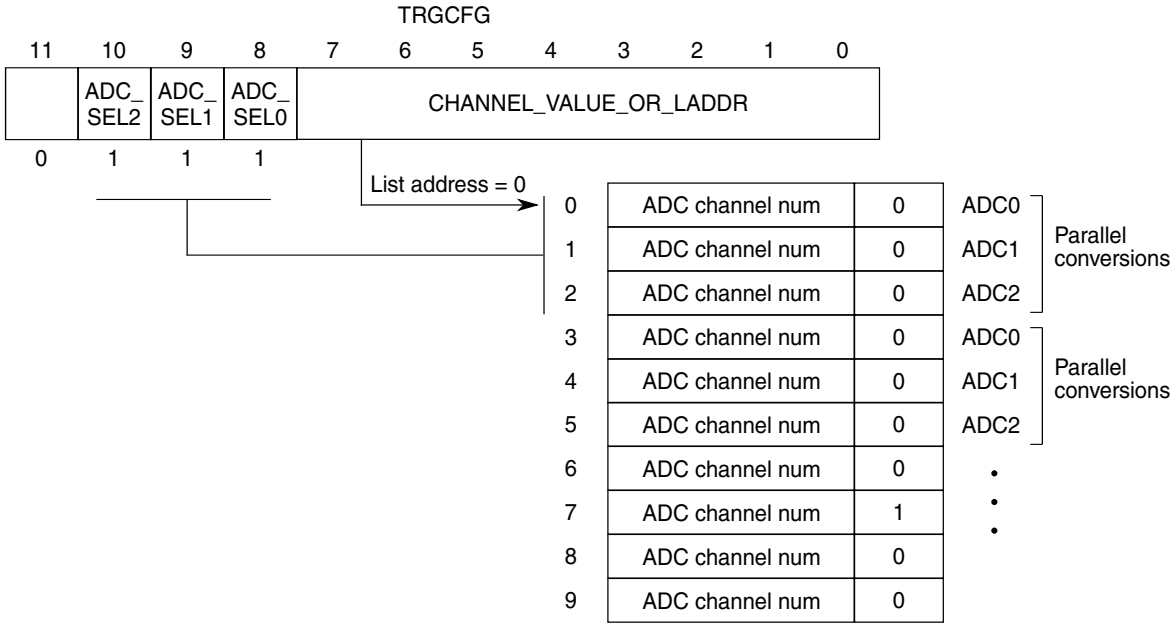

Figure 427. Example: MPC with three ADCs

64.3.4.6 MPC priority rules

MPC follows the same priority rules as for single conversions, which is based on the trigger input number: the lower the trigger, the higher the priority. However, MPC cannot start until all ADCs selected for the CL are available; that is, they are not currently

engaged in conversion. For example, if a trigger input asserts for a CL using ADC0 and ADC1, BCTU does not initiate the CL until ADC0 and ADC1 are both available.

Also, if ADC0 is available but there is a higher priority trigger for ADC1, the MPC does not start. If trigger inputs assert for two MPCs that have at least one ADC in common, the lower trigger number has higher priority. A priority conflict occurs only when separate requested CLs have at least one ADC in common. If the MPCs use different ADCs, there is no conflict and the MPCs execute at the same time.

64.3.5 Modes

64.3.5.1 Module Disable (Low Power state)

Module disable (MCR[MDIS]) stops the BCTU clock, resulting in reduced power consumption.

When you disable BCTU (write 1 to MDIS), it:

- Waits for the completion of any in-progress conversions before stopping the clock.
- Ignores all trigger inputs.
- Does not trigger any ADC conversion requests.
- Maintains any asserted trigger inputs, which you can clear if necessary.

When you re-enable BCTU (write 0 to MDIS) and global triggers are enabled (MCR[GTRGEN]), BCTU processes all active asserted trigger inputs and sends conversion requests to ADCs according to the priority scheme.

64.3.6 Clocking

This module has two clock ports.

1. ipg_clk_bctu - is the main clock of complete BCTU IP.
2. ipg_clk_s - is the gated IPG clock to be used in BCTU registers only.

64.3.7 Software reset

You can reinitialize all BCTU registers to their reset values with software reset (MCR[Software_Reset]).

Software reset does not clear any active trigger inputs, but it does put the ADC interface into the Reset state. Therefore, to avoid data incoherency, you must terminate any BCTU-triggered conversions or wait until they are complete before asserting software reset.

64.3.8 Interrupts and DMA requests

Table 365. Interrupts and DMA requests

Event	Enable interrupt	Enable DMA request	Description
Trigger Flag	MCR[TRGEN]	—	Interrupt request on assertion of trigger flag (MSR[TRGF])
ADC Data Ready	MCR[IEN*n*]	MCR[DMA*n*]	Interrupt or DMA request when ADC result data is available (ADC*n*DR)
CL Last	MCR[LIST_IEN]	—	Interrupt request when the last conversion of any CL executes
FIFO Watermark	FIFOCR[IEN_FIFO*n*]	FIFOCR[DMA_EN_FIFO*n*]	Interrupt or DMA request when the number of valid FIFO entries exceeds the FIFO

64.4 BCTU register descriptions

All BCTU registers are 32 bits wide. 8-bit write operations are allowed. The BCTU module does not include any coherence mechanism, so application software must ensure coherency.

NOTE

- You must always write 0 to reserved writable registers and fields. Read accesses of reserved registers and fields do not return meaningful data.
- For registers with write protection, if protection is active and you attempt to write to those registers, register content is unaffected and BCTU issues a transfer error.

64.4.1 BCTU memory map

BCTU base address: 4008_4000h

BCTU_1 base address: 406C_4000h

Field	Function
2 IEN2	Interrupt Enable For ADC2DR Enables an interrupt request when BCTU writes a new conversion result to ADC Data (ADC*n*DR). Also enables an interrupt request on an overrun in ADC*n*DR, which indicates the previous data has been overwritten by a new conversion result. See also MSR[NDATA*n*] and MSR[DATAOVR*n*]]. Enabling ADC*n*DR DMA (DMA*n* field) disables the interrupt for new data in ADC*n*DR, but the interrupt for ADC*n*DR data overrun remains enabled. 0b - Disable 1b - Enable
1 IEN1	Interrupt Enable For ADC1DR Enables an interrupt request when BCTU writes a new conversion result to ADC Data (ADC*n*DR). Also enables an interrupt request on an overrun in ADC*n*DR, which indicates the previous data has been overwritten by a new conversion result. See also MSR[NDATA*n*] and MSR[DATAOVR*n*]]. Enabling ADC*n*DR DMA (DMA*n* field) disables the interrupt for new data in ADC*n*DR, but the interrupt for ADC*n*DR data overrun remains enabled. 0b - Disable 1b - Enable
0 IEN0	Interrupt Enable For ADC0DR Enables an interrupt request when BCTU writes a new conversion result to ADC Data (ADC*n*DR). Also enables an interrupt request on an overrun in ADC*n*DR, which indicates the previous data has been overwritten by a new conversion result. See also MSR[NDATA*n*] and MSR[DATAOVR*n*]]. Enabling ADC*n*DR DMA (DMA*n* field) disables the interrupt for new data in ADC*n*DR, but the interrupt for ADC*n*DR data overrun remains enabled. 0b - Disable 1b - Enable

64.4.3 Module Status (MSR)

Offset

Register	Offset
MSR	8h

Function

Indicates the status of various BCTU functions, including:

- Whether conversion data is available for each ADC
- CL operation, such as the last conversion command executed in a CL
- Whether BCTU triggered any of the ADCs

All flag fields become 0 upon assertion of a low-power (software) or clock-stop (hardware) request. You can turn off individual flags by writing 1 to the field.

64.4.4 Trigger Configuration (TRGCFG_0 - TRGCFG_44)

Offset

For a = 0 to 44:

Register	Offset
TRGCFG_a	18h + (a × 4h)

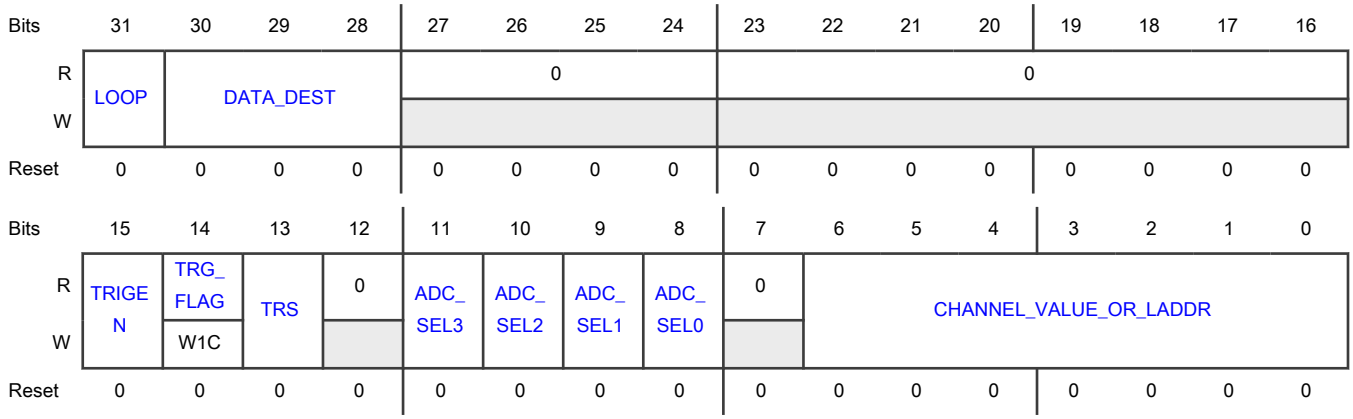
Function

Configures the corresponding trigger:

- Specifies the target ADC and ADC channel to use for conversion.
- Specifies whether to use a CL or a single ADC conversion command.

Access: User read/write

Diagram



Fields

Field	Function
31 LOOP	Loop Specifies that the current trigger executes in a loop; that is, the triggered conversion repeats until you disable Loop. Each loop-triggered conversion wins the priority evaluation among all pending triggers, and executes only if it is the highest-priority triggered conversion at the moment the conversion starts. 0b - Disable 1b - Enable
30-28 DATA_DEST	Data Destination Specifies the destination for storing the conversion results. You can route each ADC's conversion result to either of the following: • ADC-specific data registers • One of the available FIFOs BCTU routes conversion results to different destinations based on the trigger index that requested the conversion. You cannot duplicate the same data in more than one destination. 000b - ADC-specific data registers 001b - FIFO1 010b - FIFO2 011b - FIFO3 All other values are reserved.
27-24 —	Reserved
23-16 —	Reserved
15	Trigger Enable

9 ADC_SEL1	ADC Select 1 Selects ADC *1* for conversion. 0b - Deselects 1b - Selects
8 ADC_SEL0	ADC Select 0 Selects ADC *0* for conversion. 0b - Deselects 1b - Selects
7 —	Reserved
6-0 CHANNEL_VALUE_OR_LADDR	Channel or CL Address Depending on the value of TRS: • 0: Specifies the ADC channel for conversion • 1: Specifies the address of the first CL position to execute

64.4.5 Write Protection (WRPROT)

Offset

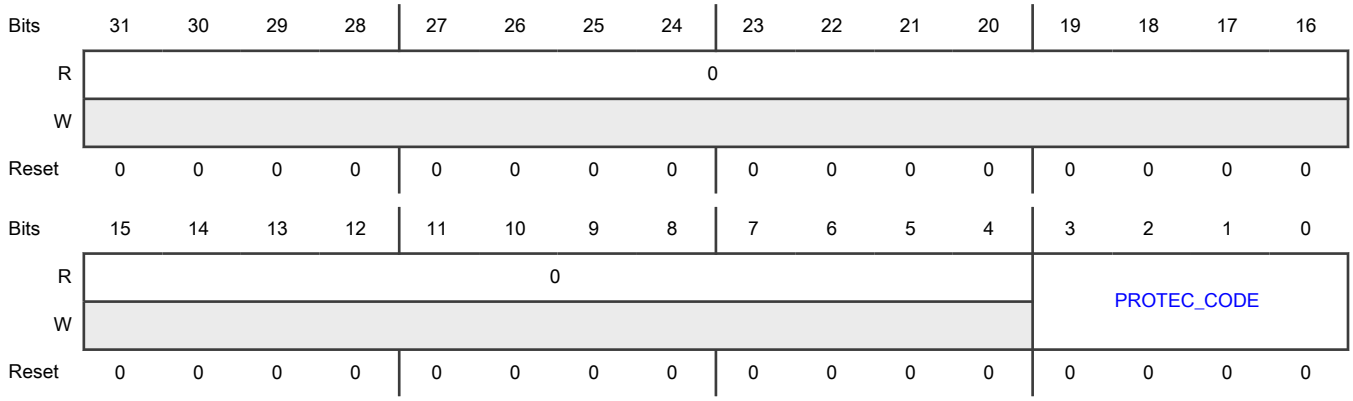
Register	Offset
WRPROT	228h

Function

Enables write protection at reset exit. To allow writes to protected registers, you must write a special code into PROTEC_CODE. There are two codes to remove protection: one that permanently disables the protection; one that disables protection during one write cycle to a protected register, after which the protection code returns to the initial (protected) value of 0000b.

Access: User read/write

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 PROTEC_CODE	Protection Code Controls the protection of write-protected registers. **NOTE** You can write this field only in Normal mode (MCR[MDIS] is 0). 0000b - Enable protection 1001b - Disable protection for one write cycle 1010b - Disable protection permanently

64.4.6 Software Trigger 1 (SFTRGR1)

Offset

Register	Offset
SFTRGR1	22Ch

Function

Allows you to trigger conversions on the associated triggers.

To use a software trigger, you must first disable the corresponding hardware trigger (TRGCFG_x[TRIGEN]).

BCTU writes 0 to a software trigger field on completion of the triggered conversion.

Access: User read/write; this register is write protected by Write Protection (WRPROT). If protection is enabled, writes to this register generate a transfer error and do not modify its content.

64.4.7 Software Trigger 2 (SFTRGR2)

Offset

Register	Offset
SFTRGR2	230h

Function

Allows you to trigger conversions on the associated triggers.

To use a software trigger, you must first disable the corresponding hardware trigger (TRGCFG_*n*[TRIGEN]).

BCTU writes 0 to a software trigger field on completion of the triggered conversion.

Access: User read/write; this register is write protected by Write Protection (WRPROT). If protection is enabled, writes to this register generate a transfer error and do not modify its content.

11-8 —	Reserved
7 —	Reserved
6-0 ADC_CHL_y_plus_1	ADC Channel Selection Plus 1 Specifies the ADC channel to use for the (*y* + 1) element of the CL, where *y* equals (2 x *m*).

64.4.11 FIFO Result Data (FIFO1DR - FIFO3DR)

Offset

Register	Offset
FIFO1DR	450h
FIFO2DR	454h
FIFO3DR	458h

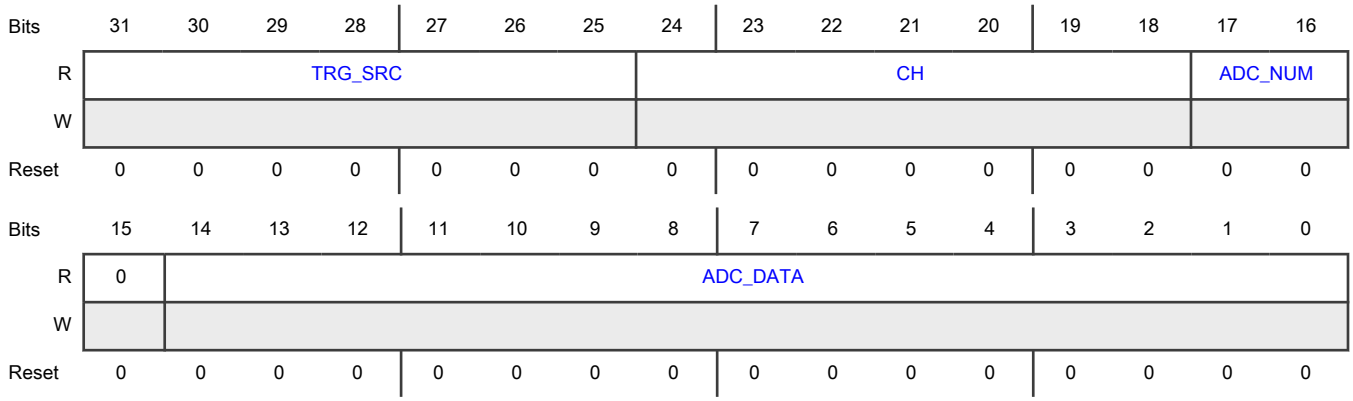
Function

Contains the ADC conversion result and information about the conversion:

- ADC channel
- Trigger source
- ADC number

Access: User read

Diagram



Fields

Field	Function
31-25 TRG_SRC	Trigger Source Indicates the trigger number used to trigger the conversion.
24-18 CH	Channel Indicates the ADC channel used for the conversion.

7-4 —	Reserved
3-0 WM_FIFO1	FIFO1 Watermark Level Specifies the watermark level for FIFO1.

64.4.14 FIFO Error/Status (FIFOERR)

Offset

Register	Offset
FIFOERR	468h

Function

Allows you to clear FIFO error and status flags. Each FIFO has its own error and status flags that can be configured to generate an interrupt. FIFO Status (FIFOSR) maintains the status of these flags. BCTU writes a 1 to these flags, and you must then clear them using FIFOERR.

Access: User read/write

Chapter 65
Trigger MUX (TRGMUX)

65.1 Chip-specific TRGMUX information

65.1.1 TRGMUX input output configuration and instances

This chip has 2 instance of TRGMUX module.

- TRGMUX_APP
- TRGMUX_MSC

The device supports the triggering scheme between peripherals. For the supported trigger sources and destination, see the TRGMUX connectivity file attached to this document.

NOTE

eTPU is supported for S32K396 only.

This device has 8 pads (SIUL2) mapped from TRGMUX inputs and TRGMUX outputs are mapped to the eMIOS channels, hence two timers channels can use a single pin of the device to do input capture.

While using TRGMUX, below points need to be taken care:

- Pulses which are visible on pads depends on the pad type. Different pad supports different frequencies. For more details on pad types and their respective bandwidth, see section "IO signal table" in "Signal Multiplexing" chapter.
- End of conversion (EOC) signals of SDADC modules are mapped on TRGMUX inputs as trigger sources. The EOC signal is asserted after ADC conversion regardless whether conversion is signaled by polling flags, interrupt or DMA transfer. The signal shall not be used to start injected conversion on same SDADC channel as it will overwrite current result register.
- The minimum pulse length requirement is 1.5X of destination clock, so that it gets properly sampled at the destination IP connected to TRGMUX outputs, otherwise there are chances of missing the triggers generated from source. For example, the trigger generated from PAD for ADC conversion should be kept high/low for at least 1.5X of ADC clock so that it gets sampled in ADC clock domain. To ensure this, pulse stretchers have been placed before some of the hardware modules mapped on TRGMUX outputs.
- Some PADS are being shared by both ADC and TRGMUX. It is recommended that trigger initiated from such PADS should not be used to trigger a conversion on the ADC channel mapped on same PAD. Failing to do this will cause congestion on same PAD.
- Out of all the pads mapped on TRGMUX, first four pads have glitch filters. For details, see the TRGMUX connectivity file attached to this document. The trigger pulse width should honour the pulse width requirement as per Glitch Filter specifications. The same signal can be observed at output pin if the pulse width of the input data signal is more than 400ns and no output signal should be observed if the pulse width of the input data signal is less than 20ns. A signal with a pulse width that is between 20ns and 400 ns should not be applied as the behavior is not guaranteed.
- Trigger outputs are grouped peripheral-wise and have a common lock bit based on TRGMUX REGx. For instance, normal_trigger, injected_trigger and external_sync of ADC_0 are grouped onto TRGMUX_REG0 and have a common lock bit.
- The other instance, TRGMUX_MSC, includes both instances of eTPU and the TRGMUX connection at its input. The output of trgmux_msc goes to DSPI_MSC and TRGMUX.

65.1.2 Pulse stretchers in TRGMUX

TRGMUX has some hardware modules on its input side running at faster clock than some of the IPs present on output side. For instance, eMIOS reload outputs running at 160 MHz can trigger LPI2C trigger input clocked at 40 MHz, in that case there is a high chance that trigger from eMIOS will be missed. Following Pulse stretchers are added for the IPs on output side of TRGMUX.

Table 366. Pulse stretchers in TRGMUX

Evaluation Parameter	ADC_0/1/2/3/4/5/6 external trigger to sync the start pulse	SD_0/1/2/3 Hardware trigger	BCTU_0 trigger 39/40/41	BCTU_1 trigger 39/40/41	FlexIO trigger input_0/1/2/3	LPI2C_0 Trigger input	LPSPI_0/1/2 Trigger input	CM7_0/1/2_RXEV
IP expects	synchronized single cycle pulse	Async Pulse	Synchronized pulse	Synchronized pulse	IP requirement is to have 2 cycle pulse of flexio_clk	IP requirement is to have 2 cycle pulse of lpi2c_clk	IP requirement is to have 2 cycle pulse of lpspi_clk	single cycle pulse
Frequency	CORE_CLK	PLAT_AIPS_CLK	CORE_CLK	CORE_CLK	CORE_CLK	AIPS_SLOW_CLK	LPSPI_0 PLAT_AIPS_CLK LPSPI_1/2-AIPS_SLOW _CLK	CORE_CLK
Inside IP	Used as combo signal	Synchronized inside IP	flopped inside IP and clear after ADC conversion completed	flopped inside IP and clear after ADC conversion completed	synchronized inside IP	synchronized inside IP	synchronized inside IP	-
At SoC	Since it an ASYNC signal and IP required synchronized single cycle pulse, so a pulse stretcher is added to convert pulse from any frequency domain into a single cycle pulse of CORE_CLK	Pulse stretcher is added to convert any pulse into a two cycle pulse of scan_clk	Since slow IP such as LPCMP or from PAD can also trigger BCTU and BCTU wants that trigger should clear after the ADC conversion. So a pulse stretcher is added which convert any size of pulse to a single cycle pulse of BCTU clock (CORE_CLK)	Since slow IP such as LPCMP or from PAD can also trigger BCTU and BCTU wants that trigger should clear after the ADC conversion. So a pulse stretcher is added which convert any size of pulse to a single cycle pulse of BCTU clock (CORE_CLK)	Pulse stretcher is added to convert any pulse into a two cycle pulse of flexio_clk	Pulse stretcher is added to convert any pulse into a two cycle pulse of lpi2c_clk	Pulse stretcher is added to convert any pulse into a two cycle pulse of lpspi_clk	Pulse stretcher is added to convert any pulse into a single cycle pulse of CORE_CLK

Table continues on the next page...

Table 366. Pulse stretchers in TRGMUX (continued)

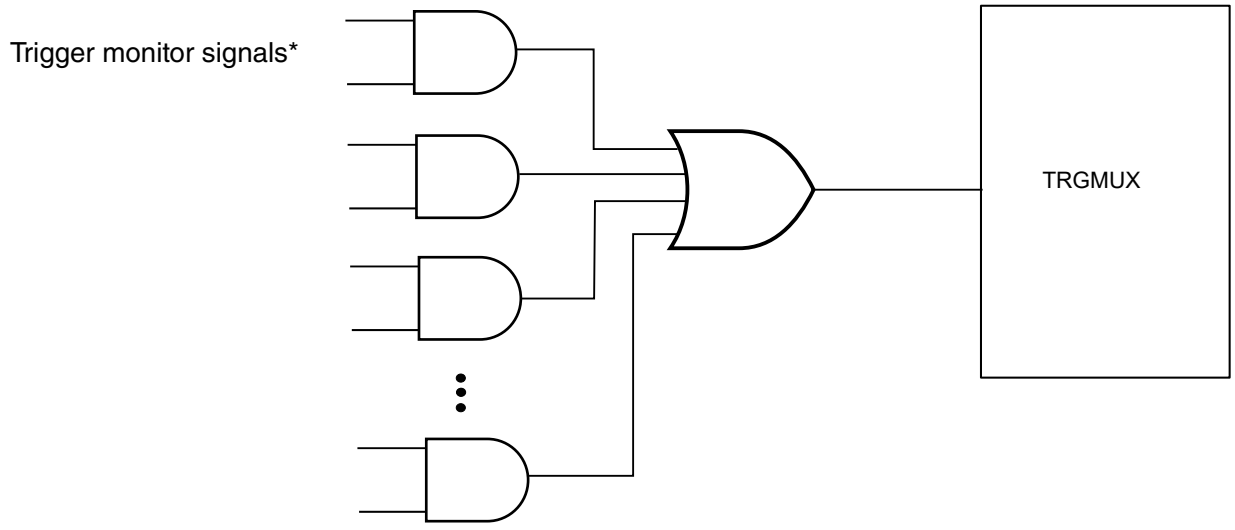
Evaluation Parameter	ADC_0/1/2/3/4/5/6 external trigger to sync the start pulse	SD_0/1/2/3 Hardware trigger	BCTU_0 trigger 39/40/41	BCTU_1 trigger 39/40/41	FlexIO trigger input_0/1/2/3	LPI2C_0 Trigger input	LPSPI_0/1/2 Trigger input	CM7_0/1/2_RXEV
Output slot at which pulse stretcher is added	2, 6, 10,14,18,22,26	28, 32, 36, 40	52, 53, 54	56, 57, 58	124, 125, 126, 127	244	144, 148, 152	232, 233, 234

NOTE

The trigger outputs which have pulse stretcher before them, there should be at least a gap of 5 cycle of destination clock for back to back trigger.

65.1.3 Trigger monitor

A trigger monitor is added before the TRGMUX inputs. You can configure the UDR registers in SIUL2 named as MUX* registers with offset from 0x100 to 0x11C to select which trigger needs to propagate to the above TRGMUX inputs. By default after coming out of reset, all the enables are 0. Hence no trigger will be coming to these 3 TRGMUX inputs.



*See the TRGMUX connectivity sheet attached to this document for the details of trigger monitor signals.

Figure 428. Trigger monitor

65.2 Overview

TRGMUX allows you to configure the trigger inputs for various peripherals.

65.2.1 Block diagram

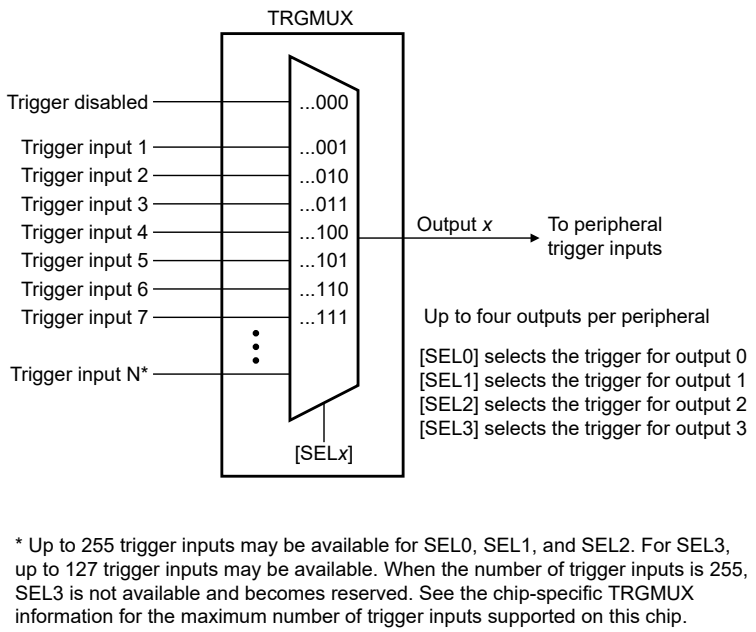


Figure 429. Block diagram

65.2.2 Features

- Configurable trigger sources for peripherals
- Dedicated TRGMUX register for each peripheral

65.3 Functional description

65.3.1 Clocking

This module has no clocking considerations.

65.3.2 Interrupts

This module has no interrupts.

65.4 External signals

This module has no external signals.

65.5 Initialization

This module does not require initialization.

65.6 TRGMUX register descriptions

65.6.1 TRGMUX memory map

You can only write to TRGMUX registers in Supervisor mode.

Table 367. Select bit fields

Field	Description
SEL*x*	Specifies the MUX select for the peripheral trigger inputs. Use this field to select the trigger sources for peripheral modules. 0h - LOGIC 0 (VSS) 1h - LOGIC 1 (VDD) 2h - Trigger_monitor_mux0 3h - Trigger_monitor_mux1 4h - Trigger_monitor_mux2 5h - SD_End of conversion_01 6h - SD_End of conversion_23 7h - SD_SW_TRG_OUT_01 8h - SD_SW_TRG_OUT_23 9h - LPCMP_0_COUT output Ah - LPCMP_1_COUT output Bh - eDMA_0_eDMA0 DONE Ch - eDMA_0_eDMA16 DONE Dh - eDMA_1_eDMA0 DONE Eh - eDMA_1_eDMA16 DONE Fh - eMIOS_0_RELOAD_OUT_CH[23] 10h - eMIOS_0_RELOAD_OUT_CH[22] 11h - eMIOS_0_RELOAD_OUT_CH[8] 12h - eMIOS_0_RELOAD_OUT_CH[0] 13h - eMIOS_0_IPP_DO_eMIOS_CH[0] 14h - eMIOS_0_IPP_DO_eMIOS_CH[1] 15h - eMIOS_0_IPP_DO_eMIOS_CH[2] 16h - eMIOS_0_IPP_DO_eMIOS_CH[3] 17h - eMIOS_0_IPP_DO_eMIOS_CH[4] 18h - eMIOS_0_IPP_DO_eMIOS_CH[5] 19h - eMIOS_0_IPP_DO_eMIOS_CH[6] 1Ah - eMIOS_0_IPP_DO_eMIOS_CH[7] 1Bh - eMIOS_0_IPP_DO_eMIOS_CH[8] 1Ch - eMIOS_0_IPP_DO_eMIOS_CH[9] 1Dh - eMIOS_0_IPP_DO_eMIOS_CH[10] 1Eh - eMIOS_0_IPP_DO_eMIOS_CH[11] 1Fh - eMIOS_0_IPP_DO_eMIOS_CH[12] 20h - eMIOS_0_IPP_DO_eMIOS_CH[13]

Chapter 66
CoolFlux DSP Subsystem (DSPSS)

66.1 Chip-specific DSPSS information

66.1.1 CoolFlux configuration

NOTE

Pulse type triggers are not supported.
Please configure DSPSS_DSP0_CFG[dspss_dsp0_core_trigger_safety_cfg] and DSPSS_DSP0_CFG[dspss_dsp0_core_trigger_cfg] bits accordingly.

66.1.2 CoolFlux debug interface

The following sections describe the usage of the debug interface.

66.1.2.1 CoolFlux Arm Cortex-M7 co-debugging

Four external conditions can generate a break by using the break_in[3:0] signals. Of these four signals, one can be selected to generate break events. When the selected signal is sampled as low, then high, on successive clk's, a break is generated.

The selection is done with the instructions listed in the below table. apb_dbg_bic[3:0] select the corresponding break_in[3:0] signal to be the break signal. This means that all other break_in signals will be disabled. apb_dbg_bids disables all break_in[3:0] signals.

Table 369. Instructions for setting hardware breakpoints

Instruction	Opcode	Description
apb_dbg_bids	<ID>10 0011 1000	Disables the external breakpoint function. None of the break_in signals will cause a break.
apb_dbg_bic0	<ID>10 0011 1001	A rising edge on break_in(0) will cause a break.
apb_dbg_bic1	<ID>10 0011 1010	A rising edge on break_in(1) will cause a break.
apb_dbg_bic2	<ID>10 0011 1011	A rising edge on break_in(2) will cause a break.
apb_dbg_bic3	<ID>10 0011 1100	A rising edge on break_in(3) will cause a break.

The break_out signal can be used to output the halted, the debug_mode signal or a breakpoint hit event:

- The debug_mode signal is active while the CoolFlux DSP16LC is in debug mode.
- The halted signal is active when the CoolFlux DSP16LC has been halted by an eopi instruction, an eopci instruction or by an eopc instruction.
- An internal breakpoint is hit.

The selection is done with the instructions listed in the table below.

Table 370. Break_out signal selection

Instruction	Opcode	Description
apb_dbg_bods	<ID>10 0011 0000	break_out is low
apb_dbg_both	<ID>10 0011 0001	break_out means halted
apb_dbg_bodm	<ID>10 0011 0010	break_out means debug mode
apb_dbg_bpox	<ID>10 0011 0011	break_out means breakpoint hit

66.1.2.2 Cross break interface

This chapter describes the usage of the cross break interface.

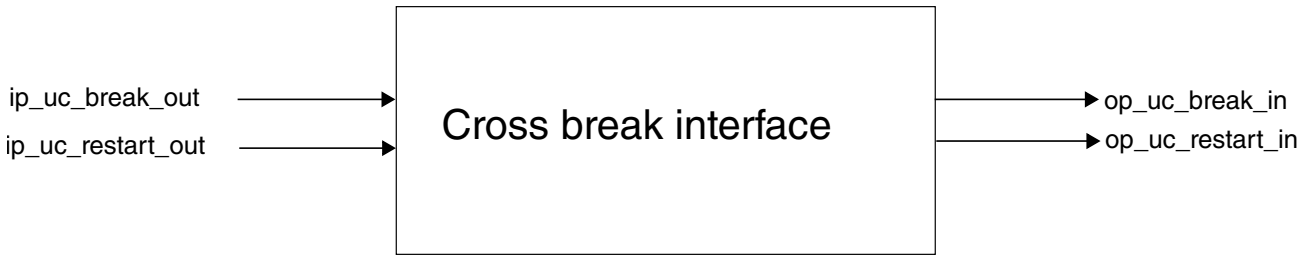

Figure 430. Cross break interface

The design has a cross break module that makes it possible to put the micro-controller and DSP into debug mode at the same time. It also allows the micro-controller to restart when the DSP restarts at the same time. The architecture is shown in the figure below.

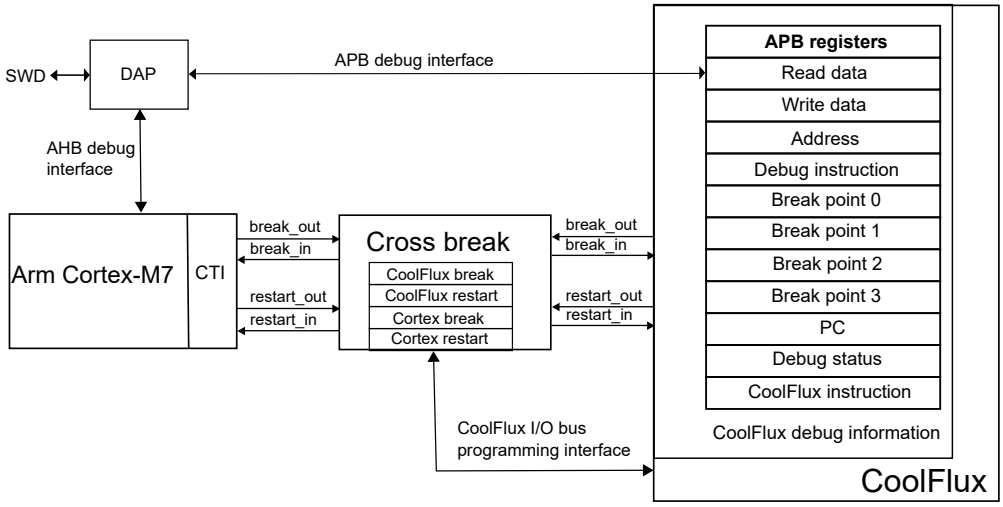

Figure 431. Cross break interface architecture

The cross break module connects the debug signals between the micro controller and the DSP. It allows both processors to enter debug mode at the same time. It also allows to restart the micro-controller at the moment the DSP leaves debug mode. For the purpose four configuration bits are provided. All four bits are disabled by default. In order to use them, they independently need to be enabled explicitly.

Enabling the DSP break configuration allows the CoolFlux to enter debug mode when the micro-controller enters debug mode, using the ip_uc_break_out from the micro-controller.

Enabling the UC break configuration allows the micro-controller to enter debug mode when the CoolFlux BSP32 enters debug mode, using the op_uc_break_in towards the micro-controller.

Enabling the DSP restart configuration allows the micro-controller to restart from debug mode when the micro-controller goes out of debug mode, using the ip_uc_restart_out towards the micro-controller.

Enabling the UC restart configuration allows the micro-controller to restart from debug mode when the CoolFlux goes out of debug mode, using the op_uc_restart_in towards the micro-controller.

66.2 Introduction

DSPSS is a signal processing block. It is built to implement FIR filtering capability for motor resolver application. CoolFlux DSP is the main processing block of this subsystem which provides multi-threaded processing capability (up to 4 threads). The subsystem has dedicated program and data memories for parallel access. This block processes samples obtained from SDADC interface and then keeps the processed data in local SRAM, which is then accessed by core or DMA.

66.2.1 Block diagram

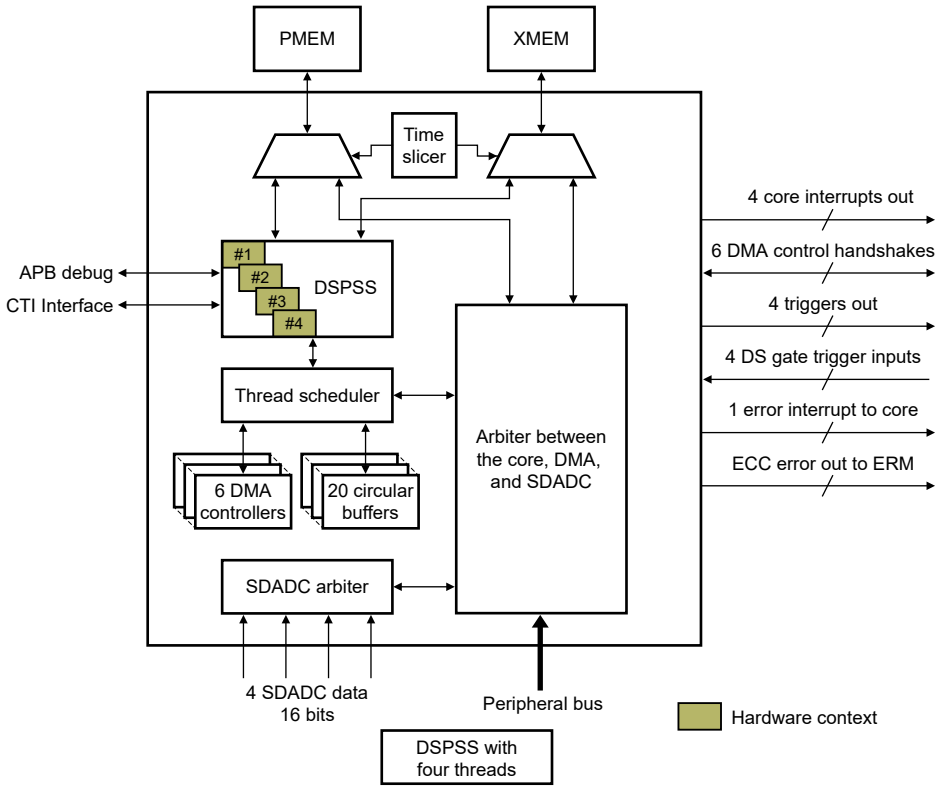

Figure 432. DSPSS block diagram

66.2.2 Features

- One instance of DSPSS with four-thread hardware multi-threading support.
- Memories
  - Single-port program memory (PMEM) and data memory with ECC (XMEM) interfaces running at twice the frequency of DSP and host core interface frequency.
  - 32 KB of program memory.
  - 24 KB of data memory.
  - XMEM and PMEM ECC error run status to ERM and FCCU.
  - Two virtual ports for two masters (DSP and peripheral bus master) on PMEM and XMEM interfaces.

- ECC algorithm for PMEM and XMEM is Single Error Correction with Double Error Detection (SECDED).
- In PMEM, only 32-bit data RW accesses are allowed.
- In XMEM, 32-bit and 16-bit aligned data RW accesses are allowed from the peripheral bus interface.
- In XMEM, 16-bit data RW accesses are allowed from DSP.

- DMA
  - Six DSP firmware-controlled DMA request channels and hardware control response handling.
- Buffer management
  - Circular buffer support for DSP and HOST core. This buffer is aligned at 4-byte address boundary in XMEM.
  - Circular buffer support for DSP and DMA. This buffer is aligned at 4-byte address boundary in XMEM.
  - Circular buffer support for DSP and SDADC. This buffer is aligned at 4-byte address boundary in XMEM.
  - No two circular buffers can point to the same region in XMEM.
- Thread Scheduling
  - Hardware scheduling of threads based on sample and clock threshold.
  - No hardware scheduling of threads. In this mode, DSP firmware can switch context via an instruction. Hardware scheduler will not schedule any thread in this mode.
  - Per thread suspension and re-enable support through software.
  - Thread re-enabling flow controlled through software.
  - The default thread that DSP starts to execute after reset de-assertion is Thread-0.
- Triggers and Interrupts
  - DSP trigger to host core per thread.
  - Four triggers to TRIGMUX. DSP firmware controls these triggers. Write a 1 to set the trigger and write a 0 to reset the trigger.
  - DSP error interrupt to host.
  - Supports multiple trigger inputs, like DS gate.
- SDADC Interface
  - 16-bit aligned accesses from SDADC interface to XMEM.
  - ECC is calculated for 32-bit data in PMEM and 16-bit data in XMEM.
- Miscellaneous
  - Digital Stream (DS) gate status register for DSP firmware to control result gate.
  - Debug and CTI interface for DSPSS debug support.

66.3 Functional description

The following sections describe functional details of DSPSS.

66.3.1 DSPSS components

This table describes the functions of the main components of DSPSS.

Table 371. DSPSS components

Component	Function
cf16L	DSP multi-thread core for processing (for example, FIR, FFT) incoming SDADC data.
Scheduler	This is the hardware scheduler block inside DSPSS. Schedules the thread on the DSP core for data processing depending on the scheduling mode.
Software configuration registers	Block for configuring DSPSS for various applications.
Time division multiplexer (time slicer)	Time division multiplexer or arbiter for accessing XMEM and PMEM through various masters (DSP and Cortex-M7 core).
DMA-read buffer monitor	DMA read buffer pointers are monitored. If there is an address mismatch between the IPS interface and internally-maintained pointer, an error interrupt is generated.
DMA-write buffer monitor	DMA write buffer pointers are monitored. If there is an address mismatch between the IPS interface and internally-maintained pointer, an error interrupt is generated.
DSP core buffer region	Scratch pad area between the Cortex-M7 core and DSP core. Read and write pointers are maintained inside the monitor and underflow and overflow errors are generated. Cortex-M7 core is notified through the interrupt.

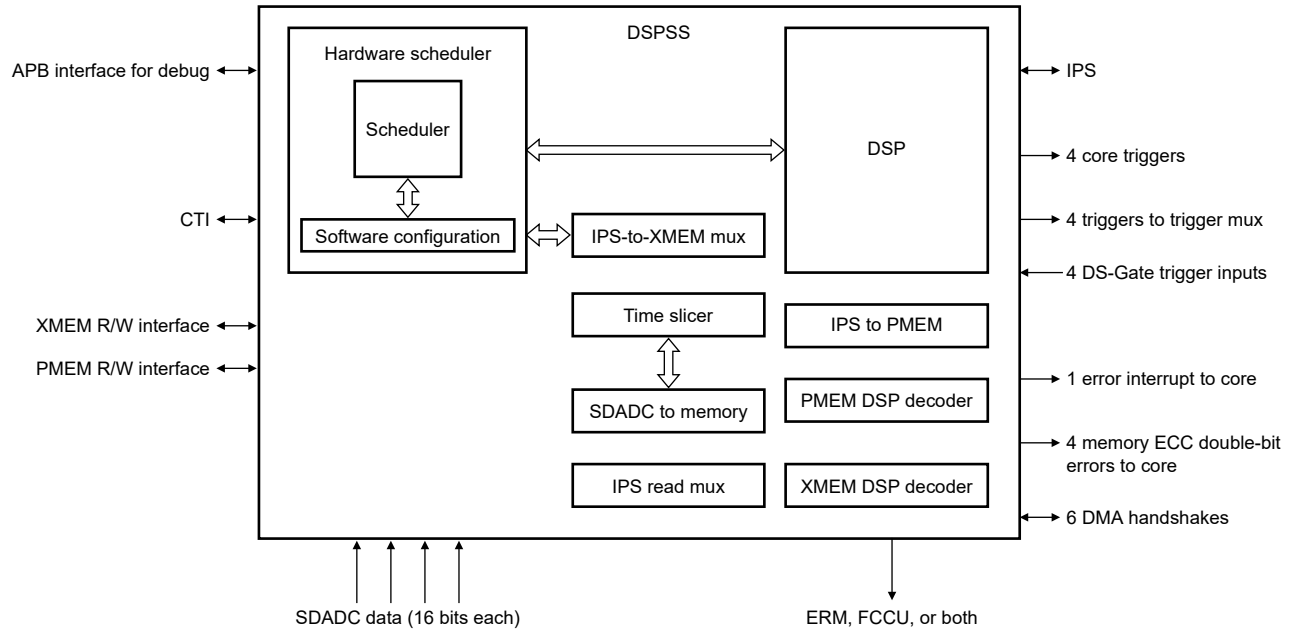

Figure 433. DSPSS components

66.3.2 SDADC interface

The SDADC pushes data through the SDADC interface shown in the system diagram. Every ADC sample is 16 bits and is received using SDADC clock. The sample path to XMEM goes through two levels of arbitration. SDADC data is written into XMEM only if you enable the thread; otherwise, the hardware scheduler drops the data. The write path to PMEM is not supported.

1. Level 1 arbitration is round-robin across four SDADC inputs.
2. Arbitration of SDADC flow:
    a. On reset deassertion, the grant is parked with ADC0.
    b. When a request is made from one or more masters at a time, grant is first given to the master where the grant vector is currently parked (if there is a request from the current master); otherwise, masters are given grants in round-robin.
    c. If there is no request, the grant vector is parked with the last requester.
3. Level 2 arbitration is between the SDADC arbitration winner and access from CORE or DMA.
4. Level 2 arbitration has default high priority for access via CORE or DMA. SDADC data can be given higher priority over the core when you write 1 to DSPSS_DSP0_CFG[XMEM_CTRL_PRIORITY].

66.3.2.1 SDADC input buffer

SDADC data is written into the core-allocated SDADC buffer in XMEM. Because DSP firmware is managing the read pointer of this region, only DSP firmware manages overflow and underflow errors.

66.3.3 Scheduling modes

DSPSS is software-programmable. You should program one of these scheduling modes:

1. Sample Threshold mode
2. Clock Threshold mode
3. Software mode

All threads will be scheduled based on one type of mode.

Changing scheduling modes is possible only after DSPSS is reset.

66.3.3.1 Sample Threshold mode

1. This is the default mode and is active when SCHEDULER_MODE_CFG[SCHEDULER_MODE] is 00b.
2. SCHEDULER_MODE_CFG[SCHD_SEQ_1] has no meaning in Sample Threshold mode.
3. In this mode, the thread that first reaches the respective sample threshold that you programmed is scheduled first (if only that thread is enabled).
4. The thread switching is requested as soon as the sample threshold is reached. After the DSP processes the requested thread, the next thread in the pipeline is scheduled next. The process then repeats.
5. Software has access to thread configuration registers to enable scheduler scheduling the threads on DSPSS. The configuration involves the following attributes in scheduler configuration register space:
    - Per-thread buffer configuration registers
    - Per-thread sample threshold register
    - Per-thread enable registers
    - Soft reset register to control the initialization of DSPSS
6. Hardware scheduler maintains the SDADC input buffer write pointer. The DSP firmware manages the corresponding read pointer and maintains the input buffer overflow and underrun.

66.3.3.2 Clock Threshold mode

1. Active when you or the chip writes 01b to SCHEDULER_MODE_CFG[SCHEDULER_MODE].

2. In this mode, you program the scheduling sequence using SCHEDULER_MODE_CFG[SCHD_SEQ_1], SCHEDULER_MODE_CFG[SCHD_SEQ_2], SCHEDULER_MODE_CFG[SCHD_SEQ_3], and SCHEDULER_MODE_CFG[SCHD_SEQ_4].
3. Threads are scheduled in the order SCHEDULER_MODE_CFG[SCHD_SEQ_1] first and SCHEDULER_MODE_CFG[SCHD_SEQ_4] last. Default sequence is thread 0 first and thread 3 last.
4. When the thread is enabled and is part of the scheduling sequence, scheduler sends a context request to DSPSS. DSP processes the requested thread for the number of clock cycles programmed in the threshold register for that thread.
5. Thread switching is requested after the clocking threshold of the current thread is reached.
6. The figure below shows the sequence of threads scheduled by the hardware scheduler:

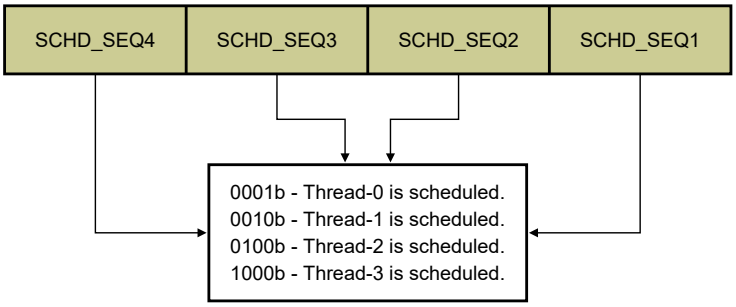

Figure 434. Clock Threshold mode thread sequencing

7. Hardware scheduler maintains the SDADC input buffer write pointer. DSP firmware manages the corresponding read pointer and maintains the input buffer overflow and underrun.

66.3.3.3 Software Scheduling mode

1. Active when you write 10b to SCHEDULER_MODE_CFG[SCHEDULER_MODE].
2. Hardware scheduling is not used in this mode, and you switch context using the switch context instruction in firmware.
3. Hardware scheduler maintains the SDADC input buffer write pointer. DSP firmware manages the corresponding read pointer and maintains the input buffer overflow and underrun.
4. You can write 1 to SCHEDULER_THRD_EN to enable, or write 0 to disable, data streams for a specific thread.
5. You should not use software suspension through DSPSS using THREAD_SUSPEND_REQ*n*[SUSPEND_REQ].
6. You are responsible for disabling the threads.

66.3.4 Using DSPSS in Sample Threshold mode

In Sample Threshold mode (the default mode), you must specify the following parameters at boot time:

1. Program execution code start pointer for each thread in PMEM.
2. The default thread that executes the reset routine is thread 0. The reset routine is used to program internal register space for DSP threads.
3. Memory allocation for input buffer and output buffer in XMEM for every thread.
4. The stack space of each DSP instance.
5. The relation between the threshold for a thread and buffer size is **THREAD_THRESHOLD × N = THREAD_END_ADDR[15:1] - THREAD_START_ADDR[15:1]**.
6. The value of N should be an integer > 1.

NOTE

DSPSS_SCHEDULER_XMEM_TH*n*[SCHEDULER_THRD_TH] signifies the number of samples to be processed in an active thread. It can be Block length in the FIR filter use case or it can be number of samples in the FFT use case (64, 256, or 512 sample points).

7. After the block of data or threshold in the example FIR case above is processed, the DSP suspends the thread by incrementing the XMEM data pointer to the next DSPSS_SCHEDULER_XMEM_ADDR_TH*n*[SCHEDULER_THRD_START_ADDR] + DSPSS_SCHEDULER_XMEM_TH*n*[SCHEDULER_THRD_TH] and the program counter (PMEM pointer) to call the block processing function or start the block processing code.
8. This process repeats indefinitely.

The process for FFT processing is similar.

66.3.4.1 DSPSS boot flow in Sample Threshold mode

1. Load the four threads program code in PMEM.
2. Load the reset routine for DSP in PMEM.
3. You need to initialize PMEM and XMEM with 0h at boot time.
4. Program the DSPSS_SCHEDULER_DSP_CFG_TH*n*[DSPSS_SCHEDULER_DSP_PCINIT] values for every thread in Hardware scheduler of DSPSS. The PCINIT value for each thread should be in multiples of 8 PMEM locations (DSP programming guideline).
5. The default thread that DSP starts to execute after reset is deasserted is thread-0. If thread-0 is not enabled, DSP should be loaded with a sleep instruction.
6. If any thread is not enabled in the beginning but is expected to be enabled at a later point in time, it is recommended to program the PCINIT for those threads also.
7. Program the thread start and end addresses using DSPSS_SCHEDULER_XMEM_ADDR_TH*n*[SCHEDULER_THRD_START_ADDR] and DSPSS_SCHEDULER_XMEM_ADDR_TH*n*[SCHEDULER_THRD_END_ADDR] in the DSPSS hardware scheduler.
8. Program the sample threshold value for every enabled thread using DSPSS_SCHEDULER_XMEM_TH*n*[SCHEDULER_THRD_TH].
9. Program SCHEDULER_MODE_CFG[NEXT_REQ_HALT_ACK_WAIT_CTRL], if threads are to be scheduled as soon as they are ready to schedule. In this case, whenever the number of samples from a particular thread reaches the threshold value, the thread is scheduled without waiting for the halt acknowledge for the currently running thread (sleep state).
10. Deassert the DSP reset using DSPSS_DSP0_CFG[SCHED_DSP_RST_CTRL_EN] in DSPSS.
11. Reset deassertion of DSP should be chosen based on the application requirement.
12. Whenever there is a reset routine to be executed inside DSP after reset deassertion, you must write 0 to DSPSS_DSP0_CFG[SCHED_DSP_RST_CTRL_EN] and you must write 1 to DSPSS_DSP0_CFG[dspss_scheduler_dsp0_reset].
    - When you write 0 to DSPSS_DSP0_CFG[SCHED_DSP_RST_CTRL_EN], DSP exits reset and executes the reset routine with default thread 0.
    - DSP samples the PC_INIT value for each thread.
    - Program the thread enable using DSPSS_SCHEDULER_XMEM_TH*n*[SCHEDULER_THRD_EN]. ADC streams should be enabled after threads are enabled.

NOTE

If DSPSS_DSP0_CFG[SCHED_DSP_RST_CTRL_EN] is written to 0 in the above steps, then the threads should be enabled after the reset routine is executed. The status of completion of the reset routine can be managed in multiple ways; for example, DSP triggering the Cortex-M7 core or the Cortex-M7 core polling the sleep status of thread 0 (when a sleep instruction is executed at the end of the reset routine).

13. When there is no reset routine to be executed inside DSP after reset deassertion, you can write 1 to DSPSS_DSP0_CFG[SCHED_DSP_RST_CTRL_EN] (after this, you must also write 1 to DSPSS_DSP0_CFG[dspss_scheduler_dsp0_reset]). In this case, the module deasserts the DSP reset along with the first context request.
    - Program the thread enable using DSPSS_SCHEDULER_XMEM_TH*n*[SCHEDULER_THRD_EN]. ADC streams should be enabled after threads are enabled.
    - The module deasserts reset to the DSP along with the first context request.
    - DSP samples the PC_INIT value for each thread.
    - DSP starts to execute the thread that was scheduled by Hardware scheduler.
14. Hardware scheduler schedules DSP contexts based on the corresponding threshold values.
15. After DSP processes the data block of a thread, DSP should write to DSP_TO_DMA_REQUEST_STATUS*n*[DSP_TO_DMA_REQUEST_STATUS] to initiate a trigger to DMA. This allows DMA to start the processed data transfer to eTPU memory. The request remains asserted until the last DMA write performed through the DMA interface is completed. DSP can also use the Hardware scheduler to program HW_CTRL_DMA_REQ_RESPONSE*n*[START] and HW_CTRL_DMA_REQ_RESPONSE*n*[NUM_OF_DMA_REQ] to send back-to-back triggers to DMA for the programmed number of requests.
16. After DMA acknowledges the DSP request, DSP can poll DSP_TO_DMA_REQUEST_STATUS*n*[DMA_TO_DSP_ACK_STATUS] for the status of that acknowledge.
17. DSP should execute a sleep instruction in the corresponding thread to notify DSPSS of processing completion.

66.3.5 Using DSPSS in Clock Threshold mode

In Clock Threshold mode, you must specify the following parameters at boot time:

1. Program execution code start pointer for each thread in PMEM.
2. The default thread executing the reset routine for the threads programming is thread-0. The reset routine is the default library function for programming the internal register space of DSP threads.
3. Memory allocation for input buffer and output buffer in XMEM for every thread.
4. The stack space of each DSP instance.

66.3.5.1 DSPSS boot flow in Clock Threshold mode

1. Load the 4 threads program code in PMEM.
2. Load the reset routine for DSP in PMEM.
3. You need to initialize PMEM and XMEM at boot time.
4. Write 01b to SCHEDULER_MODE_CFG[SCHEDULER_MODE].
5. In this mode, program the scheduling sequence in SCHEDULER_MODE_CFG[SCHD_SEQ_1], SCHEDULER_MODE_CFG[SCHD_SEQ_2], SCHEDULER_MODE_CFG[SCHD_SEQ_3], SCHEDULER_MODE_CFG[SCHD_SEQ_4].
6. Threads are scheduled in the order SCHEDULER_MODE_CFG[SCHD_SEQ_1] first and SCHEDULER_MODE_CFG[SCHD_SEQ_4] last. Default sequence is thread-0 first and thread-3 last, then the sequence repeats itself.

7. Program the DSPSS_SCHEDULER_DSP_CFG_TH*n*[DSPSS_SCHEDULER_DSP_PCINIT] values for every thread in the Hardware scheduler of DSPSS. The PCINIT value for each thread should be in multiples of eight PMEM locations (DSP programming guideline).
8. The default thread that DSP starts to execute after reset is deasserted is thread-0. If the thread-0 is not enabled, DSP should be loaded with a sleep instruction.
9. If any thread is not enabled in the beginning but is expected to be enabled at a later point in time, it is recommended to program the PCINIT for those threads also.
10. Program the thread start and end address using DSPSS_SCHEDULER_XMEM_ADDR_TH*n*[SCHEDULER_THRD_START_ADDR] and DSPSS_SCHEDULER_XMEM_ADDR_TH*n*[SCHEDULER_THRD_END_ADDR] in the Hardware scheduler of DSPSS.
11. Program the clock threshold value for every enabled thread using DSPSS_SCHEDULER_XMEM_TH*n*[SCHEDULER_THRD_TH]. This field represents the number of DSP clock cycles the Hardware scheduler waits before scheduling the next thread. Minimum value of this field should be 12h because acknowledgement of any context request may take up to eight cycles of DSP clock.
12. Deassert the DSP reset using DSPSS_DSP0_CFG[SCHED_DSP_RST_CTRL_EN] in DSPSS.
13. You should choose the DSP reset deassertion based on the application requirement.
14. Whenever there is a reset routine to be executed inside DSP after reset deassertion, DSPSS_DSP0_CFG[SCHED_DSP_RST_CTRL_EN] should be set to 0 and DSPSS_DSP0_CFG[dspss_scheduler_dsp0_reset] should be set to 1.
    - When you write 0 to DSPSS_DSP0_CFG[SCHED_DSP_RST_CTRL_EN], DSP exits reset and executes the reset routine with default thread 0.
    - DSP samples the PC_INIT value for each thread.
    - Program the thread enable using DSPSS_SCHEDULER_XMEM_TH*n*[SCHEDULER_THRD_EN]. You should enable the ADC streams after enabling the threads.

    NOTE

    If DSPSS_DSP0_CFG[SCHED_DSP_RST_CTRL_EN] is 0 in the above steps, you should enable the threads after the reset routine is executed. The status of completion of the reset routine can be managed in multiple ways; for example, DSP triggering the Cortex-M7 core or the Cortex-M7 core polling the sleep status of thread 0 (when a sleep instruction is executed at the end of the reset routine).
15. When there is no reset routine to be executed inside DSP after reset deassertion, DSPSS_DSP0_CFG[SCHED_DSP_RST_CTRL_EN] can be written to 1 (after this, you should also write DSPSS_DSP0_CFG[dspss_scheduler_dsp0_reset] to 1). In this case, reset to DSP is deasserted along with the first context request.
    - Program the thread enable using DSPSS_SCHEDULER_XMEM_TH*n*[SCHEDULER_THRD_EN]. ADC streams should be enabled after threads are enabled.
    - Reset to DSP is deasserted along with the first context request.
    - DSP samples the PC_INIT value for each thread.
    - DSP starts to execute the thread that was scheduled by Hardware scheduler.
16. When enabled, a thread is scheduled as per the sequence defined in the scheduling sequence. The clock count timer begins counting for the time the thread is required to be active. When the timer expires, a new thread request is scheduled as defined in SCHEDULER_MODE_CFG[SCHD_SEQ_1].
17. After DSP processes the data block of a thread, DSP should write 1 to DSP_TO_DMA_REQUEST_STATUS*n*[DSP_TO_DMA_REQUEST_STATUS] to initiate a trigger to DMA. This allows DMA to start the processed data transfer to eTPU memory. The request remains asserted until the last DMA write performed through the DMA interface is completed. DSP can also use the Hardware scheduler to program

HW_CTRL_DMA_REQ_RESPONSE*n*[START] and HW_CTRL_DMA_REQ_RESPONSE*n*[NUM_OF_DMA_REQ] to send back-to-back triggers to DMA for the programmed number of requests.

18. After DMA acknowledges the DSP request, DSP can poll DSP_TO_DMA_REQUEST_STATUS*n*[DMA_TO_DSP_ACK_STATUS] for the status of that acknowledge.
19. DSP should execute a sleep instruction in the corresponding thread to notify DSPSS of processing completion.
20. If threads are required to be scheduled as per the sequence defined in SCHEDULER_MODE_CFG[SCHD_SEQ_1], SCHEDULER_MODE_CFG[SCHD_SEQ_2], SCHEDULER_MODE_CFG[SCHD_SEQ_3], and SCHEDULER_MODE_CFG[SCHD_SEQ_4], then you must write to SCHEDULER_MODE_CFG[NEXT_REQ_HALT_ACK_WAIT_CTRL] before enabling the thread. In this case, a thread remains active for the time until DSP executes the sleep instruction. After that, the next active thread defined in scheduling sequence is scheduled.

66.3.6 Hardware scheduler flow

Hardware scheduler flow (for Sample Threshold mode) is shown in Figure 435.

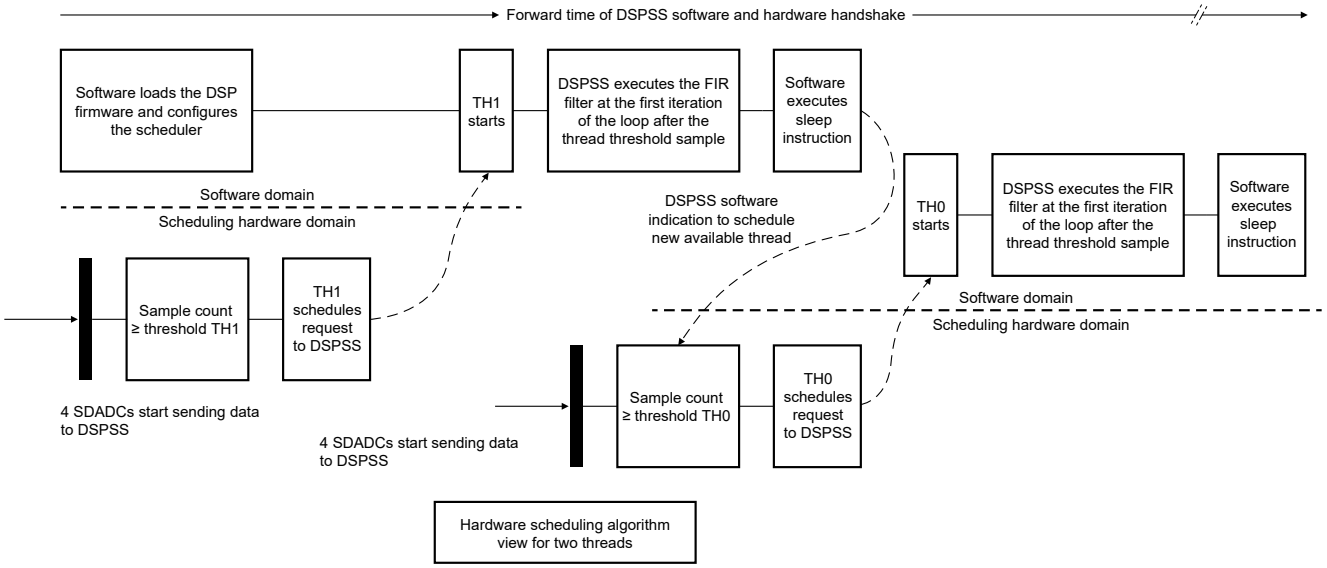

Figure 435. Hardware scheduler flow

Data and Task scheduling flow is shown in Figure 436.

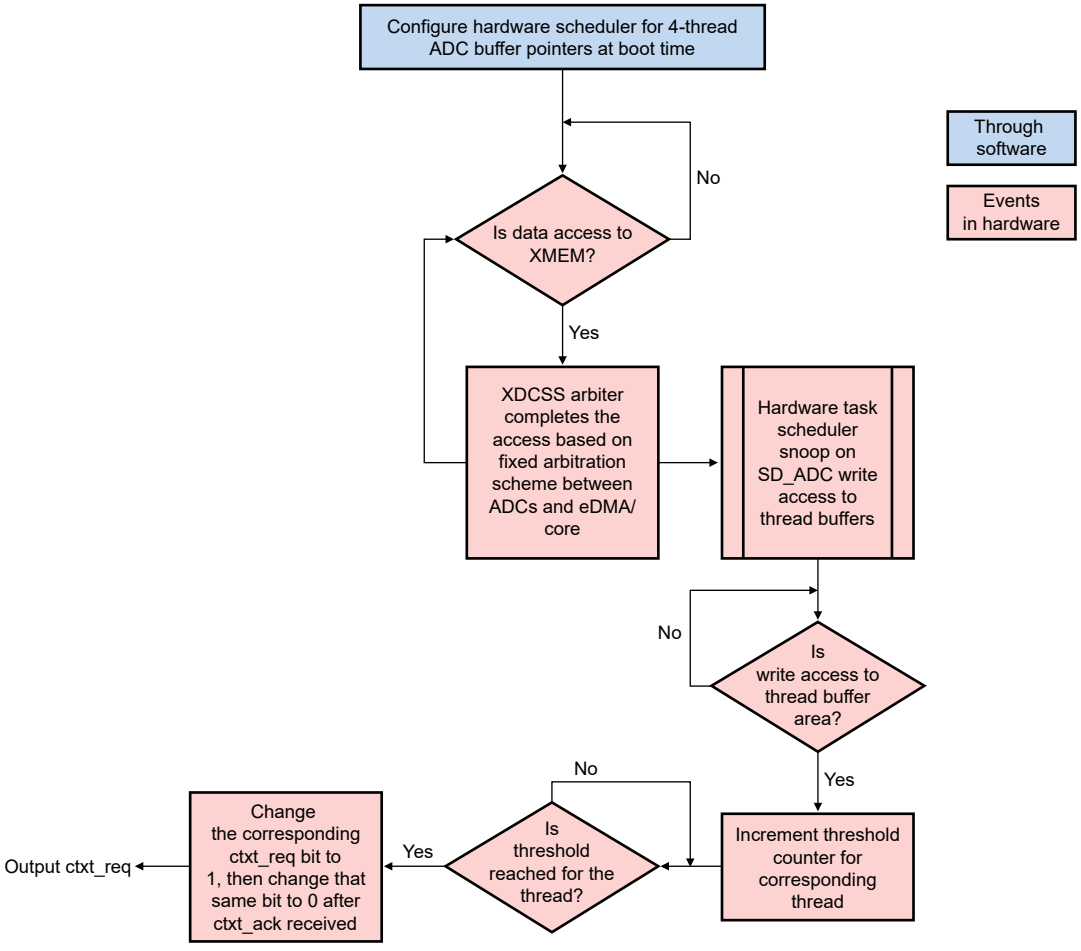

Figure 436. Data and task scheduling flow

66.3.7 DMA interface

DSPSS supports six DMA channels controlled through the DSP firmware. The DSP firmware triggers the DMA request through Single Request mode, or Hardware-Assisted DMA Request mode for multiple requests.

- Single Request Mode: DSP triggers a DMA request using DSP_TO_DMA_REQUEST_STATUS*n*[DSP_TO_DMA_REQUEST_STATUS]. This allows DMA to start the processed data transfer to the destination. The request remains asserted until the last DMA write performed through the DMA interface is completed.
- Hardware-Assisted DMA Request mode: DSP can use the hardware scheduler to send back-to-back triggers to DMA for the programmed number of requests if you program HW_CTRL_DMA_REQ_RESPONSE*n*[START] and HW_CTRL_DMA_REQ_RESPONSE*n*[NUM_OF_DMA_REQ]. If host or DSP is required to halt this mode, write 1 to HW_CTRL_DMA_REQ_STOP*n*[STOP].

66.3.7.1 DMA buffer space

DMA_READ_BUFFER: DSP writes the processed data in this buffer. After DSP processes the data block, DSP triggers the DMA through IO to transfer the processed data in this buffer into eTPU memory.

- Configure the buffer address in XMEM by programming the start and end addresses using registers DMA_READ_ADDR*n*[DMA_READ_START_ADDR] and DMA_READ_ADDR*n*[DMA_READ_END_ADDR].

- If DSP processed data is to be written at a different address than the buffer start address, DSP should update DMA_CURR_RD_PTR*n*[DMA_CURR_READ_PTR]. Cortex-M7 core should program DMA to start reading from the same address.
- Enable DMA_READ_BUFFER monitoring by writing 1 to DMA_BUFFER_CFG[DMA_READ_EN].
- The write pointer of DSP in the DMA-READ buffer is maintained inside the DSP firmware.
- When DMA monitoring logic is enabled, DMA should not read the same location twice or perform a random access on the DMA region. If you do this, the monitoring logic generates an address mismatch error.
- Only DSP firmware manages overflow and underflow errors in this buffer.
- DSP and Cortex-M7 core can access the current read pointer by reading DMA_CURR_RD_PTR*n*[DMA_CURR_READ_PTR]. You can also access the wrap status of the read pointer by reading DMA_CURR_RD_PTR*n*[DMA_READ_PTR_WRAP].
- DSPSS resets DMA_CURR_RD_PTR*n*[DMA_CURR_READ_PTR] to the buffer start address on the positive edge of DMA_BUFFER_CFG[DMA_READ_EN].
- DSPSS monitors the corresponding peripheral bus address and the internally maintained read pointer and generates an error if there is a mismatch.
- DSPSS supports a status field, DMA_ERROR_STATUS*n*[DMA_ADDR_MISMATCH_RD_BUFFER], for every DMA read buffer for the address mismatch error.
- DSPSS supports a status field, DMA_ERROR_STATUS*n*[DMA_XFR_ERR_READ], for every DMA read buffer if DMA initiates any read access other than half-word or word size in the DMA read buffer.
- If interrupts are enabled through INTERRUPT_ENABLE_REGISTER[DMA_READ_BUFFER_ERR_INTR_EN] and INTERRUPT_ENABLE_REGISTER[DMA_READ_BUFFER_XFR_ERR_INTR_EN], DSPSS reports address mismatch errors and transfer errors to Cortex-M7 core through the interrupt.
- If mismatch errors are reported, you should write 0 to DMA_BUFFER_CFG[DMA_READ_EN]. You should take the corrective action and then you should re-enable the buffer monitoring logic.

Table 372. DMA CURR READ POINTER

Event	Effect on pointer
Write 1 to DMA_BUFFER_CFG[DMA_READ_EN]	DSPSS updates DMA_CURR_RD_PTR*n*[DMA_CURR_READ_PTR] to DMA_READ_ADDR*n*[DMA_READ_START_ADDR]
DSP IO interface updates DMA_CURR_RD_PTR*n*[DMA_CURR_READ_PTR]	DSP IO should update the pointer before you enable the monitoring logic. When you enable buffer monitoring, pointer does not reset to DMA_READ_ADDR*n*[DMA_READ_START_ADDR] when you enable DMA_BUFFER_CFG[DMA_READ_EN].
Last location of DMA write buffer is reached	Pointer wraps to DMA_READ_ADDR*n*[DMA_READ_START_ADDR]
Last location of XMEM is reached	Pointer wraps to the first location of memory

DMA_WRITE_BUFFER: XMEM space where DMA writes data that DSP can use during operation. Read pointer of DSP in the DMA write buffer is maintained inside DSP firmware. Only DSP firmware manages overflow and underflow errors.

- Configure the buffer address in XMEM by programming the start and end addresses using registers DMA_WRITE_ADDR*n*[DMA_WRITE_START_ADDR] and DMA_WRITE_ADDR*n*[DMA_WRITE_END_ADDR]. This can also be done through the DSP IO interface.
- If DMA write data is to be written at a different address than the buffer start address, then DSP should update the DMA_CURR_WR_PTR*n*[DMA_CURR_WRITE_PTR]. Cortex-M7 core should program DMA to start writing from the same address.
- Enable the DMA_WRITE_BUFFER monitoring by writing 1 to DMA_BUFFER_CFG[DMA_WRITE_EN].
- DSP read pointer for DMA write buffer is maintained inside DSP firmware.

- When DMA monitoring logic is enabled, DMA should not write the same location twice or perform a random access on the DMA region. If you do this, the monitoring logic generates an address mismatch error.
- Last and first location accesses of read and write masters should be aligned to avoid address mismatch errors.
- Only DSP firmware manages overflow and underflow errors in this buffer.
- DSP core can access the current write pointer by reading DMA_CURR_WR_PTR*n*[DMA_CURR_WRITE_PTR]. You can also access the wrap status of the write pointer by reading DMA_CURR_WR_PTR*n*[DMA_WRITE_PTR_WRAP].
- DMA_CURR_WR_PTR*n*[DMA_CURR_WRITE_PTR] is reset to buffer start address on the positive edge of DMA_BUFFER_CFG[DMA_WRITE_EN].
- DSPSS monitors the corresponding peripheral bus address and the internally-maintained write pointer and generates an error if there is a mismatch.
- DSPSS supports a status register DMA_ERROR_STATUS*n*[DMA_ADDR_MISMATCH_WR_BUFFER] for every DMA write buffer, for the address mismatch error.
- DSPSS supports a status register DMA_ERROR_STATUS*n*[DMA_XFR_ERR_WRITE] for every DMA write buffer, if DMA initiates any write access other than half-word or word size in the DMA write buffer.
- If interrupts are enabled through INTERRUPT_ENABLE_REGISTER[DMA_WRITE_BUFFER_ERR_INTR_EN] and INTERRUPT_ENABLE_REGISTER[DMA_WRITE_BUFFER_XFR_ERR_INTR_EN], DSPSS reports an address mismatch error and transfer error to Cortex-M7 core through the interrupt.
- If mismatch errors are reported, you should write 0 to DMA_BUFFER_CFG[DMA_WRITE_EN]. You should take the corrective action and then you should re-enable the buffer monitoring logic.

Table 373. DMA CURR WRITE POINTER

Event	Effect on pointer
Write 1 to DMA_BUFFER_CFG[DMA_WRITE_EN]	DSPSS updates DMA_CURR_WR_PTR*n*[DMA_CURR_WRITE_PTR] to DMA_WRITE_ADDR*n*[DMA_WRITE_START_ADDR]
DSP IO interface updates DMA_CURR_WR_PTR*n*[DMA_CURR_WRITE_PTR]	DSP IO should update the pointer before enabling the monitoring logic. When you enable buffer monitoring, pointer does not reset to DMA_WRITE_ADDR*n*[DMA_WRITE_START_ADDR] when you enable DMA_BUFFER_CFG[DMA_WRITE_EN].
Last location of DMA write buffer is reached	Pointer wraps to DMA_WRITE_ADDR*n*[DMA_WRITE_START_ADDR]
Last location of XMEM is reached	Pointer wraps to the first location of memory

66.3.8 DSP core buffer

DSPSS supports a per-thread circular buffer shared between Cortex-M7 core and DSP. The control configuration determines the read and write pointer owners. Programmable hardware support is available to monitor the state of the read and write pointers updated by the respective DSP core to generate the overflow and underflow status of the buffer. Perform the steps below to enable the DSP core buffer:

1. Configure the buffer address in XMEM by programming the start and end addresses using DSP_CORE_BUF_ADDR*n*[DSP_CORE_BUF_START_ADDR] and DSP_CORE_BUF_ADDR*n*[DSP_CORE_BUF_END_ADDR].
2. Configure the read and write owners of the buffers by programming DSP_CORE_BUFFER_CFG[DSP_CORE_BUFFER_MASTER].
3. Enable the DSP_CORE buffer by writing 1 into DSP_CORE_BUFFER_CFG[DSP_CORE_BUFFER_EN].
4. When DSP and Cortex-M7 core interact with each other in this scratch pad area, the current read and write pointers are updated in DSPSS to reflect the accesses of the respective owners.

5. DSP core can access the current read pointer by reading DSP_CORE_CURR_RD_PTR*n*[DSP_CORE_CURR_RD_PTR]. Wrap status of the read pointer can also be accessed by reading through the same register.
6. DSP core can access the current write pointer by reading DSP_CORE_CURR_WR_PTR*n*[DSP_CORE_CURR_WR_PTR]. Wrap status of the write pointer can also be accessed by reading through the same register.
7. DSPSS supports a status register DSP_CORE_BUFFER_STATUS*n*i>[DSP_CORE_BUFFER_OVF] for every DSP core buffer, for the underflow and overflow errors of this buffer.
8. If interrupts are enabled through INTERRUPT_ENABLE_REGISTER2[DSP_CORE_BUFFER_OVERFLOW_IE] and INTERRUPT_ENABLE_REGISTER2[DSP_CORE_BUFFER_UNDERRUN_IE], overflow and underflow errors of the buffer are reported to Cortex-M7 core through the interrupt.

Table 374. DSP core current read/write pointer

Event	Effect on pointer
Write 1 to DSP_CORE_BUFFER_CFG[DSP_CORE_BUFFER_EN]	DSPSS updates DSP_CORE_CURR_RD_PTR*n*[DSP_CORE_CURR_RD_PTR] and DSP_CORE_CURR_WR_PTR*n*[DSP_CORE_CURR_WR_PTR] to DSP_CORE_BUF_ADDR*n*[DSP_CORE_BUF_START_ADDR]
DSP updates DSP_CORE_CURR_RD_PTR*n*[DSP_CORE_CURR_RD_PTR] and DSP_CORE_CURR_WR_PTR*n*[DSP_CORE_CURR_WR_PTR] through IO	DSP IO should update the pointer before enabling the monitoring logic. When buffer monitoring is enabled, pointer does not reset to DSP_CORE_BUF_ADDR*n*[DSP_CORE_BUF_START_ADDR] when DSP_CORE_BUFFER_CFG[DSP_CORE_BUFFER_EN] is enabled.
Last location of DSP core buffer is reached	Pointers wrap to the DSP_CORE_BUF_ADDR*n*[DSP_CORE_BUF_START_ADDR]
Last location of XMEM is reached	Pointers wrap to the first location of memory

66.3.9 Clocking

The table below lists the clocking frequency requirements. Except for Debug clock, all the clocks are synchronous to each other. System bus clock and DSP clock are inverted with respect to each other.

Table 375. Clock description

Clock name	Description	Frequency requirement(MHz)
DSP clock	DSP core and hardware scheduler clock	160 MHz
System bus clock	Software Configuration clock	160 MHz
RAM clock	XMEM,PMEM and time-slicer clock	320 MHz; should be twice the DSP clock or System bus clock frequency
SDADC clock	Clock for SDADC data received at DSPSS	80 MHz
Debug clock	APB interface clock for DSPSS debug	160 MHz

66.3.10 DSPSS triggers

66.3.10.1 Triggers

DSPSS supports different triggers to host core (Cortex-M7 core). DSP can use these triggers for signaling Cortex-M7 core, or for trigger mux functionality.

66.3.10.1.1 Triggers to host core

There is support for a per-thread trigger interface to Cortex-M7 core that can be used to trigger the core. DSP firmware controls these triggers. All triggers are generated on host clock (peripheral clock). DSPSS clears the status when you write 1 to the field.

O_CORE_TRIGGER: There is support for a per-thread trigger output interface. DSP firmware controls the trigger by writing 1 into DSPSS_DSP_IO_INTF0[DSP_TRIGGER_CORE_TH1 to start any DSPSS function outside the DSPSS subsystem. These triggers have level and pulse support from DSPSS, and Cortex-M7 core can configure them through DSPSS_DSP0_CFG[dspss_dsp0_core_trigger_cfg].

O_CORE_TRIGGER_SAFETY: There is support for trigger-to-core for the safety threads on the output interface. DSP firmware controls the trigger by writing 1 into DSPSS_DSP_CORE_TRIGGER_SAFETY[DSP_TRIGGER_SAFETY_1] to start any hardware function outside DSPSS. These triggers have level and pulse support from DSPSS, and Cortex-M7 core can configure them through DSPSS_DSP0_CFG[dspss_dsp0_core_trigger_safety_cfg]

O_TRIGMUX_TRIGGER: There is support for trigger-to-trigger mux for gasoline engine applications. Implementation of DSPSS actions is defined in upper level of hierarchy. DSP firmware controls the trigger by writing 1 into DS_GATE_TRIGMUX_REGISTER*n*[DS_GATE_TRIGMUX_TRIGGER] to start any hardware function outside DSPSS. DSP firmware clears this by writing 0 back to the same register field.

66.3.11 DSPSS interrupts

66.3.11.1 Understanding DSPSS error levels

There are multiple possible error sources within DSPSS. This table describes the levels at which different errors can occur. These errors can generate an interrupt to the host core if the corresponding interrupt is enabled.

Table 376. DSPSS error levels

DSPSS errors at different levels	Description
DSP	If firmware detects any error resulting inside DSP during the operation, this can be signaled to Cortex-M7 core. DSP acknowledge, corresponding to a context change request timeout, could indicate a DSP pipeline in a hung state and should be communicated to Cortex-M7 core.
Errors in SDADC input buffer	Errors resulting from the SDADC input buffer inside XMEM. For example, request FIFO overflow error, SDADC FIFO overflow or underrun error.
Errors in DMA read buffer	An error resulting from the pointer mismatch between DMA and the internally-maintained current read pointer triggers an error notification to core. If any unaligned access from DMA is received, error notification to Cortex-M7 core is asserted. **NOTE** If Cortex-M7 core asserts DMA_BUFFER_CFG[MAP_XFR_DMA_ERR_ON_IPS], then DMA address mismatch errors are reported as transfer errors.
Errors in DMA write buffer	An error resulting from the pointer mismatch between DMA and the internally-maintained current write pointer triggers an error notification to core. If any unaligned access from DMA is received, error notification to Cortex-M7 core is asserted. **NOTE** If Cortex-M7 core asserts DMA_BUFFER_CFG[MAP_XFR_DMA_ERR_ON_IPS], then DMA address mismatch errors are reported as transfer errors.

Table continues on the next page...

Table 376. DSPSS error levels (continued)

DSPSS errors at different levels	Description
Errors in DSP Cortex-M7 core buffer	An error resulting from an overflow or underrun inside this buffer triggers an error notification to core.

66.3.11.1.1 Error and interrupts

ERM Interface: ERM interface is the output interface of DSPSS for ERM and FCCU. Multi-bit ECC errors and single-bit ECC errors inside XMEM and PMEM are reported for the DSP and Cortex-M7 core accesses separately. If a single-bit error is detected, error position is also provided at the ERM interface.

TRIG_ERR: There is support for an error interrupt to the CORE through the output trigger error signal. DSP firmware, as well as through programmable enables for different hardware error status scenarios listed below, triggers this interrupt. Error Map Association is defined in the following table:

Table 377. Decipher error sources

Source of error	Details	Error level	Associated field
DSP ACK TIMEOUT_ERROR	DSPSS asserts a non-recoverable error when it does not receive an acknowledgement against the context request within the maximum time for DSP acknowledgement. This could be the result of DSP pipeline in a hung state, and therefore you must reset DSPSS and restart everything again.	DSP	DSP_ACK_TIMEOUT_CFG_AND_ERR_CTRL[DSP_ACK_TIMEOUT_ERR]
DSP initialization error	DSPSS asserts a non-recoverable error when the initialization completion status of DSP is deasserted because of an issue internal to the DSP core. You must reset DSPSS and restart everything again.	DSP	CURR_ACTIVE_THRD[DSP_INIT_COMP]
DSP firmware detects internal DSP ERROR	DSPSS asserts a non-recoverable error when DSP firmware detects any issue inside the DSP core. An example of this is SDADC buffer overflow or underrun errors through the pointers it is managing inside the firmware. Host core determines the action in this case.	DSP	DSP_TO_CORE_TRIG_ERR_STATUS*n*[DSP_TO_CORE_TRIG_ERR_STATUS]
Request FIFO threshold crossing	When the total number of requests inside the DSP thread accumulator FIFO reaches the programmed threshold, an interrupt is reported to Cortex-M7 core. Host core determines the action in this case; for example, the system can be restarted, or one or more threads can be disabled by suspending them.	DSPSS	DSP_ACK_TIMEOUT_CFG_AND_ERR_CTRL[REQ_ACC_FIFO_INTR]
Request FIFO overflow error	Asserted when the internally-maintained request FIFO overflows. Request FIFO can maintain 16 requests at a time. A DSP processing rate slower than the supported SDADC data rate would cause this error. Software must reset DSPSS, check the SDADC data rate or the DSP processing rate, then restart everything.	SDADC input buffer	SDADC_SYNC_FIFO_ERROR_STATUS[REQ_FIFO_OVERFLOW]

Table continues on the next page...

Table 377. Decipher error sources (continued)

Source of error	Details	Error level	Associated field
SDADC async FIFO overflow error	Asserted when the SDADC asynchronous FIFO overflows. This could be the result of SDADC data not getting a slot over the peripheral bus to be written into XMEM. Host core must suspend the corresponding thread or reset DSPSS.	SDADC input buffer	SDADC_SYNC_FIFO_ERROR_STATUS[OVERFLOW]
Address mismatch error in DMA read buffer	Asserted when there is a pointer mismatch between DMA and the internally-maintained current read pointer. Host core must reconfigure DMA or take any associated action.	DMA read buffer	DMA_ERROR_STATUS*n*[DMA_ADDR_MISMATCH_RD_BUFFER]
Address mismatch error in DMA write buffer	Asserted when there is a pointer mismatch between DMA and the internally-maintained current write pointer. Host core must reconfigure DMA or take any associated action.	DMA write buffer	DMA_ERROR_STATUS*n*[DMA_ADDR_MISMATCH_WR_BUFFER]
Unaligned DMA access error in DMA write buffer	Asserted when there is a DMA unaligned write access on DMA interface. You must correct the access types.	DMA write buffer	DMA_ERROR_STATUS*n*[DMA_XFR_ERR_WRITE]
Unaligned DMA access error in DMA read buffer	Asserted when there is a DMA unaligned read access on DMA interface in DMA read buffer. You must correct the access types.	DMA read buffer	DMA_ERROR_STATUS*n*[DMA_XFR_ERR_READ]
Overflow in DSP-Cortex-M7 core buffer	Asserted when the write pointer of the write master overflows in the buffer. You must reconfigure the DSP core CBUF and restart the monitoring logic.	DSP core shared buffer	DSP_CORE_BUFFER_STATUS*n*[DSP_CORE_BUFFER_OVF]
Underrun in DSP-Cortex-M7 core buffer	Asserted when the read pointer of read master is ahead of the write pointer of write master. You must reconfigure the DSP core CBUF and restart the monitoring logic.	DSP core shared buffer	DSP_CORE_BUFFER_STATUS*n*[DSP_CORE_BUFFER_UNDF]

66.3.12 Thread re-enabling

When you or DSPSS suspends or disables an active thread, you might be required to re-enable the same thread at a later point time during DSPSS operation. Whenever a thread is suspended, DSP executes a goto-PCINIT instruction corresponding to that thread and returns to the start of the program. Threads can be suspended or disabled for the following reasons:

- Multi-bit Errors on Memory Access: Whenever there is a multi-bit error in data or program memory, an error is reported over the ERM interface. You should reset DSPSS to re-enable the threads and the subsystem. See .
- Suspension request from Cortex-M7 core (host): If there is an issue in the system pipeline or for other reasons, Cortex-M7 core can assert the suspension request using THREAD_SUSPEND_REQ*n*[SUSPEND_REQ]. After the request is asserted, hardware scheduler suspends the thread on priority, but waits for the currently executing thread to complete. Before sending a suspend request, it first sends a dummy context request followed by suspend request to change the context to the thread for which Cortex-M7 core set the suspension. After the thread is suspended, DSPSS schedules the other threads in the pipeline. Before initiating the thread suspension, you should ensure that there is no pending DMA request from the DSPSS interface. If there is any pending request, it needs to be completed to avoid the possibility of the DMA interface becoming hung. See DMA interface.
- Thread PCINIT change during DSPSS operation: To do this, the new PCINIT value is first programmed into DSPSS_SCHEDULER_DSP_CFG_TH*n*[DSPSS_SCHEDULER_DSP_PCINIT], and then the thread is suspended by setting up a suspension request for that thread in THREAD_SUSPEND_REQ*n*[SUSPEND_REQ]. Before initiating the PCINIT

change flow, you should ensure that there is no pending DMA request from the DSPSS interface. If there is any pending request, it needs to be completed to avoid the possibility of the DMA interface becoming hung. See DMA interface.

66.3.12.1 Thread suspension on software request

You can suspend a running thread for one or more reasons; for example, a malfunction of other components in the system related to one of the ADC streams, or you wish to change the software DSP is currently executing on the ADC stream. Software suspension should not be performed in Software Scheduling mode. The thread re-enable flow consists of the following steps.

1. You assert the suspension request using THREAD_SUSPEND_REQ*n*[SUSPEND_REQ].
2. DSPSS automatically disables DSPSS_SCHEDULER_XMEM_TH*n*[THREAD_EN] corresponding to that thread.
3. After the request is asserted, the hardware scheduler suspends the thread on priority but waits for the currently executing thread to complete.
4. Before sending a suspend request, DSPSS first sends a dummy context request followed by a suspend request to change the context to the thread for which Cortex-M7 core asserts suspension after the context of the currently-active thread changes inside DSP.
5. DSP suspends the currently running thread and executes a goto-PCINIT instruction, and returns to the start of the program.
6. After the thread is suspended, hardware scheduler schedules the other threads in the pipeline.
7. When the suspension of thread is completed, DSP asserts the suspend acknowledgement signal to send acknowledgement for the thread that DSP suspended.
8. DSPSS deasserts the suspension request inside THREAD_SUSPEND_REQ*n*[SUSPEND_REQ], the register field for which you asserted the suspension request.
9. When suspend acknowledgement is received from DSP, the suspend status is asserted in DSPSS_DSP_TH_STATUS*n*[dspss_th_suspended].
10. Cortex-M7 core can again enable the thread using DSPSS_SCHEDULER_XMEM_TH*n*[THREAD_EN] after DSPSS_DSP_TH_STATUS*n*[dspss_th_suspended] is asserted. Cortex-M7 core should write 1 to clear this field. DSP firmware can also be requested to clear this field as part of the program.

To change the PCINIT value of a thread, first program the new PCINIT value into DSPSS_SCHEDULER_DSP_CFG_THn[DSPSS_SCHEDULER_DSP_PCINIT], then the above steps can be performed.

66.4 DSPSS register descriptions

This section presents the DSPSS registers that are available to the Cortex-M7 core. Not all of these are available, or available in the same way, to the DSP core; see DSPSS_IO register descriptions.

DSPSS registers are word-accessible. Transfer errors are generated for the holes in the register space. A transfer error is also generated if any access is not aligned to word-access, or if XMEM is accessed beyond the 24 KB space. Transfer error is not generated for write accesses on read-only registers.

66.4.1 DSPSS memory map

dspss_0 base address: 406D_C000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Thread Start And End Address Location Configuration (DSPSS_SCHEDULER_XMEM_ADDR_TH0)	32	RW	0000_0000h
4h	Thread Threshold And Enable (DSPSS_SCHEDULER_XMEM_TH0)	32	RW	0000_0000h

66.4.2 Thread Start And End Address Location Configuration (DSPSS_SCHEDULER_XMEM_ADDR_TH0 - DSPSS_SCHEDULER_XMEM_ADDR_TH3)

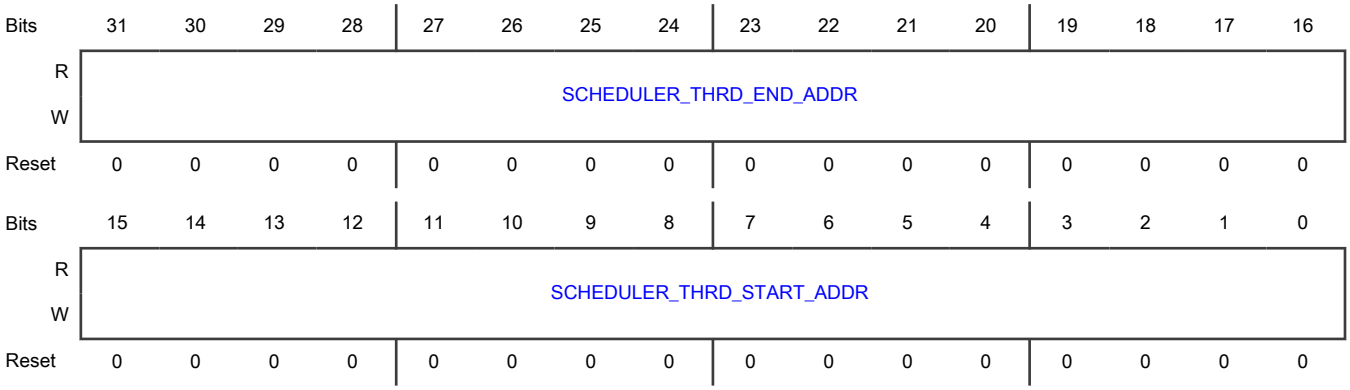
Offset

Register	Offset
DSPSS_SCHEDULER_XMEM_ADDR_TH0	0h
DSPSS_SCHEDULER_XMEM_ADDR_TH1	300h
DSPSS_SCHEDULER_XMEM_ADDR_TH2	600h
DSPSS_SCHEDULER_XMEM_ADDR_TH3	900h

Function

Contains the start and end address memory location for respective threads in memory.

Diagram



Fields

Field	Function
31-16 SCHEDULER_THRD_END_ADDR	End Address Specifies the end address of the SDADC input buffer to write the SDADC data in the XMEM. The end address is byte-address-aligned.
15-0 SCHEDULER_THRD_START_ADDR	Start Address Specifies the start address to write the SDADC data in the XMEM. The start address must be a multiple of 4. This field is byte-aligned, but the programming must be word-aligned (4 bytes). This is due to the fact that all the buffers in XMEM are aligned at 4-byte boundaries.

66.4.3 Thread Threshold And Enable (DSPSS_SCHEDULER_XMEM_TH0 - DSPSS_SCHEDULER_XMEM_TH3)

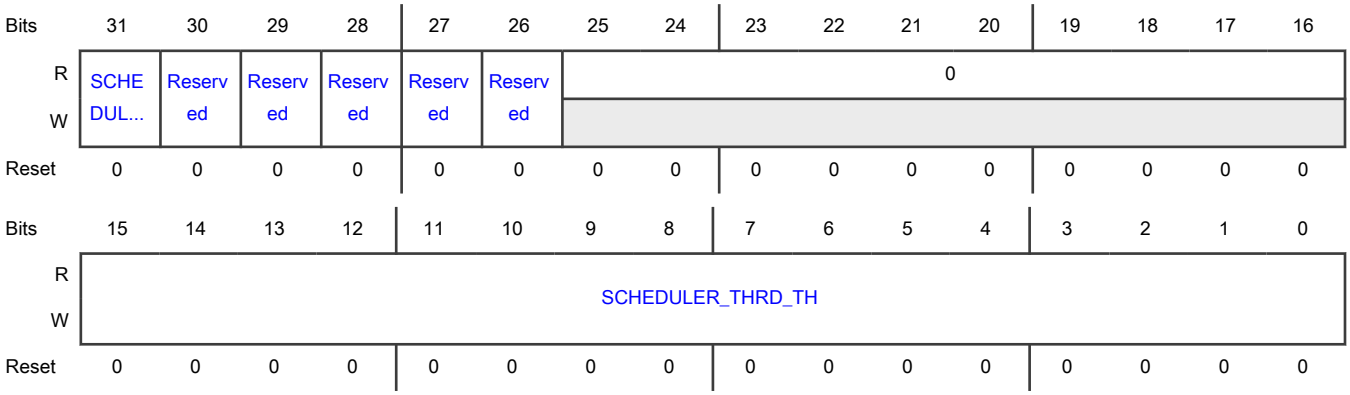
Offset

Register	Offset
DSPSS_SCHEDULER_XMEM_TH0	4h
DSPSS_SCHEDULER_XMEM_TH1	304h
DSPSS_SCHEDULER_XMEM_TH2	604h
DSPSS_SCHEDULER_XMEM_TH3	904h

Function

Programs the threshold for scheduling the respective thread for DSP operation.

Diagram



Fields

Field	Function
31 SCHEDULER_THRD_EN	Thread Enable Enables the thread. Use this field only in Software Scheduling mode. For other modes, disable threads using only the thread-suspension mechanism. If you write 0 to this field in the middle of an operation, the already-running thread is unaffected. The disabling affects only future thread scheduling. 0b - Disable 1b - Enable

27 —	Reserved
26 —	Reserved
25-16 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-0 SCHEDULER_THRD_TH	Thread Threshold Specifies different parameters depending on SCHEDULER_MODE_CFG[SCHEDULER_MODE] as follows:

In this mode:	SCHEDULER_THRD_TH specifies:
Sample Threshold (SCHEDULER_MODE = 0)	Number of ADC samples for which a thread is scheduled
Clock Threshold (SCHEDULER_MODE = 1)	Number of clock cycles for which a thread is scheduled

66.4.4 PC Initial Value (DSPSS_SCHEDULER_DSP_CFG_TH0 - DSPSS_SCHEDULER_DSP_CFG_TH3)

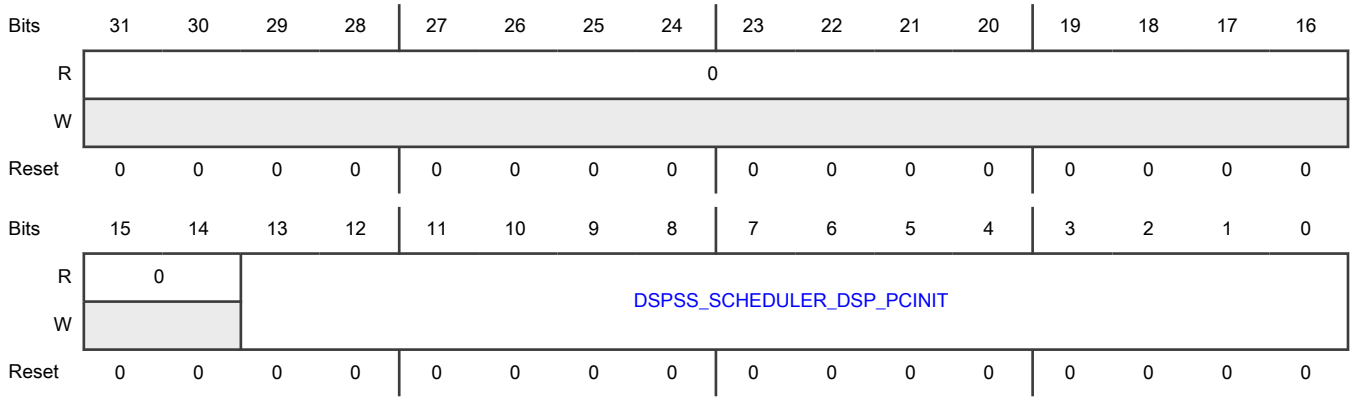
Offset

Register	Offset
DSPSS_SCHEDULER_DSP_CFG_TH0	8h
DSPSS_SCHEDULER_DSP_CFG_TH1	308h
DSPSS_SCHEDULER_DSP_CFG_TH2	608h
DSPSS_SCHEDULER_DSP_CFG_TH3	908h

Function

Specifies the PC initial value for the threads inside the DSP.

Diagram



Fields

Field	Function
31-14 —	Reserved
13-0 DSPSS_SCHEDULER_DSP_PCINIT	PC Initial Value Specifies the PC initial value for the thread inside the DSP. This field is aligned at word boundaries.

66.4.5 Current XMEM Write Pointer (DSPSS_SCHEDULER_CURR_XMEM_ADDR_TH0 - DSPSS_SCHEDULER_CURR_XMEM_ADDR_TH3)

Offset

Register	Offset
DSPSS_SCHEDULER_CURR_XMEM_ADDR_TH0	Ch
DSPSS_SCHEDULER_CURR_XMEM_ADDR_TH1	30Ch
DSPSS_SCHEDULER_CURR_XMEM_ADDR_TH2	60Ch
DSPSS_SCHEDULER_CURR_XMEM_ADDR_TH3	90Ch

Function

This register gives the latest write-pointer value of SDADC input buffer (which resides in XMEM). The pointer is updated for each data write from SDADC interface to the buffer.
