14-0 DSPSS_SCHEDULER_CURR_XMEM_ADDR	Current Write Pointer Location Indicates the current location of the write pointer in data memory for the thread. The MSB denotes wrap bit; it toggles after every wrap. The remaining bits denote the pointer value.

66.4.6 Last Scheduled-Request Address (DSP_SDADC_CURR_READ_PTR0 - DSP_SDADC_CURR_READ_PTR3)

Offset

Register	Offset
DSP_SDADC_CURR_READ_PTR0	14h
DSP_SDADC_CURR_READ_PTR1	314h
DSP_SDADC_CURR_READ_PTR2	614h
DSP_SDADC_CURR_READ_PTR3	914h

Function

Indicates the last address for which a request was scheduled in Sample Threshold mode.

Both the Cortex-M7 core and the DSP core can access this register.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-14 —	Reserved
13-0 DSP_SDADC_CURR_READ_PTR	Address Pointer Indicates the address value for which the last request was scheduled in Sample Threshold mode.

66.4.7 Start And End Pointers For DSP And Cortex-M7 Core Shared Buffer (DSP_CORE_BUF_ADDR0 - DSP_CORE_BUF_ADDR3)

Offset

Register	Offset
DSP_CORE_BUF_ADDR0	1Ch
DSP_CORE_BUF_ADDR1	31Ch
DSP_CORE_BUF_ADDR2	61Ch
DSP_CORE_BUF_ADDR3	91Ch

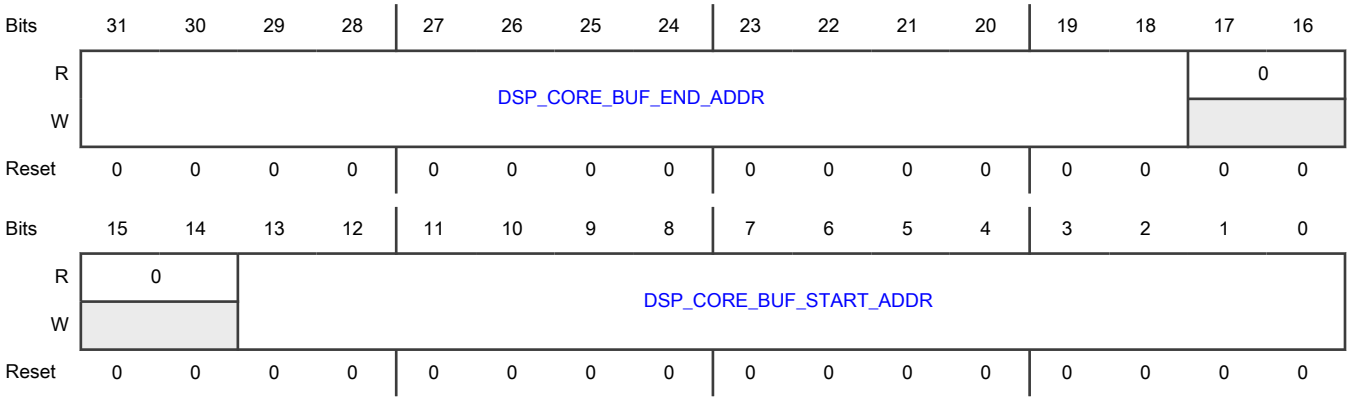
Function

Specifies the start and end pointers for the DSP and Cortex-M7 core scratch-pad area that the two cores share.

Both the Cortex-M7 core and the DSP core can access this register.

The fields in this register are half-word aligned.

Diagram



Fields

Field	Function
31-18 DSP_CORE_BUF_END_ADDR	End Pointer Specifies the end pointer for the circular buffer defined for the scratch pad between the two buffers. The address rolls back to the start address after reaching the last location.
17-14 —	Reserved
13-0 DSP_CORE_BUF_START_ADDR	Start Pointer Specifies the start pointer for the circular buffer defined for the scratch pad between the two buffers.

66.4.8 Read Pointer In DSP Buffer (DSP_CORE_CURR_RD_PTR0 - DSP_CORE_CURR_RD_PTR3)

Offset

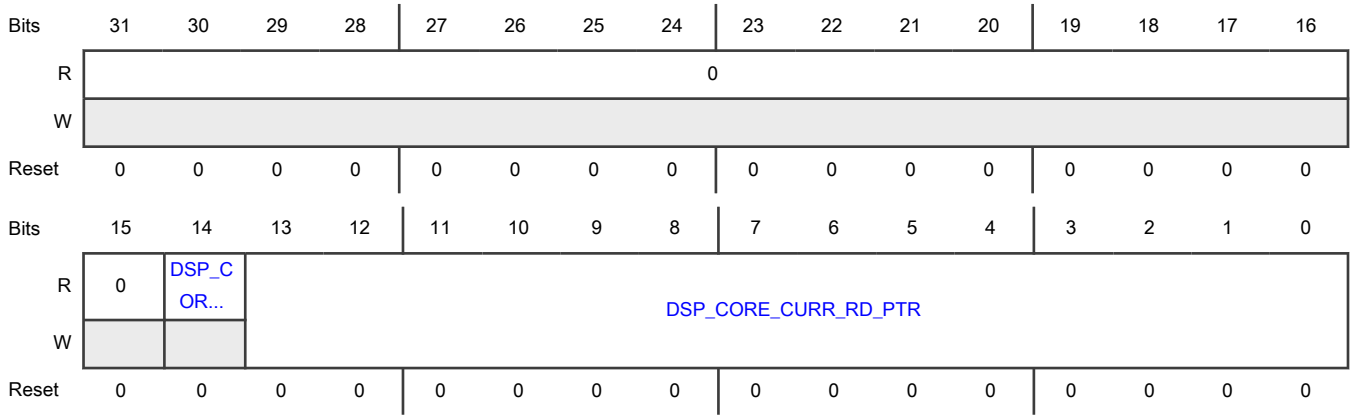
Register	Offset
DSP_CORE_CURR_RD_PTR0	28h
DSP_CORE_CURR_RD_PTR1	328h
DSP_CORE_CURR_RD_PTR2	628h
DSP_CORE_CURR_RD_PTR3	928h

Function

Specifies the current value of the DSP/core read pointer in the DSP buffer.

Both the Cortex-M7 core and the DSP core can access this register. DSP_CORE_BUFFER_CFG[DSP_CORE_BUFFER_EN] enables this functionality.

Diagram



Fields

Field	Function
31-15 —	Reserved
14 DSP_CORE_CURR_RD_PTR_WRAP	Wrap Status Indicates the current read pointer wrap status of the DSP core buffer space inside XMEM. DSPSS changes DSP_CORE_CURR_RD_PTR_WRAP to 1 whenever DSP_CORE_CURR_RD_PTR exceeds the defined end address of this region. DSPSS changes DSP_CORE_CURR_RD_PTR_WRAP to 0 when the current write pointer also wraps around.
13-0 DSP_CORE_CURR_RD_PTR	Read Pointer Specifies the current read pointer value of the DSP core buffer space inside XMEM. The start address for the buffer space is DSP_CORE_BUF_ADDR*n*[DSP_CORE_BUF_START_ADDR] unless the master loads a new value. If an underflow or overflow error occurs in this buffer space, the Cortex-M7 core can update this pointer to restart the sharing of information with DSP in this space.

66.4.9 Write Pointer In DSP Buffer (DSP_CORE_CURR_WR_PTR0 - DSP_CORE_CURR_WR_PTR3)

Offset

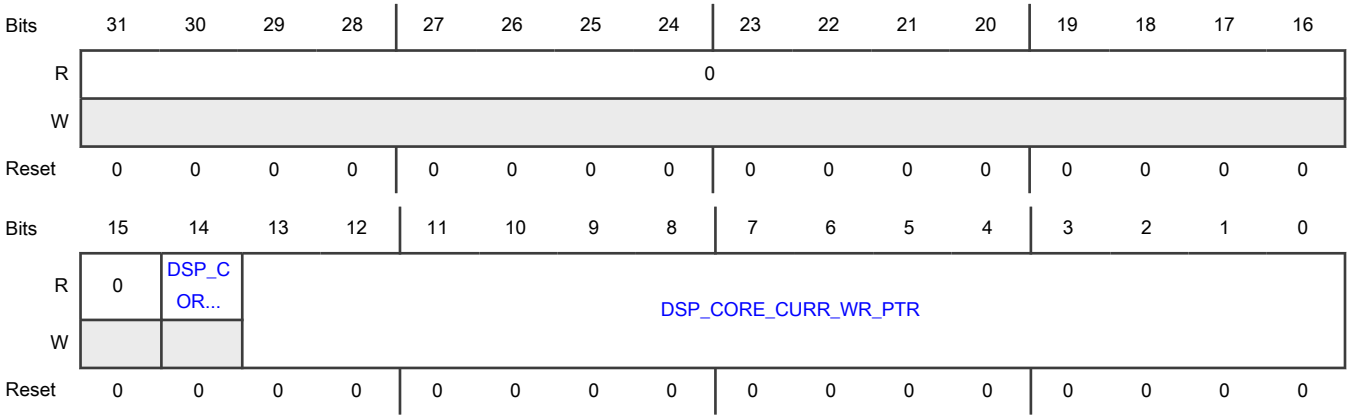
Register	Offset
DSP_CORE_CURR_WR_PTR0	2Ch
DSP_CORE_CURR_WR_PTR1	32Ch
DSP_CORE_CURR_WR_PTR2	62Ch
DSP_CORE_CURR_WR_PTR3	92Ch

Function

Specifies the current value of the DSP/core write pointer in the DSP buffer.

Both the Cortex-M7 core and the DSP core can access this register. DSP_CORE_BUFFER_CFG[DSP_CORE_BUFFER_EN] enables this functionality.

Diagram



Fields

Field	Function
31-15 —	Reserved
14 DSP_CORE_CURR_WR_PTR_WRAP	Wrap Status Indicates the current write pointer wrap status of the DSP core buffer space inside XMEM. DSPSS changes DSP_CORE_CURR_WR_PTR_WRAP to 1 whenever DSP_CORE_CURR_WR_PTR exceeds the defined end address of this region.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	DSPSS changes DSP_CORE_CURR_WR_PTR_WRAP to 0 when the current read pointer also wraps around.
13-0 DSP_CORE_CURR_WR_PTR	Write Pointer Specifies the current write pointer value of the DSP core buffer space inside XMEM. The start address for the buffer space is DSP_CORE_BUF_ADDR*n*[DSP_CORE_BUF_START_ADDR] unless the master loads a new value. If an underflow or overflow error occurs in this buffer space, the Cortex-M7 core can update this pointer to restart the sharing of information with DSP in this space.

66.4.10 Reference DMA Read Region (DMA_READ_ADDR0 - DMA_READ_ADDR5)

Offset

Register	Offset
DMA_READ_ADDR0	30h
DMA_READ_ADDR1	330h
DMA_READ_ADDR2	630h
DMA_READ_ADDR3	930h
DMA_READ_ADDR4	C30h
DMA_READ_ADDR5	F30h

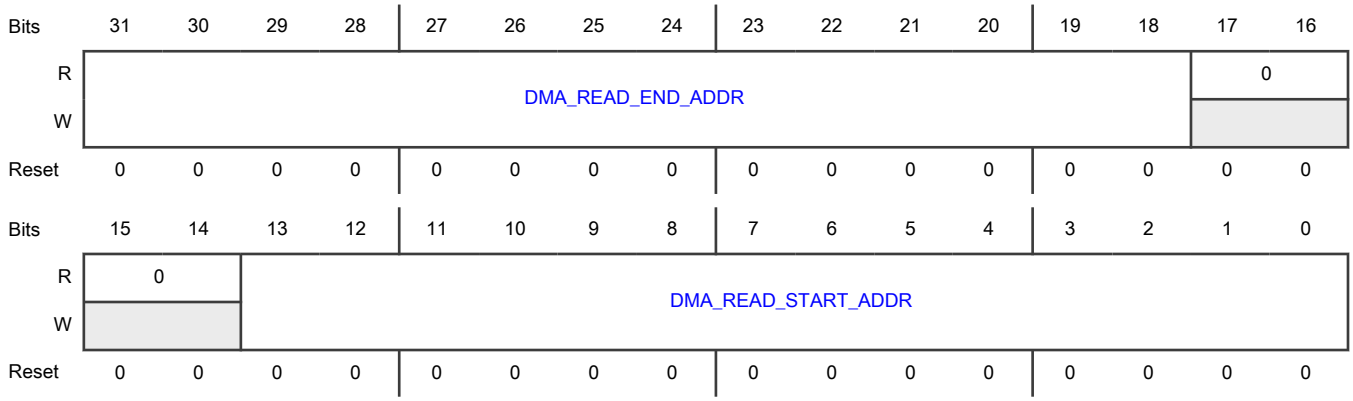
Function

Specifies the start and end addresses of the DMA_READ circular buffer.

DSP is the write master of this region. The address fields are half-word aligned.

Both the Cortex-M7 core and the DSP core can access this register.

Diagram



Fields

Field	Function
31-18 DMA_READ_END_ADDR	End Address
17-14 —	Reserved
13-0 DMA_READ_START_ADDR	Start Address

66.4.11 DMA Error Status (DMA_ERROR_STATUS0 - DMA_ERROR_STATUS5)

Offset

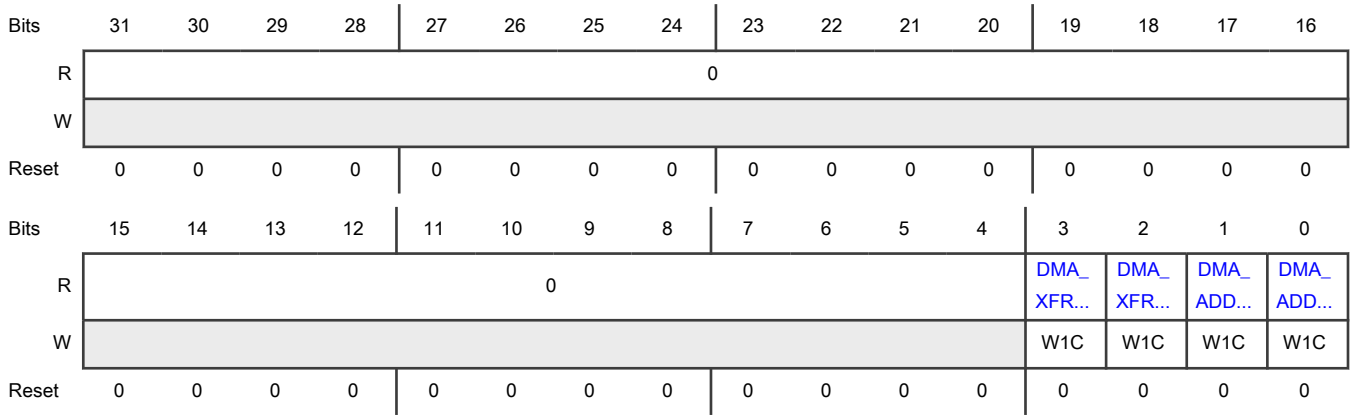
Register	Offset
DMA_ERROR_STATUS0	38h
DMA_ERROR_STATUS1	338h
DMA_ERROR_STATUS2	638h
DMA_ERROR_STATUS3	938h
DMA_ERROR_STATUS4	C38h
DMA_ERROR_STATUS5	F38h

Function

Contains flags that indicate the status of DMA errors.

Both the Cortex-M7 core and the DSP core can access this register.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 DMA_XFR_ERR_READ	Transfer Error Read Flag Indicates when any access other than half-word or word is made in the DMA-READ buffer. Status of these bits are valid only when DMA_BUFFER_CFG[DMA_READ_EN] is set. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No such error occurred 1b - This error occurred When writing 0b - No effect 1b - Clear the flag
2 DMA_XFR_ERR_WRITE	Transfer Error Write Flag Indicates when any access other than half-word or word is made in the DMA-WRITE buffer. Status of these bits are valid only when DMA_BUFFER_CFG[DMA_WRITE_EN] is set. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No such error occurred 1b - This error occurred When writing

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No effect 1b - Clear the flag
1 DMA_ADDR_MISMATCH_RD_BUFFER	Address Mismatch Read Flag Indicates when a read-access address from DMA doesn't match the expected current read pointer and the address is within the address range of the DMA buffer, as specified in the DMA_READ_START_ADDR and DMA_READ_END_ADDR fields of Reference DMA Read Region (DMA_READ_ADDR0 - DMA_READ_ADDR5). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No such error occurred 1b - This error occurred When writing 0b - No effect 1b - Clear the flag
0 DMA_ADDR_MISMATCH_WR_BUFFER	Address Mismatch Write Flag Indicates when a write-access address from DMA doesn't match the expected current write pointer and the address is within the address range of the DMA buffer, as specified in the DMA_WRITE_START_ADDR and DMA_WRITE_END_ADDR fields of Reference DMA Write Region (DMA_WRITE_ADDR0 - DMA_WRITE_ADDR5). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No such error occurred 1b - This error occurred When writing 0b - No effect 1b - Clear the flag

66.4.12 Reference DMA Write Region (DMA_WRITE_ADDR0 - DMA_WRITE_ADDR5)

Offset

Register	Offset
DMA_WRITE_ADDR0	40h

Table continues on the next page...

Table continued from the previous page...

Register	Offset
DMA_WRITE_ADDR1	340h
DMA_WRITE_ADDR2	640h
DMA_WRITE_ADDR3	940h
DMA_WRITE_ADDR4	C40h
DMA_WRITE_ADDR5	F40h

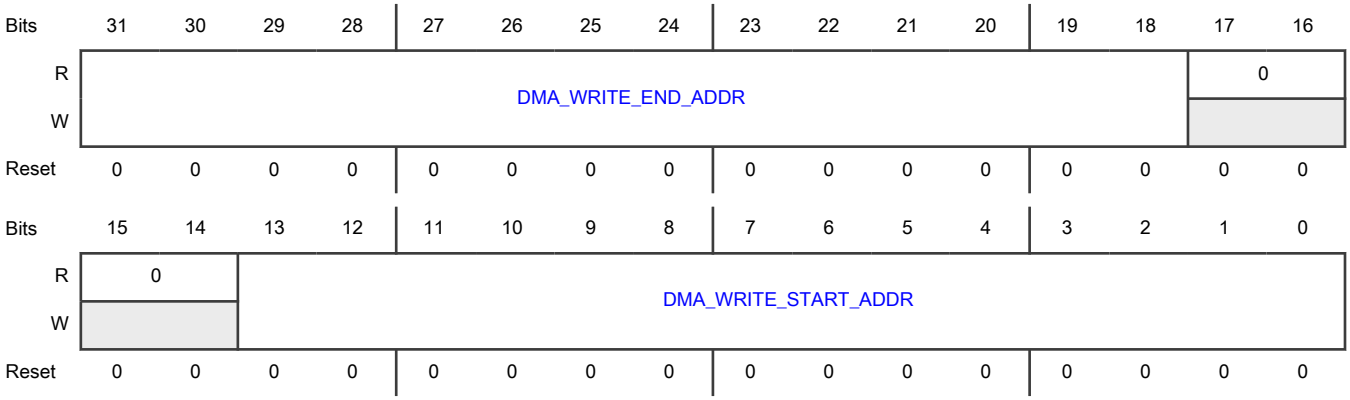
Function

Specifies the start and end addresses of the DMA_WRITE circular buffer.

DMA is the write master of this region. The address fields are half-word aligned.

Both the Cortex-M7 core and the DSP core can access this register.

Diagram



Fields

Field	Function
31-18 DMA_WRITE_END_ADDR	End Address
17-14 —	Reserved
13-0 DMA_WRITE_START_ADDR	Start Address

66.4.13 DMA Current Write Pointer (DMA_CURR_WR_PTR0 - DMA_CURR_WR_PTR5)

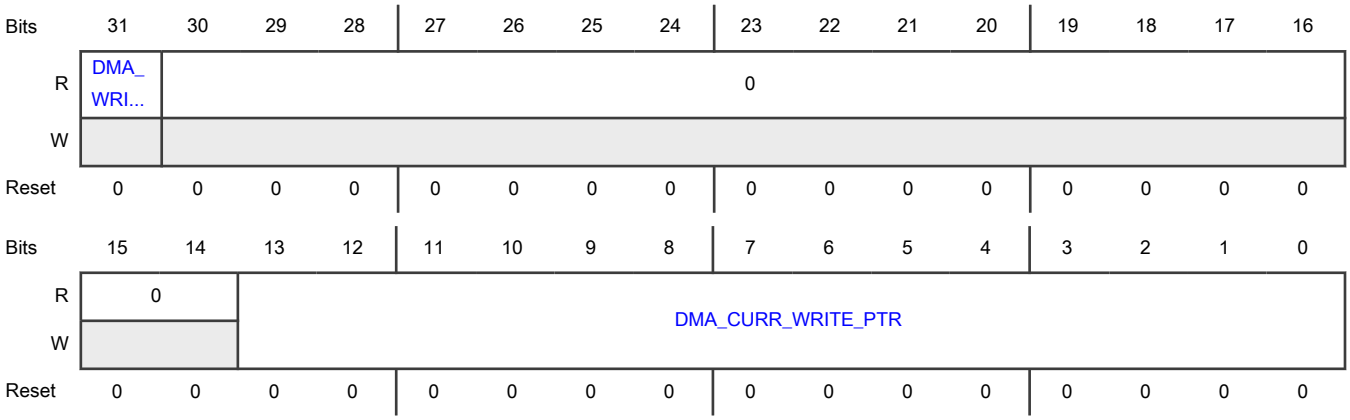
Offset

Register	Offset
DMA_CURR_WR_PTR0	44h
DMA_CURR_WR_PTR1	344h
DMA_CURR_WR_PTR2	644h
DMA_CURR_WR_PTR3	944h
DMA_CURR_WR_PTR4	C44h
DMA_CURR_WR_PTR5	F44h

Function

Specifies the current DMA write pointer inside the DMA buffer in XMEM.

Diagram



Fields

Field	Function
31 DMA_WRITE_PTR_WRAP	DMA-WRITE Buffer Wrap Toggles whenever the write pointer in the DMA-WRITE buffer wraps.
30-14 —	Reserved
13-0 DMA_CURR_WRITE_PTR	Write Pointer Specifies the current DMA write pointer in the DMA-WRITE region. When the Cortex-M7 core writes 1 to the corresponding bit in DMA_BUFFER_CFG[DMA_WRITE_EN], DMA_CURR_WRITE_PTR increments after every DMA write access in the defined DMA-WRITE region.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	DSP maintains the read pointer for this buffer in firmware. Both the Cortex-M7 and DSP cores can update this field before the start of monitoring logic. This is provided for the case where the master (Cortex-M7 core) overwrote the data in a location different from the last write location. This update can happen only when DMA_ERROR_STATUS*n*[DMA_XFR_ERR_WRITE] is not 0.

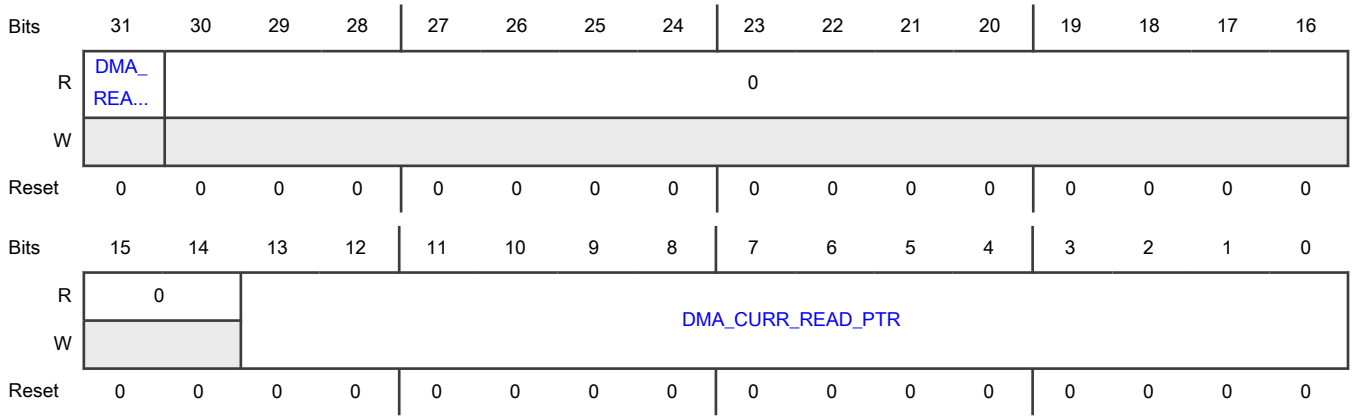
66.4.14 DMA Current Read Pointer (DMA_CURR_RD_PTR0 - DMA_CURR_RD_PTR5)

Offset

Register	Offset
DMA_CURR_RD_PTR0	48h
DMA_CURR_RD_PTR1	348h
DMA_CURR_RD_PTR2	648h
DMA_CURR_RD_PTR3	948h
DMA_CURR_RD_PTR4	C48h
DMA_CURR_RD_PTR5	F48h

Function
Specifies the current DMA read pointer inside the DMA buffer in XMEM.

Diagram



Fields

Field	Function
31	DMA-READ Buffer Wrap Toggles whenever the read pointer in the DMA-READ buffer wraps.

Table continues on the next page...

Table continued from the previous page...

Field	Function
DMA_READ_PTR_WRAP	This field returns to its reset value when you enable DMA buffer monitoring (write 1 to the corresponding bit in DMA_BUFFER_CFG[DMA_READ_EN]).
30-14 —	Reserved
13-0 DMA_CURR_READ_PTR	Read Pointer Specifies the current DMA read pointer in the DMA-READ region. DSP maintains the write pointer for this buffer in firmware, because DSP controls the DMA request. When the Cortex-M7 core writes 1 to the corresponding bit in DMA_BUFFER_CFG[DMA_READ_EN], DMA_CURR_READ_PTR increments after every DMA read access in the defined DMA-READ region. Both the Cortex-M7 and DSP cores can update this field before the start of monitoring logic. This is provided for the case where the master (Cortex-M7 core) overwrote the data in a location different from the last write location. This update can happen only when DMA_ERROR_STATUS*n*[DMA_XFR_ERR_READ] is not 0.

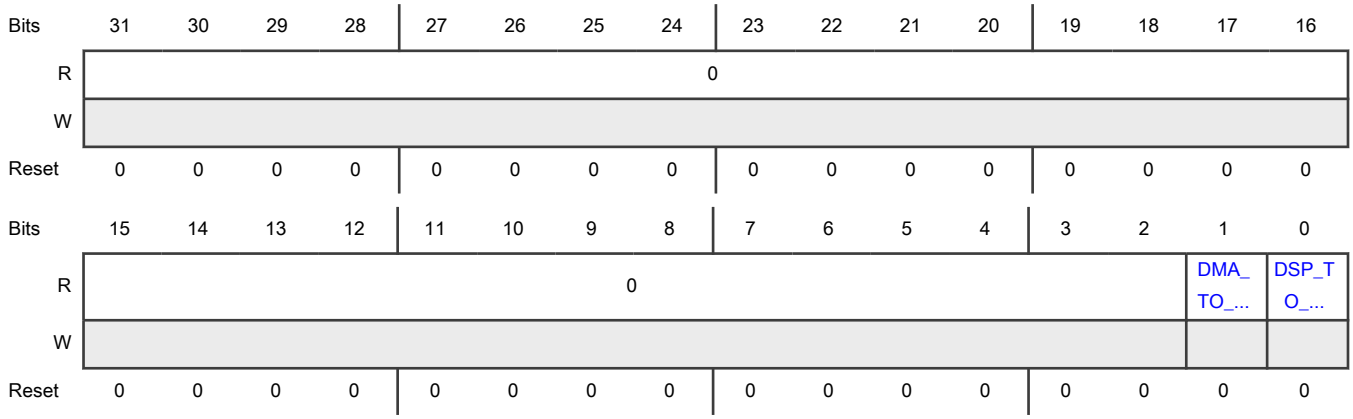
66.4.15 DMA Request Status (DSP_TO_DMA_REQUEST_STATUS0 - DSP_TO_DMA_REQUEST_STATUS5)

Offset

Register	Offset
DSP_TO_DMA_REQUEST_STATUS0	50h
DSP_TO_DMA_REQUEST_STATUS1	350h
DSP_TO_DMA_REQUEST_STATUS2	650h
DSP_TO_DMA_REQUEST_STATUS3	950h
DSP_TO_DMA_REQUEST_STATUS4	C50h
DSP_TO_DMA_REQUEST_STATUS5	F50h

Function

Diagram



Fields

Field	Function
31-2 —	Reserved
1 DMA_TO_DSP_ACK_STATUS	DMA Acknowledgment Status 0b - Acknowledgment for current DMA request is pending 1b - DMA acknowledges the current DMA request
0 DSP_TO_DMA_REQUEST_STATUS	DMA Request Status DMA Request Status The DSP core changes this field to 1 to initiate DMA on XMEM. DSPSS changes this field to 0 after the DMA request completes. 0b - DMA request is complete 1b - Initiate DMA request

66.4.16 Thread Suspend Request For Thread Disabling/PCINIT Change (THREAD_SUSPEND_REQ0 - THREAD_SUSPEND_REQ3)

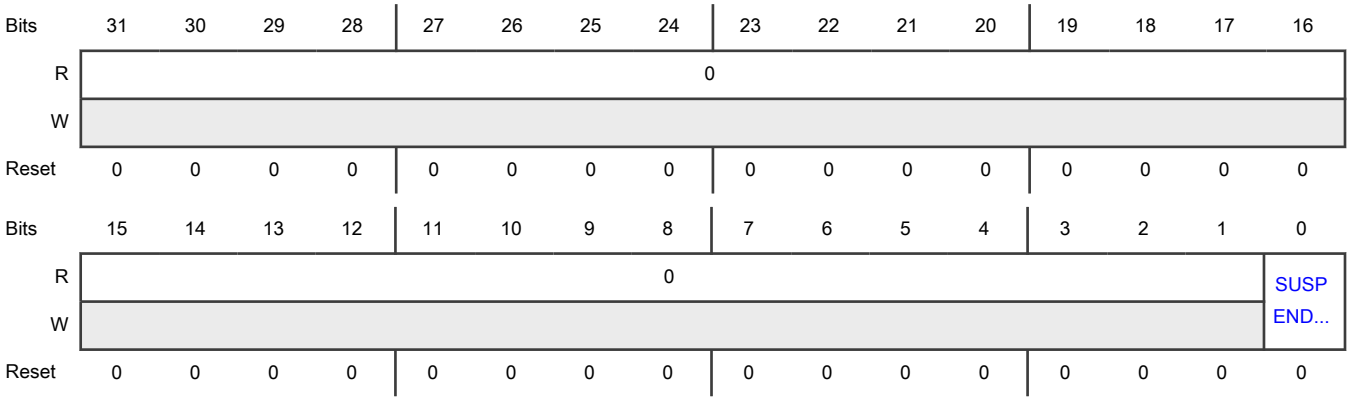
Offset

Register	Offset
THREAD_SUSPEND_REQ0	54h
THREAD_SUSPEND_REQ1	354h
THREAD_SUSPEND_REQ2	654h
THREAD_SUSPEND_REQ3	954h

Function

Requests a thread suspension.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 SUSPEND_REQ	Suspend Request Specifies whether to initiate a suspend request. 0b - Do not initiate 1b - Initiate

66.4.17 Thread Status (DSPSS_DSP_TH_STATUS0 - DSPSS_DSP_TH_STATUS3)

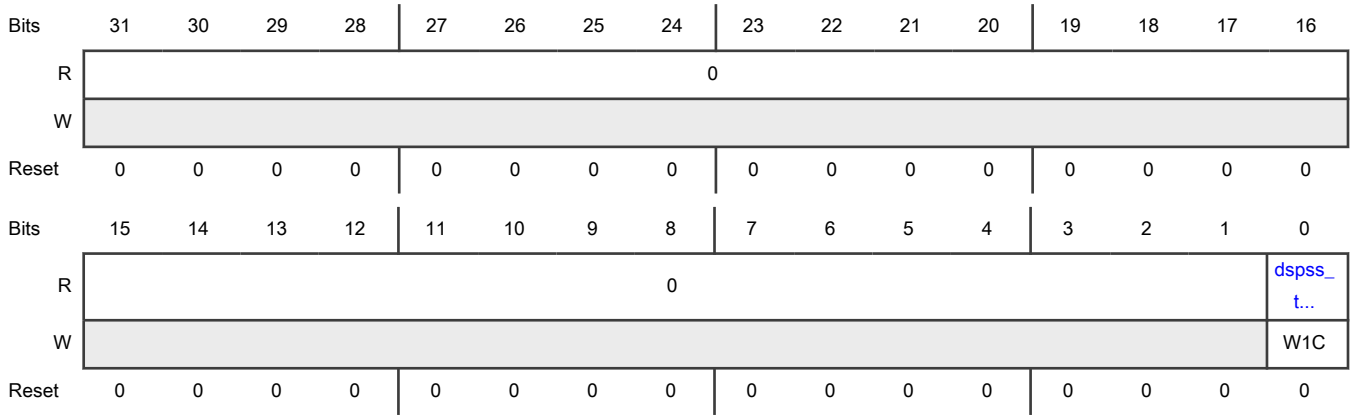
Offset

Register	Offset
DSPSS_DSP_TH_STATUS0	5Ch
DSPSS_DSP_TH_STATUS1	35Ch
DSPSS_DSP_TH_STATUS2	65Ch
DSPSS_DSP_TH_STATUS3	95Ch

Function

Indicates the status of DSP0 for thread *n*.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 dspss_th_suspended	Thread Status Indicates whether the thread is suspended or not. 0b - Not suspended 1b - Suspended

66.4.18 DSP Core Buffer Status (DSP_CORE_BUFFER_STATUS0 - DSP_CORE_BUFFER_STATUS3)

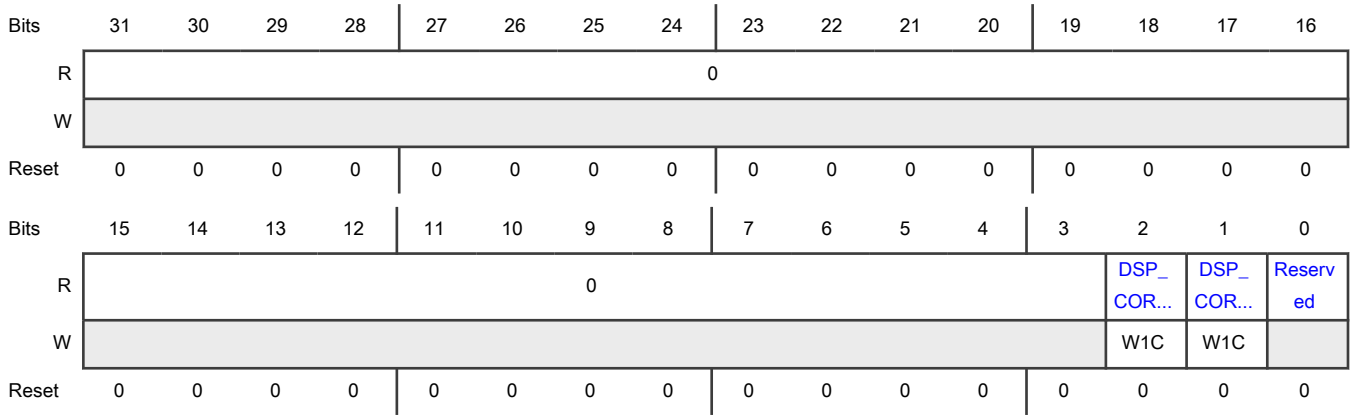
Offset

Register	Offset
DSP_CORE_BUFFER_STATUS0	7Ch
DSP_CORE_BUFFER_STATUS1	37Ch
DSP_CORE_BUFFER_STATUS2	67Ch
DSP_CORE_BUFFER_STATUS3	97Ch

Function

Indicates the status of the DSP core buffer.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 DSP_CORE_BUFFER_UNDF	Buffer Underflow Flag When DSP_CORE_BUFFER_CFG[DSP_CORE_BUFFER_EN] = 1, indicates that the DSP core buffer space underflowed. You must disable the buffer before the Cortex-M7 core or DSP core clears this flag. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No underflow 1b - Underflow occurred When writing 0b - No effect 1b - Clear the flag
1 DSP_CORE_BUFFER_OVF	Buffer Overflow Flag When DSP_CORE_BUFFER_CFG[DSP_CORE_BUFFER_EN] = 1, indicates that the write pointer inside the DSP core buffer overflowed. You must disable the buffer before the Cortex-M7 core or DSP core clears this flag. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No overflow

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Overflow occurred When writing 0b - No effect 1b - Clear the flag
0 —	Reserved

66.4.19 DSP To Cortex-M7 Core Error Trigger (DSP_TO_CORE_TRIG_ERR_STATUS0 - DSP_TO_CORE_TRIG_ERR_STATUS3)

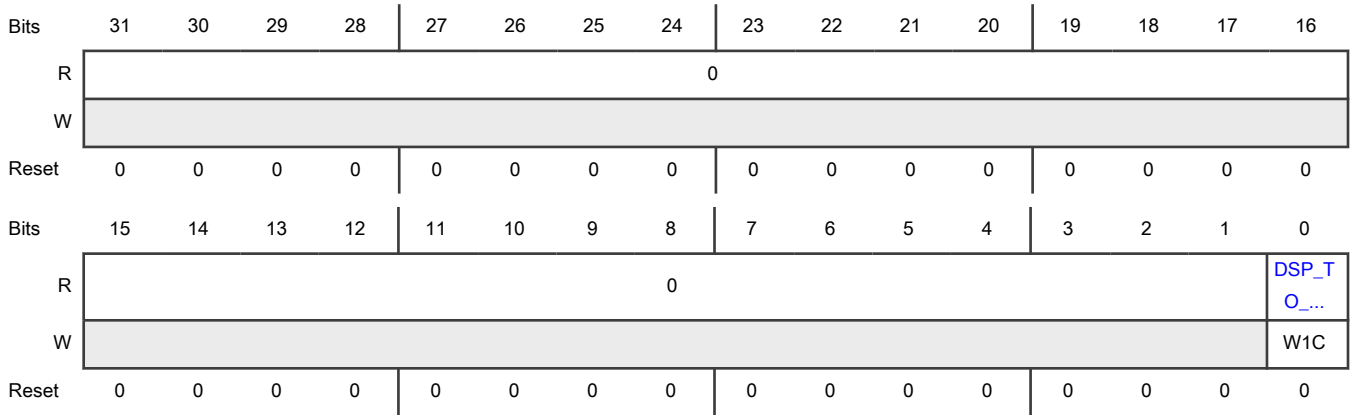
Offset

Register	Offset
DSP_TO_CORE_TRIG_ERR_STATUS0	80h
DSP_TO_CORE_TRIG_ERR_STATUS1	380h
DSP_TO_CORE_TRIG_ERR_STATUS2	680h
DSP_TO_CORE_TRIG_ERR_STATUS3	980h

Function

Indicates an error.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 DSP_TO_CORE_TRIG_ERR_STATUS	Error Status Indicates an error. DSP sets this flag whenever DSP encounters an error. The Cortex-M7 core clears this flag. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Error did not occur 1b - Error occurred When writing 0b - No effect 1b - Clear the flag

66.4.20 DSP Output Control (DS_GATE_STATUS_REGISTER0 - DS_GATE_STATUS_REGISTER3)

Offset

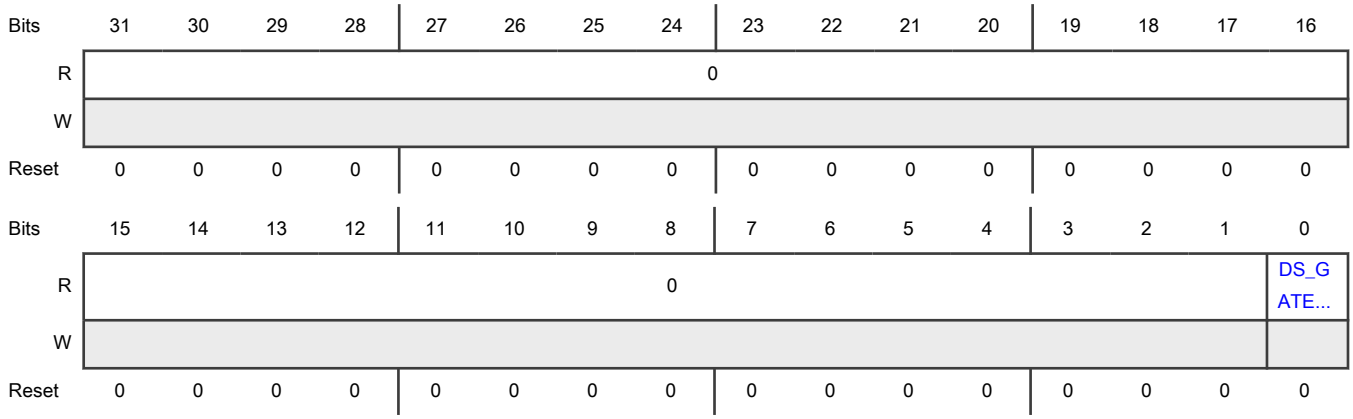
Register	Offset
DS_GATE_STATUS_REGISTER0	84h
DS_GATE_STATUS_REGISTER1	384h
DS_GATE_STATUS_REGISTER2	684h
DS_GATE_STATUS_REGISTER3	984h

Function

Exchanges information between DSPSS and the rest of the chip.

This is a general-purpose register for which the DSP software defines the action. DSP reads this register.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 DS_GATE_STATUS_REGISTER	General-Purpose Data Exchange Exchanges general-purpose information according to the DSP software. The Cortex-M7 core and DSP read this field.

66.4.21 DSP Trigger To TRIGMUX (DS_GATE_TRIGMUX_REGISTER0 - DS_GATE_TRIGMUX_REGISTER3)

Offset

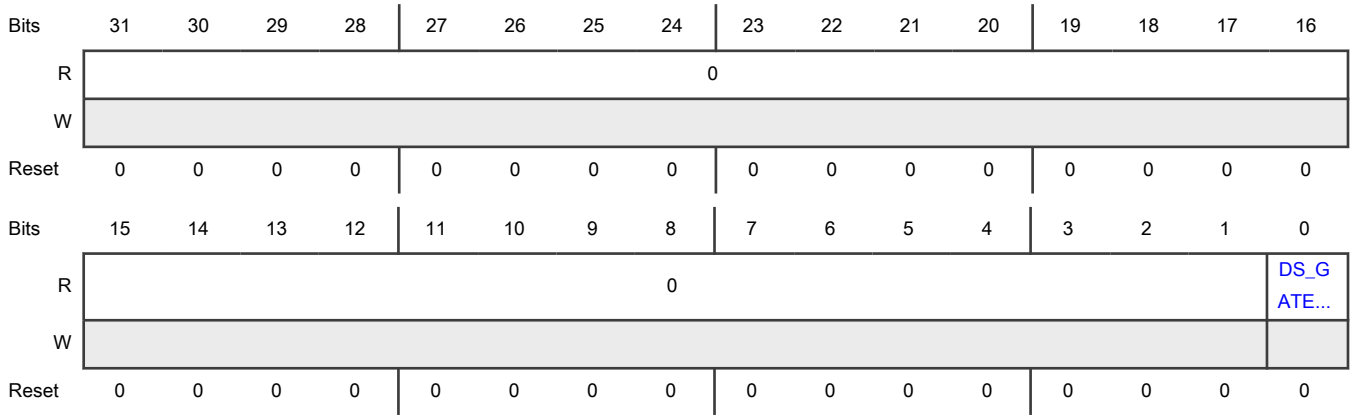
Register	Offset
DS_GATE_TRIGMUX_REGISTER0	88h
DS_GATE_TRIGMUX_REGISTER1	388h
DS_GATE_TRIGMUX_REGISTER2	688h
DS_GATE_TRIGMUX_REGISTER3	988h

Function

Sends a trigger to TRIGMUX for the respective thread.

The DSP core reads and writes to this register.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 DS_GATE_TRIGMUX_TRIGGER	Trigger To TRIGMUX Sends a trigger. The DSP firmware writes 1 to this field. The DSP DW writes 0 to this field. 0b - Do not send a trigger 1b - Send a trigger

66.4.22 Stop DMA Request (HW_CTRL_DMA_REQ_STOP0 - HW_CTRL_DMA_REQ_STOP5)

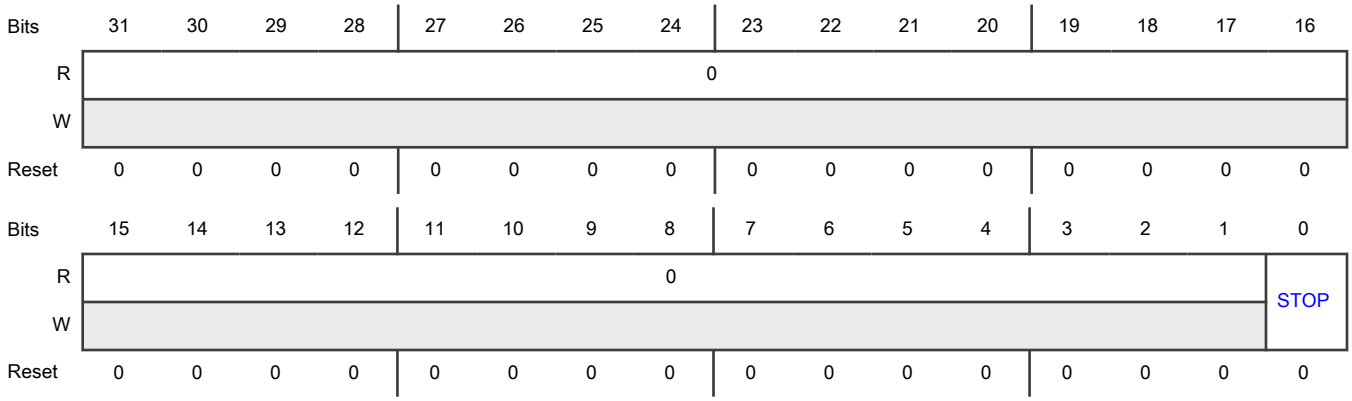
Offset

Register	Offset
HW_CTRL_DMA_REQ_STOP0	8Ch
HW_CTRL_DMA_REQ_STOP1	38Ch
HW_CTRL_DMA_REQ_STOP2	68Ch
HW_CTRL_DMA_REQ_STOP3	98Ch
HW_CTRL_DMA_REQ_STOP4	C8Ch
HW_CTRL_DMA_REQ_STOP5	F8Ch

Function

Stops the assertion of a new request at the DMA interface.

Diagram



Fields

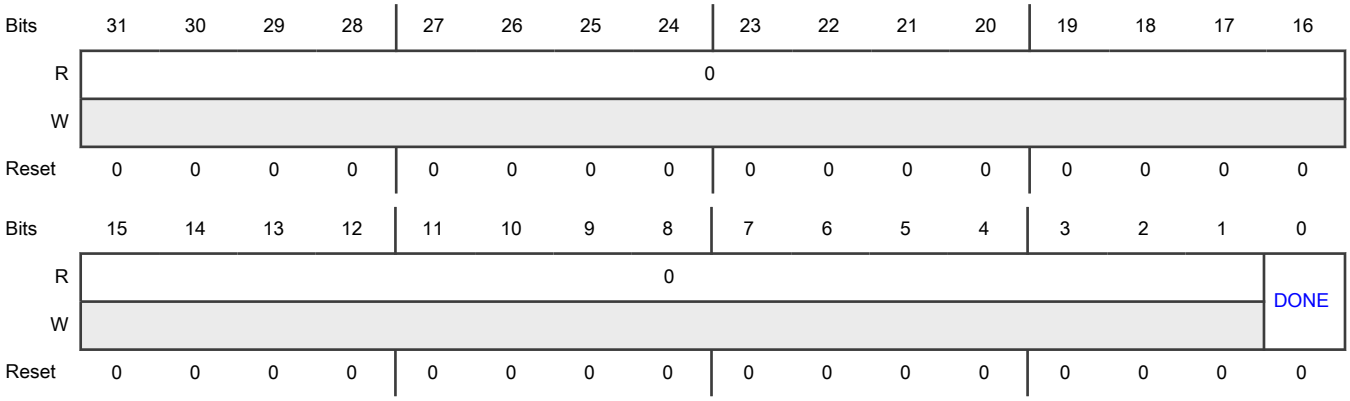
Field	Function
31-1 —	Reserved
0 STOP	Stop Request Works with HW_CTRL_DMA_REQ_RESPONSE*n*[START] to stop the assertion of another DMA request. The Cortex-M7 and DSP cores write 1 to this field. DSPSS changes this field to 0 when DMA asserts ipd_dma_done_lw or when DMA_ERR_CTRL*n*[DONE] = 1. 0b - Do not stop 1b - Stop

66.4.23 DMA Error Control (DMA_ERROR_CTRL0 - DMA_ERROR_CTRL5)

Offset

Register	Offset
DMA_ERROR_CTRL0	90h
DMA_ERROR_CTRL1	390h
DMA_ERROR_CTRL2	690h
DMA_ERROR_CTRL3	990h
DMA_ERROR_CTRL4	C90h
DMA_ERROR_CTRL5	F90h

Diagram



Fields

Field	Function
31-1 —	Reserved
0 DONE	Dummy Done The Cortex-M7 core should write 1 to this field when an error or hang occurs during a DMA transfer. DSPSS changes this field back to 0 after one peripheral-bus clock cycle. If the DSP core used Hardware-Assisted DMA mode, use this field only after writing 1 to HW_CTRL_DMA_REQ_STOP*n*[STOP].

66.4.24 Hardware Control Handling for DMA Request And Response (HW_CTRL_DMA_REQ_RESPONSE0 - HW_CTRL_DMA_REQ_RESPONSE5)

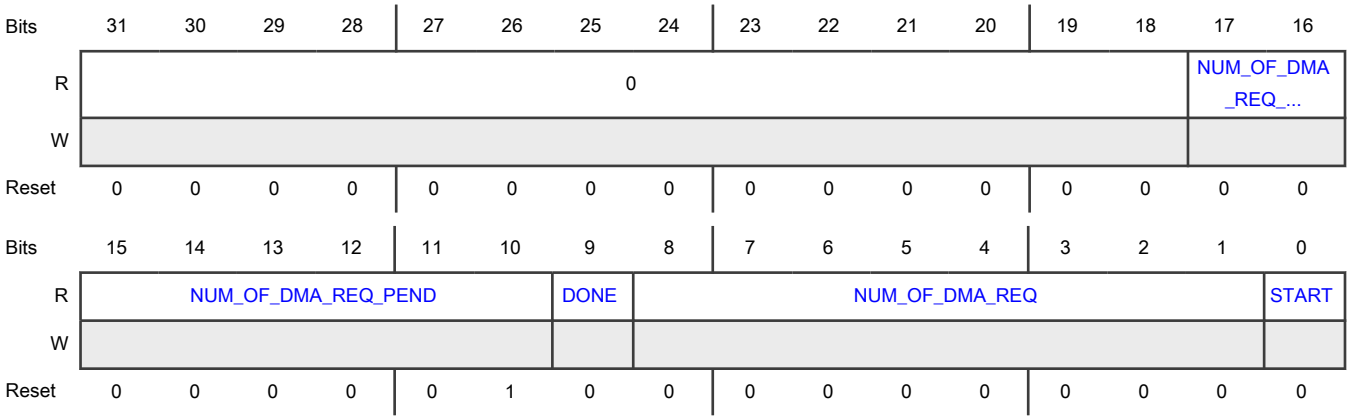
Offset

Register	Offset
HW_CTRL_DMA_REQ_RESPONSE0	94h
HW_CTRL_DMA_REQ_RESPONSE1	394h
HW_CTRL_DMA_REQ_RESPONSE2	694h
HW_CTRL_DMA_REQ_RESPONSE3	994h
HW_CTRL_DMA_REQ_RESPONSE4	C94h
HW_CTRL_DMA_REQ_RESPONSE5	F94h

Function

HW generates request as soon DSP FW programs the count and sets the start bit. These configurations are common for all the threads across the DSP.

Diagram



Fields

Field	Function
31-18 —	Reserved
17-10 NUM_OF_DMA_REQ_PEND	Number of Pending DMA Requests Indicates the number of DMA requests that are remaining at a given time. This is the real-time status. After all the requests are serviced, this field becomes 0. If HW_CTRL_DMA_REQ_STOP*n*[STOP] = 1, no new requests are sent to DMA and therefore NUM_OF_DMA_REQ_PEND gives information about the number of requests that are pending.
9 DONE	Done Generating DMA Requests Indicates whether DMA request generation is finished. DSPSS changes this field to 1 after either of the following occurs: • DSPSS finishes generating the expected number of DMA requests (as you specified in HW_CTRL_DMA_REQ_RESPONSE*n*[NUM_OF_DMA_REQ]). • You write 1 to DMA_ERROR_CTRL*n*[DONE]. The DSP firmware must write 0 to this field before launching new hardware-assisted DMA requests. 0b - Not finished 1b - Finished
8-1 NUM_OF_DMA_REQ	Number of DMA Requests Indicates the number of requests to generate when HW_CTRL_DMA_REQ_RESPONSE*n*[START] = 1. This field must not be updated dynamically during the ongoing DMA transfer. Your DSP firmware can update NUM_OF_DMA_REQ only when HW_CTRL_DMA_REQ_RESPONSE*n*[DONE] = 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 START	Start Request Indicates the start of a hardware request. After every DMA-done event, DSPSS asserts a new request until the total number of request reaches HW_CTRL_DMA_REQ_RESPONSE*n*[NUM_OF_DMA_REQ]. Your DSP firmware must program this again if it must use this feature. Ongoing DMA operation does not stop when the thread is suspended through an mbit error. If you require DMA operation to be halted, the Cortex-M7 core must write 1 to HW_CTRL_DMA_REQ_STOP*n*[STOP].

66.4.25 DSPSS Soft Reset (DSPSS_SOFT_RESET_REGISTER)

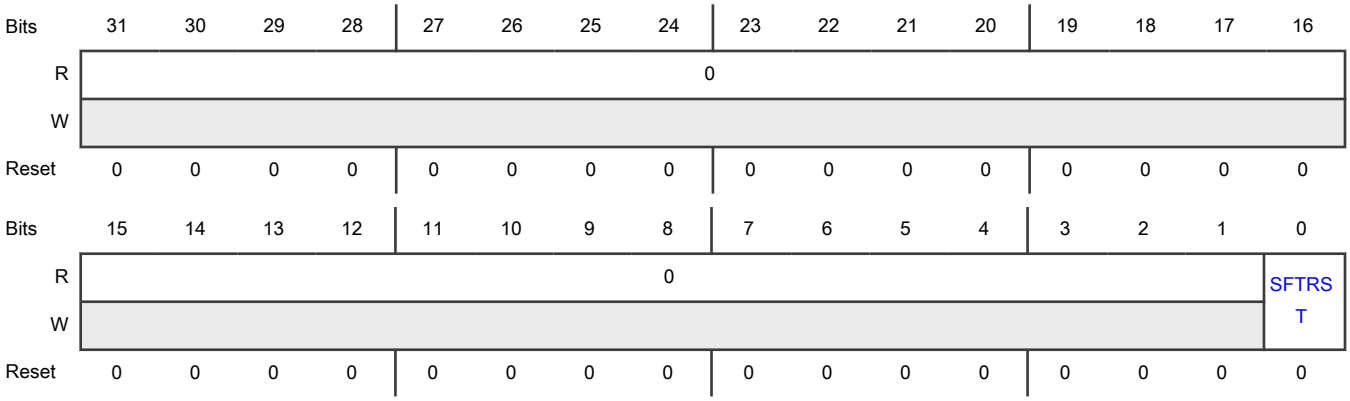
Offset

Register	Offset
DSPSS_SOFT_RESET_REGISTER	BE4h

Function

Performs a soft reset.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 SFTRST	Soft Reset Performs a soft reset.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Writing 1 to this field resets everything inside DSPSS except the DSP core. Before writing 1 to this field, ensure that DSP threads are either not running or in Sleep mode. 0b - Do not reset 1b - Reset

66.4.26 DSP ACK Timeout Configuration And Error Control (DSP_ACK_TIMEOUT_CFG_AND_ERR_CTRL)

Offset

Register	Offset
DSP_ACK_TIMEOUT_CFG_AND_ERR_CTRL	BE8h

Function

Configures the DSP to acknowledge a context-request timer, and controls the required actions after a timeout.

Diagram

23	DSP ACK Timeout Error Flag For Thread 3 Indicates a acknowledgment timeout error for thread 3.

Table continues on the next page...

Table continued from the previous page...

Field	Function
DSP_ACK_TIMEOUT_ERR_TH3	DSPSS sets this flag when DSP_ACK_TIMEOUT_EN = 1 and the DSP core fails to acknowledge the context request change within DSP_ACK_TIMEOUT_TIMER cycles. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No such error occurred 1b - This error occurred When writing 0b - No effect 1b - Clear the flag
22 DSP_ACK_TIMEOUT_ERR_TH2	DSP ACK Timeout Error Flag For Thread 2 Indicates a acknowledgment timeout error for thread 2. DSPSS sets this flag when DSP_ACK_TIMEOUT_EN = 1 and the DSP core fails to acknowledge the context request change within DSP_ACK_TIMEOUT_TIMER cycles. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No such error occurred 1b - This error occurred When writing 0b - No effect 1b - Clear the flag
21 DSP_ACK_TIMEOUT_ERR_TH1	DSP ACK Timeout Error Flag For Thread 1 Indicates a acknowledgment timeout error for thread 1. DSPSS sets this flag when DSP_ACK_TIMEOUT_EN = 1 and the DSP core fails to acknowledge the context request change within DSP_ACK_TIMEOUT_TIMER cycles. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No such error occurred 1b - This error occurred When writing 0b - No effect

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Clear the flag
20 DSP_ACK_TIMEOUT_ERR_TH0	DSP ACK Timeout Error Flag For Thread 0 Indicates a acknowledgment timeout error for thread 0. DSPSS sets this flag when DDSP_ACK_TIMEOUT_EN = 1 and the DSP core fails to acknowledge the context request change within DSP_ACK_TIMEOUT_TIMER cycles. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No such error occurred 1b - This error occurred When writing 0b - No effect 1b - Clear the flag
19-15 REQ_COUNT_ACC_FIFO	Context Requests In Request FIFO Indicates the real-time number of context requests inside the request FIFO.
14 REQ_ACC_FIFO_INTR	Interrupt Status On Request FIFO Threshold Cross
13-9 REQ_ACC_FIFO_THRESHOLD_FOR_INTR	Interrupt Threshold For Request FIFO Specifies the threshold value of the thread-accumulator FIFO. An interrupt occurs if the number of thread requests equals or exceeds this value. Do not write a value greater than 16d to this field. 0_0000b-1_0000b - Threshold as defined in the description All other values are reserved.
8 DSP_ACK_TIMEOUT_ERR	DSP ACK Timeout Error Flag Indicates a acknowledgment timeout error. DSPSS sets this flag when DSP_ACK_TIMEOUT_EN = 1 and the DSP core fails to acknowledge the context request change within DSP_ACK_TIMEOUT_TIMER cycles. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No such error occurred

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - This error occurred When writing 0b - No effect 1b - Clear the flag
7 —	Reserved
6 DSP_ACK_TIMEOUT_EN	DSP ACK Timeout Enable 0b - Disable 1b - Enable
5-0 DSP_ACK_TIMEOUT_TIMER	DSP ACK Timeout Timer Configuration Specifies the maximum number of DSP clock cycles for DSP to acknowledge the context-change request. If DSP does not respond during that time (for example, due to a DSP hardware problem), DSPSS sets the timeout-error flag (DSP_ACK_TIMEOUT_CFG_AND_ERR_CTRL[DSP_ACK_TIMEOUT_ERR]). You must write a value of 8d or greater to this field. 00_0000b-00_0111b - Reserved All other values - Clock cycles as defined in the description

66.4.27 Disable Monitoring of ECC Errors In XMEM And PMEM (ECC_ERROR_MONITOR_THREAD_SUSPEND_CTRL)

Offset

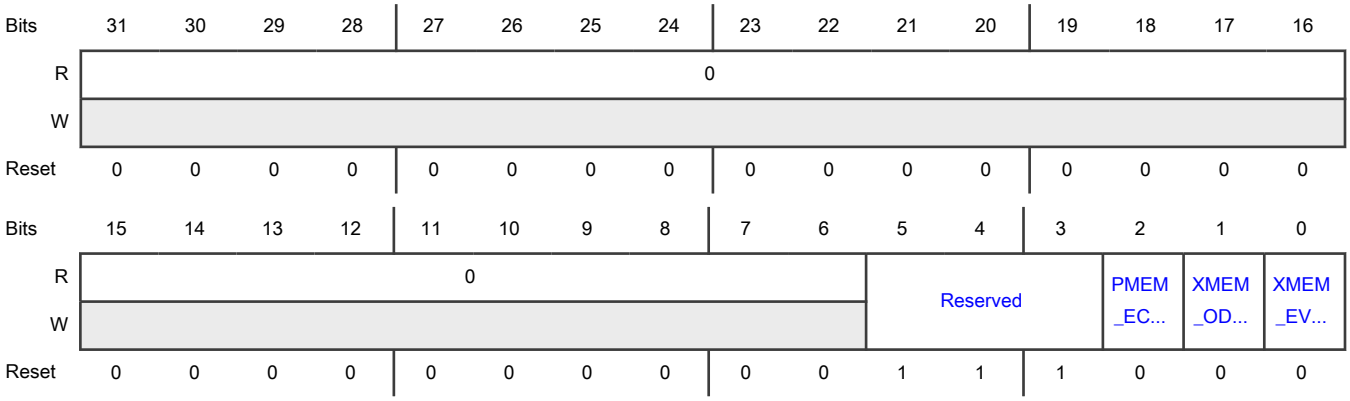
Register	Offset
ECC_ERROR_MONITOR_THREAD_SUSPEND_CTRL	BECh

Function

Disables ECC error monitoring for:

- PMEM.
- The odd instance of XMEM.
- The even instance of XMEM.

Diagram



Fields

Field	Function
31-6 —	Reserved
5-3 —	Reserved
2 PMEM_ECC_ERROR_DIS	Error Monitoring Disable For PMEM Disables the ECC error monitor for PMEM. 0b - Enable 1b - Disable
1 XMEM_ODD_ECC_ERROR_DIS	Error Monitoring Disable For Odd XMEM Disables the ECC error monitor for the odd instance of XMEM. 0b - Enable 1b - Disable
0 XMEM_EVEN_ECC_ERROR_DIS	Error Monitoring Disable For Even XMEM Disables the ECC error monitor for the even instance of XMEM. 0b - Enable 1b - Disable

66.4.28 Interrupt Enable (INTERRUPT_ENABLE_REGISTER2)

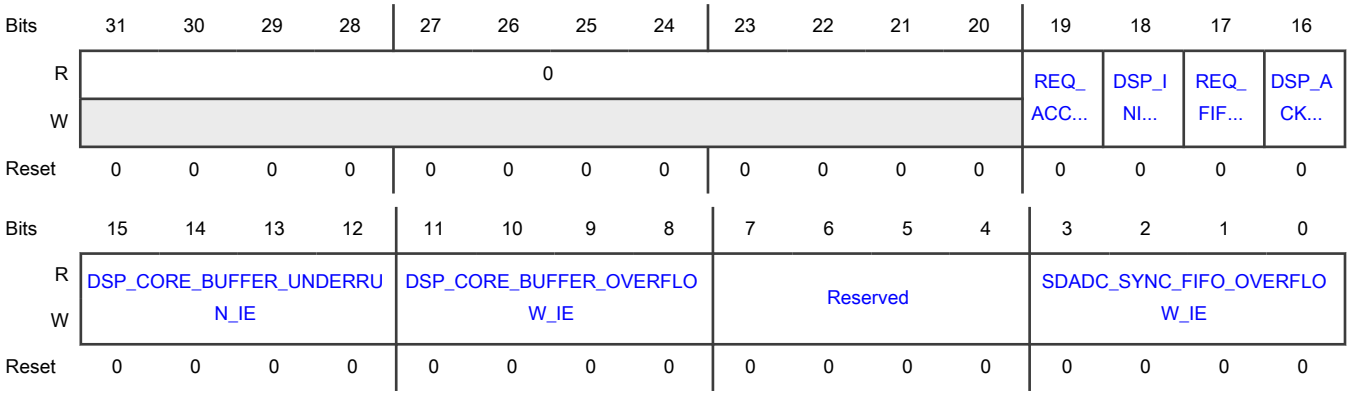
Offset

Register	Offset
INTERRUPT_ENABLE_REGISTER2	BF0h

Function

Enables various interrupts.

Diagram



Fields

Field	Function
31-20 —	Reserved
19 REQ_ACC_FIFO_THRESHOLD_CROSS_INT_EN	Interrupt enable: Request accumulator FIFO Use this field if you need an interrupt whenever the thread-request accumulator FIFO crosses the programmed threshold. This tells you if a buildup exists in the request FIFO. 0b - Disable 1b - Enable
18 DSP_INIT_LOW_IE	Interrupt enable: DSP_INIT_LOW 0b - Disable 1b - Enable
17 REQ_FIFO_ERR_IE_EN	Interrupt enable: REQ_FIFO_ERR 0b - Disable 1b - Enable
16 DSP_ACK_TIMEOUT_ERR_IE	Interrupt enable: DSP_ACK_TIMEOUT Error 0b - Disable 1b - Enable
15-12 DSP_CORE_BUFFER_UNDERRUN_IE	Interrupt enable: DSP-CORE BUFFER Underrun Error Contains bits that enable the interrupts for individual threads. Within this field, bit *m* enables the interrupt for thread *m*. For example, bit 2 enables the interrupt for thread 2.
11-8	Interrupt enable: DSP-CORE BUFFER Overflow Error

Table continues on the next page...

Table continued from the previous page...

Field	Function
DSP_CORE_BUFFER_OVERFLOW_IE	Contains bits that enable the interrupts for individual threads. Within this field, bit *m* enables the interrupt for thread *m*. For example, bit 2 enables the interrupt for thread 2.
7-4 —	Reserved
3-0 SDADC_SYNC_FIFO_OVERFLOW_IE	Interrupt enable: SDADC_SYNC_FIFO_OVERFLOW Contains bits that enable the interrupts for individual threads. Within this field, bit *m* enables the interrupt for thread *m*. For example, bit 2 enables the interrupt for thread 2.

66.4.29 FIFO Overflow Status (SDADC_SYNC_FIFO_ERROR_STATUS)

Offset

Register	Offset
SDADC_SYNC_FIFO_ERROR_STATUS	BF4h

Function

Indicates the overflow status of the request FIFO and SDSDC sync FIFO.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-9	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
8 REQ_FIFO_OVERFLOW	Request FIFO Overflow Flag DSPSS sets this flag when the request FIFO overflows. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No overflow occurred 1b - Overflow occurred When writing 0b - No effect 1b - Clear the flag
7-4 —	Reserved
3-0 OVERFLOW	SDADC Sync FIFO Overflow Flag Contains flags that enable the interrupts for individual threads. Within this field, bit *m* represents the flag for thread *m*. For example, bit 2 is the flag for thread 2. DSPSS sets a flag in this field when the respective SDADC sync FIFO overflows.

66.4.30 Configuration For DSP-Core Buffer (DSP_CORE_BUFFER_CFG)

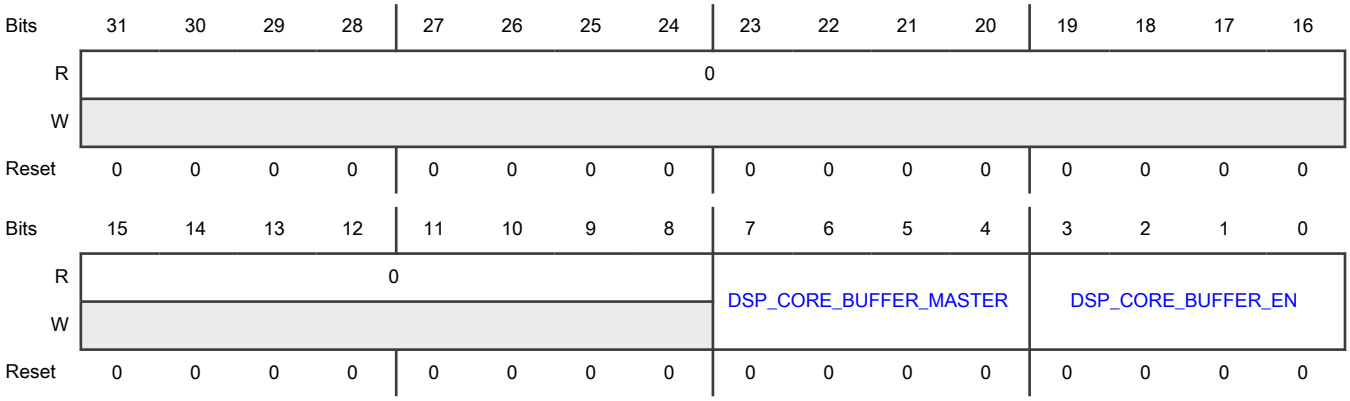
Offset

Register	Offset
DSP_CORE_BUFFER_CFG	BFCh

Function

Configures the DSP core buffer.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-4 DSP_CORE_BUFFER_MASTER	Programming the current read/write ownership inside the DSP_CORE buffer in XMEM. This register is provided for software use only. Hardware does not prohibit any access to any of the regions based on the value programmed in this field. Contains bits that control submodule access in the respective DSP-CORE buffer region for individual threads. Within this field, bit *m* controls access for thread *m*. For example, bit 2 controls the access for thread 2. For each bit: • A value of 0 means the Cortex-M7 core has only write access and DSP has only read access. • A value of 1 means the Cortex-M7 core has only read access and DSP has only write access.
3-0 DSP_CORE_BUFFER_EN	DSP Core Buffer Enable Enables the pointer monitoring logic in the buffer specified by the addresses inside DSP_CORE_READ_PTR and DSP_CORE_WRITE_PTR. This is one hot encoded. LSB is the buffer enable for TH-0 and MSB is for TH-3.

66.4.31 DMA Buffer Configuration (DMA_BUFFER_CFG)

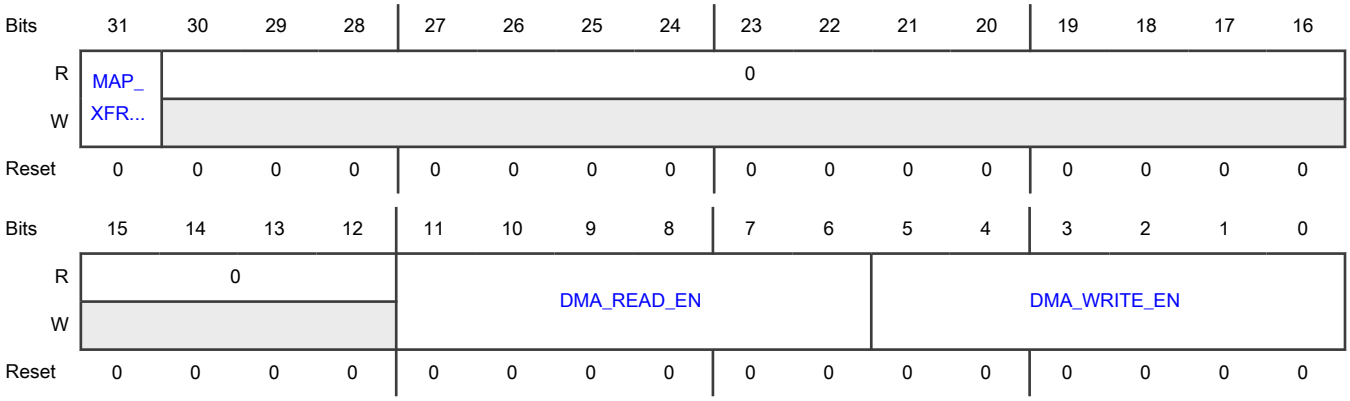
Offset

Register	Offset
DMA_BUFFER_CFG	C00h

Function

Configures the DMA-READ and DMA-WRITE buffers.

Diagram



Fields

Field	Function
31 MAP_XFR_DMA_ERR_ON_IPS	When set, the DMA_ADDR_MISMATCH_RD_BUFFER/DMA_ADDR_MISMATCH_RD_BUFFER errors are mapped on IPS_XFR_ERR.
30-12 —	Reserved
11-6 DMA_READ_EN	DMA-READ Buffer Monitor Enable Contains bits that enable the monitoring of the read pointer for individual buffers. Within this field, bit *m* enables the monitoring for DMA-*m*. For example, bit 2 enables the monitoring for DMA-2.
5-0 DMA_WRITE_EN	DMA-WRITE Buffer Monitor Enable Contains bits that enable the monitoring of the write pointer for individual buffers. Within this field, bit *m* enables the monitoring for DMA-*m*. For example, bit 2 enables the monitoring for DMA-2.

66.4.32 Thread Scheduling Mode Selection (SCHEDULER_MODE_CFG)

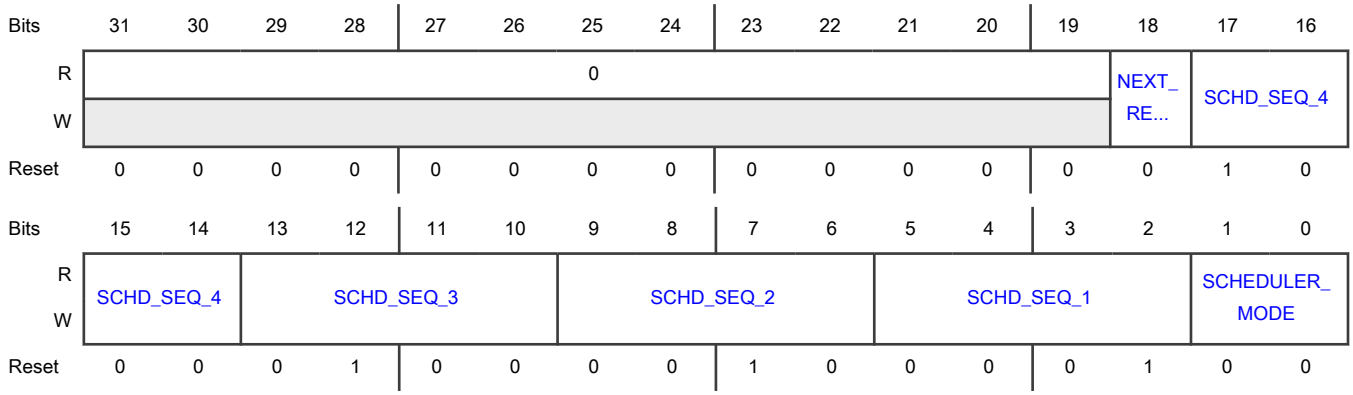
Offset

Register	Offset
SCHEDULER_MODE_CFG	C04h

Function

Configures DSP threads. These configurations are common for all the threads across the DSP.

Diagram



Fields

Field	Function
31-19 —	Reserved
18 NEXT_REQ_HALT_ACK_WAIT_CTRL	Thread Scheduling Control Specifies the relationship between the mode and the scheduling of the next thread, as follows:

Value	Next-thread scheduling in Sample Threshold mode	Next-thread scheduling in Clock Threshold mode
0	When halt_ack (the sleep instruction) from DSP is received for the current ongoing thread	When the threshold reaches the clock-threshold value for the last scheduled thread
1	As soon as the sample accumulation crosses the programmed threshold	When halt_ack is received for the last scheduled thread

17-14 SCHD_SEQ_4	Schedule For Fourth Thread Specifies the fourth thread to be scheduled in Clock Threshold mode. **NOTE** Threads are scheduled only if they are enabled. 0001b - Thread 0 0010b - Thread 1 0100b - Thread 2 1000b - Thread 3
13-10 SCHD_SEQ_3	Schedule For Third Thread Specifies the third thread to be scheduled in Clock Threshold mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE Threads are scheduled only if they are enabled. 0001b - Thread 0 0010b - Thread 1 0100b - Thread 2 1000b - Thread 3
9-6 SCHD_SEQ_2	Schedule For Second Thread Specifies the second thread to be scheduled in Clock Threshold mode. **NOTE** Threads are scheduled only if they are enabled. 0001b - Thread 0 0010b - Thread 1 0100b - Thread 2 1000b - Thread 3
5-2 SCHD_SEQ_1	Schedule For First Thread Specifies the first thread to be scheduled in Clock Threshold mode. **NOTE** Threads are scheduled only if they are enabled. 0001b - Thread 0 0010b - Thread 1 0100b - Thread 2 1000b - Thread 3
1-0 SCHEDULER_MODE	Scheduler Mode Selection Selects the mode for thread scheduling. You can change scheduling modes only after a DSPSS reset. 00b - Sample Threshold mode and hardware thread scheduling 01b - Clock Threshold scheduling mode; the SCHD_SEQ_n fields in this register establish the sequence of scheduling 10b - Software scheduling; no hardware scheduling 11b - Reserved

66.4.33 DSP0 Reset And Core Trigger Configuration (DSPSS_DSP0_CFG)

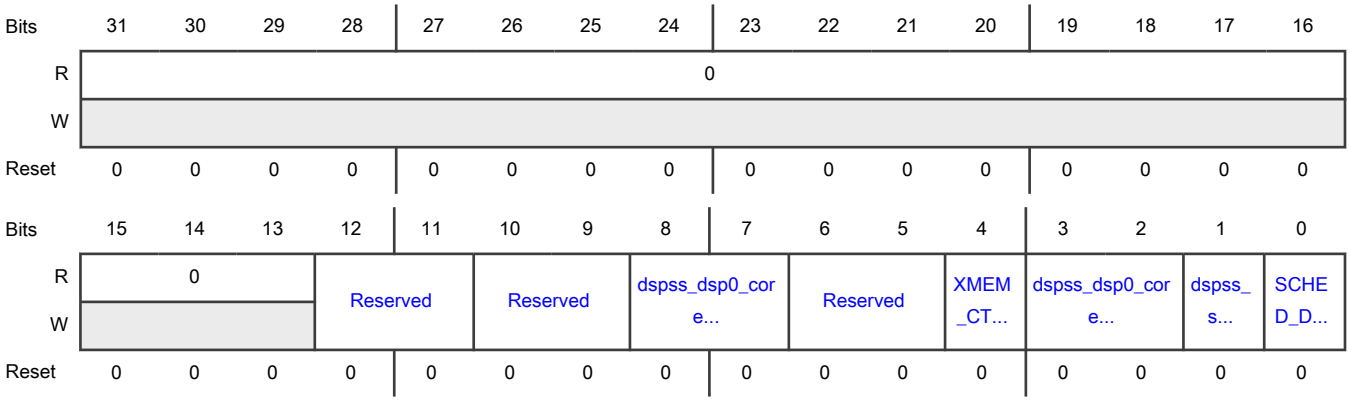
Offset

Register	Offset
DSPSS_DSP0_CFG	C08h

Function

Configures DSP reset and core-trigger options.

Diagram



Fields

Field	Function
31-13 —	Reserved
12-11 —	Reserved
10-9 —	Reserved
8-7 dspss_dsp0_core_trigger_safety_cfg	Core Trigger Configuration Controls whether a trigger to the core occurs, and if it does, what type of trigger it is. 00b,11b - No trigger 01b - Pulse trigger 10b - Level-signal trigger
6-5 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 XMEM_CTRL_PRIORITY	XMEM Priority Access Control Specifies what module has priority for XMEM access between SDADC and the Cortex-M7 core with DMA. 0b - Core with DMA 1b - SDADC
3-2 dspss_dsp0_core_trigger_cfg	Core Trigger Configuration Controls whether a trigger to the core occurs, and if it does, what type of trigger it is. 00b,11b - No trigger 01b - Pulse trigger 10b - Level-signal trigger
1 dspss_scheduler_dsp0_reset	Thread Reset Assertion Control Controls the reset assertion and deassertion for the thread inside DSP. When this field is 1 and SCHED_DSP_RST_CTRL_EN is 0, the DSP reset deasserts.
0 SCHED_DSP_RST_CTRL_EN	Reset Assertion Control Controls the reset assertion and deassertion of DSP. 0b - Reset deasserts whenever dspss_scheduler_dsp0_reset is 1. 1b - DSPSS releases the reset when the sample/clock threshold is achieved and scheduling request is sent.

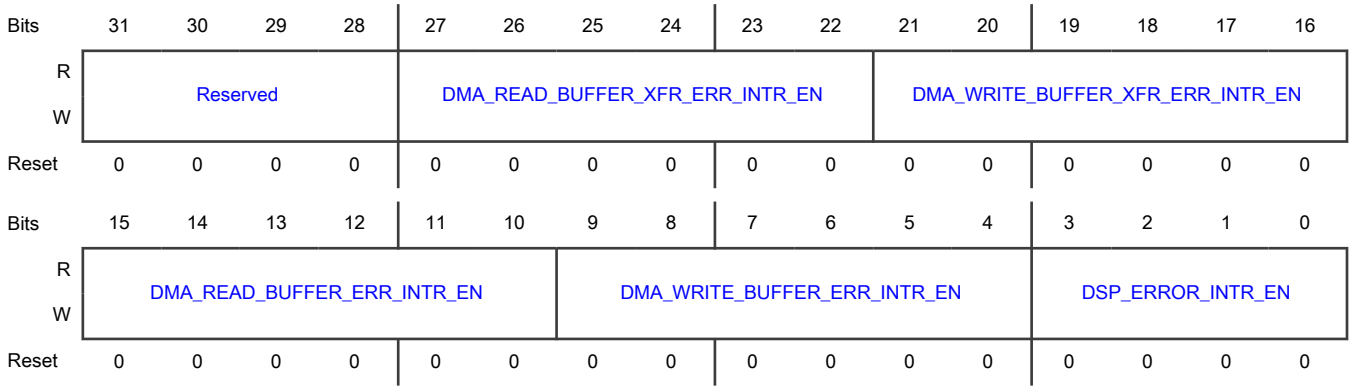
66.4.34 Interrupt Enable (INTERRUPT_ENABLE_REGISTER)

Offset

Register	Offset
INTERRUPT_ENABLE_REGISTER	C10h

Function
Enables various interrupts.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-22 DMA_READ_BUFFER_XFR_ERR_INTR_EN	Interrupt Enable for DMA-READ Buffer XFR Errors Contains bits that enable the interrupts for individual DMAs. Within this field, bit *n* enables the interrupt for DMA *n*. For example, bit 2 enables the interrupt for DMA-2.
21-16 DMA_WRITE_BUFFER_XFR_ERR_INTR_EN	Interrupt Enable for DMA-WRITE Buffer XFR Errors Contains bits that enable the interrupts for individual DMAs. Within this field, bit *n* enables the interrupt for DMA *n*. For example, bit 2 enables the interrupt for DMA-2.
15-10 DMA_READ_BUFFER_ERR_INTR_EN	Interrupt Enable for DMA-READ Buffer Pointer Mismatch Errors Contains bits that enable the interrupts for individual DMAs. Within this field, bit *n* enables the interrupt for DMA *n*. For example, bit 2 enables the interrupt for DMA-2.
9-4 DMA_WRITE_BUFFER_ERR_INTR_EN	Interrupt Enable for DMA-WRITE Buffer Pointer Mismatch Errors Contains bits that enable the interrupts for individual DMAs. Within this field, bit *n* enables the interrupt for DMA *n*. For example, bit 2 enables the interrupt for DMA-2.
3-0 DSP_ERROR_INTR_EN	Interrupt Enable for DSP Errors Contains bits that enable the interrupts for individual threads. Within this field, bit *n* enables the interrupt for thread *n*. For example, bit 2 enables the interrupt for thread 2. The corresponding status field is DSP_TO_CORE_TRIG_ERR_STATUS*n*[DSP_TO_CORE_TRIG_ERR_STATUS].

66.4.35 DSP Trigger to Core (DSPSS_DSP_IO_INTF0)

Offset

Register	Offset
DSPSS_DSP_IO_INTF0	C14h

Function

Works with DSP Safety Trigger to Core (DSPSS_DSP_CORE_TRIGGER_SAFETY) to send triggers to the host core.

DSP directly changes the fields in this register to 1 whenever DSP intends to send a trigger to the Cortex-M7 core. The Cortex-M7 core uses a write-1-to-clear operation to return the fields to 0.

Diagram

3 DSP_TRIGGER_CORE_TH3	Trigger for Thread 3
2 DSP_TRIGGER_CORE_TH2	Trigger for Thread 2
1 DSP_TRIGGER_CORE_TH1	Trigger for Thread 1
0	Trigger for Thread 0

Table continues on the next page...

Table continued from the previous page...

Field	Function
DSP_TRIGGER_CORE_TH0	

66.4.36 DSP Core Status (CURR_ACTIVE_THRD)

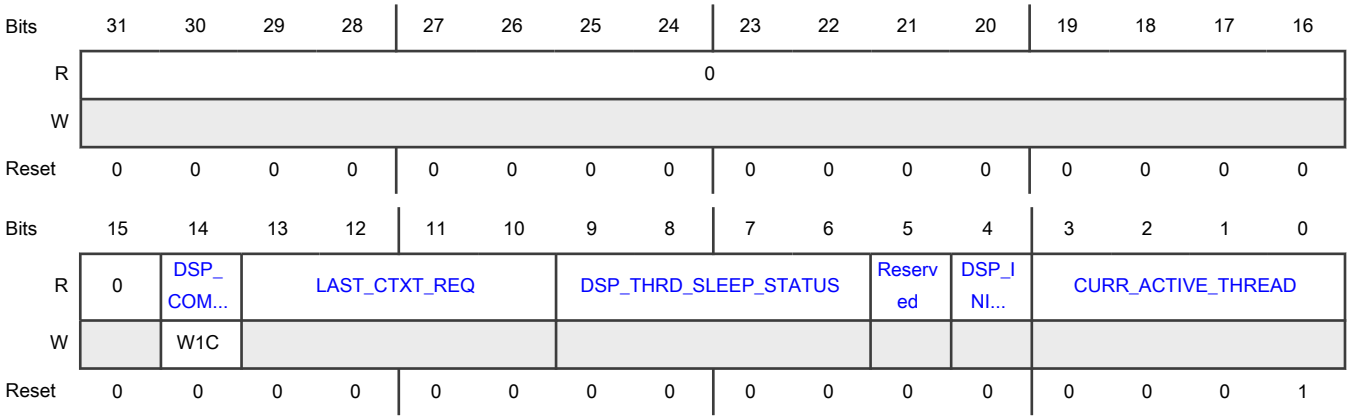
Offset

Register	Offset
CURR_ACTIVE_THRD	C1Ch

Function

Provides various status indicators relevant to the DSP core.

Diagram



Fields

Field	Function
31-15 —	Reserved
14 DSP_COMP_LOW	DSP_COMP_LOW If during the DSPSS operation, stop_ack_n is de-asserted due to any instruction execution or any other reason inside DSP, this field is set. An interrupt for the same is given on trig_err in this case if interrupt is enabled. 0b - DSP is active. 1b - DSP is inactive.
13-10	Last Context Request

Table continues on the next page...

Table continued from the previous page...

Field	Function
LAST_CTXT_REQ	Indicates the last thread for which DSPSS gave a request in Software Scheduler mode. 0001b - Thread 0 0010b - Thread 1 0100b - Thread 2 1000b - Thread 3 All other values are reserved.
9-6 DSP_THRD_SLEEP_STATUS	Thread Sleep State Indicates which threads are in Sleep state. 0001b - Thread 0 0010b - Thread 1 0100b - Thread 2 1000b - Thread 3 All other values are reserved.
5 —	Reserved
4 DSP_INIT_COMP	Initialization Complete Indicates whether DSP completed initialization. This field directly reflects the status signal from the DSP core. 0b - Not complete 1b - Complete
3-0 CURR_ACTIVE_THREAD	Current Context Connected to DSP Execution Pipeline Indicates the current context that DSP is processing or currently available for execution. DSP executes thread 0 by default. Therefore, when DSP is in reset, thread 0 is the current active thread that is connected to the DSP execution pipeline. In that case, this field value is 0001b. **NOTE** When the current thread moves to Sleep state, this does not change the status of this field. For update latency of this field, see the CoolFlux Interface Manual section 9.2. Contact your NXP marketing representative to obtain this manual. 0001b - Thread 0 0010b - Thread 1 0100b - Thread 2 1000b - Thread 3 All other values are reserved.

66.4.37 DSP Safety Trigger to Core (DSPSS_DSP_CORE_TRIGGER_SAFETY)

Offset

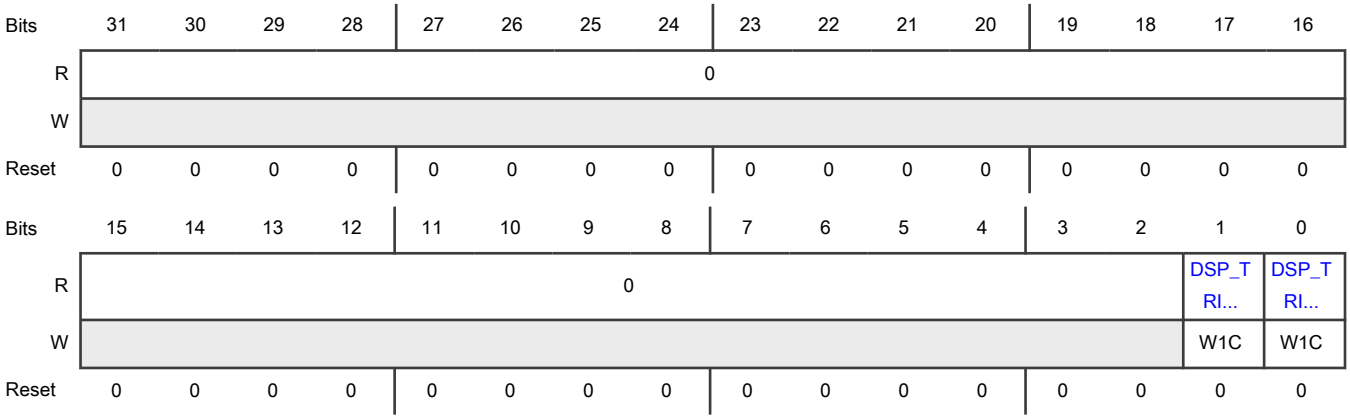
Register	Offset
DSPSS_DSP_CORE_TRIGGER_SAFETY	C24h

Function

Works with DSP Trigger to Core (DSPSS_DSP_IO_INTF0) to send triggers to the host core.

DSP directly changes the fields in this register to 1 whenever DSP intends to send a trigger to the Cortex-M7 core. The Cortex-M7 core uses a write-1-to-clear operation to return the fields to 0.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 DSP_TRIGGER_SAFETY_2	Safety Thread Trigger 1
0 DSP_TRIGGER_SAFETY_1	Safety Thread Trigger 0

66.5 DSPSS_IO register descriptions

This section presents the DSPSS registers that are available to the DSP core. Not all of these are available, or available in the same way, to the Cortex-M7 core; see DSPSS register descriptions.

The DSPSS_IO address interface supports only half-word addressing and the DSP C compiler compiles accordingly.
For example:

- A value of 6h on DSP IOMEM represents the access on LSB half-word of the register with address Ch in the memory map below.
- A value of 7h on IO address bus represents the access on MSB half-word of the register with address Ch in the map.

The following table relates the memory-map address with the software-defined address in the compiled code.

Table 378. Memory-map and DSP software-compiled addresses

Register mnemonic	Software IO address	Memory map address	Half-word location
DSP_CORE_BUF_ADDR0	Eh	1Ch	15:0
DSP_CORE_BUF_ADDR0	Fh	1Ch	31:16
DMA_WRITE_ADDR5	7A0h	F40h	15:0
DMA_WRITE_ADDR5	7A1h	F40h	31:16

66.5.1 DSPSS_IO memory map

dspss_1 base address: 0h

Offset	Register	Width (In bits)	Access	Reset value
Ch	Current XMEM Write Pointer (DSPSS_SCHEDULER_CURR_XMEM_ADDR_TH0)	32	R	0000_0000h
14h	Last Scheduled-Request Address (DSP_SDADC_CURR_READ_PTR0)	32	R	0000_0000h
1Ch	Start And End Pointers For DSP And Cortex-M7 Core Shared Buffer (DSP_CORE_BUF_ADDR0)	32	RW	0000_0000h
28h	Read Pointer In DSP Buffer (DSP_CORE_CURR_RD_PTR0)	32	RW	0000_0000h

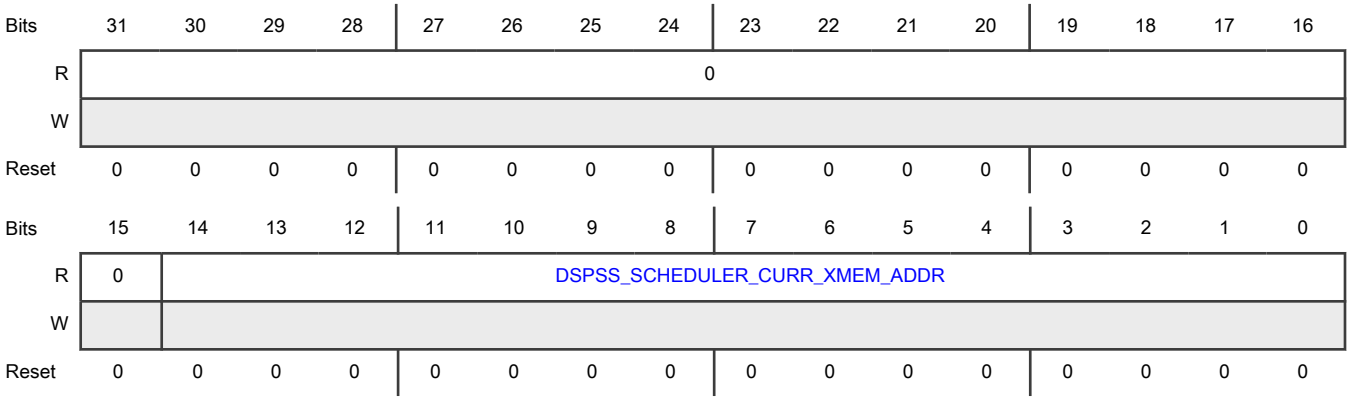
Diagram



Fields

Field	Function
31-1 —	Reserved
0 DONE	Dummy Done See DMA Error Control (DMA_ERROR_CTRL0 - DMA_ERROR_CTRL5).

66.5.20 Hardware Control Handling for DMA Request And Response (HW_CTRL_DMA_REQ_RESPONSE0 - HW_CTRL_DMA_REQ_RESPONSE5)

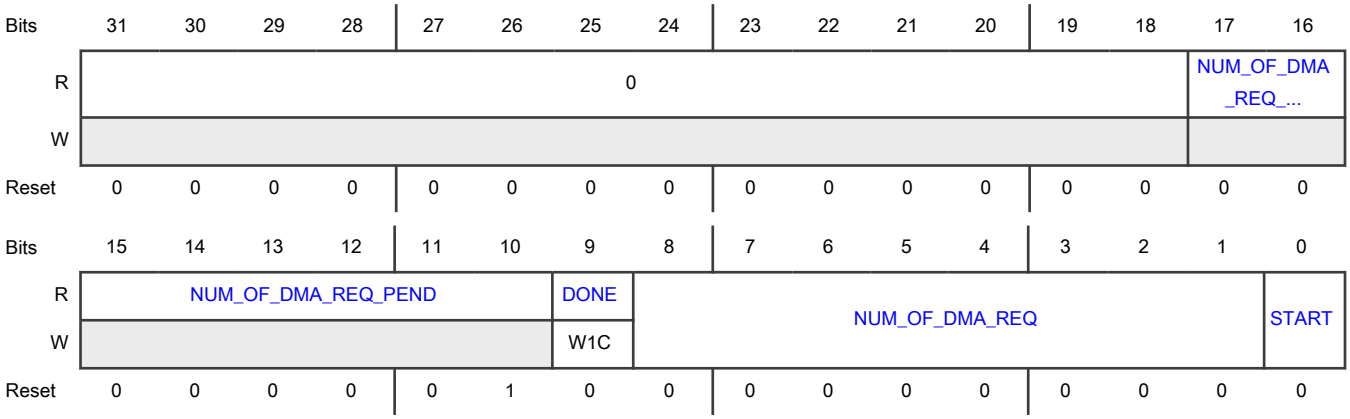
Offset

Register	Offset
HW_CTRL_DMA_REQ_RESPONSE0	94h
HW_CTRL_DMA_REQ_RESPONSE1	394h
HW_CTRL_DMA_REQ_RESPONSE2	694h
HW_CTRL_DMA_REQ_RESPONSE3	994h
HW_CTRL_DMA_REQ_RESPONSE4	C94h
HW_CTRL_DMA_REQ_RESPONSE5	F94h

Function

See Hardware Control Handling for DMA Request And Response (HW_CTRL_DMA_REQ_RESPONSE0 - HW_CTRL_DMA_REQ_RESPONSE5) for the definition of this register.

Diagram



Fields

Field	Function
31-18 —	Reserved
17-10 NUM_OF_DMA_REQ_PEND	Number of Pending DMA Requests See Hardware Control Handling for DMA Request And Response (HW_CTRL_DMA_REQ_RESPONSE0 - HW_CTRL_DMA_REQ_RESPONSE5).
9 DONE	Done Generating DMA Requests See Hardware Control Handling for DMA Request And Response (HW_CTRL_DMA_REQ_RESPONSE0 - HW_CTRL_DMA_REQ_RESPONSE5).
8-1 NUM_OF_DMA_REQ	Number of DMA Requests See Hardware Control Handling for DMA Request And Response (HW_CTRL_DMA_REQ_RESPONSE0 - HW_CTRL_DMA_REQ_RESPONSE5).
0 START	Start Request See Hardware Control Handling for DMA Request And Response (HW_CTRL_DMA_REQ_RESPONSE0 - HW_CTRL_DMA_REQ_RESPONSE5).

66.5.21 DSP Trigger to Core (DSPSS_DSP_IO_INTF0)

Offset

Register	Offset
DSPSS_DSP_IO_INTF0	C14h

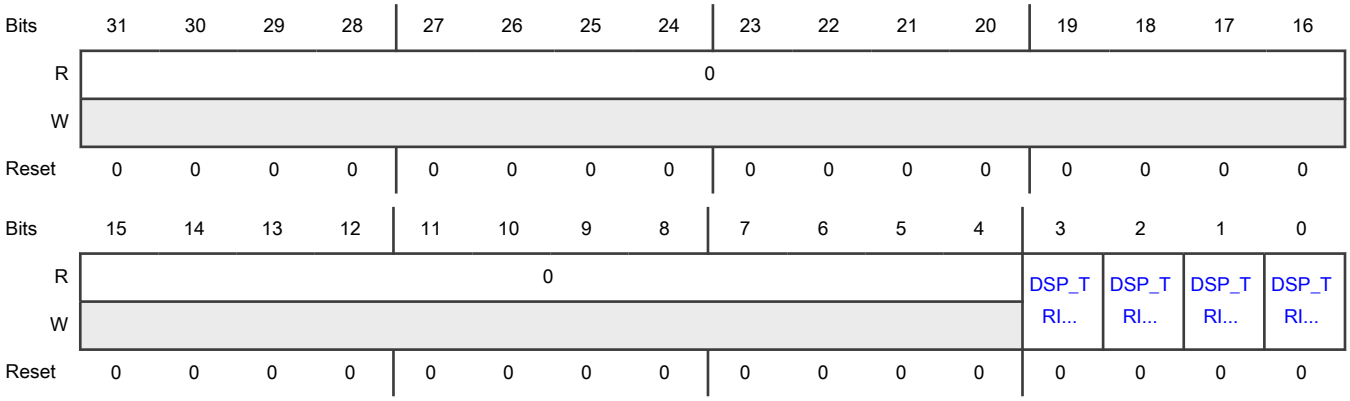
Function

See DSP Trigger to Core (DSPSS_DSP_IO_INTF0) for the definition of this register.

NOTE

NXP recommends not using DSP to write 0 to the fields of this register. This is because only the Cortex-M7 core can return the fields to 0.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 DSP_TRIGGER_CORE_TH3	Trigger for Thread 3 See DSP Trigger to Core (DSPSS_DSP_IO_INTF0).
2 DSP_TRIGGER_CORE_TH2	Trigger for Thread 2 See DSP Trigger to Core (DSPSS_DSP_IO_INTF0).
1 DSP_TRIGGER_CORE_TH1	Trigger for Thread 1 See DSP Trigger to Core (DSPSS_DSP_IO_INTF0).
0 DSP_TRIGGER_CORE_TH0	Trigger for Thread 0 See DSP Trigger to Core (DSPSS_DSP_IO_INTF0).

66.5.22 >DSP Safety Trigger to Core (DSPSS_DSP_CORE_TRIGGER_SAFETY)

Offset

Register	Offset
DSPSS_DSP_CORE_TRIGGER_SAFETY	C24h

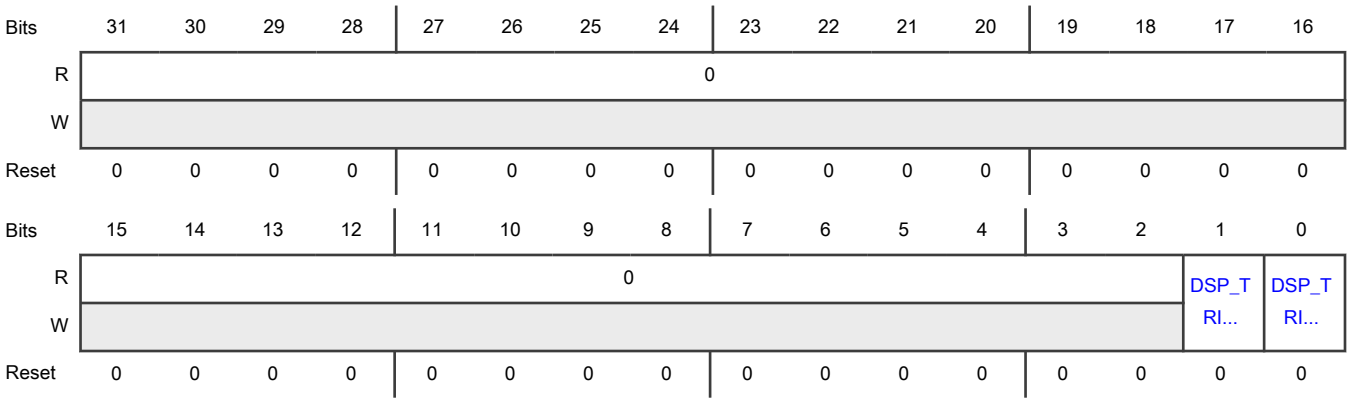
Function

See DSP Safety Trigger to Core (DSPSS_DSP_CORE_TRIGGER_SAFETY) for the definition of this register.

NOTE

NXP recommends not using DSP to write 0 to the fields of this register. This is because only the Cortex-M7 core can return the fields to 0.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 DSP_TRIGGER_SAFETY_2	Safety Thread Trigger 1 See DSP Safety Trigger to Core (DSPSS_DSP_CORE_TRIGGER_SAFETY).
0 DSP_TRIGGER_SAFETY_1	Safety Thread Trigger 0 See DSP Safety Trigger to Core (DSPSS_DSP_CORE_TRIGGER_SAFETY).

66.5.23 Thread Status Info n (DSPSS_DSP_THREAD_INFO0 - DSPSS_DSP_THREAD_INFO3)

Offset

Register	Offset
DSPSS_DSP_THREAD_INFO0	1200h
DSPSS_DSP_THREAD_INFO1	1204h

Table continues on the next page...

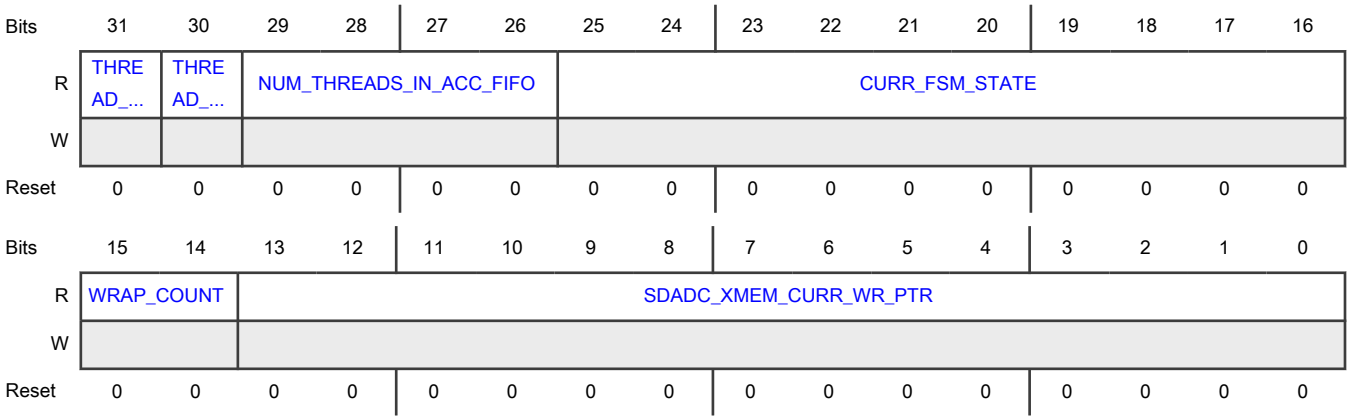
Table continued from the previous page...

Register	Offset
DSPSS_DSP_THREAD_INFO2	1208h
DSPSS_DSP_THREAD_INFO3	120Ch

Function

Indicates the status of different parameters pertaining to ongoing threads in the hardware scheduler.

Diagram



Fields

Field	Function
31 THREAD_ACC_FIFO_OVF	Accumulator FIFO Overflow Indicates whether the thread accumulator FIFO has overflowed. 0b - No overflow 1b - Overflow
30 THREAD_ACC_FIFO_FULL	Accumulator FIFO Full Indicates whether the thread accumulator FIFO is full. 0b - Not full 1b - Full
29-26 NUM_THREADS_IN_ACC_FIFO	Number of Threads In Accumulator FIFO Indicates the number of threads that are currently waiting to be scheduled in the thread accumulator FIFO.
25-16	Hardware Scheduler Current FSM State

Table continues on the next page...

Table continued from the previous page...

Field	Function
CURR_FSM_STATE	00_0000_0001b - IDLE state. Nothing happens in this state. This is the scheduler's default state after reset. 00_0000_0010b - CLOCK_MODE state. If Clock Threshold mode is active, the scheduler waits in this state for a request to be scheduled. 00_0000_0100b - SAMPLE_MODE state. If Sample Threshold mode is active, the scheduler waits in this state for a request to be scheduled. 00_0000_1000b - REQ_TO_DSP state. A CTXT request to DSP is given. 00_0001_0000b - ACK_FROM_DSP state. The scheduler waits for the current active thread to change to last requested context. 00_0010_0000b - DSP_SLEEP_WAIT state: The scheduler waits in this state until the DSP acknowledges the Sleep instruction. 00_0100_0000b - SOFTWARE_SCHD_MODE state. If Software mode is active, the scheduler stays in this state until you or DSPSS assert a suspend request. When the suspension completes, the scheduler returns to this state again. 00_1000_0000b - WAIT_SUSPEND_CURR_THRD state. The scheduler enters this state when the thread suspension request asserts, and remains in this state until it receives a suspend acknowledgment from DSP. 01_0000_0000b - SUSPEND_CURR_THRD state. The scheduler asserts a suspend request to DSP.
15-14 WRAP_COUNT	Wrap Count Indicates the wrap count in XMEM. Saturated after three.
13-0 SDADC_XMEM_CURR_WR_PTR	Current Write Pointer Indicates the current write pointer of SDADC data in XMEM.

Chapter 67
Enhanced Time Processing Unit (eTPU)

67.1 Chip-specific eTPU information

67.1.1 Device-specific features

- Single instance in dual engine configuration, 2x32 channels
- 32KB SCM, 7 bit ECC
  - eTPU generates bus faults when accessing the reserved memory slots of SCM.
- 8KB SDM, 20 bit ECC (20 bit ECC to support byte access ECC).
- eTPU Supports NEXUS Class 3 Debug and chip supports AMBA Trace Bus (ATB), which is an Arm debug protocol. So, there is NEXUS to ATB Converter in between eTPU and DEBUG Trace.
- For eTPU triggers details, see the TRGMUX connectivity file attached to this document.
- Engine 1 and Engine 2 STAC registers information

Table 380. Engine 1 and Engine 2 register information

Engine	Timebase	Server ID
1	TCR1	0
1	TCR2	2
2	TCR1	1
2	TCR2	3

NOTE

Since reaction channel is not implemented hence shared subsystem area feature is not available in S32K396.

NOTE

- Only one instance of eTPU is supported in S32K396.
- eTPU is not supported in S32K37.

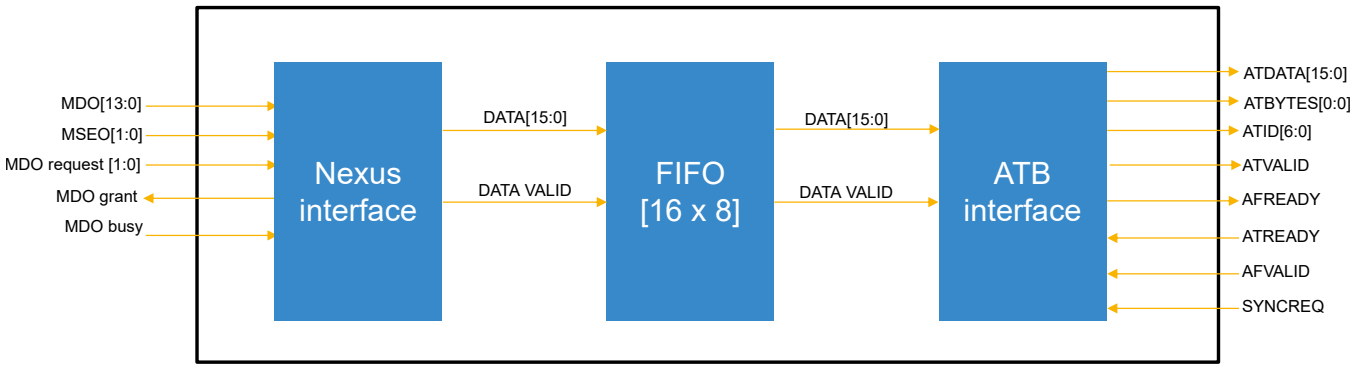
NOTE

The interaction of the eTPU with other peripherals is detailed in the PCMC Block diagram. The eTPU is connected to TRGMUX through etp_odis.

NOTE

Unaligned access is not supported.

67.1.2 Nexus to ATB interface converter



NOTE

eTPU supports NEXUS interface for DEBUG. To enable this functionality, NEXUS to ATB converter is used. For other eTPU DEBUG related information, such as CTI, EVTO, EVTI, refer to Table 765. And, for IPG related information, see Figure 682.

67.1.3 Guidelines for configuring ETPU output channel events

While triggering an ETPU channel, through the ETPU output channel events, the ETPU.PSTO register should be configured to ensure ETPU output cycles to be at least two system clock cycles.

67.1.4 eTPU output disable channel groups

The output display channel group are defined in the following table:

Table 381. Output display channel groups

Output display signal	eTPU channels
eTPU_1/2_odis[0]	0 to 7
eTPU_1/2_odis[1]	8 to 15
eTPU_1/2_odis[2]	16 to 23
eTPU_1/2_odis[3]	24 to 31

NOTE

See Input Glitch Filter chapter for details of IGF channel mapping.

67.1.5 Time base Synchronization

The following figure shows the synchronization between eTPU time bases and eMIOS time bases.

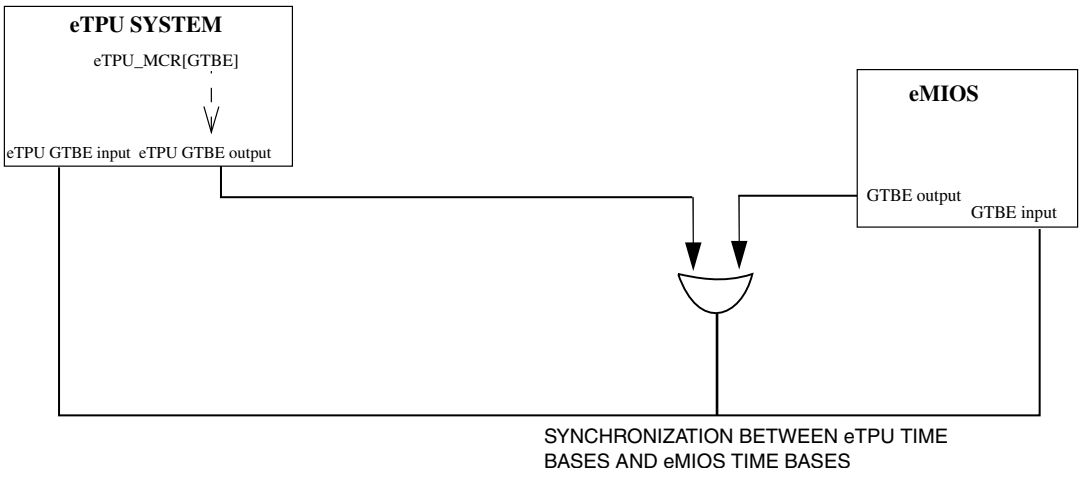


Figure 437. Time base Synchronization between eTPU time bases and eMIOS time bases

67.2 Overview

eTPU is an intelligent, semi-autonomous coprocessor designed for timing control. Operating in parallel with the Host CPU, the eTPU processes instructions and real-time input events, performs output waveform generation, and accesses shared data without Host intervention. Consequently, for each timer event, the Host CPU setup and service times are minimized or eliminated.

High-level assembler, compiler, and documentation enable customers to develop their own functions on the eTPU.

eTPU architecture aims at high resolution timing capabilities. From a system perspective, high-resolution timing is limited by Host CPU overhead required for servicing timing tasks such as period measurement, pulse measurement, pulse width modulated waveform generation, and so on. On the eTPU, high-resolution timing is achieved by three main capabilities:

- Reduced latency: pin actions are immediate.
- Reduce or eliminate host interrupt service time.
- Double action channel capability reducing the channel request rate.

eTPU provides higher resolution than the Host CPU can achieve and creates no Host overhead for servicing timing tasks.

Latency is the interval from occurrence of an event to the start of event servicing. eTPU can service its own events without interrupting the Host. There are two types of timing events:

- Input pin transition.
- Selected Time Base match, that is, a selected Time Base counter reached or exceeded a pre-programmed value.

Service time is the time spent servicing an event. In general, in microcontrollers the service time is constrained because the instruction set is not optimized for time function synthesis. The eTPU instruction set is optimized, so that time functions can be implemented with much fewer instructions than the Host CPU. Instructions execute faster, service time is reduced and program memory compacted.

Instructions executed by the eTPU are connected directly to the eTPU timing hardware and allow parallelism of hardware-related actions.

67.2.1 Block diagram

The figure below shows a top-level eTPU block diagram. It displays a dual eTPU Engine configuration.

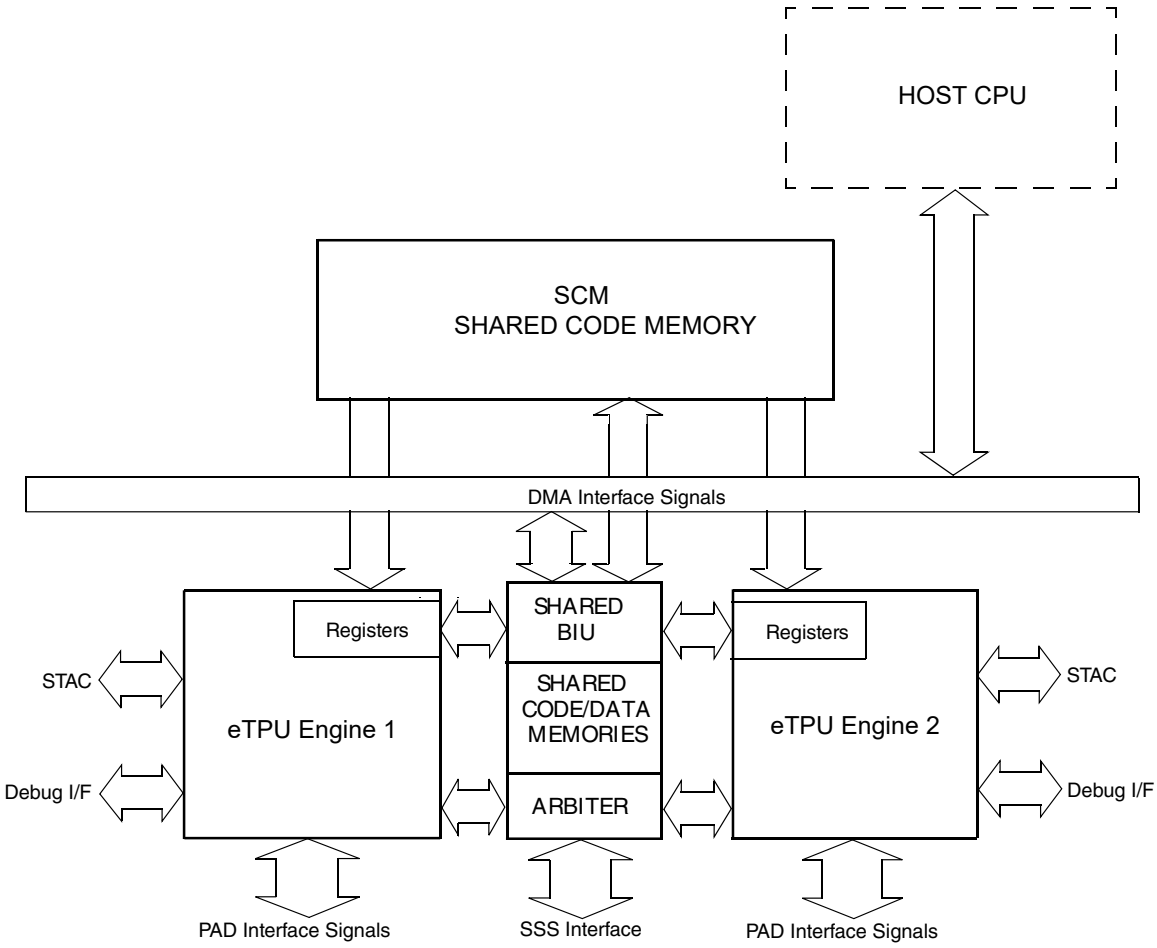

Figure 438. eTPU block diagram

eTPU Engine is responsible for processing input pin transitions and output pin waveform generation based on the **Time Bases**. Each eTPU Engine has its own microprocessor and dedicated hardware for processing signals on I/O pins and can also interface with external time bases through the STAC bus.

Both eTPU Engine CPUs, from this point on, called **microengines**, fetch microinstructions from a **Shared Code Memory - SCM**.

Shared Data Memory - **SDM -** holds eTPU application parameters and work data. It is accessed by Host and both microengines.

Bus Interface Unit - BIU - allows Host to access eTPU registers, SCM, and SDM.

Each I/O signal pair is associated with a dedicated **Channel**, which provides hardware for input signal processing and output signal generation, in relationship with selected Time Bases.

The eTPU, as a microprocessed subsystem, works much like a typical real-time system: it runs microengine code from instruction memory (SCM) to handle specific events, accessing data memory (SDM) for parameters, work data, and application state information; events may originate from I/O Channels (due to pin transitions and/or time base matches), Host CPU requests, or inter-channel requests; events that call for local eTPU processing activate the microengine by issuing a **Service Request**. The Service Request microcode may set an interrupt to the Host CPU. I/O channel events cannot directly interrupt the Host CPU.

Each Channel is associated with a **Function**, which defines its behavior: the Function is a software entity consisting, within the eTPU, of a set of microengine routines that attend to Service Requests. The Function routines are also responsible for Channel configuration. Function routines reside in SCM, which may contain several Functions. A Function may be assigned to several Channels, but a Channel can be associated with just one Function at a given moment. The association between Functions and Channels is defined by Host CPU, and is explained in detail in Functions and threads.

eTPU hardware supplies resource sharing features that support concurrency:

- A hardware **Scheduler** dispatches the Service Request microengine routines based on a set of priorities defined by the Host CPU. Each Channel has its associated priority.
- A Service Request routine cannot be interrupted until it ends. This sequence of uninterrupted instruction execution is called a **Thread**.
- Channel-specific context (registers and flags) is automatically switched between the end of a Thread and the beginning of the next one.
- SDM arbitration, a dual-parameter coherency controller, and semaphores can be used to ensure coherent access to eTPU data shared by both eTPU Engines and Host CPU.

67.2.1.1 eTPU Engine

Each eTPU Engine consists of all blocks that are duplicated in a dual eTPU configuration: two 24-bit time bases, independent timer channels, a task scheduler, a microengine, and a Host interface. In addition, a 32-bit Shared Data Memory (SDM) is used for two eTPU Engines data storage and for passing information between the eTPU Engines and the Host CPU.

The following figure shows the block diagram for the eTPU Engine.

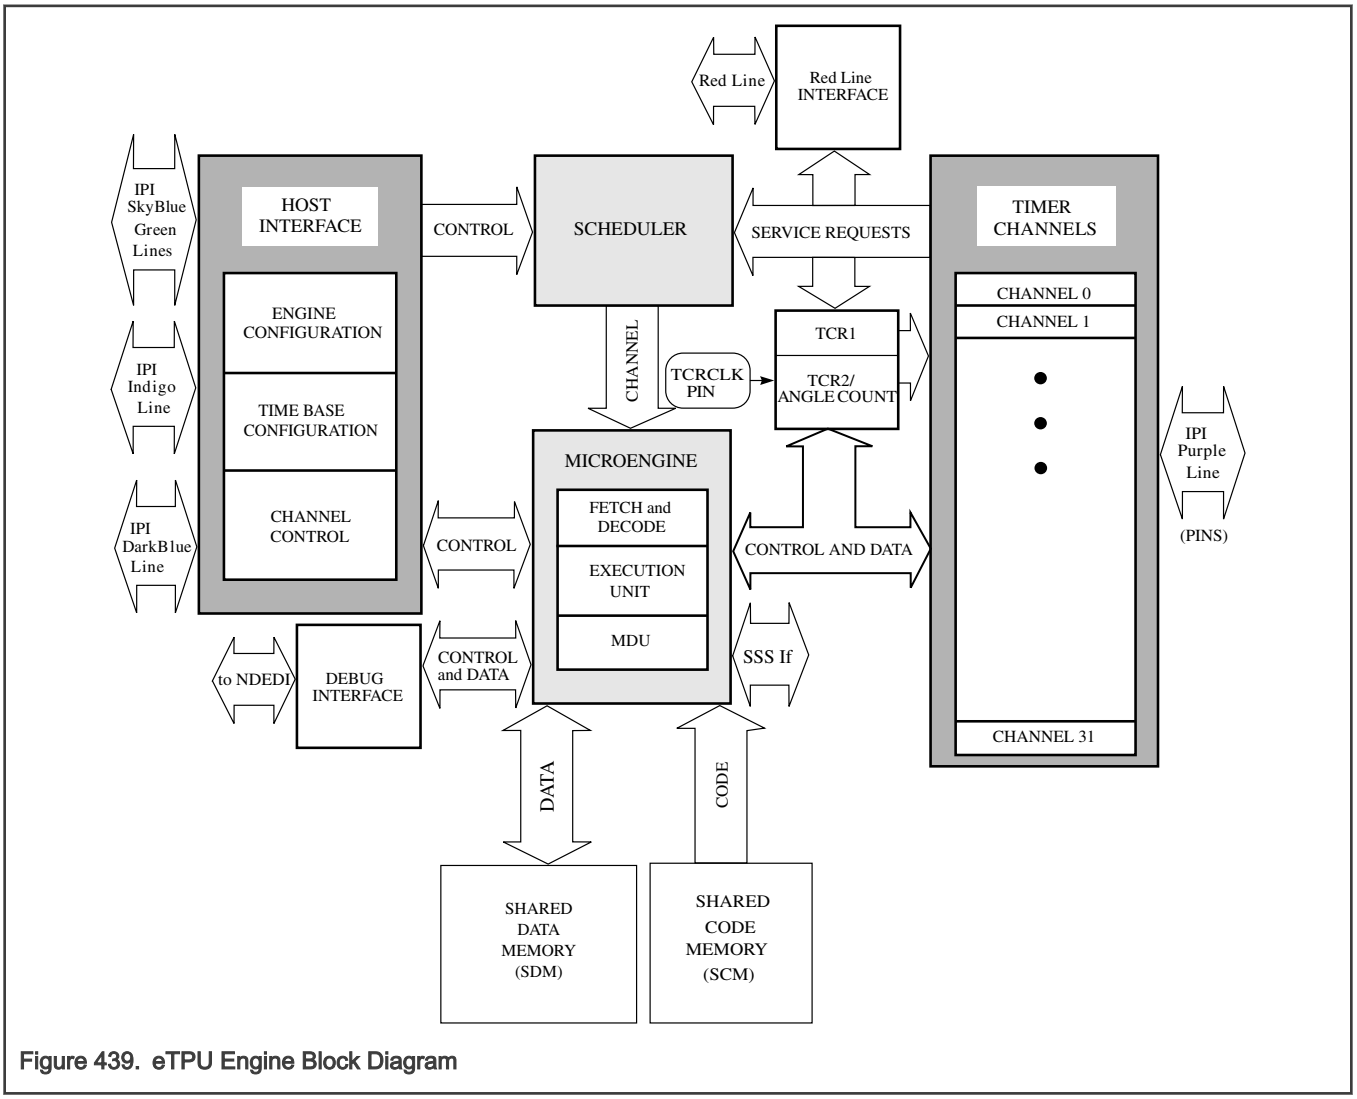

Figure 439. eTPU Engine Block Diagram

eTPU Engines 1 and 2 are sometimes called eTPU 1 and eTPU 2 for short throughout this chapter.

67.2.1.1.1 Time Bases

Two 24-bit counters TCR1 and TCR2 provide reference time bases for all match and input capture events. Prescalers for both time bases are controlled by the Host CPU through bit fields in the eTPU Engine configuration registers. The eTPU is able to export/import time to/from TCR1 or TCR2 in accordance to the STAC bus specification.

The clock for each of TCR1 and TCR2 clock can be independently derived from the eTPU clock or from an external input via the TCRCLK clock pin. In addition, the TCR2 timebase can be derived from special angle-clock hardware which enables implementing angle-based functions. This feature is added to support advanced angle-based engine control applications.

For further details refer to Time bases.

67.2.1.1.2 eTPU Timer Channels

Each eTPU Engine has 32 independent channels, each corresponding to an Input/Output signal pair. The channel time resolution is 24 bits, and are all identical.

Each channel consists of logic which supports two events and output controls. The event logic contains two 24-bit capture registers, two 24-bit match registers, greater-equal and equal-only comparators. Supporting two events enables many combinations of double action functions (for example the channel can handle two events with a single microcode service).

The channel configuration can be changed immediately by the microengine. Each channel can perform double capture, double match and other capture-match combinations. Channel modes available can do ordered or unordered match. Some modes are also provided that can block one match by the occurrence of the other. Service request can be generated on one or both of the match events.

Input signal can be separated from output signal in each channel. They can, optionally, be combined in a single I/O pin driver. An output buffer enable is controlled by the SIU (or SIUL). Digital filters are provided for the input signals, with distinct filtering modes available.

Each channel can use any time base or angle counter for either match or capture operation. For example, a match on TCR1 can capture the value of TCR2. The channels can request service from the microengine due to recognized pin transitions (input events) or timebase matches.

Channel configuration combinations:

- Single input capture, no match
- Single input capture with single match timeout
- Single input capture with double match timeout with several double match sub-modes
- Double input capture with single or double match timeout with several double match sub-modes
- Single output match
- Double output match with several double match sub-modes
- Input-dependent output generation

The double match functionality has various combinations for generation of service request and determining pin actions. For more details refer to Enhanced Channels.

In addition to the predefined channel configurations above, the user can also program its own channel configuration, defining how input captures, matches and service-requests are related.

67.2.1.1.3 Host interface

The Host interface allows the Host CPU to control the operation of the eTPU. The Host CPU must initialize the eTPU by writing to the appropriate Host interface registers to assign a Function and priority to each channel. In addition, the Host writes to the Host Service Request and channel configuration registers to further define Function operation for each initialized channel. Refer to Host interface for a detailed description.

When the SCM is implemented by RAM, the Host must first initialize it with the proper microcode program prior to enabling any eTPU Function, and then enable eTPU access (which also disables Host access).

67.2.1.1.4 Shared Data Memory - SDM

The SDM works as data RAM which can be accessed by the Host CPU and up to two eTPU Engines. This memory is used for information transfer between the Host CPU and the eTPU, as data storage for the eTPU microcode program or for communication between the two eTPU Engines. SDM width is 32 bits, and is accessible by the Host as byte, 16-bit or 32-bit wide. eTPU can access it as full 32-bits, lower 24-bits or upper byte (8-bit).

The host can also access the SDM space mirrored in other area with Parameter Sign Extension (PSE). Parameter Sign Extension accesses differ from the usual host accesses to the original SDM area as follows:

- Writes are effective only to the lower 3 bytes of a word: the word's most significant byte is kept unaltered in SDM.
- Reads return the lower 3 bytes of a word sign-extended to 32 bits, i.e.: the most significant bit of the word's 2nd most significant byte is copied in all 8 bits of the most significant read byte.

Each eTPU channel can be associated with a variable number of parameters located in the SDM, according to its selected Function. In addition, the SDM can be fully shared between two eTPU Engines, enabling direct communication between them.

High flexibility of the SDM utilization is achieved as follows:

- Each channel has a programmable base address pointing to the address of its first parameter with two parameter granularity. This way the SDM can be partitioned according to the actual function needs.
- The microcode can access the first parameters of the selected channel in channel relative access mode.
- Each Engine can access all the SDM address space in indirect addressing mode. Blocks of data are easily transferred using stack operation.
- Absolute addressing mode can access the first parameters, implementing a shared pool of parameters holding global variables.

In the Host address space each parameter occupies four bytes. eTPU usage of the upper byte is achieved by having a 32-bit P register which can access the upper byte, the lower 24 bits or all the 32 bits. The microcode can switch between access sizes at any time.

Each Function may require a different number of parameters. During the eTPU initialization the Host has to program channel base addresses, allocating proper parameters for each channel according to its selected Function.

67.2.1.1.5 Shared Subsystem Area

The Shared Subsystem (SSS) area is a memory map region used by both the host and the eTPU to access registers of the reaction channel, giving the user the option to control them by the host, the eTPU code, or a combination of both .

67.2.1.1.6 Scheduler

Out of reset, all channels are disabled. The Host CPU makes a channel active by assigning it one of three priorities: high, middle, or low. The Scheduler determines the order in which channels are serviced based on channel number and assigned priority. The priority mechanism, implemented in hardware, ensures that all requesting channels are serviced. For additional details refer to Scheduler.

67.2.1.1.7 Microengine

eTPU microengine is a simple RISC implementation which performs each instruction in a microcycle of two eTPU clocks, while prefetching the next instruction through an instruction pipeline. Instruction execution time is constant unless it gets wait states from the SDM arbitration. Two eTPU Engines share code memory without having any performance degradation by interleaving their accesses (the Shared Code Memory has one-clock access time).

Instruction width is 32 bits. The microengine instruction set provides basic arithmetic and logic operations, flow control (jumps and subroutine calls), SDM access, and Channel configuration and control. The instruction formats are defined in such a way that allow particular combinations of two or three of these operations with non-conflicting resources to be executed in parallel in the same microcycle.

Microengine has also an independent Multiply/Divide/MAC unit that performs these complex operations in parallel with other microengine instructions.

Channel functionality is tightly integrated to the instruction set through Channel Control operations and conditional Branch operations, which support jumps/calls on Channel-specific conditions. This allows quick and terse Channel configuration and control code, contributing to reduced service time.

Detailed description can be found in Microengine.

67.2.1.1.8 Dual eTPU Engine System

A typical eTPU implementation includes two eTPU Engines sharing SDM and the same code in SCM.

The two eTPU Engines share the Bus Interface Unit (BIU) and the data memory (SDM) which enable Host-eTPU and eTPU Engine-Engine communication. The shared BIU includes coherency logic which supports dual parameter (8 bytes) coherency in transfers between Host and eTPU, using a temporary parameter area within the SDM. More details on this can be found on Parameter sharing and coherency.

67.2.2 Features

The following sections show eTPU features and enhancements.

67.2.2.1 eTPU Feature Summary

The eTPU includes these distinctive features:

- Up to 32 channels for each eTPU Engine, each channel is associated with an Input/Output signal pair.
  - enhanced input digital filters on the input pins for improved noise immunity. The eTPU digital filter can use 2 samples, 3 samples or work in continuous mode.
  - Identical, orthogonal channels, except for channel 0: each channel can perform any time function. Each time function can be assigned to more than one channel at a given time, so each signal can have any functionality. Channel 0 has the same capabilities of the others, but can also work with special Angle Counter logic (see below).
  - Link Service Request allows activation of a Channel function by request of another channel, even between eTPU Engines.
  - Host Service Request allows activation of a Channel function by Host CPU request
  - each channel has an event mechanism which supports single and double action functionality in various combinations. It includes two 24-bit capture registers, two 24-bit match registers, 24-bit greater-equal and equal-only comparators.
- Two independent 24-bit time bases for channel synchronization:
  - first time base clocked by eTPU clock with programmable prescaler division from 1 to 512 (in steps of 2), or by output of second time base prescaler.
  - first time base can also be clocked by external signal with programmable prescaler division of 1 to 256.
  - second time base clocked by external signal with programmable prescaler division from 1 to 64.
  - second time base external clock source can be replaced by eTPU clock divided by 8.
  - both time bases can be exported or imported via Shared Time and Counter bus.
  - second time base counter can work as an Angle counter, enabling angle based applications to match angle instead of time.
  - second time base can also be used as a pulse accumulator gated by external signal.
- Event-triggered RISC processor (microengine):
  - 3 stage pipeline implementation (fetch, decoding and execution), with separate instruction memory - SCM - and data memory - SDM (Harvard architecture)
  - fixed-length instruction execution in one microcycle of two eTPU clocks

- interleaved SCM access in dual eTPU Engine avoids contention in time for instruction memory
- SDM with interleaved access in dual eTPU Engine avoids contention for data memory
- instruction set with embedded Channel support, including specialized Channel control subinstructions and conditional branching on Channel-specific flags.
- channel-oriented addressing: channel-bound address mode with Host configured Channel Base Address allows channel data isolation, independent of microengine application code.
- channel-bound data address space of up to 32-bit parameters (bytes)
- global parameter address mode allows access to common Channel data of up to 32-bit parameters (bytes)
- support for indirect and stacked data access schemes.
- parallel execution of: data access, ALU, Channel control and flow control sub-instructions in selected combinations.
- 32-bit microengine registers and 24-bit resolution ALU, with 1 microcycle addition and subtraction, absolute value, bitwise logical operations on 24-bit, 16-bit, or byte operands; single bit manipulation, shift and rotate operations, sign extension and conditional execution.
- additional 24-bit Multiply/MAC/Divide unit which supports all signed/unsigned Multiply/MAC combinations, and unsigned 24-bit Divide. The MAC/Divide unit works in parallel with the regular microcode commands.

- Resource sharing features support channel sharing of channel registers, memory and microengine time:
  - hardware Scheduler works as a "task management" unit, dispatching event service routines by predefined, Host-configured priority.
  - automatic Channel context switch when a "task switch" occurs, i.e., one Function Thread ends and another begins to service a request from other Channel: Channel-specific registers, flags and parameter base address are automatically loaded for the next serviced channel.
  - individual channel priority setting in 3 levels: high, middle and low.
  - Scheduler priority scheme allows calculation of worst case latency for event servicing and ensures servicing all channels by preventing permanent blockage.
  - SDM shared between Host CPU and both eTPU Engines, supporting communication either between Channels and Host or inter-channel.
  - hardware implementation of 4 Semaphores supports resource sharing between both eTPU Engines.
  - Hardware semaphores directly supported by the microengine instruction set.
  - dual parameter coherency hardware support allows atomic (to host) access to 2 parameters by microengine(s) in back-to-back accesses.
  - coherent dual-parameter controller allows atomic (to microengines) accesses to 2 parameters by the host.
- Development support features:
  - Nexus class 3 debug support (optional, associated with the eTPU-Nexus Block NDEDI).
  - Software breakpoints.
  - Debug interface supporting single-step execution, forced microinstruction execution, Hardware breakpoints and watchpoints on several conditions.
- Safety support features:
  - SCM (code memory) continuous signature-check built-in self test (MISC - Multiple Input Signature Calculator), runs concurrently with eTPU normal operation.

67.2.2.2 eTPU Plus Enhancements over eTPU

eTPU Plus features include the enhancements below in addition to all eTPU features

- TCR1, channel logic and digital filters (both channel and TCRCLK) now have an option to run at divisions of full eTPU clock speed, besides eTPU clock / 2 (see T2/T4 channel timing) .
- Channels support unordered transitions: transition B can now be detected before transition A. Related to this enhancement, TDLA and TDLB can now be independently negated by microcode (see Channel Mode Logic and Event Flags).
- Channel logic can now work on full eTPU clock, allowing faster response with slow clocks (see T2/T4 channel timing).
- Added a new User Programmable Channel Mode: the blocking, enabling, service request and capture characteristics of this channel mode can be programmed via microcode (see General Channel registers).
- Microinstructions now provide an option to issue Interrupt and Data Transfer requests selected by CHAN . They can also be requested simultaneously at the same instruction (see Channel Interrupt and Data Transfer Requests).
- Channel Flags 0 and 1 can now be tested for branching, besides selecting the entry point (see Branch Operations).
- Channel digital filters can be bypassed, and can be clocked by full eTPU clock (see Bypass Mode).

Backward compatibility is maintained so that all legacy object code (both Host and microcode) runs on eTPU Plus without modification.

67.2.2.3 eTPU2 enhancements over eTPU Plus

eTPU2 features include the enhancements below in addition to all eTPU Plus enhancements and eTPU features.

- Scheduler priority-passing mechanism can now be disabled (see Priority passing disabling).
- New Watchdog mechanism kills threads over a programmable timeout (see Watchdog).
- New counter allows microengine load information collection for performance analysis (see Idle Counter).
- Channels 1 and 2 (besides channel 0) can now be selected to control the EAC (see the TBCR_ENG1 and TBCR_ENG2 eTPU Time Base Configuration Registers).
- Timebase prescalers are now reset when the GTBE input is negated, guaranteeing synchronization with eMIOS in all cases (see Global time base enable (GTBE)).
- New MISC flag indicates when an SCM signature calculation round is completed. This allows measuring of the average MISC scan period in a real application situation (see the eTPU Module Configuration Register - MCR).
- New channel TCCEA flag allows continuous capture even after TDLA is set, making it fully compatible with TPU behavior (see TCCEA - Transition Continuous Capture Enable).
- New branch condition PRSS tells the pin state at the time when a channel (match or transition) service request occurred (see Pin Control Registers).
- MRLEA/B can now be negated independently by microcode (see Disable Matches).
- New Engine Relative address mode allows a function to access SDM address space common to one engine, but distinct between engines (see Engine Relative Addressing Mode under SDM Addressing Modes).
- Memory error support for Code (SCM) and Data (SDM) memories: error detection, correction, and hardware-assisted soft-error fixing (see Memory error support).
- Sharing of microengine and host accesses to subsystem modules (for instance, the Reaction Module), allowing their control by the eTPU, the host, or both (see Shared subsystems support).

Backward compatibility is maintained so legacy object code (both Host and microcode) runs on eTPU2 without modification.

67.2.2.4 eTPU2 Plus enhancements over eTPU2

eTPU2 Plus features include the enhancements listed below in addition to all eTPU features, eTPU Plus enhancements and eTPU2 enhancements.

- Watchdog can now be configured to disable thread forced ending and channel blocking, allowing it to monitor thread lengths with no interference on the application.

- EAC Angle Tick Generator can now be clocked by the TCR2 prescaler output, as an alternative to the TCR1 clock.
- EAC now supports up to 7 missing teeth on hardware.

Backward compatibility is maintained so legacy object code (both Host and microcode) runs on eTPU2 Plus without modification.

67.3 Functional description

67.3.1 Modes of operation

eTPU can be seen as capable of working in the following modes:

- **User Configuration Mode**

  User has the ability to program the eTPU Cores with User Time Functions, having access to the Shared Code Memory (SCM).

- **User Mode**

  User does not access the eTPU Shared Code Memory:

  — Use of predefined eTPU Functions

  — No need for eTPU Core programming ability

- **Debug Mode**

  User debugs eTPU code, accessing special Trace/Debug features via Nexus interface:

  — hardware breakpoint/watchpoint setting

  — access to internal registers

  — single-step execution

  — forced instruction execution

  — software breakpoint insertion and removal.

- **Module Disable Mode**

  eTPU Engine clocks are stopped through a register write to the MDIS field in eTPU Engine 1 Configuration Register (ECR_ENG1) and eTPU Engine 2 Configuration Register (ECR_ENG2), saving power. Input sampling stops. eTPU Engines can be in Module Disable Mode independently. Module Disable Mode stops only the Engine clock, so that the Shared BIU, and Global Channel registers can be accessed, and interrupts and DMAs can be cleared and enabled/disabled. An Engine only enters Module Disable Mode when any currently running thread is finished (see Functions and threads).

- **Stop Mode**

  Stop Mode is entered when eTPU answers assertion with . The definition of which clocks are stopped is made at the MCU level, which defines whether or not registers can be accessed, interrupts and DMA requests cleared.

These modes are loosely selected: there is no unique register field or signals to choose between them. Some features of one mode can be used with features of other mode(s). More on this subject can be found on eTPU mode selection below.

NOTE

Throughout this chapter, an engine is said to be "stopped" if it is either in Module Disable mode or Stop mode.

67.3.1.1 eTPU mode selection

User and User Configuration are the production operating modes, and differ from each other only in access to SCM. User programmability is only possible with a RAM SCM.

On chips where the SCM is implemented as a RAM, it can either be accessed directly from IP-Bus for code loading, or for software breakpoint setting . On chips with a ROM SCM, an internal SCM Emulation RAM may be used, depending on the specific MCU implementation, to replace ROM SCM for test or debug purposes. SCM Emulation RAM is selected in a MCU-specific way. For more details, see SCM Emulation.

Debug Mode is characterized by the use of the debug interface features. Specifically, Nexus blocks provide Nexus class 3 debug features. For more information on debug features, refer to Development support features.

Module Disable Mode is entered by setting the MDIS field in eTPU Engine 1 Configuration Register (ECR_ENG1) and eTPU Engine 2 Configuration Register (ECR_ENG2). eTPU Engines can be individually stopped going into Module Disable Mode (there is one eTPU_SCR_ECR register for each Engine). Each engine can leave Module Disable Mode by writing MDIS=0 (which can only be done if VIS=0).

Stop Mode is activated by IP-Bus (). In this case, the eTPU waits for both eTPU Engines to enter in Stop mode, and then asserts the line. eTPU leaves Stop Mode when is negated, but only if VIS=0. If is negated and VIS = 1, eTPU will leave Stop Mode as soon as VIS = 0.

NOTE

An Engine can stay in Module Disable mode when it leaves Stop Mode if its bit MDIS = 1, even if the other leaves it.

67.3.2 Functions and threads

eTPU processing is event-driven, in the sense that eTPU microcode only runs to service a request from an event. Service Requests may result from the occurrence of any of the following events:

- Host CPU writing a non-zero value to the channel HSR (Host Service Request) field in C*a*HSRR_ENG1 and C*a*HSRR_ENG2.
- Occurrence of a time base match, an input signal transition, or a specific combination of them (depending on the Channel Mode currently configured).
- A Link Service Request.

A given event is always associated to only one Channel:

- There is one HSR register field for each Channel
- Each signal is associated with only one Channel, which has its own Match registers and independent mode configuration.
- Each Link Service Request can have only one Channel as a target.

Service Request processing is done by a set of microengine routines. A set of related routines that implement a specific channel application is called a **Function**. One or more Functions reside on SCM, limited only by the SCM space available, size of microcode Functions and the number of entry points available. Each Engine can be controlled by up to 32 Functions at a time.

A Function can be assigned to several channels, but only one Function can be assigned to a given Channel at a time. This is defined by the Host through the Channel Configuration Registers (see Channel Configuration Control memory map and registers).

The term **Thread** will be used hereafter to refer to a service routine of a Function, or its execution. A Thread is constructed of a specific number of microinstructions, typically the code necessary to calculate the next phase of waveform to be input to, or output from, a given channel. Once a Thread begins, its execution cannot be interrupted. A Thread normally finishes when an END microinstruction is executed.

A given Thread is selected and called by the Scheduler depending on the following:

- the type of event that generated the service request.
- the Function assigned to the target channel.
- target channel pin state.
- the state of the channel logic.
- the priority assigned to the target channel, relative to the priorities of other channels with pending service requests

The mechanism to select a thread based on the channel Function and type of event is described in Entry Points.

The priority mechanism that determines the order of Thread execution among pending service requests is described in Scheduler.

67.3.2.1 Entry Points

67.3.2.1.1 Entry table

Each Thread has its **Entry Point**, which contains the SCM address of its first instruction, besides other information. For a complete Entry Point description, see Entry Point format.

Once the Scheduler chooses a channel among pending Service Requests, the Entry Point is taken from an **Entry Table**, based on the Function assigned for the channel and other conditions. Entry Table layout is shown in the following figure.

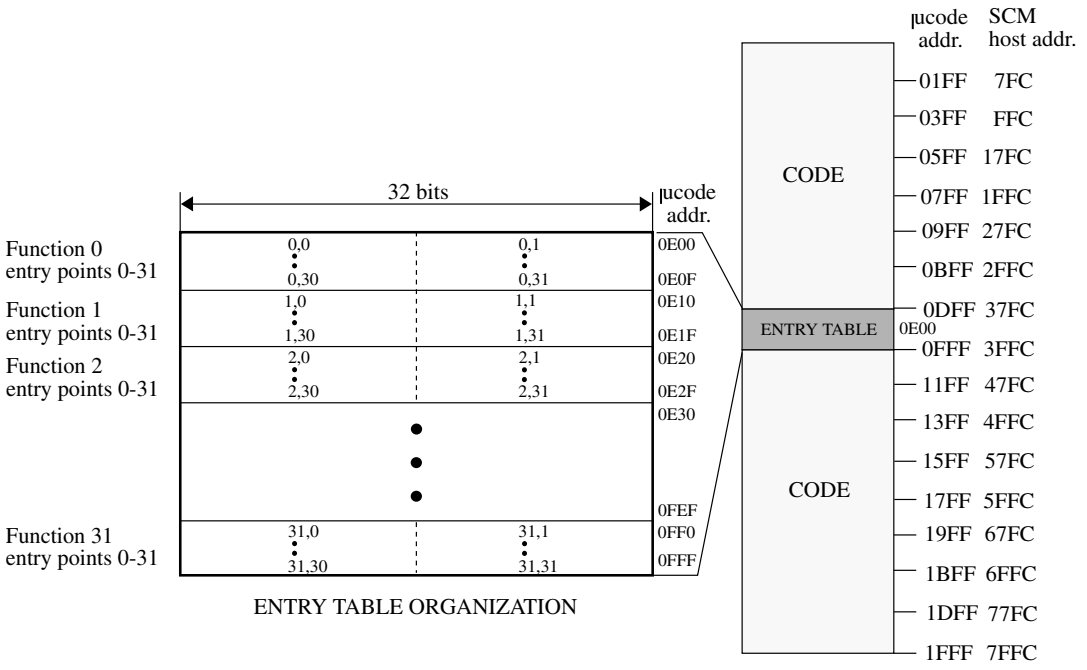

Figure 440. Entry table

The Entry Table is organized by Functions. Each Function can have up to 32 Entry Points of 16 bits each, corresponding to 32 possible Threads per Function. Each Entry Point location in the table corresponds to a combination of events and channel states (see Entry Point address generation). A single Thread can be associated to more than one combination, having its Entry Point repeated in the table. Each 32-bit word in the Entry Table holds two Entry Points.

Note that the Entry Table can be placed in any SCM address multiple of the Entry Table size, determined by the ETB field in eTPU Engine 1 Configuration Register (ECR_ENG1) and eTPU Engine 2 Configuration Register (ECR_ENG2). However, it is recommended to place the Entry Table at the start of the SCM to get continuous code memory and to ease the eventual migration of the code from larger parts down to smaller ones without rearranging the binary image, but this is not a restriction. Unused Entry Points may be used for microcode, so this organization extends the microcode continuous area to the unused area of the Entry Table. For this purpose, Function numbers should be selected from 0 up to 31. If, for example, only 8 functions are implemented, only the Entry Table locations for Functions 0 to 7 are used, and the Entry Table locations for functions 8 to 31 can be used as microinstruction memory (adding extra continuous 1536 bytes for microprogram usage).

One way of implementing different sets of Functions is having more than one Entry Table, and configuring the eTPU with the appropriate one for the application by changing the ETB field in eTPU Engine 1 Configuration Register (ECR_ENG1) and eTPU Engine 2 Configuration Register (ECR_ENG2). Note that the Engines can use different Entry Tables, with or without the same set of Functions.

67.3.2.1.2 Entry Point address generation

The Entry Point address within the Entry Table is determined by the Function assigned to the Channel, the state of the Channel, the type of event, and the condition encoding scheme. Together with the Entry Table base address, they form the Entry Point Address at the SCM, as shown in the following figure.

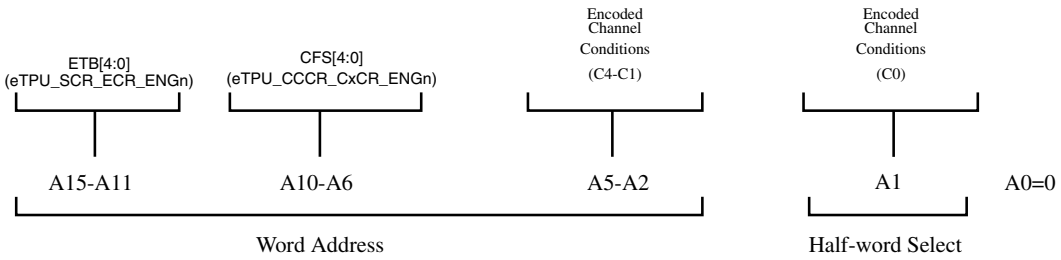

Figure 441. Entry Point Address (host address offset)

The type of event and channel state are coded in the Encoded Channel Conditions field C -C0, according to one of two encoding schemes:

- Standard Entry Table Condition encoding scheme, shown in Standard condition encoding scheme, which privileges Host Service Requests.
- Alternate Entry Table Condition encoding scheme, shown in Alternate condition encoding scheme, which focus on other events and state decoding.

The events that take part on condition encoding generate a Service Request, and have four origins:

1. Match Recognition (caused by greater/equal match, or equal-only, between the value TCR1/2 and the value stored in the channel match registers). eTPU channels support single and double match in various modes of match recognition; see Match Recognition.
2. Transition Detect Service Request (channel input signal transition detection of a selected edge). The eTPU channels support single and double transition, which together with the double match options provide various modes of transition detection; see Transition detection and Time Base Capture.
3. Channel Linking Service Request (microcode writing the channel number to the LINK register). Link service request allows one channel to activate another (see Channel link). Links may also come from Shared Subsystem units (see Shared subsystems support).
4. Host Service Request (Host writes a non-zero value to the HSR bits of the channel; see Host Service Requests).

NOTE

Even if a Transition or Match Service Request is inhibited (by channel mode/state or SRI), the Transition Detection and Match Recognition are taken into account for condition encoding. That is, the MRLA/B and TDLA/B flags are used, not their respective Service Requests.

Columns Host Request Bits, Link Request, MatchA/TransB, and MatchB/TransA determine the type of event. A non-zero value in these columns represents the recognition of the event, while "x" indicates that its recognition is irrelevant. Values 1 and 0 mean that event was recognized or not, respectively. Note that Match and Transition events may occur and not be recognized, and in this case it assumes value 0 for the condition encoding. The recognition of such an occurred event depends on the channel mode assigned and other conditions, as described in Enhanced Channels.

The **Host Service Request Bits** column refers to the value written by the Host CPU to the Host Service Request Registers (C*a*HSRR_ENG1 and C*a*HSRR_ENG2) of the Channel being serviced. Note that the bits on this row are coded (3-bit representation). If the value of HSR is not zero, then the Host actually requested service.

The **Link Request** column refers to the occurrence of a Channel Link or SSS Link requests.

The **MatchA/TransB** column refers to the recognition of either a Match event specified by MatchA channel register or the detection of a channel input signal event specified by the IPACB configuration register (see Pin Control Registers).

The **MatchB/TransA** column refers to the recognition of either a Match event specified by MatchB channel register or the detection of a channel input signal event specified by the IPACA configuration register (see Pin Control Registers).

For the channel input signal, MatchA and MatchB provide double timeout conditions which depend on the channel mode programming (see Channel Modes). If the channel is used for output only, there are no transition detections, so the MatchB/

TransA column represents only Match B, and MatchA/TransB column the Match A. In this case Match A and Match B are separated to give better state resolution in double match output functions. For more information about channel requests refer to Enhanced Channels.

Besides those events, the following channel state conditions help to determine the Entry Point:

1. Channel Flags 0 and 1: these are channel-internal flags (not in SDM) associated with a channel. Their values are set by microcode (see Channel flags operations).
2. Input Pin state or Output Flip Flop: the state (0 or 1) of the channel input signal after the Enhanced Filter (see Enhanced digital filter (EDF)), or the state driven to the output signal. Which one (input or output) is used is selected by the ETPD field in C*a*CR_ENG1 and C*a*CR_ENG2.

The two Entry Table Condition encoding schemes combine events and state conditions differently, as detailed in the following sections.

67.3.2.1.3 Standard condition encoding scheme

In this scheme, shown in the following table, all 7 HSR combinations are used and other event type columns are marked "x" when HSR is non-zero, indicating that Host Service Request has priority over any other type of event. However, when an HSR service thread is called (entry numbers 0 to 9), other events may also have been recognized, and it is microcode responsibility to check them.

When HSR is 0, i.e., Host did not issue a Service Request to the channel, the other event conditions, the input signal state and channel flags determine the Entry Point. Note that channel flag 1 does not influence the encoding in this scheme.

Table 382. Standard channel condition encoding scheme

No.	Encoded channel conditions [C4-C0]	Host Service Request bits	Link request	MatchA/ TransB	MatchB/ TransA	In/output pin state[1]	Channel Flag1	Channel Flag0
0	001	00000	x	x	x	0	x	0
1	00001	001	x	x	x	0	x	1

1. The ETPD field in C*a*CR_ENG1 and C*a*CR_ENG2 selects between input and output pin state.

67.3.2.1.4 Alternate condition encoding scheme

This scheme is shown in the following table. Because the HSR bits cannot be tested by microcode, only three distinct Host Service Requests can be used:

1. HSR=010 or 011, which are coded into the same Entry Points (0 to 3)
2. HSR=100, 101 or 001, which are all coded into Entry Point 4

3. HSR=110 or 111, which are both coded into Entry Point 5

The remaining Entry Points use both channel flags for better state decoding, making this scheme better for Functions which need more states and/or faster state decoding, without needing many HSRs.

Table 383. Alternate channel condition encoding scheme

No.	Encoded channel conditions [C4-C0]	Host Service Request bits	Link request	MatchA/ TransB	MatchB/ TransA	In/Output pin state[1]	Channel Flag1	Channel Flag0
0	00000	01x	x	x	x	0	x	0
1	00001	01x	x	x	x	0	x	1

67.3.2.1.5 Entry Point format

Entry Point information includes a Preload-Parameter selection field, a Match Enable field, and the first microcode address of the thread. The Entry Point format is illustrated in the following figure.

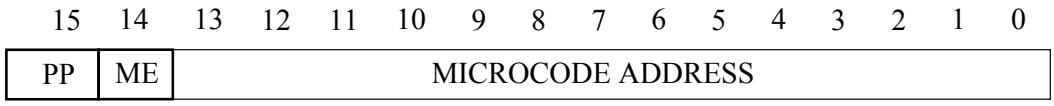

Figure 442. Entry Point format

PP - Preload Parameter

PP indicates which pair of channel parameters are loaded into registers P and DIOB from the SDM prior to the execution of a thread. Preloading occurs during the time-slot transition period (see Time Slot Transition).

1 = microengine register P is preloaded from parameter 2 and DIOB from parameter 3.

0 = microengine register P is preloaded from parameter 0 and DIOB from parameter 1.

The parameter numbers are offsets from the channel parameter base address. For more info, see Parameter Access.

ME - Match Enable

Table continues on the next page...

Table continued from the previous page...

ME specifies whether match event recognitions are enabled or disabled for the thread associated with the entry point during the thread execution. If they are disabled, a match recognition can only occur after channel service. For more details refer to Match Recognition.

1 = Matches are enabled during the thread.

0 = Matches are disabled during the thread.

The disabling of Match A/B recognition by MEF is dependent on IPACA/B configuration on the serviced channel (see Pin Control Registers). If IPACA=1xx, Match A is not disabled by ME=0. Likewise, IPACB=1xx overrides the effect of ME on Match B to "always on" If IPACA/B=0xx, Match A/B is disabled for two microcycles during TST (see Time Slot Transition) and is re-enabled when Entry Point is loaded, if ME=1. Note that if the comparator is in equal-only mode and the time base reaches the value of the Match register during the time that recognition is disabled (beginning of TST, plus whole thread if ME=0), the match recognition is lost. If the comparator is in greater-equal mode, the match event may be recognized after the disabling period if it satisfies the "greater-than" condition.

MICROCODE ADDRESS - Starting Microcode Address

This field specifies the microcode address on which the thread is to begin execution.

67.3.2.2 Time Slot Transition

The Time Slot Transition period (also called TST for short) is the interval between the servicing of two channels, during which all Channel-specific context is loaded for the new serviced Channel. The primary tasks completed during this period include:

- Set MEF for the TST wait-states, if any.
- Reset MEF for the first two microcycles (after eventual wait-states).
- Update of the CHAN register with the number of the new channel to be serviced.
- Parallel update of ERTA and ERTB from CaptureA and CaptureB registers of the new serviced channel.
- Sampling of the branch conditions of the new channel to be serviced into the branch logic (this means flags TDLA/B, MRLA/B, LSR, FM[1], FM[0], and PSS). The branch conditions are coherent with the timebase capture values sampled into ERTA/B (if MRLA/B, TDLA/B are set at the same time of the sampling, either both old flag state and capture values are sampled, or both new values are sampled).
- Formation of the entry point address.
- Copy the ME bit in the Entry Point into MEF.
- Access to the entry point location and getting the first microinstruction address.
- Preload of two parameters from the SDM into P (32 bits) and DIOB (24 bits).
- Fetch the first instruction of the thread to be executed for the new channel.
- Preset the RAR register value (see RAR Register).

The preload operation is 32-bit wide for P and 24-bit wide for DIOB. The P register is loaded with all the 32-bit parameter. The DIOB register is loaded with the lower 24-bits of the parameter. The microcode can switch at any time to access the lower 24-bits, upper byte, or all the 32-bits of any parameter in the SDM. Preload of P-DIOB pair of parameters is atomic with respect to Host and CDC accesses, and so are coherent with their dual-parameter coherent transfers. For more details see Parameter sharing and coherency.

No instructions are executed at the Engine where the time slot transition period occurs, but the other Engine can execute normally. Match A/B is unconditionally disabled on the first two TST microcycles, if IPACA/B=0xx (respectively). During the rest of time slot transition, match recognition can be disabled or not, depending on IPACA/B field and ME. See Match Recognition.

Time Slot Transition takes a minimum of 3 microcycles (6 eTPU clocks), which may be extended due to SDM arbitration wait-states for the first preload access (see SDM arbitration). When no wait-states are received (), DIOB is preloaded twice, one for each PP value, and the correct value remains in DIOB when the Entry Point is loaded. and show the timing for one and two wait-states, respectively.

Registers B, C, D and SR are not altered by TST and keep their values from the previous thread. The values of registers A, MACL and MACH are not guaranteed at the thread start.

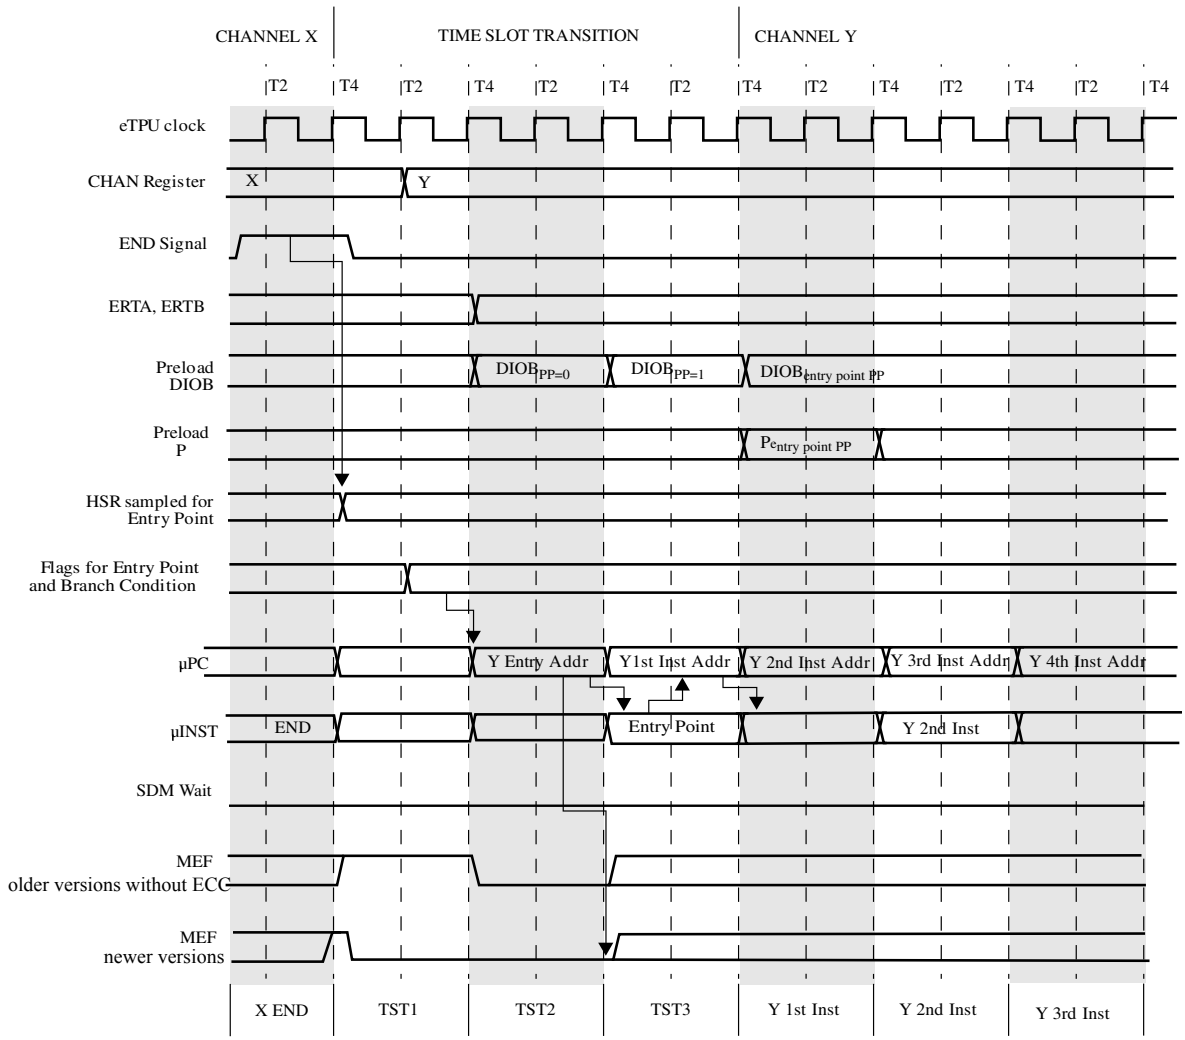

Figure 443. TST Timing - No Wait-states

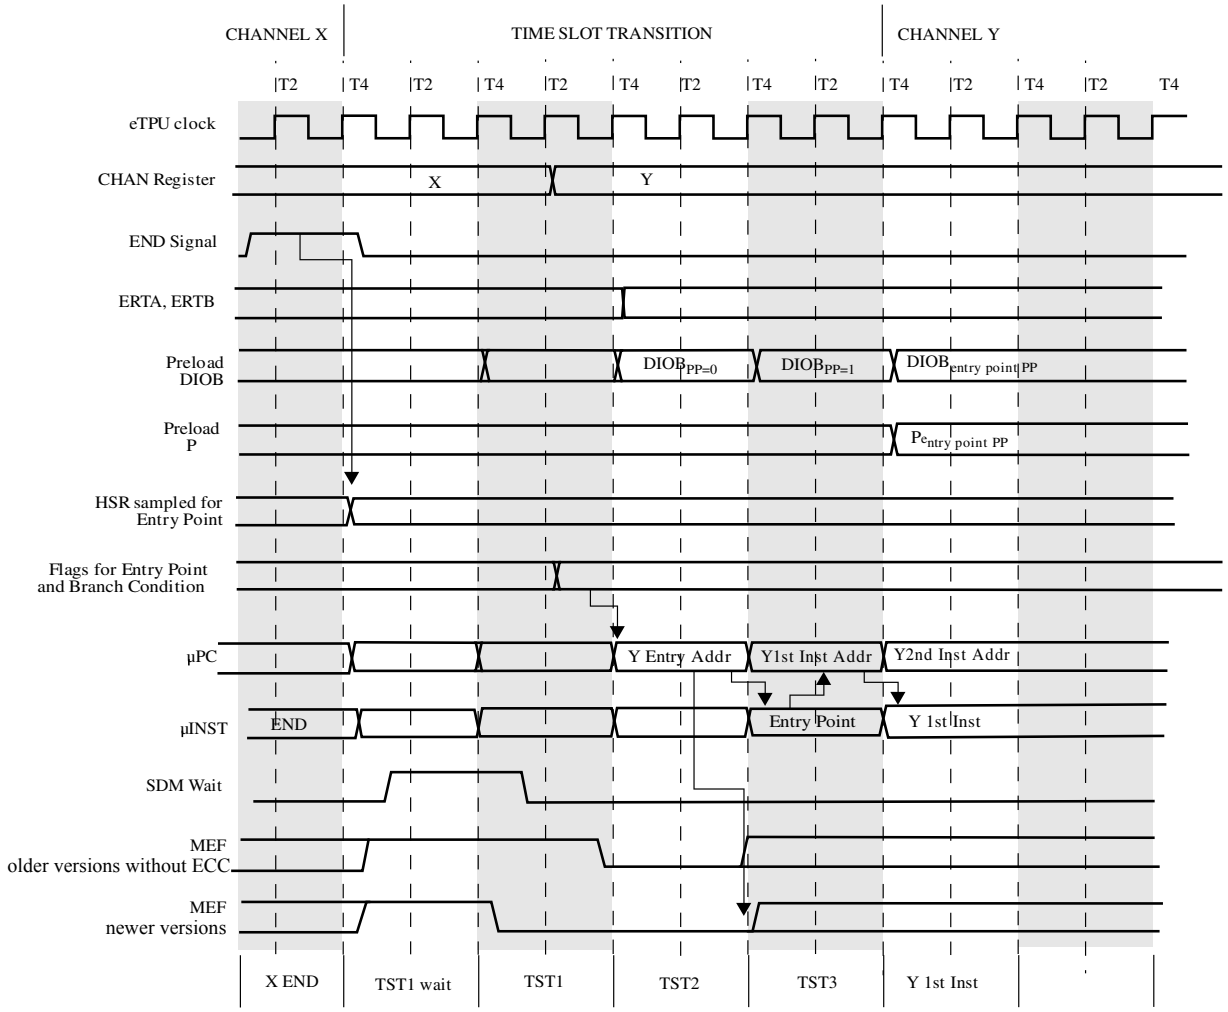

Figure 444. TST Timing - 1 Wait-State

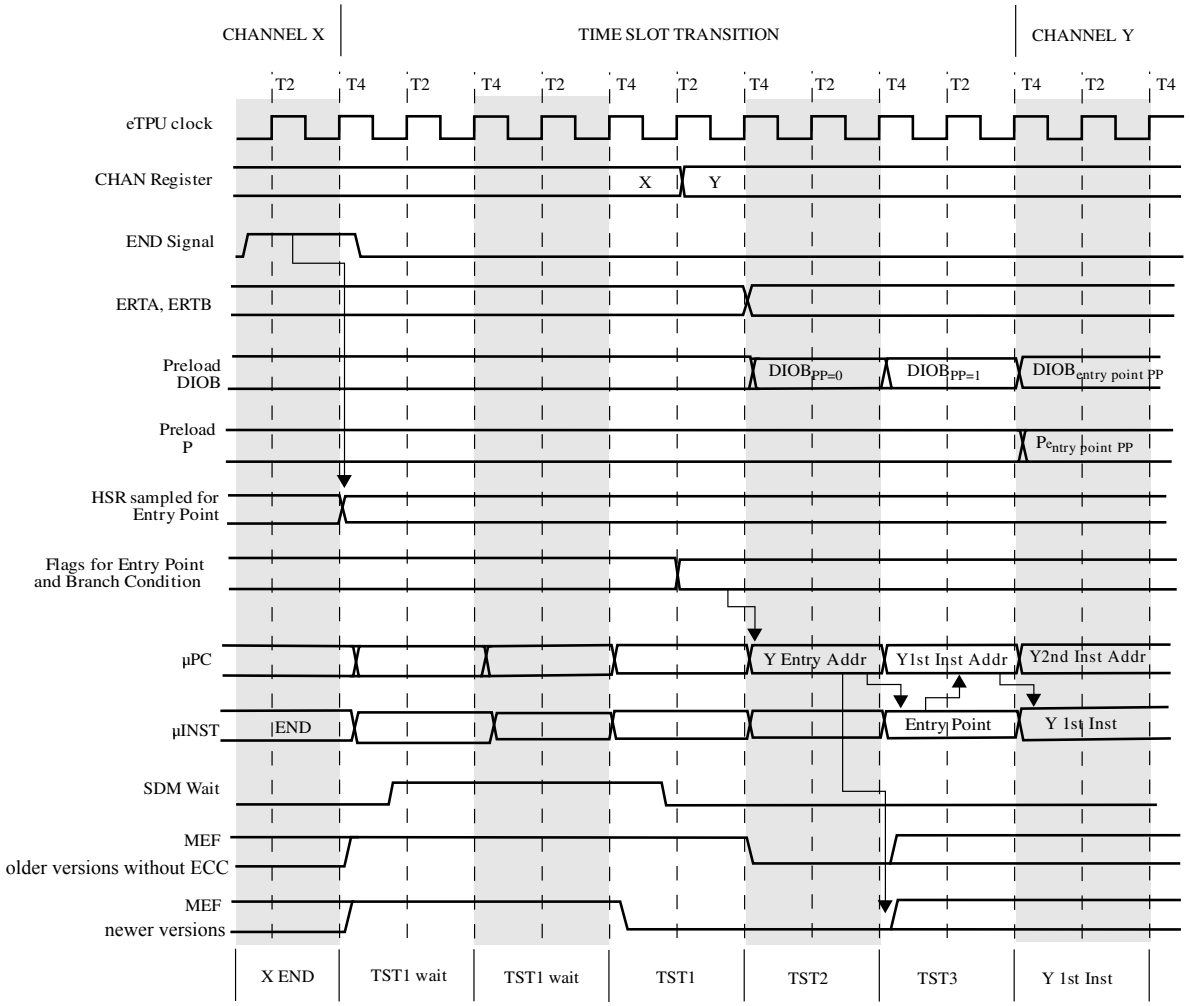

Figure 445. TST Timing - 2 Wait-states

For more information on Channel-specific registers and flags, refer to Enhanced Channels. For more information on P, ERTA/B and DIOB registers refer to Registers.

67.3.2.2.1 Thread gap

The MEF timing has changed from previous eTPU/eTPU2 versions, now being reset for two microcycles from the start of TST.[5] Therefore, two consecutive threads with ME=0 serving the same channel could block any match until the end of the second thread (see Time Slot Transition). This could cause latency problems and also break compatibility with legacy code, so the thread transition logic was modified to introduce a one-microcycle gap between consecutive threads servicing the same channel, as shown in the following figure. During the gap MEF is set to one, regardless of the previous or the next entry point ME field. The thread gap is inserted only between threads serving the same channel.

[5] the new MEF timing is found on all eTPU2 instances starting from the first version with Memory Error Support; all previous eTPU2 versions maintain the former MEF timing .

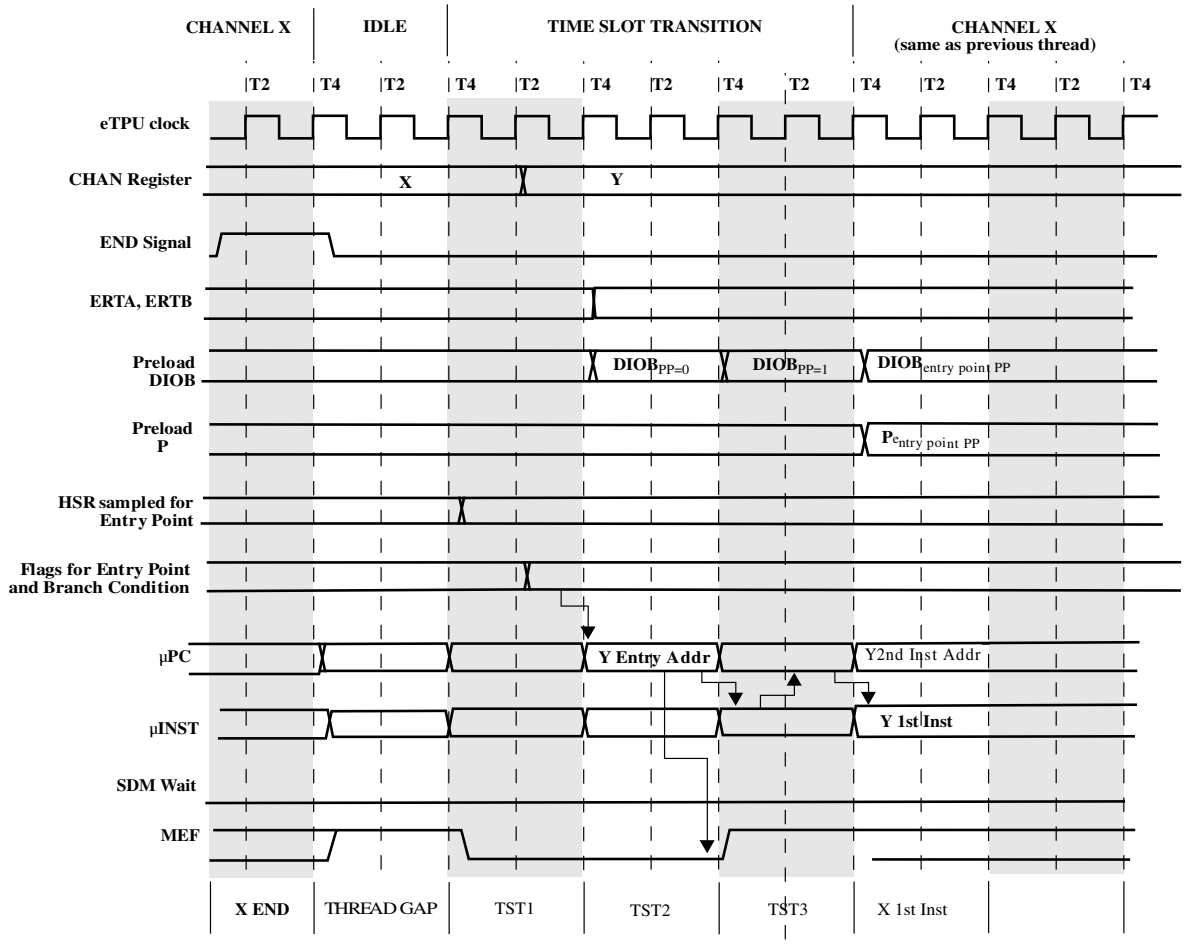

Figure 446. Thread gap

67.3.2.3 Thread ending

Threads can finish by either:

- an instruction with the END field active (see Ending Current Thread - END).
- a forced END by host writing to the FEND field in eTPU Engine 1 Configuration Register (ECR_ENG1) and eTPU Engine 2 Configuration Register (ECR_ENG2).
- a forced END caused by Watchdog timeout (see Watchdog) .
- a forced END caused by a non-correctable memory error (see Memory error support) .

67.3.2.4 Watchdog

Each engine has a watchdog mechanism to prevent a thread or a sequence of threads from running too long, impacting the latency of the other channel services . The watchdog is configured through eTPU Watchdog Timer Register for Engine 1 (WDTR_ENG1) and eTPU Watchdog Timer Register for Engine 2 (WDTR_ENG2) . When the watchdog is enabled, an internal counter increments on each microcycle when a thread is executing . If the count is greater than the value specified in the WDCNT field in eTPU Watchdog Timer Register for Engine 1 (WDTR_ENG1) and eTPU Watchdog Timer Register for Engine 2 (WDTR_ENG2) and a thread is still executing, the watchdog:

1. If the WMO field in eTPU Watchdog Timer Register for Engine 1 (WDTR_ENG1) and eTPU Watchdog Timer Register for Engine 2 (WDTR_ENG2) is negated, forces an END of the thread, allowing other channels to be serviced

2. Sets the WDS status bit of the serviced channel in eTPU Watchdog Status Register for Engine 1 (WDSR_ENG1) and eTPU Watchdog Status Register for Engine 2 (WDSR_ENG2) .
3. If the WMO field in eTPU Watchdog Timer Register for Engine 1 (WDTR_ENG1) and eTPU Watchdog Timer Register for Engine 2 (WDTR_ENG2) is negated, the channel is disabled, not initiating any thread until its WDS bit is cleared (however, its CPR field in C*a*CR_ENG1 and C*a*CR_ENG2 is not changed).
4. Issues a Global Exception and sets MCR[WDTO1] (engine 1) or MCR[WDTO2] (engine 2) , regardless of the WMO bit state .

If the WMO field in eTPU Watchdog Timer Register for Engine 1 (WDTR_ENG1) and eTPU Watchdog Timer Register for Engine 2 (WDTR_ENG2) is asserted, the watchdog can be used to monitor the execution time threshold of a thread or thread sequence without interfering with the eTPU code execution .

The watchdog can be configured in one of the following modes, defining how the internal watchdog count is reset:

- **Thread Length Mode**: the watchdog count is reset at the end of each thread.
- **Busy Length Mode**: the watchdog count is reset when the microengine goes idle . A sequence of threads, one right after another, keeps the count running . The counter is also reinitialized when a thread is forced to end, so that a new count begins if another TST initiates at the following microcycle.

The following applies to the watchdog mechanism:

- Microcycles during TST and SDM access wait-states (on TST or instruction execution) are counted.
- If the watchdog count equals WDCNT in the last microinstruction (with SDM wait-states or not) of a thread servicing a channel, its WDS bit is not set.
- If the watchdog count expires (gets greater than WDCNT) during the TST, the thread is forced end on its first instruction.
- The watchdog count does not wrap, so that a thread (in thread length mode) or a thread sequence (in busy length mode) that lasts for more than the maximum value of WDCNT does get a forced end.

NOTE

Watchdog must not be enabled when the microengine enters halt mode.

The counter does not run when the engine is stopped, and resets when the watchdog is disabled .

67.3.3 Host interface

67.3.3.1 System configuration

System Configuration Registers are described in System Configuration memory map and registers. Detailed explanation of the configured functionalities is found throughout Functional description and a specification for the initial configuration sequence is found in Configuration sequence.

67.3.3.2 Interrupts and data transfer requests

67.3.3.2.1 Interrupt types and sources

Each one of the eTPU channels can be a source of two requests: **Channel Interrupt** request and **Data Transfer Request**. Channel Interrupts are targeted to a Host CPU. Data Transfer Requests may be targeted to a data transfer module (for example, a DMA controller). Interrupt and Data Transfer registers are used by the Host to enable interrupts and data transfer requests, indicate their status and service them. Interrupt and Data Transfer requests have the same sets of registers and external signals, and are handled in the same way. They differ only by the fact that Data Transfer Requests are also cleared by the assertion of respective .

NOTE

Interrupt and Data Transfer requests can be cleared even when Engines are in Module Disable Mode, through the Global Channel Registers, and also for Data Transfer requests.

Channel Interrupts and Data Transfer Requests can only be issued by eTPU microcode, through one of the Channel Control instruction fields (see Channel Interrupt and Data Transfer Requests).

Both Channel Interrupt and Data Transfer requests can be individually enabled for each channel.

eTPU Interrupt and Data Transfer Registers are mirrored in two organizations: grouped by Channel and grouped by type (interrupt status, interrupt enable, data transfer status, data transfer enable). This allows either "channel-oriented" or "bundled channel" Host interrupt service schemes, or a combination of them. For a detailed description, refer to the Channel Register Layout and Global Channel Registers sections.

eTPU can also assert a **Global Exception** interrupt indicating a global illegal state. There are six possible sources for a Global Exception:

- Execution of an illegal instruction by the microengine (see Illegal instructions). This Global Exception source is flagged by MCR[ILF1] and MCR[ILF2].
- An SCM signature mismatch detected by the Multiple Input Signature Calculator - MISC. See SCM test - multiple input signature calculator. This source is flagged by MCR[SCMMISF].
- Microcode request, through microinstruction field CIRC (see Channel Interrupt and Data Transfer Requests). This Global Exception source is flagged by MCR[MGE1] (Engine 1) and MCR[MGE2] (Engine 2). The cause of this illegal state is application-dependent. The microcode may write an error code into the SDM to indicate the cause of the exception, for instance.
- A Watchdog timeout, flagged by MCR[WDTO1] and MCR[WDTO2] (see Watchdog) .
- An SDM or SCM non-correctable error on a microengine or host access, flagged by MCR[SDMERR] and MCR[SCMERR], respectively (see Memory error support) .
- Bus errors on microengine accesses to the Shared Subsystem Area, flagged by MCR[SSAERR] (see Shared subsystems support) .
-

Global Exceptions cannot be directly disabled within eTPU, except by disabling its sources (Memory Error, SSS, MISC and microcode), and it is cleared by writing 1 to MCR[GEC]. Clearing Global Exception clears all Global Exception source status bits (ILF1, ILF2, SCMMISF, MGE1, MGE2, SSAERR, SCMERR, SDMERR). If GEC is written 1 at the same time any of the sources issues a Global Exception, both the interrupt and the status bit of that source remains asserted. The assertion of Global Exception by one of the sources above does not prevent the others from asserting it too, so any number of them, in any combination, can be flagged.

NOTE

There can be a race between the clear of a Global Exception and occurrence of a new set condition, such that the set happens just before the clear and cannot be sensed by the Host. Therefore, Global Exception cannot be used as a normal interrupt source. It should only be used for emergency procedures.

Memory Error Correction support (see Memory error support) has a distinct interrupt source, which can activate on any correctable error occurrence, either to SCM or SDM accesses, but does not activate on non-correctable errors (which assert Global Exception instead) . Memory Error Correction interrupt asserts when it is enabled through MECR[MECIE] (see eTPU Memory Error Status Register (MESR)) and either DCERR or CCERR in eTPU Memory Error Status Register (MESR) is asserted . The interrupt is negated when both DCERR and CCERR are negated, or MECIE is negated .

67.3.3.2.2 Interrupt and Data Transfer Request overflow

If a Channel Interrupt was issued, its status bit is still set, and microcode issues another Channel Interrupt, the Interrupt Overflow status bit is set for that channel. Interrupt Overflow status can be checked by the Host in the CIOS field of C*a*CR_ENG1 and C*a*CR_ENG2, mirrored in eTPU Channel Interrupt Overflow Status Register for Engine 1 (CIOSR_ENG1) and eTPU Channel Interrupt Overflow Status Register for Engine 2 (CIOSR_ENG2). Interrupt Overflow status is not cleared automatically when Interrupt Status is cleared. The same mechanism and respective registers (eTPU Channel Data Transfer Request Overflow Status Register for Engine 1 (CDTROSR_ENG1) and eTPU Channel Data Transfer Request Overflow Status Register for Engine 2 (CDTROSR_ENG2)) are available for Data Transfer Requests.

If interrupt is set and cleared at the same time, set prevails and overflow is not altered (keeps the same state as it was before, asserted or not).

Global Exception has no overflow status.

67.3.3.3 Parameter Access

67.3.3.3.1 Parameter Access Widths

From the Host side the SDM address space is mapped in bytes, and each 32-bit parameter occupies 4 contiguous, aligned bytes. The Host can read/write the SDM by 8-, 16-, or 32-bit accesses in aligned addresses.

In 32-bit access, Host can access all 32 bits or only the lower 24 bits with an automatic sign extension (see Parameter Sign Extension area).

67.3.3.3.2 Parameter Addresses and Endianness

To access parameter number xxx, eTPU Microengine(s) would select address xxx. The Host would add *(xxx*4)* to the SDM base address to access the same parameter. For example, parameter 0x101 is seen by the Host in *(SDM base address +0x404)*. An example of SDM memory map is shown in SDM organization. The Host can access the SDM with a 32-bit-wide bus cycle to a four-byte aligned address, 16-bit-wide bus cycle to a two-byte aligned address, or 8-bit wide bus cycle to any byte address.

The address of the 24-bit parameters and the most significant byte depends on the endianness of the MCU. For more details, see the Endianness.

67.3.3.3.3 Parameter concurrency

Host accesses to parameters may occur in parallel with eTPU Microengine accesses. Readings taken from a group of parameters while they are being simultaneously updated may lack coherency. eTPU provides mechanisms to ensure parameter coherency in accesses from both Host side and Microengine side, including the use of a coherent dual-parameter transfer mechanism, described in detail on Parameter sharing and coherency.

67.3.3.3.4 Parameter Sign Extension area

The SDM address space to the Host is mirrored in a Parameter Sign Extension (PSE) area (see Memory map). Accesses from the Host to the PSE area differ from accesses to the standard SDM address space as follows:

- **Writes**: the most significant byte of the parameters is not written, and the SDM retains the old byte value, regardless of the Host access size.
- **Reads**: the most significant bit of the 24-bit parameter (that is, the MSB of the second most significant 32-bit parameter byte) is repeated in the 8 most significant bits of the read value on all 32-bit reads and most significant 16- and 8-bit reads.

The same parameters written in the standard SDM address space are read from the PSE area with the same offsets, and vice-versa. See Endianness for a reference of the address offsets in big and little endian machines.

This feature reliefs the Host from extending the signal of 24-bit eTPU parameters before calculations, and from read-modify-write accesses to modify 24-bit parameters at the SDM.

67.3.3.4 SDM organization

The SDM internal partition for channel allocation is dynamic and programmed in the Channel Registers (see C*a*CR_ENG1 and C*a*CR_ENG2).

The Host application is responsible for allocating a different parameter base address to each channel during the initial eTPU configuration, and to allocate enough parameters for the selected Function, with no unintentional overlapping between parameters of different functions.

Besides channel parameters, global areas may have to be allocated for parameters that are shared by more than one channel, in one or both Engines. Also, temporary parameter areas should be reserved to be used by the coherent parameter transfer

mechanisms described in Parameter sharing and coherency, if necessary. An SDM organization example is shown in the following figure.

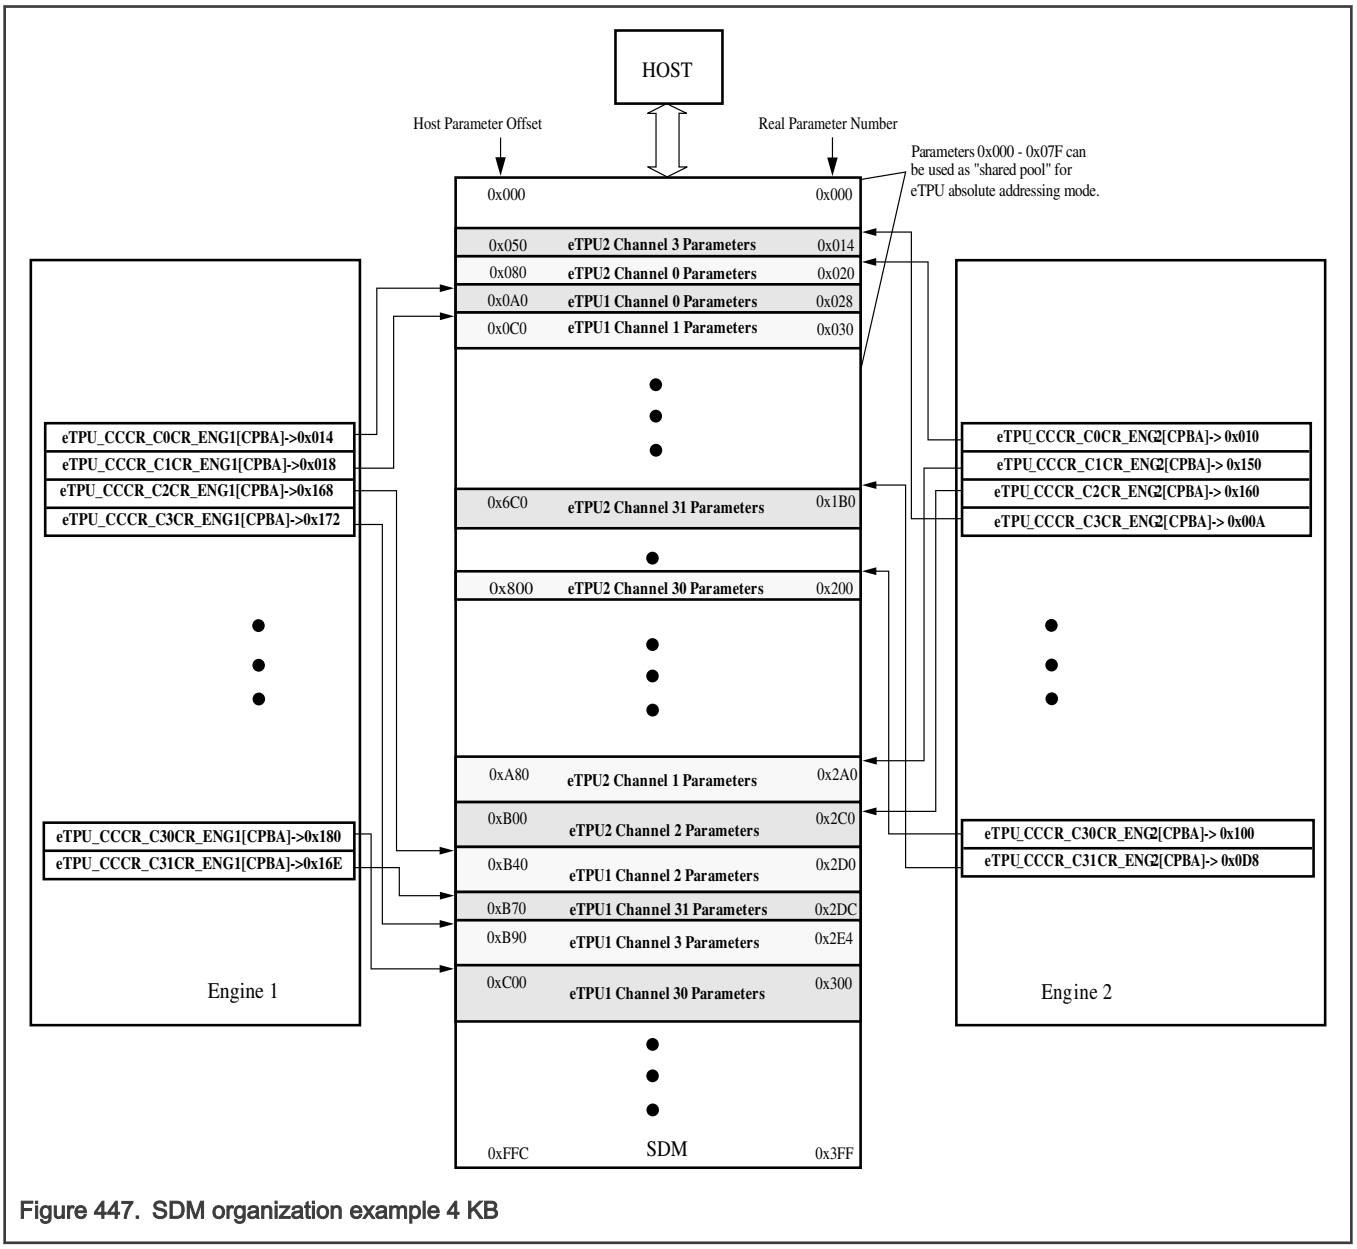

Figure 447. SDM organization example 4 KB

Single-engine eTPU or dual eTPU system may require fewer parameters than the maximum number provided by the SDM. Since the SDM partition is fully dynamic, there is no limitation of fixed channel addresses, and the reduced array can be fully utilized.

67.3.3.5 Host Service Requests

Host CPU can request immediate service from a channel by writing a non-zero value to the Host Service Request register field - HSR (see CaHSRR_ENG1 and CaHSRR_ENG2). There is one HSR field for each channel, so that writing to it generates a Service Request to the respective channel only. A zero value in HSR means no Host Service Request is pending for the channel.

HSR value turns to 000 automatically at the end of microengine service for that channel, but only if the thread started due to an HSR.

The meaning of a non-zero HSR value depends on the Function assigned for the channel. These bits are part of the conditions which select the Function entry point, and cannot be tested by microcode. For more details, refer to Entry Points.

If Host writes HSR=000 when a thread for the same channel is already running, the thread runs until the end and is not aborted. If Host writes HSR>000 when an HSR thread for the same channel is already running, HSR value resets at the end of the thread, and no new HSR will be pending. If HSR is written before its value is resolved by the scheduler during TST, the entry point will obey the new HSR value, and if this new value is 000, no service thread is executed for the HSR.

The scheduling of HSRs is completely asynchronous with Host accesses, and there is no race-free manner to change an HSR value before service thread execution, so generally the safe way is: write HSR>0 only when HSR=0. Error recovery or emergency host procedures may require one to the safely abort service and reset channel state when an HSR is already pending or executing. In these cases, the procedure below should be followed:

1. Disable the channel, writing CPR=00 in C*a*CR_ENG1 and C*a*CR_ENG2. That will prevent any pending HSR to be serviced.
2. Check if the channel is currently being serviced, reading its service status bit in eTPU Channel Service Status Register for Engine 1 (CSSR_ENG1) and eTPU Channel Service Status Register for Engine 2 (CSSR_ENG2). If it is, wait for the time necessary to finish the service pending, or check again until HSR == 0, or channel service bit in eTPU Channel Service Status Register for Engine 1 (CSSR_ENG1) and eTPU Channel Service Status Register for Engine 2 (CSSR_ENG2) is cleared.
3. Write HSR with the error recover value. This value should, possibly combined with other host-defined flags in SDM or FM bits, initiate a channel reset or error recovery procedure.
4. Re-enable the channel, writing CPR value > 0 in C*a*CR_ENG1 and C*a*CR_ENG2.

67.3.3.6 SCM access

Only Host can access SCM as data. Depending on the specific device, SCM may be implemented as a RAM or ROM. This determines Host accesses to the SCM as shown below.

67.3.3.6.1 SCM RAM implementations

When SCM is implemented as RAM, the Host may read or write to SCM by setting MCR[VIS]=1. If VIS=0 and Host tries to access SCM space, a bus error is issued, writes are ineffective and read data is meaningless. Both Engines must be stopped or halted to set VIS=1.

NOTE

It is necessary to turn VIS bit on to set software breakpoints (see Software breakpoints).

67.3.3.6.2 SCM low power

SCM turns off its internal clocks when both Engines are stopped (STF field in eTPU Engine 1 Configuration Register (ECR_ENG1) and eTPU Engine 2 Configuration Register (ECR_ENG2) asserted), MCR[VIS], and MISC is not enabled (SCMMISEN=0). The SCM clocks are automatically turned on if either one of the STF bits is negated or VIS turns to 1, or SCMMISEN turns to 1.

SCM clocks are not turned off if any of the Engines is not stopped, even if they are both halted.

The conditions for SCM Clocks and MISC activation are summarized in the following table.

Table 384. SCM clocks and MISC activation

STF in eTPU_SCR_ECR_ENG1	STF in eTPU_SCR_ECR_ENG2	VIS in eTPU_SCR_MCR	SCMMISEN in eTPU_SCR_MCR	SCM clocks	MISC
0	x	0	1	On	On
0	x	0	0	On	off
x	0	0	1	On	On

Table continues on the next page...

Table 384. SCM clocks and MISC activation (continued)

STF in eTPU_SCR_ECR_ENG1	STF in eTPU_SCR_ECR_ENG2	VIS in eTPU_SCR_MCR	SCMMISEN in eTPU_SCR_MCR	SCM clocks	MISC
x	0	0	0	On	off
1	1	0	0	off	off
1	1	0	1	On	On
1	1	1	0	On	off
1	1	1	1	On	off[1]
0	0	x	0	On	off
0	0	x	1	On	On

1. MISC resets and stays so when VIS=1, restarting automatically when VIS goes 0 if SCMMISEN=1.

67.3.3.6.3 SCM off-range data

When read accesses are made, either by the Host or by a microengine, to addresses above the limit corresponding to MCR[SCMSIZE], the value read comes from eTPU SCM Off-range Data Register (SCMOFFDATAR). The Host can program the register at initialization with an opcode value with operations that try to protect or recover the system from runaway code, for instance: terminate the thread, clear channel flags, disable match and transition service requests, issue an interrupt, jump to an error recovery procedure[6]. Writes to unimplemented addresses do not return error and can write on unspecified mirror addresses, so they should be avoided.

67.3.3.7 Bus error conditions

Follows a summary of the possible causes of bus errors on host accesses to the eTPU memory space:

- Read or write access to the SCM with MCR[VIS] = 0.
- Read or write access to the channel registers with eTPU_SCR_ECR_ENG*n* bits MDIS = 1, or bit STF = 1 (see eTPU Engine 1 Configuration Register (ECR_ENG1) and eTPU Engine 2 Configuration Register (ECR_ENG2)).
- Write access to the Time Base Registers with eTPU_SCR_ECR_ENG*n* bits MDIS = 1, or bit STF = 1 (see eTPU Engine 1 Configuration Register (ECR_ENG1) and eTPU Engine 2 Configuration Register (ECR_ENG2)).
- Non-correctable errors in the SCM on reads of any size or writes less than 32-bits wide when MECR[CEDD] = 0.
- Non-correctable errors in the SDM on reads when MECR[DEDD] = 0.
- Accesses to the Shared Subsystem Area, when propagating a bus error issued by the attached subsystem.

67.3.4 Scheduler

Every Function is composed of one or more Threads. A Thread consists of a group of instructions that, once begins execution, cannot be interrupted by host or channel events. Each active channel intents to be serviced, being granted time for Thread execution. Since one microengine handles several channels operating concurrently, the Function threads must be executed serially.

The task of the Scheduler is to recognize and prioritize the channels needing service and to grant execution time to each channel. The time given to an individual Thread for execution or service is called a **Time Slot**. The duration of a time slot is determined by the number of instructions executed in the Thread plus SDM wait-states received, and varies in length.

[6] Only part of these suggested operations can be parallelized in a single instruction, see Microinstruction formats.

At any time, an arbitrary number of channels can require service. To request service, channel logic, eTPU microcode or Host application notifies the Scheduler by issuing a Service Request.

67.3.4.1 Channel enabling and priority assignment

Every channel is assigned one of three priority levels - high, middle, or low - by the Host CPU, through the CPR field in C*a*CR_ENG1 and C*a*CR_ENG2). These registers are also used to disable the channel, which is equivalent to assigning it a "null" priority. In this case, the Scheduler does not grant any of its Service Requests.

It is possible to change the channel priority level or disable it dynamically. If the Host disables a channel when it is currently being serviced, channel service thread will complete. This means that it is possible for the output level of a channel signal to change, or a Host interrupt occur, even after its priority register was written to "null". For instance, if an output transition is scheduled, the transition will occur even after the channel is disabled.

Service requests previously pending or that occur while a channel is disabled remain asserted while the channel is disabled, and are serviced if the channel is enabled again, in due time determined by the priority scheme and concurrent requests from other channels. Channels are disabled after reset, and it is recommended to configure a Host Service Request for initialization of a channel before that channel is enabled to active priority (see Initialization/application information).

67.3.4.2 Channel priority schemes

The Scheduler holds a Service Grant register with one bit for each channel. Once the Scheduler grants a time slot to channel, the Service Grant bit for that channel is asserted in the Service Grant register. When the Service Grant bit of a channel is set, the channel may request new service but is not serviced again before its Service Grant bit is cleared.

When all channels in a same priority level are serviced, their Service Grant bits are cleared at the end of the thread, one eTPU clock before the next serviced channel is calculated, according to the scheme below[7]:

- Clear all grant bits of priority High if all channels of that priority that are requesting have their grant bits in 1.
- Clear all grant bits of priority Medium if all channels of that priority that are requesting have their grant bits in 1.
- Clear all grant bits of priority Low if all channels of that priority that are requesting have their grant bits in 1.
- Clear all grant bits of disabled channels.

This scheme assures that no channel is left with its grant bit forever asserted (preventing it from being serviced again), even if the channel priorities are reassigned during the execution.

Priority level is determined based on the maximum latency desired for each channel. A channel having a Function that requires the most frequent or more immediate service should be allocated a high priority level.

The eTPU employs a **primary** and a **secondary priority scheme**. These two schemes ensure frequent servicing of high-demand Functions and ensure a minimum time allocation to all channels requesting service, regardless of their priority level. The primary scheme prioritizes requesting channels that have different priority levels; the secondary scheme prioritizes requesting channels that have the same priority level.

Initially, a channel requests service and is granted a time slot by the Scheduler: Service Grant bit is asserted. If only high-level channels constantly receive service first because of their priority level, middle- and low-level channels would only be serviced by default, i.e., if no high-level channels request service. To ensure that each priority level receives an opportunity for servicing, every time slot has a fixed priority level that the Scheduler honors first. Divided into sets of seven, time slots are numbered from one to seven. The figure below illustrates the numbered time slots in sets of seven (fields A and B) and identifies their assigned default priority level. The high level has more time slots than the middle and low levels. Out of every seven time slots available, four are assigned to honor high-level channels first, two are assigned to honor middle-level channels first, and one is assigned to honor low-level channels first. Only one request (in each Engine) is serviced per time slot. When no channel requests service and the microengine is idle the priority scheme is initialized to time slot one, to prevent priority inversion on the next request[8].

[7] Grant bits are also cleared in the next clock, when the service channel is chosen, or when the microengine is idle, using the same scheme.

[8] Priority inversion would occur in the following situation: no channel is requesting service, and the current time slot is primarily assigned to a low-priority channel. If the Scheduler was not reset to time slot one and two channels requested service at the same time, one with high priority and the other with low priority, the channel to be serviced would be the low-priority channel.

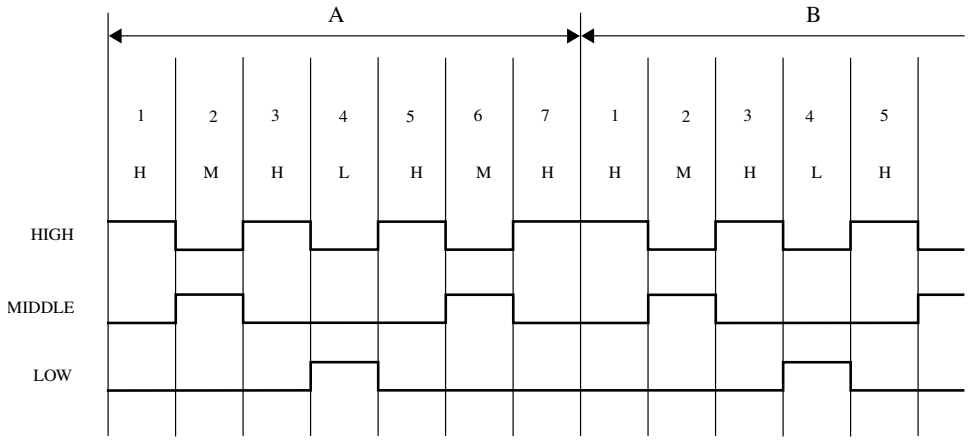

Figure 448. Time Slot Priority levels

67.3.4.2.1 Primary scheme - priority among channels on different levels

Although time slot priority assignment is fixed, the servicing priority is not. The primary scheme acknowledges the priority level assigned to a time slot, granting service first to a channel having the same priority. In Channel priority schemes, time slot one has a high-level assignment; therefore, a high-level channel requesting service is recognized first. However, if no high-level channel requests service, the Scheduler recognizes a requesting middle-level channel. If this level has no request, the Scheduler continues to the low-level. If no requests occur, the Scheduler truncates the seven state cycle and starts a new cycle at time slot one, waiting for the first request. Granting service to a different-level channel is called priority passing. The order of passing always gives the highest priority to the assigned level, and the second priority to the higher of the remaining requesting priority levels as shown in the following table.

Table 385. Priority Passing

Assigned Priority Level	Next Priority Level	Next Priority Level
High	Middle	Low
Middle	High	Low
Low	High	Middle

When priority is passed to another level, that level is serviced and the fixed-priority-level sequence is resumed with the next time slot.

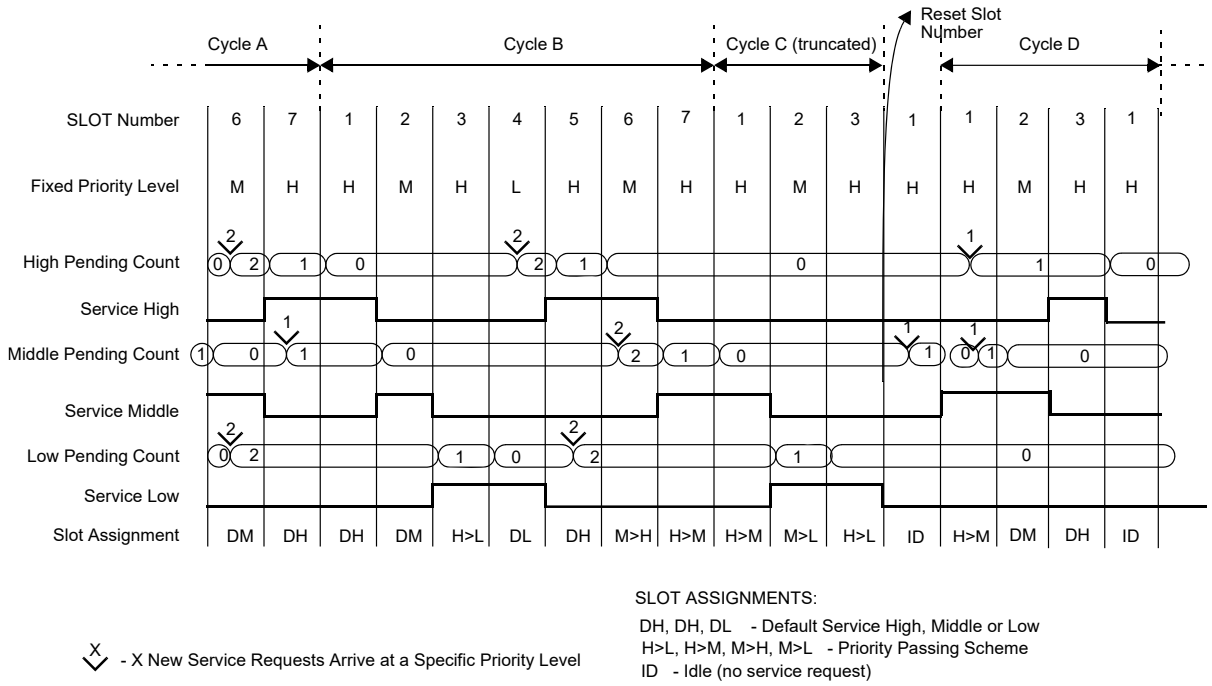

Figure 449. Priority passing example

Examples of priority passing are shown in the above figure. Each cycle contains seven time slots (or less if no service request exist). In cycle B, no high-level or middle-level service requests are present before time slot three which is assigned by default to high-level priority. Thus, time slot three is passed to the low level. In cycle B there are also no middle-level service requests before time slot six, so it passes the priority to a requesting high-level channel. During time slot six no more high level requests are left, but two new middle-level requests arrive, and there are also three low level pending service requests. Thus, time slot seven of cycle B and time slot one of cycle C are passed to the middle-level which is the next priority level after high. Time slots two and three of cycle C are passed to the low level which contains the three remaining channel service requests. At time slot three of cycle C the last low level request is serviced, and the Scheduler passes to idle state. At this point the cycle C is truncated and the Scheduler passes to time slot one of cycle D.

67.3.4.2.2 Priority passing disabling

The priority-passing scheme allows a case where a high priority channel looses to a lower priority one right after another lower priority has been serviced, exemplified in the Cycle D on Primary scheme - priority among channels on different levels. A middle priority channel wins time slot 1 due to priority passing from high to middle. While it is being serviced, two new service requests arrive, one high and one middle priority. The high priority request looses to the middle one on next time slot 2 by default priority assignment.

This priority inversion can be avoided by setting the SPPDIS field in the eTPU_SCR_ECR_ENG*n* registers (see eTPU Engine 1 Configuration Register (ECR_ENG1) and eTPU Engine 2 Configuration Register (ECR_ENG2)), which disables the priority-passing mechanism. When priority passing is disabled, at the end of the thread the slot number is incremented until a time slot that matches the priority of one of the requesting channel(s). The time slot advance takes no extra clocks. If no channel requests service, the time slot counter stays at time slot 1. The priority selection scheme with disabled priority passing is summarized in the following table.

Table 386. Priority Passing Disabling

At the end of time slot	servicing priority	if any request of priority	service it on time slot	else if any request of priority	service it on time slot	else if any request of priority	service it on time slot
1	High	Medium	2	High	3	Low	4
2	Medium	High	3	Low	4	Medium	6
3	High	Low	4	High	5	Medium	6
4	Low	High	5	Medium	6	Low	4
5	High	Medium	6	High	7	Low	4
6	Medium	High	7	Medium	2	Low	4
7	High	High	1	Medium	2	Low	4

An example of the priority passing disabling scheme is illustrated in the figure below. The sequence of service requests is the same as in the example of Primary scheme - priority among channels on different levels, and although the time slot incrementing differs, the priorities granted are the same for cycle B. Cycle C has one of the low-priority channels serviced before the second middle one. Cycle D, however, no longer has the priority inversion.

In cycle B, after the time slot 2 only a low-priority request remains, so the time slot count advances directly to 4, which has a low priority assigned. Time slot keeps on 4 for the next service, as only a low-priority request remains also, and only time slot 4 is assigned to low. Two high priority services contend for the next time slot 5 (assigned to High). The second high priority channel is serviced on the next time slot, jumped to 7 because there is no middle request, ending cycle B. Cycle C starts with time slot 2, as there are no high priority requests and two middle and two low ones. After the first middle service, time slot count skips 3 assigned to high (no high requests), and services a low-priority channel on time slot 4. It follows the same scheme until there are no other requests and cycle C is truncated, resetting the time slot counter to 1.

Cycle D begins with a middle request, jumping to time slot 2. During this service two requests arrive, one high and one middle. Unlike what happened with priority passing, the next serviced is the high priority channel, as the time slot increments to 3. The second middle priority channel request in cycle D is finally serviced next, on time slot 6.

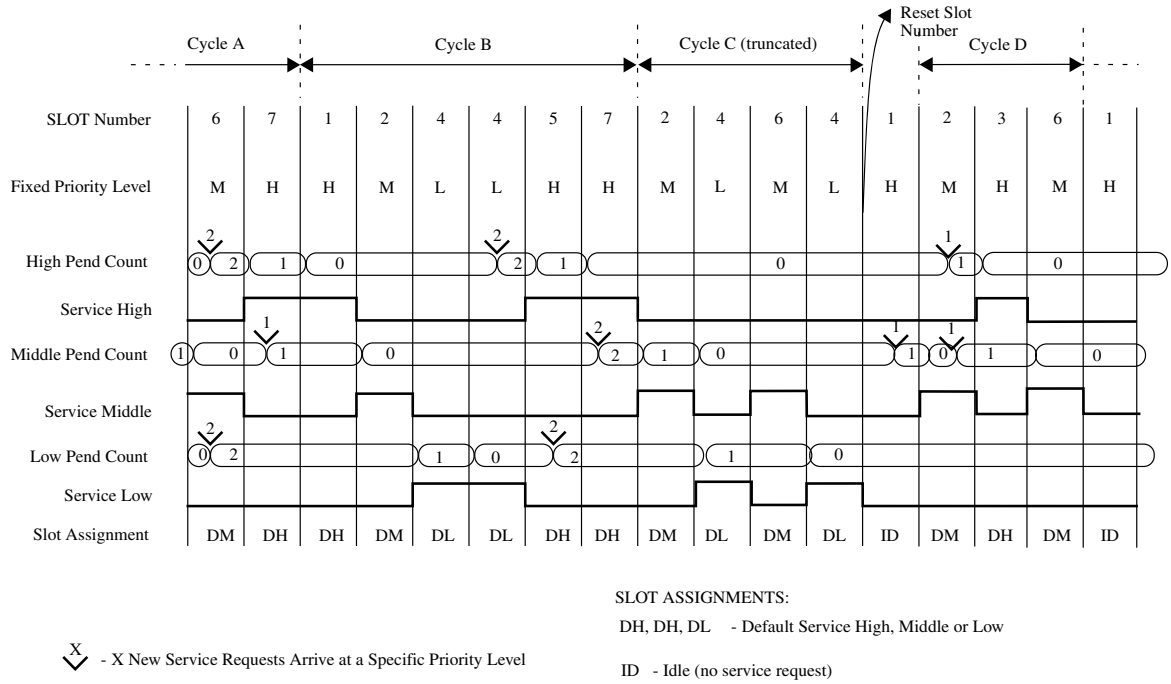

Figure 450. Priority passing disabling example

67.3.4.2.3 Secondary Scheme - Priority Among Channels on the Same Level

Because channels can randomly request service, channels having the same priority level will inevitably request service simultaneously. A secondary scheme prioritizes these requests. The Scheduler services channels on each of the three priority levels, beginning with the lowest numbered channel on that level.

67.3.4.2.4 Priority Scheme Example

The overall priority scheme simultaneously incorporates both primary and secondary schemes. Combining both schemes in the following example conveys their correlation.

1. One high-priority and one low priority channels request service, while the Scheduler is in time slot one. Having its service request bit asserted, a single high-level channel is granted the time slot, which has high-level priority (primary scheme) and its service grant bit is asserted. At the end of the thread, the service grant bit is negated (no more requests of high priority level channels).
2. The Scheduler proceeds to time slot two, which has middle-level priority; however, no middle-level channel is requesting service. Priority is passed to the high level, but no high-level channel is requesting service; therefore, priority is passed again, and service is granted to the single requesting low-level channel. Once serviced, this channel's grant bit is negated (no more low-level requests).
3. The Scheduler resumes with the fixed-priority sequence on time slot three; however, no channels are requesting service. The Scheduler returns to time slot one, waiting for requests.
4. Two high-level and two middle-level channels simultaneously request service. Being in time slot one which is assigned high priority, the Scheduler finds the lowest numbered high-level channel (secondary scheme) and selects it for service. This channel's service grant bit is asserted.
5. The Scheduler continues to time slot two, which has middle priority (primary scheme), and allocates the slot to the lowest numbered middle-level channel requesting service (secondary scheme). The Scheduler notes the still unserviced middle-level channel and proceeds to time slot three.
6. Time slot three is allocated for high priority. The slot is allocated to the remaining unserviced high-priority channel, and the channel's service grant bit is asserted. The Scheduler checks again at the end of the thread. All service grant bits

of high-level requested channels are asserted; therefore, all high-priority channels that requested have been allocated execution time. Under this condition, all service grant bits of the high-level serviced channels are negated. The Scheduler proceeds to time slot four.

7. Time slot four is allocated for low-priority channel; however, no low-level channel is requesting service. Priority is passed to the high level, but no high-level channel is requesting service; therefore, priority is passed again, and service is granted to the remaining middle-level channel which requests service. This channel's service grant bit is asserted. The Scheduler checks again at the end of the thread. All grant bits of middle-level requested channels are asserted; therefore, all middle-priority channels have been allocated execution time. Under this condition, all service grant bits of the middle-level serviced channels are negated. The Scheduler proceeds to time slot five. Meanwhile a low priority channel requests service.
8. Time slot five is allocated for high-priority channels, but there are no more requests from high-priority or middle priority channels. The single low-level channel which required service is granted time slot five. Once serviced, the channel's service grant bit is asserted. Next, the service grant bit is negated (no more requests of low priority level channels).
9. The Scheduler resumes with the fixed-priority sequence on time slot six; however, no channels are requesting service. The Scheduler returns to time slot one and waits for requests.

67.3.4.3 Time slot latency

Latency is the amount of time between a service request and the beginning of service on that channel. The following factors affect latency:

- Number of active channels
- Number of channels on a priority level
- Number of available time slots on a priority level
- Number of microcycles required to execute a thread of a Function
- Number of SDM accesses during execution of a Function thread
- eTPU clock frequency

Each time slot may require a different number of microcycles, depending on the thread of a Function to be executed. This variation is shown in the figure below.

For more details on latency evaluation, see Estimating Worst Case Latency.

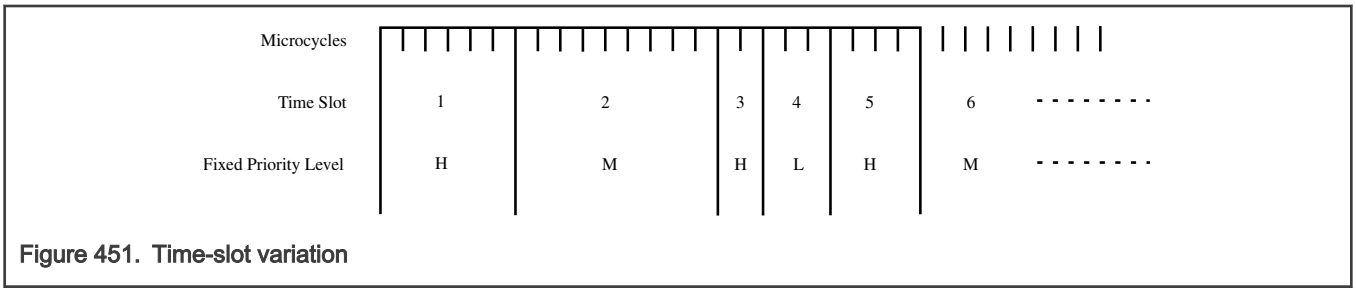

Figure 451. Time-slot variation

67.3.5 Parameter sharing and coherency

SDM can be concurrently accessed by Host and Microengines (two in a Dual eTPU Engine system). In general, there is no guaranteed order by which a group of parameters is accessed, which may lead to a lack of internal consistency if two or more related parameters are read when only part of them is updated.

eTPU provides mechanisms to guarantee parameter coherency. The most generic mechanisms for Host-eTPU coherency, suitable for any number of parameters, are:

- the use of Transfer Service Thread mechanism.
- the mailbox (or "software semaphore") mechanism.

These mechanisms, described in Multiple parameter coherency methods, use microcode to transfer parameters from temporary buffers in SDM to their definitive locations (or vice-versa). These methods have the disadvantage of wasting processing and code memory resources.

eTPU also provides a **Coherent Dual-parameter Controller - CDC** - mechanism. It is used by Host to coherently transfer pairs of parameters from/to a parameter buffer located on SDM to/from the locations on SDM where parameters are accessed directly by the channels. Coherency is guaranteed by SDM access arbitration. Although limited to two parameters only, it has lower latency and wastes no microengine resources[9]. CDC usage is described in Coherent Dual-parameter Controller (CDC).

For parameters shared by both Engines, eTPU provides **Hardware Semaphores**. Coherency is assured given the semaphores are used to prevent concurrent access to the changing parameters. Microengine can request semaphores using specific microinstructions (see Semaphore Operations). Hardware Semaphores are described in detail in Hardware Semaphores.

Neither Host nor CDC have access to the hardware semaphores, but they can be combined with microcode transfer mechanisms if Host must coherently access parameters which are also shared by both Engines.

In order to ensure coherent access to a group of parameters by two or more contenders, **each contender must have atomic access** to the shared parameters. Atomicity conditions are discussed in Host side atomic access and Microengine Side Atomic Accesses.

67.3.5.1 Host side atomic access

Host side atomic accesses can be achieved by either of following ways:

- For one parameter, the SDM should be accessed by 32-bit-wide data transfers to ensure coherency
- For two parameters only, using the Coherent Dual Parameter Controller.
- Indirectly, for any number of parameters, by requesting microcode to coherently access SDM in its behalf. The host side atomicity problem becomes, then, a microengine side atomicity problem. Some methods that use this approach to achieve coherency are described in Multiple parameter coherency methods.

67.3.5.2 Microengine Side Atomic Accesses

67.3.5.2.1 Microengine Single Parameter Atomicity

SDM should be accessed by 32-bit-wide data transfers to ensure atomicity for 32-bit parameters. This applies either to Host-Microengine coherency or Microengine-Microengine coherency in a dual eTPU Engine system.

67.3.5.2.2 Microengine Dual Parameter Atomicity

Microengine has the ability to access two parameters coherently in back-to-back accesses, at random addresses: once it accesses SDM, it has priority over Host for another access in the next microcycle (see SDM arbitration). Note that it applies **only to Microengine-Host** coherency. For Microengine-Microengine coherency in a dual eTPU Engine system, one must use Hardware Semaphores (see Hardware Semaphores).

Microengine dual back-to-back accesses are guaranteed to be atomic in relation to Host accesses or Coherent Dual-parameter Controller, regardless of semaphore usage: Host or CDC accesses cannot break-up a back-to-back Microengine access, neither Microengine can break a CDC transfer, due to the SDM arbitration mechanism described in SDM arbitration.

Atomicity is not guaranteed if microengine enters halt state in the middle of a back-to-back access (see Microengine Halt State): Host can access SDM while microengine is halted in the middle of a back-to-back access.

67.3.5.2.3 Microengine Side Multiple Atomicity

Hardware Semaphores must be used for Microengine-Microengine coherency (more than 1 parameter) since two or more accesses from one Microengine are not atomic with respect to the other.

[9] A microengine access to the SDM in the moment CDC is performing the transfer may suffer a maximum of two wait-states.

For multiple Microengine-Host coherency, the software methods described in Multiple parameter coherency methods, or similar ones, must be used. Some of these methods rely on the fact that parameter access of a thread is atomic in relation to another thread in the same Engine, since a thread cannot be suspended (preempted).

For 1 parameter coherent access, or dual parameter coherency between only one Microengine and Host, the alternatives shown in previous sections apply.

67.3.5.3 Coherent Dual-parameter Controller (CDC)

Dual-parameter coherency is supported by a Coherent Dual-parameter Controller hardware (CDC), which contends with microengine for SDM access. CDC atomically transfers, upon Host's command, two parameters from one area of the SDM to another. One area is a temporary (buffer) area, where the two parameters are directly read or written by the Host. This temporary area has to begin in an SDM address multiple of 2 words, and the two parameters must be sequential. The other area is the channel parameter area where the microcode normally accesses the parameters, usually with the channel relative address mode (see SDM Addressing Modes). In this area, the parameters transferred by CDC don't have to be sequential. A transfer from the temporary area to the channel area, when the Host sends data to the channel, is called a **write transfer**. Inversely, in a **read transfer** the parameters are copied from the channel area to the temporary area (channel to Host).

Coherency is guaranteed by the SDM access contention rules implemented in the SDM arbiter (see SDM arbitration). CDC transfers are coherent in respect to the two Engines, so the target parameters in the channel area may be shared by channels on them both. During CDC operation, the Host may suffer from 3 up to eTPU clocks wait states[10], and the Microengine(s) may suffer up to 2 microcycle wait-states[11]. CDC accesses are atomic with respect to Microengine(s) accesses to the SDM. Even when neither engine is in TST, CDC may suffer up to 4 eTPU clock internal wait-states from SDM arbiter, meaning 9 wait-states to Host, so that it does not break atomic back-to-back accesses from microengine(s). CDC also cannot break TST preload accesses. Host can initiate CDC back-to-back transfers: there is no need of idle cycles between two transfers.

NOTE

SDM memory error detection and correction does not affect the number of wait-states to host due to CDC (see Memory error support) .

CDC can be used to atomically fix SDM soft errors . For more details, see Error fixing .

67.3.5.3.1 CDC programming

The Coherent Dual-parameter Controller Register (see eTPU Coherent Dual-Parameter Controller Register (CDCR)) is used to configure and initiate CDC transfers between the temporary area and channel parameter area. Host asserts STS bit in order to start the data transfer. CDC then contends for the SDM and starts the transfer. When the data transfer is complete, STS returns to 0. Host receives wait-states for writing STS = 1 while CDC contends for SDM and during the transfer. The write access ends when CDC finishes the transfer. Host receives wait-states during the CDC transfer. If Host writes eTPU Coherent Dual-Parameter Controller Register (CDCR) with STS = 0 or does not write the STS byte, the CDC transfer does not occur. CDC programming can be summarized as follows:

1. If it is a write transfer, that is, from Host to channel, write the two parameters into temporary area.
2. Write CDCR[STS]=1 and the remaining CDC programming parameters: parameter width (32 or 24 bits, field PWIDTH), transfer direction (read or write, field WR), temporary parameter area base address (field PBBASE), and the absolute addresses of the parameters to be transferred (concatenation of the fields CTBASE and PARM0/1).
3. If it is a read transfer -- that is, from channel to host -- read the two parameters from the temporary area into Host memory/registers.

[10] The maximum number of Host wait states on CDC occurs when both microengines overlap their TSTs, delayed 3 eTPU clocks from each other.

[11] One microcycle takes two eTPU clocks. Microengines get wait-states in multiples of microcycles, while Host and CDC wait-states are multiples of eTPU clocks.

67.3.5.4 Hardware Semaphores

eTPU provides Hardware Semaphores accessible by the Microengine only. It is the responsibility of the application to ensure proper use of the semaphores (i.e., agree upon a specific semaphore and use it properly, to ensure coherency).

The eTPU microinstruction set has support for locking and freeing the semaphores, described in Semaphore Operations, and this is the only way to access them.

There are four semaphores available, which reduces the amount of collisions by assigning unrelated data transfers to different semaphores. Semaphores are used for parameters which can be shared by channels in different Engines, and for Engine-to-Engine synchronization. Semaphores are also the only way to ensure coherent access to parameters shared between the two Microengines.

Attempting to lock one semaphore (even not successfully) frees the other locked by the same Engine, ensuring one can lock just one semaphore at a time. That prevents deadlock conditions between the two Engines.

Microcode END command or Engine being in idle state (no thread executing) automatically releases all semaphores from one Engine side, even if a semaphore lock is done in parallel. However, it is recommended to write the microcode in a way which locks semaphores for the shortest required period, and frees them without waiting for the END command, to improve the performance of the other microengine. Semaphores are free after reset. An Engine can only free a sempaphore locked by itself.

Semaphore lock requests are always **non-blocking**, in the sense that they do not suspend the requester in case the semaphore is already locked. The semaphore status after the lock request - indicating if it was successfully locked or not - must be tested through the SMLCK microengine branch condition (see Branch conditions).

67.3.5.5 SDM arbitration

Up to four entities can access SDM:

- Two Microengines (in a dual eTPU Engine system)
- The Coherent Dual-parameter Controller (CDC)
- The Host CPU (direct memory-mapped access)

The following rules specify the access priorities for contended access. They have dual parameter access atomicity, but only between the microengine and CDC (not Host accesses through bus).

1. Microengine accesses from the two eTPU Engines are interleaved between each other, but not with Host or CDC accesses;
2. The eTPU microengine(s) gives priority for SDM accesses to either the Host CPU or the CDC under any of the following conditions:
    a. The microengine has completed accessing the second parameter in a back-to-back SDM access.
    b. The SDM was not accessed during the last arbitration slot for the microengine and the host does not loose the access to the other engine in the current arbitration slot
    c. CDC is transferring data, after its first (read) access. Note that the CDC can be in middle of a data transfer of another pair of parameters, unrelated to the ones that microengine tries to access.
3. The eTPU microengine takes priority for SDM accesses under either of the following conditions:
    a. the Host CPU or CDC has done a data transfer during the last access arbitration slot for the engine. Also, the Host CPU does not hold a pending access against the other eTPU microengine.
    b. the microengine is arbitrating for the access of its second parameter in a back-to-back access. All pairs of back-to-back parameter accesses are coherent with respect to Host and CDC (not to the other microengine).

The direction (read or write) of any individual access by Host or microengine is irrelevant to the arbitration. The use of Normal or PSE SDM area by the Host is also irrelevant to the arbitration.

[12] If microengine tries to access the SDM in the following microcycles, the third and fourth consecutive accesses are considered the first and second of a new back-to-back dual access.
[13] The microengine access slot is between its own T4 and T2 edges (see Microcycle and I/O timing).

The first parameter preloading in a TST is considered first access by the arbiter, regardless of any access made at the END microinstruction of the previous thread, that is, the last access of a thread and the first preload are never considered a back-to-back access. On the other hand, the TST preload accesses are considered back-to-back and are, therefore, atomic with respect to Host or CDC.

NOTE

The Zero SDM operation (see Zero SDM Operation) is considered an SDM access for arbitration purposes both on writes and reads; the fact that read SDM data is discarded is irrelevant for arbitration.

67.3.6 Enhanced Channels

Enhanced Channels comprise hardware support for input digital signal processing and output signal generation. Each Channel is associated with one input and one output signal. Enhanced Channel logic is combined with Function microcode (and optionally Angle Mode logic) to implement Channel I/O functionality.

eTPU's Enhanced Channels are capable of **dual action**, meaning that each channel logic can handle two events at different times and/or cause two separated actions - these actions and events can be mutually dependent (with the first either blocking or enabling the other), or both independent, depending on the programmed **Channel Mode**.

Each Enhanced Channel contains event logic containing two **Event Register sets**, each set supporting one input and/or output action, the pair implementing dual action support. Each Event Register set contains two 24 bit registers: Match and Capture. The **Match register** holds the pending match value which is compared against one of the two time bases by an equal-only/greater-equal comparator. The **Capture register** captures one of the two time bases as a result of a Match or Transition detection. Service Requests are issued on particular combination of match and capture events, defined by the selected Channel Mode.

In the context of the eTPU channels, a **Match** is a comparison between a time base value and a channel Match register. If those two values are coincident, or the time base value is greater than the value of the Match register, a **Match Event occurs**. Depending on the channel mode of operation and current state of the channel logic, the match event may be recognized, i.e., change the state of the channel, or be ignored. A match event recognized by the channel logic is called a **Match Recognition**. Match Recognitions can cause, also depending on Channel Mode and current state, the channel to request service, configuring a **Match Service Request**.

eTPU uses two kinds of comparator to assert a Match Event: an **Equal comparator**, in which both the Match Register and the value of the selected time base must match exactly, and a **Greater-Equal comparator**. The Greater-Equal comparator considers any time base value between the range [N : N+0x800000-1] as a valid match against the value of N in the Match Register, even when the value N+0x800000-1 wraps around the point of origin (0x0). See the following figure for an illustration of the matching values on a Greater-Equal comparator.

The second source of events for the eTPU channel is a **Transition** detected at the corresponding channel's input signal. Two distinct Transition detections can be programmed individually for each channel, allowing recognition of all possible combinations of edge detection. It is also possible to check the sampled state of an input signal upon the occurrence of a Match: the sampling of the expected value is treated as a Transition, even if the input signal did not necessarily toggled at the time of the Match, or at any time at all.

Like Match Events, **Transitions Events** may or not be recognized by the channel logic. When they are, a **Transition Detection** occurs. As well as Match Recognitions, Transition Detections can issue a Channel Service Request, depending on Channel Mode and current state.

Transition Detections and Match Recognitions are sometimes simply called Transitions and Matches throughout this document, for short.

Input and output signals can be processed separately by the channel logic and microcode, and can also be combined such that Matches and Transitions are used to cause **output signal actions**. The output signals can also be directly controlled by microcode. Many event combinations are allowed for a channel, given the possibility of configuring pairs of matches and transitions for the dual action logic, where each event is able to block or enable the next one. There is a full set of Channel Modes described in Channel Modes, exploring all the capabilities mentioned here.

Each channel has its own set of registers and flags. They are selected, and made accessible to the Microengine, according to the value written into the microengine **CHAN Register** that points to the desired channel . Every time the CHAN register is written, even if with the same previous value, a channel is selected and its flags and registers are updated. For further detail, see the Channel Selection Register-CHAN topic in the General Channel Registers section .

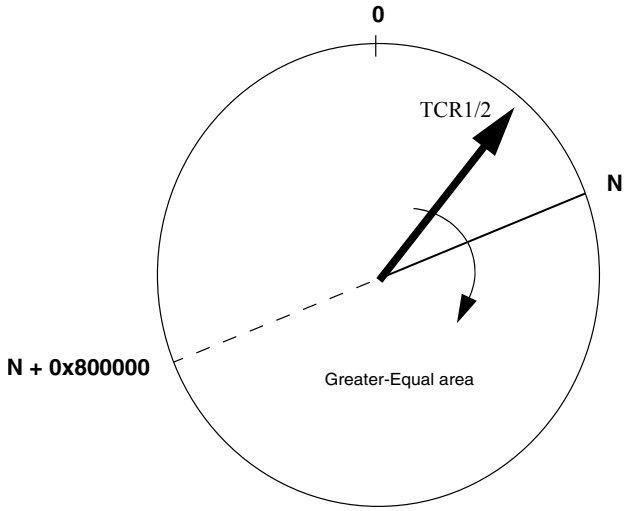

Figure 452. Greater equal comparator

Beyond the request of services due to the signal and timing internal to each channel, one eTPU channel microcode can explicitly request service from another channel through the microengine **LINK Register**. A microcode write to the LINK Register asserts a service request to the channel whose number matches the contents of LINK. See Channel link for a complete description of this mechanism.

These service requests originated in the eTPU Enhanced Channels (either time base match, input signal transition, or link service request) result in a call to the corresponding channel service routine, which is the sequence of microinstructions that is called a **Thread**. For further detail, see Functions and threads.

In addition to Event Logic, each Channel has an Output Buffer Enable signal, controlled by microcode, and an Enhanced Digital Filter, which eliminates spurious glitches on input pin signal. See the chip-specific eTPU information for how the Output Buffer Enable signal is controlled.

A high level diagram of Channel logic and registers is shown in the following figure.

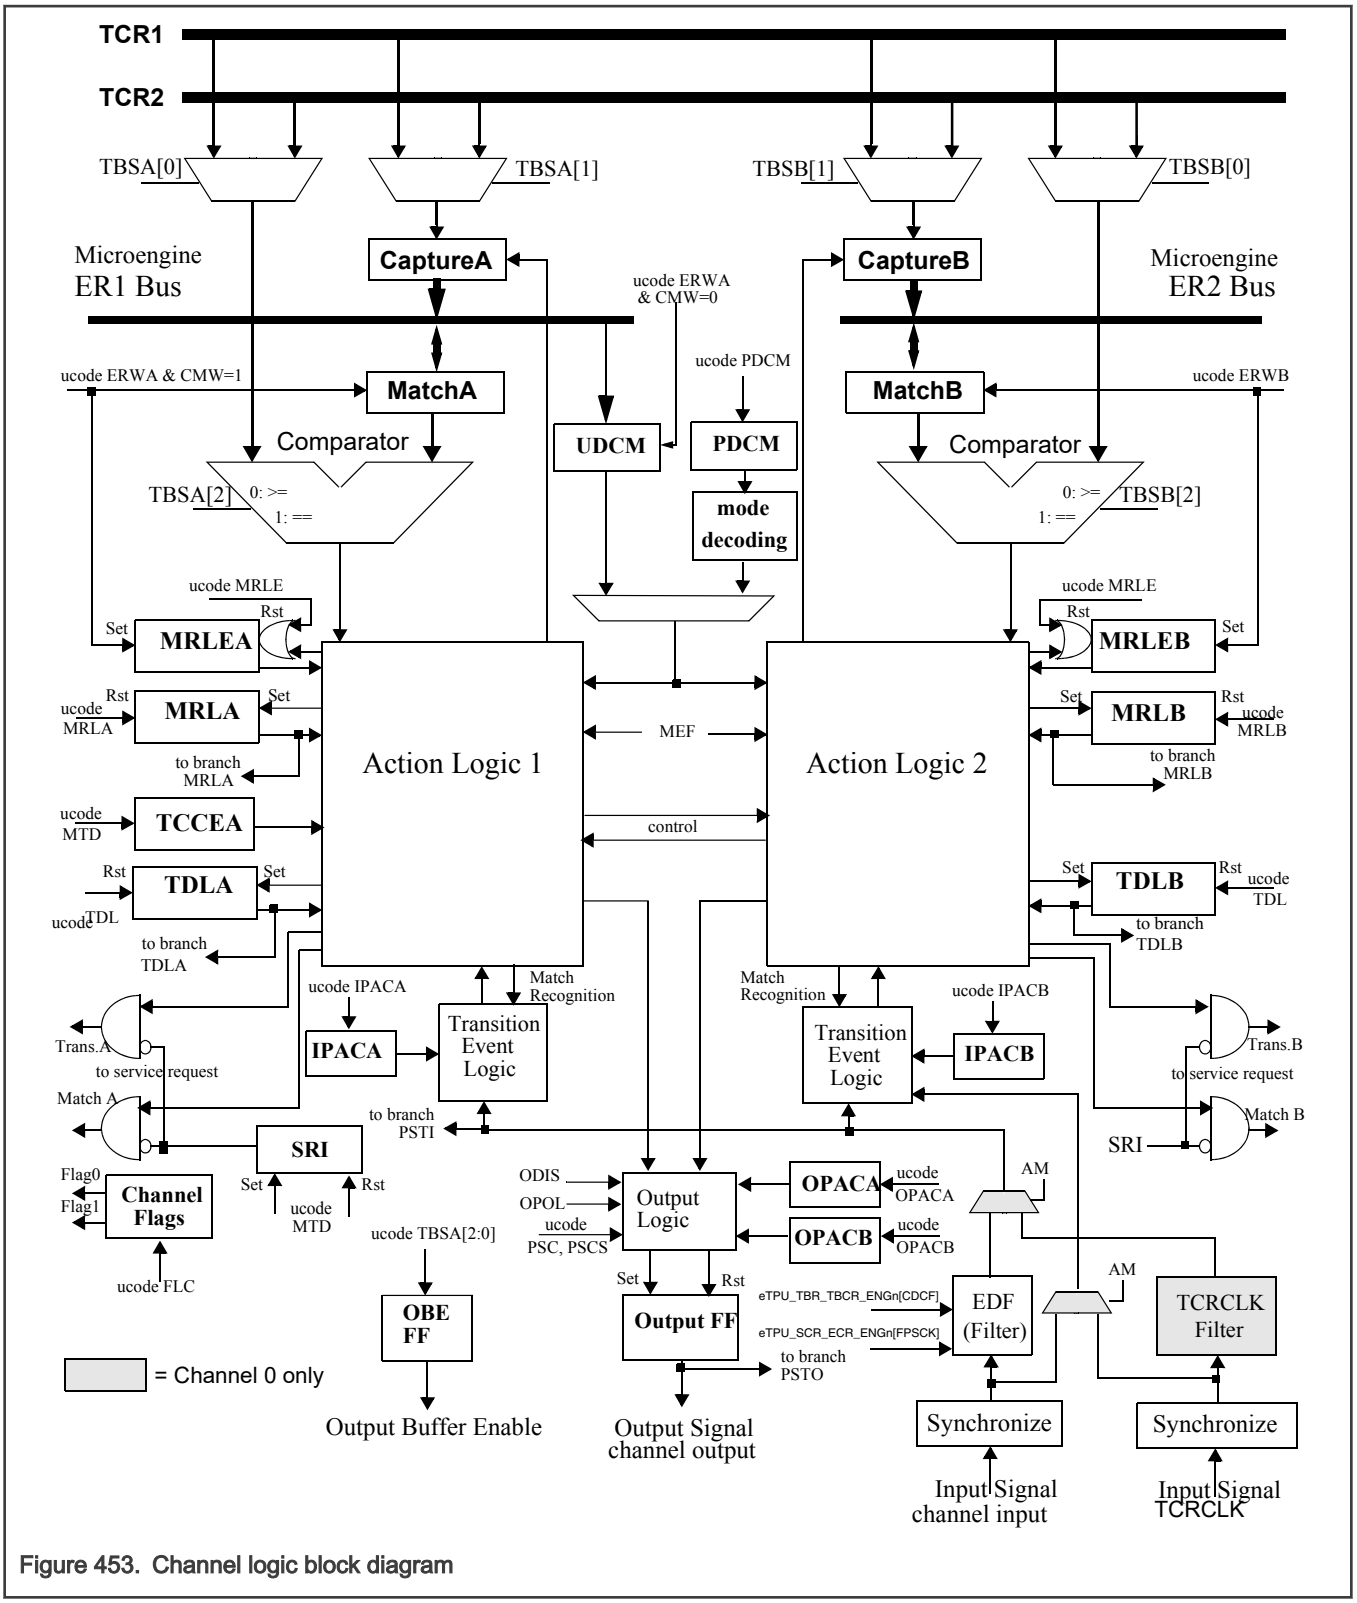

Figure 453. Channel logic block diagram

67.3.6.1 Channel registers and flags

Channel configuration and control registers can be divided in the following groups:

- **Host Configuration and Control registers**, which define channel Function and parameter allocation in SDM, input signal filtering, manage Host interrupts, and are used for Host Service Requests; they can only be accessed by Host, except for the Function Mode bits which can be also tested by microcode.
- **Event Registers**, which can only be accessed by eTPU Microengine, through dedicated Channel Control microinstruction operations (see Channel Control and Configuration Microoperations); these registers are directly used to implement channel functionality, and include channel event status latches which can be directly tested by Microengine branch instructions.
- **Pin Control registers**, which basically define pin state and transition polarity (but not input signal filtering); they are accessible only by dedicated Channel Control microinstruction operations.
- **Link registers**, which implement the channel link mechanism that allows one channel to request service to another one; they are accessible only by microinstruction operations.
- **General Channel registers**: CHAN, SRI, Flag0/1, PDCM, UDCM.

Most of those registers are channel exclusive, i.e., there is one copy of them for each channel. Microcode can access registers from only one channel at a time. The Channel Selection (CHAN) register (see Channel Selection Register - CHAN), accessible only by microcode, defines the channel whose registers are being accessed, with exception of link register and function mode. CHAN register assumes the value of the channel to be serviced at the beginning of TST.

The Service Request Inhibit - SRI - register controls the generation of Service Requests on matches and transitions, also affecting channel logic behavior. For a full description see SRI - Match/Transition Service Request Inhibit Latch. Flag0/1 are used to select channel service threads based on channel software state. See Flag1,Flag0 - Channel "state resolution" flags for more details.

Host Configuration and Control registers are described in Channel Configuration Control memory map and registers.

Time Base configuration is common to all channels, and described in Time bases. Time Base selection for matches and captures, however, is individual to each channel, and is part of the Event Registers.

Link registers are described in Channel link.

The following sections describe the Event Registers and Pin Control registers.

67.3.6.1.1 ER - Event Registers

Each channel contains two identical Event Register sets, named ERA and ERB, corresponding to the two actions supported. Each Event Register set contains:

- a 24-bit Match register (Match A or Match B), which holds a match value. This value is compared against the selected match time base (TCR1 or TCR2).
- a 24-bit Capture register (CaptureA or CaptureB), which samples the selected capture time base (TCR1 or TCR2)
- a Time Base Selection register (TBSA or TBSB)
- a Match Recognition status flag (or latch) (MRLA or MRLB)
- a Match Recognition Enable latch (MRLEA or MRLEB)
- a Transition Detection flag (or latch) (TDLA or TDLB)
- a Transition Continuous Capture enable (TCCEA only)

ERA and ERB are associated with the first and second events in double action modes, not necessarily in that order. The order of Match events associated with ERA and ERB depends on the programmed channel mode, the MatchA and MatchB values, and the timebases selected by TBSA and TBSB. Similarly, the order of Transition events associated with ERA and ERB depends on the programmed channel mode, and the transition detection selected by IPACA and IPACB.

These registers are directly or indirectly accessed by the microcode. TBSA and TBSB registers are defined in TBSA and TBSB - Time Base Selection Registers. The other registers are explained in Match Recognition and Transition detection and Time Base Capture.

Access to the Event Registers is qualified by the channel currently selected by the microengine (i.e., the channel value currently in the CHAN register). During the channel transition period (automatic CHAN assignment), or whenever CHAN is written by microcode, Capture values of the new selected channel are sampled into Microengine registers ERTA and ERTB, therefore

becoming visible to the microcode. At the same time, updated values of MRLA, MRLB, TDLA and TDLB are sampled into the branch logic, making the register values and the flags coherent with respect to each other and with the thread selected by the Scheduler. [14]

NOTE

The Function Mode bits are also sampled from the Host interface on Time Slot Transition, so that they remain constant to microengine even when Host changes them.

During service, the microcode can access updated values of the Event Registers of any channel by writing the channel number to CHAN. Writing CHAN with the same value (CHAN := CHAN) updates ERTA and ERTB with the new captured values, the branch logic with updated MRLA/B and TDLA/B flags. Writing CHAN with a different value does the same with the values from the newly selected channel.

Match values are also accessed through ERTA and ERTB Microengine registers, which are copied to/from the channel MatchA and MatchB registers by specific microinstruction operations.

Microcode writes to the flags and selections (MRLA/B, TDLA/B and TBSA/B) are immediately effective to the channel. The MRLA/B and TDLA/B branch conditions are also immediately reset when their correspondent flags are reset by microcode. Match registers are indirectly written by microcode through ERTA/B. MRLEA/B is unconditionally asserted when respective Match register is updated from ERTA/B, and its negation is immediate.

The following table summarizes Event Registers accesses.

Table 387. Event Registers microcode accesses

Register	Access type	Sampled from channel	Update to channel	Microcode fields[1]	Reset value[2]
CaptureA, CaptureB	read through ERTA/B	to ERTA/B on CHAN assignment	no	T2ABD	n.a.
MatchA, MatchB	read and write through ERTA/B	to ERTA/B by microcode	from ERTA/B by microcode	ERWA, CMW, ERWB, T4ABS	n.a.
MRLEA, MRLEB	write to 0 (negate) directly; write to 1 (assert) upon MatchA/B update from ERTA/B	no	immediate	MRLE, ERWA, ERWB	0, 0
TBSA, TBSB	write only	no	immediate	TBSA, TBSB	000, 000
MRLA, MRLB	flag test on branch, write to 0 (negate) only	on CHAN assignment	immediate	BCC (test) MRLA, MRLB (reset)	0, 0
TDLA, TDLB	flag test on branch, write to 0 (negate) only	on CHAN assignment	immediate	BCC (test) TDL (reset)	0, 0
TCCEA	write only	no	immediate	MTD	0

[14] The thread selected is determined by the Entry Point which, in turn, is determined partially by the channel latches. See Entry Point address generation.

1. See Microinstruction Set.
2. n.a. means that value of the register is undetermined after reset.

67.3.6.1.1.1 MatchA and MatchB Registers

MatchA and MatchB registers hold a match value to be compared against the selected channel time base. A match value can only be written into the Match register by microcode, through ERTA/B microengine registers (see Write Channel Match and UDCM Registers). Microcode can also read the Match register as a special T4ABS source operation, when T4ABS=0101, and the source for T4ABS is selected from the second register set. In this operation, MatchA/B registers are copied into ERTA/B registers (see Selecting sources and destination). For more information on time base matches, see Match Recognition.

67.3.6.1.1.2 CaptureA and CaptureB Registers

CaptureA and CaptureB registers capture the selected channel time base. CaptureA/B registers cannot be directly written or read by microcode. During the Time Slot Transition (TST) or during CHAN assignment, CaptureA/B registers are copied into ERTA/B microengine registers. For more information, see Transition detection and Time Base Capture.

67.3.6.1.1.3 TBSA and TBSB - Time Base Selection Registers

TBSA/B are 3-bit registers which have the following effect on channel configuration:

- Selection of the timebase (TCR1 or TCR2) to be compared against the match values in MatchA and/or MatchB registers.
- Selection of the timebase (TCR1 or TCR2) to be captured in the CaptureA and/or CaptureB registers by a match or transition detection event.
- Selection of comparator mode to be used with MatchA and MatchB registers: equal-only or greater-equal.

After reset TBSA/B are 000. The following table shows values of TBSA and TBSB for configuration selection. Note that the time base selection for capture is independent of the time base selected for matches.

Table 388. TBSA/B Programming States

TBS bit	2	1	0
bit value	Comparator selection	Capture time base selection	Match time base selection
0	greater or equal	TCR1	TCR1
1	equal-only	TCR2	TCR2

TBSA/B are written through the microcode fields TBSA/B (see Comparator and Time Base Selection). Note that microcode field TBSA is also used to control the OBE pin control register (see Pin Control Registers), which is separate from the TBSA register.

67.3.6.1.1.4 MRLA/B - Match Recognition Latches

See MRLA/B - Match Recognition Latches.

67.3.6.1.1.5 MRLEA/B - Match Recognition Latch Enable

See MRLEA/B - Match Recognition Latch Enable.

67.3.6.1.1.6 TDLA/B - Transition Detection Latch

See TDLA/B - Transition Detect Latches.

67.3.6.1.1.7 TCCEA - Transition Continuous Capture Enable

See TCCEA - Transition Continuous Capture Enable.

67.3.6.1.2 Pin Control Registers

Pin Control Registers are replicated one per channel, accessed only by microcode and qualified by the CHAN register in the same way as Event Registers.

The following table lists Pin Control Registers, explained in following subsections, and their accesses.

Table 389. Pin Control Registers microcode accesses

Register	Access type	Sampled from channel	Update to channel	Microcode fields[1]	Reset value
IPACA, IPACB	write only	no	immediate	IPACA, IPACB	000,000
OPACA, OPACB	write only	no	immediate	OPACA, OPACB	000,000
PSTI	flag test on branch	no	no	BCC	0
PSTO	flag test on branch, write	no	immediate	BCC (test) PSC, PSCS (set)	0
OBE[2]	write only	no	immediate	TBSA values 1000,1001	0 (negated)
PSS	flag test on branch	on CHAN assignment	no	BCC	n.a.[3]
PRSS	flag test on branch	on CHAN assignment	no	BCC	n.a.[4]

1. See Microinstruction Set.
2. Although this register exists for code compatibility reasons, OBE functionality is not available on this chip.
3. PSS is PSTI or PSTO sampled on CHAN assignments and at thread start.
4. PRSS is PSTI sampled on channel service request.

67.3.6.1.2.1 IPACA/B and OPACA/B - Input and Output Pin Action Control Registers

These registers determine the transition detections and output pin actions which takes place due to match or transition events. Each field is three bit wide. After reset, the IPACA/B and OPACA/B registers are set to 000. IPACA and IPACB registers are mutually independent and have identical encoding, and so do OPACA and OPACB. The table below shows IPAC and OPAC encoding. Note that transition detections are independent from the output actions, but some options of output actions are triggered by transition detections. Output actions can also be triggered by Matches. For a detailed definition of Transition Detections, see Transition detection and Time Base Capture.

IPACA/B define the Transition events treated by channel logic. Although the name "transition" is generically used for the transition detections, IPAC options 100 and 101 do not really detect transitions: they actually sample the state of the input signal at the occurrence of the corresponding Match (Match A used for IPACA, Match B used for IPACB).

Table 390. IPACA/B and OPACA/B Encoding

Value	IPAC meaning	OPAC meaning
000	Do not detect transitions	Do not change output signal
001	Detect rising edge only	Match sets output signal high
010	Detect falling edge only	Matchsets output signal low
011	Detect either edge	Match toggles output signal
100	Detect input signal = 0 on Match	Transition sets output signal low
101	Detect input signal = 1 on Match	Transition detection sets output signal high
110	reserved	Transition detection toggles output signal
111	n.a.	n.a.

67.3.6.1.2.2 Output Pin Control Logic and Pin State Output Register - PSTO

The output signal control logic uses OPACA/B, the Pre-defined Channel Mode (PDCM) and the User Defined Channel Mode (UDCM), and the microcode Pin State Control (PSC and PSCS) fields. It is responsible for setting the Pin State Output (PSTO) register to the specified logic value required by microcode, by input events, or by Match A and/or Match B events. The PSTO register stores the driven pin state determined by the Pin Control logic. The Output Buffer Enable signal, if used at MCU integration, must be set by microcode (using TBSA field) to make the pad propagate the PSTO register output to the actual pin.

PSTO register output also goes to the microengine branch logic, enabling branching on the driven pin state (see OBE - Output Buffer Enable control latch). PSTO is set to 0 on reset.

The PSC and PSCS microcode fields are used for setting the PSTO register to a fixed value, or to the value specified by the OPACA or OPACB microcode field, as shown in the following table.

Table 391. PSC and PSCS encoding

PSC	Output pin action
00	Force pin state according to OPACA (PSCS=0) or OPACB (PSCS=1).
01	Force pin high.
10	Force pin low.
11	Do not change pin state.

See Channel Control and Configuration Microoperations for details.

On occurrence of match recognitions or transition detections, the pin control logic sets PSTO value according to the event number (Match A/Transition A or Match B/Transition B) and the contents of OPACA/IPACA or OPACB/IPACB registers. There are cases in which two match or transition events may occur at the same time, each of them trying to force a different pin action. The resolution of the selected match event which sets the value depends on the Pre-defined Channel Mode (PDCM) register and the User Defined Channel Mode (UDCM). For details refer to Match/Transition Pin Action Conflict Resolution.

67.3.6.1.2.3 PSTI and PSS - Pin State Input and Pin Sampled State Registers

During the time slot transition period, or whenever the CHAN register is written by microcode, the filtered[15] input signal PSTI or output signal PSTO (selected by the ETPD field in C*a*CR_ENG1 and C*a*CR_ENG2) is sampled into the branch logic as the PSS flag (see Conditional/unconditional branch). The microcode can then branch on either the currently driven (PSTO) or input (PSTI) pin state, or on sampled pin state (PSS, which is stable as long as CHAN does not change).

NOTE

If a transition occurs simultaneously (after the filter) with the CHAN assignment, PSS samples the new pin value. Therefore, if TDLA/B is cleared simultaneously with the assignment CHAN := CHAN, the occurrence of a transition at this very moment can still be tested with PSS.

67.3.6.1.2.4 PRSS - Pin Request Service Sample

Channel logic can, depending on its state and programmed mode, request service to the eTPU microengine (see Functions and threads) . When the channel logic issues a service request, the filtered input signal PSTI is sampled into an internal channel flag PRSS . There is one such PRSS flag for each channel (see Pin Control Registers) . Channel PRSS keeps its value until all its service request sources are cleared and until a new channel service request rises .

NOTE

Only channel service requests update PRSS. It is not updated by host service requests (HSRs) or by link service requests. Moreover, a channel service request updates PRSS even if the channel is disabled (its CPR set to 0, see C*a*CR_ENG1 and C*a*CR_ENG2).

The channel PRSS flag is sampled into the branch logic as the PRSS flag (see Conditional/unconditional branch) during the time slot transition period, or whenever the CHAN register is written by microcode.

67.3.6.1.2.5 OBE - Output Buffer Enable control latch

OBE latch drives the Output Buffer Enable signal, which can be used to control the output signal pad driver. Channel output comes disabled from reset. If an Output Buffer Enable signal[16] from eTPU is used on MCU integration and a signal is desired to be output in a channel, OBE signal must be set by microcode. Microcode field TBSA is used to set/reset the Output Buffer Enable control when microcode field TBSA bit 3 is 1, according to the following table.

Table 392. TBSA Output Buffer control

microcode TBSA[2:0]	meaning when TBSA[3]=1
000	enable output buffer
001	disable output buffer
111	do nothing
other values	reserved

[15] The filter can be bypassed.
[16] There is one independent signal for each channel.

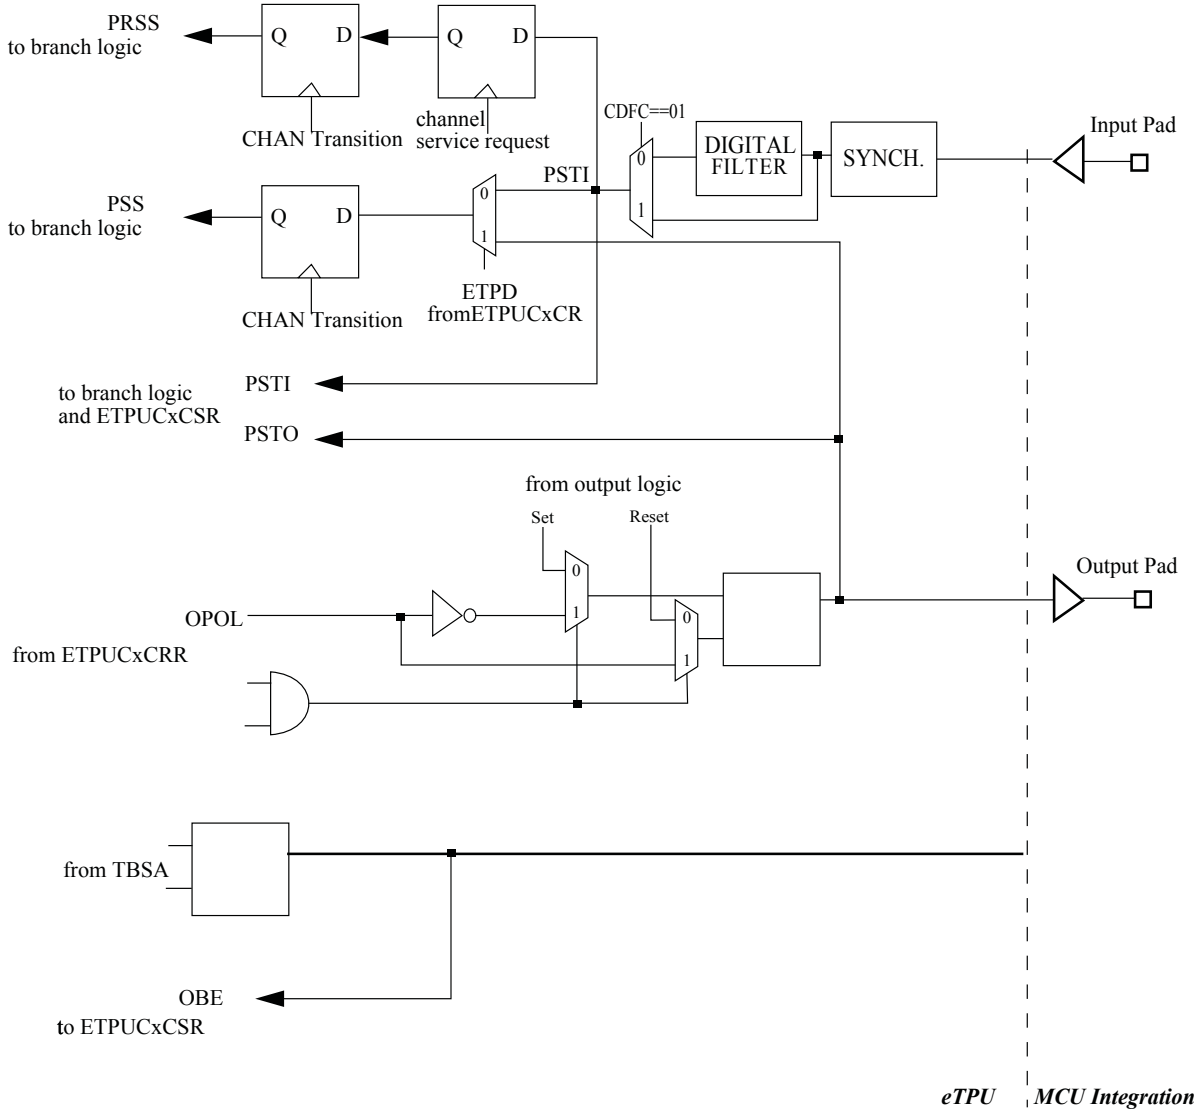

Figure 454. Pin State Input/Output Logic

67.3.6.1.3 General Channel registers

These registers control other aspects of channel logic. Except for CHAN, they are unique per channel. The following table summarizes the registers and access options.

Table 393. General Channel registers microcode access

Register	Access type	Sampled from channel	Update to channel	Microcode fields[1]	Reset value
CHAN	read/write	n.a.	n.a.	T4ABS, T4BBS, T2ABD	defaults to serviced channel at thread start
PDCM	write only	no	immediate	PDCM	1100 (sm_st)

Table continues on the next page...

Table 393. General Channel registers microcode access (continued)

Register	Access type	Sampled from channel	Update to channel	Microcode fields[1]	Reset value
UDCM	write only	no	from ERTA by microcode	CMW, ERWA	parameter value defined at integration
SRI	write only	no	immediate	MTD	1
Flag1, Flag0	branch flag test, write	no	immediate	BCC,FLC	0, 0

1. See Microinstruction Set.

67.3.6.1.3.1 Channel Selection Register - CHAN

CHAN is the register that holds the number of the channel that qualifies the context of most Channel Registers, including Pin Control and ER accesses, and is common to all channels in a same Engine.

When a thread begins executing, the contents of CHAN are automatically updated on Time Slot transition to the number of the channel to be serviced. Serviced channel is constant during channel servicing, but the selected channel can be changed any time by microengine writing into CHAN register.

Some microinstructions are affected by the serviced channel instead of CHAN. These are:

- Conditional branch using LSR (see LINK Register) or Function Mode (see C*a*SCR_ENG1 and C*a*SCR_ENG2).
- Negate channel flag LSR, Interrupt CPU and Data Transfer Request (see Channel Interrupt and Data Transfer Requests).

When CHAN register is written, accesses are qualified by the new CHAN register value from the instruction following CHAN assignment on, except CaptureA/B sampling into ERTA/B and Match register writing from ERTA/B (see CHAN assignment, Read Match and ERWA/B).

Writing CHAN (including with the same value, CHAN:= CHAN) updates ERTA and ERTB with the new captured values, the branch logic with updated MRLA/B and TDLA/B flags.

The following table shows the commands, flags and registers selected by the CHAN register value.

Table 394. CHAN-selected features

Feature used	Selected by CHAN
Channel-relative SDM access	YES
Branch using PSS, PRSS, PSTI and PSTO channel flags	YES
Branch using MRLA/B, TDLA/B, Flag0/1[1]	YES
Branch on all other conditions[2]	no
ERTA/B Value	YES
Configure (selected) channel	YES
Channel commands applied to: MRLA/B, TDLA/B, TBSA/B, IPACA/B, OPACA/B, PSC, PSCS, OBE, PDCM, MRLE, Flag0/1	YES
Channel command: set/reset SRI	YES

Table continues on the next page...

Table 394. CHAN-selected features (continued)

Feature used	Selected by CHAN
Channel command: write to Match registers (ERWA/B)	YES[3]
Channel command: read Match registers into ERTA/B	YES
Clear LSR	no
Channel interrupts and data transfer requests (CIRC)	optionally

1. In TPU, these conditions retained the old values.
2. See Branch Operations
3. If write Match (ERWA/B) occurs at the same time of a CHAN assignment, the channel which is target of the write is the one selected by the new CHAN value. See CHAN assignment, Read Match and ERWA/B.

67.3.6.1.3.2 PDCM - Predefined Channel Mode

PDCM determines the channel mode assigned to the channel. Channel mode defines much of the channel logic behavior, specially how matches blocks and enables transitions and vice-versa, as well as occurrence of time base captures and service requests based on matches and transitions. For a complete description see Channel Modes.

PDCM is a 4-bit register set by the microcode field of the same name (see Predefined Channel Modes), and cannot be read or tested in branch instructions. The table below relates the PDCM value with channel modes. The second column specifies the mnemonic used to reference the mode, introduced in Channel Modes Overview. There is one PDCM for each channel, initialized with 1100 on reset.

PDCM is also used to select the User Programmable Channel Mode . If this selection is made, the channel behavior is defined by the settings of the UDCM register (see UDCM - User Defined Channel Mode).

Table 395. PDCM encoding

PDCM	Channel mode
0000	em_b_st
0001	em_b_dt
0010	em_nb_st
0011	em_nb_dt
0100	m2_st
0101	m2_dt
0110	bm_st
0111	bm_dt
1000	m2_o_st
1001	m2_o_dt
1010	User Defined Channel Mode

Table continues on the next page...

Table 395. PDCM encoding (continued)

PDCM	Channel mode
1011	reserved
1100	sm_st[1]
1101	sm_dt
1110	sm_st_e
1111	n.a.[2]

1. This is the reset value, also compatible with TPU channel behavior.
2. This value is used as a neutral (do not change) value in the PDCM microinstruction field.

67.3.6.1.3.3 UDCM - User Defined Channel Mode

UDCM holds the control signals that define the channel logic behavior in terms of Match and Transition blocking and enabling, captures and service requests triggered by events . The register layout is defined in the figure below . The individual fields are defined in Channel Mode Logic and Event Flags . There is one UDCM register for each channel, which can be independently programmed.

UDCM can only be written into the Match register by microcode, through ERTA/B microengine registers (see Write Channel Match and UDCM Registers).

13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSR		MCAP	M1ET	M1EM2	M1BM2	M2BM1	M2BT	T1BM1	T2BM1	TBM2	T1ET2	TSR	TCAP

Figure 455. UDCM Register

67.3.6.1.3.4 SRI - Match/Transition Service Request Inhibit Latch

SRI blocks channel service requests due to the assertion of MRLA/B and/or TDLA/B. SRI does not affect recognition of Link Service Requests or Host Service Requests, neither MRLA/B or TDLA/B microcode branch tests nor Entry Table selection[17]. SRI is asserted during reset and is controlled by microcode field MTD.

To unburden the microengine, SRI asserted configures a channel "dumb" regarding the servicing of match and capture channel service requests. Even with SRI=1, TDLA/B and MRLA/B can still be asserted, and the level specified by the OPAC (Output Pin Action Control) registers will be output to the pin.

67.3.6.1.3.5 Flag1,Flag0 - Channel "state resolution" flags

Each channel has a pair of flags, simply called Flag0 and Flag1, that can be set/reset by microcode through microinstruction field FLC. FLC sets/resets Flag0/1 of the channel selected by CHAN. These flags can be tested by microcode, and are also used to resolve the microcode entry point for the channel service (see Entry Points"). Flag0 and Flag1 are, so, typically used for fast state resolution. FLC microinstruction field also allows Flag1,Flag0 to be copied from selected bits of P register high byte, which is also meant to be used to hold application state. Flag0 and Flag1 are both zero out of reset.

67.3.6.2 Match Recognition

The match operation is performed every microcycle by comparing the channel MatchA and MatchB registers against the value of the TCR bus specified for each match. TCR1 or TCR2 bus is selected according to TBSA and TBSB fields. Both results have effect on the next clock cycle (see Microcycle and I/O timing).

[17] In TPU, SRI also blocked TDL and MDL branches and enabled any transition to capture time base.

A Match A/B event is qualified by a set of match enabling conditions to the Match Recognition Registers MRLA/B. To recognize the match, the following match enabling conditions are required:

- For IPACA/B=0xx, Match Enable Flag (MEF), qualified by the channel currently being serviced must be asserted. For IPACA/B =1xx, Match A/B is always enabled (even during Time Slot Transition - TST), regardless the state of the Match Enable Flag (MEF). See MEF - Match Enable Flag for the conditions of MEF assertion.
- Match Recognition Latch Enable 1/2 (MRLEA/B) is asserted. A match event recognition may only occur if its corresponding MRLEA/B bit is set, which only happens upon a write to a channel match register by the microcode, copied from ERTA/B. MRLEA/B is negated when the respective match occurs or, in some double match channel modes, when a match for the other Match register occurs. It ensures that the greater-equal comparison will not cause additional matches[18].
- In selected modes (see Channel Modes), the particular conditions of MRL and TDL flags of the other event, i.e.:
  - MRLA, TDLA enable or block MRLB;
  - MRLB, TDLB enable or block MRLA.
- The respective MRL is negated.
- In selected modes (see Channel Modes), the state of its respective TDL flag.

If the Match A and/or Match B conditions are met, the channel immediately forces the pin state if specified by the appropriate OPACA/B registers (Output Pin Action Control 1/2) and, in some cases, by IPACA/B registers. Refer to IPACA/B and OPACA/B - Input and Output Pin Action Control Registers.

If both Match A and Match B events occur at the same time, with conflicting pin actions, the priority over the pin action is mode dependent. For further details on pin action resolution refer to Match/Transition Pin Action Conflict Resolution.

67.3.6.2.1 MRLA/B - Match Recognition Latches

MRLA/B indicate the recognition of a match event detected by the comparator. They can be asserted either on T2 or T4 (see Microcycle and I/O timing). Assertion of MRLA/B issues a match Service Request in specific channel modes, depending on previous events and state of SRI. After reset MRLA and MRLB are both negated.

When MRLA or MRLB is asserted, it may change the output signal level according to the Input and Output Pin Action Control registers (refer to IPACA/B and OPACA/B - Input and Output Pin Action Control Registers). Assertion of MRLA/B causes a capture of one or two time bases, according to the selected mode capturing scheme (see Transition detection and Time Base Capture)

A match recognition is self-blocking, regardless of Channel Mode: once MRLA (MRLB) has been asserted, it negates its associated MRLEA (MRLEB) register, preventing future match recognitions, until the associated match register is rewritten by microcode. The microcode has to enable new matches by updating the new match value in the MatchA (MatchB) register[19]. In addition, assertion of MRLA/B can block its twin MRLB/A, depending on the channel mode. In some double match blocking channel modes, Match A/B event blocks the occurrence of Match B/A in a "first win" scheme.

It is the transition from 0 to 1 in MRL that causes the Match actions, except the service request: apart from MRLEA/B negation(s) and service request, no action due to a Match occurs if MRL was already set to 1, even if the other MRL assert conditions are satisfied. However, if a Match and a microoperation negating its corresponding MRL occur at the same time, MRL negation by microcode overrides its assertion, but any dependable captures and pin action occurs anyway (if MRL was already negated before), and also the negation of MRLE(s) (the respective one and, in some channel modes, the other, regardless of MRL state before). Note that MRLE must have been set before (by writing a new Match value).

67.3.6.2.2 MEF - Match Enable Flag

MEF is a one-bit latch that is unique for all channels in an Engine.

MEF can selectively enable assertion of MRLA/B, depending on the IPACA/B field. For IPACA/B=0xx, MEF=1 enables assertion of MRLA/B for the scheduled channel during service. For IPACA/B=1xx, Match A/B is always enabled, regardless the state of the

[18] Microcode can also negate MRLEA/B.
[19] Before that, microcode should also negate MRLA (MRLB), otherwise an old match may be recognized by the scheduler and serviced as a new one

MEF, but it still depends on the other Match recognition conditions. Matches of channels not being serviced are never disabled by MEF.

MEF is not accessible by Microengine or Host. MEF is negated for two microcycles in the beginning of the time slot transition period. After two microcycles (plus wait-states) into TST, the ME bit in the entry point is copied to MEF to allow selective enabling of MRL for each thread (refer to Time Slot Transition). MEF is asserted unconditionally soon after a thread ends.

If a channel service needs to postpone a programmed match, MEF assures that microcode wins the race against match event after time slot transition (only for IPAC=0xx).

Note that a match event may be lost during the periods when MEF is negated only if:

- the match comparator is configured for "equal-only" behavior, and
- IPACA/B=0xx, and
- TCR increments at the rate of eTPU clock divided by 2 or faster.

When the comparator is configured as "greater-equal", the match event that occurred when MEF was negated may be recognized after MEF is asserted again, due to the "greater than" condition.

67.3.6.2.3 MRLEA/B - Match Recognition Latch Enable

MRLEA/B is negated upon the assertion of its respective MRLA/B. In blocking match channel modes it may also be negated together with the assertion of the twin MRLB/A. The MRLEA/B bits ensure that data captured due to the first match event will not be overwritten when MRLA/B is negated: due to greater-equal comparison, the match condition continues to be true, but should not cause another capture event.

In addition to negation by local match event, the microcode can negate both MRLEA and MRLEB, to block pending matches, and also MRLA/B, individually. This action will prevent future match events from the selected channel.

Writing the MatchA/B registers by microcode to schedule the next match values sets MRLEA and/or MRLEB and enables new matches. This setting overrides the MRLE negation conditions due to channel logic or microcode (see Channel Modes). By combining write to Match A/B with MRLEA/B negation microinstructions, the microcode can negate one MRLE while asserting the other.

NOTE

If the MRLE negation conditions continue after writing MatchA/B registers, the respective MRLE does not keep asserted. For instance, if MRL=1 and a match is programmed for a time value in the past during a thread with ME=1, then MRLE will be cleared soon after MatchA/B is written, even though a match does not occur (because MRL was already asserted, neither captures nor pin toggles occur).

When the match register is updated (with MRLE already asserted before) and field MRLA/B = 1 (no clear, see Clear Transition/Match Event Registers) and MRLA/B flag is zero, the eTPU behaves exactly as the TPU, that is: a match that comes concurrently with the rewrite of the match register, matching the old value, sets the MRL, as if the setting of the MRLE due to match register write had precedence over its clear by the match at that moment. After this simultaneous operation, the MRLE value stays at 1, and the captured time base value, if any, reflects the match value.

When the match register is updated (with MRLE already asserted before) and field MRLA/B = 0 (clear MRL, see Clear Transition/Match Event Registers) and MRLA/B flag is zero, the match captures will occur, the MRLA/B flag will keep negated, and MRLE will stay asserted. Special care must be taken when a match is reprogrammed on a channel running at T2/T4 timing, please see the details in the “T2/T4 Channel Timing” section.

67.3.6.3 Transition detection and Time Base Capture

Time Base Capture(s) occur when the value of a specified TCR is sampled into the CaptureA and/or CaptureB register. TBSA[1] and TBSB[1] select which TCR will be captured in CaptureA and CaptureB, respectively.

A capture event may occur due to either of the following events:

- The assertion condition of Match Recognition Latch (MRL), even if MRL is simultaneously negated by microcode
- The assertion condition of Transition Detection Latch (TDL), even if TDL is simultaneously negated by microcode.

- Any Transition Event specified by IPACA if both the Transition Detection Latch TDLA and Transition Continuous Capture Enable TCCEA are asserted.

A capture event occurs together with the assertion of MRL or TDL either on T2 or T4 positive edges, and captures the time-base value that caused the match, even if TCR1/2 increments concurrently with the assertion (see Microcycle and I/O timing). MRLA/B and TDLA may, depending on the channel mode, inhibit the capture of the second event's TCR into CaptureA/B. As a general rule, values captured by signal transitions are not overwritten by values captured by match events.

When the enable bit TCCEA is asserted, captures due to Transition Events also occur after TDLA is asserted . Those captures happen on transition events specified by IPACA, and the TCR value is saved into CaptureA register only .

The capturing scheme is defined by the Channel Mode programmed at register PDCM, or at register UDCM when User Defined Channel Mode is selected. For more information on mode-dependent capture schemes refer to Channel Modes.

67.3.6.3.1 TDLA/B - Transition Detect Latches

TDLA/B indicate detection of specific transition occurrences on a channel input signal. TDLA and TDLB assertion causes service request in single and double transition predefined modes, respectively. TDLB assertion does not cause Service Request in single transition predefined modes, and TDLA assertion does not cause Service request in double transition predefined modes. In single transition channel predefined modes TDLB can be asserted on the second transition, but does not generate Service Request. Yet on predefined modes, TDLB assertion is enabled only if TDLA is asserted to detect an ordered input signal double transition. All the restrictions above, however, may be overridden by using the User Defined Channel Mode. The IPACA and IPACB registers indicate the programmed edges of the first and second detected transition, respectively.

The sampling of a determined value (0 or 1) on the input signal due the occurrence of a Match is also treated as a "transition", depending on IPACA/B programming (see IPACA/B and OPACA/B - Input and Output Pin Action Control Registers). When using a channel mode where the transition1 is initially blocked and IPACA is programmed to detect such "transitions", the occurrence of a Match A only unblocks the transition after the sampling. It means that the transition on the first Match (IPACA configurations 100 and 101) is not effective on predefined modes where Transition A is enabled by Match A (m2_st, m2_dt, m2_o_st and m2_o_dt) or user-defined modes with UDCM bit M1ET asserted. A Transition A can still happen after the Match A, however, if MatchA register is reprogrammed without clearing MRLA.

TDLA/B assertion conditions initiates a capture event of one or both selected TCR buses. TDLA or TDLB transition event generates a Service Request, depending on channel mode, previous events and the state of SRI. For more information on service request scheme refer to Entry Point address generation" and Channel Modes.

Assertion of TDLA/B occurs on either T2 or T4 positive edges. The capture event occurs on the same clock, and captures the time base value present when TDLA/B was asserted. TDLA and TDLB are negated during reset and may also be negated independently by microcode. TDLA/B is reset by no way other than reset and microcode.

It is the transition from 0 to 1 in TDL that causes the Transition actions: even if TDL assert conditions are satisfied, no action due to a Transition occurs if TDL was already set to 1. However, if a Transition and a microoperation negating TDLs occur at the same time and TDL was already negated, TDL negation by microcode overrides its assertion, but any dependable captures and pin action occurs anyway.

67.3.6.3.2 TCCEA - Transition Continuous Capture Enable

TCCEA enables capture from transitions after the TDLA flag is set . TCCEA is negated on reset, so that a capture occurs only when TDLA asserts . TCCEA can be set and reset by microcode only, through the instruction field MTD (see Disable Match and Transition Service Requests) . It can only be set together with inhibiting of the channel service requests (SRI = 1)[20].

When TCCEA is asserted, the transition events specified by IPACA that occur after TDLA is set also cause captures, into the CaptureA register only . However, output actions related to transition events are still blocked by TDLA.

67.3.6.4 Channel Modes

The Enhanced Channels support various modes of operation combining Match A/B recognition and transition detection events which set MRLA/B and TDLA/B. The channel mode is individually set for each channel by eTPU microcode, through the PDCM

[20] TCCEA provides compatibility with TPU when service request is inhibited.

register (see PDCM - Predefined Channel Mode). The PDCM register selects among a set of 13 predefined channel modes, and also a user-defined channel mode.

The order in which events occur, combined with assigned channel mode, establish which following event detections are inhibited and/or enabled, as well as the actions taken: Time Base capture, flag setting (MRLA/B, TDLA/B), match disabling (MRLEA/B), output signal transition, and Service Request. Those channel mode characteristics are fixed in the predefined modes, but can be individually programmed in the user-defined channel mode.

A generic description of channel modes from the usage point of view can be found in Channel Modes Overview. Each mode is named with a mnemonic acronym for terse reference. The individual programmed attributes of the user-programmable channel mode are also described.

The modes are used differently for input and output signals, as explained in Predefined Channel Modes on Input Signal Processing and Channel Modes on Output Signal Generation. Modes also allow combining input processing and output generation in a single channel, as exemplified in Combining input and output signals.

Channel Mode Logic and Event Flags shows a structural definition of channel logic and its relation to channel modes. A dynamic, event-oriented view of each channel mode can be found in Channel Mode Summary.

67.3.6.4.1 Channel Mode Logic and Event Flags

shows a more detailed diagram of channel mode logic. The logic shown here is not necessarily identical to the actual channel logic implementation, but is equivalent with respect to conditions for event blocking, enabling, capture, and service requests.

Signals MSR, TSR, MCAP, TCAP, M1ET, M1EM2, M1BM2, M2BM1, M2BT, T1BM1, T2BM1, TBM2 and T1ET2 are decoded from programmed channel mode PDCM in predefined modes, and come directly from the UDCM register when user-defined mode is selected:

- TSR (1 bit) defines Service Requests issued by Transitions, as shown in .
- MSR (2 bits) defines Service Requests issued by Matches, as shown in .
- TCAP (1 bit) defines time base captures caused by Transitions, as shown in
- MCAP (1bit) defines time base captures caused by Matches, as shown in .
- M1ET, M1EM2, M1BM2, M2BM1, M2BT, T1BM1, T2BM1, TBM2, T1ET2 (1 bit each) define Match and Transition reciprocal blocking and enabling, as well as Transition ordering, as shown in and .

shows the decoded values of those control signals for each predefined channel mode. The first column shows the mnemonic reference for the predefined channel modes described in the following sections.

Changing PDCM or the UDCM when user mode is selected may set or reset any of the channel flags, or issue captures and service requests, so it is advisable to switch channel modes only in a quiescent channel state, with channel flags MRLEA/B, TDLA/B, MRLA/B cleared. Furthermore, an event flag asserted in one mode may keep asserted after the mode programming change, even if the flag is impossible to be set in the new mode.

Table 396. MSR signals - Match Service Requests

value	MSR
00	issue no Service Requests on Matches
01	issue Service Request on Match B only
10	issue Service Request on 2nd[1] Match
11	issue Service Request on both Matches

1. 2nd Match means the Match that happens after the 1st Match in time, either Match A or Match B.

Table 397. TCAP and TSR signals - Transition Captures and Service Requests

value	TCAP	TSR
0	1st Transition captures Time Bases corresponding to Transition A and Transition B[1] Transition A captures corresponding Time Base if it is the second transition; Transition B captures corresponding Time Base if it is the second transition.	issue Service Request on the 1st Transition
1	Transition A captures corresponding Time Base. Transition B captures corresponding Time Base.	issue Service Request on the 2nd[2] Transition

1. Match capture(s) never overwrites a Transition capture. Transition captures can always overwrite a Match capture.
2. 2nd Transition means the Transition that happens second in time, either Transition A or Transition B

Table 398. MCAP signal - Match Capture

value	MCAP
0	Match A captures corresponding Time Base; Match B captures corresponding Time Base
1	either Match captures Time Bases corresponding to Match A and Match B[1]

1. Match capture(s) never overwrites a Transition capture. Transition captures can always overwrite a Match capture.

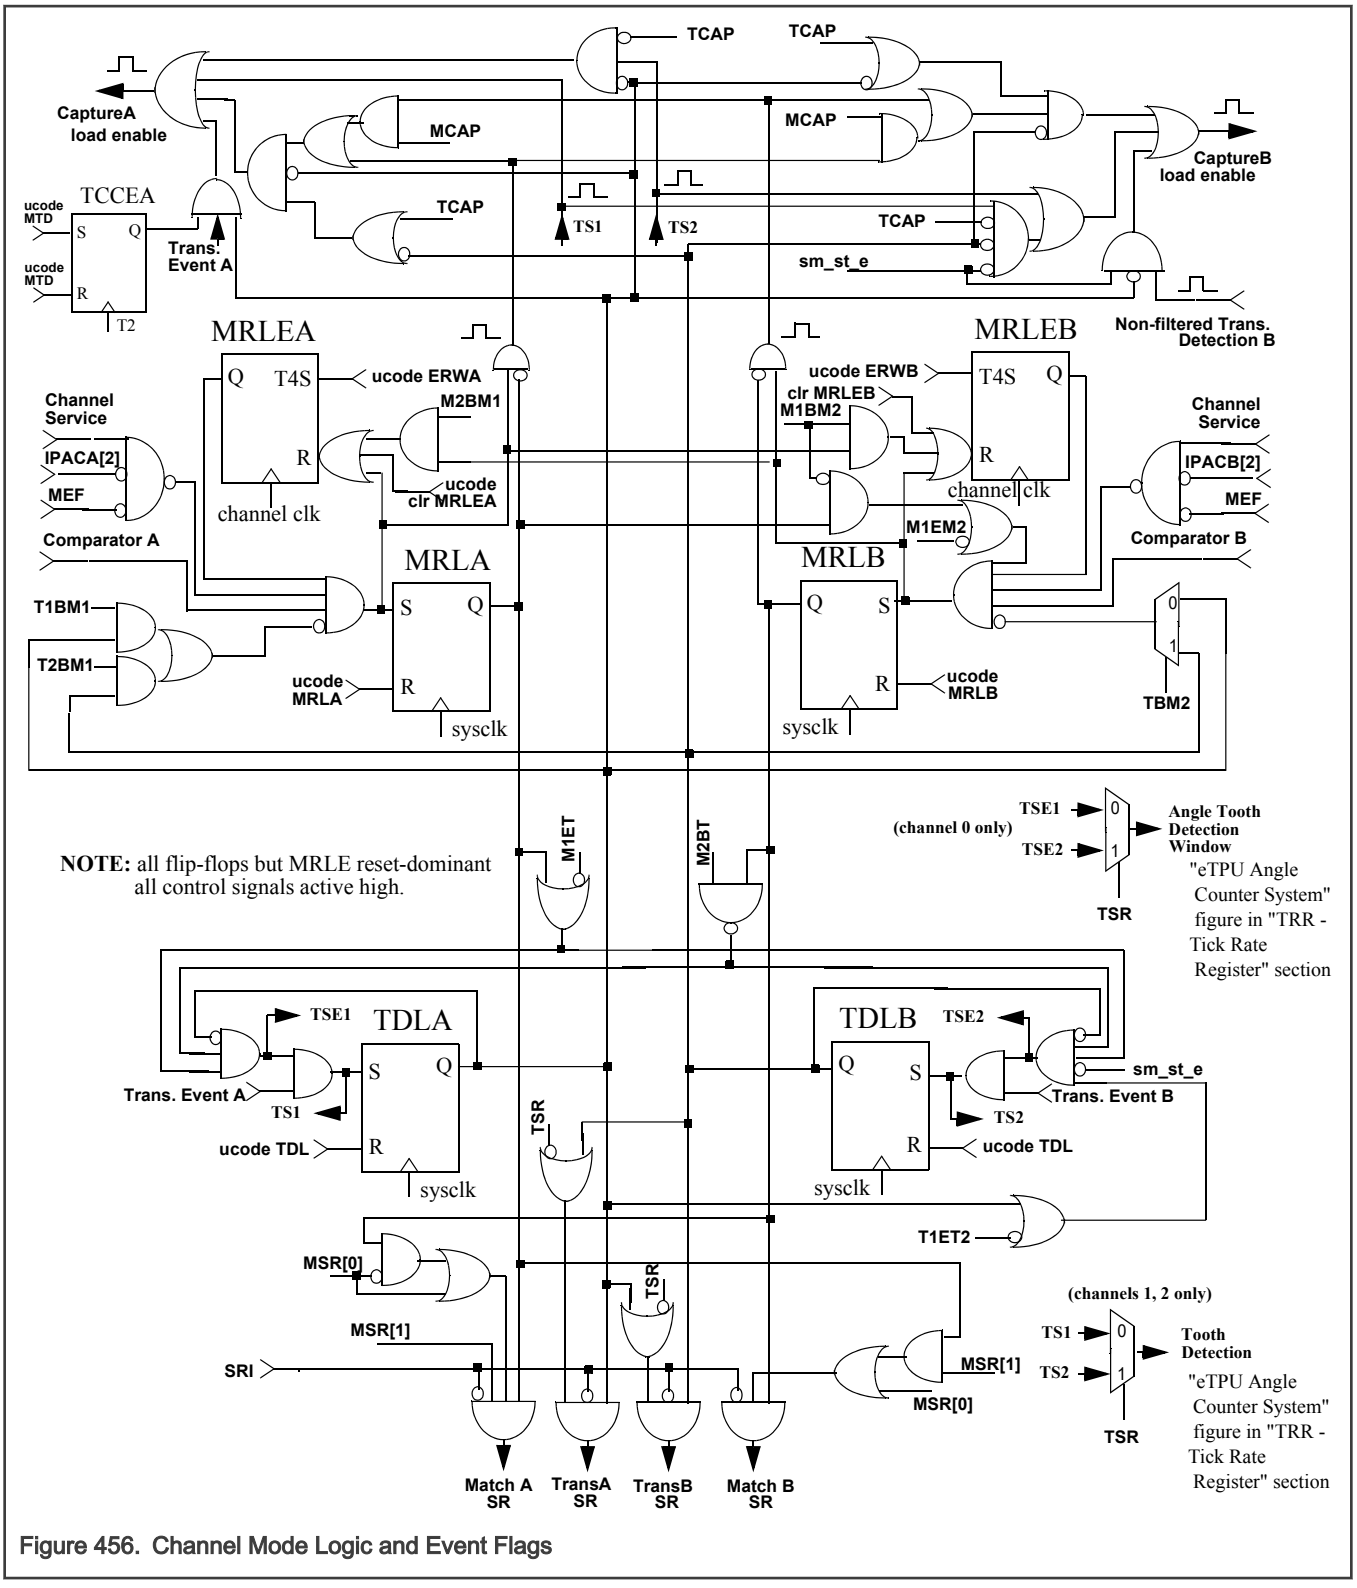

Figure 456. Channel Mode Logic and Event Flags

67.3.6.4.2 Channel Modes Overview

The predefined channel modes are divided, according to the way they treat transitions, in two basic modes:

- **Single Transition Modes** (mnemonic suffix **_st**): in these modes the first transition (flagged in TDLA) issues a service request, and captures both time bases (selected by TBSA[1] and TBSB[1]) except on sm_st_e. The second transition (flagged in TDLB) does not issue a service request, but it captures time base selected by TBSB[ ], except on sm_st_e.
- **Double Transition Modes** (mnemonic suffix **_dt**): in these modes the second transition (flagged in TDLB) issues a service request, and each transition captures its own selected time base (Transition A and Transition B capture time bases selected by TBSA[1] and TBSB[1], respectively).

In predefined modes, Transition B is always (but not only) enabled by Transition A, so that transitions are always ordered: TDLA is set on the first transition and TDLB on the second. Unordered transitions are possible with user-defined mode, when UDCM bit T1ET2=0. Matches are generally not ordered, except on specific ordered match modes m2_o_st and m2_o_dt. Match capture(s) never overwrites a Transition capture, while Transition captures can always overwrite a Match capture, either in predefined or user-defined modes.

The following general rules apply to both predefined and user-defined modes:

- Blocking of one Match by the other, when it occurs, is done through MRLEs.
- Matches always block themselves by resetting their own MRLEs (Match A always blocks Match A, Match B always blocks Match B).

Predefined modes differ mostly by the way matches affects and are affected by other matches and transitions, as explained in next sections. However, some general rules on Match blocking apply:

- Match B is blocked by first transition (TDLA) in single transition modes, and by second transition (TDLB) in double transition modes.
- Both Matches are blocked by first transition in single transition modes.

NOTE

The rules above and in following sections may be overruled by the state of the channel latches if they are set/reset by microcode or if channel mode is changed. Care must be taken to change channel modes, and is advisable to reset channel flags MRLA/B, TDLA/B and MRLEA/B before writing PDCM, or to UDCM when user-defined mode is selected.

67.3.6.4.2.1 Either match, blocking modes (em_b_st, em_b_dt)

In these modes the first match recognition that occurs blocks the other match recognition and generates a service request. They end up with one service request for two programmed match recognitions where only the first match recognition has an actual effect. If both match recognitions occur at the same time, both MRLA and MRLB are set, before the mutual blocking takes effect. The associated logic is shown in the following figure.

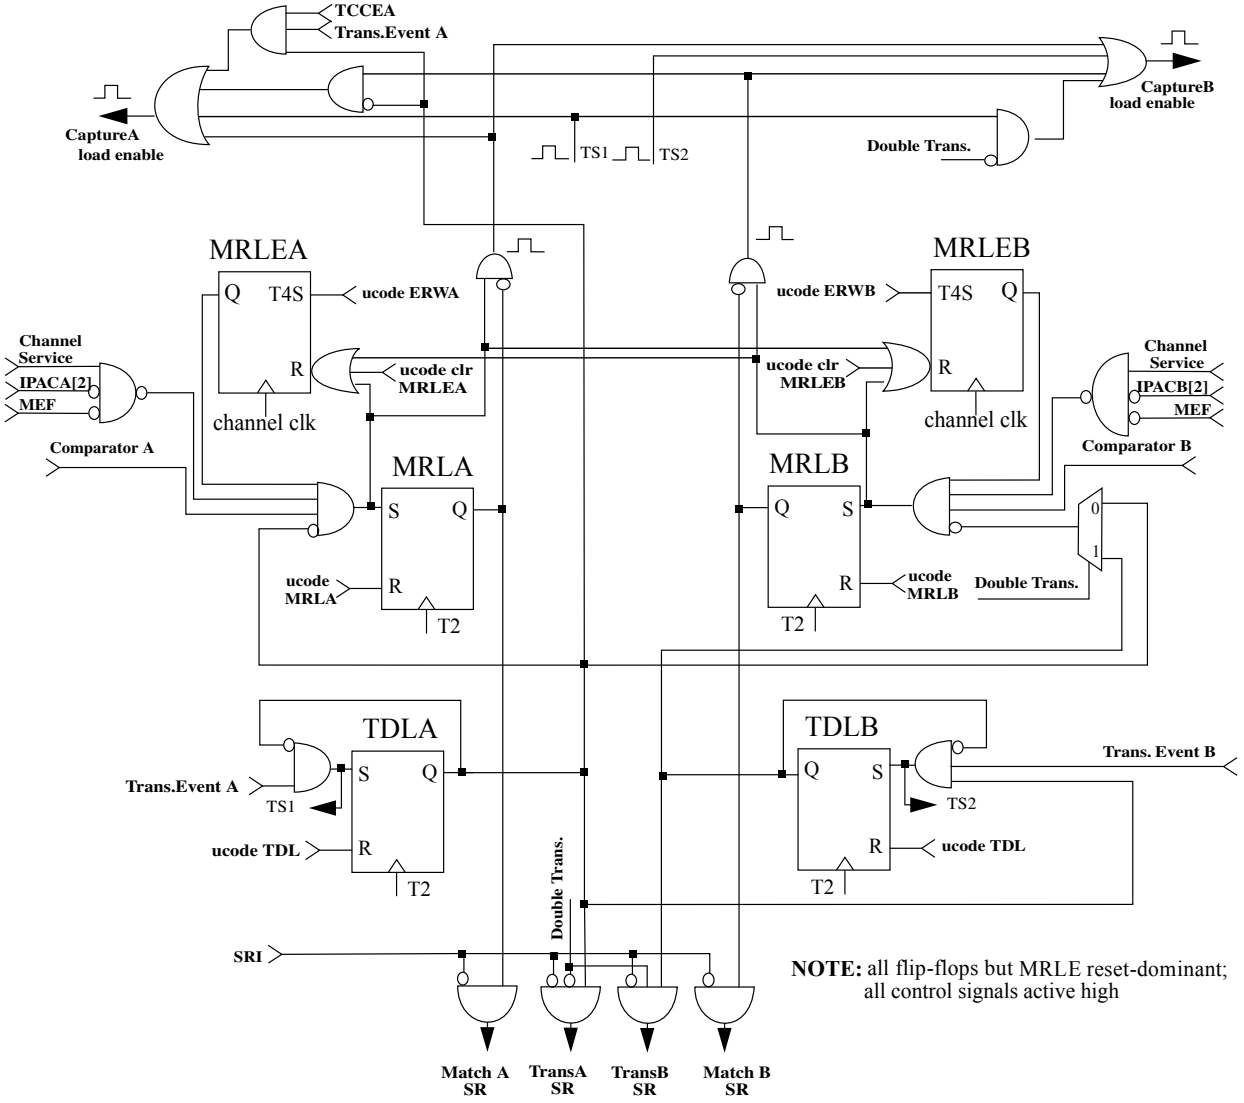

Figure 457. Either match, blocking_modes (em_b_st, em_b_dt)

67.3.6.4.2.2 Either match, non-blocking modes (em_nb_st, em_nb_dt)

In these modes both match recognitions are independent and each of them generates service request. Each match recognition captures its related time base and does not block the other. The associated logic is shown in the following figure.

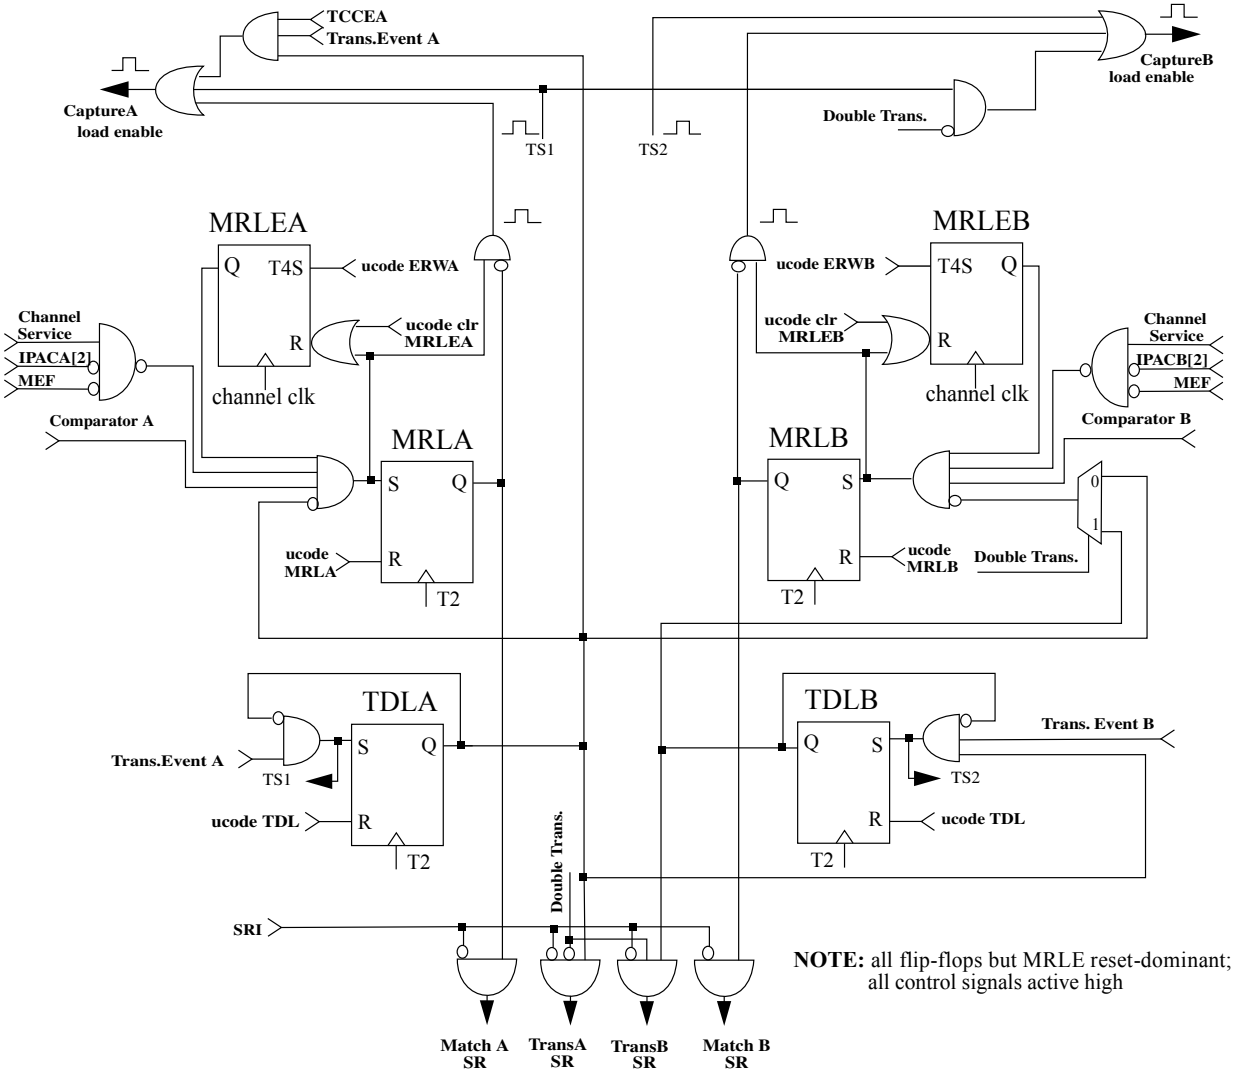

Figure 458. Either match, non-blocking modes (em_nb_st, em_nb_dt

67.3.6.4.2.3 Match B request modes (m2_st, m2_dt)

In these modes transitions are initially blocked, and are enabled by Match A. Match B recognition generates the match service request and disables Match A recognition. Each match recognition captures its own programmed timebase. In case of simultaneous match recognition, both MRLA and MRLB are set, and OPACB register has priority over OPACA for selecting the pin action. The associated logic is shown in the following figure.

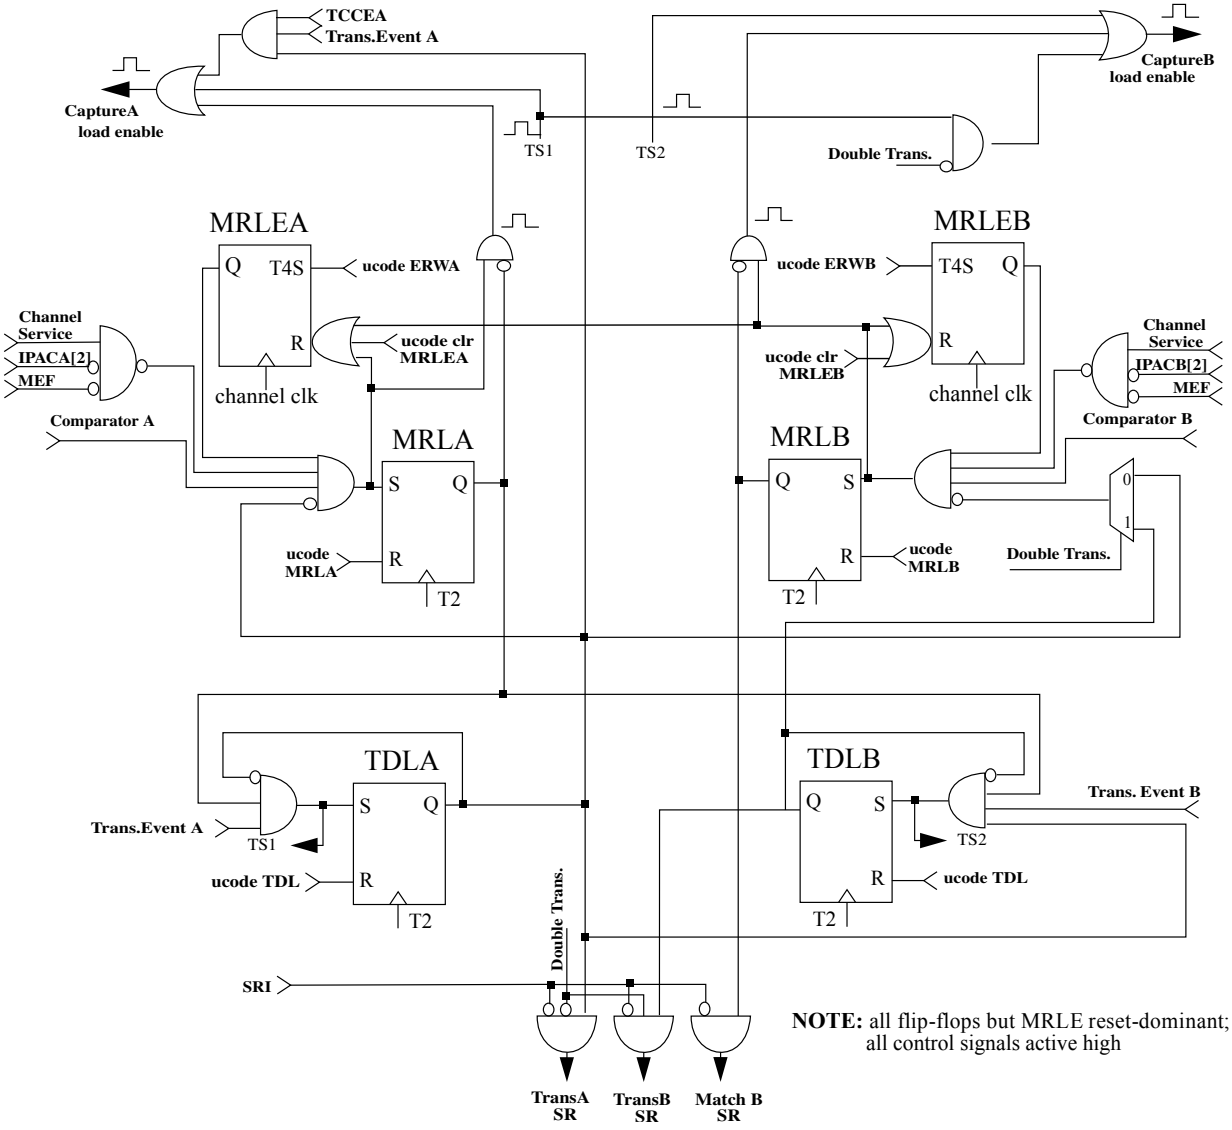

Figure 459. Match B request modes (m2_st, m2_dt)

67.3.6.4.2.4 Both match request modes (bm_st, bm_dt)

In these modes, match service request is generated only after both match recognitions occurred. By definition this is a non-blocking match mode: match recognitions do not block each other, implementing a last-served scheme. Unlike other double transition modes, bm_dt blocks Match A with Transition B (not with Transition A), so that the second transition blocks both matches. The associated logic is shown in the following figure.

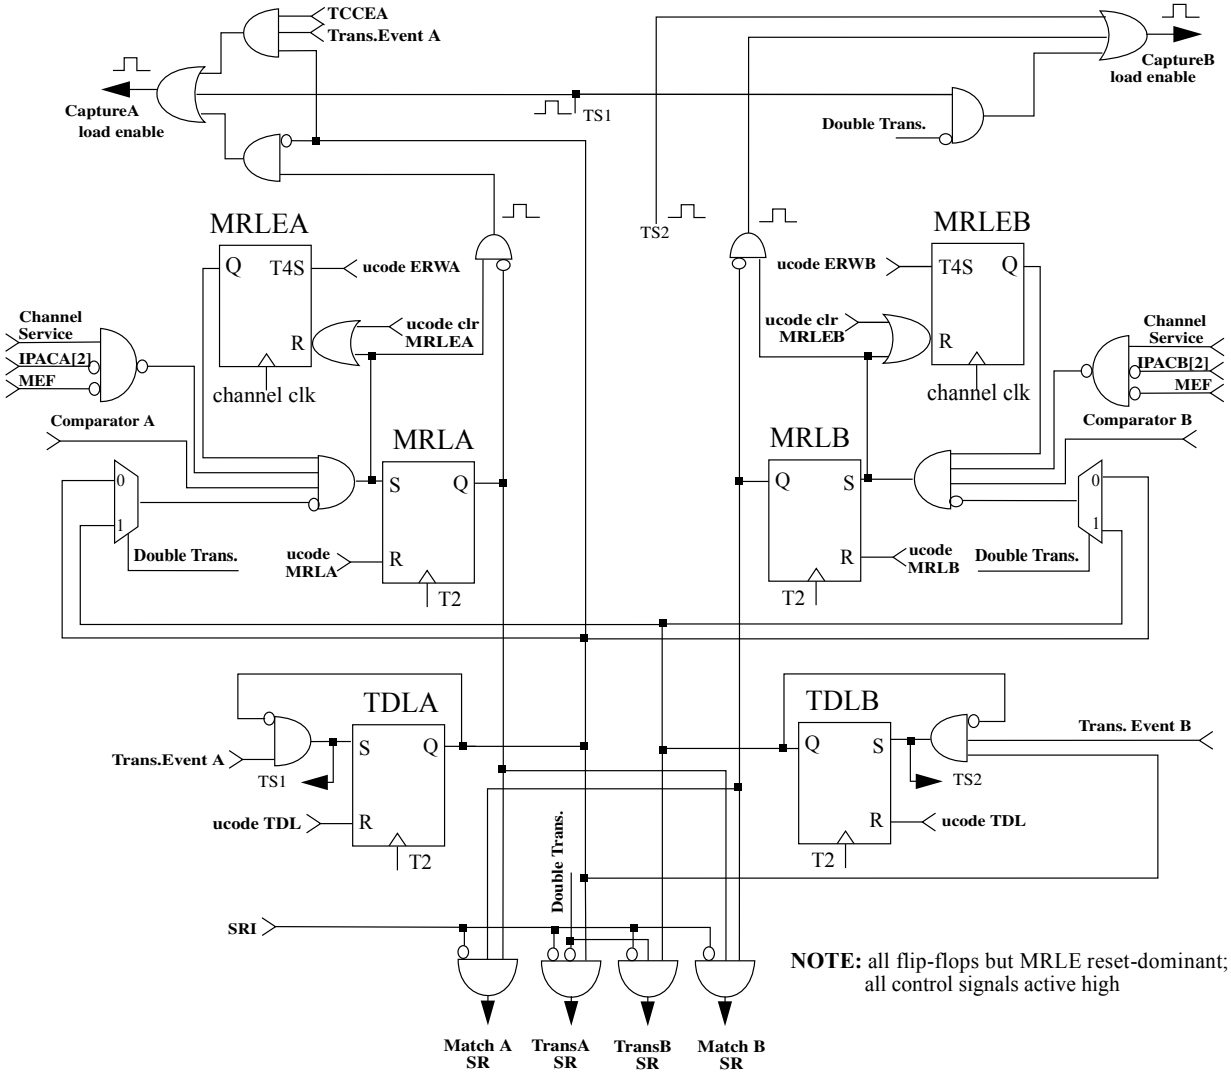

Figure 460. Both match request modes (bm_st, bm_dt)

67.3.6.4.2.5 Ordered modes with match B request (m2_o_st, m2_o_dt)

These are ordered match modes on which Match A recognition must precede Match B recognition (ordered 1->2). Match A asserts MRLA and enables Match B and transitions. Match B asserts MRLB, generates a match service request, and blocks both transitions. The associated logic is shown in the following figure.

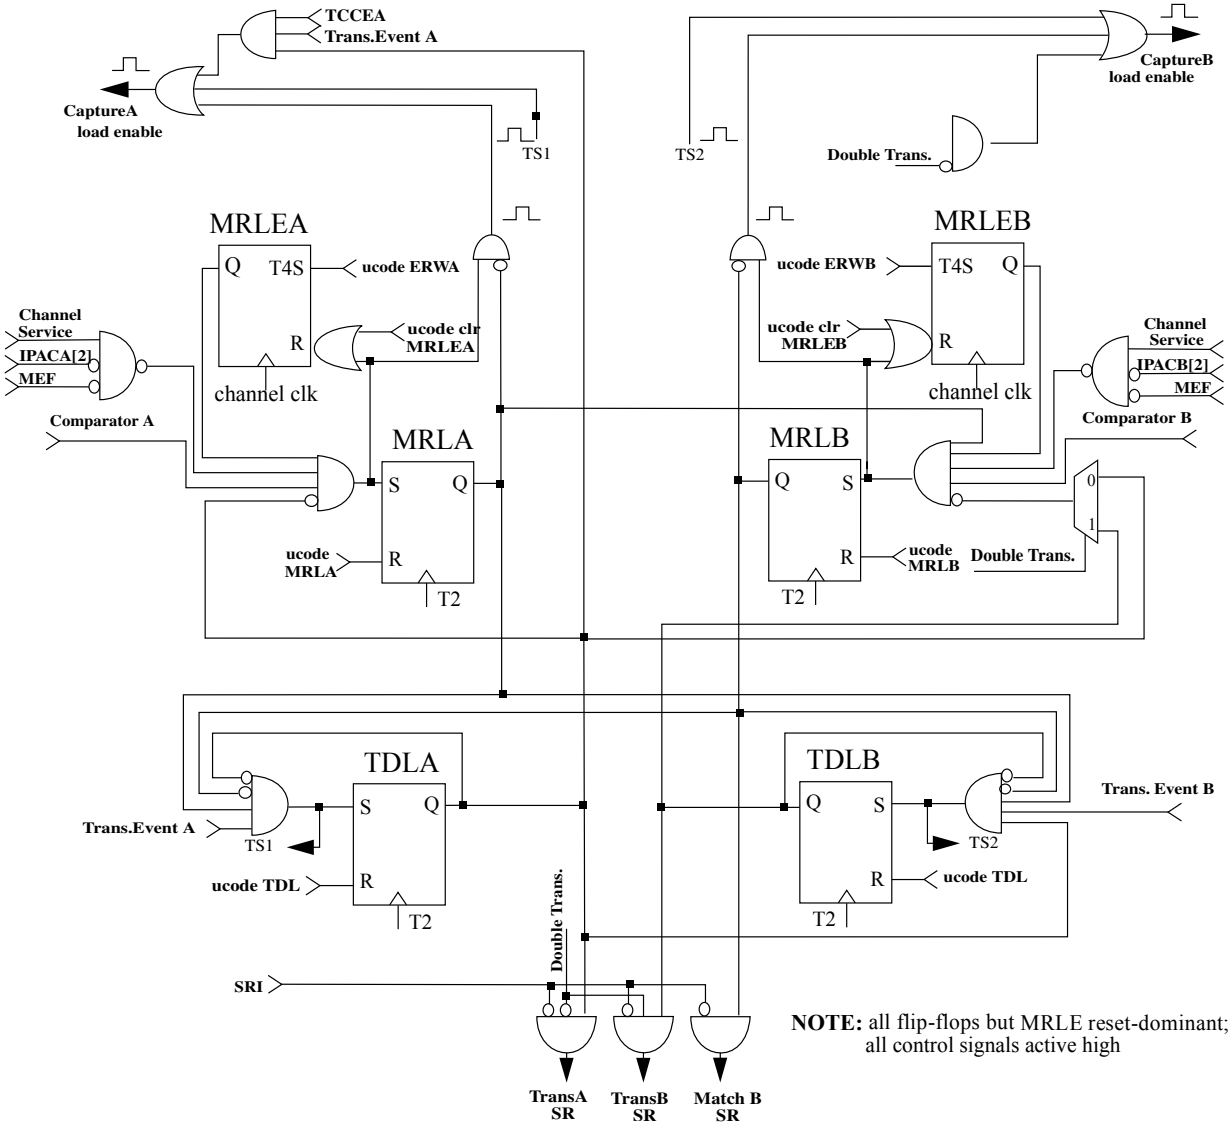

Figure 461. Ordered modes with match B request (m2_o_st, m2_o_dt)

67.3.6.4.2.6 Single match modes (sm_st, sm_dt)

Single match modes support single or double transition with single match recognition. MRLB is never set, and MRLEB has no effect. The associated logic is shown in the following figure.

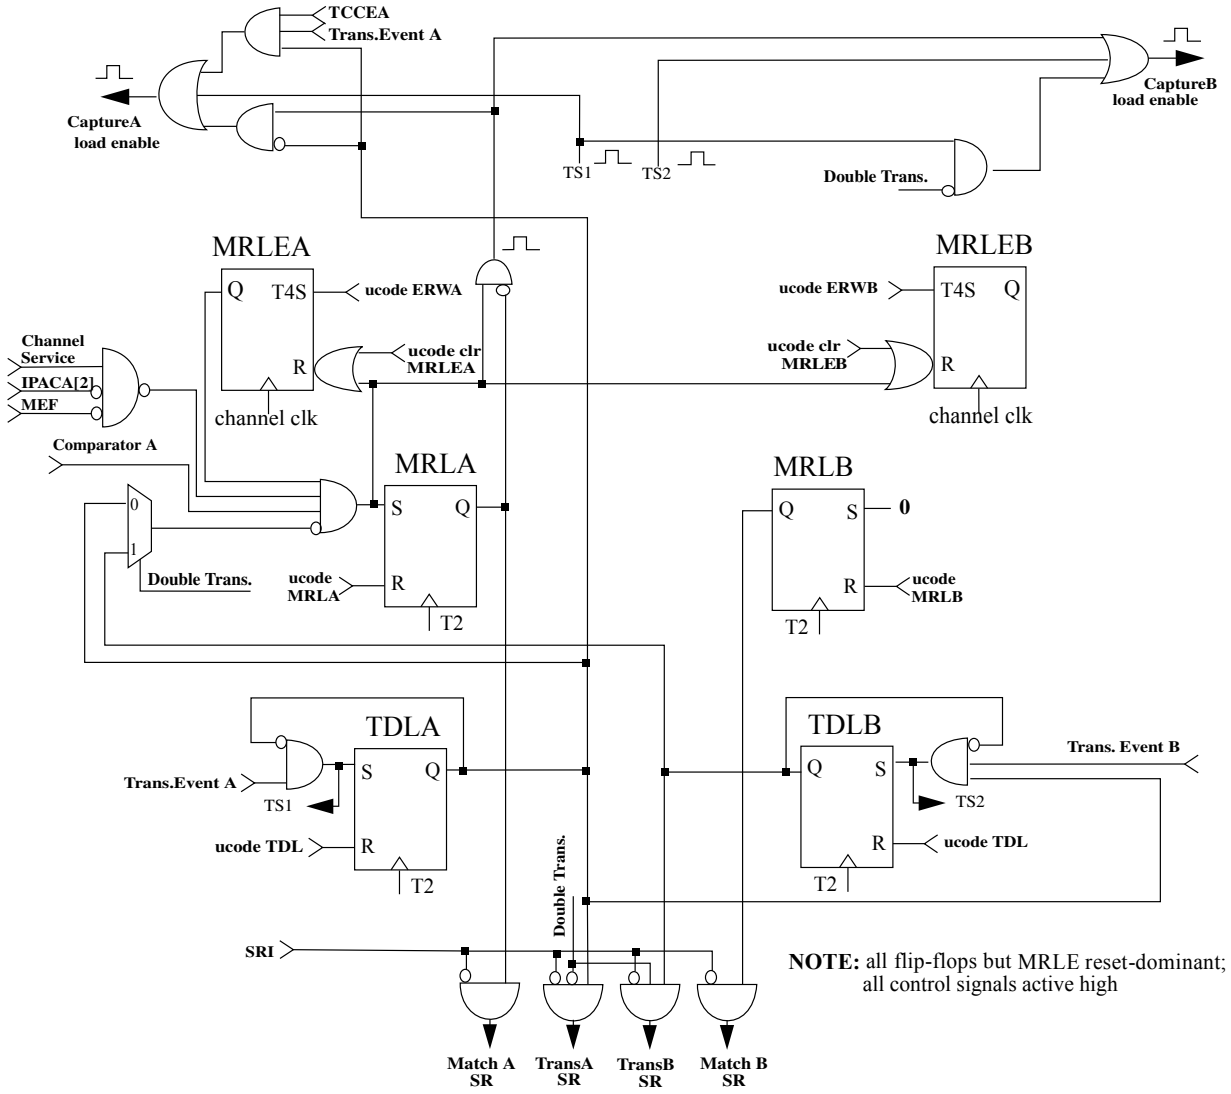

Figure 462. Single match modes (sm_st, sm_dt)

67.3.6.4.2.7 Single match enhanced mode (sm_st_e)

This is an enhanced single transition and single capture mode, which provides non-filtered input captures in addition to the single capture, allowing one to measure the delay of the digital filter. In an output channel, it has the same functionality of sm_st (captures both time bases at once due to a match recognition). The associated logic is shown in the following figure.

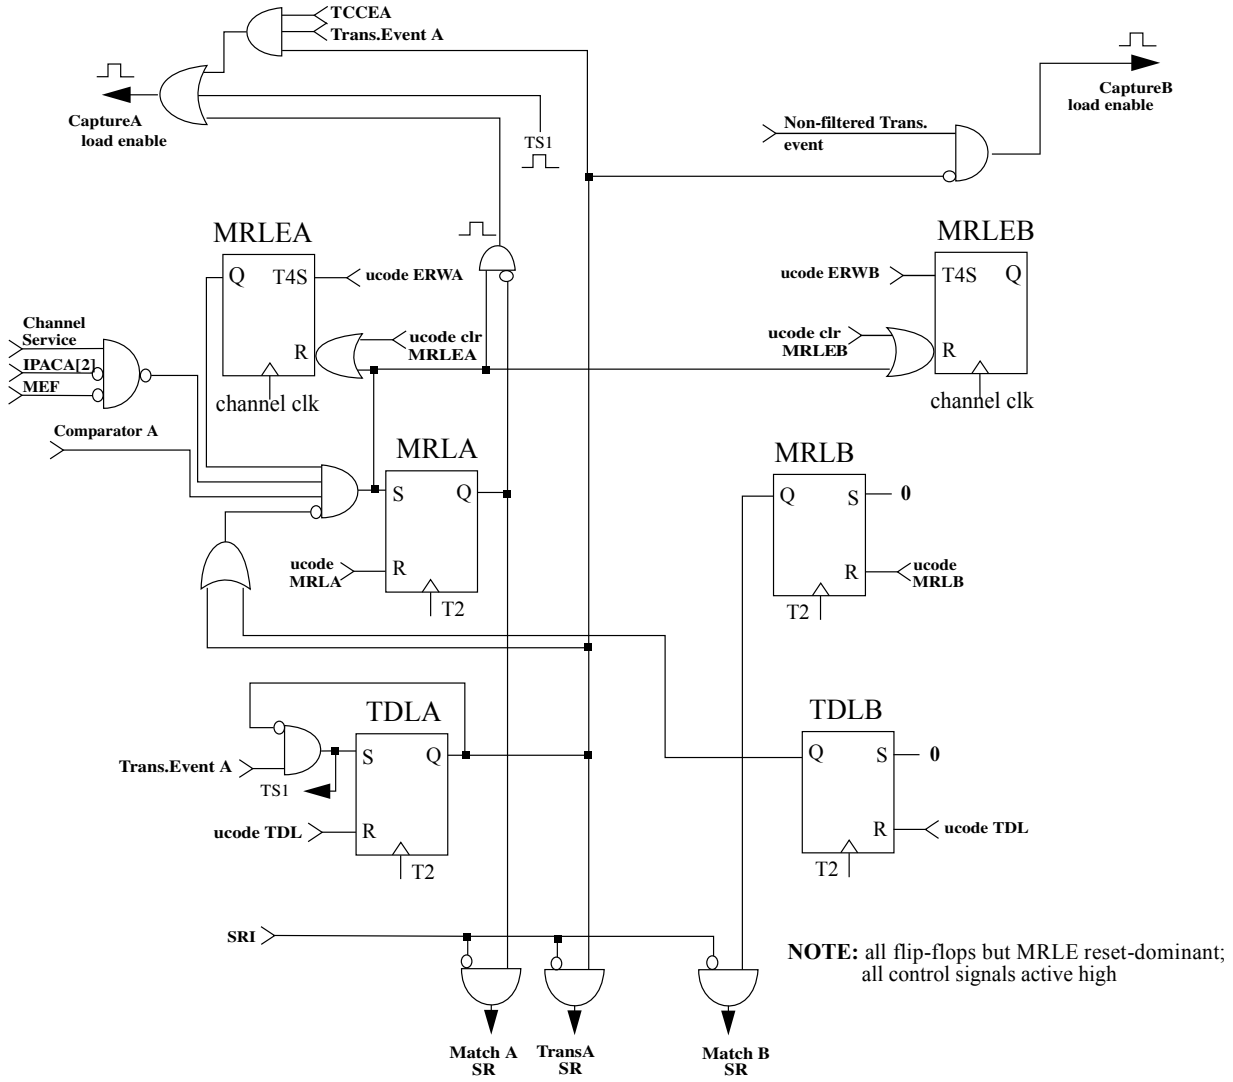

Figure 463. Single match enhanced mode (sm_st_e)

67.3.6.4.3 Predefined Channel Modes on Input Signal Processing

When processing an input signal, the predefined channel modes can be classified in the following primary mode groups:

- Single Transition, Single Match: em_b_st, sm_st, sm_st_e
- Single Transition, Double Match: em_nb_st, bm_st, m2_st, m2_o_st
- Double Transition, Single Match: em_b_dt, sm_dt
- Double Transition, Double Match: em_nb_dt, bm_dt, m2_dt, m2_o_dt

In single transition modes, TDLA assertion may capture both time bases at once, while in double transition modes each transition captures its related time base in its related capture register.

Double transition is always ordered, i.e. TDLB is enabled by TDLA and generates the service request.

The channel logic supports various input modes with combinations of single/double transition and single/double match, explained in the following subsections.

67.3.6.4.3.1 Either Match, Blocking, Single Transition (em_b_st)

On an input signal, this mode provides double timeout mechanism on a programmed transition edge with two timebases. The signal transition blocks both pending matches, indicating that no timeout condition occurred. The two match recognitions block each other, giving good separation in the entry table as to which match recognition caused the first timeout condition, and generating only one service request. Either match performs timebase captures which do not overwrite captures by transitions.

67.3.6.4.3.2 Either Match, Blocking, Double Transition (em_b_dt)

In double transition mode each transition is related to one match recognition. TDLA assertion captures its related timebase, blocks Match A and enables TDLB. TDLB assertion blocks Match B, captures its related timebase and generates a service request. Match recognitions block each other, so if there is a match timeout condition on TDLA, only one match service request is generated. This mode is good for qualifying two signal transitions by match timeout mechanisms, with one service request. Note that although TDLA assertion does not block Match B recognition, the value captured in CaptureA by TDLA assertion is not overwritten by this recognition. The second transition blocks Match B. Either match performs timebase captures which do not overwrite captures by transitions.

67.3.6.4.3.3 Either Match, Non Blocking, Single Transition (em_nb_st)

On an input signal, this is a double timeout mechanism of independent match recognitions of two different timebases. The match recognitions do not block each other, such that the microcode can check if one or two match recognitions occurred before their related signal transition. The signal transition detection (by IPACA) asserts TDLA, blocks both matches, captures both time bases and generates a transition service request, indicating that none of the two timeout conditions occurred. Any combination can be easily resolved by microcode (for example, signal transition after Match A and before Match B, or signal transition after both Match A and Match B).

Another possible use of this mode is allocating one match recognition for transition timeout and the other for another non-critical timed task, adding functionality to a single channel. Since the transition detection blocks both match recognitions, the match recognition of the other timed task is based on the fact that the comparator checks greater-equal conditions. It may be delayed if it occurs in the period between the signal transition detection (which blocks it) and the time TDLA is negated by microcode. If matches are enabled during the service, the same code can check if the match recognition of the timed task occurred in this period, by negating TDLA and writing to the CHAN register its own value (in order to update the MRLA flag in the branch logic).

67.3.6.4.3.4 Either Match, Non Blocking, Double Transition (em_nb_dt)

In this mode each transition is related to one match recognition, and the match recognitions are independent of each other. This mode can be used to give independent timeout conditions for the first and the second signal transition recognitions, and call service in any case of any timeout condition.

The first transition detection programmed in IPACA sets TDLA, captures its related timebase, blocks Match A recognition and enables TDLB assertion. The second transition detection programmed in IPACB sets TDLB, blocks Match B recognition, captures its related timebase and generates a service request. Any match recognition that occurs captures its related time base and generates a match service request, independent on the other match recognition.

67.3.6.4.3.5 Match B Request, Single Transition (m2_st)

On an input signal, this mode provides an open window filter for a single signal transition. MRLA assertion opens the window, and enables transition detection on TDLA from this time on. MRLB assertion blocks Match A (by negating MRLEA), providing conditional window opening, because transitions are indirectly blocked. It also generates service request, but if it happens after Match A it does not block transitions, providing a non-blocking timeout mechanism for the estimated signal transition time (typically it indicates a missing transition, or mis-prediction of the transition time).

Transitions can be detected from the microcycle following MRLA assertion. The Transition A detection asserts TDLA, blocks both matches, captures both timebases and generates service request.

Using this mode, the channel can replace software open window filtering of qualified transitions with the channel hardware window. The window opening and timeout can be scheduled for any of the two time bases or combination of them. Typically, Match A will be used to open a prediction window, and Match B will be used as a timeout condition which does not close the prediction

window. This configuration improves noise immunity from early signal transitions, and reduces the probability for blocking late signal transitions due to timeout mis-prediction.

Using these conditions, the microcode can easily resolve the state:

- If TDLA and MRLA are asserted and MRLB negated, signal transition is in the expected range.
- If MRLA and MRLB are both asserted, and TDLA is asserted, the signal transition had a timeout condition due to Match B mis-prediction.
- If MRLB is asserted and TDLA negated, a timeout condition occurred, and the expected signal transition had not occurred yet.
- If MRLA is negated and MRLB is asserted, the conditional window did not open at all (for example: a time window is open only after a specific angle, otherwise it is not opened).

67.3.6.4.3.6 Match B Request, Double Transition (m2_dt)

This mode is used as an open window filter for two signal transitions. In this case the Match A recognition opens the window (unless Match B recognition occurred first), and Match B recognition blocks Match A and generates a match service request. It is similar to m2_st, but in this case, it is the second transition that blocks Match B. MRLB assertion is a global timeout condition for the two pulses. Like m2_st, MRLB can conditionally eliminate the window from opening.

Using the TDLA, TDLB, MRLA and MRLB conditions, the microcode can easily resolve the state, in a similar manner as m2_st, with additional information on the second transition (TDLB).

67.3.6.4.3.7 Both Match Request, Single Transition (bm_st)

On an input signal, this is a double timeout mechanism on two different time bases. Both match recognitions must occur before the signal transition to generate a match timeout service request. Assertion of TDLA blocks both Match A and Match B recognitions, and captures both time bases, indicating there was no double timeout condition from both time bases.

Using the same timebase implements two timeout conditions, the first only sets its related MRL and the second generates a service request. Using these flags allows the microcode to check if one or both match recognitions precede the signal transition.

67.3.6.4.3.8 Both Match Request, Double Transition (bm_dt)

In this mode the first transition detection does not block matches, since both match recognitions are required to generate a match service request. The second transition detection asserts TDLB, blocks Match A and Match B, captures its related timebase and generates transition service request. In this mode, a Match A recognition which occurs after the assertion of TDLA does not capture a new value in CaptureA, to preserve the actual signal transition time. Assertion of TDLA, however, always captures its related timebase.

This mode allows putting a double match timeout condition on the second transition. Typically, a pulse trailing edge timing can be checked against two time bases, to indicate if the pulse has not ended when both MRLA and MRLB are asserted. When a transition service request is generated by TDLB assertion, the state of MRLA and MRLB indicates which timeout condition occurred, if any.

67.3.6.4.3.9 Ordered Mode with Match B Request, Single Transition (m2_o_st)

On an input channel, this mode provides a closing window filter for a single signal transition. Match A assertion captures its programmed time base in CaptureA, opens the filter window (enables assertion of TDLA), and enables assertion of MRLB. Match B recognition captures its related timebase, closes the window (disables assertion of TDLA) and generates a service request. Due to Match A and Match B ordering, the window is opened for at least one microcycle. Match B recognition indicates a window timeout condition which blocks late signal transitions, outside the prediction window. Transition detection blocks both matches, indicating the transition occurred inside the estimated window. Transitions can be detected from the microcycle following MRLA assertion until the microcycle on which MRLB is asserted. When TDLA is asserted inside the window range it disables both matches, captures both time bases and generates a transition service request.

Using this mode, the channel can replace software window filtering of qualified transitions with the channel hardware window. The window opening and closing time can be scheduled for any of the two time bases or a combination of them.

67.3.6.4.3.10 Ordered Mode with Match B Request, Double Transition (m2_o_dt)

In this mode the channel logic implements a window filter for two detected signal transitions. MRLA assertion captures its related timebase and enables the assertion of both TDLA and TDLB. MRLB assertion captures its related timebase and disables the assertion of both TDLA and TDLB. Transitions can be detected from the microcycle following MRLA assertion until the microcycle on which MRLB is asserted. The first signal transition (following MRLA assertion) asserts TDLA, captures its related timebase and enables assertion of TDLB. The second signal transition detection asserts TDLB, blocks Match B, captures its related timebase and generates the service request.

If both signal transitions occur inside the scheduled window, Match B recognition is blocked. If one or both signal transitions do not occur inside the scheduled window, Match B recognition generates a match service request and blocks further transition detections. The microcode can resolve the state using MRLA, MRLB, TDLA and TDLB, which affect the entry point selection.

67.3.6.4.3.11 Single Match Enhanced Mode (sm_st_e)

This is an enhanced single transition and single match channel mode which provides timing information of the digital filter delay.

The CaptureA register captures the timebase selected by TBSA due to transition detection specified by IPACA or match recognition, as in sm_st mode. Initially, the CaptureB register continuously captures the unfiltered IPACB-selected signal transitions from the digital filter input, directly from the signal synchronizer. When an IPACA-qualified, filtered transition detection occurs, TDLA is set, MRLA assertion is blocked, and, in addition, captures into CaptureB are also blocked. On service, CaptureA and CaptureB (copied into ERTA and ERTB) holds the time of the qualified transition detection (ERTA), and the time of the last signal transition at the input of the digital filter (ERTB). Subtracting the time in ERTB from the time in ERTA provides the delay of the digital filter.

In a quiet environment, the two captures provide the accurate delay of the digital filter in granularity of two eTPU clocks. In a noisy environment, false transitions may be detected at the input of the digital filter due to the noise, and the delay measurement may be reduced, especially if IPACB selects both edge detection. The microcode can do sanity checks on this value to recognize noise effects (for example: calculated delay is less than the minimum delay of the digital filter).

NOTE

In Channel 0, if eTPU_TBR_TBCR_ENG*n*[AM]=01 (Angle Mode), the unfiltered input comes from TCRCLK input and the filtered input comes from the TCRCLK filter output. The edge is selected by IPACA/B, and is independent of the edge selection by eTPU_TBR_TBCR_ENG*n*[TCR2CTL].

67.3.6.4.3.12 Single Match, Single Transition (sm_st)

In this mode, a match or transition detection captures at once both timebases. The mode recognizes a single transition with single match timeout. Either TDLA or MRLA generates service request and captures both timebases. Assertion of TDLA blocks future assertions of MRLA.

67.3.6.4.3.13 Single Match, Double Transition (sm_dt)

In this mode, the first transition detection asserts TDLA, captures a timebase in CaptureA and enables TDLB. The second signal transition asserts TDLB, blocks Match A, captures a timebase in CaptureB and generates a service request.

Match A (before TDLB) captures into CaptureB the timebase selected by TBSA, in order not to overwrite the captured value of TDLA.

This mode is used for scheduling one timeout condition on two input signal transitions (pulse timeout).

67.3.6.4.4 Channel Modes on Output Signal Generation

Since channel logic can generate output signal transitions based on Matches, the channel can be viewed as working in the following primary mode groups for signal generation:

- Single Match: em_b_st, sm_st, sm_st_e, em_b_dt, sm_dt
- Double Match: em_nb_st, bm_st, m2_st, m2_o_st, em_nb_dt, bm_dt, m2_dt, m2_o_dt

The channel logic supports various match channel modes with single/double match, as explained in the following subsections.

67.3.6.4.4.1 Either Match, Blocking Modes (em_b_st, em_b_dt)

On an output signal these modes are useful when using two different time bases to set a required signal transition. The first match condition which is met sets a required pin action, captures both time bases, blocks any effects of the other recognition, and generates a service request. Because the first match recognition blocks the other, the microcode can get good separation in the function entry table as to which match caused the timeout first, and both time bases are captured, enabling the microcode to compare one timebase to the other at the moment of the match recognition. These modes can be used for:

- Scheduling a required pin action to the first match recognition of two different time bases.
- Canceling a programmed pin action scheduled on one time base by match on another timebase (as a consequence of Match/Transition Pin Action Conflict Resolution). Microcode has to set the OPAC register of the canceling match to no-action and the OPAC register of the other match to the required pin action which may be blocked. If Match A is the canceling match, it blocks the pin action also in case of two matches at the same time, since it has priority in this case. If Match B is the canceling match, it does not block the pin action in case of two matches at the same time.

67.3.6.4.4.2 Either match, non-blocking modes (em_nb_st, em_nb_dt)

On an output signal these modes are useful in combination with the ME bit set on the entry point, to define an interlaced operation. For example, each match recognition can set a pin action, and the second pin action is not sensitive to microcode latency (ME bit asserted). Example for usage is PWM interlaced function on which the latency is determined by the period and not the duty cycle.

Another possibility is using one match for pin actions and the other match for an unrelated timed task without pin action (double the functionality of a single channel).

67.3.6.4.4.3 Match B Request Modes (m2_st, m2_dt)

On an output signal, these modes can generate narrow pulses or do conditional pin actions. A conditional pin action means that the pin state is changed only if the match recognitions occurred in the correct order, since the Match B recognition which generates the service request also has priority over the pin action and blocks future Match A recognitions.

Setting OPACA to a desired pin action and OPACB to no-action, and using different time bases for Match A and Match B defines a conditional OPACA pin action which can be blocked by Match B recognition. For example, setting Match A on time and Match B on angle can limit the pin action to a maximum angle value.

When pulses are generated, the service is requested at the trailing edge of the pulse, after MRLB is asserted.

67.3.6.4.4.4 Both Match Request Modes (bm_st, bm_dt)

On an output signal, each match recognition can affect the pin state, and capture its programmed time base. This way the pin action can be programmed separately for both match recognitions. For example, both match recognitions can negate the signal, and service request is generated after both conditions are met. This mechanism can set two conditions to do a required pin action, and the first recognition changes the signal, but service is called only after both conditions occur.

When using the same time base, these modes can generate narrow pulses in any required order. For example, in a PWM function, when duty cycle is below 50% the function can get service on the low time and program the pulse to the required duty cycle of the high time. When duty cycle is equal or above 50%, the function can get service on the high time and program a negative pulse with the width of the required low time. To switch between the two states the function can program once the same transition time to MatchA and Match B with a required pin action, and on the next service program double match for the new state.

Another usage is generating a required pin action on one programmed time and service request later on another time, after the second match recognition occurs, or capturing some timebase on one time and generating a required signal transition and service request later.

67.3.6.4.4.5 Ordered Modes with Match B Request (m2_o_st, m2_o_dt)

The order of the match recognitions imply that OPACA register programmed pin action always precede the OPACB register pin action. Setting OPACA to no-action, based on the greater-equal comparator, enables using Match A on one time base to delay

the signal effect of Match B on the other time base. This method implements a conditional pulse extension or conditional delay on signal transition.

These modes can also be used for deferred pulse generation with microcode service request after its trailing edge (if Match A condition comes after Match B condition). Another option is having Match A recognition associated with output pin actions and Match B recognition for a timed microcode task which has to be scheduled at a programmed time which may be delayed by the Match A pin action.

67.3.6.4.4.6 Single Match Modes (sm_st, sm_dt, sm_st_e)

There is no difference between plain and enhanced Single Match modes on an output signal.

Match A recognition generates service request and sets the pin state according to OPACA register. It captures at once the timebase selected by TBSA in CaptureA and the timebase selected by TBSB in CaptureB.

67.3.6.4.4.7 Match/Transition Pin Action Conflict Resolution

In output signals, matches and/or transitions automatically cause pin actions defined by the OPACA/B and/or IPACA/B channel control registers (see Pin Control Registers). Simultaneous matches/transitions may be associated with different, possibly contradictory, pin actions. These conflicts are resolved according to the table below.

If an OPACA/B=000 (no action) prevails over non-zero OPAC according to the table below, then if Match A/Transition A and Match B/Transition B occur simultaneously, no output pin action occurs, that is: a match on the action logic with OPAC=000 inhibits simultaneous actions of the other OPAC, if prevailing according to the following table. That also applies when output actions are caused by inputs (OPAC=1xx).

Table 402. Simultaneous Match Pin Action Priority

Channel Mode	Priority
em_nb_st / em_nb_dt	OPACA
em_b_st / em_b_dt	OPACA
bm_st / bm_dt	OPACA
m2_st / m2_dt	OPACB
m2_o_st / m2_o_dt	in these modes there is no possibility of simultaneous matches
user-defined	OPACB if M2BM1 = 1 and M1BM2 = 0, OPACA otherwise

67.3.6.4.5 Combining input and output signals

The processing of input signal can be combined with output signal generation. A detected input transition can trigger an output signal edge, even without microcode intervention, by using OPAC options 1xx.

The channel set-up examples below show these two capabilities combined (see the figure below).

The **first example** implements a fast (no microcode intervention) short-circuit protection feedback mechanism for driving high-current output devices. The signal after the high-current driver feeds back to the channel input. The input signal is normally delayed from the output signal by the device turn-on delay. After the channel output turns on, the channel logic must check if the driver output (connected to the channel input) follows the driven value after the maximum device turn-on delay. If it does not, the driver output is probably shorted, and the channel output must be turned off immediately to avoid damaging the device.

Match A causes the output to be driven high (for simplicity the output and input signals are shown as positive logic). It also causes a transition A, because IPACA=100 and the input is still low. Match B occurs after the expected driver delay, and causes a service request. If the output is shorted, a Transition B occurs on Match B because IPACB=100. This will cause the output to go low immediately, because OPACB=100.

In the **second example**, an output pulse is generated from an input transition without microcode intervention. Match A opens a window for transitions and also enables Match B. A rising edge on input sets output high. On Match B the window closes, and input signal is checked: if sampled high, the output resets; otherwise it stays high.

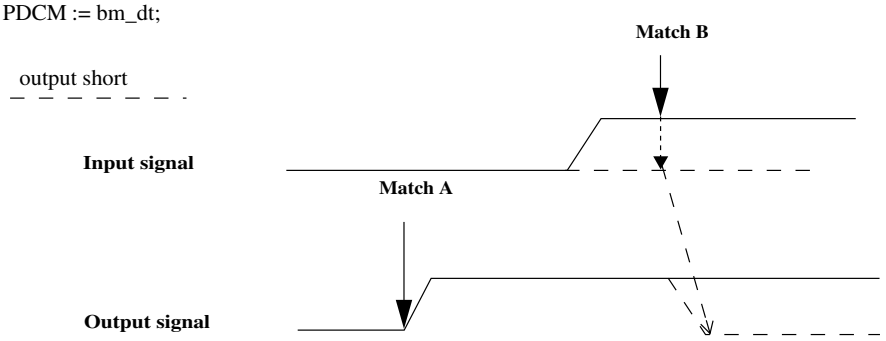
In the **third example**, a pulse is generated depending on the value sampled on the input signal at a predetermined time. Match A samples the input signal, causing a Transition. Low level on input sets output low, otherwise it stays high. Match B sets output high. In both cases a service request is issued (microcode intervention), at the beginning and at the end of the pulse (Match B), if required (SRI := 0).

NOTE

When IPAC = 1xx, a match event can cause simultaneously a Match recognition and a Transition detection. Depending on the Channel Mode, these Match and Transition may have conflicting effects on other Transition/Match blocking or enabling. In these cases, blocking always prevails over enabling, effective on the next microcycle.

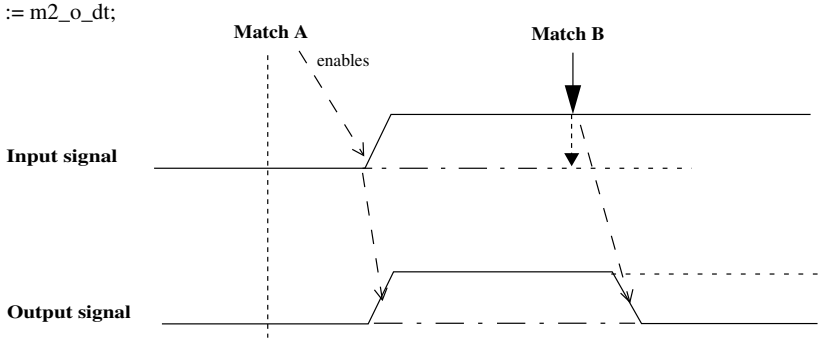
Example 1: Short-circuit protection feedback

IPACA := 100; OPACA := 001; MatchA := output activate time;
IPACB := 100; OPACB := 100; MatchB := MatchA + max. high-current driver turn-on delay;
PDCM := bm_dt;



Example 2: Pulse generation on windowed input transition

IPACA := 001; OPACA := 101; MatchA := window open time;
IPACB := 101; OPACB := 100; MatchB := window close time, input sampling;
PDCM := m2_o_dt;



Example 3: Pulse generation on input sampling

IPACA := 100; OPACA := 100; MatchA := window open time,input sampling;
IPACB := 000; OPACB := 001; MatchB := window close time = MatchA + pulse width;
PDCM := em_nb_dt;

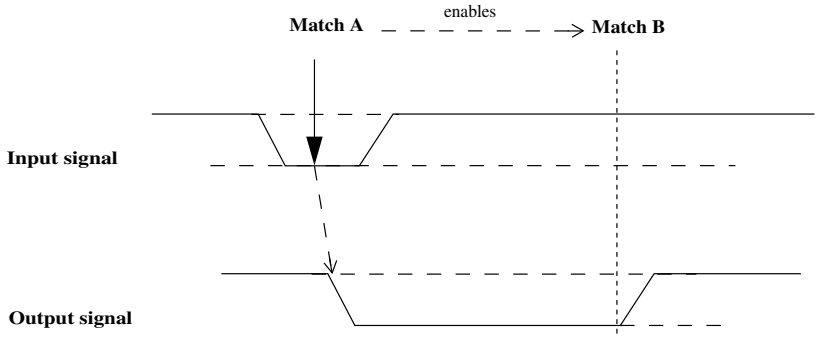


Figure 464. Input output combination

67.3.6.4.6 Channel Mode Summary

The initial state considered for all submodes is channel flags MRLEA and MRLEB asserted, MRLA, MRLB, TDLA and TDLB negated. From initial state one can follow the table below and verify how each submode behaves in a determined sequence of

events. Note that the actions performed by an event type depend on all previous events following the initial state, for a given channel submode.

There are three columns for each event: one for event type, one for enable/disable actions and one for capture. **Event type** column can be matchA, matchB, transA and transB (for double transition modes). **Enable/disable actions** column (identified as "**[blocks](enables)**" in column head) specifies which other events are enabled or disabled. Initially disabled events (specified in **"initially blocked"** column) are usually enabled by other events.

In double transition submodes, the first transition detected is always considered transA and the second is considered transB. This means that transA event actually enables the detection of transB event. This is not explicit in the table, since it is a general behavior for all double transition submodes.

A sequence of four events (two matches and two transitions) are necessary to describe the behavior of some channel submodes. When a determined sequence of events has less than four events, the other event columns are left blank.

Cells in an **"event type"** column that have light-grayed background indicate that a service request is generated. More than one event in the same event sequence can issue service request.

NOTE

The two tables below do not exhaust all possibilities of channel logic event sequences, because it does not account for possible microcode interventions. For instance, if matches are blocked by first transition and microcode resets TDLA, the matches become enabled again, and from this point on the channel behaves as if the first transition had never occurred.

Table 403. Channel Mode Summary 1 of 2

Mode	Initially Blocked	1st Event			2nd Event		
		Event Type	[Blocks] (Enables)[1]	Capture	Event Type	[Blocks] (Enables)	Capture

1. Transition 1 always enables Transition 2.
2. Shading indicates that a service request is generated.
3. It is not possible to include all functionality of this submode in table.

67.3.6.5 Channel link

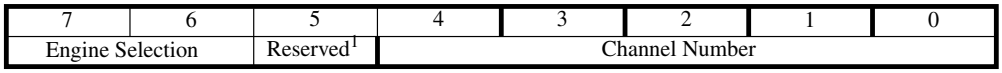
A channel can issue service requests to other channels through microcode, by assigning to the write-only microengine register LINK (refer to LINK Register) a value which specifies the target channel of the Link Service Request, as shown in the figure below.

Writing to the LINK register issues a link request to the target channel, setting its LSR flag. Each channel has its own LSR flag, which can be tested as a microcode branch condition (see Conditional/unconditional branch) and reset through the microcode field LSR (see Clear Link Service Request). The link branch condition samples, at the TST start, the value used to calculate the Entry Point.

Writing LINK with another channel target value in the same thread issues a Link Service Request to the new target, without negating the service request to the former one. This allows a channel to issue service requests to any number of channels, including itself. Neither LINK nor LSR microengine accesses are qualified by the CHAN register, i.e., they always access the serviced channel LINK and LSR, regardless of the value written in CHAN.

Channels can also receive link service requests from the Shared Subsystem Units (see Shared subsystems support) . These links are set by the interrupt signals from the shared subsystem and are level-sensitive, that is, they keep on requesting link service as long as the interrupt is active . Therefore, it is not enough to clear the link service request through the LSR instruction field: one must clear beforehand the respective shared subsystem unit interrupt source .

If microcode executes an instruction with field LSR=0 (clear Link Service Request), the link branch condition is cleared. However, the link service request itself is cleared only if no link from other channel was received by the serviced channel during the same thread[21]. Note that this applies only to links that come from the other engine or the same channel: if only Shared Subsystem link was received during the thread, the link service is also cleared with field LSR=0. If microengine clears LSR of its channel and, simultaneously, Link Service Request is issued to the current serviced channel, the branch condition is cleared but the link service request remains pending.



NOTES:
1 reserved bit must be written 0.

Figure 465. Microengine link register

A channel can issue Link Service Requests to channels in any of two Engines, determined by the LINK register field Engine Selection (2 bits), as shown in the following table. In a Single Engine eTPU, Link is ignored when sent to the other engine, or engine 2.

[21] That can only happen if the link service request came from the other Engine, or from the serviced channel itself.

Table 405. LINK Engine Selection

Engine Selection	Description
00	this Engine
01	Engine 1
10	Engine 2
11	the other Engine

There is no explicit hardware mechanism to allow the thread to identify the link service request source, but it can be done by a software protocol using SDM parameters. All links are negated on reset.

67.3.6.6 Enhanced digital filter (EDF)

EDF eliminates passing of signal transitions which are caused by noise. Its purpose is to eliminate false transition service requests caused by noise pulses which are shorter than a programmed width.

See the chip-specific eTPU information for connections between eTPU and input glitch filters.

EDF has three modes of operations, selected by the CDFC field in eTPU Engine 1 Configuration Register (ECR_ENG1) and eTPU Engine 2 Configuration Register (ECR_ENG2). These modes offer selections of trade-off between noise immunity and signal latency. CDFC also allows the filter to be bypassed. Filter clock prescaler gives an example of minimum detected signal pulse and maximum filtered noise pulse in the three EDF operation modes. In Angle Mode, if AM=01, the EDF in channel 0 is replaced with the digital filter and synchronizer of the TCRCLK signal. In this mode, channel 0 works in combination with the Angle Counter logic, and their operation is fully synchronized.

Following subsections provide the functional description of the eTPU channel digital filter.

67.3.6.6.1 Two-sample mode

In this mode the EDF works like the TPU2/3 digital filter. It uses the filter clock which is the eTPU clock divided by (2, 4, 8,.., 256) as a sampling clock. The filter clock is selected by the FPSCK field ineTPU Engine 1 Configuration Register (ECR_ENG1) and eTPU Engine 2 Configuration Register (ECR_ENG2). The EDF compares two consecutive samples. If both samples have the same value, the input signal state is updated. Note that when the FPSCK field selects the eTPU clock divided by two, the EDF works like the TPU1 four-clock digital filter.

67.3.6.6.2 Three-Sample mode

In this mode, like in the TPU2/3 mode, the EDF uses the filter clock as a sampling clock. The EDF compares three consecutive samples. If all three samples have the same value, the input signal state is updated.

The Three-Sample mode gives more signal latency than the Two-Sample mode, but also better noise immunity and better ratio between minimum detected signal pulse to maximum filtered noise pulse. When a certain filter clock frequency is selected for Two-sample mode, double filter clock frequency can be selected to get better latency in Three-sample mode.

67.3.6.6.3 Continuous mode

In this mode the EDF compares all the values sampled at the rate of eTPU clock divided by two, between two consecutive filter clock pulses. If the signal is continuously stable for the entire digital filter clock period (i.e. all the samples have the same signal value), the input signal state is updated.

This method gives the same latency and the same ratio between minimum detected signal pulse to maximum filtered noise pulse, as the Two-Sample mode, as long as there is no noise. Each sampled noise delays the signal transition detection by at least a whole digital filter clock period.

The Continuous mode gives the best noise immunity by comparing multiple samples of the noise. On the other hand, when a short noise pulse appears in the middle of the filter clock period at the same time of a real signal transition, the Continuous mode may reject a real signal transition and delay the response to the first filter clock period in which the signal is continuously stable. This may add to the latency and also to the minimum detected signal pulse in a noisy environment.

67.3.6.6.4 Bypass Mode

In bypass mode the signal that feeds the edge detection comes directly from the output of the synchronizer, not filtered. Bypass mode automatically makes the channel logic work in T2/T4 timing mode (see Channel timing modes).

67.3.6.6.5 Filter clock prescaler

Each channel configured as an input has an associated synchronizer followed by a digital filter connected to the signal that samples signal transitions. After reset, the digital filter filters out high and low pulse widths smaller than the period of two eTPU clocks with eTPU_SCR_ECR_ENG*n* field FCSS = 0, or 1 eTPU clock with FCSS = 1 (see eTPU Engine 1 Configuration Register (ECR_ENG1) and eTPU Engine 2 Configuration Register (ECR_ENG2)), preventing these transitions from being input to the transition detect logic. For FPSCK=0 and FCSS = 0, the synchronizer and digital filter are guaranteed to pass pulses that are as wide as or wider than four eTPU clocks, meaning a minimum period of 8 eTPU clocks. These figures are halved by setting FCSS = 1. By changing the FPSCK field in eTPU Engine 1 Configuration Register (ECR_ENG1) and eTPU Engine 2 Configuration Register (ECR_ENG2) the user can select a lower clock rate for the filter signal to define wider valid pulses and filter out wider noise pulses. The filter prescaler clock control is a division of the eTPU clock. To guarantee pulse detection by the digital filter, the pulse must cover at least the stated number of samples at the filter clock rate. For example, a two sample digital filter must sample two points in the pulse to detect it. The table below shows the minimum guaranteed detected pulse width and the maximum filtered noise pulse width. The table refers only to the digital filter operation. The external pulses may have to be wider (to ensure detection) or narrower (to ensure filtering) depending on the rise/fall delay differences in the MCU receivers and internal logic. Delays introduced by synchronizer, filter and edge detection logic are explained in Input/output signal delays.

The TCRCLK signal also has a synchronizer and a filter. The FCSS bit has no influence on the clock prescaler of the TCRCLK filter, which works like the channel filter with FCSS=0.

Table 406. Pulse widths and delays

Filter control (FPSCK)		Filter clock period	Min. width guaranteed detected / max. width filtered (min. filter delay / max. filter delay)	
FCSS = 0	FCSS = 1		Two-Sample or Continuous mode	Three-Sample or Integrator[1] mode
not avail.	000	1	2 / 1 (2 / 3)	3 / 2 (3 / 4)
000[2]	001	2	4 / 2 (3 / 3)	6 / 4 (5 / 5)
001	010	4	8 / 4 (5 / 7)	12 / 8 (9 / 11)
010	011	8	16 / 8 (9 / 15)	24 / 16 (17 / 23)

100	101	32	64 / 32 (33 / 63)	96 / 64 (65 / 95)
101	110	64	128 / 64 (65 / 127)	192 / 128 (129 / 191)
110	111	128	256 / 128 (129 / 255)	384 / 256 (257 / 383)
111	not avail.	256	512 / 256 (257 / 511)	768 / 512 (513 / 767)

1. Integrator mode is available for TCRCLK filtering only, see TCRCLK digital filter.
2. These delays also apply to the TCRCLK filter when TCRCF selects eTPU clock/2 as filter clock.

NOTE

The TCRCLK filter is clocked as if FCSS = 0, always dividing eTPU clock /2 using FPSCK, regardless of the FCSS field .

67.3.6.7 Channel timing modes

Channels can work on two different timing schemes, defining the period of channel clocking, tied to T2 and T4 microengine phases, as explained in subsections below. Microengine T2 and T4 phases are shown in Microcycle and I/O timing.

67.3.6.7.1 T2 channel timing

In T2 timing mode the channel event state can only be updated every two eTPU clocks (see Execution and channel timing). Pin state, TDLs, MRLs and Capture registers are updated on the microengine's T2 clock phase. MRLE clears also happen on T2, but MRLE setting occurs on T4, together with the Match register write by microcode (see Write Channel Match and UDCM Registers).

Channels work in T2 timing mode when either the T4DIS field in C*a*CR_ENG1 and C*a*CR_ENG2 is 1 or all the following conditions are true:

- The TCR1CS field in eTPU Engine 1 Time Base Configuration Register (TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (TBCR_ENG2) is 0.
- The Enhanced Digital Filter is not configured as bypass (see Enhanced digital filter (EDF)).
- The FCSS field in eTPU Engine 1 Configuration Register (ECR_ENG1) and eTPU Engine 2 Configuration Register (ECR_ENG2) is 0 (see Filter clock prescaler).

67.3.6.7.2 T2/T4 channel timing

In T2/T4 timing mode the channel event state can be updated on any eTPU clock (see Execution and channel timing). Pin state, TDLs, MRLs, MRLEs, and Capture registers are updated either on microengine's T2 or T4 clock phases. MRLE clears can happen on T2 or T4, but MRLE setting occurs on T4 only, together with the Match register write by microcode (see Write Channel Match and UDCM Registers).

Channels work in T2/T4 timing mode when the T4DIS field in C*a*CR_ENG1 and C*a*CR_ENG2 is 0 and either one the following conditions are true:

- The TCR1CS field in eTPU Engine 1 Time Base Configuration Register (TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (TBCR_ENG2) is 1.
- The Enhanced Digital Filter is configured as bypass (see Enhanced digital filter (EDF)).
- The FCSS field in eTPU Engine 1 Configuration Register (ECR_ENG1) and eTPU Engine 2 Configuration Register (ECR_ENG2) (see Filter clock prescaler).

T2/T4 timing mode demands special care on channel microcode that reprograms a match in a thread with matches enabled (entry point ME=1, see the “Entry Points” section). When the match register is written and the MRLA/B flag(s) is(are) cleared in the same instruction, a match can occur after MRLA/B is cleared, together with the set of respective MRLE. In this case, both MRL and MRLE will be set, and a match service request will occur if enabled. However, the match happened on the old match value, not on the new (reprogrammed) one. In order to prevent this ambiguity to the code that services the match, it is advisable to clear the MRLE (besides MRL) together with the match reprogramming, avoiding the match on the old value to occur while the new match value is being written. The set of the MRLE due to match reprogramming prevails over the MRLE clear, thus allowing the new programmed match to occur in the future.

A similar case occurs when a match is blocked by a transition, the blocking TDL is cleared and the blocked match is reprogrammed at the same instruction: in T2/T4 timing mode: a match can occur on the old match value. The solution is the same as the case above, that is, clear the respective MRLE in the same instruction.

67.3.7 Clocking

eTPU consists of these clocks:

- System clock

- Gated system clock
- Engine clock

67.3.8 Time bases

Each eTPU engine has two Time Counter Registers, TCR1 and TCR2. They provide 24-bit time bases, shared by all 32 channels. Any channel can use both time bases to:

- Match channel's internal registers MatchA or MatchB;
- Capture time base value to channel's internal registers, CaptureA and/or CaptureB, when a match recognition or an Input transition detection occurs. For more information on channel events refer to Enhanced Channels.

The TCR1 and TCR2 counters are accessible by the microcode for read and write operations. Its current value is used for getting the current time, and the captured values are used for channel relative time calculations of future events. When they are written at the same time they are incremented from any clock source, the written value prevails.

TCR1 with eTPU_TBR_TBCR_ENG*n*[TCR1CS]=0 and TCR2 values are updated in T2 and read in T4 (see Microcycle and I/O timing). TCR1 can also work at full-speed eTPU clock, and so be updated on both T2 and T4, when eTPU_TBR_TBCR_ENG*n*[TCR1CS]=1. Both TCR1 and TCR2 values can be imported from or exported to the STAC bus. When their values are imported (Clients), these registers are written from the bus and can only be read by microcode.

The TCR2 counters between the two Engines are out of phase by 1 eTPU clock, even when Time Bases are shared between them through . It also applies to TCR1 counters if eTPU_TBR_TBCR_ENG*n*[TCR1CS]=0, but they can be in phase otherwise.

67.3.8.1 Timer Count Register 1 (TCR1)

TCR1 can be used in the following modes:

- Internally Clocked Mode
- Externally Clocked Mode
- Bus Client Mode

The host program can read TCR1 time base through eTPU Engine 1 Time Base 1 (TCR1) Visibility Register (TB1R_ENG1) and eTPU Engine 2 Time Base 1 (TCR1) Visibility Register (TB1R_ENG2).

The TCR1 bus runs through all the local engine channels. In channels which select TCR1 as MatchA and/or MatchB source, when its value is greater or equal to the programmed match value, a Match A and/or Match B event occurs on that channel. A recognized match event sets its related Match Recognition Latch 1 or 2, and according to the Predefined Channel Modes (PDCM) it may generate a channel service request. For details on eTPU channels see Enhanced Channels.

67.3.8.1.1 Externally Clocked mode

TCR1 can be driven externally by the TCRCLK input, after the digital filter. The TCR1 clock source is configured by the TCR1CTL bit, as shown in the following figure. For more information on clock source selection, see eTPU Engine 1 Time Base Configuration Register (TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (TBCR_ENG2).

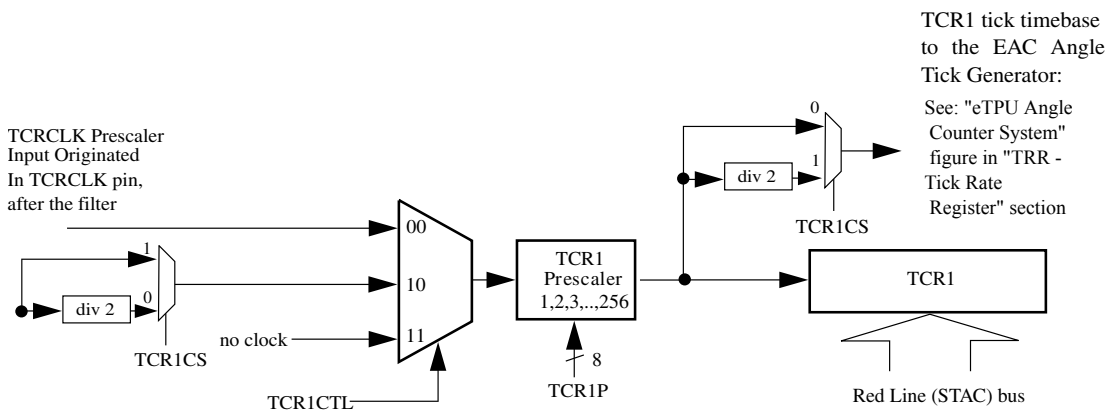

Figure 466. TCR1 clock selection

67.3.8.1.2 Internally Clocked Mode

TCR1 can be driven by the eTPU clock or eTPU clock divided by 2, before the prescaler. TCR1CTL can also be used to freeze TCR1 clock independently of TCR2 (unlike GTBE).

67.3.8.1.3 TCR1 clock prescaling

Any clock source selected by TCR1CTL is prescaled by a factor of 1 to 256, selected by the TCR1P field in eTPU Engine 1 Time Base Configuration Register (TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (TBCR_ENG2). For more information on prescaler configuration, see eTPU Engine 1 Time Base Configuration Register (TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (TBCR_ENG2). The TCR1 Prescaler resets when the eTPU GTBE input is negated. After reset, it starts counting up to TCR1P when the eTPU GTBE input is asserted. When TCR1 increments (the eTPU GTBE input = 1), the prescaler starts a new count and the new TCR1P becomes effective. When TCR1 is written by microcode, the prescaler is reloaded with TCR1P and it becomes effective, if the eTPU GTBE input is asserted.

67.3.8.1.4 STAC Bus Client Mode

In this mode the TCR1 register is continuously updated from the bus, and the clock selection and prescaling logic becomes ineffective. It is not writable by the microcode, and when read, it reflects the bus imported value. The use of EAC is not allowed in client mode. This mode is configured through eTPU Engine 1 STAC Configuration Register (STAC_ENG1) and eTPU Engine 2 STAC Configuration Register (STAC_ENG2).

67.3.8.1.5 STAC Bus Server mode

TCR1 bus can be exported to the bus as a server, providing time information to other peripherals. This mode is configured through eTPU Engine 1 STAC Configuration Register (STAC_ENG1) and eTPU Engine 2 STAC Configuration Register (STAC_ENG2).

67.3.8.2 Timer Count Register 2 (TCR2)

The TCR2 is a 24-bit counter which can be used in the following modes:

- Pin Transition Mode: Count the rise, fall, or both transitions of TCRCLK signal.
- Angle Clock Mode: Count internal tooth angle in combination with the eTPU Angle Counter (EAC) hardware which implements an Angle PLL, and generates angle information to the channels. This mode is targeted for angle-based applications.
- (STAC) Bus Client Mode: TCR2 is driven by an external source (see STAC Bus Client mode).
- Gated Mode: Count with rate derived from the eTPU clock divided by eight. The TCRCLK signal is used to gate this count, enabling pulse accumulator operations.
- Internally Clocked Modes: TCR2 is driven by internal clock, with count rate of eTPU clock divided by eight.

All clock sources pass through a prescaler. In addition, the TCR2 count can be originated from the EAC which is a hardware angle clock and angle counter. shows the diagram for TCR2 clock control. When TCR2 is not driven by the EAC or , the eTPU_TBR_TBCR_ENG*n*[TCR2CTL] field selects the clock source, also allowing TCR2 to be frozen independently of TCR1 (see eTPU Engine 1 Time Base Configuration Register (TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (TBCR_ENG2)). When in Angle Mode, TCR2CTL selects the TCRCLK edge sensitivity.

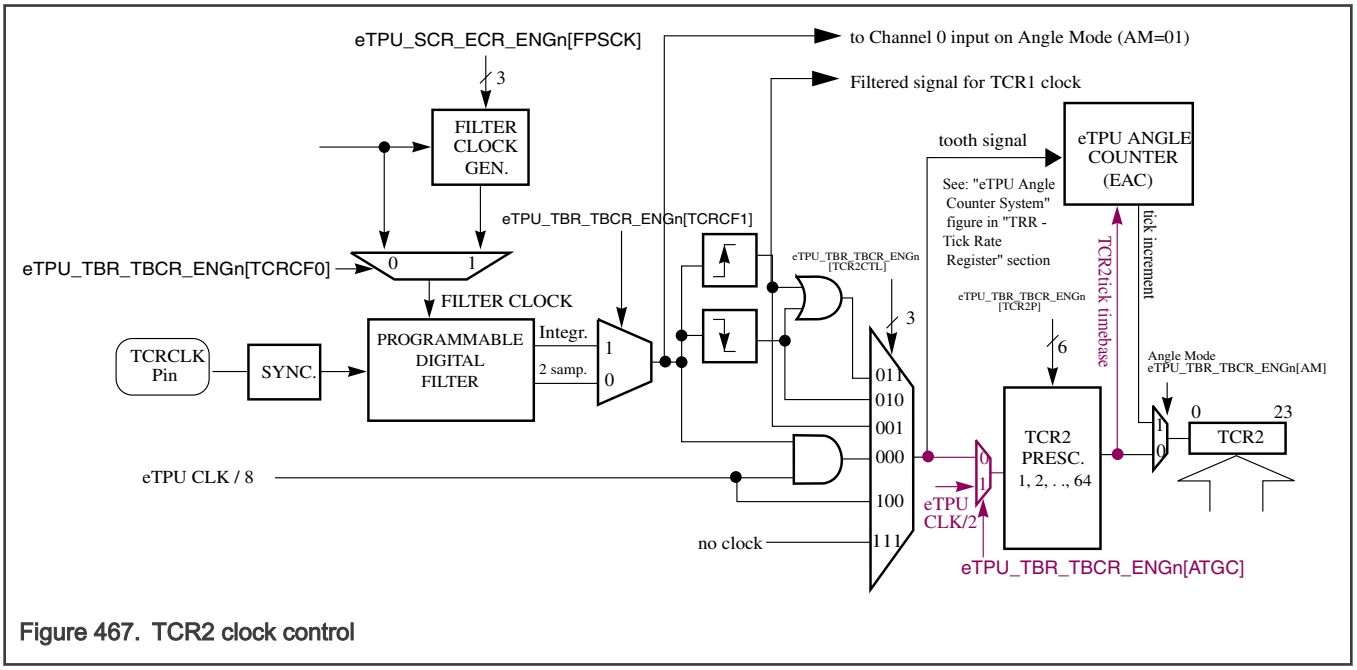

Figure 467. TCR2 clock control

The TCRCLK signal input is passed through a synchronizer and a programmable digital filter. In Angle Mode with AM=01, synchronizer and filter are also used in Channel 0, replacing its input synchronizer and filter, to get the same timing in the EAC and Channel 0. The TCRCLK synchronizer is an improved filter that provides best latency while maintaining proper noise filtering (see the field TCRCF in eTPU Engine 1 Time Base Configuration Register (TBCR_ENG1))

The TCR2 bus runs through all the local engine channels. It transitions on clock T2 (see Microcycle and I/O timing). In channels which select TCR2 as MatchA and/or MatchB source, TCR2 value is compared against MatchA and/or MatchB registers. A recognized match event sets its related Match Recognition Latch 1 or 2, and according to the Predefined Channel Modes (PDCM) it may generate a channel service request. For details on eTPU channels see Enhanced Channels.

The TCR2 counter is accessible by the microcode for read and write operations. Its current value is used for getting the current counter value (representing signal transitions, time or angle), and the captured values are used for channel relative count calculations of future events. The TCR2 value is readable to the host through eTPU Engine 1 Time Base 2 (TCR2) Visibility Register (TB2R_ENG1) and eTPU Engine 2 Time Base 2 (TCR2) Visibility Register (TB2R_ENG2). When the TCR2 bus value is imported from the bus (client mode), TCR2 is not writable by the microcode, and read access from the microcode or from the host reflect the imported TCR2 value.

67.3.8.2.1 TCR2 clock prescaling

Except in Angle Mode, any clock source selected by TCR2CTL is prescaled by a factor of 1 to 64, selected by eTPU_TBR_TBCR_ENG*n*[TCR2P]. For more information on prescaler configuration, see eTPU Engine 1 Time Base Configuration Register (TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (TBCR_ENG2). The TCR2 Prescaler resets when the eTPU GTBE input is negated. After reset, it starts counting up to TCR2P when the eTPU GTBE input is asserted. When TCR2 increments (the eTPU GTBE input = 1), the prescaler starts a new count and the new TCR2P becomes effective. When TCR2 is written by microcode, the prescaler is reloaded with TCR2P and it becomes effective, if the eTPU GTBE input is asserted.

The counter that divides the eTPU clock by 8 before the prescaler also resets when the eTPU GTBE input is negated, or when TCR2 is written by microcode.

In Angle Mode the TCR2 prescaler is not used to directly increment TCR2, but can be used, selected by programming eTPU_TBR_TBCR_ENG*n*[ATGC]=1, as a clock source for the EAC generation of the angle ticks which increments TCR2 . In this case, the TCR2 prescaler input is eTPU clock/2, independently of TCR2CTL . See Generating the angle ticks for details .

67.3.8.2.2 TCR2 Gated mode

TCR2 Gated mode is selected in the eTPU_TBR_TBCR_ENG*n*[TCR2CTL] field. In this mode the TCRCLK signal enables or disables transfer of the eTPU clock divided by 8 to the TCR2 prescaler. By programming the prescaler, TCR2 can run at rates from eTPU clock divided by eight down to eTPU clock divided by 512, in steps of eight eTPU clock divisions. For more information, see eTPU Engine 1 Time Base Configuration Register (TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (TBCR_ENG2).

67.3.8.2.3 TCR2 Signal Transition modes

These modes are selected when eTPU_TBR_TBCR_ENG*n*[TCR2CTL] is set to rise, fall or "rise-and-fall". In these modes the TCRCLK signal is the TCR2 clock source, and its maximum transition rate depends on the TCRCLK digital filter mode of operation. The TCRCLK digital filter can be programmed to use the eTPU clock divided by two, or use the same filter clock of the channels, controlled by eTPU_TBR_TBCR_ENG*n*[TCRCF]. It contains an up-down counter which operates as a digital integrator, optimizing signal latency in the selected mode and clock rate.

When eTPU clock divided by two is selected, the synchronizer and the digital filter are guaranteed to pass pulses that are wider than four eTPU clocks (two filter clocks). Otherwise the TCRCLK is filtered with the same filter clock as the channel input signals. For details on TCRCLK and channels digital filter control, see eTPU Engine 1 Time Base Configuration Register (TBCR_ENG1), eTPU Engine 2 Time Base Configuration Register (TBCR_ENG2), and Enhanced digital filter (EDF).

67.3.8.2.4 STAC Bus Client mode

In this mode the TCR2 register is continuously updated from the bus, and the clock selection and prescaling logic becomes ineffective. It is not write accessible for the microcode, and when read, it reflects the bus imported value. The use of EAC is not allowed in client mode. This mode is configured througheTPU Engine 1 STAC Configuration Register (STAC_ENG1) and eTPU Engine 2 STAC Configuration Register (STAC_ENG2).

67.3.8.2.5 STAC Bus Server mode

When TCR2 bus is exported to the bus as a server, it can provide either time or angle bus to other peripherals, according to its operation mode. This mode is configured through eTPU Engine 1 STAC Configuration Register (STAC_ENG1) and eTPU Engine 2 STAC Configuration Register (STAC_ENG2). To provide sequential update of the clients, the Angle tick rate must not be faster than the programmed update rate. This requirement puts a limitation on the angle clock count rate on high rate mode. In this case the Angle and Angle Fraction accumulator (see Angle Tick Generator and Tick rate register (TRR)) are advanced at rate of eTPU clock divided by eight. Therefore, the update rate for the Angle Bus must not be slower than eight eTPU clocks.

67.3.8.2.6 TCR2 bus in Angle Clock mode

In this mode the TCR2 counter operates as part of the eTPU Angle Counter (EAC). The TCR2 bus value reflects this angle representation in which it counts Angle Ticks. Angle Mode is selected when eTPU_TBR_TBCR_ENG*n*[AM]=1.

Note that when TCR2 works in Angle Mode, it does not count directly from the TCR2 clock input which indicates tooth signal transition. Its Angle counter is controlled by the Count Control and High Rate logic (see Count Control and High Rate Logic), which provides the interpolated pin position, and handle cases of missing tooth, acceleration, de-acceleration and mechanical corrections.

The EAC uses the TCRCLK signal to get the tooth transition indications. The eTPU_TBR_TBCR_ENG*n*[TCR2CTL] field has to be set for the appropriate tooth edge detection rise, fall, "rise-and-fall" or none. TCR2 count clock comes from the EAC control and not directly from the physical tooth. This way the EAC control processes the signal transitions and handles missing teeth and flywheel mechanical corrections. Note that when TCR2CTL selects "none" for tooth edge selection, the TCR2 is not necessarily frozen, but can still be incremented by the EAC logic.

In Angle Mode, eTPU channel 0, 1 or 2 operation is combined with the EAC operation. When channel 0 is selected for EAC operation, the TCRCLK digital filter is used both by the EAC and by channel 0 to get full synchronization between the two logics.

The eTPU Angle Counter (EAC) logic runs continuously and updates the TCR2 Angle counter, eliminating the microcode latency in updating the TCR2 value.

67.3.8.3 STAC interface

Both time bases TCR1 and TCR2 can be shared between the Engines and with other blocks in the same MCU. Each one of both eTPU engines can drive their time bases to the (Shared Time and Count) bus, acting as a server, while any other block can capture the value into its resources and behave like a client. For further reference about the bus operation see eTPU Engine 1 STAC Configuration Register (STAC_ENG1) and eTPU Engine 2 STAC Configuration Register (STAC_ENG2).

The eTPU can export to the bus or import from the bus the following internal resources:

- TCR1: Can be exported to or imported from the bus. TCR1 can only be imported from bus when the engine is not in Angle Mode. When TCR1 is imported from the bus, it becomes read-only for the microcode and reflects the imported values. For details, see Timer Count Register 1 (TCR1).
- TCR2: Can be exported to or imported from the bus. TCR2 can only be imported from the bus when engine is not in Angle Mode. When TCR2 is imported from the bus, it becomes read-only for the microcode, and reflects the imported values. When exported to the bus, TCR2 can work in either Angle Mode or as a free running counter associated with the TCRCLK signal. For details, see EAC - eTPU Angle Counter.

Proper configuration of the following bits is necessary to determine what can drive the bus: eTPU_TBR_TBCR_ENG*n*[AM] and eTPU_TBR_STAC_ENG*n*[REN2, RSC2], according to the following table.

Table 407. bus and host read sources

AM (eTPU_TBR_TBCR_ENG*n*)	REN2, RSC2 (eTPU_TBR_STAC_ENG*n*)	TCR2 bus source (Host read of eTPU_TBR_TB2R_ENG*n*)	bus driver
00	0× (disabled)	TCR2/Time	×
01, 10 or 11	0× (disabled)	TCR2/Angle	×
00	11 (Server)	TCR2/Time	TCR2/Time
01, 10 or 11	11 (Server)	TCR2/Angle	TCR2/Angle
01, 10 or 11	10 (Client)	not allowed[1]	

1. client configuration in Angle Mode is also not allowed for TCR1.

Note that Angle Mode is not available for bus clients: configuring both at the same time brings unspecified results and must be avoided. When TCR2 is a standalone counter or a Bus server, the same value that is driven to the internal TCR2 bus is also exported to the bus (either Time Count or Angle).

bus configuration is provided by the eTPU_TBR_STAC_ENG*n* fields REN1/2 and RSC1/2. REN1/2 enable the interface to interact with the resource (either TCR1 or TCR2 bus). RSC1/2 configure the resource (either TCR1 or TCR2 bus) as Server or Client.

Each time base / angle count resource from each engine receives a unique 4-bit hardwired address that identifies it as a potential server. This address is used by the Controller to coordinate which resource will drive the bus at a given time-slot. For any time-slot there is a server driving the bus upon selection of the Controller, and there may be a client linked to that server by the eTPU_TBR_STAC_ENG*n* fields bits SRV1/2 on each Engine. When the server address on the Red Line bus matches the value in SRV1/2, the client will load the information into the appropriate resource. For information on eTPU Bus configuration, see eTPU Engine 1 STAC Configuration Register (STAC_ENG1) and eTPU Engine 2 STAC Configuration Register (STAC_ENG2).

The eTPU does not include a Controller module, which is instantiated once in the system integration.

NOTE

Setting a timebase as client of itself is not allowed.

67.3.8.4 Global time base enable (GTBE)

MCR[GTBE] enables time bases in both engines, allowing them to be started synchronously. GTBE is divided in two block interface signals: the eTPU GTBE output and the eTPU GTBE input. GTBE bit sets the eTPU GTBE output , and the eTPU GTBE input enables time bases to start. For more details, see the chip-specific eTPU information. If MCR[GTBE] must enable only the eTPU time bases, the eTPU GTBE output is simply connected to the eTPU GTBE input. These two cases are shown in the figure below. Synchronization logic can be as simple as an OR logic gate.

Once the eTPU GTBE input transitions to 1, the Engine 1 Time Bases start 1 eTPU clock earlier than Time Bases in Engine 2, except when TCRCLK is selected as clock source or TCR1 when eTPU_TBR_TBCR_ENG*n*[TCR1CS] = 1. This happens independently of prescaler values as long as they are the same for both engines, because the prescalers also freeze when the eTPU GTBE input = 0. Microcode can always write to TCR1/2 registers, with either value of the eTPU GTBE input.

NOTE

The timebase prescalers are reset when the GTBE input is negated.

67.3.8.5 TCRCLK digital filter

The TCRCLK signal has an improved integrating digital filter with a 2-bit up-down counter. The counter counts up to 3 when a high signal level is detected, or down to 0 when a low level is detected. The signal state is updated to one when the counter stops at 3, or zero when the counter stops at 0. The eTPU_TBR_TBCR_ENG*n*[TCRCF] field (see eTPU Engine 1 Time Base Configuration Register (TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (TBCR_ENG2)) determines whether the TCRCLK signal input (after a synchronizer) is filtered with the same filter clock as the channel input signals (see Enhanced digital filter (EDF)) or uses the eTPU clock divided by 2, and also whether the TCRCLK digital filter works in integrator mode or the same two sample mode as the channel filters (see TBSA and TBSB - Time Base Selection Registers).

The TCRCLK filter delay and prescaling determine the minimum detectable TCRCLK pulse widths and, therefore, its maximum frequency, as shown in Filter clock prescaler and Filter clock prescaler. The TCRCLK signal delay from the module input to TCR1/TCR2 incrementing or detection in the EAC logic is explained in Input/output signal delays.

67.3.9 EAC - eTPU Angle Counter

67.3.9.1 General

The EAC logic contains a mechanism which follows the flywheel angle, based on the tooth rate. This hardware works in combination with the TCRCLK signal, the TCR2 counter and Channel 0, 1 or 2 (depending on the eTPU_TBR_TBCR_ENG*n*[AM] field) to generate angle information on the TCR2 bus which is passed to all the local engine channels. The EAC helps to implement a digital angle PLL (see Tick rate register (TRR)), which combines hardware with microcode processing at channel 0, 1 or 2. The angle measurement is based on history knowledge of the tooth period, for predicting the period of the next tooth. The tooth period is partitioned into a programmable number of **Angle Ticks**. The eTPU application will use the divider in the MAC/Divide unit to calculate an integer and a fraction part of the angle tick such that the full tooth period gets the correct programmed number of angle ticks with no accumulated error.

Each single tooth can be divided in angle ticks, up to 1024. In a 60 teeth flywheel, 128 Angle Ticks per tooth provide resolution of ~0.05 degrees per tick, which meets the accuracy requirement of 0.1 degrees in current automotive applications.

The measurement of one tooth in angle ticks is independent on engine RPM; it is the tooth period itself (and the corresponding tick period) that is re-calculated for each new tooth, based on the difference between the estimated tooth and the actual detection.

For these applications, one of the eTPU channels 0, 1 or 2 is dedicated to service the physical tooth detection. Channel 0 shares the same filtered input as the TCRCLK signal to get the same timing as the EAC. The TCRCLK edge detection is selected by the eTPU_TBR_TBCR_ENG*n*[TCR2CTL] field for the EAC, and by IPACA/B on channel 0, which must be set to detect the same edge(s). When channels 1 or 2 are selected to work with the EAC, IPACA/B is used to select the tooth signal edge detection for both the channel and the EAC, and the tooth signal that feeds the EAC is the same filtered input which feeds the channel.

Channel 0, 1 or 2 generates the signal transition service request, and can also be used for generation of a window filter on this transition, to qualify TCR2 clocks. For this purpose, the selected channel should be configured with double match window filtering mode (refer to Channel Modes). Depending on the channel mode set for the channel, Match A recognition opens the window, and Match B recognition may close it or leave it open. See Angle Logic and Channel Modes for details. Match B also generates a time-out service request. Its input signal transition comes from the tooth. The window can be defined by microcode to open at a predefined point inside the tooth period, and stay open for a desired percentage to the tooth period. The window can be measured in angle or time This method improves the noise immunity by allowing transition detection only on an expected period, a feature which was software responsibility in previous TPU versions.

The EAC supports deceleration, acceleration, last tooth and missing tooth scenarios. The large range of angle ticks per tooth can be used to cover longer tick counts caused by one or more missing teeth, or to provide extra resolution for future application requirements. In case of a missing tooth, the EAC can be configured to insert a dummy tooth or to simply measure a longer tooth.

Tick rate register (TRR) shows the block diagram of the Angle Counter system. TCR1 or TCR2 prescaler is used as a time base which measures the tooth period and is used for partitioning the period to angle ticks.

67.3.9.2 Angle Mode registers

In Angle Mode, the registers described below control eTPU angle operations. They are accessible only by microengine as source and destination registers in microinstructions. When eTPU is not in angle mode (eTPU_TBR_TBCR_ENG*n*[AM] field is negated), all Angle Mode registers can be used as general purpose registers.

67.3.9.2.1 TPR - Tooth Program Register

TPR provides configuration for the Angle Counter circuit. In this register, the microcode can properly adjust the tooth count (controlling last tooth, missing teeth, dummy tooth insertion, halt until tooth detection) and the number of angle ticks per tooth (field TICKS). Note that this register is sampled into a temporary register in the EAC logic when the High Rate Mode is detected (see High rate mode (acceleration) and TPR Buffering), which means that changes to this register may take effect only for the next tooth.

See Count Control and High Rate Logic and to Special Cases of Missing Teeth and Last Tooth until Handling False Tooth Detection for a detailed explanation about the use of this register. The figure below provides a detailed description of TPR register.

Several conflict issues on TPR writes are explained in Special TPR write cases.

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	LAST	MISSCNT [1:0]		IPH	HOLD	MISS CNT [2]	TICKS									
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 468. TPR

Table 408.

LAST —Last Tooth Indication

Asserted by microcode and negated when a tooth is detected or inserted via IPH.

1 = Last Tooth - reset TCR2 Counter at the end of the tooth tick count (after physical tooth or IPH=1) when MISSCNT=0.

0 = Not Last Tooth.

If the tooth is detected or inserted before the tooth tick count completes (going High Rate mode, see High rate mode (acceleration)), LAST resets immediately, but TCR2 resets only when the tooth count completes and MISSCNT=0.

Table continues on the next page...

Table 408. (continued)

MISSCNT — Missing Tooth Counter

Decremented on each estimated tooth, stops at zero. Used for generation of up to 7 "Dummy Teeth" whenever it holds a non-zero value.

If the tooth is detected or inserted before the missing tooth tick count completes (going High Rate mode, see High rate mode (acceleration)), MISSCNT resets immediately, but missing teeth count continues in High Rate mode (see TPR Buffering).

IPH — Insert Physical Tooth

This bit generates a dummy physical tooth which has the same effect as a real physical tooth, and resets itself subsequently. If EAC is in Halt mode, it switches back to Normal mode[1]. If EAC is in Normal Mode, it switches to High Rate Mode. If Angle Logic is frozen by HOLD=1 (see below), it returns to the state it was at the freezing moment.

1 = Insert dummy physical tooth.

0 = No Operation.

NOTE

IPH reads as 1 in the next microinstruction after it is asserted, negating subsequently. However, it can be set twice in two consecutive microinstructions to generate two teeth and make the EAC go from Halt to Normal to High Rate Mode.

HOLD — Force EAC Hold

This bit forces the EAC to halt its operation in a special EAC freeze mode until a new physical tooth (a real one or emulated with IPH=1) is detected. Assertion of this bit immediately freezes the EAC in the middle of the tooth period. When a new physical tooth is detected, the bit is automatically negated by the EAC. The HOLD bit can be used for synchronizing the EAC tooth count, in case that a false physical tooth is detected due to noise.

1 = Force EAC to halt until detection of a physical tooth.

0 = Normal Operation.

TICKS — Angle Ticks Number in the Current Tooth

This field defines the number of angle ticks in the current physical tooth. It partitions the tooth period to the required number of angle ticks. The actual number of angle ticks in a tooth is (TICKS+1).

NOTE

In High Rate mode (see High rate mode (acceleration)), TPR writes are immediately effective only for bits IPH and HOLD. All other fields changes are "buffered" and become effective when EAC leaves High Rate mode. See also Special TPR write cases.

NOTE

Bits LAST, IPH and HOLD must not be asserted all at once

1. Missing a physical tooth naturally causes EAC to get into Halt mode.

67.3.9.2.2 TCR2 - Timer Counter 2

In Angle Mode, TCR2 (see the following figure) counts angle ticks instead of time.

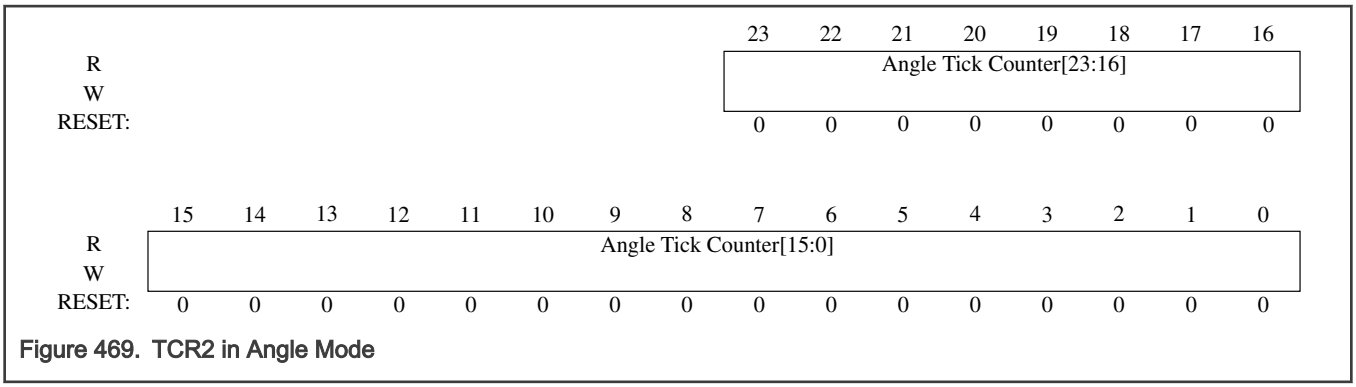

Figure 469. TCR2 in Angle Mode

This 24-bit free-running counter is used to generate an accumulated Angle Fraction value. It is updated by the Angle Tick Generator - refer to Angle Tick Generator for more details. Refer to Count Control and High Rate Logic for a detailed explanation about the use of this register in Angle Mode.

TCR2 provides continuous count of the angle in units of angle ticks. The Angle Tick Counter in TCR2 can be reset due to "Last Tooth" microcode indication. TCR2 Prescaling is disregarded in Angle Mode: physical tooth detection is done by EAC regardless of the value set in TCR2P.

67.3.9.2.3 Tick rate register (TRR)

The exact period of the Angle Tick is programmed in the Tick Rate Register (see the figure below) by microcode. The TRR time unit depends on eTPU_TBR_TBCR_ENG*n*[ATGC] (see):

- if ATGC=0, the TRR time unit is the period of TCR1 clocks taken as eTPU clocks divided by 2*(TCR1P + 1), even if TCR1CS=1 (see eTPU Engine 1 Time Base Configuration Register (TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (TBCR_ENG2)).
- if ATGC=1, the TRR time unit is given by the eTPU clock divided by 2*(TCR2P+1), using the TCR2 prescaler fed by eTPU clock/2 (independently of TCR1CS) .

See Calculating the angle tick period integer and fraction for a complete description about the mechanism to calculate the value to be written into this register.

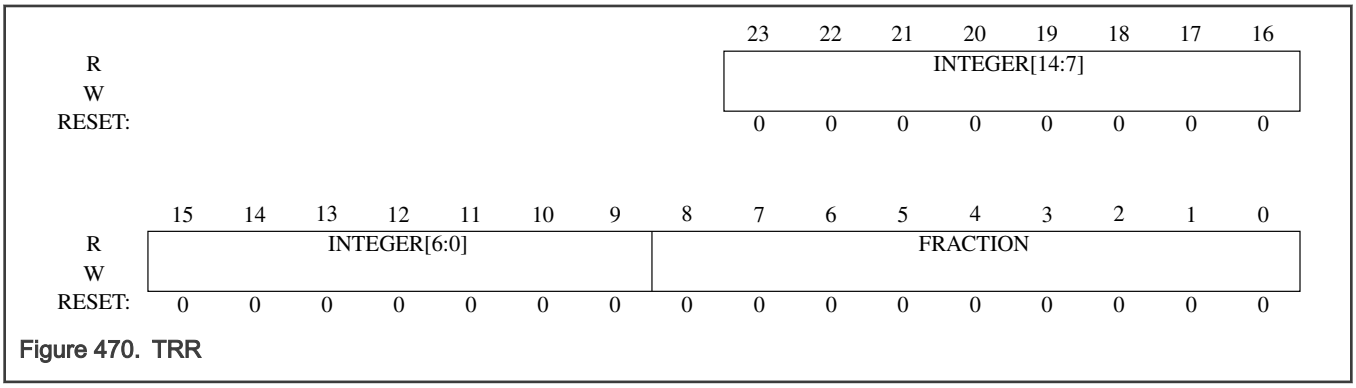

Figure 470. TRR

INTEGER — The integer part of TCR1/TCR2 clocks in one Angle Tick.

This number, decremented by one, works as a down counter preload value. A value of INTEGER=0 represents an integer of 32768. A new value written is reloaded into the counter (becoming effective) when a new tick starts or a tooth is detected or inserted via IPH.

FRACTION — Nine-bit fractional part of TCR1/TCR2 clocks in one angle tick.

Table continues on the next page...

Table continued from the previous page...

The FRACTION value is accumulated in the EAC Fraction Accumulator, and whenever the result overflows (that is, the accumulated fraction added up to an integer), the Tick Prescaler is halted for one TRR time unit.

67.3.9.3 Acceleration and Deceleration

Acceleration and deceleration affect the new tooth period relative to the known period of the last tooth. Changes in tooth period may be extreme at very low engine RPM (such as cold start and warm start). The worst case of tooth period changes is caused during missing teeth, since there is more time for changes in angular velocity to be unnoticed by the EAC hardware. For example, on cold start (~20 RPM) there may be extreme acceleration: the ratio between a known tooth period before two missing teeth and the new tooth period after the missing teeth can be very high (up to a factor of 75). Acceleration and deceleration effects from tooth to tooth are less extreme as the engine climbs to high RPM.

In case of deceleration, the estimated tooth period ends before the actual tooth detection arrives. In this case, the EAC hardware waits at the end of the current tooth period, when it is said to be in **Halt mode**, until the real tooth indication is received, then continues with normal operation (**Normal mode**). See Tick rate register (TRR).

In case of acceleration, the actual tooth period is shorter than the estimated tooth period. As a result, a new physical tooth indication arrives before the end of the estimated tooth period. In this case the EAC closes the gap on **High Rate mode** by counting on eTPU clock divided by eight to the end of the tooth, advances to the next tooth, and switches back to normal operation mode. See Tick rate register (TRR).

The reason that the EAC does not jump directly to the next tooth is the need to provide sequential angle count throughout the whole tooth period, for channels or external clients (if TCR2 is a server) which compare angle in "equal" mode. These peripherals must get all the valid angle values in a sequential manner, to avoid missing angle matches.

TCR2 advancing from one tooth to another is a continuous count, and can be optionally reset at the end of the tooth. An estimated tooth is generated after the Tooth Tick Counter reaches the TICKS programmed value.

The EAC works continuously and switches automatically between Normal, Halt and High Rate modes. It relies on the microcode to calculate the estimated tooth period on every tooth, and to update the correct angle tick and tooth parameters in the EAC control registers. On high RPM, tooth period changes are reduced from tooth to tooth, and the EAC may follow the angle with good accuracy for several teeth without microcode intervention.

The EAC handles missing teeth by insertion of "dummy" teeth, or by enlarging the expected tooth period. It is a good practice to locate the flywheel missing teeth in non-critical angles, since a missing tooth may increase the angle measurement error (acceleration and deceleration is detected late).

67.3.9.4 Angle Tick Generator

The Angle Tick Generator is responsible for generating a programmed number of angle ticks in the tooth period. It generates the ticks in an average rate which ensures completion of the correct number of angle counts in the estimated period of the tooth, since the count of one tooth in angle ticks is independent on engine RPM. The main output of the Angle Tick Generator is the tick clock that feeds TCR2 in Angle Mode, as well as the internal Tooth Tick Counter (see Tick rate register (TRR)). The Tooth Tick Counter counts ticks within a tooth, from 0 up to TICKS, is controlled by the Angle Tick Generator logic and cannot be accessed by microcode. Refer to Calculating the angle tick period integer and fraction for a generic presentation of the angle tick count and the measurement of a single tooth period.

67.3.9.4.1 Calculating the angle tick period integer and fraction

On each tooth the microcode has to update the exact period of a single angle tick used for counting the internal angle in the tooth. The period of an angle tick is determined by the EAC configuration, see Generating the angle ticks for details.

The microcode can use the eTPU MAC Divider unit (see MAC and Divide Unit (MDU)) to divide the tooth period by the number of angle ticks per tooth, which is stored in the TICKS field of TPR (refer to Angle Mode registers). This division yields the integer part of the angle tick period and the remainder. Dividing again the remainder shifted left nine positions, by the number of angle ticks per tooth translates the remainder to a 9-bit fraction. The microcode concatenates the 15-bit integer and the 9-bit fraction

to a 24-bit value and writes it to TRR. The new rate is effective immediately after the next Angle Tick is generated by the Angle Tick Generator[22].

For high RPM, note that shifting the tooth period value nine positions to the left prior to the first divide operation would calculate, in one operation, the integer and the fraction. For example: On 60 teeth flywheel running at 1000 RPM, tooth period is 1 msec. If TCR1/TCR2 counts @25 MHz, it counts 25,000 times in a tooth, which can be represented by 15 bits. Therefore the tooth period can be shifted nine positions to the left prior to divide operation, and be represented with 24 bits.

Using shift left nine positions and one divide operation would get the result in MACL register (in MDU) which holds the integer and nine bits of the fraction:

NOTE

In the pseudo code above, the tooth period (ToothPeriod) is not, in general, the value of estimated tooth time. It is obtained by microcode by subtracting TCR1 values between two teeth detections, converted to TCR2 periods if ATGC=1. Its comparison with the estimated tooth time indicates acceleration (if minor) or deceleration (if greater) to the microcode.

On low RPM the initial tooth period, measured in TCR1/TCR2 counts, may be too big to be shifted nine positions to the left. For lower RPM (for example 500 RPM) the tooth period cannot be represented by 15 bits, and shifting it nine positions to the left would lose the MSB. In this case, two divide operations are required as follows: first divide the Tooth Period by the number of TICKS - the integer is stored in MACL and remainder in MACH. MACL is saved in another register. MACH is shifted 9 positions to the left and divided again by TICKS. In parallel with the second divide, the register which saved the original MACL is shifted left 9 positions. After the divide MACL contains the 9 bits fraction and the other register contains the 15-bit integer, shifted left nine times. The logical OR of the two registers is written to the TRR:

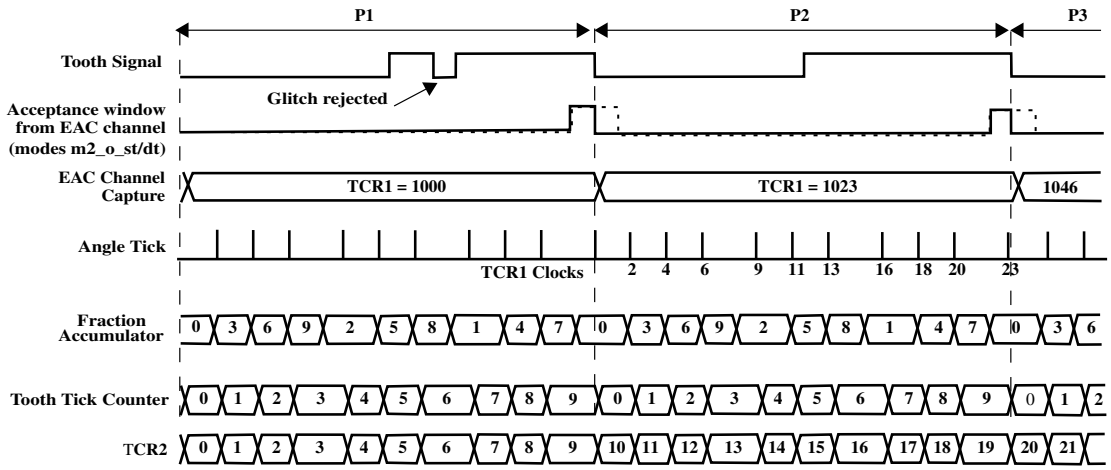

Figure 471. Angle ticks generation

67.3.9.4.2 Generating the angle ticks

The integer part of TRR is preloaded to a prescaler, which counts in time intervals as follows (see Tick rate register (TRR)):

- If eTPU_TBR_TBCR_ENG*n*[ATGC]=0, one unit of TCR1 clock period (if TCR1CS=0) or twice the TCR1 clock period (if TCR1CS=1)[23], that is, eTPU clock period*2*(TCR1P+1) (independently of TCR1CS).
- If ATGC=1, two units of the eTPU clock period multiplied by the TCR2 prescaler factor, that is, eTPU clock period*2*(TCR2P+1) .

[22] In High-rate mode, the tick keeps being updated at the rate of eTPU clock/8 until it goes back to Normal mode, when the new TRR value is used.

[23] The EAC logic overall runs at a rate of eTPU clock divided by 2, therefore the tick generator takes the halved TCR1 clock when TCR1CS=1 and ATGC=0.

When the down counter reaches zero, it generates an angle tick pulse to the Angle Counter Logic and a Load pulse to the Fraction Accumulator. It is then preloaded with most updated TRR integer part. Due to the Load pulse, the 9-bit fraction is accumulated in a 9-bit Fraction Accumulator. If a fraction overflow condition occurs (the 9-bit adder asserts carry out), the accumulator saves the lower 9 bits of the addition result, which is the remaining fractional part. The carry out bit indicates an accumulated integer "one" which means that the angle tick is early by one input clock. It halts the prescaler operation for one input clock to compensate the accumulated error generated by the integer prescaler. As a result, the average angle tick period takes into account both the integer and the fraction parts. The accuracy depends on the bit count of the fraction. Using 9-bit fraction part while the width of the field TICKS in register TPR is 10 bits provides accuracy of two LSB on a full scale (TICKS=1023) or one LSB on lower scale (TICKS<=511).

When the Tick Prescaler gets High Rate mode indication from the Angle Counter Logic, it generates angle ticks at a rate of eTPU clock divided by eight. In this case it does not generate Load pulses to the Fraction Accumulator, ignores its "hold" input and preloads internally to a fixed period of eight eTPU clocks. When High Rate mode is entered, the prescaler is preloaded to a period of eight eTPU clocks before its first angle tick generation, ensuring separation of at least eight eTPU clocks between the last Normal mode angle tick and the first High Rate mode angle tick. The fraction accumulator resets when the tick count advances to the next tooth, or when TRR is written by the microcode.

67.3.9.5 Count Control and High Rate Logic

The Count Control and High Rate Logic controls TCR2 operation in Angle Mode, using the angle ticks generated by the Angle Tick Generator. Count Control logic is responsible for advancing, holding and resetting the TCR2 and Tooth Tick Counter in the proper timing, such that the TCR2 time base will reflect the correct estimated angle. This logic also includes the Tooth Program Register (TPR, see Angle Mode registers for more information).

The Count Control and High Rate Logic handles deceleration, acceleration, missing teeth and last tooth. On High Rate (acceleration) it ensures that the angle bus scans all valid angle values in a rate which can be traced by the bus. This operation enables external clients (if TCR2 is a server) or channels working in "equal-only" comparator mode to match the TCR2 exported angle information in "equal" mode, in an exact match.

Because the eTPU channels are capable of capturing either TCR1 or TCR2 due to signal transition, the microcode can get either the angle or time of the physical pin transition. Since the EAC channel (0, 1 or 2) is connected to the physical tooth, the microcode can get the EAC error in angle domain (tooth appears at the wrong angle) or time domain (physical tooth captured time into the EAC channel, relative to the estimated tooth time). Note that in angle mode, the transition detect logic of the channel 0, if selected as the EAC channel, is fed from the digital filter of the TCRCLK signal, and not from the channel 0 internal digital filter. This ensures synchronous operation of channel 0 and the EAC hardware.

Another feature of the eTPU channel, when working in Single Match And Single Transition Enhanced Mode (refer to Single Match Enhanced Mode (sm_st_e)), is capturing a single time base due to signal transition before and after the digital filter. This option allows subtracting the digital filter delay to get accurate signal transition timing on the channel. This way, the TCRCLK signal may be programmed with a slow and reliable digital filter, and get accurate time measurement of the digital filter delay.

To assert the end of the estimated tooth period the Count Control and High Rate logic compares the TICKS field in TPR (refer to Angle Mode registers) with the current value of the tooth tick counter. When the Tooth Tick value is greater or equal to TICKS, it determines the end of the estimated tooth period. On acceleration this event occurs during High Rate mode operation, after the arrival of a physical tooth. In deceleration, this event occurs during Normal Mode, before the arrival of a physical tooth. On constant angular velocity, this event appears together with the arrival of a physical tooth.

The following sections describe the operation of the Counter Control and High Rate logic.

67.3.9.5.1 Normal mode

In Normal mode the Counter Control logic advances TCR2 and the Tooth Tick counter as if the engine has a constant speed during the tooth period. It receives the angle ticks from the Angle Tick Generator in an average rate which is determined by the Tooth Rate Register (TRR). This is the reset mode.

When the Tooth Tick Counter is about to reach the last value effectively stored in TPR field TICKS plus one, the hardware detects the end of the estimated tooth period. If the physical tooth and the estimated tooth arrive at the same time the EAC stays in Normal mode, the Tooth Tick Counter is reset, and TCR2 is incremented (depending on TPR bits LAST and MISSCNT). If the physical

tooth and the estimated tooth do not arrive at the same time, either acceleration or deceleration is detected, and the EAC switches to the proper mode. See the figure below for a detailed diagram of Normal Mode behavior.

The microcode which services the EAC channel physical tooth transition may update TRR according to various conditions to give the best estimation of the current tooth period, according to the previous tooth period and other engine parameters.

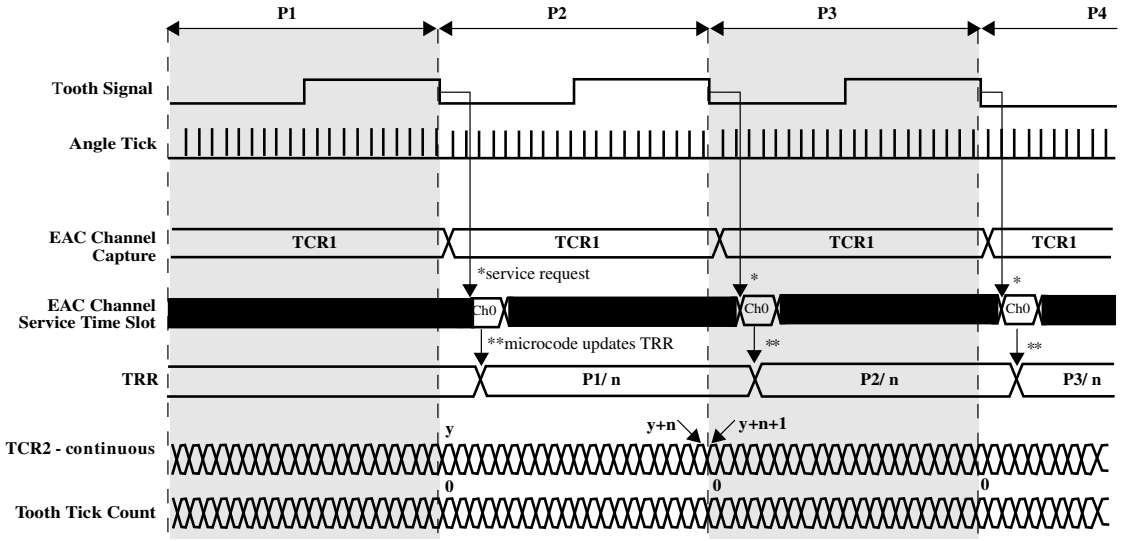

Figure 472. Normal mode

67.3.9.5.2 Halt mode (deceleration)

In case of deceleration, the Tooth Tick Counter reaches the TICKS value before the arrival of the next tooth. The Count Control logic does not reset neither advances TCR2 and Tooth Tick Counters. The Count Control logic halts TCR2 and Tooth Tick Counters at the end of the tooth, waiting for the physical tooth to arrive.

When the physical tooth is detected the EAC switches back to Normal Mode and releases TCR2 to count the angle ticks of the new tooth, also resetting the Tooth Tick Counter. Only then TCR2 may wrap to 0, if TPR bit LAST is asserted. See the figure below for a detailed diagram of Halt Mode behavior.

The microcode service caused by the physical tooth determines the deceleration, calculates the new tooth period and Angle Tick period and updates TRR. This operation slows the angle tick rate generated by the Angle Tick Generator on-the-fly, to the rate required for the new tooth period.

Since the microcode service is initiated by the physical tooth edge, microcode latency may introduce a small angle error caused by using the TRR value of the previous tooth at the beginning of the current tooth. On high RPM, deceleration is relatively small but the microcode latency may take a significant percentage of the tooth period. On low RPM microcode service latency takes little percentage of the tooth period, but there may be cases of extreme acceleration and deceleration. The microcode latency can be calculated knowing TCR1 value during the service time, and TCR1 value captured in the EAC channel due to the physical tooth pin transition. The duration of the Halt mode is obtained using the estimated tooth time.

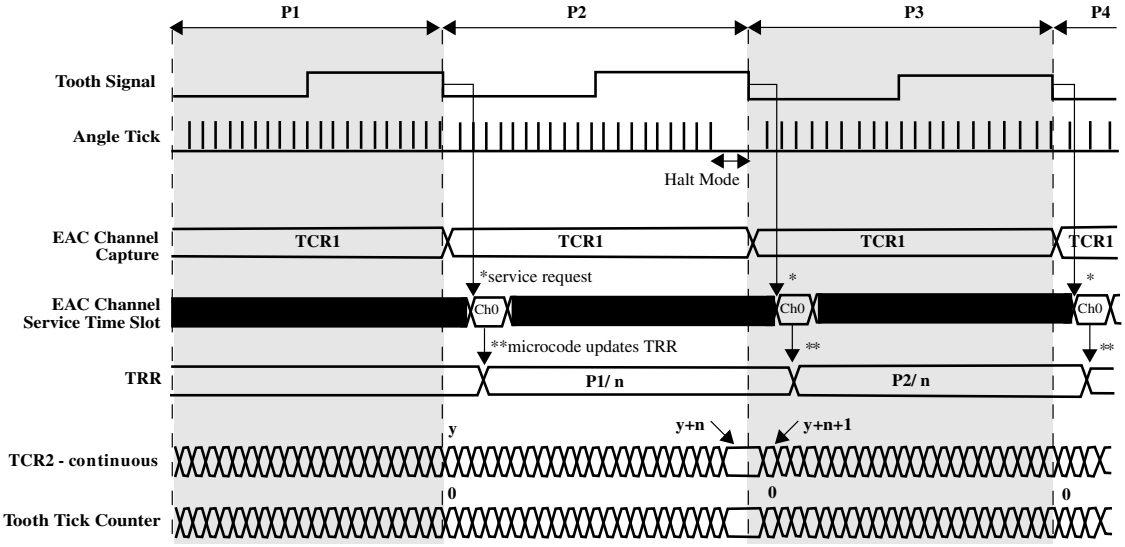

Figure 473. Halt mode (deceleration)

67.3.9.5.3 High rate mode (acceleration)

In case of acceleration, the next tooth arrives before the Tooth Tick Counter reaches the TICKS value. In this case the High Rate logic is responsible for closing the gap and advancing the tooth on the correct timing. The High Rate mode operates as follows:

- When the acceleration is detected (physical tooth arrives before the Tooth Tick Counter reaches the TICKS value), the Count Control and High Rate logic switches to High Rate mode in which both the Tooth Tick Counter and TCR2 count at rate of eTPU clock divided by eight, until the Tooth Tick Counter reaches the current TICKS value. To ensure correct operation, the TICKS value is sampled in the logic at the beginning of the mode.
- At this point, which represents the estimated tooth edge, the logic resets the Tooth Tick Counter and advances TCR2 (or resets it if LAST is asserted and MISSCNT = 0).
- The control logic switches back to Normal Mode, using the most updated TRR value as input to the Angle Tick Generator. The logic samples the updated TICKS value for the tooth estimation, last tooth indication and number of missing teeth from TPR.

In High Rate mode the angle ticks are provided at high speed until the end of the current tooth. This operation is required to scan all the valid angle values of the current tooth, in a rate which is not too high for the bus continuous update, but much higher than the rate dictated by TRR.

EAC channel microcode, which services the physical tooth transition detection, can start its service either before High Rate mode operation is complete (the Tooth Tick Counter has not reached the TICKS value) or after the EAC switched back to Normal mode. Any physical teeth received while the EAC is in High Rate Mode does not alter the immediate EAC state, but it is still detected by the EAC channel logic and can, therefore, alter future EAC behavior (for instance, closing the tooth detection window - see Angle Logic and Channel Modes).

At the beginning of High Rate mode operation, the TPR value is preloaded into a temporary register in the Counter Control Logic, used for scanning all the valid values to the end of the current tooth, with its appropriate LAST and MISSCNT attributes. While the EAC is in High Rate mode operation, the effect of microcode update of TPR fields LAST, MISSCNT and TICKS is delayed to the next estimated tooth, after the High Rate mode operation is complete (see Special TPR write cases). This is because the current physical tooth represents the next estimated tooth. If the microcode updates this field after High Rate mode operation is complete, the current physical tooth and estimated tooth are the same, and the effect is immediate. Either in High-Rate mode or not, the value read by microengine is the same written, even if not yet effective, until the EAC resets LAST and/or IPH, or decrements MISSCNT. Typically the microcode service may occur during the High Rate mode on extreme acceleration situation at low RPM. Therefore, the microcode operations are always related to the real physical tooth. From the above it can be seen that the microcode updates of the TICKS field in TPR affect the end time of the current physical tooth. For correct operation, this field should be updated before the Tooth Tick Counter has reached either the old or the new TICKS value.

During High Rate mode operation, TRR is ignored and the Angle Tick Generator uses eTPU clock divided by eight. Therefore, the TRR update by microcode will take effect only after the EAC switches back to Normal mode. If microcode service occurs after the Tooth Tick Counter has been reset, the EAC is already back in Normal mode, and some angle ticks may have been counted at the rate of the previous tooth. In this case the new TRR value will have immediate effect on the angle tick period, and the microcode should take into consideration the delay from the physical tooth to the estimated tooth in calculation of the next tooth period. See the figure below for a detailed diagram of High Rate Mode behavior.

An angle error may be introduced by the duration of the High Rate mode. Also, the scheduler latency may introduce a small accumulated error by using TRR value of the previous estimated tooth at the beginning of the current tooth. After the estimated tooth has advanced, the duration of the High Rate mode operation is the actual delay from the physical tooth edge to the estimated tooth edge. This delay can be obtained by comparing the estimated tooth time with the EAC channel capture register which captured TCR1 on the physical pin transition.

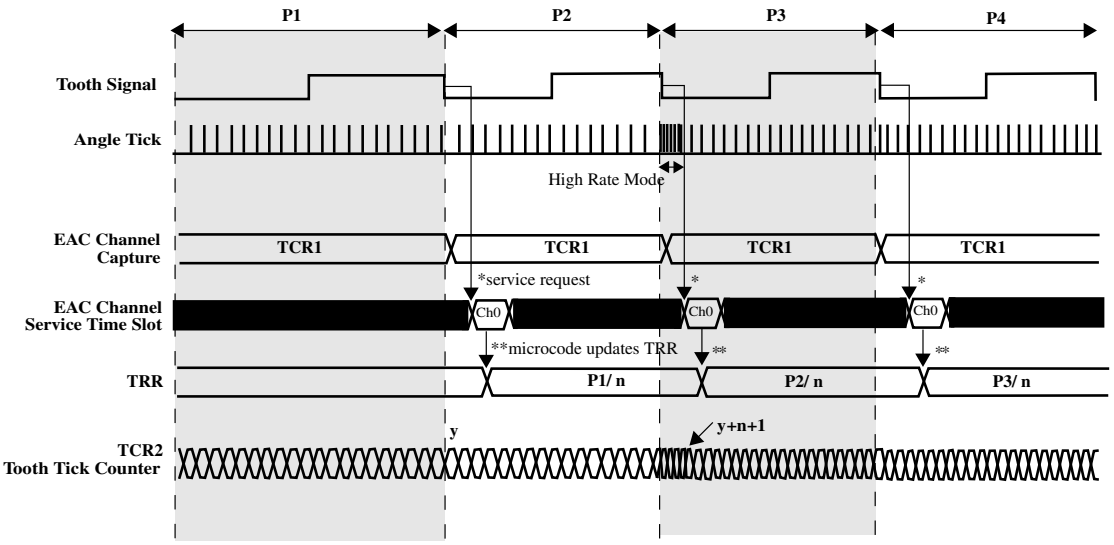

Figure 474. High rate mode (acceleration)

67.3.9.6 Special Cases of Missing Teeth and Last Tooth

The EAC handles cases of up to three missing teeth and the last tooth in the engine cycle. The following paragraphs describe these functions.

67.3.9.6.1 Handling the Last Tooth

The microcode can set the TCR2 counter to work in engine periods (wrap-around count) or continuous angle measurement.

For periodic operation, during the last engine cycle tooth the EAC microcode has to set the LAST flag in TPR. As a result, when the tooth period is ended, the Counter Control Logic generates a reset command to both the Tooth Tick Counter and TCR2 instead of an advance command. The operation resets the TCR2 based angle count, indicating a new period of the engine cycle. This implementation provides an engine cycle based periodic angle measurement.

67.3.9.6.2 Handling Missing Teeth

The EAC can handle up to three missing teeth in two ways:

- Count the angle ticks relative to the last physical tooth. The microcode should update the TPR TICKS field to the number of angle ticks included in two, three or four teeth, according to the flywheel type (one, two or three missing teeth). EAC hardware works in its regular manner.
- Insert a "dummy" tooth instead of the missing tooth, at the estimated point in time. After the "dummy" tooth, the Angle Tick Counter is incremented as if there was a physical tooth. A "dummy" tooth can be inserted only during Normal or High Rate operation modes. The microcode inserts "dummy" teeth by writing to the MISSCNT field in TPR.

In the first option the missing tooth is not counted on the angle measurement. For example, a flywheel with 59 physical teeth and one missing tooth can be considered as 58 identical teeth numbered (0-57) and tooth number 58 has a double number of angle TICKS. In this case a 720 degrees engine cycle has 118 teeth. TCR2 reflects the real angle, since it counts angle ticks continuously.

In the second option, the missing teeth are counted as "regular" teeth by automatic insertion of "dummy" teeth. The microcode has to write a non-zero value to the MISSCNT field in TPR. This field is a 3-bit down counter which affects the operation of the Counter Control logic.

For example, a flywheel with 59 physical teeth (0-58) and one missing tooth (59) can be considered as 60 teeth numbered (0-59), all having the same number of angle ticks. The microcode has to write "001" to the MISSCNT bits during the period of tooth number 58 to indicate that next tooth (59) is missing.

When the Tooth Tick Counter reaches the TICKS value, TCR2 is incremented as if a physical tooth has been detected. In addition, the MISSCNT value initializes a "dummy tooth counter" which is decremented to indicate the number of left "dummy teeth" which still need to be generated. Because a dummy tooth was counted, EAC does not enter Halt Mode and Tooth Tick Counter continues incrementing in the absence of a physical tooth detection.

In case of extreme acceleration on very low RPM (cold start) there can be a situation that the first physical tooth after one or two missing teeth appears even before the "dummy" tooth is generated. Due to the acceleration the EAC switches to High Rate mode in order to run through all the valid angle values, including the dummy teeth. When the Tooth Tick Counter reaches the TICKS value on High Rate mode, and the "dummy tooth" down counter is not zero, the generated "dummy tooth" advances to the next tooth and decrements the "dummy tooth" counter, but does not switch the EAC back to Normal mode. The last "dummy tooth" decrements the counter to zero, indicating that no more dummy teeth are to be inserted, and the next tooth is an estimated physical tooth. The EAC continues at High Rate mode until the Tooth Tick Counter reaches the TICKS value again, then advances to the next tooth while switching back to Normal mode. When in High Rate mode, the TPR register does not reflect the MISSCNT downcounting, see TPR Buffering for details.

MISSCNT can be rewritten before it reaches 0, allowing it to count more than 7 missing teeth, as long as no physical tooth arrives between the first MISSCNT write and the rewrite.

67.3.9.6.3 Combining missing teeth and last tooth

The Last Tooth indication takes effect when there are no more missing teeth to be generated, that is, the "dummy tooth" counter value is zero. If, for example, the microcode sets the missing teeth counter to "10" (two missing teeth) and sets the LAST flag, the first and the second dummy teeth will increment TCR2, and the third estimated tooth, which correlates with the physical tooth (the first of the next cycle), will reset TCR2, because LAST was set. This scheme enables the microcode to define one or more missing teeth to be replaced by "dummy tooth" insertion, and the end of the engine cycle in one service request. It is assumed that the two missing teeth must come together in the same engine cycle, and not split between two engine cycles (either the missing teeth are both last in an engine cycle or both not last, but not last in one engine cycle and first in the next).

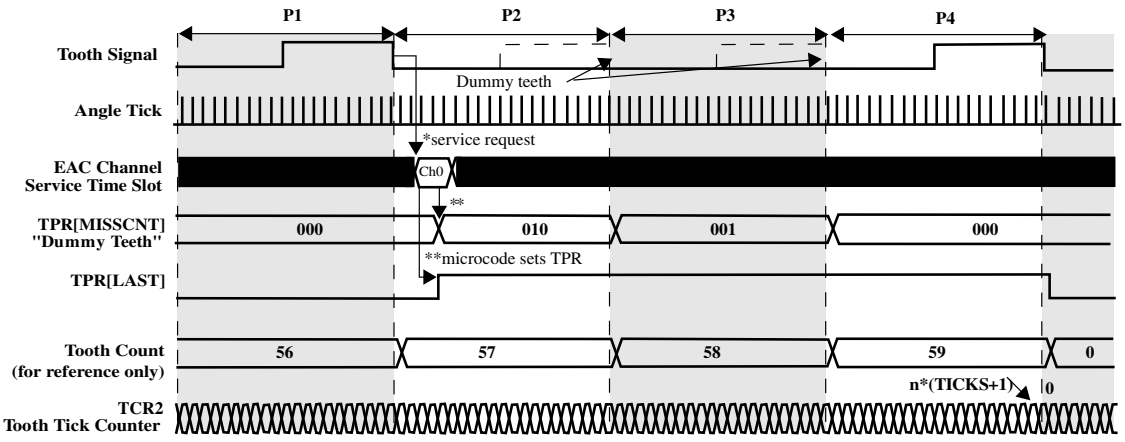

Figure 475. Combining missing teeth and last tooth

67.3.9.7 Handling Mechanical Tooth Correction

The EAC can handle tooth edge detection errors caused by flywheel mechanical errors. The eTPU application can hold a vector of tooth mechanical errors with one entry per tooth. This error can be measured in angle ticks which are independent of engine RPM. The TRR can be updated to the fixed period of any tooth, including its mechanical error.

Because TCR2 counts continuously, without being reset, the mechanical correction is transparent. Though the tooth has its own programmed TICKS value, TCR2 simply counts angle ticks, disregarding the boundary between two adjacent teeth.

67.3.9.8 Handling Mis-detected Tooth

When a physical tooth signal is missed by the engine sensor, the EAC may get into Halt mode at the end of the estimated tooth period, expecting the physical arrival. In this case, a Match timeout event of EAC channel will call service which detects extreme deceleration. The microcode can assert the IPH bit in TPR, to force the detection of the missed physical tooth. It can also calculate the accumulated angle bus error, and fix the next estimated tooth period, to close the gap.

67.3.9.9 Handling False Tooth Detection

Most of the false tooth detection, caused by noises on the engine tooth sensor, can be eliminated by the window blanking filtering, timed by EAC channel match recognitions. The EAC also provides means of fixing false detection of an additional tooth which passed the window filter. When such an event occurs, the EAC switched to High Rate mode (advancing to the next tooth) and when the next physical tooth arrives, an extreme acceleration is detected: the EAC sees the remaining portion of the current tooth period as another tooth period. The microcode can detect the situation when the acceleration in not realistic, or when immediately after the detection of this extreme acceleration, the following tooth indicates extreme deceleration back to the original RPM.

When the microcode detects such a case, the Tooth Counter has been advanced by mistake to the next tooth. The microcode can set the HOLD bit in the TPR, forcing the EAC to freeze and wait for the next physical tooth to close the gap. When the next physical tooth arrives, HOLD is automatically negated and the EAC proceeds from that point to the remaining portion of the tooth period, in the same mode it was when HOLD bit was asserted.

67.3.9.10 Angle Logic and Channel Modes

The TCRCLK transition detection is qualified by a signal that comes from channel 0 (see Tick rate register (TRR)) and depends on the particular mode (PDCM) programmed for that channel. This configures a window for TCRCLK detection for the angle logic which is the same (except on High Rate mode, see High rate mode (acceleration)) used to set the TDLA flag on single transition modes, and TDLB on double transition modes (see signals TSE1,TSE2 in Channel Mode Logic and Event Flags). The same applies when channels 1 or 2 are used to control EAC (see signals TS1, TS2 in Channel Mode Logic and Event Flags). As a consequence, the window depends on the channel mode as follows:

- on all modes, the window closes upon a tooth edge detection: TDLA asserted on single transition modes, TDLB asserted on double transition modes.
- on mode m2_st: the window opens on Match A (which enables Transition A) and does not close with Match B. If Match B comes before Match A, it blocks Match A and, hence, Transition A.
- on mode m2_o_st: the window opens on Match A (which enables Transition A) and closes on Match B. Match B is enabled by Match A, so it cannot come before.
- on all other Single Transition modes, the window is "always open", independently of matches.
- on mode m2_dt: the window opens on Transition A, which is enabled by Match A. The window does not close with Match B, but if it comes before Match A the later gets blocked and, hence, blocks Transitions. Match A is also a condition for the window, so the microcode closes it by clearing MRLA.
- on mode m2_o_dt: the window opens on Transition A, which is enabled by Match A. The window closes on Match B, which is enabled by Match A. Match A is also a condition for the window, so the microcode closes it by clearing MRLA.
- on all other Double Transition modes, the window opens on Transition A.

67.3.9.11 Restarting angle logic

It is not recommended to change the eTPU_TBR_TBCR_ENG*n*[AM] field while GTBE=1. However, if the angle logic must be restarted without interfering with the timebase count running on TCR1, the procedure below must be followed:

1. Program eTPU_TBR_TBCR_ENG*n*[AM]=00 and TCR2CTL=111 at once. That prevents TCR2 from incrementing while the angle logic is disabled. The angle logic state machine resets to Normal mode and the tick prescaler to the initial count with AM=00, but not the microengine registers TPR and TRR.
2. Start a thread to reconfigure the EAC. The thread must set the EAC controlling channel (0, 1 or 2) flags in a state, depending on the channel mode, that lets the channel tooth detection window open (see Angle Logic and Channel Modes). It can optionally write TCR2 with an angle preset value equivalent to the first tooth expected after restart. The thread must also set TPR bit HOLD=1. The TPR bit IPH must be 0.
3. After the thread is finished, program eTPU_TBR_TBCR_ENG*n*[AM]=01, 10 or 11, and TCR2CTL according to the desired tooth edge selection if AM=01.

The first tooth detected after this procedure restarts the TCR2 counting, unfreezing the Angle Mode logic into normal mode.

67.3.9.12 Special TPR write cases

This section describes how simultaneous modification of TPR fields are resolved, and how the effect of TPR writes depend on the EAC mode.

67.3.9.12.1 TPR Buffering

In High Rate mode (see High rate mode (acceleration)), TPR writes are immediately effective only for bits IPH and HOLD. Writes to all other fields are "buffered" and become effective when EAC leaves High Rate mode. However, if TPR is written a second time immediately after IPH is asserted in Normal mode, the second write behaves as if EAC is still in Normal mode. Wait at least two microcycles before writing to TPR a second time (after execution of two nop instructions, for example), so the TPR write is buffered, acknowledging High Rate mode. If the write happens in the next microcycle after IPH assertion, the next write to TPR register may fail.

MISSCNT and LAST can be written with any value during High Rate mode, and the value that prevails for the next tooth is the one sampled when EAC goes back to Normal mode (or the value written in Normal or Halt mode thereafter). If MISSCNT and/or LAST are not zero when High Rate mode begins, they are sampled into the internal EAC logic and are effective while High Rate lasts (missing teeth count continues, and TCR2 is reset at the end of High Rate if LAST = 1). However, their values in TPR are reset when High Rate mode starts. After that and until the end of High Rate mode, the value read by microcode is the same written. This behavior prevents read-modify-writes to TPR from unwillingly rewriting LAST or MISSCNT.

NOTE

When the Angle mode is configured (AM = 1) and global time base is disabled (GTBE = 0) on EAC transition to high-rate mode, the writes into TPR registers (fields LAST, MISCNT, or TICKS) while GTBE = 0 are not set and, after GTBE is enabled again (GTBE = 1), buffered values are not updated, so information is lost.

67.3.9.12.2 IPH and LAST

If both IPH and LAST are asserted in the same microinstruction with HOLD=0, the EAC acts as if LAST was set first and then IPH right after, so that:

- in Normal mode, it goes to High Rate with LAST=1;
- in Halt mode, it goes to Normal Mode resetting LAST (and TCR2);
- in High Rate mode, IPH is ignored and LAST becomes effective in the next tooth (physical or inserted) after it goes back to Normal mode.

67.3.9.12.3 IPH and TICKS

Because of different results depending on the EAC mode at the time of TPR write, it is not advisable to write 1 to IPH and change TICKS at the same microinstruction. A consistent behavior is obtained if IPH is written first and TICKS on the second

microinstruction after (for instance with a nop between them), making the new TICKS value valid for the next tooth regardless of the mode.

The mode-dependent behavior is (assuming HOLD=0):

- in Normal mode, the new TICKS value becomes valid before EAC goes High Rate due to the IPH;
- in Halt mode, the EAC goes to Normal mode, and new TICKS is valid for the next tooth;
- in High Rate mode, the new TICKS value is effective when EAC leaves High Rate mode, and IPH is ignored;

67.3.9.12.4 IPH and MISSCNT

If both IPH and MISSCNT are written non-zero values with HOLD=0:

- in Normal mode, at the next microcycle the EAC goes to High Rate mode, the MISSCNT field in TPR goes to 0, and the missing teeth are counted in High Rate mode.
- in Halt mode, the EAC goes to Normal mode for one microcycle and then, yet another microcycle later, goes to High Rate mode, counting the missing teeth. The TPR fields IPH and MISSCNT are zeroed on the transition from Normal to High Rate mode.
- in High Rate mode, IPH is ignored (resetting at the next microcycle) and MISSCNT is buffered (see TPR Buffering).

67.3.9.12.5 IPH and HOLD

If IPH and HOLD are asserted at once, IPH cancels the HOLD and both reset. The EAC is not frozen, regardless of the EAC mode (High Rate, Normal or Halt).

67.3.9.12.6 LAST and HOLD

If LAST and HOLD are written 1 at once, LAST asserts and EAC is frozen. Afterwards, when a physical tooth is detected or IPH is asserted, the EAC is unfrozen in the same state it was before, and LAST is kept asserted.

67.3.10 Microengine

Each eTPU engine has a microengine that fetches, decodes and executes microinstructions. The Microengine only works when there are service requests to be attended, otherwise it turns to idle state, controlled by Hardware Scheduler (see Scheduler).

Microcode is stored in Shared Code Memory (SCM) that is 32-bit wide. Microengine can access SDM using a different bus from the one used to accesses code memory, so that code and data can be accessed at the same time (Harvard Architecture).

Some of eTPU functionality can only be made through the microengine, like configuring channels and interrupting host. Microengine gives eTPU a high degree of flexibility, since any desired treatment for channel's events can be implemented; however, that flexibility comes at the cost of channel service's latency. Latency is worsened when channels from a same eTPU engine contend for microengine service. In the figure below, a block diagram of microengine architecture is shown.

Follows a summary of Microengine features:

- P, DIOB, A, B, C, D, SR, RAR, LINK, CHAN, MACL, MACH, ERTA, ERTB, TCR1, TCR2, TPR, TRR registers are accessible by microcode.
- 24-bit ALU and Post-ALU shifter performs basic arithmetic and logical operations described in ALU and Post-ALU Shifter.
- MDU (MAC/Divide Unit) performs integer MAC, multiply and divide operations.
- Fixed Microinstruction Size of 32bits.
- Fixed-length instruction execution (2 eTPU clocks)
- Static superscalar operation

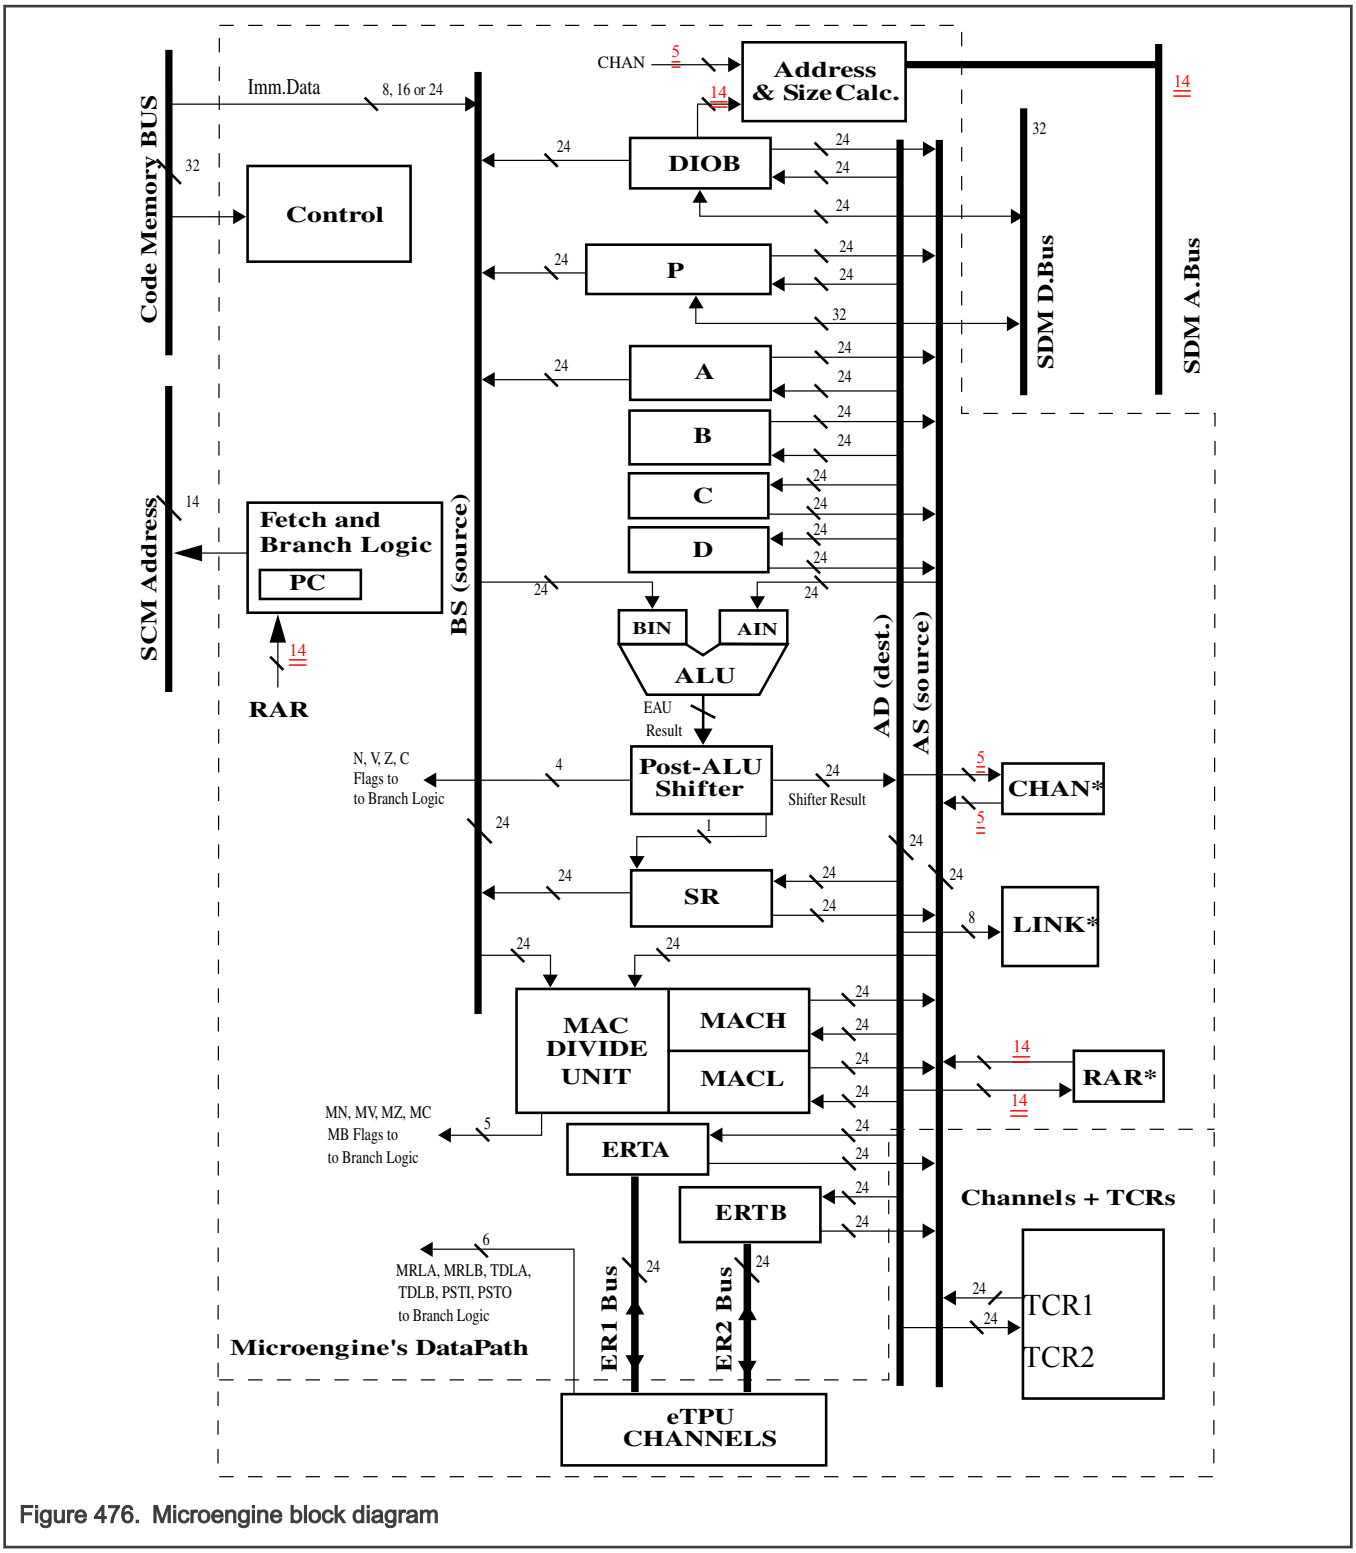

Figure 476. Microengine block diagram

67.3.10.1 Registers

eTPU microengine accesses a total of 18 registers. Fourteen of them are special purpose (registers A, B, C and D are for general use). Special purpose registers except CHAN and LINK can also be used as general use if the operation that use their contents are not performed. Register description is intended to just introduce their functionalities and not to provide detailed explanation of it since it will be described in Microinstruction Set. Registers less than 24 bits in size are right-justified.

None of the registers have guaranteed reset values. However, some are initialized just before the thread starts (see Time Slot Transition).

67.3.10.1.1 P Register

P register is the only one that is 32-bit wide. It can be used as source and destination for arithmetic/logical operation, and as source and destination for SDM read/write operations.

For P source/destination possibilities in ALU/MDU microoperations, see Selecting sources and destination.

When P is used as SDM read/write operations source or destination there are only 3 possibilities of access: all 32 bits, lower 24 bits and upper 8 bits. SDM operations are explained in detail in SDM Microoperations.

P is automatically loaded with one parameter before the thread starts (parameter preload). For more information see Entry Point format and Time Slot Transition.

Upper 8 bits of P register can be used as application state, since these bits can be tested as branch conditions. P[31:24] is also used in dispatch microoperation (see Dispatch Microoperation), and bit pairs P[29:28], P[27:26], P[25:24] can be directly copied into Channel flags 1 and 0 using field FLC. Together with Entry Table Condition Encoding, it provides fast state resolution without code execution.

67.3.10.1.2 DIOB Register

DIOB is an abbreviation for Data Input/Output Buffer. DIOB is 24-bit wide and can be used as source and destination for arithmetic/logical operations as well as SDM data source and destination. DIOB only can be accessed as 24 bits, both in arithmetic/logical and SDM read/write operations. When using DIOB to perform an SDM access, only lower 24 bits of SDM will be accessible (SDM upper 8 bits always remains unchanged).

DIOB can also be used as SDM addressing register, when DIOB contents is used as absolute SDM address (-bit wide). In this case DIOB can also be pre-decremented or post-incremented (see Indirect Addressing Mode).

DIOB is automatically loaded with one parameter before the thread starts (parameter preload). For more information see Entry Point format and Time Slot Transition.

67.3.10.1.3 ERTA and ERTB Registers

ERTA/B registers are 24-bit wide and can be used as source or destination in arithmetic/logical operations. ERTA/B are the only source for channel's match registers write (see Write Channel Match and UDCM Registers). ERTA can also be the source for UDCM write.

When a thread starts to be executed, ERTA and ERTB are loaded with a copy of CaptureA and CaptureB registers respectively. ERTA/B can be used to receive a copy of MatchA and MatchB registers. ERTA/B are the only destination of MatchA/B read operation (see Special T4ABS Source Operation: Read Match Registers).

ERTA and ERTB also receive a copy of CaptureA and CaptureB registers when CHAN register is written (see CHAN Register). For more information about Capture and Match registers see MatchA and MatchB Registers and CaptureA and CaptureB Registers.

67.3.10.1.4 SR register - Shift Register

SR is a 24-bit wide register that can be used as source and destination register for arithmetic/logical operations. SR can shift right its contents by 1 bit at time and, at the same time, receive in its bit 23 the lost bit of a shift-right operation in post-ALU shifter (ALU and Post-ALU Shifter), allowing SR to be used to perform 48-bit shift right (see Shift Operations).

67.3.10.1.5 MACH and MACL Registers

Both MACH and MACL are 24-bit registers, part of MAC/Divide unit (see MAC and Divide Unit (MDU)). They can be used as source and destination in most arithmetic/logic operations. When multiply or divide operations are used (multiply-accumulate included), MACH and MACL have special purpose and some restrictions apply, see MAC and Divide Unit (MDU) for more information.

67.3.10.1.6 LINK Register

Link Register is an 8-bit wide register and can be used only as destination in arithmetic operations. LINK is a write-only command register, which precludes its use as a source register for ALU operations. When LINK register is written, it issues a service request for the channel number and eTPU engine equal to the number written in LINK register (see Functions and threads and Channel link for information about Link Service Request).

67.3.10.1.7 RAR Register

RAR is a -bit register and can be used as source and destination in arithmetic operations. RAR also receives the contents of PC register when a subroutine call is executed. The contents of RAR register is loaded into PC when a return from subroutine is executed. RAR is loaded with value 0x3FFF during TST. For more information about subroutine call and return see Branch Operations and Return from subroutine respectively.

67.3.10.1.8 CHAN Register

CHAN is a -bit register that can be used as source and destination in arithmetic operations. The contents of CHAN register affects the execution of many channel-related microinstructions, because its number indicates the **selected channel**. CHAN register must not be used to store temporary values in arithmetic operations. For more details, refer to Channel Selection Register - CHAN.

67.3.10.1.9 Counter Registers: TCR1, TCR2, TPR and TRR

All these registers are 24-bit wide except TPR, which is a 16-bit register. They can be read or written in arithmetic/logical operations, and have special-purpose uses for time base and angle mode operations. For more information about those registers see Time bases and EAC - eTPU Angle Counter.

67.3.10.1.10 General Purpose Registers: A, B, C and D

A, B, C and D are 24-bit general purpose registers, which can be used to store intermediate values and do not have other specific uses with any eTPU feature.

67.3.10.2 ALU and Post-ALU Shifter

The ALU executes 24-bit arithmetic and logical operations. ALU's output goes directly to a 1-bit shifter, called post-ALU shifter, so it is possible, for example, to add and shift using only one microinstruction.

In some microinstruction formats, it is not possible to specify the operation executed by ALU. In these cases ALU will always perform addition.

In formats which have the field ALUOP for ALU operation selection, all of them can be performed, including add/subtract using C (carry) flag as ALU's carry-in, bitwise AND/OR/NOT/XOR, and shift/rotate of 2, 4, 8 and 16 bits. See ALU/MDU Operation Selection.

Subtraction, inversion, increment and decrement can be performed by combinations of source inversion and setting ALU's carry-in to 1.

ALU always performs 24-bit operations on its inputs, called **A-source** and **B-source**, and outputs a 24-bit result. 8-, and 16-bit inputs are zero padded to 24 bits. Likewise, ALU 24-bit output is always truncated to the destination register size.

67.3.10.2.1 ALU flags

Four flags - Carry, Negative, Overflow, Zero - described below, are related to ALU and post-ALU shift operations. Operation size and shifting affect flags generation logic. Operation size determines the result boundary to be used for flags generation. Operation size is determined by size of sources and destination (see Flags Sampling Control). For more information about flag generation, see Flags Sampling Control. ALU flags can be used as branch condition (see Conditional/unconditional branch) or conditional ALU/MDU operation (see Conditional ALU/MDU Operation Execution).

Field CCS/CCSV in microinstructions can force **no update** of all flags. Not all flags are updated in all ALU operations: Overflow is updated only on addition and absolute value operations, Carry flag is updated in most ALU operations, and only Zero and Negative are updated in all ALU operations.

ALU flags are never updated when microinstruction starts an MDU operation, regardless of CCS/CCSV, but are updated normally afterwards, on ALU operations that are executed in parallel with an ongoing MDU operation (MDU has its own flags).

NOTE

Operation size can be smaller than destination register. For example: 0xFFFF + 0x0001 (both 16-bit sources) stores 0x10000 in a 24-bit register and sets Zero and Carry flags because operation size is 16 bits.

67.3.10.2.1.1 Carry flag (C)

In an unsigned addition without shifting, Carry flag is the ALU carry from bit 7 to 8, 15 to 16, or 23 to 24 on 8-, 16- and 24-bit operation sizes respectively. In an unsigned subtraction without shifting, Carry Flag represent the sign of ALU's result considering operation size (Carry Flag equal to 1 means a negative result).

Carry flag definition is operation-dependent. The Carry flag in add/subtraction with Post-ALU shift is defined in ALU ADD operation with and without shifting. Find the definitions for other operations in the following sections.

67.3.10.2.1.2 Negative flag (N)

Negative flag indicates the sign of result based on the operation size, regardless of the operation performed, as shown in the following table.

Table 409. Negative (N) flag behavior

Operation size	Value
8 bits	N = result[7]
16 bits	N = result[15]
24 bits	N = result[23]

NOTE

The N flag may not reflect the sign of the value actually written into the destination register, if it does not have the same size of the operation (see Flags Sampling Control). This is always the case for registers RAR (14 bits) and CHAN (5 bits).

67.3.10.2.1.3 Overflow (V)

Overflow is updated only on addition (with or without carry) and absolute value operations. In signed operations, overflow flag indicates that the result of arithmetic operation (add or subtraction) can not be represented by a word of the size of the operation. Overflow flag behavior for addition is defined in the following table. Overflow flag for Absolute operation is explained in Absolute Value operation. V Flag is calculated using ALU adder output (i.e., it is not affected by 1-bit shift/rotate operations).

Table 410. Overflow flag on addition - V

Op. size	Value[1]
8 bits	(AS[7] & BS[7] & !alu_adder_output[7]) | (!AS[7] & !BS[7] & alu_adder_output[7])
16 bits	(AS[15] & BS[15] & !alu_adder_output[15]) | (!AS[15] & !BS[15] & alu_adder_output[15])
24 bits	(AS[23] & BS[23] & !alu_adder_output[23]) | (!AS[23] & !BS[23] & alu_adder_output[23])

1. BS is taken after any inversion by the BINV field, but not added to the carry bit (CIN field)

NOTE

For V-flag definition on the absolute operation, see “Absolute Value Operation".

67.3.10.2.1.4 Zero flag (Z)

Zero flag equal to 1 indicates that the result from the ALU, limited to the operation size, is zero, regardless of the operation performed, whether the result is written, or where it is written. It depends on the operation size, as shown in the following table.

Table 411. Zero flag - Z

Operation size	Value
8 bits	Z = (result[7:0] == 0x00)
16 bits	Z = (result[15:0] == 0x0000)
24 bits	Z = (result[23:0] == 0x000000)

67.3.10.2.2 ALU ADD operation with and without shifting

ADD operation is selected by ALUOP or ALUOPI fields and when none of them is available in a microinstruction format[24]. Optionally, result can be shifted or rotated right by 1 bit, which is selected by SHF, ALUOP or ALUOPI fields. See Microinstruction Set for more details. The following table describes how CIN and BINV fields change ADD operation behavior.

Table 412. Types of ADD operations

BINV	CIN	Operation (adder output)
1	1	AS + BS
1	0	AS + BS + 1
0	0	AS - BS
0	1	AS - BS - 1

ALU adder output can be 1-bit shifted or 1-bit rotated right as follows:

Shift right:

```
if BINV==1
  result [23:0] = adder_output[24:1]
else
  result [23:0] = adder_output [24:1] xor 0x800000
endif
```

Shift left:

```
result[23:1] = adder_output[22:0]
result[0]    = 0
```

[24] ALU operations only occur on formats where a destination field is found (T2ABD/T2D).

Rotate right:

```
case(opsize/CCSV)
8-bit:
  result[6:0]   = adder_output[7:1]
  result[7]     = adder_output[0]
  result[23:8]  = adder_output[23:8]
16-bit:
  result[14:0]  = adder_output[15:1]
  result[15]    = adder_output[0]
  result[23:16] = adder_output[23:16]
24-bit:
  result[22:0]  = adder_output[23:1]
  result[23]    = adder_output[0]
```

NOTE

Only for the Post-ALU rotate right, the operation size is determined by the field CCSV (see Flags Sampling Control). For example: if CCSV=00, T4ABS=P (24-bits), T4BBS=A (24 bits), T2ABD=B (24 bits), and ALUOP="Add ROR", then B gets A+P with bits 7:0 rotated, even though the operation size is 24 bits.

The following table describes Carry flag behavior.

Table 413. Carry flag update on ADD operation

BINV[1]	Op. size	shift/rotate	Value
1	8 bits	none	adder carry from bit 7 to bit 8
1	16 bits	none	adder carry from bit 15 to bit 16
1	24 bits	none	alu_adder_output[24]
0	8 bits	none	!adder carry from bit 7 to bit 8
0	16 bits	none	!adder carry from bit 15 to bit 16
0	24 bits	none	!alu_adder_output[24]
0 or 1	8 bits	shift left	alu_adder_output[7]
0 or 1	16 bits	shift left	alu_adder_output[15]
0 or 1	24 bits	shift left	alu_adder_output[23]
0 or 1	x	shift right	alu_adder_output[0]
1	8 bits	rotate right	adder carry from bit 7 to bit 8
1	16 bits	rotate right	adder carry from bit 15 to bit 16
1	24 bits	rotate right	alu_adder_output[24]
0	8 bits	rotate right	!adder carry from bit 7 to bit 8

Table continues on the next page...

Table 413. Carry flag update on ADD operation (continued)

BINV[1]	Op. size	shift/rotate	Value
0	16 bits	rotate right	!adder carry from bit 15 to bit 16
0	24 bits	rotate right	!alu_adder_output[24]
			except on max-constant generation (see Max Const Generation With T4BBS=111)

1. BINV has no effect on carry-out when used to code max constant (see Max Const Generation With T4BBS=111).

Flags N and Z on shift are updated according to the result after shift. Flag V with shift is updated according to the ADD operation only, the same way as without shift.

67.3.10.2.3 ADC Operation

ADC operation is selected by the ALUOP field. CIN field is ignored when this operation is selected. The following table describes how BINV change ADC operation behavior.

Table 414. Types of ADC operations

BINV	CIN	Operation
1	x	AS + BS + C flag
0	x	AS - BS - C flag

Flags behave exactly the same way as for ADD operation without shift/rotate.

67.3.10.2.4 Bitwise Operations

Bitwise AND, OR and XOR are selected by ALUOP field. On these operations CIN field is ignored and BINV field inverts (bitwise NOT) BS. C and V Flags are never updated on these operations. The following table describes AND, OR and XOR bitwise operations.

Table 415. Types of Bitwise Operations

ALUOP	BINV	Operation
10000	1	AS | BS
10000	0	AS | (~BS)
10001	1	AS ^ BS
10001	0	AS ^ (~BS)
10010	1	AS & BS
10010	0	AS & (~BS)

67.3.10.2.5 Set Bit / Clear Bit Operations

These operations set or clear the AS bit determined by BS[4:0]. If the bit number resolves to a value greater than 23, no bit is set or cleared (i.e., result is equal to AS). On these operations CIN field is ignored and BINV field inverts (bitwise NOT) BS. C and V flags are never updated for set/clear bit operations. These operations **override** B-Source size to 8 bits.

set bit (BINV = 1):

```
result = AS | (1 << BS)
```

clear bit (BINV = 1):

```
result = AS & ~(1 << BS)
```

set bit (BINV = 0):

```
result = AS | (1 << (31 - BS))
```

clear bit (BINV = 0):

```
result = AS & ~(1 << (31 - BS))
```

67.3.10.2.6 Exchange Bit

Exchange the AS bit determined by BS with C flag. If the bit number resolves to a value greater than 23, no exchange is performed (i.e., result is equal to AS and C flag is not updated). This operation **overrides** BS size to 8 bits. On this operation, CIN field is ignored and BINV field inverts (bitwise NOT) BS. V flag is never updated on exchange bit operation. C flag is always updated, regardless of CCSV, unless BS > 23.

Exchange Bit (BINV=1):

```
if BS <= 23
begin
  temp_C_flag = AS[BS]
  if C_flag == 1
    result = AS | (1 << BS)
  else
    result = AS & ~(1 << BS)
  C_flag = temp_C_flag
end
```

Exchange Bit (BINV = 0):

```
if (31 - BS) <= 23
begin
  temp_C_flag = AS[31 - BS]
  if C_flag == 1
    result = AS | (1 << (31 - BS))
  else
    result = AS & ~(1 << (31 - BS))
  C_flag = temp_C_flag
end
```

67.3.10.2.7 Multibit shift/rotate operations

These operations shift or rotate AS by 2, 4, 8 or 16 bits. Size of shift/rotate is determined by BS[1:0]. The following table describes the number of shifted/rotated bits depending on BS[1:0] value.

Table 416. Number of shifted/rotated bits for each BS[1:0] value

BS[1:0]	Bits shifted/rotated
0	2
1	4
2	8
3	16

Shift right is a logical operation (i.e., zeros are inserted on left). Multibit shift and rotate operations **overrides** BS size to 8 bits. The shifts and rotate operate on 24 bits, independently of the operation size.

V flag is never updated for multibit shift or rotate operations. Carry flag behavior is described in the following table. CIN is ignored in these operations, but BINV is effective.

Table 417. Carry flag value on multibit shift/rotate operations

ALUOP	BS[1:0]	C flag value[1]
11001 (shift left)	0	AS[22]
11001 (shift left)	1	AS[20]
11001 (shift left)	2	AS[16]
11001 (shift left)	3	AS[8]
11010 (shift right)	0	AS[1]
11010 (shift right)	1	AS[3]
11010 (shift right)	2	AS[7]
11010 (shift right)	3	AS[15]
11011 (rotate right)	0	AS[2]
11011 (rotate right)	1	AS[4]
11011 (rotate right)	2	AS[8]
11011 (rotate right)	3	AS[16]

1. CCS/CCSV can disable flag update on multibit shift/rotate, but the specified flag size in CCSV is ignored for the C flag.

67.3.10.2.8 Absolute Value operation

Absolute Value operation is selected by ALUOP field. On this operation, AS is interpreted as a signed number and its absolute value is the result. V and N flags are updated with the result signal determined by the operation size. AS bit 23 after size override and sign extension (if any, see A-Source Size Override), regardless of A-source register size, is used to check the operand signal and is copied to C-flag. Note that if AS is 8-bit or 16-bit, its sign is taken into account and copied to C only if sign-extension is performed. The following table summarizes flag updating for Absolute Value operation.

This operation is independent of B-source. Instruction fields T4BBS, BINV and CINV are ignored in this operation. The Absolute Value operation size is the minor between A-source size and Destination size.

Table 418. ALU flags in Absolute Value operation

operation size	V, N[1]	C	Z
8	alu_output[[7]	AS[23]	alu_output[7:0] == 0
16	alu_output[15]		alu_output[15:0] == 0
23	alu_output[23]		alu_output[23:0] == 0

1. V, N can be 1 on 8- and 16-bit Absolute Value, because the operand sign is always taken from bit 23. V, N can also be 1 in 23-bit Absolute Value (or 8-bit and 16-bit with sign extension), if the operand is 0×800000 (0×80, 0×8000).

67.3.10.3 MAC and Divide Unit (MDU)

MDU is an autonomous resource in the microengine which can carry out sequential multiply, multiply-accumulate, fractional multiplication and divide operations, selected through the microinstruction fields ALUOP or ALUOPI. The unit supports signed and unsigned multiply and fractional multiplication of any combination of 8, 16 or 24 bit operands[25], and also signed and unsigned 24-bit multiply-accumulate. Divide operation is unsigned, and both operands are always 24-bit wide.

Depending on the size of operands and the type of operation, MDU can take more than one microcycle to execute the operation, but microengine continues to execute microinstructions in parallel. When the microcode issues an END command, any MDU executing operation terminate immediately and is left incomplete. When selecting an operation that uses MDU, the result is always placed in MACH and MACL registers, and the register selected as destination does not have its value changed (Selecting sources and destination). During calculations, MACH and MACL holds temporary values and should not be written, otherwise the result is unspecified. One must not start an MDU operation while MDU is already busy: the result is unspecified for both the ongoing operation and the started one.

MDU Operations update its own set of 5 flags, described in MDU Flags. MDU operations never update C, N, V and Z flags. CIN and BINV microinstruction fields affect MDU operations according to the following table.

Table 419. CIN and BINV with MDU Operations

B-source operand	BINV	CIN	Op. Performed
signed	1	1	AS mdu_op BS
	0	0	AS mdu_op (-BS)
	1	0	reserved
	0	1	reserved
unsigned[1]	1	1	AS mdu_op BS
	1	0	AS mdu_op (BS+1)
	0	x	reserved

1. includes the B-source (unsigned) in fmults (signed) operations.

[25] There is no distinct selection of 24-bit fractional multiplication, for it works exactly as a 24-bit ordinary multiplication.

67.3.10.3.1 Multiply and Multiply-Accumulate Operation Length

MDU needs 2 sources, A source and B source, to perform an operation. The time needed to perform a multiply or multiply-accumulate is:

- on 24-bit x 8 bit multiplies: 2 microcycles (one start-MDU plus one execution microcycle)
- on 24-bit x 16 bit multiplies: 3 microcycles (one start-MDU plus two execution microcycles)
- on 24 bit x 24 bit multiplies/macs: 4 microcycles (one start-MDU plus three execution microcycles)

An internal pipeline in MDU allows multiply-accumulate (or even non-fractional multiply) operations to start one microinstruction before a multiplication or multiply-accumulate (signed or unsigned) has been completed (e.g., one can start one multiply or multiply-accumulate once every three microinstructions). However, by doing that it is not possible to read the result in MACH and MACL (although the MDU flags can be tested), so this is intended to be used in a multiply-accumulate sequence. It is also allowed to mix different sizes in multiply/mac sequences.

Multiply-accumulate operations are similar to multiply operations, except that the contents of MACH and MACL registers are added to the multiplication result.

When multiply or multiply accumulate operations finish, MACL and MACH hold the least and the most significant 24-bit words, respectively.

67.3.10.3.2 Divide Operation Length

The divide operation is always unsigned. The division completes in 13 microcycles, meaning that after the start divide microinstruction, one has to wait for 12 microcycles and then read the result and the remainder in MACH and MACL registers. During the 12 execution microcycles, microengine can execute microinstructions unrelated to the MDU.

67.3.10.3.3 Signed Multiplication (mults)

MDU signed multiplication is defined as follows:

```
(signed) MACH,MACL = (signed) AS * (signed) BS
```

MC and MV flags are reset. MZ is set if result is 0, resets otherwise. MN is set if result is negative.

67.3.10.3.4 Unsigned Multiplication (multu)

MDU unsigned multiplication is defined as follows:

```
(unsigned) MACH|MACL = (unsigned) AS * (unsigned) BS
```

MC and MV flags are reset. MZ is set if result is 0, resets otherwise. MN is a copy of the most significant bit of result.

67.3.10.3.5 Signed Multiply-Accumulate (macs)

MDU signed multiply-accumulate is defined as follows:

```
(signed/unsigned) {MACH,MACL} += (signed) AS * (signed) BS
```

MC is not altered.

MV is set if result can not be represented by a 48-bit signed number. MACS never resets MV flag: it is left as is if no overflow occurs, or set it otherwise. This allows checking the overflow flag only once at the end of a series of multiply-accumulate operations in a scalar product calculation.

```
if (({MACH,MACL} += AS * BS < -2^47) || ({MACH,MACL} += AS * BS > 2^47 - 1))
  MV = 1
```

MZ is set if result is 0, resets otherwise. MN is a copy of the most significant bit of result.

Note that only 24-bit multiply-accumulate is available.

67.3.10.3.6 Unsigned Multiply-Accumulate (macu)

MDU Unsigned Multiply-Accumulate is defined as follows:

```
(signed/unsigned) {MACH,MACL} += (unsigned) AS * (unsigned) BS
```

MC is set if result can not be represented by a 48-bit unsigned non-negative number. MACU never resets MC flag: MC flag is left as is if no carry occurs, or set otherwise. This allows checking the carry flag only once at the end of a series of multiply-accumulate operations in a scalar product calculation.

```
if (({MACH,MACL} += AS * BS < 0) || ({MACH,MACL} += AS * BS > 2^48 - 1))
  MC = 1
```

MV is not altered.

MZ is set if result is 0, resets otherwise. MN is a copy of the most significant bit of result.

Note that only 24-bit multiply-accumulate is available.

67.3.10.3.7 Signed Fractional Multiplication (fmults)

MDU Signed Fractional Multiplication takes the B-Source as an **unsigned** 8- or 16-bit[26] fraction between 0 and $(2^8 - 1)/2^8$ (inclusive) for the 8-bit operation, or between 0 and $(2^{16}-1)/2^{16}$ (inclusive) for the 16-bit operation. Only A-Source is taken as a signed number. The value of B-Source is considered the unsigned numerator of a fraction with denominator 2^8 or 2^{16} for the 8- and 16-bit operations, respectively.

The integer part of the result is stored in MACH, and the fractional part in MACL. The result is signed, so that the concatenation of MACH and MACL form a 48-bit fixed point number with a 24-bit integer part, both for 8- and 16-bit operations. To calculate the unsigned numerator of the fractional part (with denominator 2^{24}) of the result, one must take the absolute value of MACL considering the signal of the result (not MACL alone), i.e.: if flag MN=1, invert MACL and add 1.

MDU flags are updated in the same way as in the Signed Multiplication.

67.3.10.3.8 Unsigned Fractional Multiplication (fmultu)

MDU Unsigned Fractional Multiplication takes both A-Source and B-Source as unsigned operands. B-Source is taken as an 8- or 16-bit[27] fraction between 0 and $(2^8 - 1)/2^8$ (inclusive) for the 8-bit operation, or between 0 and $(2^{16}-1)/2^{16}$ (inclusive) for the 16-bit operation. The value of B-Source is considered the numerator of a fraction with denominator 2^8 or 2^{16} for the 8- and 16-bit operations, respectively.

The integer part of the result is stored in MACH, and the fractional part in MACL. The fractional part in MACL is the numerator of a fraction with denominator 2^{24}. The concatenation of MACH and MACL form a 48-bit fixed point number with a 24-bit integer part, both for 8- and 16-bit operations.

MDU flags are updated in the same way as in the Unsigned Multiplication.

[26] 24-bit fractional signed/unsigned multiplication is equivalent to mults/multu.
[27] 24-bit fractional signed/unsigned multiplication is equivalent to mults/multu.

67.3.10.3.9 Unsigned Divide (div)

At the end of a divide operation MACL holds the result of the division, taking A-source as numerator and B-source as denominator, while MACH holds the remainder. If a divide by 0 is executed, MACL holds the maximum unsigned number (0xFFFFFF) as result and flag MV is set to indicate division by 0 (otherwise reset). The contents of MACH become undetermined.

MC flag is always reset.

MZ flag is set if MACL equals 0, and reset otherwise.

MN receives a copy of MACH bit 23 (msb from the remainder).

Note that signed division is not available.

67.3.10.3.10 MDU Flags

MDU has its own flags to indicate the result and status of an MDU operation. They are: MC, MZ, MV, MN and MB. All MDU flags are updated with the final result at the end of the operation, and do not change until the next operation finishes. Therefore it is possible to start a new MDU operation and test the flags of the previous one in parallel, except for mult/mac with 8-bit operand (takes only 1 microcycle).

67.3.10.3.10.1 MDU Negative Flag - MN

MN flag is always a copy of MACH bit 23 at the end of the operation, either in signed or unsigned ones. Note that MACH holds the rest of a division operation, which is always unsigned.

67.3.10.3.10.2 MDU Carry Flag - MC

MDU carry flag indicates if the result cannot be represented by a 48-bit number, in Signed and Unsigned Multiply Accumulates. It is reset in the other operations.

67.3.10.3.10.3 MDU Zero Flag - MZ

In multiply and multiply-accumulate operations, MDU zero flag is asserted if MACH and MACL are equal to zero at the end of an operation. In divide operations, zero flag is asserted if MACL (result) is equal to 0.

67.3.10.3.10.4 MDU Overflow Flag - MV

In multiply operations, MV flag is negated and keeps negated in the end, because the result of a multiplication can always fit in a 48-bit result (MACH and MACL concatenated). In a multiply-accumulate operation, MV is asserted if the result size is wider than 48 bits. MV flag work in both signed and unsigned operations.

In divide operations it is only asserted if a divide-by-zero operation was executed.

67.3.10.3.10.5 MDU Busy Flag (MB)

MB tests as true at the next microinstruction after the MDU start operation, and as false at the last microcycle of any MDU operation execution.

67.3.10.4 Branch conditions

Microengine allows conditional branch. There are five sets of flags that can be tested in a conditional branch: ALU flags, MDU flags, P flags, Channel flags, and Semaphore flag (flag SMLCK).

When a thread starts to be executed, the values in MDU and ALU flags are not initialized. ALU flags are described in ALU flags, MDU flags are described in MDU Flags. MDU and ALU flags are updated during execution of microinstructions.

P flags are actually the upper byte of P register, which optionally can work as user-defined flags (see P Register).

Channel flags Flags0, Flag1, MRLA, MRLB, TDLA, TDLB, PSS, PRSS and PSTO are obtained from the selected channel (value in CHAN register), while channel flags, LSR, FM[0] and FM[1] are selected by the serviced channel, regardless of the CHAN value[28].

Flags TDLA/B, MRLA/B, LSR, FM and PSS, are sampled at the beginning of a thread. Flag PSS does not change during its execution while CHAN register is not written. When a write in CHAN register is performed, all flags except LSR and FM are updated according to the channel specified by CHAN value. Flags MRLA/B and TDLA/B are reset when their respective latches in channel are cleared by microcode.

Table 420. Channel flags as branch condition

Flag	Description	Service or selected channel
Flag0	State Resolution flag	reflects the selected channel (CHAN)
Flag1	State Resolution flag	reflects the selected channel (CHAN)
MRLA	Match A Recognition Latch	These flags reflect the selected channel (CHAN) (see MRLA/B - Match Recognition Latches and TDLA/B - Transition Detect Latches for more information).
MRLB	Match B Recognition Latch	
TDLA	Transition A Detection Latch	
TDLB	Transition B Detection Latch	
LSR	Link Service Request	reflects the serviced channel.
PRSS	Input Pin state sampled at service request	reflects the selected channel (CHAN). Does not change if CHAN is not changed.
PSS	Sampled Input Pin State	reflects the selected channel (CHAN). Does not change if CHAN is not changed (see Pin Control Registers).
PSTI	Current Input Pin State.	reflects the selected channel (CHAN). Changes any time.
PSTO	Current Output Pin State	reflects the selected channel (CHAN). Changes any time.
FM	Function Mode Bits	reflects the Function Mode for serviced channel (see C*a*SCR_ENG1 and C*a*SCR_ENG2)

Semaphore condition SMLCK always indicates if a semaphore is locked for the Engine, resolving as false before any lock attempt. For each trial, the SMLCK flag is updated. The SMLCK value set in one thread is not meaningful to the other. After a free, the SMLCK condition tests as false until a new lock attempt on the same thread.

Branch conditions are selected through instruction fields BCC and BCF (see Conditional/unconditional branch).

67.3.11 Microinstruction Set

Each microinstruction can execute up to 3 microoperations in parallel. Microinstructions are grouped into formats, and there are four types of microoperations:

- ALU/MDU Operations
- SDM Operations
- Channel Configuration/Control Operations
- Flow Control Operations

[28] Serviced channel does not change during execution of a thread, and it is the channel that requested a service (initial value of CHAN register when a thread starts).

Each microinstruction format is defined by a set of microinstruction fields, which determine the operations, each belonging to one of the groups above (there may be several in one group). Complete microinstruction formats are shown in Microinstruction formats.

Parallelism conflicts may arise when two operations are executed in the same microinstruction. These situations are explained in Microinstruction Parallelism Issues.

67.3.11.1 SDM Microoperations

The access to SDM is made by providing an address and a register to perform a data transfer, except semaphore operations, which are also classified in the SDM group. Only P and DIOB registers can exchange data with SDM. Microengine always addresses SDM in 32-bit boundaries, for 8, 24, or 32 bit wide data.

Direction is determined by the field RW in all addressing modes: RW=0 selects read and RW=1 selects write.

67.3.11.1.1 SDM Addressing Modes

There are 4 addressing modes in eTPU:

- Absolute
- Selected Channel Relative
- Indirect
- Engine Relative

The addressing modes Absolute and Selected Channel Relative use immediate bits to form the physical address of SDM, which is identified in microinstruction as a field called AID. AID field can be 3-, -, or -bit wide depending on the addressing mode.

67.3.11.1.1.1 Absolute Addressing Mode

In Absolute addressing mode, the address range is parameters, addressed by field AID, which in this mode is -bit wide. These parameters are located in SDM addresses from 0 to .

```
physical_address = AID[:0]
```

67.3.11.1.1.2 Selected Channel Relative Addressing Mode

In Selected Channel Relative addressing mode, only the first 8 (with 3-bit AID) or (with 7-bit AID) parameters of the selected channel are accessible, depending on the microinstruction format. Physical address is calculated using the channel parameter base address that is specified in the CPBA field of C*a*CR_ENG1 and C*a*CR_ENG2. AID field is added to channel parameter base address to compose the physical address. The address equation is:

```
physical_address = selected_channel_parameter_base_address + AID[ :0], or
physical_address = selected_channel_parameter_base_address + AID[2:0]
```

67.3.11.1.1.3 Indirect Addressing Mode

In Indirect Addressing mode the physical address is taken from DIOB register. Only DIOB bits 14 to 2 are relevant. Since the SDM word address is shifted two bits up in DIOB, its contents hold the same parameter address value used by Host. The address equation for SDM access is:

```
physical_address = DIOB[13:2], or
physical_address = (truncated to 12 bits) (DIOB / 4)
```

Indirect addressing mode is used to access the Shared Subsystem Area when eTPU_CCCR_C*x*CR_ENG*n*[SSMAE]=1 and DIOB addresses the 16 Kbytes just above the SDM range (DIOB bit 14 = 1) . See Shared subsystems support for more details . If SSMAE=0, accesses with DIOB bit 14 = 1 hit the same SDM addresses as with bit 14 = 0, providing full backwards compatibility with respect to DIOB contents .

Indirect addressing mode can have post-increment or pre-decrement on DIOB, allowing stack operations. See DIOB stack operation for more information.

67.3.11.1.1.4 Engine Relative Addressing Mode

In Engine Relative Addressing mode the physical address is the concatenation of the eTPU_SCR_ECR_ENG*n*[ERBA] field (see eTPU Engine 1 Configuration Register (ECR_ENG1) and eTPU Engine 2 Configuration Register (ECR_ENG2)) with the 7-bit AID instruction field. This allows the same function microcode, when running on distinct engines, to access different address spaces, global to the engine only.

The SDM physical word address in Engine Relative Addressing mode is calculated as follows:

```
physical address = (eTPU_SCR_ECR_ENGn[ERBA]<< 7) + AID[6:0]
```

67.3.11.1.2 SDM source/destination registers

When performing an SDM operation, only DIOB or P can be used as data source or destination. P is 32-bit wide, and DIOB is 24-bit wide. Microinstruction field P/D (1 bit) is used to choose between P and DIOB as data the source or destination. When the P/D field is not available in microinstructions that support SDM access, the source/destination is P.

Table 421. SDM source/destination Register Selection

P/D	Meaning
0	P access
1	DIOB access

67.3.11.1.3 SDM Operation Size

When using DIOB register to perform SDM data transfers, the operation size is always 24-bit wide (lower 24 bits of SDM). When using P register, the operation size can be 8-, 24- or 32-bit wide, which is controlled by microcode RSIZ field (2 bits). RSIZ meaning is shown in the following table.

Table 422. SDM P access Size

RSIZ	P access	DIOB access
00	full 32-bit access (i.e. P[31:0]=SDM[addr] [31:0])	RESERVED
01	only upper 8 bits are transferred (i.e. P[31:24] = SDM[addr] [31:24])	RESERVED
10	only lower 24 bits are transferred (i.e. P[23:0] = SDM[addr] [23:0])	DIOB = SDM[addr] [23:0
11	RESERVED	RESERVED

RSIZ is not available in all microinstructions that support SDM access. In microinstructions where RSIZ field is not available, SDM access will be 24 bits by default.

When performing a Zero SDM write operation (see Zero SDM Operation), RSIZ defines the size of operation regardless of the P/D field (SDM source/destination registers).

67.3.11.1.4 SDM access direction

RW field defines the direction of the access in the SDM. The access direction is summarized in the following table.

Table 423. SDM access direction

R/W	Meaning
0	read SDM parameter into P or DIOB registers
1	write SDM parameter from P or DIOB registers

67.3.11.1.5 Zero SDM Operation

Zero SDM operation is controlled by microcode field ZRO (1bit). When ZRO field is 0, the data portion written in SDM or in P/DIOB (SDM read) registers will always be 0x0. When performing a Zero SDM write operation, the RSIZ is relevant regardless of the P/D field (usually RSIZ is meaningful only for P/D = 0), which means that zero SDM write operation can be performed with 32, 24 or 8 bits according to SDM operation size. These conditions are summarized in the following table.

Table 424. Zero SDM Operation

ZRO	RW	P/D	Meaning
0	0	0	Clear P register. Size is determined by RSIZ field. See SDM Operation Size
0	0	1	Clear DIOB (all 24 bits), independently of RSIZ
0	1	x	Clear SDM parameter. Size is determined by RSIZ field. See SDM Operation Size
1	RW	P/D	Regular SDM operation

NOTE

When field STC is present, STC=11 also disables Zero SDM operation (see DIOB stack operation). The conflicts with DIOB operations (see DIOB stack operation) and ALU operations are resolved like a normal SDM operation (see ALU and SDM Operations).

Zero SDM read operations do check memory errors on the read data, however discarded . Zero SDM write operations normally update the ECC of the written data .

67.3.11.1.6 DIOB stack operation

SDM Indirect Addressing Mode (see Indirect Addressing Mode) is used if STC field (2 bits) exists in the microinstruction, controlling automatic increment/decrement of DIOB register, as shown in the following table, thus allowing stack operations. DIOB is incremented and decremented in word addresses, only from bits 15 down to 2, i.e.: the bits 23 to 16 and 1 to 0 are left untouched by STC pre-decrement and post-increment.

Table 425. DIOB Post-Increment / Pre-Decrement - STC

STC	Meaning
00	Post-Increment of DIOB
01	Pre-Decrement of DIOB
10	No Increment/Decrement (normal access)
11	No SDM Access[1]

1. Also disables Zero SDM operation.

67.3.11.1.7 Semaphore Operations

Semaphore lock and free operations are available through eTPU microcode. For more information about semaphores see Hardware Semaphores. There are 2 microinstruction fields that control semaphore operations: FL (1 bit) and SMPR (2 bits). Serviced channel sees 4 semaphores, selected by field SMPR.

Table 426. Semaphore Operations Fields

Field	Meaning
FL	0 = free semaphore, 1 = lock semaphore
SMPR	semaphore number selector

When freeing a semaphore, the field SMPR has no meaning. This is because only one semaphore can be locked at a time by each engine, so when freeing a semaphore it is not necessary to specify its number.

NOTE

If microcode tries to lock a semaphore already locked for the same Engine, the semaphore continues locked for the Engine and the SMLCK branch condition resolves as true.

67.3.11.2 ALU/MDU Operations

ALU/MDU microoperations mostly comprises two sources, one destination and one operation. The operation is generally selected through fields ALUOP, ALUOPI or SHF. In formats where there is no operation selection field (ALUOP, ALUOPI or SHF), the operation performed is always addition; however, it is possible to perform subtraction, increment or decrement using fields BINV (see B-Source Inversion) and CIN (see Carry-in Control).

67.3.11.2.1 Source and Destination Register Set Selection

Microcode field T4ABS allows selection of a source from either one of two register sets, shown in Selecting sources and destination. The same applies to T2ABD, used for ALU destination selection with other two register sets, as shown in Selecting sources and destination. Microinstruction fields ABSE and ABDE control the register set selection for source and destination, respectively, when available at the format. In formats without ABSE/ABDE, the field T4BBS determines the register sets used by T2ABD and T4ABS, as shown in Microinstructions without fields ABSE and ABDE.

67.3.11.2.1.1 Microinstructions With Fields ABSE and ABDE

In microinstructions where ABSE and ABDE fields are available (1 bit each), ABSE controls register set selection for T4ABS and ABDE controls register set selection for T2ABD. The following table shows the meaning of values for ABSE and ABDE fields.

Table 427. Register Set Selection by ABSE or ABDE

ABSE or ABDE	Register Set Selected
0	second
1	first

67.3.11.2.1.2 Microinstructions without fields ABSE and ABDE

When ABSE and ABDE are not available in a microinstruction format, register set is selected by T4BBS field. The following table explains how to select a register set either for T4ABS and T2ABD.

Table 428. Register set selection by T4BBS without ABSE and ABDE

T4BBS	Register set for T2ABD	Register set for T4ABS
0xx	first	first
100	second	second
101	second	first
110	first	second
111	first	first
none[1]	first	first

1. Refers to operations with immediate data as B-source, without ABSE and ABDE.

67.3.11.2.2 Selecting sources and destination

All ALU/MDU operations need 2 sources (called AS and BS) and 1 destination (called AD), except for some of those that use immediate data (see Operations With Immediate Data). Fields T4ABS (4 bits), ABSE (1 bit), T4BBS (3 bits) select sources, while T2ABD (4 bits) and ABDE (1 bit) select the destination. When MDU is used (multiply/divide), T2ABD destination selection is ignored and results are stored in MACH and MACL (see MAC and Divide Unit (MDU)). ABSE and ABDE are not available in some microinstruction formats that support ALU/MDU operations. However, in all formats where ABSE is available, ABDE is also available and vice-versa. The existence of ABSE/ABDE fields changes the meaning of T4BBS field, as shown in the table below. On instructions with immediate data, it is used as B-source (see Operations With Immediate Data).

All sources and destinations have a size associated to it, and these sizes are used to select flag sample position (see Flags Sampling Control). Sizes can be 8, 16 or 24 bits. Registers that are not exactly of one of these sizes are treated as the immediately upper size (e.g., CHAN[4:0] is an 8-bit source). See Flags Sampling Control for more information.

Some parallelism issues arise when selecting P, DIOB, ERTA or ERTB as destination registers, since they can be modified by other microoperations in the same microinstruction (see Microinstruction Parallelism Issues for details).

Table 429. B source selection - T4BBS

T4BBS	Meaning in microinstruction formats with ABSE/ABDE	Meaning in microinstruction formats without ABSE/ABDE[1]
000	BS[23:0] = P[23:0]	
001	BS[23:0] = A[23:0]	
010	BS[23:0] = SR[23:0]	
011	BS[23:0] = DIOB[23:0]	
100	reserved	BS = 0
101	reserved	BS = 0
110	reserved	BS = 0
111	BS=0, or Max const., if CIN=0 and BINV=0 (see Generating "max" constant).	

1. T4BBS also selects A-source and destination register set in this case, according to Microinstructions without fields ABSE and ABDE.

T4ABS selects one source from 2 register sets, shown in the following table. ABSE and T4BBS control which set T4ABS field uses to select the source. For more information about how to select a register set for T4ABS and T2ABD see Source and Destination Register Set Selection. All sources are zero-filled to 24 bits, unless sign-extension is specified (see A-Source Size Override).

Table 430. A source selection - T4ABS

T4ABS	First register set		Second register set	
	Selected register	Size	Selected Register	Size
0000	AS[7:0]=P[7:0]	8	AS[7:0]=0	8
0001	AS[7:0]=P[15:8]	8	AS[23:0]=C[23:0]	24
0010	AS[7:0]=P[31:24]	8	AS[15:0] = TPR[15:0]	16
0011	AS[23:0] = ERTB[23:0]	24	AS[23:0] = B[23:0]	24
0100	AS[23:0] = D[23:0]	24	AS[23:0] = TRR[23:0]	24
0101	AS[15:0] = P[15:0]	16	AS[7:0] = 0, read_match[1]	8
0110	AS[15:0] = P[31:16]	16	AS[13:0] = RAR[13:0]	16
0111	AS[7:0] = P[23:16]	8	AS[23:0] = MACH[23:0]	24
1000	AS[23:0] = P[23:0]	24	AS[23:0] = MACL[23:0]	24
1001	AS[23:0] = A[23:0]	24	AS[4:0]=CHAN[4:0]	8
1010	AS[23:0] = SR[23:0]	24	AS[:2] = CHAN_BASE[2]	16
1011	AS[23:0] = DIOB[23:0]	24	AS[13:0] = ENGINE_BASE[3]	16
1100	AS[23:0] = TCR1[23:0]	24	Reserved	-
1101	AS[23:0] = TCR2[23:0]	24	Reserved	-
1110	AS[23:0] = ERTA[23:0]	24	Reserved	-
1111	AS[23:0] = 0	24	Reserved	-

1. T4ABS=0101 with second register set also reads MatchA/B registers into ERTA/B (see Special T4ABS Source Operation: Read Match Registers).
2. CHAN_BASE is the selected channel's base SDM address in channel relative address mode (see CHAN_BASE as a source).
3. ENGINE_BASE is the eTPU_SCR_ECR_ENG*n*[ERBA] field shifted left 9 positions.

T2ABD selects the destination from 1 of 2 register sets, shown in the following table. ABDE and T4BBS control which set T2ABD field uses to select the destination.

Table 431. Destination selection - T2ABD

T2ABD	First register set		Second register set	
	Selected register	Size	Selected Register	Size
0000	A[23:0] = AD[23:0]	24	C[23:0] = AD[23:0]	24
0001	SR[23:0] = AD[23:0]	24	LINK[7:0] = AD[7:0]	8
0010	ERTA[23:0] = AD[23:0][1]	24	TPR[15:0] = AD[15:0]	16
0011	ERTB[23:0] = AD[23:0][2]	24	B[23:0] = AD[23:0]	24
0100	DIOB[23:0] = AD[23:0]	24	CHAN[4:0] = AD[4:0]	8
0101	P[15:0] = AD[15:0]	16	D[23:0] = AD[23:0]	24
0110	P[31:16] = AD[15:0]	16	RAR[12:0] = AD[12:0]	16
0111	P[23:0] = AD[23:0]	24	MACH[23:0] = AD[23:0]	24
1000	TCR1[23:0] = AD[23:0]	24	MACL[23:0] = AD[23:0]	24
1001	TCR2[23:0] = AD[23:0]	24	Reserved	-
1010	P[31:24] = AD[7:0]	8	Reserved	-
1011	P[23:16] = AD[7:0]	8	Reserved	-
1100	P[15:8] = AD[7:0]	8	Reserved	-
1101	P[7:0] = AD[7:0]	8	Reserved	-
1110	TRR[23:0] = AD[23:0]	24	Reserved	-
1111	no destination selected[3]	24	Reserved	-

1. T2ABD=0010 with first register set also writes to MatchA or UDCM registers of the selected channel if field ERWA=0 (see Write Channel Match and UDCM Registers).
2. T2ABD=0011 with first register set also writes to MatchB register of the selected channel if field ERWB=0.
3. if no destination is selected, ALU flags are updated, although the result is lost.

67.3.11.2.2.1 Max Const Generation With T4BBS=111

When T4BBS = 111, BINV = 0, and CIN = 0, the value assigned to BS will be 0x800000, and not 0x0 as expected. See Generating "max" constant for detailed explanation about this.

67.3.11.2.2.2 Special T4ABS Source Operation: Read Match Registers

When T4ABS = 0101 and the source for T4ABS is selected from the second register set, the constant 0x00 is used as AS (8-bit size) and the following register transfer is performed in parallel as well: match registers of the selected channel (value in CHAN register) are copied to ERTA/ERTB registers, where ERTA receives the value of MatchA register and ERTB receives the value of MatchB register (see ER - Event Registers). Note that ALU destination can still be chosen by T2ABD in parallel. When ERTA or ERTB is selected by T2ABD, a parallelism issue arises (see ALU Operations and Read Match Registers).

67.3.11.2.2.3 CHAN_BASE as a source

Each channel has a parameter base address in SDM, which is configured in C*a*CR_ENG1[CPBA] and C*a*CR_ENG2[CPBA]. CHAN_BASE, which represents a parameter address (CPBA*2), can be used as A-source using T4ABS=1010 when T4ABS selects a source from the second register set. In this case, CHAN_BASE is loaded into AS[13:2] to form the byte address (AS[23:14]=0, AS[1:0]=0). For example, in Indirect addressing mode, where the destination register is DIOB, CHAN_BASE is loaded into DIOB[13:2], which is the parameter address, and DIOB[13:0] represents the byte address. CHAN_BASE is the base address of the selected channel (given by CHAN register).

67.3.11.2.3 Flags Sampling Control

This section explains how the flags Z (zero), C (carry), N (negative) and V (overflow) are updated in an ALU operation. When there are post-ALU shift operations, the ALU Carry Out is not directly sampled in Carry flag, but passed to the post-ALU shifter (see Shift Operations). Since the size of source operands in ALU operations is variable, flags can be sampled as an operation of 8, 16 or 24 bits wide. The operation size selection is automatic, based on defined sizes of sources and destination, using the equation:

```
operation_size = minor(size_of(destination), greater(size_of(A-Source),
size_of(B-Source)))
```

Operation size can also be shown with the following table:

Table 432. Operation Size Determination

A Source	B Source	Destination	Operation Size
x	x	8 bits	8 bits
8 bits	8 bits	x	8 bits
16 or 24 bits	x	16 bits	16 bits
16 bits	8 or 16 bits	24 bits	16 bits
8 or 16 bits	16 bits	24 bits	16 bits
24 bits	x	24 bits	24 bits
x	24 bits	24 bits	24 bits

NOTE

Whenever BS = (constant) 0, its size is considered 8 bits, and all 24 bits in B-bus are set to 0. Therefore, all operations with BS = (constant) 0 have their size determined by AS and Destination only.

CCS field (1 bit) controls whether flags will be updated or not (). When CCS bit exists in a microinstruction, the operation size will be used to sample flags. In some microinstructions CCS field is replaced by CCSV (2 bits,). Flag sampling according to CCSV can be set as defined by the operation size, or fixed as 8 or 16 bit operations.

NOTE

For the post-ALU rotate right operation, CCSV also determines the rotate size: whether 8-bit, 16-bit, or determined by the operation size.

Table 433. Flag Sampling Using CCSV field

CCSV	Meaning
00	sample flags as an 8 bit operation
01	sample flags as a 16 bit operation
10	sample flags as defined by operation size
11	do not sample flags

Table 434. Flag Sampling Using CCS field

CCS	Meaning
0	sample flags as defined by operation size
1	do not sample flags

When neither CCS nor CCSV are present in the microinstruction, flags are not sampled. CCS and CCSV do not affect the Carry update on Exchange Bit operation (see Exchange Bit), but does control the N and Z flags.

67.3.11.2.4 B-Source Inversion

The data selected as second source (T4BBS) can be inverted (bitwise boolean NOT) before operation. This is controlled by microinstruction field BINV (1 bit, in the following table). A zero value for BINV activates B-source inversion.

Table 435. B-Source Inversion - BINV

BINV	Meaning
0	invert B-source[1]
1	keep B-source bus unchanged

1. Except on max-constant selection, see Generating "max" constant.

BINV also selects between *adc* or *sbc* enhanced ALU operation, using inverted C flag as carry-in besides BS inversion for *sbc*. Note that BINV does not invert carry in fixed-carry operations (see Carry-in Control).

When BINV = 0, T4BBS = 111 and CIN = 0, the value assigned to BS is 0x800000, instead of 0x0. See Generating "max" constant for more details.

67.3.11.2.5 Carry-in Control

CIN field (1 bit,) controls the carry-in for addition/subtraction operations. Functionality of CIN field depends on the arithmetic operation selected by ALUOP. When ALUOP is not available in microinstruction, the operation selected is *add*. For carry-in control in MDU operations, see the following table.

Table 436. ALU Carry-In Control

operation	CIN=0	CIN=1
add (addition)	carry-in used is 1[1]	carry-in used is 0

Table continues on the next page...

Table 436. ALU Carry-In Control (continued)

operation	CIN=0	CIN=1
adc (addition with carry)[2]	carry-in used is C flag	
sbc (subtraction with borrow)[3]	carry-in used is inverted C flag	

1. Except on max-constant selection, see Generating "max" constant.
2. Selected by ALUOP=11000 and BINV=1
3. Selected by ALUOP=11000 and BINV=0

67.3.11.2.5.1 Generating "max" constant

When T4BBS = 111, CIN = 0 and BINV = 0, BS is assigned to 0x800000 (called "max constant") instead of 0x000000. This is an exception for CIN and BINV fields: when "max constant" is selected, the carry in is 0 and B-source ("max constant" itself) is not inverted, neither the carry out.

"Max constant" is the value which, added to a time base value minus 1, gives the farthest wrapped time base value that satisfies a channel greater-equal comparison. See Enhanced Channels for more info.

67.3.11.2.6 Shift Operations

There are three types of shift operations: ALU, post-ALU and Shift Register. ALU shift operations are covered in ALU/MDU Operation Selection. Post-ALU and Shift Register are covered in the following sections.

67.3.11.2.6.1 Shift Register Operations

SR can be used as a general purpose register and it can easily shift-right its contents, combined or not to post-ALU shift operations. If field SRC (1 bit) in microcode is 0, SR will shift its contents 1 bit to the right according to the algorithmic description below. SR shifting operation depends also on SHF or ALUOP fields. ALUOP and SHF never exist both on the same microinstruction format.

Table 437. Shift Register Control - SRC

SRC	Meaning
0	shift right SR 1 bit
1	no shift

SR Operation:

```
SR[22:0] = SR[23:1];
if SHF == "01" or ALUOP == "10110" then
 SR[23] = ALU_OUT[0];
else
  SR[23] = 0;
endif;
```

67.3.11.2.6.2 Post-ALU shift operations

Post-ALU shift can be selected by SHF field (2 bits) or by some specific ALUOP field values. SHF and ALUOP fields are never both available in the same microinstruction format. When selecting post-ALU shift operation using ALUOP field, ALU will always add the sources before shifting the result.

Table 438. Post-ALU shift operation

Post ALU operation	SHF[1]	ALUOP
shift left (1 bit)	00	10101
shift right (1 bit)	01	10110
rotate right (1 bit)	10	10111
no shift/rotate	11	any other[2]

1. ALU performs AS+BS before shift/rotate for all SHF values.
2. Some ALUOP combinations perform shift/rotate, but not using the Post-ALU Shifter (see ALU/MDU Operation Selection)

Carry flag is only updated when CCS or CCSV fields allow it (see Flags Sampling Control). Algorithmic descriptions of post-ALU shift operations are presented in ALU ADD operation with and without shifting.

67.3.11.2.7 Conditional ALU/MDU Operation Execution

The 3-bit field AS/CE allows conditional execution of arithmetic operation, as shown in the following table . The same field can also be used for overriding the size of A-Source (see A-Source Size Override).

Table 439. ALU/MDU Conditional Execution

AS/CE	Meaning
000	used for A-Source size override (see A-Source Size Override)
001	
010	execute if C = 1
011	execute if C = 0
100	execute if Z = 1
101	execute if Z = 0
110	execute if N = 1
111	execute unconditionally/no size override

Other operations not related to ALU/MDU in the same microinstruction are not affected by the AS/CE field.

If a conditional operation is selected, there is no A-Source size override; similarly, when size override for A-Source is selected, the ALU/MDU operation executes unconditionally.

When a conditional ALU/MDU operation is not executed:

- the destination register is not updated. If the destination is CHAN, no actions associated with CHAN assignment occur (see Channel Selection Register - CHAN).
- the ALU and MDU flags are not updated.
- MDU does not start any operation, i.e., MACH and MACL are not updated.
- SR does not shift.
- T4ABS-selected read-match does not occur.

67.3.11.2.8 A-Source Size Override

Some values if the AS/CE field are used for A-Source Size Override, as shown in the following table.

Table 440. A-Source Size Override

AS/CE	Meaning
000	A-source size override to 8 bits
001	A-source size override to 16 bits
010	used for conditional execution (see Conditional ALU/MDU Operation Execution)
011	
100	
101	
110	
111	execute unconditionally/no size override

Register size override zero-pads an overridden source to 24-bits (if no sign extension is performed, see A-source Sign Extension) and affects operation size calculation. When register source is wider than size override, most significant bits of selected register are not used as A source (zeros are used instead). When size override is wider than selected register, register value is padded to zeros.

When size override is used with MDU operations, it affects only the operand values, but not the operation size: MDU operation size is fully determined by the operation definition (fields ALUOP, ALUOPI).

Table 441. AS/CE field A source size override functionality

Size Override	Size of Selected Register	AS Value[1]
8 bits	8 bits	reg[7:0]
8-bits	16 bits	reg[7:0]
8bits	24 bits	reg[7:0]
16 bits	8 bits	reg[15:0]
16 bits	16 bits	reg[15:0]
16 bits	24 bits	reg[15:0]

1. All values are zero-padded to 24 bits

67.3.11.2.9 A-source Sign Extension

The SEXT microinstruction field forces sign extension of A source according to the size of A operand, either overridden or not by AS/CE field, according to the following table. The sign is taken from the size-overridden value, not the original one.

Table 442. A source Sign Extension

SEXT	Meaning
0	extends sign of A source from its size to 24-bits
1	does not extend sign of A source

A-source sign is not extended in microinstructions without SEXT field, even if AS/CE field is present.

67.3.11.2.10 ALU/MDU Operation Selection

When field ALUOP is available in microinstruction, enhanced ALU operations shown in the following table can be performed, otherwise addition is performed. The ALU operations are defined in ALU and Post-ALU Shifter. The MDU operations are defined in MAC and Divide Unit (MDU).

Table 443. ALU Operation Selection - ALUOP

ALUOP	Operation	Comment
00000	AS mults BS[7:0]	signed multiplication
00001	AS multu BS[7:0]	unsigned multiplication
00010	AS fmults BS[7:0]	signed fractional multiplication
00011	AS fmultu BS[7:0]	unsigned fractional multiplication
00100	AS mults BS[15:0]	signed multiplication
00101	AS multu BS[15:0]	unsigned multiplication
00110	AS fmults BS[15:0]	signed fractional multiplication
00111	AS fmultu BS[15:0]	unsigned fractional multiplication
01000	AS mults BS[23:0]	signed multiplication
01001	AS multu BS[23:0]	unsigned multiplication
01010	AS macs BS[23:0]	signed multiply-accumulate
01011	AS macu BS[23:0]	unsigned multiply-accumulate
01100	AS div BS[7:0]	unsigned division by 8-bit value
01101	AS div BS[15:0]	unsigned division by 16-bit value
01110	AS div BS [23:0]	unsigned division by 24-bit value
01111	n.a.	RESERVED
10000	AS[23:0] | BS[23:0]	24 bit bitwise OR

Table continues on the next page...

Table 443. ALU Operation Selection - ALUOP (continued)

ALUOP	Operation	Comment
10001	AS[23:0] ^ BS[23:0]	24 bit bitwise XOR
10010	AS[23:0] & BS[23:0]	24 bit bitwise AND
10011	abs(AS)	absolute value of AS
10100	AS + BS	arithmetic addition
10101	(AS + BS) shl 1	arithmetic addition with 1-bit post-ALU shift left. (Post-ALU shift operations)
10110	(AS + BS) shr 1	arithmetic addition with 1-bit post-ALU shift right (Post-ALU shift operations)
10111	(AS + BS) ror 1	arithmetic addition with 1-bit post-ALU rotate right (Post-ALU shift operations)
11000	AS adc/sbc BS[1]	addition/subtraction with C flag (Carry-in Control)
11001	AS shl (2^(BS[1:0]+1))	AS is shifted left: 2 bits for BS=0; 4 for BS=1; 8 for BS=2; 16 for BS=3
11010	AS shr (2^(BS[1:0]+1))	AS is shifted right: 2 bits for BS=0; 4 for BS=1; 8 for BS=2; 16 for BS=3
11011	AS ror (2^(BS[1:0]+1))	AS is rotated right: 2 bits for BS=0; 4 for BS=1; 8 for BS=2; 16 for BS=3
11100	AS exch BS[4:0]	exchange C flag and AS bit determined by BS (Exchange Bit)
11101	AS setb BS[4:0]	set bit in AS determined by BS In setb and clrb operations, the register that drives A source is not changed, unless selected as destination of the operation.
11110	AS clrb BS[4:0]	clear bit in AS determined by BS[2]
11111	n.a.	RESERVED

1. Addition/Subtraction is selected by field BINV (see B-Source Inversion)
2. In setb and clrb operations, the register that drives A source is not changed, unless selected as destination of the operation.

67.3.11.2.11 Operations With Immediate Data

Immediate data can be used with some specific microinstruction formats. eTPU microcode allows 8-, 16- or 24-bit immediate data. Immediate data is loaded as B-source, so T4BBS field is not available. When using 24-bit immediate, an add is performed with A-source = 0 and flags are not updated. ALU operations are available with 8-bit immediate, although the field that selects ALU operation in this case is ALUOPI.

67.3.11.2.11.1 24-bit Immediate Destination

When using 24-bit immediate data, the destination register is selected by T2D field (2 bits), according to the following table.

Table 444. 24-bit Immediate Destination - T2D

T2D	Target Register
00	P[23:0]
01	A
10	SR
11	DIOB

67.3.11.2.11.2 Enhanced ALU Operations With Immediate Data

Enhanced operations with immediate data, selected by ALUOPI (5 bits) are allowed only with an 8 bit immediate operand (see the following table).

Table 445. ALU Operation Selection With Immediate Data - ALUOPI

ALUOPI	Operation	Comment
00000	AS mults #imm8	signed multiplication
00001	AS multu #imm8	unsigned multiplication
00010	AS fmults #imm8	signed fractional multiplication
00011	AS fmultu #imm8	unsigned fractional multiplication
00100	AS div #imm8	unsigned division
00101	n.a.	reserved
00110	n.a.	reserved
00111	n.a.	reserved
01000	AD[7:0] = AS[7:0] | #imm8, AD[23:8] = AS[23:8]	bitwise OR
01001	AD[7:0] = AS[7:0] ^ #imm8, AD[23:8] = AS[23:8]	bitwise XOR
01010	AD[7:0] = AS[7:0] & #imm8, AD[23:8] = AS[23:8]	bitwise AND
01011	AD[7:0] = AS[7:0] & #imm8, AD[23:8] = 0×0	bitwise AND with clear
01100	AD[15:8] = AS[15:8] | #imm8, AD[23:16] = AS[23:16], AD[7:0] = AS[7:0]	bitwise OR

Table continues on the next page...

Table 445. ALU Operation Selection With Immediate Data - ALUOPI (continued)

ALUOPI	Operation	Comment
01101	AD[15:8] = AS[15:8] ^ #imm8, AD[23:16] = AS[23:16], AD[7:0] = AS[7:0]	bitwise XOR
01110	AD[15:8] = AS[15:8] & #imm8, AD[23:16] = AS[23:16], AD[7:0] = AS[7:0]	bitwise AND
01111	AD[15:8] = AS[15:8] & #imm8, AD[23:16] = 0×0, AD[7:0] = 0×0	bitwise AND with clear
10000	AD[23:16] = AS[23:16] | #imm8, AD[15:0] = AS[15:0]	bitwise OR
10001	AD[23:16] = AS[23:16] ^ #imm8, AD[15:0] = AS[15:0]	bitwise XOR
10010	AD[23:16] = AS[23:16] & #imm8, AD[15:0] = AS[15:0]	bitwise AND
10011	AD[23:16] = AS[23:16] & #imm8, AD[15:0] = 0x0	bitwise AND with clear
10100	AS + #imm8	arithmetic addition
10101	(AS + #imm8) shl 1	arithmetic addition with 1-bit shift left.
10110	(AS + #imm8) shr 1	arithmetic addition with 1-bit shift right
10111	(AS + #imm8) ror 1	arithmetic addition with 1-bit rotate right

ALUOPI	Operation	Comment
11110	n.a.	reserved
11111	n.a.	reserved

67.3.11.3 Channel Control and Configuration Microoperations

Channel Control and Configuration fields set configuration values in the channel logic of the channel selected by the CHAN register, except fields LSR and CIRC.

67.3.11.3.1 Channel flags operations

Each channel has two associated hardware flags, called Channel Flag 0 and Channel Flag 1. Microcode field FLC (3 bits) allows them to be set or cleared, as shown in the following table. These flags can be tested by microcode as a branch condition, and may also influence in the Entry Point taken, allowing fast state decoding. For more details, see Entry Points.

Table 446. P flags operation - FLC

FLC	Meaning
000	Clear flag0
001	Set flag0
010	Clear flag1
011	Set flag1
100	Copy flag1:flag0 from P[25:24]
101	Copy flag1:flag0 from P[27:26]
110	Copy flag1:flag0 from P[29:28]
111	No operation

67.3.11.3.2 Comparator and Time Base Selection

TBSA and TBSB fields (4-bit wide each) are used to configure the type of the comparator and the time bases used for match or capture (see the following tables). TBSA can also be used to control the Output Buffer Enable signal (See Pin Control Registers).

Table 447. Time Base Selection A - TBSA

TBSA[3] = 0	TBSA bit	2	1	0
	bitfield	Comparator selection	Capture selection	Match TB selection
	0	greater or equal	TCR1	TCR1
	1	equal-only	TCR2	TCR2

Table continues on the next page...

Table 447. Time Base Selection A - TBSA (continued)

TBSA[3] = 1	**action**	**2**	**1**	**0**
	set OBE=1	0	0	0
	set OBE=0	0	0	1
	do nothing	1	1	1
	reserved	all other values		

Table 448. Time Base Selection B - TBSB

TBSB[3] = 0	**TBSB bit**	**2**	**1**	**0**
	bitfield	**Comparator selection**	**Capture selection**	**Match TB selection**
	0	greater or equal	TCR1	TCR1
	1	equal-only	TCR2	TCR2
TBSB[3] = 1	action	**2**	**1**	**0**
	do nothing	1	1	1
	reserved	all other values		

67.3.11.3.3 Transition Detection and Pin Action Control

IPACA/B and OPACA/B fields are used to configure transition detection sensitivity (for the channel input signal) or output pin action control (for the channel output signal), as defined in the table below. IPACA and IPACB have the same format, where IPACA is related to Match A and first transition detection, and IPACB to Match B and second transition detection. The same applies in analogue way to OPACA and OPACB.

For the output signal, configuring OPAC registers does not change the current signal state, but defines the action to be done when a match or transition detection occurs. See Match Recognition and Channel Modes on Output Signal Generation for more information.

IPACA/B=1xx also enables assertion of MRLA/B during Time Slot Transition. See Match Recognition.

Table 449. Input and Output Pin Action Control - IPACA/B and OPACA/B

value	IPAC meaning	OPAC meaning
000	Do not detect transitions	Do not change output signal
001	Detect rising edge only	Match sets output signal high
010	Detect falling edge only	Match sets output signal low
011	Detect both edges	Match toggles output signal
100	Detect input signal = 0 on Match	Transition detection sets output signal low

Table continues on the next page...

Table 449. Input and Output Pin Action Control - IPACA/B and OPACA/B (continued)

value	IPAC meaning	OPAC meaning
101	Detect input signal = 1 on Match	Transition detection sets output signal high
110	reserved	Transition detection toggles output signal
111	do not change IPAC	do not change OPAC

67.3.11.3.4 Immediate Pin State Control

It is possible to change output signal state immediately by using PSC (2 bits) and PSCS (1 bit) fields.

Table 450. Immediate Pin State Control - PSC and PSCS

PSC	PSCS	Meaning
00	0	set signal as specified by OPACA (see Transition Detection and Pin Action Control)
00	1	set signal as specified by OPACB (see Transition Detection and Pin Action Control)
01	x	set signal high
10	x	set signal low
11	x	don't change signal state

67.3.11.3.5 Write Channel Match and UDCM Registers

Match registers can have their values changed using ERWA and ERWB fields (1 bit each). They also set their respective MRLE register (see Match Recognition).

ERWA can also be used to program the UDCM register (see UDCM - User Defined Channel Mode) . The field CMW selects where the contents of ERTA is copied when ERWA is active (see the following table).

Table 451. Write MatchA/B - ERWA/B

Field	CMW	Value	Action
ERWA	1	0	write ERTA value in MatchA. Enable matches for MatchA register (MRLEA=1)
	0	0	write ERTA value into UDCM
	1	1	don't change UDCM, MatchA and MRLEA
	0	1	reserved
ERWB	1	0	write ERTB value in MatchB. Enable matches for MatchB register (set MRLEB=1)
	1	1	don't change MatchB and MRLEB

Table continues on the next page...

Table 451. Write MatchA/B - ERWA/B (continued)

Field	CMW	Value	Action
	0		
	0	0	reserved

If ERTA or ERTB is a destination of an ALU operation and, at the same time, the respective ERWA/B field is active, the new ERTA value is the one written into the MatchA/B register or the UDCM register.

67.3.11.3.6 Clear Transition/Match Event Registers

Flags MRLA, MRLB, TDLA and TDLB (see ER - Event Registers) indicate the state of matches and transitions detected in the selected channel, and it is possible to clear those flags using the microcode fields MRLA, MRLB (1 bit each) and TDL (1 or 2 bits, depending on the format). The flags cleared by these microcode fields are the actual channel flags, and also the ones sampled into the branch logic.

TDL can be one or two bits wide, depending on the microinstruction format (see Microinstruction formats) . Two-bit TDL allows independent clearing of TDLA and/or TDLB . defines the two-bit TDL field.

Table 452. Clear Transition/Match Event Registers - MRLA/B, TDL

Field	Meaning
MRLA	0 = clear MRLA event register, 1 = don't change
MRLB	0 = clear MRLB event register, 1 = don't change
TDL (1 bit)	0 = clear TDLA and TDLB flags, 1 = don't change

Table 453. Independent TDLA/B clear - two-bit TDL

value	Meaning
0 0	clear TDLA
0 1	clear TDLB
1 0	clear both TDLA and TDLB
1 1	do not clear TDLA or TDLB

67.3.11.3.7 Disable Matches

Microcode field MRLE (1 bit) allows disabling matches on channel selected by CHAN register, for both MatchA and MatchB registers, by clearing their respective MRLE bits. Matches can be enabled for each Match register using ERWA and ERWB fields (see Write Channel Match and UDCM Registers).

Table 454. Disable Matches - MRLE

MRLE	Meaning
0	Disable matches for Match A and Match B
1	don't change match enabling

Some instruction formats have a two-bit MRLE field (see Microinstruction formats) which allows independent disabling of Matches 1 and 2, as shown in the following table.

Table 455. Two-bit MRLE

MRLE	Meaning
0 0	Disable Match A (clear MRLEA)
0 1	Disable both Matches (clear MRLEA and MRLEB)
1 0	Disable Match B (clear MRLEB)
1 1	nop

67.3.11.3.8 Disable Match and Transition Service Requests

Microcode field MTD (2 bits) disables match and transition service requests for the selected channel. MTD does not disable Link Service Request and Host Service Request. MTD sets or resets register SRI (for more details see SRI - Match/Transition Service Request Inhibit Latch) and TCCEA (see TCCEA - Transition Continuous Capture Enable).

Table 456. Disable Match and Transition Service Request - MTD

MTD	Action on SRI	Action on TCCEA
00	SRI = 0: enable service requests for match and transition	TCCEA = 0: disable transition captures[1] when TDLA = 1
01	SRI = 1: disable service requests for match and transition	
10	SRI = 1: disable service requests for match and transition	TCCEA = 1: enable transition captures[2] when TDLA = 1
11	don't change	

1. Disables only captures on transition events specified by IPACA.
2. Enables only captures into CaptureA register, on transition events specified by IPACA.

67.3.11.3.9 Predefined Channel Modes

Microcode PDCM field (4 bits) defines the channel mode (see Channel Modes).

PDCM coding is shown in the table below. Note that PDCM bit 0 selects between Single Transition (PDCM[0]=0) and Double Transition (PDCM[0]=1) predefined modes.

PDCM is also used to select the user-defined channel mode, defined by the channel register UDCM (see UDCM - User Defined Channel Mode).

Table 457. Predefined Channel Modes

PDCM	Channel mode
0000	em_b_st
0001	em_b_dt
0010	em_nb_st
0011	em_nb_dt
0100	m2_st
0101	m2_dt
0110	bm_st
0111	bm_dt
1000	m2_o_st
1001	m2_o_dt
1010	**user-defined channel mode**
1011	reserved
1100	sm_st
1101	sm_dt
1110	sm_st_e
1111	keep current channel mode

67.3.11.3.10 Channel Interrupt and Data Transfer Requests

Microcode can issue Interrupt Requests, Data Transfer Requests and Global Exception through CIRC field. For more information see Interrupts and data transfer requests.

Table 458. Channel and Data Transfer Requests - CIRC

CIRC	Meaning
000	Channel Interrupt Request from selected channel
001	Data Transfer Request from selected channel
010	Channel Interrupt and Data Transfer requests from selected channel
011	Channel Interrupt and Data Transfer requests from serviced channel
100	Channel Interrupt Request from service channel

Table continues on the next page...

Table 458. Channel and Data Transfer Requests - CIRC (continued)

CIRC	Meaning
101	Data Transfer Request from service channel
110	Global Exception
111	don't request interrupt

67.3.11.3.11 Clear Link Service Request

Microcode LSR field (1 bit) is used to clear the Link Service Request flag of the serviced channel (may not be the one selected by CHAN). The LSR branch condition is always cleared, but not the Link Service Request, if another channel link was received by the serviced channel during the executing thread. See Channel link for more information.

Table 459. Link Service Request Negation Control - LSR

LSR	Meaning
0	clear Link Service Request (flag LSR)
1	don't change

67.3.11.4 Flow Control Microoperations

eTPU has *jump* and *call* microoperations to change microcode flow. Besides, eTPU has *dispatch jump* and *dispatch call* that can be used to implement a jump table. In *call* (or *dispatch call*) microoperation, the return address is saved in RAR register. If nested sub-routine calls are necessary, return address values have to be saved in a stack, usually implemented with DIOB register.

Flow Control microoperations are also provided to repeat a given microinstruction, to finish the current thread execution, and to halt the microengine.

67.3.11.4.1 Ending Current Thread - END

Microcode END field (1 bit) finishes current thread and allows other channels to be serviced. If END field is 0, the current instruction is completed and the thread is finished. END = 1 has no effect, and the next microinstruction is executed Any MDU operation (see MAC and Divide Unit (MDU)) that could be still pending when the thread is finished is left incomplete. END also releases any semaphore locked by the Engine.

67.3.11.4.2 Branch Operations

Branch operations can be **jump** or **call**. The target address of *jump* or *call* microoperations is always immediate and absolute. Branch microoperation is affected by FLS field (refer to Flush pipeline).

67.3.11.4.2.1 Selecting Jump or Call Microoperations

The only difference between *jump* and *call* microoperations is that when a *call* is executed the value of PC or PC+1 (depending on flush, see Flush pipeline) is saved in RAR register. The microcode field J/C (1 bit) selects whether *jump* or a *call* is executed, according to the following table.

Table 460. Jump / Call Selection - J/C

J/C	Meaning
0	jump

Table continues on the next page...

Table 460. Jump / Call Selection - J/C (continued)

J/C	Meaning
1	call

67.3.11.4.2.2 Branch Target Address

Microcode BAF field (14 bits) indicates the absolute address of a *jump*/*call target*.

67.3.11.4.2.3 Conditional/unconditional branch

Jump and *call* can be conditional or unconditional, depending on the BCC (6 bits) and BCF (1 bit) fields, as shown in and . BCF determines whether branch is taken when condition specified by BCC is true or false. When a branch condition uses the channel flags, the channel context is related to the channel number written in CHAN register.

Table 461. Branch Condition Inversion - BCF

BCF	Meaning
0	branch if condition determined by BCC is false
1	branch if condition determined by BCC is true

Table 462. Branch Condition Selection - BCC

BCC	Meaning	BCC	Meaning
001110	Flag 0	001111	Flag 1
100000	V ALU flag	110000	PSS channel flag
100001	N ALU flag	110001	PRSS channel flag
100010	C ALU flag	110010	"Less Than" ALU flag combination (signed) [1]
100011	Z ALU flag	110011	"Lower or Equal" ALU flag combination (unsigned)[2]
100100	MV MDU flag	110100	P[24]
100101	MN MDU flag	110101	P[25]
100110	MC MDU flag	110110	P[26]
100111	MZ MDU flag	110111	P[27]
101000	TDLA channel flag	111000	P[28]
101001	TDLB channel flag	111001	P[29]
101010	MRLA channel flag	111010	P[30]
101011	MRLB channel flag	111011	P[31]

Table continues on the next page...

Table 462. Branch Condition Selection - BCC (continued)

BCC	Meaning	BCC	Meaning
101100	LSR channel flag	111100	PSTO channel flag
101101	MB flag MDU flag	111101	PSTI channel flag
101110	FM[1] channel flag	111110	SMLCK semaphore flag
101111	FM[0] channel flag	111111	false
all other values reserved			

1. "less than" is a signed comparison, equal to the xor between ALU flags V and N; e.g., 0 < 0xFFFFFF tests as false (0 < -1).
2. "lower equal" is an unsigned comparison, equal to Z or C; e.g., 0 < 0xFFFFFF tests as true.

67.3.11.4.3 Dispatch Microoperation

Dispatch microoperation is an unconditional branch where the target address is always PC+P[31:24] (unsigned). Dispatch is affected by FLS field (refer to Flush pipeline). Dispatch microoperation is defined by R/D field (2 bits, see the following table). Field R/D can also be used to define return from sub-routine (see Return from subroutine).

Table 463. Return and Dispatch - R/D

R/D	Meaning
00	return from subroutine (see Return from subroutine)
01	dispatch jump
10	dispatch call
11	don't change microinstruction flow

67.3.11.4.4 Return from subroutine

When a subroutine *call* or a *dispatch call* microoperation is executed, the return address is saved in RAR register. To return from a subroutine a microoperation is available to load the contents of RAR register back to the PC. Fields R/D (2 bits) or RTN (1 bit, see the table below) can be used to return from subroutine. For R/D field, see Dispatch Microoperation.

Return from subroutine microoperation is affected by FLS (see Flush pipeline) when field R/D is used. Return execution through RTN always flushes the pipeline.

Table 464. Return from subroutine - RTN

RTN	Meaning
0	Return with pipeline flush
1	Do not return

67.3.11.4.5 Flush pipeline

When a branch, dispatch or subroutine return microoperation is executed, the next microinstruction can be executed unconditionally before the flow change takes effect, since microengine has a three-stage pipeline. Executing the next microinstruction after a branch maximizes execution performance. This feature is controlled by field FLS (1 bit, see the table

below). When FLS=0 the pipeline is flushed, so the next microinstruction placed after a branch is decoded as NOP if the branch is taken. If FLS=1, the microinstruction placed after the branch is executed, either if the branch is taken or not, as shown in the figure below.

Flush also controls which value is stored in RAR in a call: in case of no flush, it is the address of the branch/dispatch instruction + 2, even if RAR is the ALU destination of the instruction after the call; in case of a flush, it is the address of the instruction following branch/dispatch.

If a branch with no flush is followed by another branch with no flush, the instructions are executed in the following order:

1. first branch
2. second branch
3. first branch's destination instruction
4. second branch's destination instruction, and the flow proceeds normally from then on

The destination of the first branch must not be another flow changing instruction (branch, return or dispatch). Similar flows apply when returns or dispatches are used instead of branches. This scheme can be used to implement quick table look-ups with a dispatch replacing the first branch, for instance.

Table 465. Flush Pipeline - FLS

FLS	Meaning
0	flush pipeline when jump / call / dispatch jump / dispatch call / return is executed
1	do not flush pipeline when jump / call / dispatch jump / dispatch call / return is executed

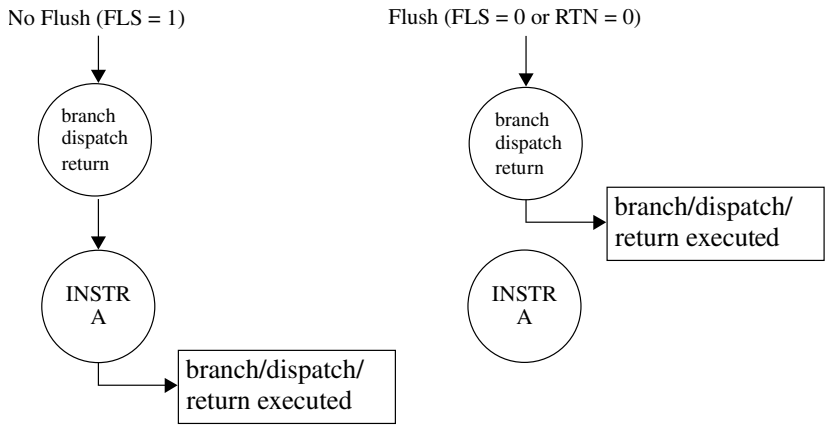

Figure 477. Flush pipeline

67.3.11.4.6 HALT microinstruction

HALT is a microinstruction provided to implement software breakpoints (see Software breakpoints). Note that HALT is coded as a microinstruction format, not a field (see Microinstruction formats). The execution of this instruction puts the microengine in halt state. For more information about the implications of microengine halt state, see Microengine Halt State. HALT is valid only if software breakpoints are enabled at the Debug interface . If software breakpoints are not enabled, HALT executes as a NOP and is treated as an Illegal Instruction (see Illegal instructions).

67.3.11.4.7 NOP microinstruction

There is not a unique microinstruction with an assigned opcode to do No Operation. NOP microinstruction is achieved through any of the formats shown on Microinstruction formats where the user can assign to each individual field the corresponding value

for "No Operation". However, to prevent future impacts of instruction changes on object code compatibility, the instruction value 0x4FFFFFFF should always be used for NOP.

67.3.11.5 Illegal instructions

An instruction is considered illegal if any reserved field value is used, including when the fields marked rsv in the instruction formats (see Microinstruction formats are assigned value 0. A HALT instruction is exceptionally considered illegal when executed with software breakpoints disabled (see HALT microinstruction). Global Exception may be issued up to two microcycles after instruction fetch. The execution results of an illegal instruction on the microengine, channel logic or host interface are unspecified, except for the HALT case.

If the microengine decodes an illegal instruction, the following actions are taken:

- A Global Exception is issued.
- The ILF1/2 flags in eTPU Module Configuration Register (MCR) are set to indicate this occurrence to the Host.
- A breakpoint occurs, if NDEDI is present and configured to do so (see the NDEDI details for more information).

67.3.11.6 Microinstruction Parallelism Issues

This section clarifies parallelism issues that arise when two non-commutative microoperations appear in the same microinstruction.

67.3.11.6.1 ALU Operations and Read Match Registers

ALU operations have only one destination register, but there is one case where source selection determines destination: read Match register in ERTA and ERTB registers. In this case if ALU destination is ERTA or ERTB a conflict arises. The ALU destination value overwrites the value read from the match registers.

67.3.11.6.2 ALU and SDM Operations

P and DIOB registers can be selected as destination by both ALU and SDM (read) microoperations in the same microinstruction. Since P and DIOB update from SDM data happens after P and DIOB update for ALU/MDU microoperations, the data read from SDM remains in P or DIOB after an operation when one of them is specified as destination for both ALU and SDM microoperations. In this case, the value loaded into P or DIOB is the one read from SDM. However, the ALU operation is executed and its flags are updated accordingly.

When P or DIOB is destination of an SDM read and also an ALU source at the same microinstruction, the value before the read is used for the ALU operation.

If DIOB is the ALU destination and P is loaded from SDM or vice-versa, no conflict occurs, and the result is the same as if operations occurred separately.

All the above also applies to Zero SDM operations.

When using P or DIOB as destination for ALU operations and also as source for a SDM write operation, the data written in SDM is the one calculated by ALU, which means it is possible to calculate a value and write it in an SDM address using only one microinstruction.

The old value of DIOB or the old value minus 4 (pre-decrement) is always used when DIOB is selected as address (indirect address mode), no matter if DIOB is selected as destination of either the SDM or ALU. For the value loaded into DIOB, refer to the following table.

Table 466. DIOB load from SDM and ALU

DIOB selected as SDM read destination?	DIOB selected as ALU destination?	DIOB load value
no	no	DIOB, --DIOB (pre-decrement), or DIOB++ (post-increment)
yes	no	SDM read data (post-inc and pre-dec ignored)
yes	yes	SDM read data (post-inc, pre-dec and ALU result ignored)
no	yes	ALU result (post-inc an pre-dec ignored)

When CHAN is the destination of an ALU operation in parallel with a channel-relative SDM access, the CHAN value used to calculate the address is the one before the ALU operation.

67.3.11.6.3 ERTA/B as ALU destination and ERWA/B

The value in ERTA and ERTB registers can be written in match registers of the selected channel by using fields ERWA and ERWB (Write Channel Match and UDCM Registers). If, at the same microinstruction, ERTA or ERTB is destination of an ALU/MDU microoperation, the value written in Match registers is the ALU/MDU result.

The same applies to UDCM when ERTA is the destination of an ALU operation and instruction fields ERWA and CMW are active .

If an ALU operation occurs in parallel with ERWA/B but ERTA/B are not the destination of an ALU/MDU operation, then UDCM and MatchA/B receives the ERTA/B value.

67.3.11.6.4 ERWA/B and MRLE

ERWA/B automatically sets the MRLEA/B channel latch, respectively (see Write Channel Match and UDCM Registers). Microinstruction fields ERWA/B independently sets MRLEA/B channel flags, regardless of MRLE.

67.3.11.6.5 CHAN assignment, Read Match and ERWA/B

When CHAN is a destination of an ALU operation it causes a read of the CaptureA/B register values into ERTA/B. The Capture registers loaded into ERTA/B are selected by the new CHAN value. The value of the CaptureA/B registers overwrites any read-match commanded simultaneously.

If CHAN assignment happens with an ERWA/B operation in the same instruction, the updated Match register(s) belong to the new selected channel.

67.3.11.6.6 Read Match and ERWA/B

If a read match operation is executed with ERWA/B in the same microinstruction, the MatchA/B registers receive the old values of ERTA/B, and the ERTA/B registers receive the old MatchA/B values simultaneously, i.e.: ERTA/B and MatchA/B swap their values.

If ERTA/B is the destination of an ALU operation at the same instruction, MatchA/B gets the ALU result (see ERTA/B as ALU destination and ERWA/B), but the ERTA/B not being written still receives the old MatchA/B values.

NOTE

Read match, ERWA/B and CHAN assignment can be active at the same instruction. Combining rules CHAN assignment, Read Match and ERWA/B and Read Match and ERWA/B, the result is: ERTA/B receives the CaptureA/B values of the new CHAN value, and MatchA/B of the new channel receives the old ERTA/B value(s).

67.3.11.6.7 Stack accesses and ALU operations

Post-increment is ignored in a stack operation (field STC) if DIOB is loaded from SDM: DIOB keeps the value read from SDM. Pre-decrement is ignored in a stack operation (field STC) if DIOB is destination of an ALU operation, for DIOB load value, but not for DIOB as address. Post-increment/pre-decrement remains valid in all other situations. These rules can be summarized in the following equivalent C code, and in ALU and SDM Operations.

```
DIOB = *DIOB[15:2];      // read without posinc/predec
*DIOB[15:2] = DIOB;      // write without posinc/predec
DIOB = *(--DIOB[15:2]);  // read with predec
DIOB = *DIOB[15:2];      // read with posinc (ignored)
*(--DIOB[15:2]) = DIOB;  // write with predec
*DIOB[15:2]++ = DIOB;    // write with posinc (value written is before
increment)
```

67.3.11.6.8 SRC and ALU/MDU operations

If operation SRC is active (field SRC = 0) and register SR is selected as destination of an ALU operation, the value of the ALU operation prevails over the shifted value.

The value of SR used as source in the ALU/MDU operation is the one before the shift.

67.3.11.6.9 Semaphore lock/free and SMLCK branch condition

When the SMLCK branch condition is tested at the same microinstruction of a semaphore lock or free, the condition is evaluated after the semaphore action (either free or lock) is taken.

67.3.11.6.10 Dispatch and SDM Read

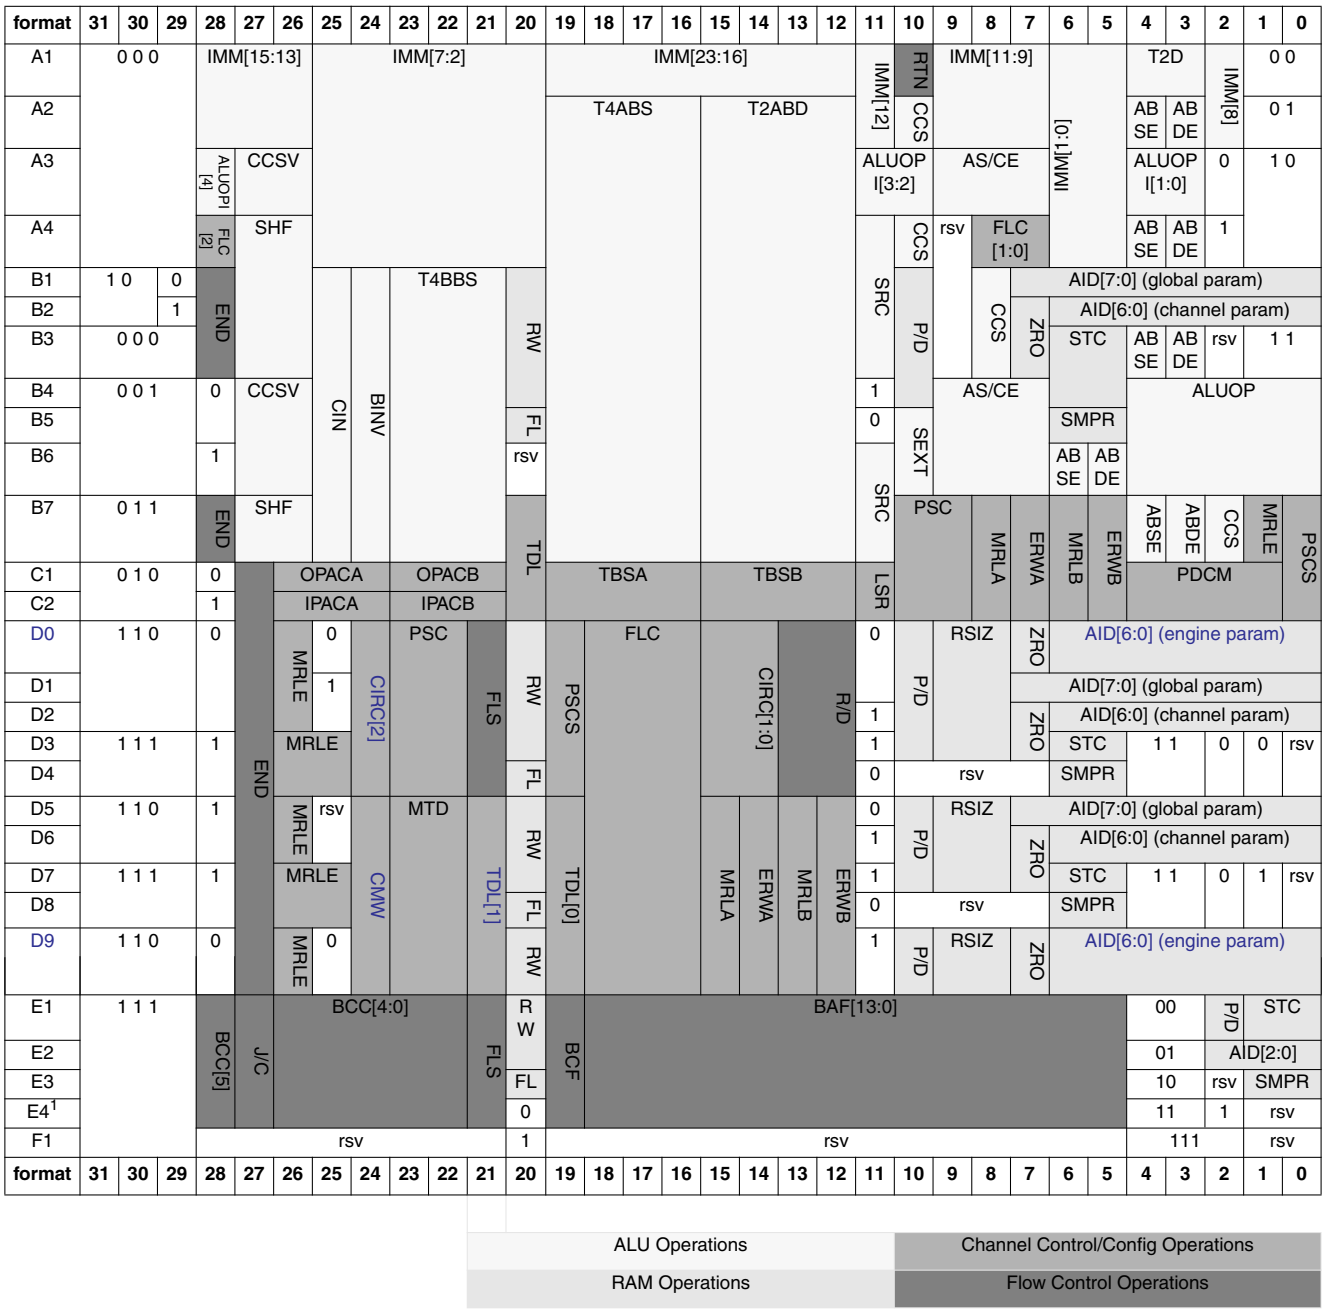
When the most significant byte of P is read from SDM (read 8 msb bits or 32 bits) and a dispatch instruction is executed simultaneously, the dispatch target address is calculated upon the P value before the read.

67.3.11.6.11 CHAN Assignment, PSC/PSCS, and clear MRLEA/B, MRLA/B, TDLA/B

When clear MRLEs, MRLA/B or TDLs is done and a CHAN assignment is done at the same time, the flag selected by the old CHAN value is cleared in the channel, but the branch conditions receive the state of the flags selected by the new CHAN.

When a pin action is commanded through PCS/PSCS and a CHAN assignment is done simultaneously, the output signal affected is selected with the old CHAN value.

67.3.11.7 Microinstruction formats



NOTES:
1 format E4 is deprecated; the same result can be obtained with format E1 with field STC=11

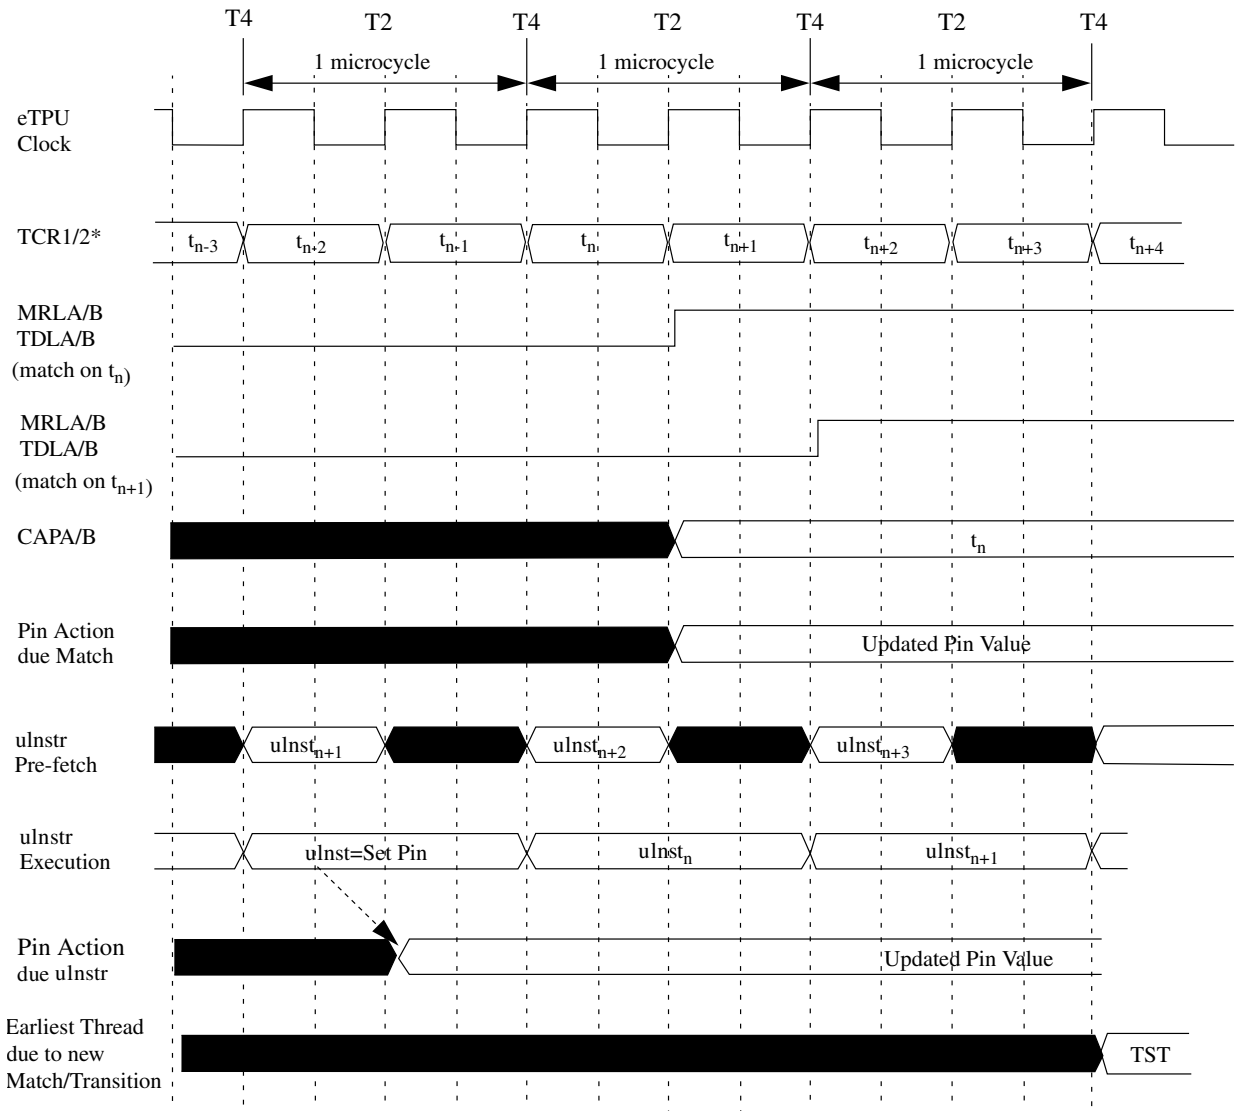
Figure 478. Microinstruction formats

All bits marked "rsvd" are reserved, and must be coded as 1.

67.3.12 Microcycle and I/O timing

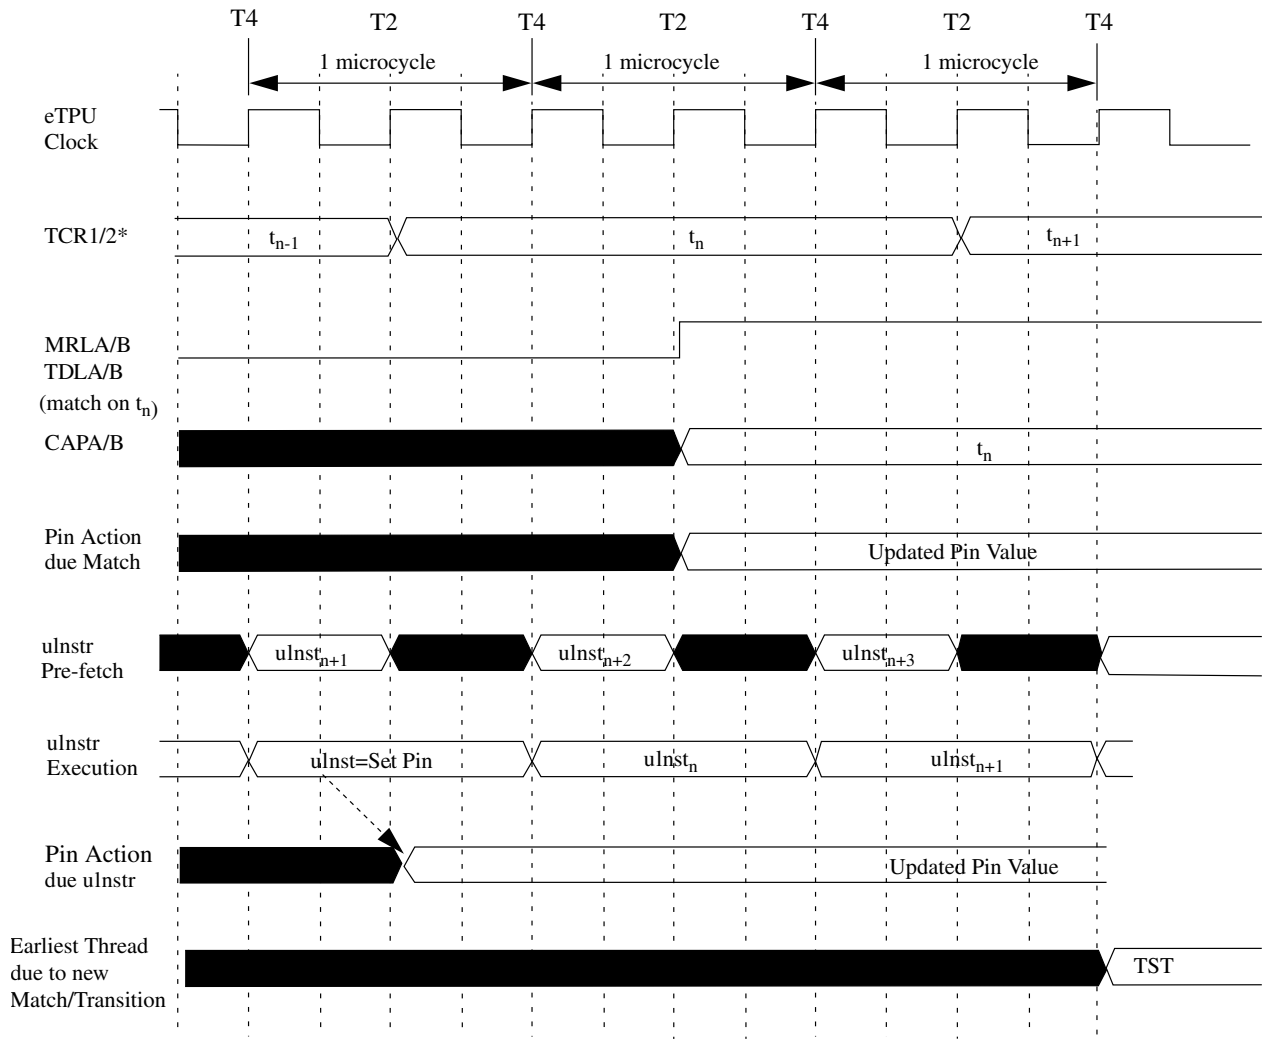
67.3.12.1 Execution and channel timing

The following figure shows the main timings related to microinstruction execution when channels and timebases run on T2 timing.



Note: *TCR clock/prescaler selection = 1 x eTPU clock

Figure 479. Execution timebase and channel T2 timing



Note: *TCR clock/prescaler selection = 4x eTPU clock

Figure 480. Execution timebase and channel T2, T4 timing

The sequential occurrence of the four T states (T1-T4) constitutes a microcycle. Only T2 and T4 are taken as reference for timings, either internal or external. T2 and T4 have the timing of the positive eTPU clock pulses, and are used in most of the eTPU logic in an edge-triggered design style.

Two additional T states are derived from the eTPU clocks: T2 and T4 . T2 occurs when the eTPU loses SDM arbitration to a bus master. T4 occurs in halt state (due to a breakpoint or assertion, for instance), or in stall state (due to an NDEDI queue full); see Development support features for more details.

T2 and T4 states are defined as microcycle timing states (not to be confounded with logic states) of one eTPU clock in which the T clocks continue to run, but the control signals associated with the clocks are unaffected. That is, no operation occurs during these states. Both T2 and T4 states occur in multiples of two eTPU clocks to keep the microengine synchronized with the free running channels, which are unaffected and keep on working as in T2 and T4.

Thus, the eTPU has two types of timing states:

- T2: hold execution for SDM access, from clock pulse T2 until one of the next T2 clock pulses of another microcycle.
- T4: hold execution in debug mode or stall, from clock pulse T4 until one of the next T4 clock pulses of another microcycle.

The two following figures show the timing of T2 and T4 timing states, respectively.

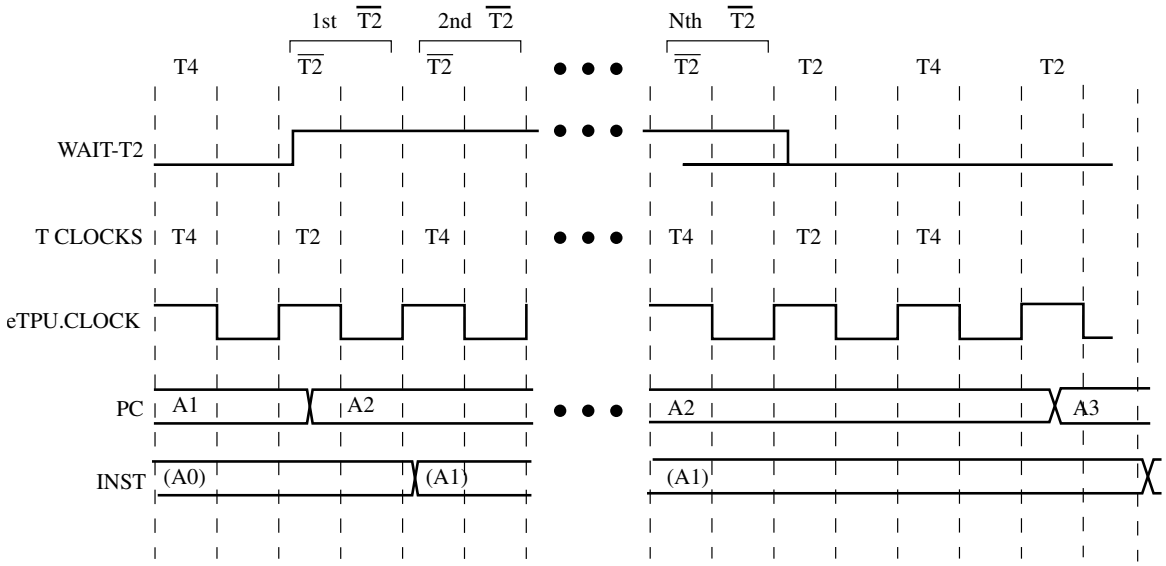


Figure 481. T2 timing

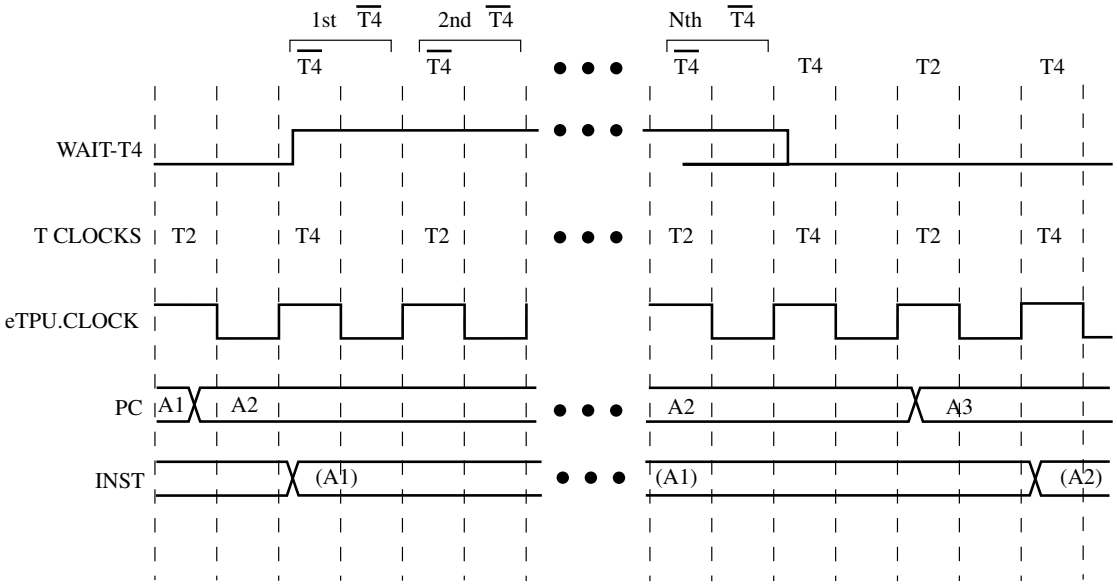

Figure 482. T4 timing

67.3.12.2 Input/output signal delays

The synchronizer, filter and edge detection logic delay the input signal transitions.

The Filter Delay varies with the filter clock (eTPU Engine 1 Configuration Register (ECR_ENG1) and eTPU Engine 2 Configuration Register (ECR_ENG2) field FPSCK) and the filter mode used, as shown in the Filter clock prescaler. For any given transition, it depends on the phase of the filter clock when the input transition happens. In integration mode (TCRCLK filtering only), it also depends on the state of the integrator counter. The Total Delay is defined as the number of eTPU clock rising edges between the input transition and the setting of TDLA/B, TCR1/2 incrementing, or EAC tooth sensing (TCRCLK) in angle mode. The synchronizer delay is 2 or 3 eTPU clocks, depending on the phase of the synchronizer when the input transition happens. The edge detection takes 1 more eTPU clock. The total delays are, thus:

```
Min. Total Delay = Min. Synchronizer Delay + Min. Filter Delay + Edge Detection Delay
Min. Total Delay = 3 + Min. Filter Delay
```

```
Max. Total Delay = Max. Synchronizer Delay + Max. Filter Delay + Edge Detection Delay
Max. Total Delay = 4 + Max. Filter Delay
```

The channel filters can be bypassed, so nullifying the filter delays in the equations above.

See the chip-specific eTPU information for connections between eTPU and input glitch filters.

The channel output flip-flops drive the eTPU output signals directly, without any synchronous delays.

67.3.13 Shared subsystems support

Shared Subsystems support allows eTPU to control other modules, either independently or sharing control with the host . A notable example of shared subsystem is the Reaction Module (see the Reaction Module chapter for details), which is connected to the eTPU as shown in the figure below. The host CPU accesses the Reaction Module through the eTPU, which can also access the same registers .

When the SSMAE field in C*a*CR_ENG1 or C*a*CR_ENG2 is 1, the eTPU channel's threads can control shared subsystems by accessing their registers, which are mapped onto the higher 16 KB of the microcode data address space (byte addresses/DIOB values 0x4000 to 0x7FFF, equivalent to parameters 0x1000 to 0x1FFF), as shown in . The shared subsystem registers are accessible by microcode only with the indirect address mode (see SDM Addressing Modes) .

When the SSMAE field in C*a*CR_ENG1 or C*a*CR_ENG2 is 0, the channel's threads can access only the SDM, mirrored throughout the whole DIOB address range .

The same Shared Subsystem register address space is accessible by the host through the Shared Subsystem Area within the eTPU memory map (see and Memory map), allowing shared control and/or supervision between the host and the eTPU . The arbitration mechanism between host and eTPU accesses is the same used for SDM accesses (see SDM arbitration) . The CDC (see Coherent Dual-parameter Controller (CDC)) cannot be used for coherent transfers between SDM and the Shared Subsystem Area, or within the Shared Subsystem Area itself .

NOTE

The detailed register map within the Shared Subsystem Area depends on the subsystem module.

Bus errors coming from the Shared Subsystem cause a Global Exception and are flagged by the MCR[SSAERR] bit on microengine accesses only . In the case of host access, the bus error only propagates to the bus, which also issues a bus error .

A Shared Subsystem may be divided into submodules or channels, hereafter called **Shared Subsystem Units** (or **Shared Units** for short), which can be individually controlled by an eTPU function (see Functions and threads)

NOTE

Shared Unit link service requests are level-sensitive to the eTPU . If it comes from an interrupt source, the link service request stays asserted as long as the interrupt is asserted and enabled, so the interrupt request must be cleared before the clear of the LSR flag in the link service request thread .

The table below summarizes the mapping of Reaction Module resources into Shared Subsystem Support .

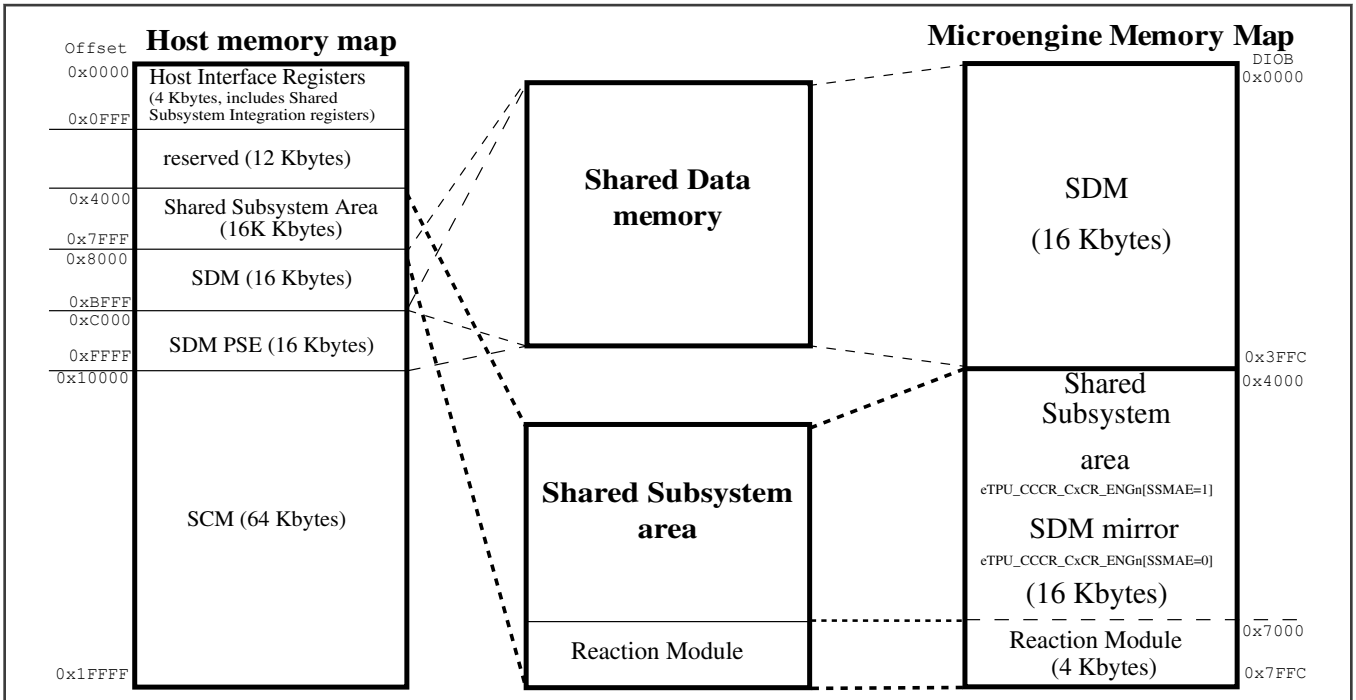

Figure 483. Shared Subsystem memory mapping

Table 467. Reaction Module Shared Subsystem support

Reaction Module resource	Host mapping	eTPU/microengine mapping
Register access	eTPU Base + 0×7000	DIOB address 0×7000 (indirect address mode)
Interrupts	See Interrupts chapter	Link Service Requests mapped through Subsystem Integration registers eTPU_SSIR_ETPUSSSIR*n*
DMA Requests	See eDMA chapter	Not applicable

67.3.14 Development support features

Following sections describe several features available to support development. Most debug features are accessible through a separate debug bus, and are not available through registers in the standard eTPU memory map. The details of the access to this interface are MCU-dependent (see Debug Interface chapter). The microengines can also be put in halt state by a device-level debug request.

NOTE

The behavior of the debug support logic is not specified in the event of a non-correctable memory error on either SCM or SDM (see Memory error support).

67.3.14.1 Nexus Class 3 Support

NDEDI is an IP block designed to support Nexus functionality for the eTPU. It provides a Nexus class 3 or class 1 debug interface, depending on the MCU (see Configuration section). Nexus is a development support external interface defined by the **IEEE standard ISTO 5001-1999**. More details about it can be found in the NDEDI details.

Some of the next subsections describe debug features provided by the eTPU microengine debug support combined with the NDEDI block.

67.3.14.2 Microengine Halt State

Halt is a microengine state where it suspends execution during a thread, or does not start executing a scheduled thread from idle state. While Idle State is entered from END execution without any other scheduled thread, microengine enters Halt State by any of the following events:

- execution of the HALT microinstruction (software breakpoint).
- external halt request through the Debug Interface (includes Nexus breakpoint request via EVTI input pin - see Nexus Class 3 Support).
- the other Engine enters halt state and they are configured to halt simultaneously (bit HTWIN is asserted via Nexus Interface).
- System level device debug request assertion and NDEDI register NDEDIETPUx_DC field CBI=1. If same register's field CBT=1, microengine halts at the next time-slot boundary, if CBT=0 it halts immediately. As a particular case, microengines come halted out of reset if is asserted, since CBI reset value is 1. Microengine does not execute out of reset, either in halt (asserted) or idle state (negated), but halt enables several other features (see below).
- occurrence of any of the hardware breakpoint conditions. See Hardware breakpoints for details.
- execution of a single-step microinstruction: microengine returns to halt state after executing a single microinstruction while in halt state. See Single-step Execution and Forced microinstruction execution for details.

When microengine enters halt state, it automatically triggers the following actions:

- Suspends input signal sampling and filters (respective Engine channels only), if NDEDI_ENGINEx_DC[PINS] = 1 at the Debug Interface.
- Releases the SDM arbitration for Host or CDC accesses, no matter if microengine was halted in the middle of a dual parameter (back-to-back) access.
- Stops TCR1/2 clocks of the respective Engine, if signal ndedi_stop_tcr is asserted at the Debug Interface.
- If the other Engine is also in halt state or stopped, allows turning the eTPU Module Configuration Register (MCR) VIS FIELD to 1.

If all halt conditions are cleared when VIS = 1, microengine(s) keep on halt state until VIS = 0, when it automatically exits halt state, except on single-step (see Single-step Execution), so that single-step execution is ignored while VIS=1.

MDU continues executing until it finishes any ongoing operation even if microengine is in halt state, except when the halted instruction is an END.

There are two kinds of halt state, depending on the previous microengine state when halted:

1. **halt_idle**, if the engine was not executing a thread when halted; the engine cannot leave halt_idle to fetch instructions, so one cannot single-step or follow a program flow; it can, however, execute forced instructions (see Forced microinstruction execution).
2. **halt_exec**, if the engine was executing a thread when halted. The engine can single-step and continue a program flow from halt_exec.

When microengine exits halt state, any dependable action is suspended and, if exiting halt_exec, the instruction pointed by the PC is fetched, while the instruction already fetched before halt is executed. Note that both the PC and the prefetched instructions can be modified during halt state, with a forced execution of a branch instruction (see Forced microinstruction execution).

67.3.14.3 Hardware breakpoints

Microengine can enter halt state through a command from the Debug Interface, configuring a hardware breakpoint. Hardware breakpoints can halt the microengine on specific conditions, listed below. These conditions depend on NDEDI configuration (see the NDEDI details for more information).

- CHAN register assignment (only by microcode, not by time slot transition).

- SDM read and/or write to a given address and/or write data. The breakpoint is always qualified by the SDM address, but the following variations are allowed:
  - break on write only, read only, or read-and-write.
  - break on higher-byte write data value, lower 24-bit write value, full word (32-bit) write value, or regardless of data. Break on read data is not supported.
- PC (program counter) value.
- Beginning of a thread with a Host Service Request pending.
- Beginning of a thread with a Link Service Request pending.
- Beginning of a thread with a Match Service Request pending.
- Beginning of a thread with a Transition Service Request pending.
- End of a thread.
- Illegal instruction execution.

All these conditions can also be qualified by the value of the CHAN register.

NOTE

Data breakpoints are not supported on Shared Subsystem Area accesses (see Shared subsystems support).

Hardware breakpoints halt the microengine before the halted instruction is executed, except on data breakpoints . Data breakpoints allow the instruction that performs the data access to be executed before the microengine is halted .

NOTE

Data breakpoints in eTPU versions before eTPU2 halt the breakpoint instruction before its execution in all cases, including data breakpoints .

On any of these conditions, halt of one microengine does not depend on the halt of the other, unless the other engine is configured to do so, via Nexus Interface. Occurrence of any of these conditions halts the microengine, that is, the conditions are logically ORed together, and they can be individually enabled.

While in halt state, the microengine can also execute any forced microinstruction not in the normal program flow (see Forced microinstruction execution) or, if in halt_exec, in single-step (see Single-step Execution).

There are situations when requests for stopping an engine, breakpoint and service can occur simultaneously. Breakpoint requests always prevails over a stop request (eTPU Engine 1 Configuration Register (ECR_ENG1) or eTPU Engine 2 Configuration Register (ECR_ENG2) bit MDIS = 1 or =1). When the eTPU is idle: stop request prevails over Service Request if there is not a hardware breakpoint request; a hardware breakpoint request leads to Debug mode immediately if there is no Service Request, and after TST if there is Service Request (regardless of stop requests). The rules above are summarized in the following table, showing the destination state of the microengine in each situation.

Table 468. Breakpoint, stop and service requests resolution from idle

Breakpoint request	MDIS	Service request	Final state
no	0	0	Idle
no	1	0	Stop
no	0	1	TST
no	1	1	Stop
Yes	0	0	Halt_idle

Table continues on the next page...

Table 468. Breakpoint, stop and service requests resolution from idle (continued)

Breakpoint request	MDIS	Service request	Final state
Yes	1	0	Halt_idle
Yes	0	1	TST
Yes	1	1	TST

When a thread is ending, it goes to Idle or TST only if there is neither a hardware breakpoint request nor a request to stop (eTPU Engine 1 Configuration Register (ECR_ENG1) or eTPU Engine 2 Configuration Register (ECR_ENG2) bit MDIS = 1 or =1). When thread is ending and there are simultaneous hardware breakpoint and stop (MDIS=1 or =1) requests, hardware breakpoint prevails and the engine enters Debug mode (Halt_idle state).

If the engine entered Debug mode after a thread finished (Halt_idle state) and a "go" command comes from the debug interface, the engine state machine goes to Idle and the rules above apply. It means that if a "go" is issued in Halt_idle state with MDIS=1, the engine goes to Idle for one microcycle and then stops (if MDIS or keeps asserted and there is no other breakpoint request).

NOTE

Hardware breakpoint requests are ignored for the first microinstruction executed when microengine leaves halt.

67.3.14.4 Hardware Watchpoints

Debug Interface allows watchpoints on the same conditions available for hardware breakpoints (see Hardware breakpoints).

NOTE

Data breakpoints are not supported on Shared Subsystem Area accesses (see Shared subsystems support) .

67.3.14.5 Software breakpoints

A software breakpoint occurs when microengine executes a HALT microinstruction. Any number of software breakpoints can be set in code, usually replacing an active microinstruction.

Like any other microinstruction, HALT increments the PC and pre-fetches the next instruction. So, before the halt state is suspended, if the original program flow must be followed, the original instruction at the HALT address must be executed, regardless if the software breakpoint is removed (replacing HALT by the original microinstruction) or not. Follows the procedure to resume execution from a software breakpoint:

1. restore the original instruction in SCM (replace HALT).
2. force a jump with flush to the original instruction (see Forced microinstruction execution).
3. if the software breakpoint must be kept: single-step and replace the original instruction with a HALT.
4. let the flow continue, issuing a GO command (leaving halt state).

Special care must be taken if HALT is followed by another HALT, and the second HALT is removed when microengine was halted by the first one. In this case, replacing the second HALT with the original microinstruction is not enough to remove the second breakpoint, because the second HALT was already prefetched and would be executed anyway when halt was suspended. The debugger must also do a forced execution of unconditional branch with flush to the original microinstruction address. That will clear the pipeline, replacing the prefetched instruction with a NOP, and load PC with the address of the removed breakpoint. So, when halt state is suspended, the original microinstruction will be fetched while NOP is executed, and program flow continues normally from then on.

NOTE

A HALT instruction placed after a no-flushing branch, dispatch or return may be a problem from the debugger application standpoint: after the HALT is executed, the eTPU debug interface informs the address of the branch/dispatch/return destination, and the debugger application has no direct way to identify which HALT instruction was executed, if multiple HALTs lead to the same address. This can be solved if the debug support block (NDEDI) has a register holding the address of the last instruction executed, otherwise one should forbid non-flushed HALT instructions. See the NDEDI details.

Software breakpoint setting and removal is possible only with SCM RAM implementations or ROM implementations with SCM RAM emulation (see SCM Emulation). There is only one way of inserting software breakpoints into SCM RAM: programming VIS=1 in eTPU Module Configuration Register (MCR), and then accessing SCM as an ordinary RAM from the bus. This can be done only if both Engines are halted or stopped.

67.3.14.6 Single-step Execution

When microengine is already in halt_exec state, it can run the next microinstruction in the normal program flow and get back to halt state. PC is incremented, or assigned the BAF value in a branch with satisfied condition. Note that the executed instruction was already prefetched in the instruction pipeline, and a new microinstruction is fetched during its execution. The prefetched instruction may be cleared during halt state by the forced execution of a branch with flush (see Forced microinstruction execution), making single-step execute a NOP instead of the next instruction in the program flow.

Single-step execution is controlled by the debug interface, and is a feature available from Nexus if eTPU is connected to the NDEDI block (see NDEDI details).

The single-step execution of a NOP instruction can be useful to control input signal sampling and filtering, if NDEDI_ENGINEx_DC[PINS] = 1 at the Debug Interface (see NDEDI details). Single-step does not happen if VIS=1.

67.3.14.7 Forced microinstruction execution

When microengine is already in halt state (either halt_idle or halt_exec), it can run forced microinstructions through the debug interface. This feature is available from Nexus if eTPU is connected to the NDEDI block (see NDEDI details). The microinstruction, specified by the user, is not fetched from SCM and comes directly from the debug interface. MDU start commands issued by forced instructions are executed, and the MDU runs the operation until the end, independently of the halt state. The microinstruction field END is ignored.

During forced execution of any instruction except Branches, Returns and Dispatches, the PC does not change, and the prefetched instruction in the pipeline is bypassed, but not discarded. When halt state is suspended, the prefetched instruction is executed and the instruction pointed by the PC is prefetched in parallel (two-stage pipeline).

Forced execution of a Branch, Dispatch or Return loads the PC with the BAF field (if branch condition is satisfied), PC+P or RAR, respectively. If branch condition is not satisfied, PC value stays unaltered. The flush control (field FLS) also works, so that a successful forced branch with flush replaces the prefetched instruction with a NOP. So, to clear the instruction pipeline during halt, all one has to do is an unconditional branch to the desired address with flush. HALT instructions must not be executed as forced.

Forced operations that depend on the serviced channel are unspecified when executed in halt_idle and must be avoided.

NOTE

Forced instructions must not be commanded when MCR[VIS] = 1.

67.3.14.8 Microengine Register Access

eTPU provides no direct access to microengine and channel registers from the bus or any other interface. However, these registers can be read and written in halt state by executing forced microinstructions (see Forced microinstruction execution). Immediate data microinstructions may be used to set register values. Some registers are not selectable for immediate data destination, so intermediary register(s) - notably P - may have to be used to carry the desired new value to the target register in two or more microinstructions. Usually the previous values of intermediary register(s) must be previously saved and restored after the whole operation.

Similar procedures apply for register reads: their contents must be dumped to SDM, where they can be read from the bus.

67.3.14.9 Microengine Flag Access

Microengine halt state allows reading the branch conditions flags through forced microinstructions or, more easily, through the NDEDI register NDEDI_ENGINEx_CFSR (see the NDEDI details). Flag conditions set by the user are seen by microengine for the next microinstruction execution. The flag set options are limited by the possibilities of forced microinstruction execution.

If the eTPU runs (not single-stepping) after exiting the halted state, the conditions modified during halt may remain only for the first microcycle after the halted state. After the first microcycle, branch conditions are altered only according to their regular update scheme.

67.3.14.10 Microengine Stall

Microengine can get into a stall state, attending a request from a debug interface signal assertion. The reason for a Stall request from NDEDI (or from any other debug support block) should be a temporary lack of resources, for instance queue full. During stall the microengine suspends execution, but all the other Engine logic continues operating: time bases, angle logic, channel logic, input sampling and filters. Stall differs from Halt, not enabling any of the debug features that Halt enables (see Microengine Halt State). It also does not break an atomic microengine access, unlike halt.

The Microengine can be stalled when idle and from the moment TST ends, before executing the first thread microinstruction, until just before the last thread microinstruction is executed. Stall requests are ignored in any other occasions. Microengines in a dual engine system can be independently stalled. If a forced end is issued when microengine is in stall coming from execution, the END is executed only when the microengine resumes execution from stall.

67.3.15 SCM Emulation

If SCM is implemented as ROM, an external RAM may be used to replace it, allowing code patching and software breakpoint setting for debugging purposes. SCM ROM replacement by Emulation RAM is MCU-dependent. The SCM may even be divided into a ROM part and a RAM part. In this case, both microengines can run code from both ROM and Emulation RAM. It is possible to make one Engine run code from RAM and the other from ROM, by using different Entry Tables. The SCM visibility conditions also apply to Emulation RAM.

All SCM implementations, either RAM, ROM or Emulation RAM, are external to the eTPU block. eTPU provides a signal to enable the switching between external SCM banks. The conditions for this switching are:

1. Both Engines stopped.
2. VIS bit = 0.

Note that these conditions also stop the clocks of the SCM interface and MISC logic.

67.3.16 Safety features

This section describes embedded safety features: MISC and memory error support.

The Multiple Input Signature Calculator (MISC) is an SCM test feature accessible through eTPU Module Configuration Register (MCR). MISC allows SCM test "on the fly", that is, while eTPU is running, with no impact on eTPU functionality or performance.

Memory Error support features comprise SCM and SDM error detection, correction, report, and soft error.

67.3.16.1 SCM test - multiple input signature calculator

The Multiple Input Signature Calculator (MISC) comprises special hardware that sequentially reads all SCM positions and calculates, in parallel, a 32-bit signature from a 32-input CRC signature calculator with the following polynomial:

$$1 + x^1 + x^2 + x^{22} + x^{31}$$

A complete description of the signature calculation procedure can be found in MISC algorithm.

Once started by the Host the MISC runs continuously, restarting after the completion of each cycle, when it sets MCR[SCMMISC]. The average time for a MISC calculation can be measured by checking SCMMISC state at regular intervals, incrementing a counter and clearing SCMMISC if it is set.

MISC accesses to the SCM array are executed if none of the engines is accessing the SCM, to avoid degradation of the microengine performance: it happens while no channel is being serviced. An ongoing MISC operation can be aborted by writing 0 to SCMMISEN.

The Host must load eTPU MISC Compare Register (MISCCMPR) with the expected value to be found at the end of the MISC cycle, and then start the signature calculation by programming field SCMMISEN = 1 in eTPU Module Configuration Register (MCR). MISC zeroes the signature accumulator and starts reading SCM data and calculating the signature. After last SCM position is read, MISC compares the value in signature accumulator against the value in eTPU_SCR_MISCCMPR: if there is a mismatch MISC stops, a Global Exception is issued and MCR[SCMMISF] assumes value 1. If no mismatch is found, MISC repeats the procedure automatically. When signature is being calculated, SCM address starts at the last SCM address and counts down to 0. The conditions for executing a MISC operation are (see also SCM low power):

- Both microengines in idle state (no channel is being serviced) or stopped, in any combination (e.g., engine 1 idle with engine 2 stopped).
- MCR[VIS] = 0.
- MCR[SCMMISEN] = 1.

Note that MISC can run regardless of SCM implementation type (RAM or ROM).

If SCMMISEN=0 or VIS=1, the MISC logic stays at its initial state, with address counter pointing to the last SCM position and accumulator reset.

MISC can also be used to perform single-bit error fixes in the SCM . For more details, see Error fixing .

67.3.16.1.1 MISC algorithm

The MISC generator is based on the following polynomial:

$G(x) = 1 + x^1 + x^2 + x^{22} + x^{31}$ (equivalent to feedback mask = 0x80400007)

The MISC signature generation starts by clearing the MISC Accumulator value to 0 and preloading the MISC Counter with the highest SCM address. It then steps through each address decrementing the counter, reading 32 bit values and following the algorithm below:

```
If the least significant bit in MISC is 1 then
    MISC = MISC right shifted by 1 bit
    MISC = MISC XOR 0x80400007
else
    MISC = MISC right shifted by 1 bit
end if
MISC = MISC XOR RAM data
```

The code example below shows an excerpt of C code that calculates the MISC signature for a given array of data, based on the previous algorithm:

```
#define SCM_size    (MAX_SCM_ADDRESS / 4)    /* last byte address - converted to 32-bit word */
#define POLY        0x80400007               /* G(x) = 1 + x^1 +x^2 + x^22 + x^31 */
/*****************************************************************************
 FUNCTION : void calc_misc()
 PURPOSE : This function calculates the MISC value.
 INPUTS NOTES : none
 RETURNS NOTES : MISC value
 GENERAL NOTES : the array 'unsigned int data[]' represents the actual memory
                 array, organized in 32-bit words.
*****************************************************************************/
unsigned int calc_misc (void)
{
```

```
  int j; /* loop counter */
  unsigned int misc = 0;
  for (j = (SCM_size-1); j >= 0 ; j--) {   /* SCM_size has the number of 32-bit words in SCM */
      if (misc & 0x1) {
          misc >>= 1;
          misc ^= POLY;
      }
      else {
          misc >>= 1;
      }
      misc ^= data[j];          /* data[j] is the actual 32-bit word taken from the SCM array
*/
  }
  return (misc);          /* final signature calculated */

};
```

The value calculated by this algorithm must be loaded into eTPU MISC Compare Register (MISCCMPR) prior to activating the SCM MISC calculator in eTPU. Once the MISC calculator is activated (bit SCMMISEN in register eTPU Module Configuration Register (MCR) is written to 1) eTPU itself will start this procedure[29] reading the SCM whenever allowed by microengine. At the end of the cycle, when all the array has been read and the SCM signature is calculated, the Host CPU can be notified via Global Exception if the MISC Accumulator does not match the value in eTPU_SCR_MISCCMPR.

The average time taken by MISC to complete the signature of the whole SCM can be given by the formula:

```
Average MISC period = S / (4 * F * (1 - L))
```

where f is clock frequency, S is SCM size in bytes and L is eTPU load (as a percentage of execution clocks over a period of time, including TST clocks).

Further detail on MISC calculation can be found on SCM test - multiple input signature calculator. The application note **AN2192 - Detecting Errors in the Dual Port RAM (DPTRAM) Module** is also a good source of information (although it refers to TPU) on MISC signature.

67.3.16.2 Memory error support

Error Correction Code (ECC) support for SDM and SCM provides guaranteed single bit error correction and double bit error detection . Error detection and correction is performed on read accesses and on write accesses less than 32-bit wide to the SCM .

SDM ECC is calculated per byte, 5 bits wide each, totalling 20 ECC bits for each 32-bit word . That allows the ECC to be updated without a read-modify-write operation on writes of any size .

Error is not checked on bytes not selected on SDM read accesses, either by the Host, CDC or microengine . For instance, the most significant byte is not checked for errors on a microengine 24-bit read access .

Error detection also works for host accesses to the PSE area (see Parameter Sign Extension area) . In this case, error is not detected in the most significant byte (bits) . Also, because of sign extension, error is always detected on the bits , regardless if they are selected, whenever the most significant byte is read .

SCM ECC is 7 bits wide, comprising the whole 32-bit word . Read-modify-write is automatically made when 16-bit or 8-bit wide writes are made into the SCM in a host access . SCM errors are also detected on Entry Table accesses during TST (see Time Slot Transition) and on MISC accesses, which are considered microengine accesses with regards to interrupt generation and error reporting .

[29] eTPU MISC hardware is optimized to read 32-bit words from memory and to calculate this CRC in parallel, rather than shifting one bit at a time. The actual implementation inside eTPU, although bringing to the same results, does not match exactly the algorithm shown here.

67.3.16.2.1 Error detection disabling

The error detection logic in SDM and SCM can be disabled by setting the eTPU Memory Error Control Register (MECR) bits DEDD and CEDD, respectively . The disabled state turns ineffective any action due to error detection, including error correction . Note that error detection is always enabled out of reset .

67.3.16.2.2 Memory error flags

SDM single (correctable) and non-correctable bit errors are flagged in eTPU Memory Error Status Register (MESR) fields DCERR and DNCERR, respectively.

SCM correctable and non-correctable errors are flagged in the eTPU_MESR_MESR fields CCERR and CNCERR, respectively .

Double bit errors are guaranteed to be flagged, while three or more simultaneous bit errors in an SDM byte or SCM word are not . An error flagged as non-correctable can be in two or more bits .

Overrun flags DCOVR and CCOVR indicate, for SDM and SCM respectively, when a correctable error occurs when DCERR, CCERR are already asserted . Similarly, overrun flags DNCOVR/CNCOVR assert when a non-correctable error occurs when DNCERR/CNCERR are asserted already .

67.3.16.2.3 Memory error reports

The address, syndrome and data of a non-correctable SDM access can be sampled into eTPU Data Error Report Address Register (DERAR), eTPU Data Error Report Syndrome Register (DERSR), and eTPU Data Error Report Data Register (DERDR), respectively. DERAR also captures the SDM read access originator, whether the host, CDC, or specific eTPU channel service .

Similarly, non-correctable SCM accesses address, syndrome and data are stored in eTPU Code Error Report Address Register (CERAR), eTPU Code Error Report Syndrome Register (CERSR), and eTPU Code Error Report Data Register (CERDR), respectively . eTPU_MESR_CERAR also captures the SCM read access originator, whether the host, MISC, or specific eTPU channel service . The occurrence of a non-correctable error overwrites the report register values from a correctable error, either on SDM (DCERR=1) or SCM (CCERR=1) .

The last address, syndrome and data of a correctable SDM access can also be sampled into eTPU_MESR_DERAR, eTPU_MESR_DERSR, and eTPU_MESR_DERDR, but only if MESR[DNCERR] is 0 . That prevents access address, syndrome and data from a correctable error to overwrite the same information from a non-correctable access .

Similarly, the last address, syndrome and data from a correctable SCM access are stored in eTPU_MESR_CERAR, eTPU_MESR_CERSR, and eTPU_MESR_CERDR only if MESR[CNCERR] is 0 .

For either SDM or SCM, a new correctable error overwrites the report registers' values from an earlier correctable error, but report values from a non-correctable error are not overwritten, as long as bit DNCERR/CNCERR is asserted, neither by a new correctable error nor by a non-correctable one .

The sampling of SDM and SCM error report registers can be disabled through the eTPU_MESR_MECR fields DRDIS and CRDIS, respectively . When DRDIS (CRDIS) is asserted, the update of the SDM (SCM) error report registers is disabled, but not of eTPU_MESR_MESR fields DCERR, DNCERR (CCERR, CNCERR) . DRDIS, CRDIS must be set before reading the respective report registers to assure their coherent reading, preventing them to be updated between reads .

67.3.16.2.4 Error detection and wait states

Microengine SDM accesses do not take any wait state due to ECC support . Host SDM read accesses take two wait-states minimum in MCUs with SDM ECC support, regardless if an error was detected or not, if the SDM error detection is enabled (eTPU Memory Error Control Register (MECR) field DEDD = 0) . Host SDM read accesses take a minimum of one wait state if the SDM error detection is disabled (MECR[DEDD] = 1) . Host SDM write accesses take one wait state minimum, regardless of ECC support presence or enabling .

Host SCM read accesses have two wait-states, regardless if an error was detected or not . Writes from the host to the SCM take one wait state on 32-bit accesses, and one additional wait state (two wait-states total on 16-bit and 8-bit wide accesses . Those figures are not affected by the SCM error detection disabling (eTPU_MESR_MECR[CEDD]) .

[30] One wait-state more, compared with eTPU versions before eTPU2 and previous eTPU2 without ECC support

67.3.16.2.5 Memory error interrupts

For **microengine accesses**, the Global Exception interrupt asserts whenever a non-correctable error is detected, either on SCM or SDM (see Interrupts and data transfer requests) . These errors are flagged by eTPU Module Configuration Register (MCR) fields SCMERR and SDMERR, respectively. Single bit errors are corrected and activate the Memory Error Correction Interrupt if it is enabled (see Interrupt types and sources), but do not generate Global Exceptions .

For **host accesses** a bus error is issued whenever a non-correctable error is detected, either on SCM or SDM (but not through the CDC) and it also generates a Global Exception . Single bit errors are corrected (if the error correction feature is available) and do not cause bus transfer errors, but assert the Memory Error Correction Interrupt if it is enabled (see Interrupt types and sources) .

67.3.16.2.6 Effect of errors on microcode execution

Correctable errors, either on SCM or SDM, do not affect microcode execution if detection/correction is enabled.

The executing thread is affected by a non-correctable SDM error as follows:

- If MECR[DTEND] = 1: on SDM errors due to a read operation, if the instruction is not also an END, the following instruction automatically executes an END, and its operations may be executed, totally or partially. On SDM errors during the TST preload, the thread automatically ends on the first instruction, if the error occurs on a preload parameter selected by the entry point bit PP (see Entry Point Format section.) The first instruction may be executed totally or partially. Data read into P or DIOB may be corrupted in either case.
- If MECR[DTEND] = 0: the TST or thread continues the execution flow normally. Data read into P or DIOB may be corrupted in either case.

The executing thread is affected by a non-correctable SCM error as follows:

- If MECR[CTEND] = 1: on SCM errors, the corrupted instruction is not executed, instead replaced by a simple END. Due to instruction prefetching, an error may be detected and yet not affect the thread execution. However, an error detected in a prefetched instruction may cause error report and global or memory error interrupts, even if not executed. If a non-correctable error occurs on the entry table read during TST (see Time Slot Transition section), the first instruction in the thread is replaced with a simple END, a global exception is issued and the reports and flags are normally updated.
- If MECR[CTEND] = 0: the execution flow continues normally, and the results depend on the particular instruction corruption.

Table 469. Error support summary if CEDD = DEDD = 0

Action		SCM		SDM	
		single bit error	double bit error	single bit error	double bit error
Memory Error Correction Interrupt		Asserts	Not asserted	Asserts	Not asserted
Global Exception		Not asserted	Asserts	Not asserted	Asserts
Bus Error (host reads)		Not issued	Issued	Not issued	Issued
Thread	CTEND = 0	Normal execution	Potential erroneous execution[1]	Normal execution	see DTEND
	CTEND = 1		Terminates before erroneous execution[2]		
	DTEND = 0		see CTEND		Potential erroneous execution
	DTEND = 1				Terminates after erroneous read[3]

Table continues on the next page...

Table 469. Error support summary if CEDD = DEDD = 0 (continued)

Action		SCM		SDM	
		single bit error	double bit error	single bit error	double bit error
Code Error Report Registers	CNCERR = 0	Updates eTPU_MESR_CERAR, eTPU_MESR_CERSR, eTPU_MESR_CERDR		Not related	
	CNCERR = 1	eTPU_MESR_CERAR, eTPU_MESR_CERSR, eTPU_MESR_CERDR not updated			
Data Error Report Registers	DNCERR = 0	Not related		Updates eTPU_MESR_DERAR, eTPU_MESR_DERSR, eTPU_MESR_DERDR	
	DNCERR = 1			eTPU_MESR_DERAR, eTPU_MESR_DERSR, eTPU_MESR_DERDR not updated	

1. The thread executes correctly if the error is detected on an instruction fetched but not executed.
2. The erroneous instruction is not executed at all, and replaced by a simple END.
3. The instruction following the erroneous read may be executed totally or partially.

67.3.16.2.7 Error Correction Code (ECC) and syndrome definition

SDM ECC is composed of 5 Hsiao code[31] bits for each data byte . **SCM ECC** is composed of 7 Hsiao code bits for each 32-bit word .

The following table shows the encoding of the SDM syndrome and global parity fields as they read in eTPU Data Error Report Syndrome Register (DERSR) . There is one syndrome and one global parity for each byte in an SDM word, numbered SYND0 to SYND3 from the least to the most significant .

Table 470. SDM syndrome definition

SYNDn (hex)	Result	SYNDn (hex)	Result
0E	error on data bit 8n+7	10	error on **code** bit 8n+4
15	error on data bit 8n+6	08	error on **code** bit 8n+3
07	error on data bit 8n+5	04	error on **code** bit 8n+2
1A	error on data bit 8n+4	02	error on **code** bit 8n+1
19	error on data bit 8n+3	01	error on **code** bit 8n
13	error on data bit 8n+2		
16	error on data bit 8n+1	00	no error
1C	error on data bit 8n	any other	non-correctable error

[31] Hsiao, M.Y;.A Class of Optimal Minimum Odd-weight-column SEC-DED Codes; IBM Journal of Research and Development http://ieeexplore.ieee.org/xpl/freeabs_all.jsp?arnumber=5391627

The following table shows the definition of the SCM syndrome field as it reads in eTPU Code Error Report Syndrome Register (CERSR).

Table 471. SCM syndrome definition

SYND (hex)	Result	SYND (hex)	Result	SYND (hex)	Result
40	error on **code** bit 6	58	error on data bit 25	46	error on data bit 11
20	error on **code** bit 5	0B	error on data bit 24	4A	error on data bit 10
10	error on **code** bit 4	54	error on data bit 23	52	error on data bit 9
08	error on **code** bit 3	15	error on data bit 22	62	error on data bit 8
04	error on **code** bit 2	16	error on data bit 21	13	error on data bit 7
02	error on **code** bit 1	34	error on data bit 20	29	error on data bit 6
01	error on **code** bit 0	25	error on data bit 19	31	error on data bit 5
		26	error on data bit 18	43	error on data bit 4
49	error on data bit 31	64	error on data bit 17	45	error on data bit 3
0D	error on data bit 30	2C	error on data bit 16	19	error on data bit 2
0E	error on data bit 29	1A	error on data bit 15	51	error on data bit 1
38	error on data bit 28	23	error on data bit 14	61	error on data bit 0
4C	error on data bit 27	2A	error on data bit 13	00	no error
1C	error on data bit 26	32	error on data bit 12	any other	non-correctable error

67.3.16.2.8 Error injection

Errors can be injected into the SDM read data path through eTPU Data Error Injection Address Register (DEIAR), eTPU Data Error Injection Data Pattern Register (DEIDPR) and eTPU Data Error Injection Parity Pattern Register (DEIPPR). They define bit flips on accesses at the specific address specified in eTPU Data Error Injection Address Register (DEIAR).

SDM error injection is enabled independently for host and microengine accesses by the eTPU Memory Error Control Register (MECR) fields HDEIE and MDEIE, respectively. You must program DEIAR, DEIDPR, and DEIPPR with HDEIE = MDEIE = 0, and only then enable error injection by setting HDEIE = 1 and/or MDEIE = 1 to avoid races (see eTPU Memory Error Status Register (MESR)).

Similarly, SCM errors can be injected into the SCM read data path through eTPU Code Error Injection Address Register (CEIAR), eTPU Code Error Injection Data Pattern Register (CEIDPR) and eTPU Code Error Injection Parity Pattern Register (CEIPPR), enabled by the eTPU Memory Error Control Register (MECR) field CEIE. Errors are injected on host accesses to the address specified in CEIAR when MCR[VIS]=1, or on microengine and MISC accesses when VIS=0 .

67.3.16.2.9 Error fixing

Single bit **soft errors** can be fixed by rewriting the right value, as corrected by the ECC logic, into the same address of the erroneous data . eTPU provides means to perform such fixes safely, coherently and concurrently with the normal operation .

SDM fixes can be done using the CDC (see Coherent Dual-parameter Controller (CDC)), limited to the lower 8 KB of SDM . The Host application simply has to program a transfer with both origin and destination positions pointing to the address of the data to be fixed . Because the PBBASE field has an address granularity of 8 bytes, a word adjacent to the one to be fixed must also be rewritten . The CDC transfer is atomic, therefore the fix is done coherently and does not interfere with the application code or data flows .

SCM fixes can be done by programming CEFR[CFIXM] (see eTPU Code Error Fix Register (CEFR)) . The fixes are performed by the MISC logic, which must be enabled (see SCM test - multiple input signature calculator) . The modes available, selected by CEFR[CFIXM], are:

- **Automatic Fix Mode (CFIXM = 11)**: the MISC logic automatically rewrites the contents of an address whenever it finds a correctable error; the CFIXM field keeps its value if a fix is made .

67.3.17 Performance monitoring features

67.3.17.1 Idle Counter

The Idle Counters eTPU Idle Register for Engine 1 (IDLER_ENG1) and eTPU Idle Register for Engine 2 (IDLER_ENG2) continuously count microcycles in which the microengine is not busy with channel service . They can be used to measure the microengine utilization by rating the count measured during a period of time to the number of microcycles contained in the period. The Idle Counters do not count microcycles when the engine is stopped, or is in TST or halt states.

67.3.17.2 Watchdog Monitor Operation

The watchdog mechanism can also be used to monitor, without interfering with the application execution, whether the execution time of any individual thread or a sequence of threads reaches a given limit. This can be achieved by asserting the WMO field in eTPU Watchdog Timer Register for Engine 1 (WDTR_ENG1) and eTPU Watchdog Timer Register for Engine 2 (WDTR_ENG2).

67.4 Detailed signal descriptions

Detailed signal descriptions are presented in the following sections.

67.4.1 eTPU channel output signals

Each signal is associated with a channel. The microcode may affect the logic level of an output signal[32] by implementing one of two actions:

- Specify the logic level output to the signal when there is a match or a transition.
- Immediately force a logic level.

The output signal may also be forced to a logic level, independently of the output value from the channel logic, by one of the four (each Engine) output disable input signals (see eTPU channel output disable signals).

The output buffer enable signals are not used.

67.4.2 eTPU channel input signals

Each signal is associated with a channel. The microcode can directly control the effect of the transition edge. Each channel can be programmed to sense a transition when a rising and/or falling edge is detected. The channel logic can also process two transition events, and relate these events to each other and to other programmed timer events. The edge sensitivities of the two transition events are configured independently by microcode. For further information refer to Enhanced Channels and Transition Detection and Pin Action Control.

Each channel input signal has an associated synchronizer made of two flip-flops sampling the signal on every other eTPU clock[33], followed by a digital filter. This digital filter can work in three sub-modes, whose purpose is to filter out noise pulses that have width

[32] Note that the minimum pulse width is one microcycle (two eTPU clocks), and slow pads may not be able to transfer it on time. For generation of very short pulses the eTPU pads have to be programmed by the system integration for fast operation mode with the voltage levels defined for fast pad operation in the MCU technology.

less then a programmed value of eTPU clocks, preventing these transitions from being input to the transition detect logic. The synchronizer and digital filter are guaranteed to pass pulses that are greater than a programmed value. All channel input filters in one Engine work on the same mode and sampling clock. For more information on channel input filters, refer to Enhanced digital filter (EDF). In one of the Angle Modes, the output of the digital filter of channel 0 is replaced by the output of TCRCLK signal digital filter (see EAC - eTPU Angle Counter).

67.4.3 Time base clock signal (TCRCLK)

is an input signal used to control the Time Bases TCR1 and TCR2. There is one independent TCRCLK input for each Engine. For pulse accumulator operations TCRCLK can be used as a gate for a counter based on the eTPU clock divided by eight. For Angle operations TCRCLK can be used to get the tooth transition indications in Angle Mode. Further details can be found on Time bases and EAC - eTPU Angle Counter.

Like the channel input signals, the TCRCLK signal has an associated synchronizer followed by a digital filter. This digital filter can work in two submodes, whose purpose is to filter out noise pulses that have width less than a programmed value of eTPU clocks, preventing these transitions from being input to the transition detect logic. The synchronizer and digital filter are guaranteed to pass pulses that are greater than a programmed value. The clock and operation submode of the TCRCLK filter is configured independently of the other channel input filters, through the TCRCF field in eTPU Engine 1 Time Base Configuration Register (TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (TBCR_ENG2). For more information on filter submodes, see TCRCLK digital filter. In one of the Angle Modes, the output of the digital filter of channel 0 is replaced with the output of TCRCLK signal digital filter (see EAC - eTPU Angle Counter).

67.4.4 eTPU channel output disable signals

Each of these four input signals are used to force the outputs of a group of 8 channels to an inactive level. When an input is active, all the channels in its group of 8 that have their fields ODIS=1 in C*a*CR_ENG1 and C*a*CR_ENG2 have their outputs forced to the opposite of the value specified in bit OPOL of the same register. Therefore, channels can be individually selected to be affected by the output disable signals, as well as their disabling forced polarity (see 'Pin State Input/Output Logic' figure in Pin Control Registers).

See the chip-specific eTPU information for details on the output channel disable group definition.

In a Dual-engine eTPU there are 8 output disable signals for the 64 channels.

67.4.5 Event in (EVTI)

Event In (EVTI) is used to initiate program and data trace synchronization messages or to generate a breakpoint. EVTI is edge-sensitive for synchronization and breakpoint generation.

67.4.6 Event out (EVTO)

Event Out (EVTO) is an output pin to development tools comprising exact timing for a single watchpoint or breakpoint occurrence. EVTO is asserted for 1 MCKO clock.

67.4.7 Breakout EVTI/O

Break events and event outputs will be generated due to any of the following breakpoint types:

- Exit of System Reset
- DBR assertion
- TWIN Engine
- SW
- MISC Error
- Illegal Instruction

[33] Sampled on the T4 microcycle phase, see Microcycle and I/O timing.

- Single Step
- EVTI
- External (ipg_debug)

The events are namely:

- BCRW (Break on Channel Register Write)
- BHSR (Break on Host Service Request)
- BLINK (Break on Link Service Request)
- BMRL (Break on Match Recognition Request)
- BTDL (Break on Transition Detect Request)
- DBR (Debug Request)
- SS (Single Step)
- SW (Software Breakpoint)
- MISC (MISC Error)
- SRBP (Software Reset Breakpoint)
- TWIN (TWIN Engine)
- EXTE (External Debug)
- EVTI (EVTI Input)
- IIBP (Illegal Instruction Breakpoint)

67.5 Initialization/application information

67.5.1 Configuration sequence

After initial power-on reset the eTPU remains in an idle state, requiring initialization of several registers before any function can begin execution. Also, SCM should be initialized with the eTPU application code prior to configuring the eTPU. Configuration procedures are summarized as follows:

1. Load the eTPU application code into SCM (see SCM access).
2. Initialize SDM (optional if no ECC support is available)
3. Initialize the SCM MISC logic (optional, see SCM test - multiple input signature calculator).
4. Initialize Watchdog (optional).
5. Initialize eTPU Engine 1 Time Base Configuration Register (TBCR_ENG1) and eTPU Engine 2 Time Base Configuration Register (TBCR_ENG2) to set up:
   - TCR1 and TCR2 prescalers and clock sources.
   - Select digital filtering mode.
   - TCRCLK signal filter control.
   - Angle mode operation (if necessary).
6. Initialize eTPU Engine 1 Configuration Register (ECR_ENG1) and eTPU Engine 2 Configuration Register (ECR_ENG2) to set up:
   - Entry table base.

[34] Except when is asserted on power-on reset: in this case, the microengines wake-up in halt state.

- Filter prescaler clock control.

7. Initialize eTPU Engine 1 STAC Configuration Register (STAC_ENG1) and eTPU Engine 2 STAC Configuration Register (STAC_ENG2) if you must set up TCR1/2 resource Client/Server operation.
8. Write to C*a*CR_ENG1 and C*a*CR_ENG2 to choose the function to be performed by each channel, and its parameter base address.
9. Write to C*a*SCR_ENG1 and C*a*SCR_ENG2 to choose among the possible variations within the function flow (FM fields).
10. Write to SDM for parameter initialization of each configured channel.
11. Write to eTPU Watchdog Timer Register for Engine 1 (WDTR_ENG1) and eTPU Watchdog Timer Register for Engine 2 (WDTR_ENG2) if you must enable and set up the Watchdog(s) mode and timeout.
12. Write to C*a*HSRR_ENG1 and C*a*HSRR_ENG2 to initialize the active channels.
13. Write to eTPU Channel Interrupt Enable Register for Engine 1 (CIER_ENG1) and eTPU Channel Interrupt Enable Register for Engine 2 (CIER_ENG2) if interrupts are to be enabled from the appropriate channels. Likewise for Data Transfer Requests (eTPU Channel Data Transfer Request Enable Register for Engine 1 (CDTRER_ENG1) and eTPU Channel Data Transfer Request Enable Register for Engine 2 (CDTRER_ENG2)). This can also be done through C*a*CR_ENG1 and C*a*CR_ENG2.
14. Write to C*a*CR_ENG1 and C*a*CR_ENG2 to enable each channel by assigning it a high, middle, or low priority (CPR field).
15. Monitor C*a*HSRR_ENG1 and C*a*HSRR_ENG2for completion of initialization.
16. Write #unique_3047/unique_3047_Connect_42_MCR.GTBE = 1 to start TCR1/TCR2 timebase counting at same time in both Engines (may be done before or never, depending on the particular application and use of Red Line bus).

67.5.2 Reset options

67.5.2.1 Hardware reset

Hardware reset is achieved by assertion of device synchronous reset. Both Engines and common logic is reset, and even the System Configuration and Global Channel registers assume their reset values.

NOTE

All eTPU input clocks must pulse during reset so that both engines are reset, even if they are in Module Disable or Stop mode.

67.5.2.2 Software reset

eTPU has no software reset. To abort infinite microcode loops, the Force END mechanism must be used (see field FEND in eTPU Engine 1 Configuration Register (ECR_ENG1) and eTPU Engine 2 Configuration Register (ECR_ENG2)).

67.5.3 Multiple parameter coherency methods

Follows a description of two methods for coherent transfer of multiple parameters between Host and eTPU. Both methods involve the use of two parameter areas: the Transfer Parameter Area (hereafter called TPA), which is the SDM area directly accessed by the Host for reads and writes, and the Permanent Parameter Area (hereafter called PPA), which are the SDM positions where channel parameters are normally accessed by the Function microcode. Note that parameters in either TPA or PPA do not have to be in sequential addresses. TPAs and PPAs allocation are completely defined by the application, and there may be any number of them, independently of the channels.

The methods described here are not the only solutions for the coherent transfer problem, and both can coexist in eTPU and even used in combination. Also note that for transfers of a pair of parameters, the Coherent Dual-parameter Controller is faster and have less impact on both eTPU and Host performance. That said, the methods are:

- **Transfer Service**: a microengine thread transfers, upon Host Service Request, data from/to a TPA to/from a PPA.Coherency is guaranteed by the fact that a thread is atomic with respect to other threads in the same Engine, and so are its transfers. If parameters in PPA are shared by both Engines, hardware semaphores have to be used to access them.
- **Mailbox**: for Host to eTPU transfers, the microcode checks a flag, set by the host, indicating the existence of new parameter data in the TPA. It can, then, either access TPA data directly or copy it to the PPA. For eTPU to Host transfers, when microcode changes PPA, it copies them to the TPA and flags updated TPA data to Host, possibly using an Interrupt or a Data Transfer Request. The Mailbox flag is reset when data is copied: by the eTPU microcode, when it transfers TPA to PPA (possibly followed by an Interrupt); by the Host, when it reads data from the TPA. This indicates that TPA is free for another transfer.

Transfer Service has the advantage of separating the task of data transfer from the functional service thread that accesses the parameters, with less impact to the latter. Compared to the Mailbox method, however, it has bigger average latency, because the Transfer Service thread has to contend for a time slot to execute. This latency can be minimized if Transfer Service thread is assigned to a separate channel with higher priority, but even so it does not guarantee that PPA is updated before the next execution of the functional thread that uses it.

Mailbox method, on the other hand, makes the functional thread check for the existence of new data (Host to eTPU). It does not have to be responsible for the transfer, though: it may access the TPA directly, and a Transfer Service can then be used to copy data from TPA to PPA.

67.5.4 Programming Hints and Caveats

67.5.4.1 Atomic dual access after a call, return

A dual, back-to-back parameter access is not atomic after a call, a jump, or a return if they occurred in parallel with an odd SDM access. It is safer to make a pair of parameter accesses that must be coherent begin at the second instruction after a call/jump/return.

67.5.4.2 Resource polling

The use of polling while waiting for a condition or a resource (except semaphore lock) should be avoided in order not to hang the microengine in long loops. This general programming guideline is greatly enforced in eTPU, as a thread cannot be preempted for any reason. Safer polling, albeit with long and indeterministic latency, can be obtained if a thread issues a channel link to the serviced channel and terminates. The microengine is then free to other tasks, and the next poll happens at the next time the channel is serviced. This mechanism can be combined with finite (timed out) loops for better latency.

67.5.4.3 Changing channel function, parameter base, or entry table scheme

Channel function, parameter base address and entry table scheme are determined by the CFS, CPBA, and ETCS fields in C*a*CR_ENG1 and C*a*CR_ENG2. They cannot be changed when the channel is enabled. If the channel is disabled first, one may still have service requests from the previous function, so before the channel is enabled again one must be sure that:

- the first thread executed in the new function is the initialization one.
- the initialization thread of the new function clears any previously pending service request.

Here is a safe procedure for function changing:

1. Disable the channel (in C*a*CR_ENG1 and C*a*CR_ENG2, write CPR = 00b).
2. Change the function configuration (fields CFS and/or CPBA and/or ETCS in C*a*CR_ENG1 and C*a*CR_ENG2).
3. Request the initialization thread, writing eTPU Channel n Host Service Request Register for Engine 1 (C0HSRR_ENG1 - C31HSRR_ENG1) and eTPU Channel n Host Service Request Register for Engine 2 (C0HSRR_ENG2 - C31HSRR_ENG2)with the initialization HSR (channel still disabled).
4. Enable the channel (in C*a*CR_ENG1 and C*a*CR_ENG2 write CPR > 0); the initialization HSR is serviced before any other formerly pending service requests, clearing them.

67.5.4.4 Checking and Clearing Interrupts of a Stopped Engine

An Engine may be stopped with interrupts (or DMA requests) pending. This includes the case when the Engine's MDIS bit is set and a thread is still running: the thread will complete execution, possibly issuing an interrupt or DMA request before the engine stops, setting the STF bit.

As soon as the engine stops the channel registers become inaccessible, issuing bus errors when accessed. Interrupts and DMA requests can still be checked and cleared through the Global Channel Registers, though. DMA requests can also be cleared by the hardware handshaking with the DMA controller when the engine is stopped.

67.5.5 Estimating Worst Case Latency

Reliable systems are designed to work under worst-case conditions. This section explains how to estimate worst-case latency (WCL) for any eTPU function in any system. The appendix covers the following topics:

- Introduction to Worst-Case Latency
- Using Worst-Case Latency Estimates to Evaluate Performance
- Priority Scheme Details used in WCL Analyses
- First-Pass WCL Analysis
- Second-Pass WCL Analysis

The first-pass WCL analysis is based on a deterministic, generalized formula that is easy to apply. Because of the generalizations in the formula, the first analysis result is almost always much worse than the real worst case. If the desired system performance is within the limits of this first analysis, then no further analysis is required; the system is well within the performance limits of the eTPU. If the desired system performance exceeds that indicated by the first analysis, the second-pass WCL analysis should be applied. The second-pass analysis is not a generalized formula, but rather uses specific system details for a realistic worst-case estimation.

67.5.5.1 Introduction to worst-case latency

NOTE

The latency calculation and examples refer to old TPU functions such as PWM, DIO etc. These functions use single action channels which have single transition and single match functionality. They are not optimized for the eTPU hardware enhancement which support various double action modes. These examples are for reference only. New eTPU functions which are optimized for the new hardware will impose different latency calculations.

Worst-case latency for a channel is the longest amount of time that can elapse between the execution of any two function threads on that channel. For example, if in a particular system, channel 5 is running PWM, the worst-case latency for channel 5 is the longest possible time between the execution of two PWM threads. The worst case time includes the time the execution unit takes to execute threads for other active channels, and other delays described later in this section. Refer to the following figure.

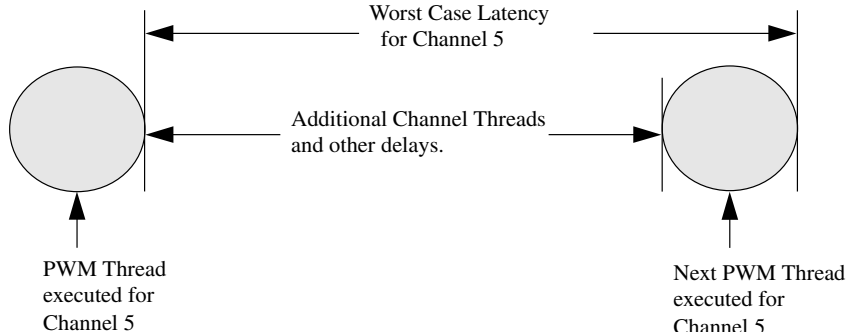

Figure 484. Worst-case latency for PWM

Worst-case latency for a channel depends both on the function running on that channel and on the activity on other channels. Since the 32 eTPU channels must all share the same execution unit, execution speed of a particular function varies with each

system. The PWM thread response is faster if there are no other active channels than if other channels are also active. In addition, changing the priority scheme and channel number assignments can change performance for a function even if the same set of functions are still active.

Each function is divided into treads, as shown in the figure below (see also Functions and threads). The eTPU Microengine executes one thread of a function at a time. For example, the Microengine might execute thread 1 of PWM, then thread 3 of DIO, then thread 2 of PWM, then thread 2 of SM, and so on. The amount of time the eTPU Microengine grants a function to execute a thread varies with the number of microcode instructions in the thread.

Since there is only one eTPU Microengine (in each eTPU Engine), the eTPU cannot actually execute the software for multiple functions simultaneously. However, the hardware for each of the channels is independent. This means that, for example, all 32 channel signals can change thread at the same moment, provided that the function software sets up the channel hardware to do so beforehand.

With Host CPU code, the system designer assigns functions to channels and initializes the functions. After initialization, functions typically run without Host intervention, except for eTPU channel interrupts to the Host to give or receive information. Most functions can run continuously with periodic servicing from the eTPU Microengine. As required, the channels request service from the eTPU Microengine, and the eTPU Scheduler determines the order in which the channels are serviced. Worst-case latency for a channel can be derived from the details of the priority scheme that the scheduler uses (see Scheduler).

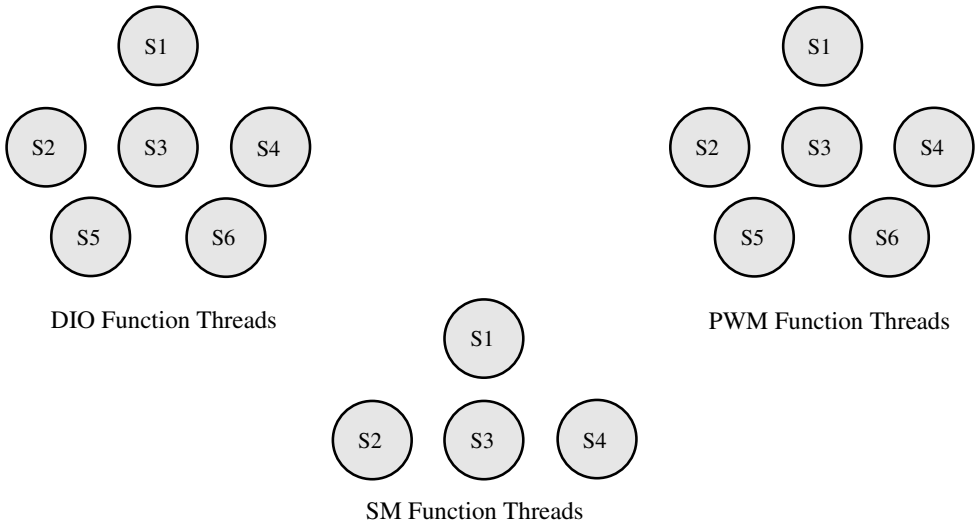

Figure 485. Function threads

67.5.5.2 Using Worst-Case Latency estimates to evaluate performance

Once WCL is found for a channel, the user must determine how to use this number to analyze performance. To analyze the performance of a channel running the PWM function, for example, some information about what happens in each thread is necessary.

The following example refers to old TPU PWM function, which is not optimized to the eTPU enhanced hardware. For PWM, thread 1 is the initialization thread, and threads 2 and 3 are used during normal function execution. (PWM threads 4, 5, and 6 are for special modes and will be assumed to be unused on channel 5). Thread 2 writes a time into the channel 5 match register and performs other operations that will cause the channel 5 signal to go from low to high at the time indicated in the match register (match time). At match time, the signal goes high and channel 5 requests service from the eTPU Microengine to execute thread 3. Thread 3 writes a time into the channel 5 match register and performs other operations that will cause the channel 5 signal to go from high to low at match time. At match time, the signal goes low and channel 5 requests service from the eTPU Microengine to execute thread 2. A PWM wave is kept running on the system by the eTPU executing thread 2, then thread 3, then thread 2, then thread 3, and so on.

Since the definition of worse-case latency assumes a fully loaded running system, initialization threads are not part of worst-case calculations. For the channel 5 example, the two PWM threads in Introduction to worst-case latency are thus the two normal running threads, threads 2 and 3.

Introduction to worst-case latency does not define which thread is thread 2 and which is thread 3. Since the worst-case latency derived from the first-pass analysis is the worst case between any2 threads (not counting initialization threads), it is safe to say that the worst-case latency shown in Introduction to worst-case latency represents both the worst-case high time and the worst-case low time.

Notice in Introduction to worst-case latency that worst-case latency is drawn from the end of the execution of the first PWM thread to the end of the execution of the next PWM thread. It is drawn from end to end because the microcode instructions that make up the threads control the channel hardware. To make sure that all the microcode instructions needed to change the pin thread have been executed, it is necessary to include the execution time of the second thread.

Thread information for each function is found in the programming notes for individual TPU functions. See NXP Programming Note TPUPN00/D, Using the TPU Function Library and TPU Emulation Mode, for a list of available programming notes. Similar documentation will we provided for the eTPU new functions.

67.5.5.3 Priority scheme details used in WCL analysis

The user assigns functions to channel numbers and gives each active channel a priority level of high, middle, or low. The Scheduler uses the channel number and channel priority level to determine the order in which to grant service.

The scheduler allocates time slots to specific priority levels of high, middle, or low. One function thread is executed in each time slot. The length of a time slot varies according to the length of the executing thread. When fully loaded, the scheduler always assigns time slots in a seven-slot sequence (see the following table). After a seven-slot sequence is completed, another seven-slot sequence begins (see). Note that in eTPU, when no service request exists, the scheduler goes to thread 1, but WCL calculation considers full load.

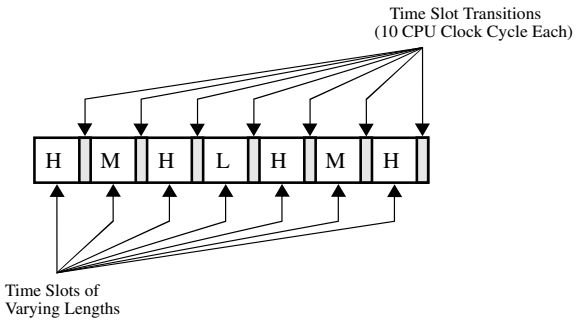

Figure 486. Time-slot sequence

This sequence scheme gives higher-priority channels more service time than lower-priority channels. High-priority channels are allocated four of seven time slots, middle-priority channels are allocated two of seven time slots, and low-priority channels are allocated one of seven time slots.

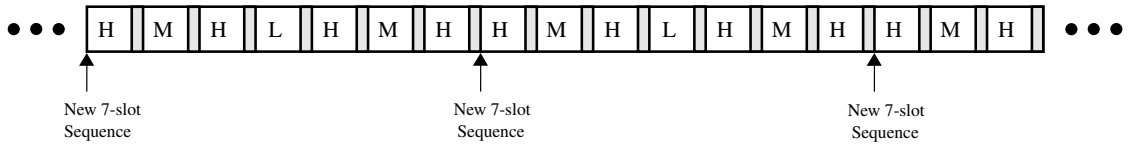

Figure 487. Multiple time-slot sequences

67.5.5.3.1 Priority Passing

If no channel of the priority level assigned to the time slot is requesting service, the eTPU scheduler can pass priority to other levels. If no high-level channel is requesting service during a high level time slot, a middle-level channel is granted service; or, if no middle level-channel is requesting service, a low-level channel is granted service. If no middle-level channel is requesting service

during a middle-level time slot, a high-level channel is granted service; or, if no high-level channel is requesting service, a low-level channel is granted service. If no low-level channel is requesting service during a low-level time slot, a high-level channel is granted service; or, if no high-level channel is requesting service, a middle-level channel is granted service. If no channel is requesting service, the time slot sequence is reset to state 1 and the scheduler idles until a request is received.

Priority passing is implemented in hardware and does not contribute to worst-case latency.

67.5.5.3.2 Time-slot transition

After each time slot, the eTPU must prepare for the next time slot. This preparation time between each time slot is called a time-slot transition. See Time Slot Transition. Time-slot transitions can take from six up to ten eTPU clocks.

67.5.5.3.3 Channel Number Priority

If more than one channel of a priority level is requesting service, the lowest numbered channel is granted service first. For example, if channels 0, 5, and 9 are all high-level channels requesting service during a high time slot, channel 0 is granted service first. Continuing this example, if channel 0 requests service again immediately after being serviced, it is not serviced again until channels 5 and 9 are serviced. This scheme is implemented so that continuously-requesting low numbered channels do not take all the time on the eTPU execution unit and leave no time for other channels.

The scheduler uses registers to keep track of which channels have been serviced and which require servicing. Each channel has two register bit: a service request register (SRR) and a service grant register (SGR). The SRR is set when a channel requests service. After the channel has been granted service, the SGR is set and the SRR is cleared.

SGRs are not cleared individually by channel, but rather as priority level groups. The clearing of a group of SGRs begins a new cycle for that priority level. An SGR group is cleared on the condition that a channel of that priority level has just been serviced, and no other channel of that priority level is requesting service (has a set SRR) and has not been granted service (has a clear SGR).

For example, if a middle-priority channel has just been serviced (either in a middle-priority time slot or a high or low-priority time slot gained by priority passing), the SRRs and SGRs of all middle-priority channels are compared. If there is no middle-priority channel with its SRR set and SGR cleared, the scheduler clears all middle-level SGRs. If there is a middle-level channel with its SRR set and SGR cleared, the scheduler does not clear the SGR group, and the requesting middle-level channel is serviced on the next middle-level time slot (or possibly sooner by priority passing).

67.5.5.3.4 SDM Collision Rate

Most function threads read or write to the eTPU SDM at least once. Because both the eTPU Microengine and Host can access the SDM but not at the same time, the Microengine may suspend execution during the SDM access while waiting for the Host to finish accessing the SDM. At other times the Host may wait for the Microengine. Wait states can take up to two eTPU clocks, when the Host accesses the SDM directly, without using CDC. Microengine(s) wait-states must be added into the worst-case latency calculation. The system designer should estimate the percentage of SDM accesses in the system that will result in Microengine wait-states. This percentage is called the RAM collision rate (RCR). In each collision with direct Host accesses to the SDM the Microengine(s) wait for two eTPU clocks.

In eTPU the Coherent Dual-parameter Controller (CDC) may also access the SDM for atomic transfers of two parameters. eTPU Microengine may wait on this operation (if it is in service time) until the transfer is complete. CDC always transfers two parameters, making four consecutive accesses (read, write, read, write) of one eTPU clock each. The system designer should estimate the percentage of SDM accesses in the system that will result in a Microengine wait due to coherent transfer, and multiply it with the average number of eTPU clocks the Microengine waits for each transfer. This percentage is called Coherent Parameter Collision Rate (CPCR).

In addition, Microengine to Microengine multiple parameter coherent communication, using the hardware semaphores, may hold one Microengine which waits to lock the semaphore while the other Microengine is holding it. This waiting is due to a software loop, not hardware wait-states. Note that single parameter access of one Microengine does not affect the timing of the other Microengine due to SDM time interlace. This implies that single parameter Microengine to Microengine communication does not affect the performance. The Microengine which waits for the semaphore will loop until it is freed by the other Microengine. This time depends on the eTPU application. The system designer should estimate the percentage of Microengine to Microengine coherent parameter communication that will result in eTPU semaphore loops, and multiply it with the average number of eTPU clocks the Microengine loops for each such transfer. This percentage is called CCR (Communication Collision Rate).

A 100% collision rate for a system is the theoretical worst case. In many systems, however, the RCR, CPCR and CCR would be very low, sometimes even near 0%. This is because the eTPU is an independent processor capable of servicing most function needs, so that the Host rarely needs to access the eTPU SDM. Also coherent Microengine to Microengine communication of more than one parameter may be rare. To find a realistic RCR, CPCR the system designer should evaluate the Host code and find the percentage of time it accesses the eTPU SDM with or without using the CDC. This percentage gives a good RCR and CPCR. The eTPU application provides a good estimation of CCR.

NOTE

The programming practice of polling a flag in the eTPU SDM causes a very high RCR and should be avoided in high-performance systems.

After the collision rate for a system is found, it can be applied to the WCL calculations for each channel. The system designer can use the collision percentage and the number of SDM accesses (with and without semaphores) to estimate the eTPU loop time for a function. Note that in old TPU functions CPCR and CCR are both zero.

The estimation of eTPU wait time is as follows:

Variables:

N1 = Number of simple RAM accesses in the longest thread

RCRWait = Maximal eTPU clocks wait time for simple RAM collision = 2

CPCRWait = Average eTPU clocks for Coherent Parameter Transfer (using CDC).

N2 = Number of eTPU-eTPU semaphore RAM accesses in the longest thread

CCRWait = Average eTPU clocks for Microengine-Microengine communication transfer.

Estimated Wait Time:

Function eTPU maximal wait time =

N1 *(RCR * RCRWait + CPCR * CPCRWait) + N2* CCR * CCRWait

67.5.5.4 First-Pass Worst-Case Latency Analysis

Following is the first-pass calculation of worst-case latency for a channel. Remember that this analysis uses generalizations that usually produce a result much worse than the real worst case. If the worst-case result from the first analysis is too long for the desired performance, use the second analysis for a more realistic worst-case analysis.

67.5.5.4.1 Worst-case assumptions and formula

To estimate worst-case latency for a channel, assume this worst-case condition: the channel has just been serviced in a time slot of its priority level, and all other channels in the system are continuously requesting service and have cleared SGRs. The worst-case latency is the time from the end of the channel's service until the end of the channel's next service. See the following figure.

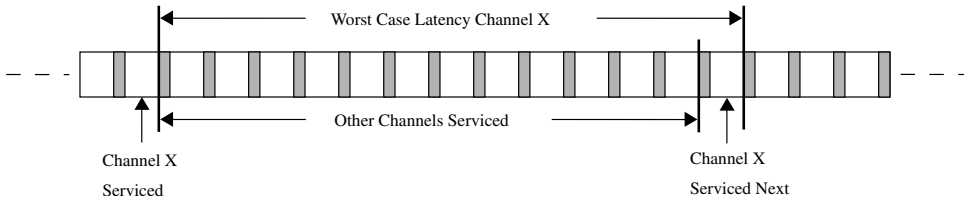

Figure 488. First-pass worst-case latency

To estimate worst-case latency:

- Find the worst-case service time for each active channel.
- Using the H-M-H-L-H-M-H time-slot sequence, map the channels that are granted for each time slot.
- Add time for six-clock time-slot transitions.

67.5.5.4.1.1 Mapping the channels for each time slot

To determine when a channel will be serviced again, it is necessary to determine which other channels will be serviced first. Do this by assuming all channels are continuously requesting service and mapping the channels into the time-slot sequence.

67.5.5.4.1.2 Adding time for time-slot transitions

Add six eTPU clocks for time-slot transitions which occur after each time slot.

67.5.5.4.2 First-pass analysis worst-case latency examples

The examples in this section assume the system configuration shown in the following table.

Table 472. System configuration example

Channel	Priority	Function[1,2]
0	High	PWM (driving a DC motor)
1	Middle	PPWA (Mode 0, measuring the DC motor speed)
2	Low	DIO (Input)

1. 9% RAM Collision Rate (RCR)
2. CPU clock rate = 40 MHz, or 25 ns per clock period

67.5.5.4.2.1 Finding the WCL for PWM on channel 0

The following shows how to find the WCL for PWM on channel 0.

1. Find the worst-case service time for each active channel.
   a. Longest thread of PWM is 24 CPU clocks with four RAM accesses.

      24 + ((4 RAM accesses+1) * 0.09 * 2 CPU clock waits) = 24.9 CPU clocks, rounded up to 25 CPU clocks (since there are no partial clock periods)

      Channel 0 worst-case service time = 25 CPU clocks.

   b. Longest thread of PPWA in mode 0 is 44 CPU clocks with nine RAM accesses.

      44 + ((9 RAM accesses+1) * 0.09 * 2 CPU clock waits) = 45.8 CPU clocks, rounded up to 46 CPU clocks

      Channel 1 worst-case service time = 46 CPU clocks.

   c. Longest thread of DIO is ten CPU clocks with four RAM accesses.

      10 + ((4 RAM accesses+1) * 0.09 * 2 CPU clock waits) = 10.9 CPU clocks, rounded up to 11 CPU clocks

      Channel 2 worst-case service time = 11 CPU clocks.
2. Assume channel 0 has just been serviced and that channels 1 and 2 are continuously requesting service. Using the H-M-H-L-H-M-H time-slot sequence, map the channels that are granted for each time slot. See the following figure.

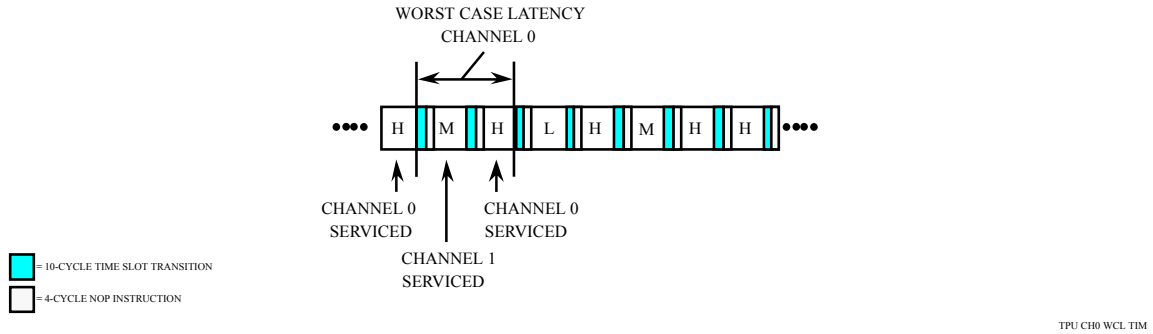

Figure 489. Next servicing for channel 0

Channel 1 will be serviced in the middle-priority time slot before channel 0 is serviced again.

3. Add time for the six-clock CPU time-slot transitions. See the above figure and the following table.

   A four-clock NOP occurs after each channel is serviced since there is one channel in each priority level, i.e., a new cycle for a priority level is started after each channel is serviced. Time-slot transitions occur after each time slot.

Table 473. Worst-case latency for channel 0

Channel 0 worst-case service time	25 clocks
Channel 1 worst-case service time	46 clocks
Two 6-clock time-slot transitions	12 clocks
Total clocks	83 clocks

83 clocks * 25 ns/clock = 2075 ns

Conclusion: in this system configuration PWM can run with a minimum high time or low time of 2075 ns.

Note that in double match eTPU system the PWM can be serviced once in each period, and there is no latency for minimum high time. The latency in eTPU PWM function will represent the minimum PWM period.

67.5.5.4.2.2 Finding the WCL for PPWA on channel 1

The following shows how to find the WCL for PPWA on channel 1.

1. Find the worst-case service time for each active channel. See step 1 of previous example.
2. Assume channel 1 has just been serviced and that channels 0 and 2 are continuously requesting service. Using the H-M-H-L-H-M-H time-slot sequence, map the channels that are granted for each time slot. See the following figure.

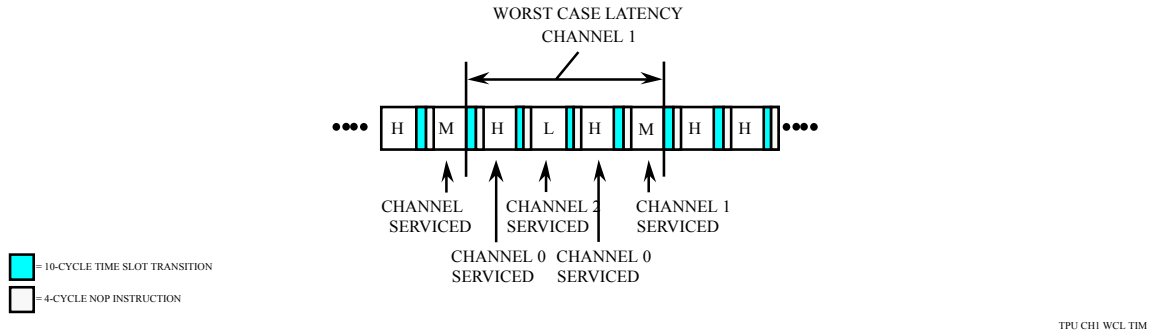

Figure 490. Next servicing for channel 1

Channel 0 will be serviced twice and channel 2 once before channel 1 is serviced again.

3. Add time for the six-clock CPU time-slot transitions. See the above figure and the following table.

Table 474. Worst case latency for channel 1

Two Channel 0 worst-case service times	50 clocks
Channel 1 worst-case service time	46 clocks
Channel 2 worst-case service time	11 clocks
Four 6-clock time-slot transitions	24 clocks
Total clocks	131 clocks

131 clocks * 25 ns/clock = 3275 ns

Conclusion: in this system configuration PPWA can measure a period or pulse of minimum 3275 ns.

Note that PPWA function optimized for eTPU hardware can use double transition mode to measure very narrow pulses with one service after the second transition, and latency will affect only the minimum gap between two input pulses. Also the function threads would have more efficient coding.

67.5.5.4.2.3 Finding the WCL for DIO on channel 2

The following shows how to find the WCL for DIO on channel 2.

1. Find the worst-case service time for each active channel. See step 1 of previous examples.
2. Assume channel 2 has just been serviced and that channels 0 and 1 are continuously requesting service. Using the H-M-H-L-H-M-H time-slot sequence, map the channels that are granted for each time slot. See the following figure.

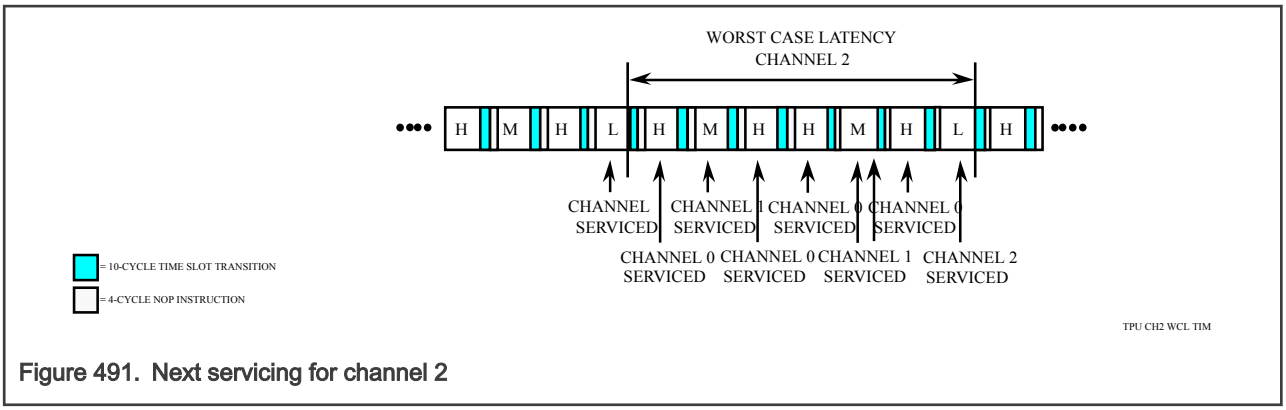

Figure 491. Next servicing for channel 2

Channel 0 will be serviced four times and channel 1 twice before channel 2 is serviced again.

3. Add time for the ten-clock CPU time-slot transitions and the four-clock NOPs. See the above figure and the following figure.

Table 475. Worst case latency for channel 2

Four Channel 0 worst-case service times	100 clocks
Two Channel 1 worst-case service time	92 clocks
Channel 2 worst-case service time	11 clocks
Seven 6-clock time-slot transitions	42 clocks
Total clocks	245 clocks

245 clocks * 25 ns/clock = 6125 ns

Conclusion: in this system configuration DIO can keep track of the input level at a minimum of every 6125 ns.

Note that DIO function optimized for eTPU hardware can use double transition mode to measure two pin transitions at a time and reduce the service time, improving the overall system performance and latency.

67.5.5.5 Second-Pass Worst-Case Latency Analysis

Following is an example of a second-pass analysis for calculating worst-case latency for a channel. The second-pass analysis is useful for higher-performance systems, since it gives a more realistic worst-case latency result than first-pass analysis.

This example uses a relatively simple system in order to illustrate the basic principles of second-pass analysis. For a more complex example of second-pass analysis, refer to Multiphase Motor Commutation TPU Function (COMM)(TPUPN09/ D).

67.5.5.5.1 Second-Pass Analysis Guidelines

Rather than use a fixed formula, a second-pass analysis relies on the application of the following guidelines.

1. The first-pass analysis makes the assumption that all channels in the system are continually requesting service. For many systems this is an unrealistic assumption. For example, if TCR1 is counting at a rate of 2 MHz (500 ns per count) and a channel is running the DIO function with a match rate of 20,000 TCR1 counts, the DIO will request service every 10 ms (20,000 * 500 ns = 10,000,000 ns or 10 ms). It is therefore unrealistic to assume that the channel running this DIO function is continuously requesting service. Figure out a realistic service request rate for each channel. Time slots can then be mapped to each channel at the real rate of request.
2. If a function is active during system initialization but not during the high-speed running mode of the system, then that system does not need to be included in the high-speed worst-case latency calculations.
3. Use a realistic SDM collision rate.

4. Be careful when assigning functions priority levels and channel numbers. Decide which function or functions will be most difficult to make perform at the desired level. Assign those channels high priority and low channel numbers. Try different priority and channel assignments to see how it affects the system.
5. The seven-slot sequence of || H | M | H | L | H | M | H || is asymmetrical when put back-to-back with other seven-slot sequences. Note that in the following sequence there are two high-priority slots next to each other:

   || H | M | H | L | H | M | H |||| H | M | H | L | H | M | H ||
6. Make sure that when mapping out channels to the sequence, you choose a worst-case slot to start the mapping. For example, when estimating WCL for a high-priority channel, do not start the mapping in the last high-priority slot in a seven-slot sequence, as that is a best case for a high-priority channel since another high-priority time slot is next.
7. Instead of always using the longest thread in the function as the worst-case thread, evaluate the threads in the function that will be used in the system and use the appropriate worst-case threads. For example, in the preceding example of first-pass analysis, the PWM was shown to be able to achieve a high time and low time of 2475 ns under worst-case conditions. This was derived using the longest PWM thread of 24 CPU clocks. This longest thread is actually thread 2, the thread that is entered after the pin has just gone high. Thread 3, the thread that is entered after the pin has just gone low, requires only 2 CPU clocks. Therefore, in the first-pass example, the high time was correctly derived, but the low time is actually shorter than was estimated.

67.5.5.5.2 Second-pass analysis example

This example requires three 50% PWM waveforms: one 5 kHz (200 ms/period) and two 50 kHz (20 ms/period), each running DC motors. (Remember that the PWM function requests service from the eTPU after each high time and after each low time, so the eTPU must handle a request every 100 ms for the 5 kHz PWM and every 10 ms for the 50 MHz PWM.)

NOTE

This example uses square waves for simplicity. Notice that to use a PWM waveform in the typical way, in which the pulse is modulated, the pulse must not be modulated in a way that violates the worst-case latency requirements.

This example also uses one DIO channel monitoring a signal level every millisecond and one PPWA channel in mode 0 monitoring the speed of the 5-kHz DC motor. The PPWA must measure periods of 5 kHz (200 ms/period).

The CPU is interrupted by the channel running the PPWA function after measuring 200 periods (every 40 ms). The interrupt service routine performs an averaging of the period accumulation and checks it against a known parameter. The interrupt service time is so short and infrequent that it is a tiny fraction of total system time. The interrupt service routine contains no polling of the SDM. Therefore a realistic RCR = 0%.

67.5.5.5.2.1 First-try system configuration

Try a system configuration that seems likely to work. If it does not, change priority levels or channel numbers.

The 5 kHz and 50 kHz PWMs are the most time-critical functions. Those are assigned high priority. PPWA is assigned middle priority. The DIO is low performance and is assigned low priority. Refer to the following table.

Table 476. First-try system configuration

Channel	Priority	Function[1], [2]
0	High	PWM at 50 kHz (needs a 4-µs WCL)
1	High	PWM at 50 kHz (needs a 4-µs WCL)
2	High	PWM at 5 kHz (needs a 40-µs WCL)
8	Middle	PPWA at 5 kHz (needs a 80-µs WCL)
15	Low	DIO as input at rate of 1 ms

1. 0% RAM collision rate
2. CPU clock rate = 40 MHz, or 60 ns per clock period

With this system configuration, worst-case service time for each active channel is determined as follows:

1. Longest thread of PWM is 24 CPU clocks with four RAM accesses.

   24 + ((4 RAM accesses+1) * 0 * 2 CPU clock waits) = 24 CPU clocks

   Channels 0-2 worst-case service time = 24 CPU clocks.

2. Longest thread of PPWA in mode 0 is 44 CPU clocks with nine RAM accesses.

   44 + ((9 RAM accesses +1)* 0 * 2 CPU clock waits) = 44 CPU clocks

   Channel 8 worst-case service time = 44 CPU clocks.

3. Longest thread of DIO is ten CPU clocks with four RAM accesses.

   10 + ((4 RAM accesses+1) * 0 * 2 CPU clock waits) = 10 CPU clocks

   Channel 15 worst-case service time = 10 CPU clocks.

   To find the WCL for channel 0, assume channel 0 has just finished service.

   Map the channels in the H-M-H-L-H-M-H sequence. See the following figure.

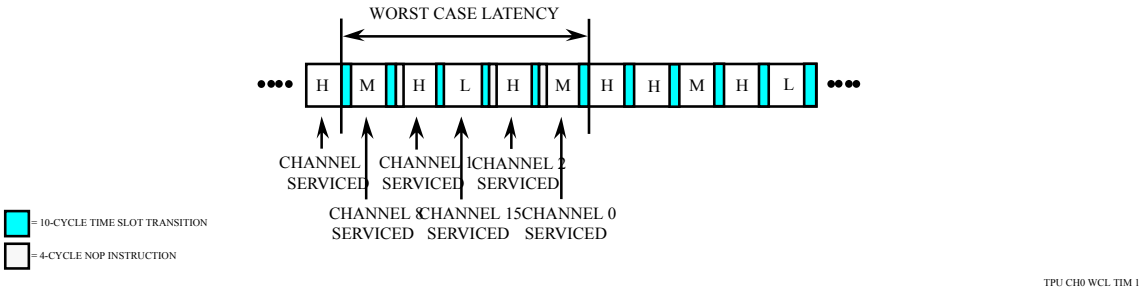

Figure 492. Worst-case latency for channel 0 first try

Conclusion: with this system configuration, worst-case latencies for channels 0 and 1 are too high (WCL for channel 1 is the same as WCL for channel 0). Try a different system configuration.

67.5.5.5.2.2 Second-try system configuration

The second-try system configuration is shown in the following table.

Table 477. Second-try system configuration

Channel	Priority	Function[1], [2]
0	High	PWM at 50 kHz (needs a 4-µs WCL)
1	High	PWM at 50 kHz (needs a 4-µs WCL)
2	Middle	PWM at 5 kHz (needs a 40-µs WCL)
8	Middle	PPWA at 5 kHz (needs a 80-µs WCL)
15	Low	DIO as input at rate of 1 ms

1. 0% RAM collision rate

2. CPU clock rate = 40 MHz, or 60 ns per clock period

To find the WCL for channel 0, assume channel 0 has just finished service. Map the channels in the H-M-H-L-H-M-H sequence. See the following figure.

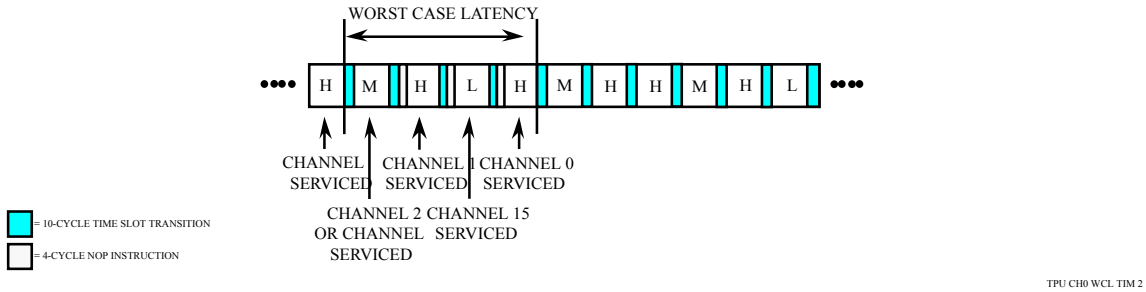

Figure 493. Worst-case latency for channel 0 second try

Conclusion: with this system configuration, the WCL of both channel 0 and channel 1 is 3.85 ms, which is within the limit of 4 ms needed for a 50-kHz PWM.

Next, find the WCL for channel 2. Assume channel 2 has just finished service. Map the channels in the H-M-H-L-H-M-H sequence. See the following figure.

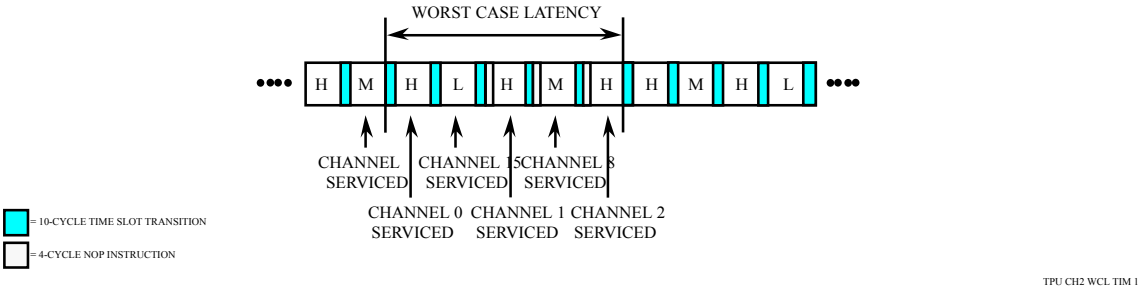

Figure 494. Worst-case latency for channel 2

Conclusion: with this system configuration, the WCL for channels 2 and 8 is 4.7 ms, which is within the 40 and 80 ms WCL requirements.

Notice that channels 2 and 8 are well within their WCL requirements. The system could be reconfigured as shown in the following table to give channels 0 and 1 a larger margin while still keeping channels 2, 8 and 15 within their WCL requirements.

Table 478. Second-try system with channel 0 and 1 reconfigured

Channel	Priority	Function[1,2]
0	High	PWM at 50 kHz (needs a 10-µs WCL)
1	High	PWM at 50 kHz (needs a 10-µs WCL)
2	Middle	PWM at 5 kHz (needs a 40-µs WCL)
8	Low	PPWA at 5 kHz (needs a 80-µs WCL)
15	Low	DIO as input at rate of 1 ms

1. 0% RAM collision rate
2. CPU clock rate = 40 MHz, or 60 ns per clock period

67.5.6 Endianness

The following table shows the parameter addresses for big and little endian machines.

Table 479. Parameter Addresses and Endianness

Parameter	byte address offset (n = word address offset)	
	big endian	little endian
32-bit	4*n	
24-bit	4*n + 1	4*n
32-bit parameter's most significant byte	4*n	4*n + 3
24-bit parameter's most significant byte	4*n + 1	4*n + 2
least significant byte	4*n + 3	4*n

67.5.7 Memory Error Service Procedures

Follows separate procedures for correctable and non-correctable error interrupt service routines. It is assumed that the non-correctable error ISR has higher priority, and cannot be preempted by the correctable error ISR. For memory error support details, see Memory error support .

NOTE

The memory error support hardware does not (and is not intended to) guarantee that no error occurred will go unreported. However, combined with the procedures below, the information loss is minimized to statistical irrelevance on most scenarios.

67.5.7.1 Non-correctable error service procedure

The basic procedure below can be followed in a Global Exception or a bus error machine check service routine. It handles the service for both SCM and SDM errors, as they are symmetrical at this level. However, a real implementation is likely to split the procedure in two, one for each memory.

1. Confirm/identify the error source, checking assertion of the eTPU Module Configuration Register (MCR) fields SCMERR and SDMERR.
2. Save the state(s) of eTPU Memory Error Control Register (MECR) fields CRDIS/DRDIS.
3. Set the eTPU Memory Error Control Register (MECR) CRDIS/DRDIS = 1 to disable further updates to the respective report registers, guaranteeing coherency.
4. Check whether the report registers were updated by a correctable or non-correctable error; to do this, check the eTPU Code Error Report Syndrome Register (CERSR) syndrome (for SCM) and/or the eTPU Data Error Report Syndrome Register (DERSR) syndromes (for SDM, only those with the respective BE flags asserted). If it is a correctable error report, skip the steps 5 and 6 for the respective memory.
5. Identify the error source (host, microengine or MISC/CDC) by checking the field ERR_ACC in the register(s) eTPU Code Error Report Address Register (CERAR) and eTPU Data Error Report Address Register (DERAR); take or schedule the appropriate application-dependent recover actions.
6. Update error statistics as needed; it may include recording the access source, address, data and syndrome from:
   - eTPU Code Error Report Address Register (CERAR)
   - eTPU Data Error Report Address Register (DERAR)

- eTPU Code Error Report Data Register (CERDR)
- eTPU Data Error Report Data Register (DERDR)
- eTPU Code Error Report Syndrome Register (CERSR)
- eTPU Data Error Report Syndrome Register (DERSR)

7. Save the status of non-correctable error overflows flagged in the eTPU Memory Error Status Register (MESR) fields CNCOVR/DNCOVR.
8. Set the eTPU Memory Error Control Register (MECR) fields CRDIS/DRDIS to the state(s) saved in the step 2. That assures the access coherency of a preempted Correctable Error Service Procedure (which may have set CRDIS/DRDIS before this procedure) is not disturbed.
9. Clear the eTPU Memory Error Status Register (MESR) fields CNCOVR/DNCOVR and CNCERR/DNCERR at once, in a single write to eTPU_MESR_MESR.
10. Use the overrun status saved on step 7 to update the error statistics, as needed.
11. Check the other Global Exception flags in eTPU Module Configuration Register (MCR); take or schedule the appropriate (application dependent) recover actions.
12. Clear the Global Exception, programming MCR[GEC] = 1.

67.5.7.2 Correctable error service procedure

The basic procedure below can be followed in a Memory Error Interrupt service routine (see Interrupts and data transfer requests). It handles the service for both SCM and SDM errors, as they are symmetrical at this level. However, a real implementation is likely to split the procedure in two, one for each memory.

1. Confirm/identify the error source, checking assertion of the eTPU Memory Error Status Register (MESR) fields CCERR/DCERR.
2. Program the eTPU Memory Error Control Register (MECR) fields CRDIS = 1 and/or DRDIS = 1, to disable further updates to the respective report registers, guaranteeing coherency.
3. Check whether the report registers were updated by a correctable or non-correctable error; to do this, check the eTPU Code Error Report Syndrome Register (CERSR) syndrome (for SCM) and/or the eTPU Data Error Report Syndrome Register (DERSR) syndromes (for SDM, only those with the respective BE flags asserted). If it is a non-correctable error report, skip the steps 4 and 5 for the respective memory.
4. Identify the error source (host, microengine or MISC/CDC) by checking the field ERR_ACC in eTPU Code Error Report Address Register (CERAR) and eTPU Data Error Report Address Register (DERAR); take or schedule the appropriate application-dependent recover actions, which may include soft-error fixing (see Error fixing).
5. Update error statistics as needed; it may include recording the access source, address, data and syndrome from:
   - eTPU Code Error Report Address Register (CERAR)
   - eTPU Data Error Report Address Register (DERAR)
   - eTPU Code Error Report Data Register (CERDR)
   - eTPU Data Error Report Data Register (DERDR)
   - eTPU Code Error Report Syndrome Register (CERSR)
   - eTPU Data Error Report Syndrome Register (DERSR)
6. Save the status of correctable error overflows flagged in the eTPU Memory Error Status Register (MESR) fields CCOVR/DCOVR.
7. Program the eTPU Memory Error Control Register (MECR) fields CRDIS/DRDIS=0.
8. Clear the eTPU Memory Error Status Register (MESR) fields CCOVR/DCOVR and CCERR/DCERR at once, in a single write to eTPU_MESR_MESR.

9. Use the saved overrun status to update the error statistics, as needed.

67.6 Memory map/register definition

The guideline for the description of all bits and fields throughout the“Memory Map/Register Definition” section is to provide only a brief explanation (without examples or method of use) of the features, since it will be used mainly as a reference for the reader that is studying the “Functional Description" section, where those features are explained in detail.

67.7 Memory map

The eTPU System simplified memory map is shown in table High-level memory map.. Each of the register areas shown may have their own reserved address areas.

There is a table detailed memory map. Offsets are relative to the eTPU Base address, which is MCU-dependent.

See the chip-specific eTPU information about accessing eTPU registers in chip-level Stop mode.

SCM unused area is decoded and returns a fixed opcode, determined by eTPU SCM Off-range Data Register (SCMOFFDATAR).

Table 480. High-level memory map

Offset	Use
0x00 – 0x1F	System Configuration Registers
0x20 – 0x2F	eTPU 1 Time Base Registers
0x30 – 0x3F	Reserved
0x40 – 0x4F	eTPU 2 Time Base Registers
0x50 – 0x5F	Reserved
0x60 – 0x6F	eTPU 1 Extra Engine Registers
0x70 – 0x7F	eTPU 2 Extra Engine Registers
0x80 – 0xFF	
0x100 – 0x13F	Memory Error Support Registers
0x140 – 0x1FF	Reserved
0x200 – 0x2FF	eTPU 1/2 Global Channel Registers
0x300 – 0x3FF	Reserved
0x400 – 0x7FF	eTPU 1 Channel Registers
0x800 – 0xBFF	eTPU 2 Channel Registers
0xC00 – 0xFFF	Shared Subsystems Integration Registers
0x1000 – 0x3FFF	Reserved[1]
0x4000 – 0x7FFF	SSS - Shared Subsystems area
0x8000 – 0xBFFF	SDM - Shared Data Memory
0xC000 – 0xFFFF	SDM PSE mirror[2]
0x10000 – 0x1FFFF	SCM - Shared Code Memory[3]

1. ETPU reserved area space 0x1000 - 0x3FFF does not generate bus errors and reads as 0.
2. Parameter Sign Extension access area, see Parameter Access.
3. SCM access is available only when bit VIS=1 on register eTPU_SCR_MCR, under certain conditions (see eTPU Module Configuration Register (MCR)).

Offset	Use
0x1000 - 0x3FFF	Reserved[3]
0x4000 - 0x7FFF	Shared Subsystems area - SSS
0x8000 - 0xBFFF	Shared Data Memory - SDM
0xC000 - 0xFFFF	Shared Data Memory - SDM - PSE mirror [4]
0x10000-1FFFF[5]	Shared Code Memory - SCM[6]

1. This register is not implemented in some MCUs; see eTPU SCM Off-range Data Register (SCMOFFDATAR).
2. These registers are not implemented in some MCUs; see Memory error support .
3. ETPU reserved area space 0x1000 - 0x3FFF does not generate bus errors and reads as 0.
4. Parameter Sign Extension access area, see Parameter Access.
5. The actual SCM size is MCU-dependent (see the chip-specific eTPU information). SCM is allocated from the starting value of the given range of offsets. When the size is not the maximum, the unused SCM address range returns the value of eTPU SCM Off-range Data Register (SCMOFFDATAR).
6. SCM access is available only when eTPU_SCR_MCR[VIS] = 1, under certain conditions (see MCR[VIS]).

67.8.1.2 eTPU Module Configuration Register (MCR)

Offset

Register	Offset
MCR	0h

Function

This register is global to both eTPU engines, and resides in the shared BIU. It gathers global configuration and status in the eTPU system, including global exception. It is also used for configuring the SCM (shared code memory) operation and test.

Diagram

Fields

Field	Function
31 GEC	Global Exception Clear. This write-only bit negates global exception request and clears global exception status bits SDMERR, SSAERR, SCMERR, WDTO1/2, MGE1/2, ILF1/2, and SCMMISF. GEC works the same way with either one or both Engines in Module Disable Mode. 0b - Keep Global Exception request and status bits SDMERR, SSAERR, SCMERR, WDTO1/2, ILF1/2, MGE1/2, and SCMMISF as is. 1b - Negate Global Exception, clear status bits SDMERR, SSAERR, SCMERR, WDTO1/2, ILF1/2, MGE1/2, and SCMMISF.
30 SDMERR	SDM Read Error This flag indicates that an SDM non-correctable read error occurred on a microengine or host (including CDC) read, generating a Global Exception. This bit is cleared by writing 1 to GEC. 0b - No Global Exception pending because of SDM read error. 1b - Global Exception requested by SDM read error is pending.
29 WDTO1	Watchdog 1 Timeout. Flag WDTO1 indicates that a Watchdog Timeout occurred in engine 1, generating a Global Exception. This bit is cleared by writing 1 to GEC. 0b - No Global Exception pending because of Watchdog timeout. 1b - Global Exception requested by Watchdog timeout.
28 WDTO2	Watchdog 2 Timeout. Flag WDTO2 indicates that a Watchdog Timeout occurred in engine 2, generating a Global Exception. This bit is cleared by writing 1 to GEC. 0b - No Global Exception pending because of Watchdog timeout.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Global Exception requested by Watchdog timeout.
27 MGE1	Microcode Global Exception Engine 1. This bit indicates that a global exception was asserted by microcode executed on engine 1. The determination of the reason why the global exception was asserted is application dependent: it can be coded in an SDM status parameter, for instance. This bit is cleared by writing 1 to GEC. 0b - No microcode-requested global exception pending. 1b - Global exception requested by microcode is pending.
26 MGE2	Microcode Global Exception Engine 2. This bit indicates that a global exception was asserted by microcode executed on engine 2. The determination of the reason why the global exception was asserted is application dependent: it can be coded in an SDM status parameter, for instance. This bit is cleared by writing 1 to GEC. 0b - No microcode-requested global exception pending. 1b - Global exception requested by microcode is pending.
25 ILF1	Illegal Instruction Flag for Engine 1. The ILFA1 flag is set by the microengine to indicate that an illegal instruction was decoded in Engine 1. This bit is cleared by host writing 1 to GEC. See Illegal instructions for more details. 0b - Illegal Instruction not detected. 1b - Illegal Instruction detected by Engine 1.
24 ILF2	Illegal Instruction Flag for Engine 2. The ILFA2 flag is set by the microengine to indicate that an illegal instruction was decoded in Engine 2. This bit is cleared by host writing 1 to GEC. See Illegal instructions for more details. 0b - Illegal Instruction not detected. 1b - Illegal Instruction detected by Engine 2.
23 SSAERR	Shared Subsystem Access Error. This flag indicates that a bus error occurred in an microengine access to the Shared Subsystem Area (see Shared subsystems support). This bit is cleared by writing 1 to GEC. **NOTE** Bus errors on host accesses to the Shared Subsystem Area do not set this bit neither asserts the Global Exception, but the bus error is propagated to the host CPU 0b - No bus error returned on a microengine Shared Subsystem Area access. 1b - Bus error returned on a microengine Shared Subsystem Area access.
22 —	Reserved
21	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
20-16 SCMSIZE	SCM Size = 64 Kbytes. This read-only field holds the number of 2 KB SCM Blocks minus 1. See the chip-specific eTPU information for this field's reset value.
15 —	Reserved
14 —	Reserved
13-12 —	Reserved
11 SCMMISC	SCM MISC Complete flag. Flag SCMMISC indicates that MISC has completed the evaluation of the SCM signature since reset or since the last time it was cleared. SCMMISC is cleared by writing 1 to it, and is not cleared when MISC is disabled (SCMMISEN=0). SCMMISC asserts at the end of the SCM memory scan, either if the signature matches or not. 0b - MISC has not yet completed an SCM signature calculation and compare since the last time SCMMISC was cleared. 1b - MISC completed at least one SCM signature calculation and compare since the last time SCMMISC was cleared.
10 SCMMISF	SCM MISC Flag. The SCMMISF bit is set by the SCM MISC (Multiple Input Signature Calculator) logic to indicate that the calculated signature does not match the expected value in eTPU MISC Compare Register (MISCCMPR), at the end of a MISC iteration. See SCM test - multiple input signature calculator for more details. This bit is cleared when Global Exception is cleared by writing 1 to GEC. 0b - Signature mismatch not detected. 1b - MISC has read entire SCM array and the expected signature does not match the value calculated.
9 SCMMISEN	SCM MISC Enable. The SCMMISEN bit is used for enabling/disabling the operation of the MISC logic. SCMMISEN is readable and writable at any time. The MISC logic will only operate when this bit is set to 1. When the bit is reset, the MISC address counter is set to the initial SCM address. When enabled, the MISC will continuously cycle through the SCM addresses, reading each and calculating a CRC. In order to save power, the MISC can be disabled by clearing the SCMMISEN bit. See SCM test - multiple input signature calculator for more details. SCMMISEN resets automatically when MISC logic detects an error, i.e., when SCMMISF transitions from 0 to 1, disabling the MISC operation.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - MISC operation disabled. The MISC logic is reset to its initial state. 1b - MISC operation enabled.
8 SCMERR	SCM Read Error. This flag indicates that an SCM non-correctable read error occurred on a host or microengine (including MISC) read, generating a Global Exception. This bit is cleared by writing 1 to GEC. 0b - No Global Exception pending because of SCM read error. 1b - Global Exception requested by SCM read error is pending.
7 —	Reserved
6 VIS	SCM Visibility Bit. VIS bit turns SCM visible to the IP-Bus and resets MISC state (but SCMMISEN keeps its value). This bit is write protected when any of the Engines is not halted or stopped. When VIS=1, the MDIS bits in the eTPU Memory Error Support registers are write protected. 0b - SCM is not visible to the slave bus. Accessing SCM address space issues a bus error, writes are protected and reads are meaningless. 1b - SCM is visible to the slave bus. MISC state is reset.
5-1 —	Reserved
0 GTBE	Global Time Base Enable. GTBE enables time bases in both Engines, allowing them to be started synchronously. **NOTE** Global Time Base Enable action may also depend on other blocks, as explained in Global time base enable (GTBE). **NOTE** When GTBE is turned off with Angle Mode enabled, the EAC must be reinitialized before GTBE is turned on again. The EAC reinitialization procedure is described in Restarting angle logic. 0b - Time bases in both Engines are disabled to run. 1b - Time bases in both Engines are enabled to run.

67.8.1.3 eTPU Coherent Dual-Parameter Controller Register (CDCR)

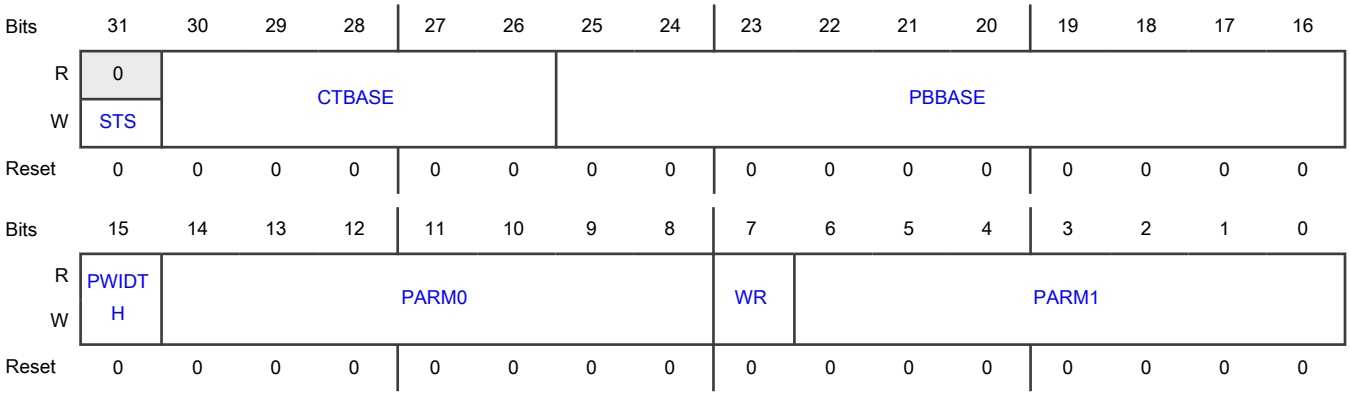
Offset

Register	Offset
CDCR	4h

Function

This register configures and controls dual-parameter coherent transfers. For more information, see Coherent Dual-parameter Controller (CDC).

Diagram



Fields

Field	Function
31 STS	Start Bit. This bit is set by the host in order to start the data transfer between the parameter buffer pointed by PBBASE and the target addresses selected by the concatenation of fields CTBASE and PARM0/1. The host receives wait-states until the data transfer is complete, when this bit is reset by the coherency logic (see Coherent Dual-parameter Controller (CDC)). Therefore, host always reads STS as 0. 0b - Write does not start a coherent transfer. 1b - Write starts a coherent transfer.
30-26 CTBASE	Channel Transfer Base. This field concatenates with fields PARM0 and PARM1 to determine the absolute word offset (from the SDM base) of the parameters to be transferred: Parameter 0 word address = {CTBASE, PARM0} + SDM base word address. Parameter 1 word address = {CTBASE, PARM1} + SDM base word address.
25-16 PBBASE	Parameter Buffer Base Address.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field points to the base address of the parameter buffer location, with granularity of 2 parameters (8 bytes). The host (byte) address of the first parameter in the buffer is PBBASE * 8 + SDM Base Byte Address. The microengine absolute (word) address of the first parameter in the buffer is PBBASE * 2.
15 PWIDTH	Parameter Width Selection. This bit selects the width of the parameters to be transferred between the PB and the target address. 0b - Transfer 24-bit parameters. The upper byte remains unchanged in the destination address. 1b - Transfer 32-bit parameters. All 32 bits of the parameters are written in the destination address.
14-8 PARM0	Channel Parameter number 0. The PARM0 and PARM1 fields in concatenation with CTBASE determine the word address offset (from the SDM base) of the parameters that are destination or source (defined by WR) of the coherent transfer. The word SDM address offset of the parameters are {CTBASE, PARM0/1}. **NOTE** PARM0 and PARM1 allow non-contiguous parameters to be transferred coherently. The parameter pointed by {CTBASE, PARM0} is the first transferred.
7 WR	Read/Write selection. This bit selects the direction of the coherent data transfer. 0b - Read operation. Data transfer is from the selected SDM address to the PB. 1b - Write operation. Data transfer is from the PB to the selected SDM address.
6-0 PARM1	Channel Parameter number 1. The PARM0 and PARM1 fields in concatenation with CTBASE determine the word address offset (from the SDM base) of the parameters that are destination or source (defined by WR) of the coherent transfer. The word SDM address offset of the parameters are {CTBASE, PARM0/1}. **NOTE** PARM0 and PARM1 allow non-contiguous parameters to be transferred coherently. The parameter pointed by {CTBASE, PARM0} is the first transferred.

67.8.1.4 eTPU MISC Compare Register (MISCCMPR)

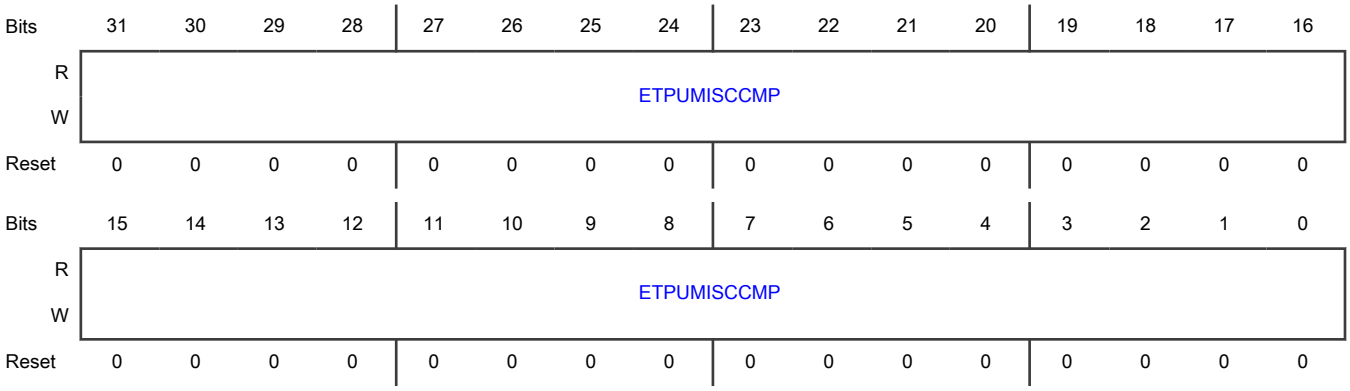
Offset

Register	Offset
MISCCMPR	Ch

Function

This register holds the 32-bit signature expected from the whole SCM array. This register must be written by the host with the 32-bit word to be compared against the calculated signature at the end of the MISC cycle. This register is global to both eTPU Engines. For more detail, see SCM test - multiple input signature calculator.

Diagram



Fields

Field	Function
31-0 ETPUMISCCMP	Expected Multiple Input Signature Register value. For details, see SCM test - multiple input signature calculator.

67.8.1.5 eTPU SCM Off-range Data Register (SCMOFFDATAR)

Offset

Register	Offset
SCMOFFDATAR	10h

Function

This register holds the 32-bit value returned when SCM array is accessed at non-implemented addresses, either by the Host or by the microengine. This register can be written by the host with the 32-bit instruction to be executed by the microengine to recover from runaway code. This register is global to both eTPU Engines. For more detail see SCM off-range data.

Diagram

Field	Function
31-0 ETPUSCMOFFDATAR	SCM Off-range read data value. See SCM off-range data.

67.8.1.6 eTPU Engine 1 Configuration Register (ECR_ENG1)

Offset

Register	Offset
ECR_ENG1	14h

Function

This register holds configuration and status fields for engine 1.

NOTE

See Register Reset Values in the chip-specific eTPU information.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R		MDIS	0	STF	0				HLTF	0			FCSS	FPSCK		
W	FEND															
Reset	0	u[1]	0	0	0	0	0	0	u[2]	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	CDFC		0	ERBA					SPPDIS	0			ETB			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Reset value is 1.

2. HLTF field reset value is 1 if, after a reset, the eTPU Nexus debug support is on and a breakpoint request is asserted. Otherwise the reset value is 0.

Fields

Field	Function
31 FEND	Force End. FEND assertion terminates any current running thread as if an END instruction have been executed (see Ending Current Thread - END). This bit is self-negating when the thread ends. **NOTE** Only on rare occasions (e.g., during a long stall, see Microengine Stall) FEND can be read as 1, because it negates as soon as the end begins execution. Writing FEND = 1 is ignored and FEND stays 0 when the microengine is in TST, halted, stopped, or idle (no thread executing). 0b - Normal operation. 1b - Ends any ongoing thread.
30 MDIS	Module Disable Bit. When MDIS is set, the Engine shuts down its internal clocks, going into Module Disable Mode. TCR1 and TCR2 cease to increment, and input sampling stops. The Engine asserts the stop flag (STF) bit to indicate that it has stopped. However, the BIU continues to run, and the Host can access all registers except for the channel registers (see channel registers starting with C*a*CR_ENG1) **NOTE** The Timebase registers can still be read with MDIS=1, but writes are ineffective and a Bus Error is issued. Global Channel Registers and SDM can be accessed normally. After MDIS is set, even before STF asserts, data read from the channel registers is not meaningful and writes are ineffective, issuing a Bus Error. When the MDIS bit is asserted while the microcode is executing, the eTPU will stop when the thread is complete. Stop completes on the next eTPU clock after the stop condition is valid. **NOTE** Once MDIS is switched from 1 to 0 or vice versa, it must not write a different value until STF changes accordingly. The MDIS bit is write-protected when VIS=1. See Register Reset Values in the chip-specific eTPU information. 0b - eTPU Engine runs. 1b - Commands Engine to stop its clocks.
29 —	Reserved
28	Stop Flag Bit.

Table continues on the next page...

Table continued from the previous page...

Field	Function
STF	Each Engine asserts its stop flag (STF) to indicate that it has stopped. Only then the host can assume that the Engine has actually stopped. The eTPU system is fully stopped when the STF bits of both eTPU Engines are asserted. In case of a stop request, the eTPU responds by acknowledging stop only after both eTPU 1 and eTPU 2 have been stopped. Engine only stops when any ongoing thread is complete also in this case. Summarizing Engine stop conditions, which STF reflects: STF_1 := (after stop completed) MDIS_1 | device stop request. STF_2 := (after stop completed) MDIS_2 | device stop request. STF_1 and STF_2 mean STF bit from engine 1 and STF bit from engine 2, respectively. See Register Reset Values in the chip-specific eTPU information. 0b - Engine is operating. 1b - Engine has stopped (after the local MDIS bit has been asserted, or after the IP-Bus stop line has been asserted).
27-24 —	Reserved
23 HLTF	Halt Mode Flag. If eTPU Engine entered halt state, this flag is asserted. The flag remains asserted while the microengine is in halt state, even during a single-step or forced instruction execution. See Development support features for further details about entering Halt Mode. 0b - eTPU Engine is not halted. 1b - eTPU Engine is halted.
22-20 —	Reserved
19 FCSS	Filter Clock Source Selection Speeds up the filter clock source before the prescaler, allowing more input capture resolution at minimum prescaling. **NOTE** FCSS=1 also makes the channel work on T2/T4 timing mode (see T2/T4 channel timing). 0b - Use eTPU clock / 2 as EDF clock source before prescaler. 1b - Use eTPU clock as EDF clock source before prescaler
18-16 FPSCK	Filter Prescaler Clock Control. FPSCK controls the prescaling of the clocks used in digital filters for the channel input signals and TCRCLK input, as shown in the table below. Filtering can be controlled independently by each engine, but all input digital filters in the same engine have same clock prescaling. For more details, see Filter clock prescaler. A new value written to FPSCK only becomes effective when the filter prescaler finishes the current count.

Table continues on the next page...

Table continued from the previous page...

Field	Function
ERBA	This field value is concatenated with the AID instruction field in engine relative address mode to form the SDM address (see Engine Relative Addressing Mode).
7 SPPDIS	Schedule Priority Passing Disable. SPPDIS is used to disable the priority passing mechanism of the microengine scheduler (see Primary scheme - priority among channels on different levels). **NOTE** SPPDIS bit must not be changed while any channel is enabled. 0b - Scheduler priority passing mechanism enabled. 1b - Scheduler priority passing mechanism disabled.
6-5 —	Reserved
4-0 ETB	Entry Table Base. The field determines the location of the microcode entry table for the eTPU functions in SCM (see Entry Points). The following table shows the entry table base address options.

ETB	Entry Table Base Address for CPU Host Address (byte format)	Entry Table Base Address for Microcode Address (word format)
00000	0x000	0x000
00001	0x800	0x200
00010	0x1000	0x400
--------	----------	---------
11110	0xF000	0x3C00
11111	0xF800	0x3E00

67.8.1.7 eTPU Engine 2 Configuration Register (ECR_ENG2)

Offset

Register	Offset
ECR_ENG2	18h

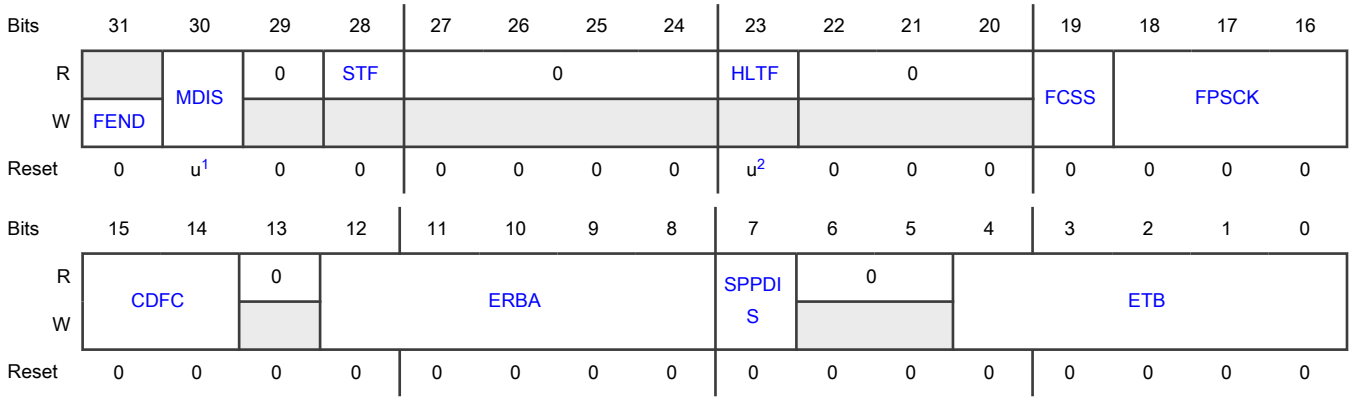
Function

This register holds configuration and status fields for engine 2.

NOTE

See Register Reset Values in the chip-specific eTPU information.

Diagram



1. Reset value is 1.
2. HLTF field reset value is 1 if, after a reset, the eTPU Nexus debug support is on and a breakpoint request is asserted. Otherwise the reset value is 0.

Fields

Field	Function
31 FEND	Force End. FEND assertion terminates any current running thread as if an END instruction have been executed (see Ending Current Thread - END). This bit is self-negating when the thread ends. **NOTE** Only on rare occasions (e.g., during a long stall, see Microengine Stall) FEND can be read as 1, because it negates as soon as the end begins execution. Writing FEND = 1 is ignored and FEND stays 0 when the microengine is in TST, halted, stopped, or idle (no thread executing). 0b - Normal operation. 1b - Ends any ongoing thread.
30 MDIS	Module Disable Bit. When MDIS is set, the Engine shuts down its internal clocks, going into Module Disable Mode. TCR1 and TCR2 cease to increment, and input sampling stops. The Engine asserts the stop flag (STF) bit to indicate that it has stopped. However, the BIU continues to run, and the Host can access all registers except for the channel registers (see channel registers starting with eTPU Channel Configuration-Control registers) **NOTE** The Timebase registers can still be read with MDIS=1, but writes are ineffective and a Bus Error is issued. Global Channel Registers and SDM can be accessed normally. After MDIS is set, even before STF asserts, data read from the channel registers is not meaningful and writes are ineffective, issuing a Bus Error. When the MDIS bit is asserted while the microcode is executing, the eTPU will stop when the thread is complete. Stop completes on the next eTPU clock after the stop condition is valid.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE Once MDIS is switched from 1 to 0 or vice versa, it must not write a different value until STF changes accordingly. The MDIS bit is write-protected when VIS=1. See Register Reset Values in the chip-specific eTPU information. 0b - eTPU Engine runs. 1b - Commands Engine to stop its clocks.
29 —	Reserved
28 STF	Stop Flag Bit. Each Engine asserts its stop flag (STF) to indicate that it has stopped. Only then the host can assume that the Engine has actually stopped. The eTPU system is fully stopped when the STF bits of both eTPU Engines are asserted. In case of IP-Bus stop, the eTPU system responds by acknowledging stop only after both eTPU 1 and eTPU 2 have been stopped. Engine only stops when any ongoing thread is complete also in this case. Summarizing Engine stop conditions, which STF reflects: STF_1 := (after stop completed) MDIS_1 | device stop request. STF_2 := (after stop completed) MDIS_2 | device stop request. STF_1 and STF_2 mean STF bit from engine 1 and STF bit from engine 2, respectively. See Register Reset Values in the chip-specific eTPU information. 0b - Engine is operating. 1b - Engine has stopped (after the local MDIS bit has been asserted, or after the IP-Bus stop line has been asserted).
27-24 —	Reserved
23 HLTF	Halt Mode Flag. If eTPU Engine entered halt state, this flag is asserted. The flag remains asserted while the microengine is in halt state, even during a single-step or forced instruction execution. See Development support features for further details about entering Halt Mode. 0b - eTPU Engine is not halted. 1b - eTPU Engine is halted.
22-20 —	Reserved
19	Filter Clock Source Selection

Table continues on the next page...

Table continued from the previous page...

Field	Function
FCSS	Speeds up the filter clock source before the prescaler, allowing more input capture resolution at minimum prescaling. **NOTE** FCSS=1 also makes the channel work on T2/T4 timing mode (see T2/T4 channel timing). 0b - Use eTPU clock / 2 as EDF clock source before prescaler. 1b - Use eTPU clock as EDF clock source before prescaler
18-16 FPSCK	Filter Prescaler Clock Control. FPSCK controls the prescaling of the clocks used in digital filters for the channel input signals and TCRCLK input, as shown in the table below. Filtering can be controlled independently by each engine, but all input digital filters in the same engine have same clock prescaling. For more details, see Filter clock prescaler. A new value written to FPSCK only becomes effective when the filter prescaler finishes the current count.

Filter control	Sample on system clock divided by:
000	2
001	4
010	8
011	16
100	32
101	64
110	128
111	256

15-14 CDFC	Channel Digital Filter Control. These bits select a digital filtering mode for the channels when configured as inputs for improved noise immunity (refer to the table below). The eTPU has three digital filtering modes for the channels which provide programmable trade-off between signal latency and noise immunity (see Enhanced digital filter (EDF)). Changing CDFC during eTPU normal input channel operation is not recommended since it changes the behavior of the transition detection logic while executing its operation.

CDFC	Selected digital filter
00	TPU2/3 Two Sample Mode: Using the filter clock which is the system clock divided by (2, 4, 8,..., 256) as a sampling clock (selected by FPSCK),"/>), comparing two consecutive samples which agree with each other sets the input signal state. This is the default reset state.
01	eTPU bypass mode: the input signal is taken unfiltered, also making the channels work on T2/T4 timing mode.[1]

67.9 Timebase memory map and registers

67.9.1 eTPU_TBR register descriptions

Time Base registers allows configuration and visibility of internally-generated time bases TCR1 and TCR2. There is one of each of these registers for each eTPU Engine.

NOTE

Writes to these registers issue bus error and are ineffective when MDIS=1. Reads are always allowed.

67.9.1.1 eTPU_TBR memory map

eTPU_6 base address: 4068_0000h

Offset	Register	Width (In bits)	Access	Reset value

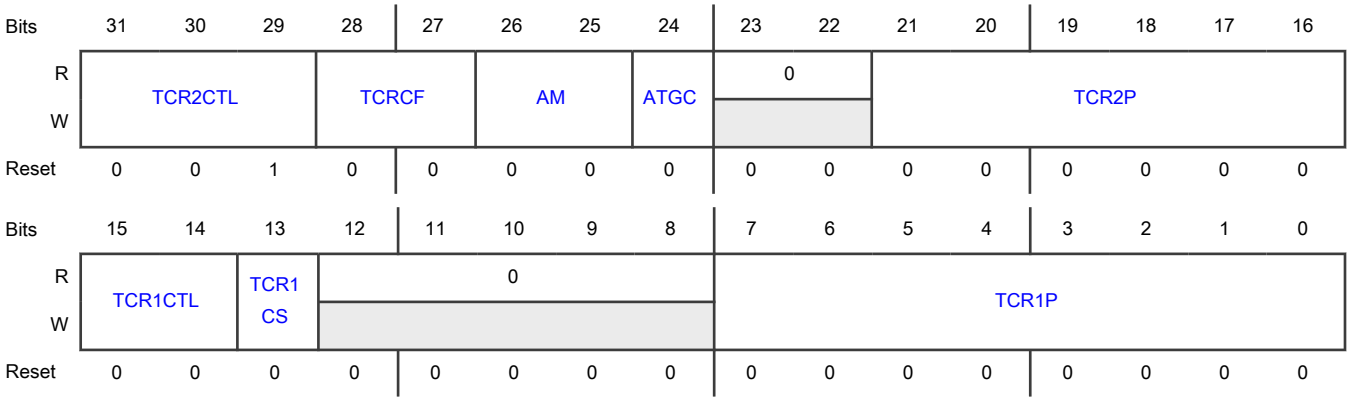
TBCR_ENG1	20h

Function

This register configures several timebase options.

Diagram



Fields

Field	Function
31-29 TCR2CTL	TCR2 Clock/Gate Control. These bits are part of the TCR2 clocking system (see Time bases). They determine the clock source for TCR2 before the prescaler. TCR2 can count on any detected edge of the TCRCLK signal or use it for gating eTPU clock divided by 8. After reset - TCRCLK signal rising edge is selected. TCR2 can also be clocked by the eTPU clock divided by 8. TCR2CTL also determines the TCRCLK edge selected for angle tooth detection in angle mode. See the following table.

TCR2CTL	AM = 0 TCR2 Clock before prescaler	AM > 0 Angle Tooth detection
000	Gated DIV8 clock (eTPU clock / 8). In this case, when the external TCRCLK signal is low, the DIV8 clock is blocked, preventing it from incrementing the TCR2 prescaler. When the external TCRCLK signal is high, TCR2 prescaler is incremented at the frequency of the eTPU clock divided by 8.	Do not use with AM > 0
001	Rise transition on TCRCLK signal increments the TCR2 prescaler.	Rising edge
010	Fall transition on TCRCLK signal increments the TCR2 prescaler.	Falling edge
011	Rise or Fall transition on TCRCLK signal increments the TCR2 prescaler.	Both edges

<tr><td>11</td><td></td><td>Channel 2 input</td><td>2</td></tr>
</table>
If TCR1 or TCR2 is a STAC Bus Client (see STAC interface), the EAC operation is not allowed, and AM must be set to 0.
NOTE
Changing AM may cause unexpected transition detections on the channel selected by AM, depending on the channel mode and state (see Transition detection and Time Base Capture). If AM must be changed with GTBE=1, the recommended procedure is described in Restarting angle logic.
</td></tr>
<tr><td>24
ATGC</td><td>Angle Tick Generator Clock.
This bit selects the clock that provides the time interval unit for Angle Tick Generation. For details, see Generating the angle ticks.
0b - TCR1 prescaler output provides time intervals for tick generation.
1b - TCR2 prescaler output provides time intervals for tick generation.</td></tr>
<tr><td>23-22
—</td><td>Reserved</td></tr>
<tr><td>21-16
TCR2P</td><td>Timer Count Register 2 Prescaler Control.
These bits are part of the TCR2 clocking system (see Time bases). TCR2 is clocked from the output of a prescaler. The prescaler divides its input by (TCR2P + 1) allowing frequency divisions from 1 to 64. The prescaler input is the eTPU clock divided by 8 (in gated or non-gated clock mode), or Internal Timebase input, or TCRCLK filtered input. This field has no effect on TCR2 in Angle Mode.</td></tr>
<tr><td>15-14
TCR1CTL</td><td>TCR1 Clock/Gate Control.
TCR1CTL is part of the TCR1 clocking system (see Time bases). It determines, together with TCR1CS, the clock source for TCR1. TCR1 can count on detected rising edge of the TCRCLK signal, the eTPU clock, or the eTPU clock divided by 2 (see the table in the TCR1CS bit description). After reset TCRCLK signal is selected.</td></tr>
<tr><td>13
TCR1CS</td><td>TCR1 Clock Source
TCR1CS provides the option to double the TCR1 incrementing speed, using eTPU clock as its clock source instead of eTPU clock / 2.
NOTE
If ATGC=0, the clock source of the EAC angle tick generator will still be an even division of eTPU clock if TCR1CS=1, obeying to the field TCR1P as if TCR1CS=0 (see Angle Tick Generator).</td></tr>
</table>

Table continues on the next page...

Table continued from the previous page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td></td><td>
<table>
<tr><th>TCR1CTL</th><th>TCR1CS</th><th>TCR1 Clock before prescaler</th></tr>
<tr><td>00</td><td>0</td><td>Selects TCRCLK as clock source for the TCR1 prescaler.[1]</td></tr>
<tr><td>01</td><td>0</td><td>Reserved</td></tr>
<tr><td>01</td><td>1</td><td>Reserved</td></tr>
<tr><td>10</td><td>0</td><td>Selects eTPU clock divided by 2 as clock source for the TCR1 prescaler.</td></tr>

<tr><td>11</td><td>0</td><td>TCR1 frozen, except as a STAC client</td></tr>
</table>
1. This selection must not be used in Angle Mode.

0b - Use eTPU clock / 2 as TCR1 clock source before the prescaler, if that clock source is selected by TCR1CTL.

1b - Use eTPU clock as TCR1 clock source before the prescaler; can only be set in specific combinations with TCR1CTL, as shown in the table. TCR1CS=1 also makes the channel work on T2/T4 timing mode.
</td></tr>
<tr><td>12-8
—</td><td>Reserved</td></tr>
<tr><td>7-0
TCR1P</td><td>Timer Count Register 1 Prescaler Control

TCR1 is clocked from the output of a prescaler. T he input to the prescaler is the internal eTPU clock divided by 2, eTPU clock, or the output of TCRCLK filter. The prescaler divides this input by (TCR1P + 1) allowing frequency divisions from 1 up to 256.

NOTE
The TCR1 prescaler counts TCR1P rising edges of TCRCLK on the 1st TCR1 increment. If TCR1CTL selects TCRCLK as TCR1 clock source and TCR1P > 0, the first TCR1 increment happens after TCR1P rising edges of TCRCLK. The second TCR1 increment happens correctly after TCR1P+1 rising edges of TCRCLK.</td></tr>
</table>

67.9.1.3 eTPU Engine 1 Time Base 1 (TCR1) Visibility Register (TB1R_ENG1)

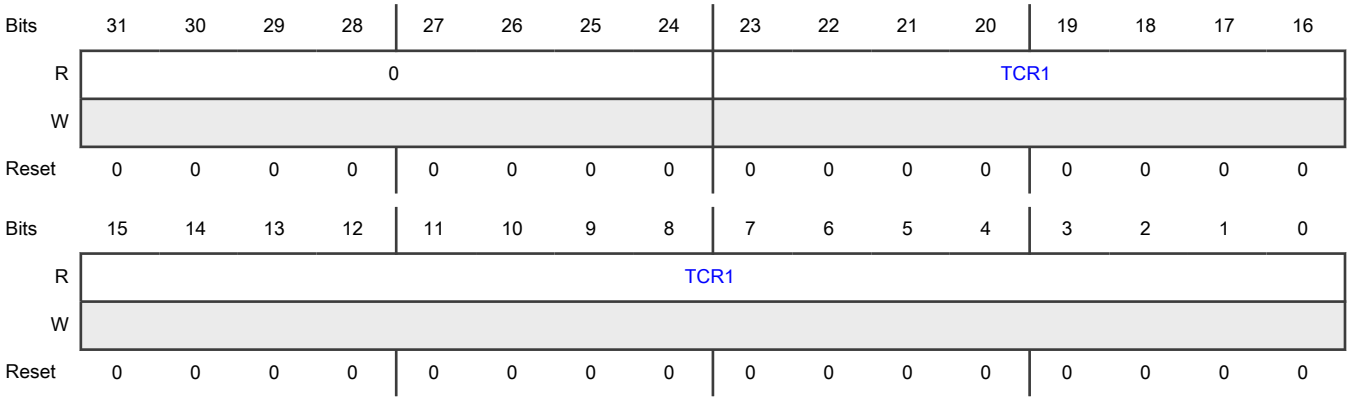
Offset

Register	Offset
TB1R_ENG1	24h

Function

This register provides visibility of the TCR1 time base for host read access (see Time bases). This register is read-only. The value of the TCR1 time base shown can be driven by the TCR1 counter or imported from STAC bus, depending on the configuration set in eTPU Engine 1 STAC Configuration Register (STAC_ENG1).

Diagram



Fields

Field	Function

This bit selects the clock that provides the time interval unit for Angle Tick Generation. For details, see Generating the angle ticks.
0b - TCR1 prescaler output provides time intervals for tick generation.
1b - TCR2 prescaler output provides time intervals for tick generation.</td></tr>
<tr><td>23-22
—</td><td>Reserved</td></tr>
<tr><td>21-16
TCR2P</td><td>Timer Count Register 2 Prescaler Control.
These bits are part of the TCR2 clocking system (see Time bases). TCR2 is clocked from the output of a prescaler. The prescaler divides its input by (TCR2P + 1) allowing frequency divisions from 1 to 64. The prescaler input is the eTPU clock divided by 8 (in gated or non-gated clock mode), or Internal Timebase input, or TCRCLK filtered input. This field has no effect on TCR2 in Angle Mode.</td></tr>
<tr><td>15-14</td><td>TCR1 Clock/Gate Control.</td></tr>
</table>

Table continues on the next page...

Table continued from the previous page...

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td>TCR1CTL</td><td>TCR1CTL is part of the TCR1 clocking system (see Time bases). It determines, together with TCR1CS, the clock source for TCR1. TCR1 can count on detected rising edge of the TCRCLK signal, the eTPU clock, or the eTPU clock divided by 2 (see the table in the TCR1CS bit description). After reset TCRCLK signal is selected.</td></tr>
<tr><td>13
TCR1CS</td><td>TCR1 Clock Source
TCR1CS provides the option to double the TCR1 incrementing speed, using eTPU clock as its clock source instead of eTPU clock / 2.
NOTE
If ATGC=0, the clock source of the EAC angle tick generator will still be an even division of eTPU clock if TCR1CS=1, obeying to the field TCR1P as if TCR1CS=0 (see Angle Tick Generator).
<table>
<tr><th>TCR1CTL</th><th>TCR1CS</th><th>TCR1 Clock before prescaler</th></tr>
<tr><td>00</td><td>0</td><td>Selects TCRCLK as clock source for the TCR1 prescaler.[1]</td></tr>
<tr><td>01</td><td>0</td><td>Reserved</td></tr>
<tr><td>01</td><td>1</td><td>Reserved</td></tr>
<tr><td>10</td><td>0</td><td>Selects eTPU clock divided by 2 as clock source for the TCR1 prescaler.</td></tr>
<tr><td>10</td><td>1</td><td>Selects eTPU clock as clock source for the TCR1 prescaler.</td></tr>
<tr><td>11</td><td>0</td><td>TCR1 frozen, except as a STAC client</td></tr>
</table>
1. This selection must not be used in Angle Mode.
0b - Use eTPU clock / 2 as TCR1 clock source before the prescaler, if that clock source is selected by TCR1CTL.
1b - Use eTPU clock as TCR1 clock source before the prescaler; can only be set in specific combinations with TCR1CTL, as shown in the table. TCR1CS=1 also makes the channel work on T2/T4 timing mode.</td></tr>
<tr><td>12-8
—</td><td>Reserved</td></tr>
<tr><td>7-0
TCR1P</td><td>Timer Count Register 1 Prescaler Control.
TCR1 is clocked from the output of a prescaler. The input to the prescaler is the internal eTPU clock divided by 2, eTPU clock, or the output of TCRCLK filter. The prescaler divides t his input by (TCR1P + 1) allowing frequency divisions from 1 up to 256.
NOTE
The TCR1 prescaler counts TCR1P rising edges of TCRCLK on the 1st TCR1 increment. If TCR1CTL selects TCRCLK as TCR1 clock source and TCR1P > 0, the first TCR1 increment happens after TCR1P rising edges of TCRCLK. The second TCR1 increment happens correctly after TCR1P+1 rising edges of TCRCLK.</td></tr>
</table>

67.9.1.7 eTPU Engine 2 Time Base 1 (TCR1) Visibility Register (TB1R_ENG2)

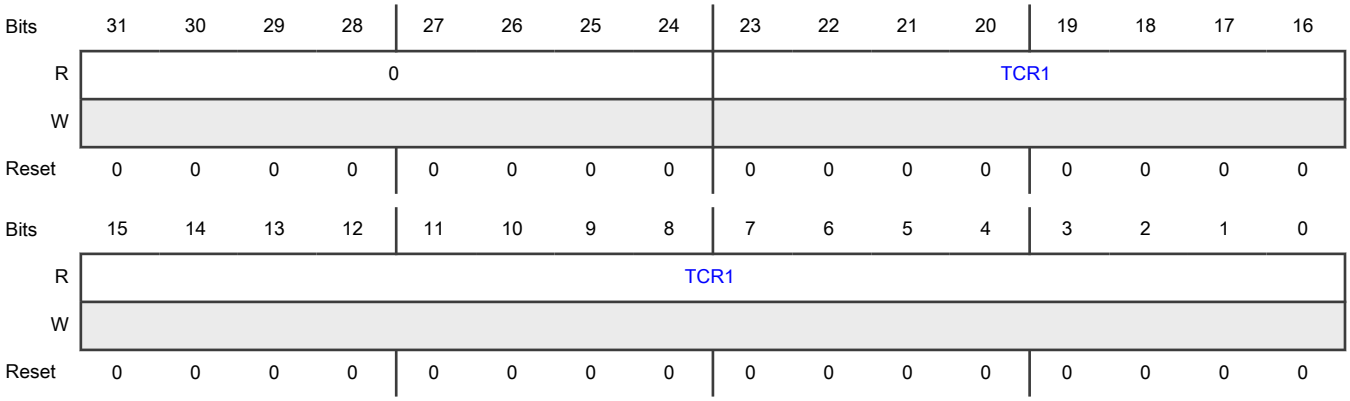
Offset

Register	Offset
TB1R_ENG2	44h

Function

This register provides visibility of the TCR1 time base for host read access (see Time bases). This register is read-only. The value of the TCR1 time base shown can be driven by the TCR1 counter or imported from STAC bus, depending on the configuration set in eTPU Engine 2 STAC Configuration Register (STAC_ENG2).

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 TCR1	TCR1 value. TCR1 value used on matches and captures. See Time bases.

67.9.1.8 eTPU Engine 2 Time Base 2 (TCR2) Visibility Register (TB2R_ENG2)

Offset

Register	Offset
TB2R_ENG2	48h

Function

This register provides visibility of the TCR2 time base for host read access (see Time bases). This register is read-only. The value of the TCR2 time base shown can be driven by the TCR2 counter or imported from the STAC bus, depending on Angle Mode and STAC configurations set in eTPU Engine 2 STAC Configuration Register (STAC_ENG2).

Fields

Field	Function
31 REN1	TCR1 Resource Client/Server Operation Enable Bit. This bit enables Client/Server operation to eTPU STAC resources. REN1 enables TCR1 STAC bus operations. 0b - Server/Client Operation for TCR1 is disabled. 1b - Server/Client Operation for TCR1 is enabled.
30 RSC1	TCR1 Resource Server/Client Assignment Bits. This bit selects the eTPU data resource assignment to be used as Servers or Clients. For Server mode, MCU-dependent value determines the unique server address assigned to each TCR. See the chip-specific eTPU information for the STAC server IDs. For a Client mode, the SRV1 field determines the Server address to which the Client listens. **NOTE** Resource identifies any parameter that changes along the time and can be exported / imported from other device. In eTPU context, a resource can be TCR1 or TCR2 (either Time or Angle values). **NOTE** When TCR1 or TCR2 is configured as a STAC Bus Client (REN2 = 1, RSC2 = 0) the eTPU Angle Clock hardware cannot be used. **NOTE** RSC1 must not be changed when the REN1 bit is asserted. 0b - TCR1 Client operation. 1b - TCR1 Server operation.
29-28 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
27-24 SERVER_ID1	Red Line STAC ID 1. STAC Server ID (read-only MCU-dependent values; see the chip-specific eTPU information for the STAC server IDs) used for TCR1 when STAC servers are used.
23-20 —	Reserved
19-16 SRV1	TCR1 Resource Server. This bit selects the address of the specific STAC Server to which the local TCR1 listens when configured as a STAC Client. SRV1 selects the STAC Server of TCR1.
15 REN2	TCR2 Resource Client/Server Operation Enable Bit. This bit enables Client/Server operation to eTPU STAC resources. REN2 enables TCR2 STAC bus operations. 0b - Server/Client Operation for resource 2 is disabled. 1b - Server/Client Operation for resource 2 is enabled.
14 RSC2	TCR2 Resource Server/Client Assignment Bits. **NOTE** Resource identifies any parameter that changes along the time and can be exported / imported from other device. In eTPU context, a resource can be TCR1 or TCR2 (either Time or Angle values). 0b - Resource Client operation. 1b - Resource Server operation.
13-12 —	Reserved
11-8 SERVER_ID2	Red Line STAC ID 2. STAC Server ID (read-only MCU-dependent values; see the chip-specific eTPU information for the STAC server IDs) used for TCR2 when when STAC servers are used.
7-4 —	Reserved
3-0 SRV2	TCR2 Resource Server. This bit selects the address of the specific STAC Server to which the local TCR2 listens when configured as a STAC Client. SRV2 selects the Red Line STAC Server of TCR2.

67.10 Engine memory map and registers

67.10.1 eTPU_ER register descriptions

This section gathers registers that are engine-related.

67.10.1.1 eTPU_ER memory map

eTPU_4 base address: 4068_0000h

Offset	Register	Width (In bits)	Access	Reset value
60h	eTPU Watchdog Timer Register for Engine 1 (WDTR_ENG1)	32	RW	0000_0000h
68h	eTPU Idle Register for Engine 1 (IDLER_ENG1)	32	RW	See section
70h	eTPU Watchdog Timer Register for Engine 2 (WDTR_ENG2)	32	RW	0000_0000h
78h	eTPU Idle Register for Engine 2 (IDLER_ENG2)	32	RW	See section

67.10.1.2 eTPU Watchdog Timer Register for Engine 1 (WDTR_ENG1)

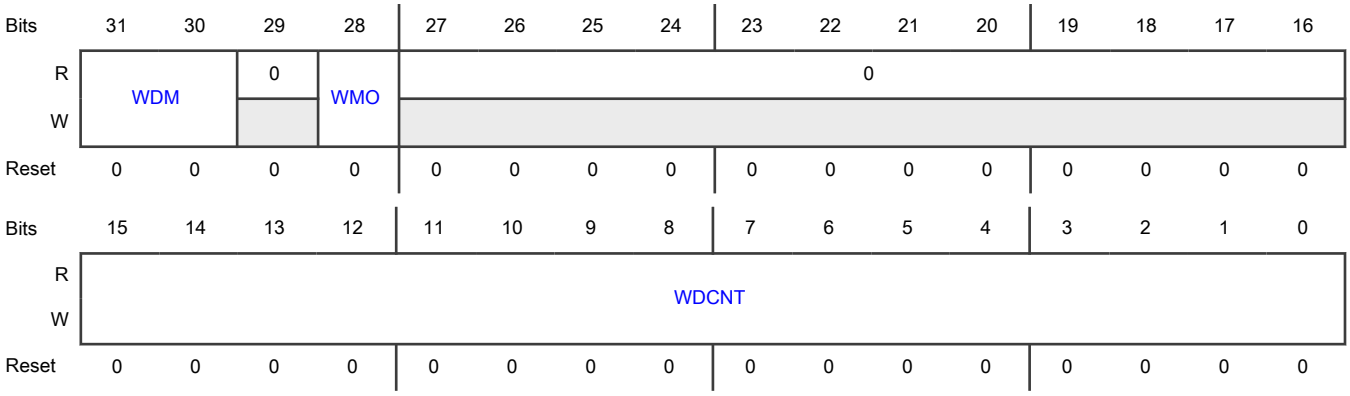
Offset

Register	Offset
WDTR_ENG1	60h

Function

This register configures the watchdog timer for the engine.

Diagram



Fields

Field	Function
31-30 WDM	Watchdog Mode. WDM selects the Watchdog operation mode. For more information on the Watchdog operation, see Watchdog).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE Before a new mode is configured, all conditions below must apply: 1. All channels must be disabled (C*a*CR_ENG1[CPR] = 00b). 2. No thread must be executing (CSSR_ENG1[SSn] reads 0). 3. The watchdog must be disabled (WDM=00). 00b - Disabled 01b - Reserved 10b - Thread length 11b - Busy length
29 —	Reserved
28 WMO	Watchdog Monitor Operation. This bit enables the monitor operation of the watchdog, inhibiting the thread ending and channel disabling in case of a timeout. The Global Exception occurs on a watchdog timeout, independently of WMO. **NOTE** WDSR_ENG1[WDS*n*], MCR[WDTO1], MCR[WDTO2], and the Global Exception always asserts in case of a watchdog timeout, independently of WMO. 0b - Force the end of the running thread and disable the service channel in case of a timeout. 1b - Do not force the end of the running thread, nor disable the service channel in case of a timeout.
27-16 —	Reserved
15-0 WDCNT	Watchdog Count. This field indicates the maximum number of microcycles allowed for a thread (in thread length mode) or a sequence of threads (in busy length mode) before the current running thread is forced to end. For more information on Watchdog operation, see Watchdog . **NOTE** The TST microcycles are also counted by the watchdog. **NOTE** Fields WDCNT and WMO must not be changed when the watchdog is enabled.

67.10.1.3 eTPU Idle Register for Engine 1 (IDLER_ENG1)

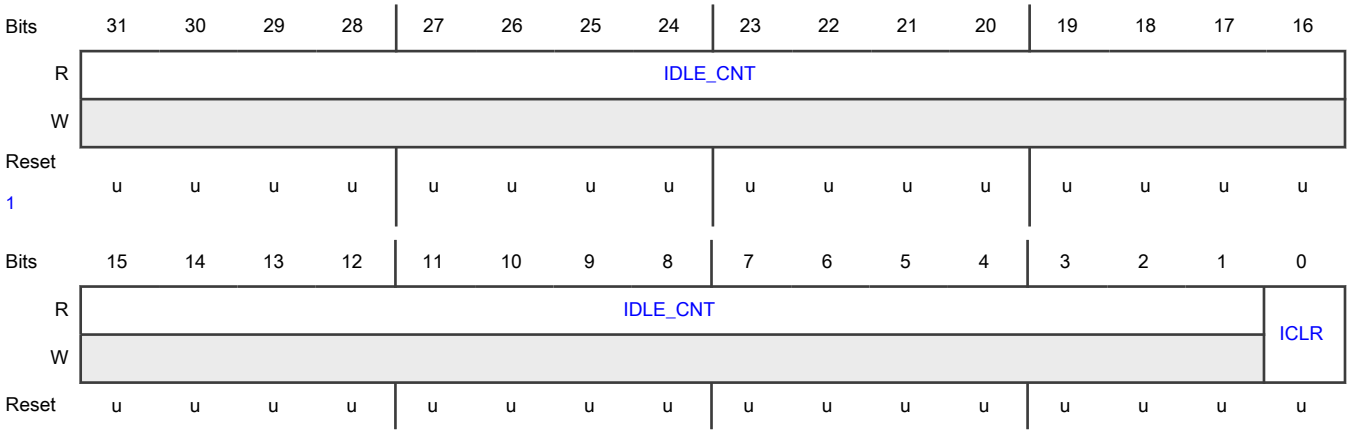
Offset

Register	Offset
IDLER_ENG1	68h

Function

This register counts the microcycles in which the microengine is idle (see Idle Counter

Diagram



1. The reset value is undefined because the counter is free running and the value varies depending on how many cycles have passed after reset before reading the value.

Fields

Field	Function
31-1 IDLE_CNT	Idle Count. This is a free running count of the number of idle microcycles in the microengine. For more information on idle counter operation, see Idle Counter. **NOTE** When the register is read, the ICLR bit is concatenated with the IDLE_CNT field (as the LSB) to form a 32-bit value.
0 ICLR	Idle Clear. Writing a 1 to this bit clears the IDLE_CNT field. **NOTE** When the register is read, the ICLR bit is concatenated with the IDLE_CNT field (as the LSB) to form a 32-bit value. 0b - Do not clear the IDLE_CNT field. 1b - Clear the IDLE_CNT field.

67.10.1.4 eTPU Watchdog Timer Register for Engine 2 (WDTR_ENG2)

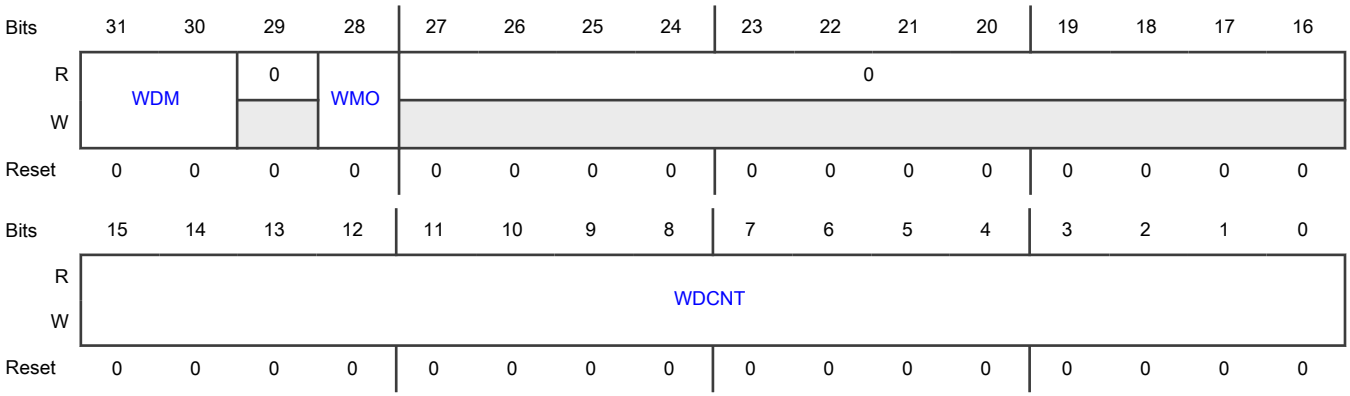
Offset

Register	Offset
WDTR_ENG2	70h

Function

This register configures the watchdog timer for the engine.

Diagram



Fields

Field	Function
31-30 WDM	Watchdog Mode. WDM selects the Watchdog operation mode. For more information on the Watchdog operation, see Watchdog . **NOTE** Before a new mode is configured, all conditions below must apply: 1. All channels must be disabled (CaCR_ENG1[CPR] = 00b). 2. No thread must be executing (eTPU Channel Service Status Register for Engine 2 (CSSR_ENG2) reads 0). 3. The watchdog must be disabled (WDM=00). 00b - Disabled 01b - Reserved 10b - Thread length 11b - Busy length
29 —	Reserved

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 FME	Field Modification Enable Negation of this bit disables the modification of all fields in the register, except MECIE, DRDIS, CRDIS and FME itself: Write accesses do not cause a bus error, regardless of FME state. 0b - Fields cannot be modified during a write access, except MECIE, DRDIS, CRDIS and FME. 1b - All fields can be modified during a write access.
30-17 —	Reserved
16 MECIE	Memory Error Correction Interrupt Enable. Enables the Memory Error Correction Interrupt (see Interrupt types and sources). 0b - Memory Error Correction Interrupt disabled. 1b - Memory Error Correction Interrupt enabled.
15 HDEIE	Host Data Error Injection Enable Enables error injection into the SDM host read path, including CDC transfers. The eTPU Data Error Injection Address Register (DEIAR) specifies the address where the error is injected, while eTPU Data Error Injection Data Pattern Register (DEIDPR) and eTPU Data Error Injection Parity Pattern Register (DEIPPR) define the bit flips on data and parity, respectively. **NOTE** Data error injection is also performed when data error detection is disabled (DEDD=1). 0b - SDM error injection disabled for host reads. 1b - SDM error injection enabled for host reads.
14 MDEIE	Microengine(s) Data Error Injection Enable. Enables error injection into the SDM microengine read path. The eTPU Data Error Injection Address Register (DEIAR) specifies the address where the error is injected, while eTPU Data Error Injection Data Pattern Register (DEIDPR) and eTPU Data Error Injection Parity Pattern Register (DEIPPR) define the bit flips on data and parity, respectively. **NOTE** Data error injection is also performed when data error detection is disabled (DEDD=1). 0b - SDM error injection disabled for microengine reads. 1b - SDM error injection enabled for microengine reads.
13-11 —	Reserved
10	Thread End on Data Non-correctable Error.

Table continues on the next page...

Table continued from the previous page...

Field	Function
DTEND	This bit controls the behavior of the microengine when a non-correctable data error occurs. For more details, see Memory error support . **NOTE** DTEND must only be changed when the engine is stopped or halted, or when all channels are disabled. 0b - Thread continues on non-correctable data read access by the microengine. 1b - Thread ends on non-correctable data read access by the microengine.
9 DRDIS	Data Error Report Disable Disables the sampling of SDM error address, data and syndrome into the eTPU Memory Error Support Registers, and eTPU_MESR register descriptions. It does not, however, disable the setting of eTPU_MESR register descriptions bits DCERR and DNCERR. **NOTE** To guarantee coherent reading of eTPU Data Error Report Address Register (DERAR), eTPU Data Error Report Data Register (DERDR), and eTPU Data Error Report Syndrome Register (DERSR), DRDIS must be asserted beforehand if SDM concurrent accesses can happen, by host or microengine. After the registers are read, DRDIS may be negated again to allow new samplings. 0b - SDM error report sampling enabled. 1b - SDM error report sampling disabled.
8 DEDD	Data Error Detection Disable. Disables SDM error detection. The disabled state turns ineffective any action due to error detection, including consequently error correction. 0b - SDM error detection enabled. 1b - SDM error detection disabled.
7 CEIE	Code Error Injection Enable. This bit enables error injection into the SCM read path, either on microengine accesses (see MCR[VIS] = 0) or host accesses (VIS = 1) eTPU Code Error Injection Address Register (CEIAR) specifies the address where the error is injected, while eTPU Code Error Injection Data Pattern Register (CEIDPR) and eTPU Code Error Injection Parity Pattern Register (CEIPPR) define the bit flips on data and parity, respectively. **NOTE** Code error injection is also performed when code error detection is disabled (CEDD = 1). 0b - SCM error injection disabled. 1b - SCM error injection enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
6-3 —	Reserved
2 CTEND	Thread End on Code Non-Correctable Error. This bit controls the behavior of the microengine when a non-correctable code error occurs. For more details, see Memory error support . **NOTE** CTEND must only be changed when the engine is stopped or halted, or when all channels are disabled. 0b - Thread continues on instruction fetch non-correctable error. 1b - Thread ends on instruction fetch non-correctable error.
1 CRDIS	Code Error Report Disable. Disables sampling of SCM error address, data and syndrome into the eTPU Code Error Report Address Register (CERAR), eTPU Code Error Report Data Register (CERDR), and eTPU Code Error Report Syndrome Register (CERSR). It does not, however, disable the setting of CCERR and CNCERR in eTPU_MESR register descriptions. **NOTE** To guarantee coherent reading of eTPU Code Error Report Address Register (CERAR), eTPU Code Error Report Data Register (CERDR), and eTPU Code Error Report Syndrome Register (CERSR), CRDIS must be asserted beforehand if SCM concurrent accesses can happen, by host or microengine. After the registers are read, CRDIS may be negated again to allow new samplings. 0b - SCM error report sampling enabled. 1b - SCM error report sampling disabled.
0 CEDD	Code Error Detection Disable. This bit disables SCM error detection. The disabled state turns ineffective any action due to error detection, including consequently error correction. 0b - SCM error detection enabled. 1b - SCM error detection disabled.

67.11.1.3 eTPU Data Error Injection Address Register (DEIAR)

Offset

Register	Offset
DEIAR	104h

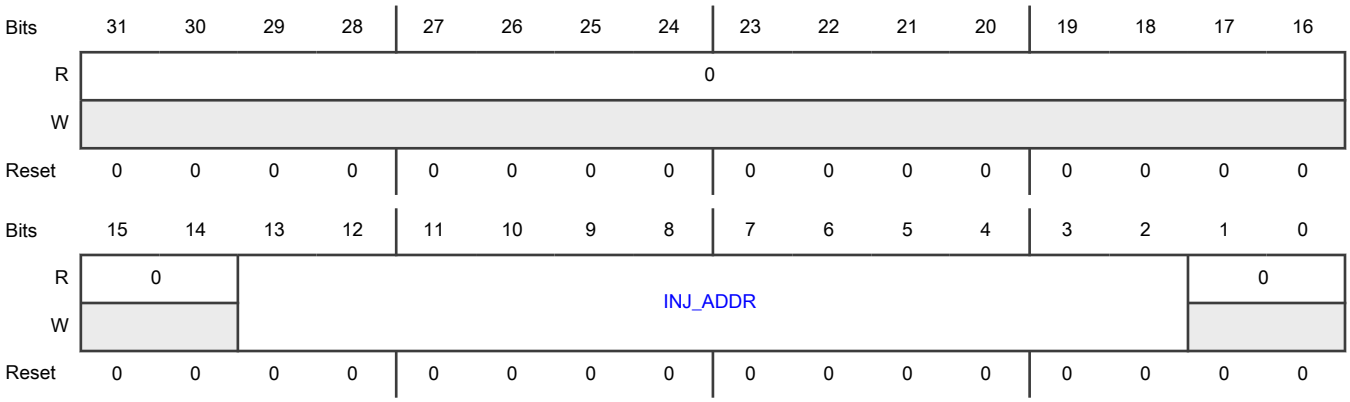
Function

This register holds the address where error is to be injected into the SDM read data path. The two least significant bits are 0 (read-only), so that the address is always word-aligned.

NOTE

This register must only be modified when MECR[HDEIE] and MECR[MDEIE] are both n negated.

Diagram



Fields

Field	Function
31-14 —	Reserved
13-2 INJ_ADDR	Injection Address. This field holds the (word) address where an error is injected into the SDM read data path, as specified by MECR[HDEIE] and MECR[MDEIE]. For more information on error injection, see Error injection.
1-0 —	Reserved

67.11.1.4 eTPU Data Error Injection Data Pattern Register (DEIDPR)

Offset

Register	Offset
DEIDPR	108h

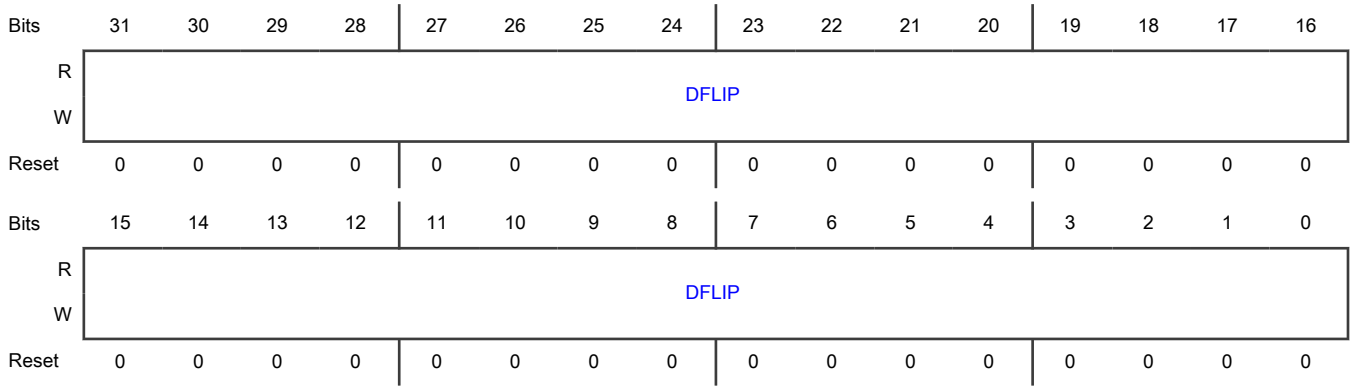
Function

This register is used to specify the bits in which error is injected into the SDM read data path.

NOTE

This register must only be modified when MECR[HDEIE] and MECR[MDEIE] are both negated.

Diagram



Fields

Field	Function
31-0 DFLIP	Data Flip bits. Each bit corresponds to a bit in the actual data read from the SDM address defined in eTPU Data Error Injection Address Register (DEIAR), specifying whether it should be inverted or not. The inversion only occurs if the SDM error injection is enabled by MECR[HDEIE] and/or MECR[MDEIE]. For more information on error injection, see Error injection. 0000_0000_0000_0000_0000_0000_0000_0000b - Read data bit is not inverted. 0000_0000_0000_0000_0000_0000_0000_0001b - Read data bit is inverted.

67.11.1.5 eTPU Data Error Injection Parity Pattern Register (DEIPPR)

Offset

Register	Offset
DEIPPR	10Ch

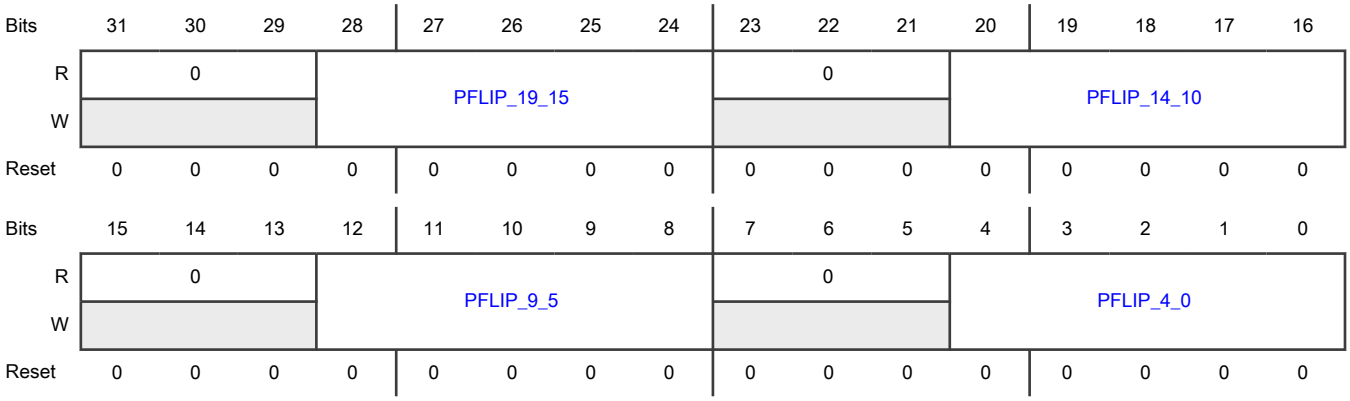
Function

This register is used to specify the bits in which error is injected into the SDM read parity path.

NOTE

This register must only be modified when MECR[HDEIE] and MECR[MDEIE] are both negated.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-24 PFLIP_19_15	Parity Flip bits. Each bit corresponds to a bit in the actual parity read from the SDM address defined in eTPU Data Error Injection Address Register (DEIAR), specifying whether it should be inverted or not. The inversion only occurs if the SDM error injection is enabled by the HDEIE and/or MDEIE fields in eTPU_MESR register descriptions. Bits PFLIP[19:15] corresponds to the parity bits for the most significant byte, PFLIP[14:10] to the next most significant byte and so on until PFLIP[4:0] for the least significant byte. For more information on error injection, see Error injection. 0_0000b - Parity data bit is not inverted. 0_0001b - Parity data bit is inverted.
23-21 —	Reserved
20-16 PFLIP_14_10	Parity Flip bits. Each bit corresponds to a bit in the actual parity read from the SDM address defined in eTPU Data Error Injection Address Register (DEIAR), specifying whether it should be inverted or not. The inversion only occurs if the SDM error injection is enabled by MECR[HDEIE] and/or MECR[MDEIE]. Bits PFLIP[19:15] corresponds to the parity bits for the most significant byte, PFLIP[14:10] to the next most significant byte and so on until PFLIP[4:0] for the least significant byte. For more information on error injection, see Error injection. 0_0000b - Parity data bit is not inverted. 0_0001b - Parity data bit is inverted.
15-13 —	Reserved
12-8	Parity Flip bits.

Table continues on the next page...

Table continued from the previous page...

Field	Function
PFLIP_9_5	Each bit corresponds to a bit in the actual parity read from the SDM address defined in eTPU Data Error Injection Address Register (DEIAR), specifying whether it should be inverted or not. The inversion only occurs if the SDM error injection is enabled by MECR[HDEIE] and/or MECR[MDEIE]. Bits PFLIP[19:15] corresponds to the parity bits for the most significant byte, PFLIP[14:10] to the next most significant byte and so on until PFLIP[4:0] for the least significant byte. For more information on error injection, see Error injection. 0_0000b - Parity data bit is not inverted. 0_0001b - Parity data bit is inverted.
7-5 —	Reserved
4-0 PFLIP_4_0	Parity Flip bits Each bit corresponds to a bit in the actual parity read from the SDM address defined in eTPU Data Error Injection Address Register (DEIAR), specifying whether it should be inverted or not. The inversion only occurs if the SDM error injection is enabled by MECR[HDEIE] and/or MECR[MDEIE]. Bits PFLIP[19:15] corresponds to the parity bits for the most significant byte, PFLIP[14:10] to the next most significant byte and so on until PFLIP[4:0] for the least significant byte. For more information on error injection, see Error injection. 0_0000b - Parity data bit is not inverted. 0_0001b - Parity data bit is inverted.

67.11.1.6 eTPU Data Error Report Address Register (DERAR)

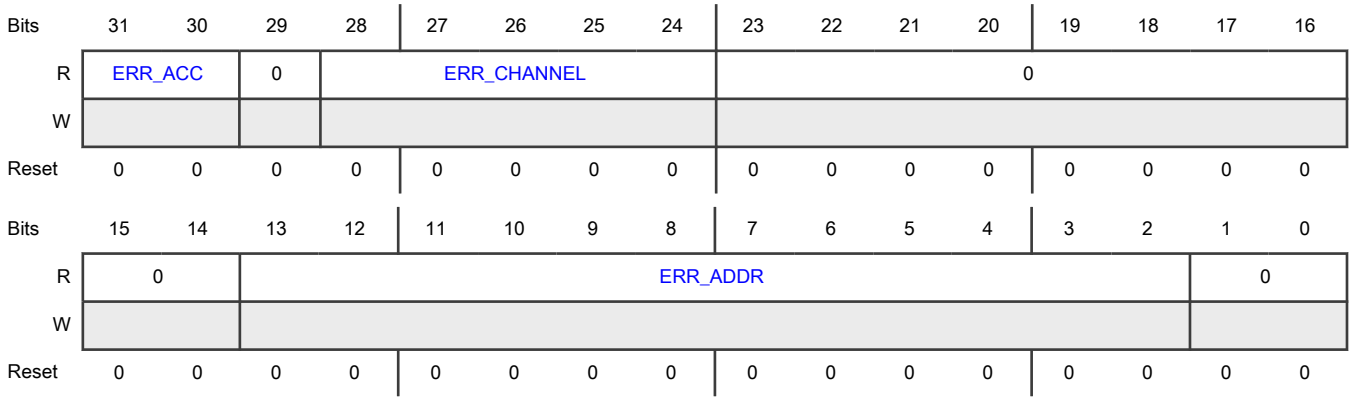
Offset

Register	Offset
DERAR	110h

Function

This register holds the address where the last non-correctable error was detected from the SDM It also captures the address of the last correctable error detected, as long as MESR[DNCERR] is 0. The two least significant bits are 0 (read-only), so that the address is always word-aligned.

Diagram



Fields

Field	Function
31-30 ERR_ACC	Error Access Source Indication. This two-bit field indicates the source of the access when the error occurred. 00b - Host - direct access 01b - Engine 1 10b - Engine 2 11b - CDC
29 —	Reserved
28-24 ERR_CHANNEL	Error Channel Access Indication. This field holds the number of the channel being serviced (not necessarily CHAN) when the error occurred. Its content is meaningful only when the field ERR_ACC indicates Engine 1 or Engine 2.
23-14 —	Reserved
13-2 ERR_ADDR	Error Address. ERR_ADDR holds the (word) address where the last captured SDM read error was detected. The last captured error is a non-correctable one if MESR[DNCERR] = 1, or a correctable one if MESR[DNCERR] = 0 and MESR[DCERR] = 1. The field is meaningless if both MESR[DNCERR] and MESR[DCERR] are 0. For more information on error detection, see Memory error support .
1-0 —	Reserved

67.11.1.7 eTPU Data Error Report Data Register (DERDR)

Offset

Register	Offset
DERDR	114h

Function

This register holds the data read with the last non-correctable error detected from the SDM. It also captures the data of the last correctable error read detection, as long as MESR[DNCERR] is 0. In both cases, the data is captured after the error correction logic. The data is meaningless if both MESR[DNCERR] and MESR[DCERR] are 0. For more information on error detection, see Memory error support .

NOTE

Data is sampled before the error correction logic.

Diagram

Fields

Field	Function
31-0 DATA	DATA. **NOTE** Individual data bytes are not meaningful when their respective BE bits in eTPU_MESR register descriptions are not asserted.

67.11.1.8 eTPU Data Error Report Syndrome Register (DERSR)

Offset

Register	Offset
DERSR	118h

Function

This register holds the syndrome read with the last non-correctable error detected from the SDM. It also captures the syndrome of the last correctable error read detection, as long as MESR[DNCERR] is 0.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	BE1	0			SYND1				BE0	0			SYND0			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 BE3	Byte Enable 3. Each BE bit corresponds to a report byte in a 32-bit aligned data word. BE3 corresponds to the most significant one. BE qualifies the error report for its respective byte. 0b - Byte was not selected for read, therefore its respective error report fields are not meaningful. 1b - Byte was selected for read, and the error report for the respective byte is meaningful.
30-29 —	Reserved
28-24 SYND3	Error Syndrome 3. SYND3 holds the syndrome of an error detected in the SDM read data path, as defined in Error Correction Code (ECC) and syndrome definition . The field is meaningless if both MESR[DNCERR] and MESR[DCERR] are 0. For more information on error detection, see Memory error support . **NOTE** Syndrome fields which have their respective BE bits negated are not meaningful.
23 BE2	Byte Enable 2. Each BE bit corresponds to a report byte in a 32-bit aligned data word. BE3 corresponds to the most significant one. BE qualifies the error report for its respective byte. 0b - Byte was not selected for read, therefore its respective error report fields are not meaningful. 1b - Byte was selected for read, and the error report for the respective byte is meaningful.
22-21 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
20-16 SYND2	Error Syndrome 2. SYND2 holds the syndrome of an error detected in the SDM read data path, as defined in the “Error Correction Code (ECC) and Syndrome Definition”section. The field is meaningless if both MESR[DNCERR] and MESR[DCERR] are 0. For more information on error detection, see Memory error support . **NOTE** Syndrome fields which have their respective BE bits negated are not meaningful.
15 BE1	Byte Enable 1. Each BE bit corresponds to a report byte in a 32-bit aligned data word. BE3 corresponds to the most significant one. BE qualifies the error report for its respective byte. 0b - Byte was not selected for read, therefore its respective error report fields are not meaningful. 1b - Byte was selected for read, and the error report for the respective byte is meaningful.
14-13 —	Reserved
12-8 SYND1	Error Syndrome 1. SYND1 holds the syndrome of an error detected in the SDM read data path, as defined in the “Error Correction Code (ECC) and Syndrome Definition”section. The field is meaningless if both MESR[DNCERR] and MESR[DCERR] are 0. For more information on error detection, see Memory error support . **NOTE** Syndrome fields which have their respective BE bits negated are not meaningful.
7 BE0	Byte Enable 0. Each BE bit corresponds to a report byte in a 32-bit aligned data word. BE3 corresponds to the most significant one. BE qualifies the error report for its respective byte. 0b - Byte was not selected for read, therefore its respective error report fields are not meaningful. 1b - Byte was selected for read, and the error report for the respective byte is meaningful.
6-5 —	Reserved
4-0 SYND0	Error Syndrome 0. SYND0 holds the syndrome of an error detected in the SDM read data path, as defined in the “Error Correction Code (ECC) and Syndrome Definition”section. The field is meaningless if both MESR[DNCERR] and MESR[DCERR] are 0. For more information on error detection, see Memory error support . **NOTE** Syndrome fields which have their respective BE bits negated are not meaningful.

67.11.1.9 eTPU Memory Error Status Register (MESR)

Offset

Register	Offset
MESR	120h

Function

This register gathers status bits of both SCM and SDM error detection and correction support.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	DCERR	0						DCOVR	CCERR	0						CCOVR
W	W1C							W1C	W1C							W1C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	DNCERR	0						DNCOVR	CNCERR	0						CNCOVR
W	W1C							W1C	W1C							W1C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 DCERR	Data Correctable Error flag. When read: 0.....No SDM correctable error occurred. 1.....An SDM correctable error occurred. Writing 1 to this bit clears the DCERR status flag. DCERR asserts even if DNCERR is asserted beforehand, but in this case the address and data of the erroneous access is not captured (see Memory Error Support memory map and registers and following sections). DCERR is cleared by writing a 1 to it. Assertion of this bit can also assert the Memory Error Correction Interrupt (see Interrupt types and sources). **NOTE** A correctable error is not considered for flagging if accompanied of a non-correctable one. Therefore, if both correctable and non-correctable data errors occur on the same access (in distinct bytes), the DNCERR flag asserts, but not the DCERR flag. 0b - Do not clear DCERR flag. 1b - Clears DCERR flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
30-25 —	Reserved
24 DCOVR	Data Correctable Overrun flag. Writing 1 to this bit clears the DCOVR status flag. 0b - Data correctable error occurred while DCOVR = 1. 1b - No data correctable error occurred while DCOVR = 1. DCOVR asserts when an SDM correctable error occurs and the DCERR flag is already asserted. Assertion of this bit causes no interrupt. A correctable error is not considered for flagging if accompanied by a non-correctable one. Therefore, if both correctable and non-correctable data errors occur on the same access (in distinct bytes), the DCOVR does not assert, even if DCERR is asserted. The DNCOVR flag, on the other hand, asserts if DNCERR is asserted.
23 CCERR	Code Error flag. When read: 0.....No SCM correctable error occurred. 1.....An SCM correctable error occurred. When written: 0.....Do not clear CCERR flag. 1.....Clears CCERR flag. The CCERR flag asserts even if CNCERR is asserted beforehand, but in this case the address and data of the erroneous access is not captured (see eTPU Code Error Report Address Register (CERAR) and the following sections). CCERR is cleared by writing a 1 at the same position. Assertion of this bit can also assert the Memory Error Correction Interrupt (see Interrupt types and sources).
22-17 —	Reserved
16 CCOVR	Code Correctable Overrun flag This bit asserts when an SCM correctable error occurs and the CCERR flag is already asserted. Assertion of this bit causes no interrupt. When read: 0.....No SCM correctable error overrun occurred. 1.....An SCM correctable error overrun occurred. Writing 1 to this bit clears the CCOVR status flag: 0b - Do not clear CCOVR flag. 1b - Clear CCOVR flag.
15 DNCERR	Data Non-Correctable Error flag DNCERR flags a non-correctable error.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When read: 0.....No SDM non-correctable error occurred. 1.....An SDM non-correctable error occurred; registers eTPU Global Channel Registers are not updated by correctable error detections. DNCERR must be cleared (by writing a 1 to it) to allow correctable error updates to eTPU Data Error Report Address Register (DERAR) and eTPU Data Error Report Data Register (DERDR). 0b - Do not clear DNCERR flag. 1b - Clear DNCERR flag.
14-9 —	Reserved
8 DNCOVR	Data Non-Correctable Overrun flag. DNCOVR asserts when an SDM non-correctable error occurs and the DNCERR flag is already asserted. Assertion of this bit causes no interrupt. When read: 0.....No SDM non-correctable error overrun occurred. 1.....An SDM non-correctable error overrun occurred. DNCOVR is cleared by writing a 1 to it. 0b - Do not clear DNCOVR flag. 1b - Clear DNCOVR flag.
7 CNCERR	Code Non-Correctable Error flag CNCERR flags a non-correctable error: When read: 0.....An SCM non-correctable error occurred; the eTPU Global Channel Registers are not updated by correctable error detections. 1....an SCM non-correctable error occurred; eTPU Code Error Report Address Register (CERAR) and eTPU Code Error Report Data Register (CERDR) are not updated by correctable error detections. CNCERR must be cleared to allow correctable error updates to eTPU Code Error Report Address Register (CERAR) and eTPU Code Error Report Data Register (CERDR). CNCERR is cleared by writing a 1 to it. 0b - Do not clear CNCERR flag. 1b - Clear CNCERR flag.
6-1 —	Reserved
0 CNCOVR	Code Non-Correctable Overrun flag.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	CNCOVR asserts when an SCM non-correctable error occurs and the CNCERR flag is already asserted. Assertion of this bit causes no interrupt. When read: 0.....an SCM non-correctable error overrun occurred. 1.....An SCM non-correctable error overrun occurred. When written: 0b - Do not clear CNCOVR flag. 1b - Clear CNCOVR flag.

67.11.1.10 eTPU Code Error Injection Address Register (CEIAR)

Offset

Register	Offset
CEIAR	124h

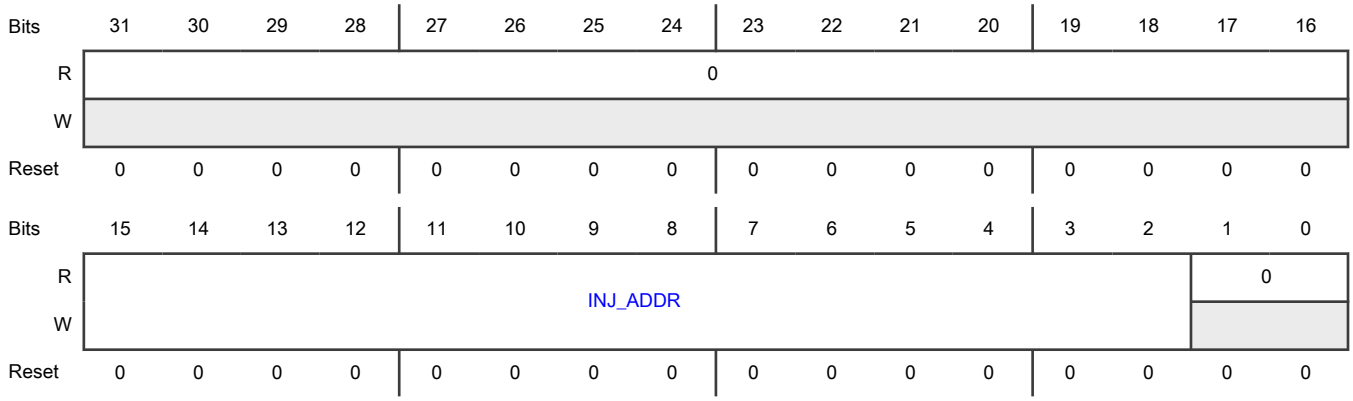
Function

This register holds the address where error is to be injected into the SCM read data path. The two least significant bits are 0 (read-only), so that the address is always word-aligned.

NOTE

This register must only be modified when MECR[CEIE] is negated.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-2 INJ_ADDR	Injection Address. INJ_ADDR holds the (word) address where an error is injected in the SCM read data path, as specified by eTPU_MESR register descriptions and eTPU_MESR register descriptions. For more information on error injection, see Error injection.
1-0 —	Reserved

67.11.1.11 eTPU Code Error Injection Data Pattern Register (CEIDPR)

Offset

Register	Offset
CEIDPR	128h

Function

This register is used to specify the bits in which error is injected into the SCM read data path.

NOTE

This register must only be modified when MECR[CEIE] is negated.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	DFLIP															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 DFLIP	Data Flip bits. Each bit corresponds to a bit in the actual data read from the SCM address defined in eTPU Code Error Injection Address Register (CEIAR), specifying whether it should be inverted or not. The inversion only occurs if the SCM error injection is enabled by MECR[CEIE]. For more information on error injection, see Error injection. 0000_0000_0000_0000_0000_0000_0000_0000b - Read data bit is not inverted. 0000_0000_0000_0000_0000_0000_0000_0001b - Read data bit is inverted.

67.11.1.12 eTPU Code Error Injection Parity Pattern Register (CEIPPR)

Offset

Register	Offset
CEIPPR	12Ch

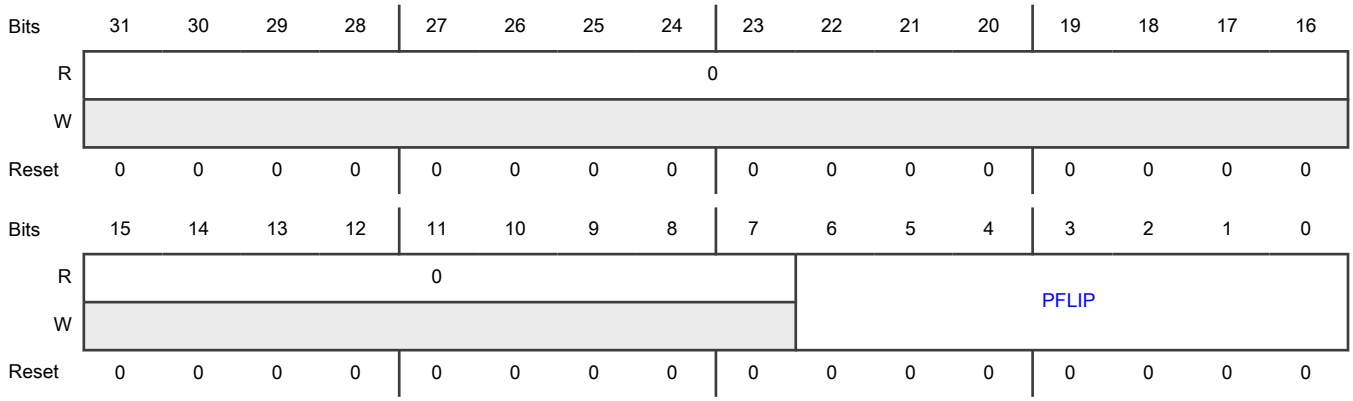
Function

This register is used to specify the bits in which error is injected into the SCM read parity path.

NOTE

This register must only be modified when MECR[CEIE] is negated.

Diagram



Fields

Field	Function
31-7 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
6-0 PFLIP	Parity Flip bits. Each bit corresponds to a bit in the actual parity/code read from the SCM address defined in eTPU Code Error Injection Address Register (CEIAR), specifying whether it should be inverted or not. The inversion only occurs if the SCM error injection is enabled by MECR[CEIE]. For more information on error injection, see Error injection. 000_0000b - Parity data bit is not inverted. 000_0001b - Parity data bit is inverted.

67.11.1.13 eTPU Code Error Report Address Register (CERAR)

Offset

Register	Offset
CERAR	130h

Function

This register holds the address where the last non-correctable error was detected from the SCM. It also captures the address of the last correctable error detected, as long as MESR[CNCERR] is 0. The two least significant bits are 0 (read-only), so that the address is always word-aligned.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	ERR_ACC		0		ERR_CHANNEL				0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	ERR_ADDR														0	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-30 ERR_ACC	Error Access Source Indication. This two-bit field indicates the source of the access when the error occurred.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - Host 01b - Engine 1 10b - Engine 2 11b - MISC
29 —	Reserved
28-24 ERR_CHANNEL	Error Channel Access Indication. This field holds the number of the channel being serviced (not necessarily CHAN) when the error occurred. Its content is meaningful only when the field ERR_ACC indicates Engine 1 or Engine 2.
23-16 —	Reserved
15-2 ERR_ADDR	Error Address. ERR_ADDR holds the (word) address where the last captured SCM read error was detected. The last captured error is a non-correctable one if MESR[CNCERR] = 1, or a correctable one if MESR[CNCERR] = 0 and MESR[CCERR] = 1. The field is meaningless if both MESR[CNCERR] and MESR[CCERR] are 0. For more information on error detection, see Memory error support .
1-0 —	Reserved

67.11.1.14 eTPU Code Error Report Data Register (CERDR)

Offset

Register	Offset
CERDR	134h

Function

This register holds the data read with the last non-correctable error detected from the SCM. It also captures the data of the last correctable error read detection, as long as MESR[CNCERR] is 0. In both cases, the data is captured after the error correction logic. The data may be meaningless if both MESR[CNCERR] and MESR[CCERR] are 0. For more information on error detection, see Memory error support .

NOTE

CODE is sampled before the error correction logic.

Fields

Field	Function
31-7 —	Reserved
6-0 SYND	Error Syndrome. SYND holds the syndrome of an error detected in the SCM read data path, as defined in Error Correction Code (ECC) and syndrome definition . The field is meaningless if both MESR[CNCERR] and MESR[CCERR] are 0. For more information on error detection, see Memory error support .

67.11.1.16 eTPU Code Error Fix Register (CEFR)

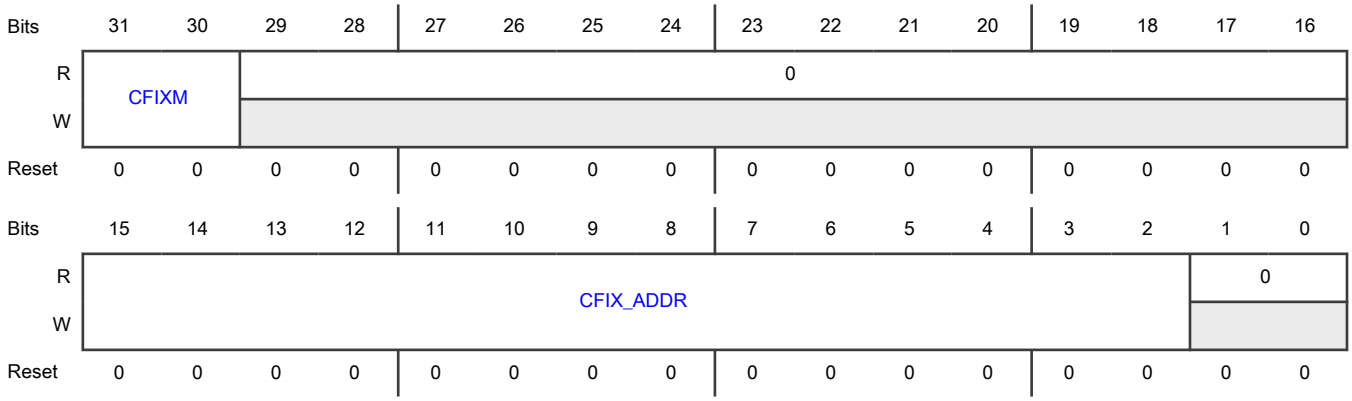
Offset

Register	Offset
CEFR	13Ch

Function

This register is used to fix single-bit error in a specified SCM position. The fix is done automatically, concurrently with code execution, by the MISC logic (see Error fixing).

Diagram



Fields

Field	Function
31-30 CFIXM	Code Fix Mode. This field specifies the SCM MISC fix logic operation mode as shown in the table below. **NOTE** The CFIXM field can only be changed to/from disabled mode.

Table continued from the previous page...

Field	Function
	<table><tr><th>Value</th><th>Mode</th><th>Description</th></tr><tr><td>00</td><td>Disabled</td><td>SCM error fix disabled.</td></tr><tr><td>01</td><td>Reserved</td><td>Reserved value, must not be used.</td></tr><tr><td>10</td><td>Reserved</td><td>Reserved value, must not be used.</td></tr><tr><td>11</td><td>Automatic</td><td>The MISC logic rewrites the code word value read (already fixed by the error correction mechanism) into the same address whenever it finds a correctable error.</td></tr></table>
29-16 —	Reserved
15-2 CFIX_ADDR	Code Fix Address. This field is used for hardware debug purposes. CFIX_ADDR may change its contents and must not be written in automatic mode. For more information on error detection and correction, see Memory error support .
1-0 —	Reserved

67.12 Global Channel memory map and registers

67.12.1 eTPU_GCR register descriptions

The registers in this section group, by type, the interrupt status and enable bits from all the channels. This organization eases management of all channels or groups of channels by a single interrupt handler routine. These bits, except the service and watchdog status, are mirrored in the individual channel registers, grouped by channel.

67.12.1.1 eTPU_GCR memory map

eTPU_1 base address: 4068_0000h

Offset	Register	Width (In bits)	Access	Reset value
200h	eTPU Channel Interrupt Status Register for Engine 1 (CISR_ENG1)	32	RW	0000_0000h

290h	eTPU Channel Service Status Register for Engine 1 (CSSR_ENG1)	32	R	0000_0000h
294h	eTPU Channel Service Status Register for Engine 2 (CSSR_ENG2)	32	R	0000_0000h

67.12.1.2 eTPU Channel Interrupt Status Register for Engine 1 (CISR_ENG1)

Offset

Register	Offset
CISR_ENG1	200h

Function

This register groups the host interrupt status from all channels.These bits are mirrored from the Channel Status Control register (see eTPU_CCCR register descriptions) and the Host must write 1 to clear a status bit.

For details about interrupts, see Interrupts and data transfer requests.

Diagram

67.12.1.4 eTPU Channel Data Transfer Request Status Register for Engine 1 (CDTRSR_ENG1)

Offset

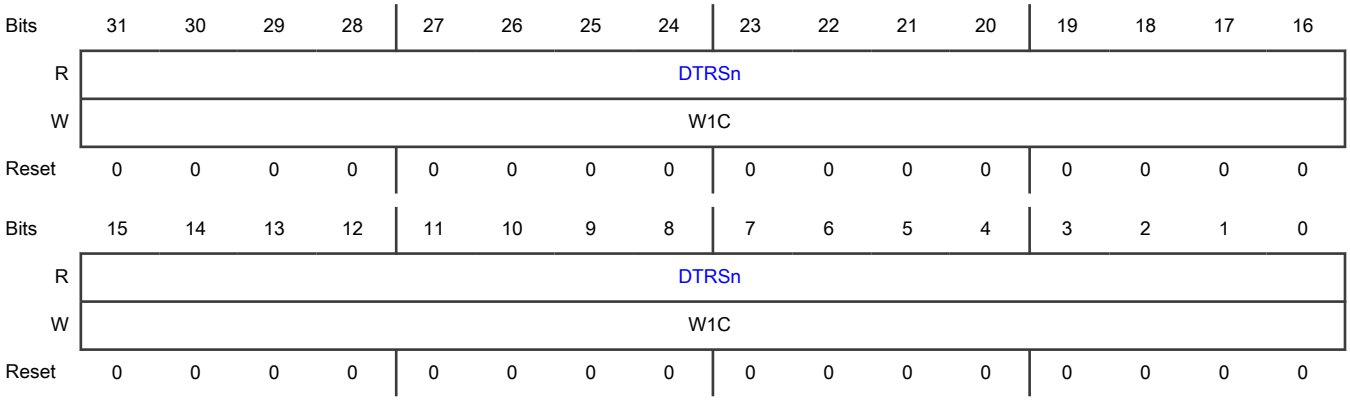
Register	Offset
CDTRSR_ENG1	210h

Function

This register groups data transfer request status from all channels. Their bits are mirrored from the Channel Status Control registers (see eTPU_CCCR register descriptions) and Host must write 1 to clear a status bit.

For details about interrupts, see Interrupts and data transfer requests.

Diagram



Fields

Field	Function
31-0 DTRSn	Channel n Data Transfer Request Status. These bits mimic the corresponding eTPU DMA requests. DTRSn can be cleared by software writing a 1 to it or by the assertion of corresponding DMA completion acknowledge line. When read: 0.....Indicates that channel n has no pending data transfer request. 1.....Indicates that channel x has a pending data transfer request. When written: 0.....Keep status bit unaltered. 1.....Clear status bit.

67.12.1.5 eTPU Channel Data Transfer Request Status Register for Engine 2 (CDTRSR_ENG2)

Offset

Register	Offset
CDTRSR_ENG2	214h

Function

This register groups data transfer request status from all channels.These bits are mirrored from the Channel Status Control registers (see eTPU_CCCR register descriptions) and Host must write 1 to clear a status bit.

For details about interrupts, see Interrupts and data transfer requests.

For details about Watchdog mechanism, see . **NOTE** The WDSn bits set in case of a watchdog timeout independently of #unique_3044/unique_3044_Connect_42_WDTR_ENG2.WMO. When read: 0.....Watchdog did not expire during execution of a channel x thread since reset or last WDSn clear. 1.....Watchdog expired during execution of a channel n thread. When written: 0.....Keep watchdog status bit unaltered. 1.....Clear watchdog status bit.

67.12.1.16 eTPU Channel Pending Service Status Register for Engine 1 (CPSSR_ENG1)

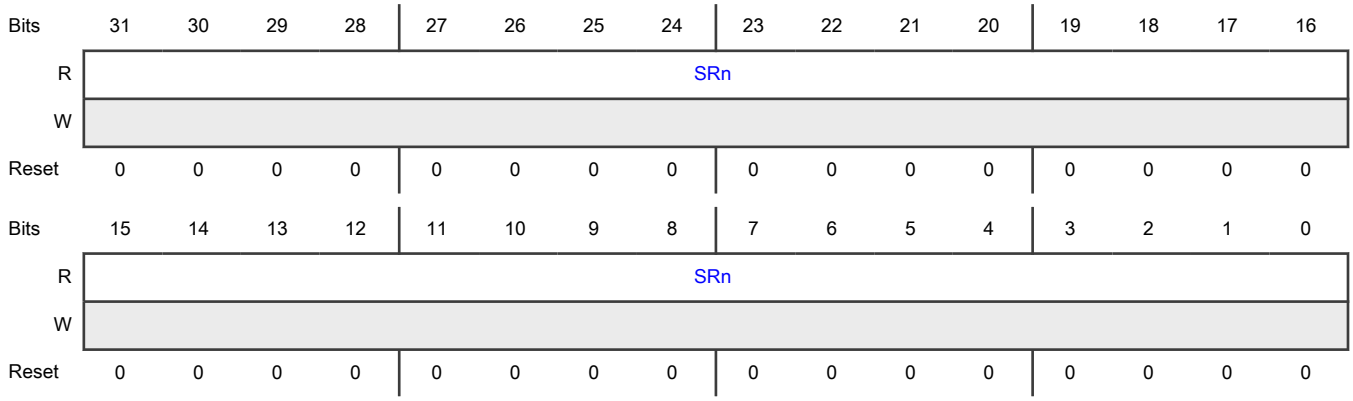
Offset

Register	Offset
CPSSR_ENG1	280h

Function

This register holds the status of the pending Channel Service Requests (see Functions and threads).

Diagram



Fields

Field	Function
31-0 SRn	Pending Service Request n. Indicates a pending Service Request for channel n. Pending SR status is a logic OR of all service requests pending: if only HSR is active, SRn clears only at the end of the thread. SRn clear due to the other request sources is microcode dependent. **NOTE** The pending service status bit for a channel is 1 when a Service Request is pending, even if the Channel is disabled (CPRn = 0). **NOTE** There can be a delay of one clock between writing HSR greater than 0 in C*n*HSRR_ENG1 of a channel and its respective bit being asserted in eTPU_GCR_CPSSR_ENG1. 0000_0000_0000_0000_0000_0000_0000_0000b - No Service Request pending for channel n. 0000_0000_0000_0000_0000_0000_0000_0001b - Pending Service Request for channel n.

67.12.1.17 eTPU Channel Pending Service Status Register for Engine 2 (CPSSR_ENG2)

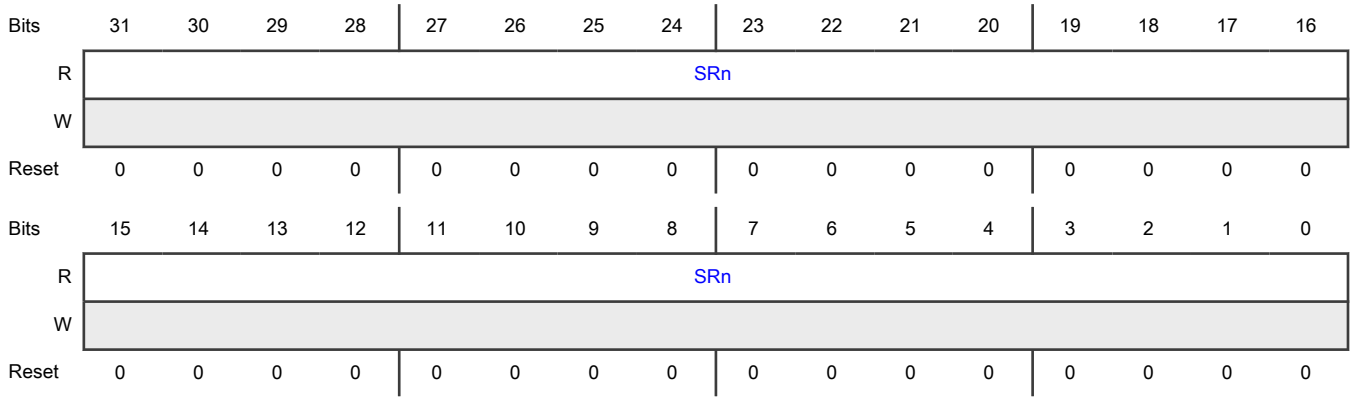
Offset

Register	Offset
CPSSR_ENG2	284h

Function

This register is a read-only register that holds the status of the pending Channel Service Requests (see Functions and threads).

Diagram



Fields

Field	Function
31-0 SRn	Pending Service Request n. Indicates a pending Service Request for channel n. Pending SR status is a logic OR of all service requests pending: if only HSR is active, SRn clears only at the end of the thread. SRn clear due to the other request sources is microcode dependent. **NOTE** The pending service status bit for a channel is 1 when a Service Request is pending, even if the Channel is disabled (CPRn = 0). **NOTE** There can be a delay of one clock between writing HSR greater than 0 in C*n*HSRR_ENG2 of a channel and its respective bit being asserted in eTPU_GCR_CPSSR_ENG2. 0000_0000_0000_0000_0000_0000_0000_0000b - No Service Request pending for channel n. 0000_0000_0000_0000_0000_0000_0000_0001b - Pending Service Request for channel n.

67.12.1.18 eTPU Channel Service Status Register for Engine 1 (CSSR_ENG1)

Offset

Register	Offset
CSSR_ENG1	290h

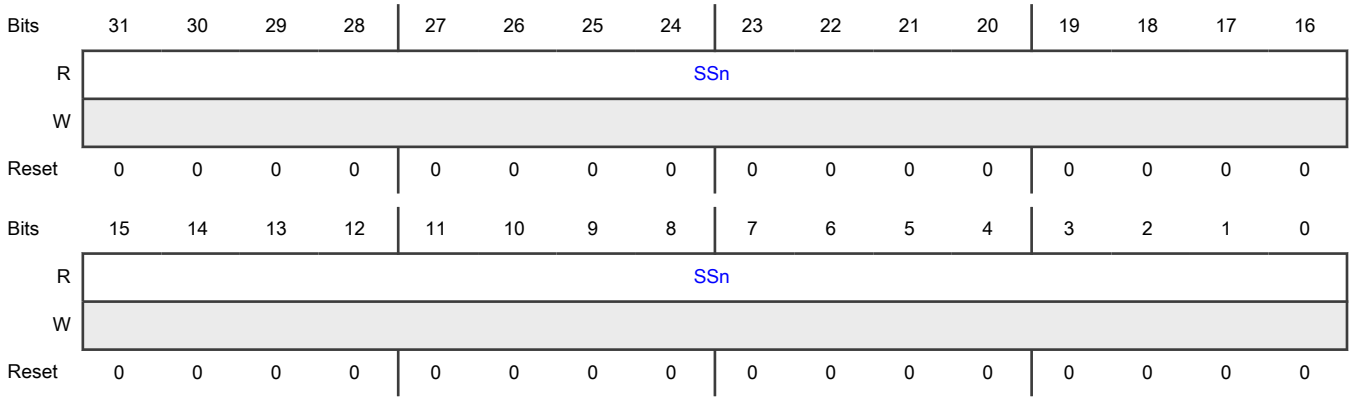
Function

This register holds the current channel service status on whether it is being serviced or not (see Functions and threads). Only one bit may be asserted in this register at a given time. When no channel is being serviced, the register read value is 0x0000_0000. This register is read-only and can be read during normal eTPU operation for monitoring the scheduler activity.

NOTE

Channel Service Status does not always reflect decoding of the CHAN register (see CHAN Register), since the latter can be changed by the service thread microcode.

Diagram



Fields

Field	Function
31-0 SSn	Service Status n. Indicates that channel n is currently being serviced. It is updated at the 1st microcycle of a Time Slot Transition (see Time Slot Transition), or when the microengine ends the thread. 0000_0000_0000_0000_0000_0000_0000_0000b - Channel n is not currently being serviced. 0000_0000_0000_0000_0000_0000_0000_0001b - channel n is currently being serviced.

67.12.1.19 eTPU Channel Service Status Register for Engine 2 (CSSR_ENG2)

Offset

Register	Offset
CSSR_ENG2	294h

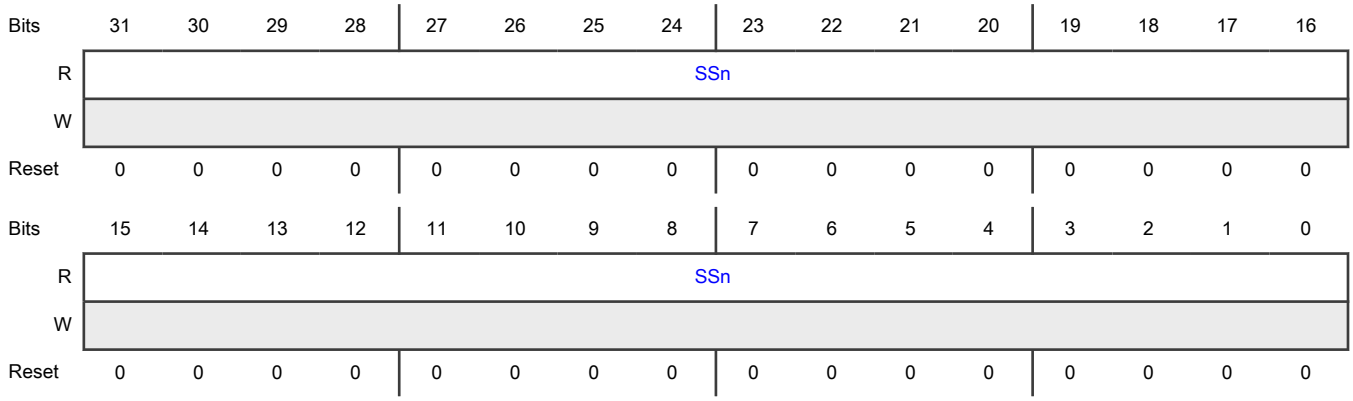
Function

This register holds the current channel service status on whether it is being serviced or not (see Functions and threads). Only one bit may be asserted in this register at a given time. When no channel is being serviced, the register read value is 0x0000_0000. This read-only register can be read during normal eTPU operation for monitoring the scheduler activity.

NOTE

Channel Service Status does not always reflect decoding of the CHAN register (see CHAN Register), since the latter can be changed by the service thread microcode.

Diagram



Fields

Field	Function
31-0 SSn	Service Status n. Indicates that channel n is currently being serviced. It is updated at the 1st microcycle of a Time Slot Transition (see Time Slot Transition), or when the microengine ends the thread. 0000_0000_0000_0000_0000_0000_0000_0000b - Channel n is not currently being serviced. 0000_0000_0000_0000_0000_0000_0000_0001b - channel n is currently being serviced.

67.13 Channel Configuration Control memory map and registers

67.13.1 eTPU_CCCR register descriptions

Each channel has a group of 3 registers used to control, configure and check status of that channel as shown in the following table. This organization eases individual channel management.

Table 482. Channel registers structure

Channel offset	Register name
0x00	eTPU_CCCR_C*n*CR_ENG*m* - eTPU Channel Configuration Register
0x04	eTPU_CCCR_C*n*SCR_ENG*m* - eTPU Channel Status/Control Register
0x08	eTPU_CCCR_C*n*HSRR_ENG*m* - eTPU Channel Host Service Request Register
0x0C	Reserved

One contiguous area is used to map all channel registers of each eTPU engine as shown in the following table.

Table 483. Channel registers mMap

Offset	Registers structure
0x400	eTPU 1 Channel 0 Registers Structure
0x410	eTPU 1 Channel 1 Registers Structure
0x420	eTPU 1 Channel 2 Registers Structure

Table continues on the next page...

Table 483. Channel registers mMap (continued)

Offset	Registers structure
0x430	-----
0x5E0	eTPU 1 Channel 30 Registers Structure
0x5F0	eTPU 1 Channel 31 Registers Structure
0x600	RESERVED
0x800	eTPU 2 Channel 0 Registers Structure
0x810	eTPU 2 Channel 1 Registers Structure
0x820	-----
0x9E0	eTPU 2 Channel 30 Registers Structure
0x9F0	eTPU 2 Channel 31 Registers Structure
0xA00	RESERVED

There are 64 structures defined, one for each available channel in the eTPU System (32 for each Engine). The base address for the structure presented can be calculated by using the following equation:

Channel_Register_Base = eTPU_Engine_Channel_Base + (channel_number * 0x10), where:

- eTPU_Engine_Channel_Base = eTPU_Base + 0x400 for Engine 1.
- eTPU_Engine_Channel_Base = eTPU_Base + 0x800 for Engine 2.

67.13.1.2 eTPU Channel n Configuration Register for Engine 1 (C0CR_ENG1 - C31CR_ENG1)

Offset

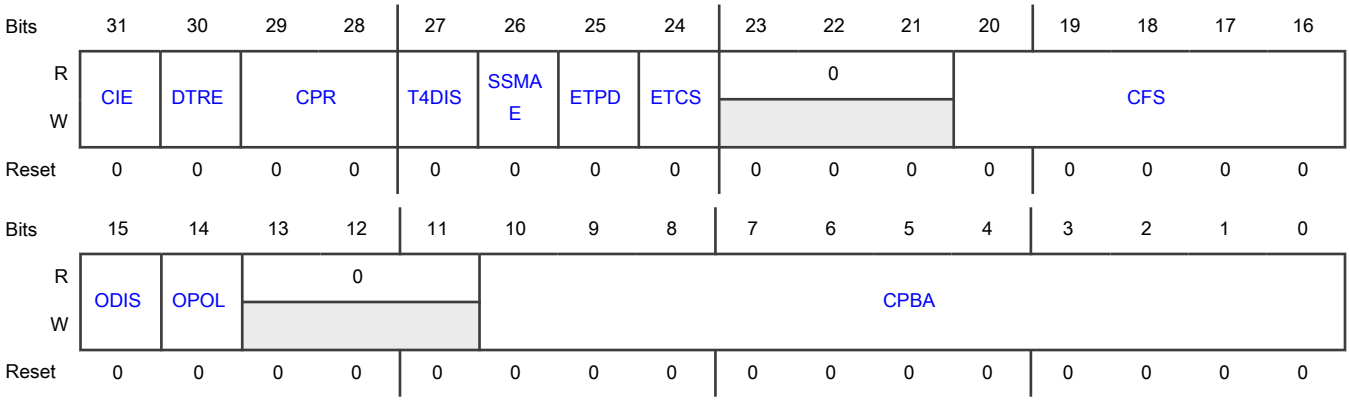
For a = 0 to 31:

Register	Offset
CaCR_ENG1	400h + (a × 10h)

Function

This register gathers configurations set individually per channel.

Diagram



Fields

Field	Function
31 CIE	Channel Interrupt Enable. This bit is mirrored from eTPU Channel Interrupt Enable Register for Engine 1 (CIER_ENG1) (see Channel Interrupt and Data Transfer Requests). 0b - Disable interrupt for this channel. 1b - Enable interrupt for this channel.
30 DTRE	Channel Data Transfer Request Enable. This bit is mirrored from eTPU Channel Data Transfer Request Enable Register for Engine 1 (CDTRER_ENG1) (see Interrupts and data transfer requests). 0b - Disable data transfer request for this channel. 1b - Enable data transfer request for this channel.
29-28 CPR	Channel Priority. This field defines the priority level for the channel, used by the Hardware Scheduler (see Scheduler). 00b - Disabled 01b - Low 10b - Middle 11b - High
27 T4DIS	T4 channel action Disable. This bit forces the channel to work on T2 timing mode, regardless of the FCSS and CDFC fields in eTPU Engine 1 Configuration Register (ECR_ENG1), or of the TCR1CS field in eTPU Engine 1 Time Base Configuration Register (TBCR_ENG1). For more details, see Channel timing modes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Channel works either in T2 or T2/T4 timing modes, depending on the TCR1CS field in eTPU Engine 1 Time Base Configuration Register (TBCR_ENG1) and the FCSS and CDFC fields in eTPU Engine 1 Configuration Register (ECR_ENG1). 1b - Channel works in T2 timing mode, regardless of the TCR1CS field in eTPU Engine 1 Time Base Configuration Register (TBCR_ENG1) or the FCSS and CDFC fields in eTPU Engine 1 Configuration Register (ECR_ENG1).
26 SSMAE	Shared Subsystem Microengine Access Enable. This bit enables the microengine access to the Shared Subsystem Area (see Shared subsystems support). When this bit is negated, DIOB address values pointing to the Shared Subsystem Area actually access SDM mirrors, in legacy mode. **NOTE** SSMAE value must only be changed when the engine is either stopped or halted. 0b - An SDM mirror is accessed when the Shared Subsystem Area is addressed by the microengine. 1b - Enables microengine access to the Shared Subsystem Area.
25 ETPD	Entry Table Pin Direction. This bit selects which channel signal, input or output, is used in the Entry Point selection. The ETPD value has to be compatible with the function chosen for the channel, selected in the field CFS. For details about Entry Table and condition encoding schemes, see Entry Points. 0b - Use PSTI for Entry Point selection. 1b - Use PSTO for Entry Point selection.
24 ETCS	Entry Table Condition Select. This bit determines the channel condition encoding scheme that selects, according to channel conditions, the Entry Point to be taken in an Entry Table. ETCS value has to be compatible with the function chosen for the channel, selected in field CFS. Two condition encoding schemes are available. For details about Entry Table and condition encoding schemes, see Entry Points. 0b - Select Standard Entry Table Condition encoding scheme. 1b - Select Alternate Entry Table Condition encoding scheme.
23-21 —	Reserved
20-16 CFS	Channel Function Select. This field defines the function to be performed by the channel (see Functions and threads). The Function assigned to the channel has to be compatible with the channel condition encoding scheme, selected by field ETCS.
15 ODIS	Output Disable.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This bit enables the channel to have its output forced to the value opposite to OPOL when the output disable input signal corresponding to the channel group that it belongs is active (see eTPU channel output disable signals and OBE - Output Buffer Enable control latch). 0b - Turns off the output disable feature for the channel. 1b - Turns on the output disable feature for the channel.
14 OPOL	Output Polarity. Determines the output signal polarity. The activation of the output disable signal forces, when enabled by the ODIS bit, the channel output signal to the opposite of this polarity (see OBE - Output Buffer Enable control latch). 0b - Output active low (output disable drives output to high). 1b - Output active high (output disable drives output to low).
13-11 —	Reserved
10-0 CPBA	Channel n Parameter Base Address. The value of this field times 8 specifies the SDM parameter base host (byte) address for channel n (2-parameter granularity; see SDM organization). As seen by the Host, the channel parameter base (byte) address is (without parameter sign extension) eTPU_Base + 0x8000 + CPBA * 8 or (with parameter sign extension), eTPU_Base + 0xC000 + CPBA*8.

67.13.1.3 eTPU Channel n Status Control Register for Engine 1 (C0SCR_ENG1 - C31SCR_ENG1)

Offset

For a = 0 to 31:

Register	Offset
CaSCR_ENG1	404h + (a × 10h)

Function

This register gathers the interrupt status bits of the channel and the Function Mode definition (read-write). Bits CIS, CIOS, and DTRS for each channel can be also accessed from eTPU Channel Interrupt Status Register for Engine 1 (CISR_ENG1), eTPU Channel Interrupt Overflow Status Register for Engine 1 (CIOSR_ENG1), and eTPU Channel Data Transfer Request Status Register for Engine 1 (CDTRSR_ENG1). Host must write 1 to clear a status bit.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	IPS	OPS	OBE	0											FM	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 CIS	Channel Interrupt Status. These bits are mirrored in eTPU Channel Interrupt Status Register for Engine 1 (CISR_ENG1). Also, see Channel Interrupt and Data Transfer Requests. When read: 0.....Channel has no pending interrupt to the Host CPU. 1.....Channel has a pending interrupt to the Host CPU. When written: 0.....Keep interrupt status bit unaltered. 1.....Clear interrupt status bit.
30 CIOS	Channel Interrupt Overflow Status. These bits are mirrored in eTPU Channel Interrupt Overflow Status Register for Engine 1 (CIOSR_ENG1). Also, see Interrupt and Data Transfer Request overflow. When read: 0.....Interrupt overflow negated for this channel. 1.....Interrupt overflow asserted for this channel. When written: 0.....Keep status bit unaltered. 1.....Clear status bit.
29-24 —	Reserved
23 DTRS	Data Transfer Request Status. These bits are mirrored in eTPU Channel Data Transfer Request Status Register for Engine 1 (CDTRSR_ENG1). Also, see Channel Interrupt and Data Transfer Requests.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When read: 0.....Channel has no pending data transfer request. 1.....Channel has a pending data transfer request. When written: 0.....Keep status bit unaltered. 1.....Clear status bit.
22 DTROS	Data Transfer Request Overflow Status. These bits are mirrored in eTPU Channel Data Transfer Request Overflow Status Register for Engine 1 (CDTROSR_ENG1). Also, see Interrupt and Data Transfer Request overflow. When read: 0.....Data transfer request overflow negated for this channel. 1.....Data transfer request overflow asserted for this channel. When written: 0.....Keep status bit unaltered. 1.....Clear status bit.
21-16 —	Reserved
15 IPS	Channel Input Pin State. This bit shows the current value of the filtered channel input signal state.
14 OPS	Channel Output Pin State. This bit shows the current value driven in the channel output signal, including the effect of the external output disable feature (see eTPU channel output disable signals). If the channel input and output signals are connected to the same pad, OPS reflects the value driven to the pad (if OBE=1). This is not necessarily the actual pad value, which drives the value in the bit IPS.
13 OBE	Output Buffer Enable. This bit shows the state of the channel output buffer enable signal, controlled by microcode.
12-2 —	Reserved
1-0 FM	Channel Function Mode. Each function uses this field for a specific configuration. These bits can be tested by microengine code (see Conditional/unconditional branch).

67.13.1.4 eTPU Channel n Host Service Request Register for Engine 1 (C0HSRR_ENG1 - C31HSRR_ENG1)

Offset

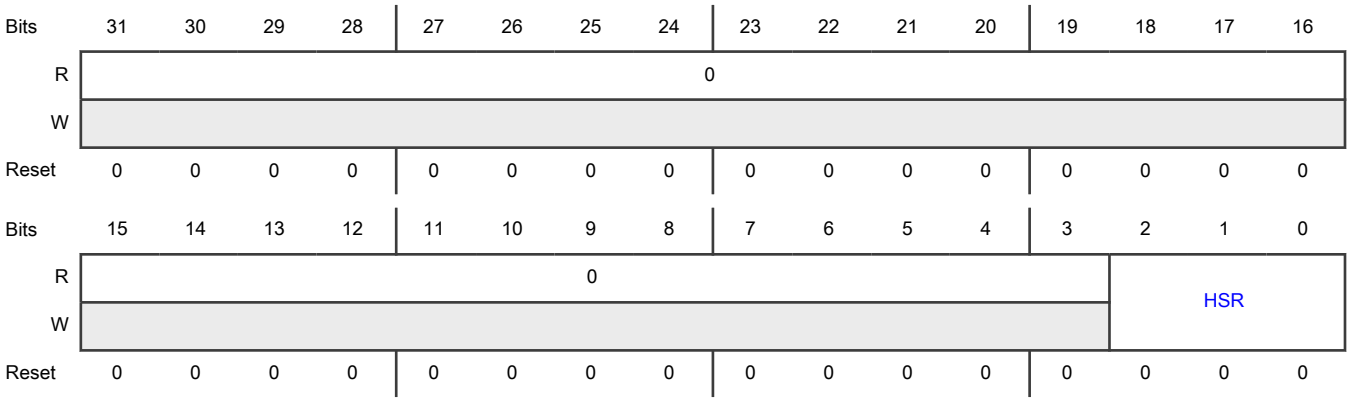
For a = 0 to 31:

Register	Offset
CaHSRR_ENG1	408h + (a × 10h)

Function

This register is used by the Host to issue service requests to the channel.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 HSR	Host Service Request This field is used by the Host CPU to request service to the channel (see Host Service Requests). HSR value turns to 000 automatically at the end of microengine service for that channel, but only if the thread started due to an HSR. Host should write HSR greater than 0 only when HSR=0. Writing HSR=000 withdraws a pending request if scheduler did not begin to resolve the Entry Point yet, but it does not abort the service thread from that point on. For more details, see Entry Points and Host Service Requests. 000b - No Host Service Request pending. 001b - Function-dependent Host Service Request pending. 111b - Function-dependent Host Service Request pending.

67.13.1.5 eTPU Channel n Configuration Register for Engine 2 (C0CR_ENG2 - C31CR_ENG2)

Offset

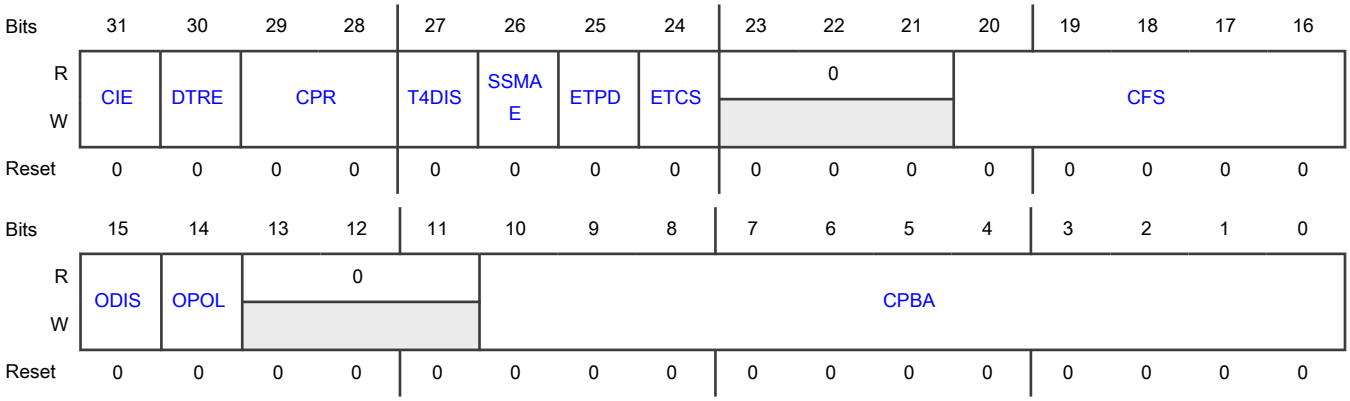
For a = 0 to 31:

Register	Offset
CaCR_ENG2	800h + (a × 10h)

Function

This register gathers configurations set individually per channel.

Diagram



Fields

Field	Function
31 CIE	Channel Interrupt Enable. This bit is mirrored from eTPU Channel Interrupt Enable Register for Engine 2 (CIER_ENG2) (see Channel Interrupt and Data Transfer Requests). 0b - Disable interrupt for this channel. 1b - Enable interrupt for this channel.
30 DTRE	Channel Data Transfer Request Enable. This bit is mirrored from eTPU Channel Data Transfer Request Enable Register for Engine 2 (CDTRER_ENG2) (see Channel Interrupt and Data Transfer Requests). 0b - Disable data transfer request for this channel. 1b - Enable data transfer request for this channel.
29-28 CPR	Channel Priority. This field defines the priority level for the channel, used by the Hardware Scheduler (see Scheduler). 00b - Disabled 01b - Low 10b - Middle 11b - High
27	T4 channel action Disable.

Table continues on the next page...

Table continued from the previous page...

Field	Function
T4DIS	This bit forces the channel to work on T2 timing mode, regardless of the FCSS and CDFC fields in eTPU Engine 2 Configuration Register (ECR_ENG2), or of the TCR1CS field in eTPU Engine 2 Time Base Configuration Register (TBCR_ENG2). For more details, see Channel timing modes. 0b - Channel works either in T2 or T2/T4 timing modes, depending on the TCR1CS field in eTPU Engine 2 Time Base Configuration Register (TBCR_ENG2) and the FCSS and CDFC fields in eTPU Engine 2 Configuration Register (ECR_ENG2). 1b - Channel works in T2 timing mode, regardless of the TCR1CS field in eTPU Engine 2 Time Base Configuration Register (TBCR_ENG2) or the FCSS and CDFC fields in eTPU Engine 2 Configuration Register (ECR_ENG2).
26 SSMAE	Shared Subsystem Microengine Access Enable. This bit enables the microengine access to the Shared Subsystem Area (see Shared subsystems support). When this bit is negated, DIOB address values pointing to the Shared Subsystem Area actually access SDM mirrors, in legacy mode. **NOTE** SSMAE value must only be changed when the engine is either stopped or halted. 0b - An SDM mirror is accessed when the Shared Subsystem Area is addressed by the microengine. 1b - Enables microengine access to the Shared Subsystem Area.
25 ETPD	Entry Table Pin Direction. This bit selects which channel signal, input or output, is used in the Entry Point selection. The ETPD value has to be compatible with the function chosen for the channel, selected in the field CFS. For details about Entry Table and condition encoding schemes, see Entry Points. 0b - Use PSTI for Entry Point selection. 1b - Use PSTO for Entry Point selection.
24 ETCS	Entry Table Condition Select. This bit determines the channel condition encoding scheme that selects, according to channel conditions, the Entry Point to be taken in an Entry Table. ETCS value has to be compatible with the function chosen for the channel, selected in field CFS. Two condition encoding schemes are available. For details about Entry Table and condition encoding schemes, see Entry Points. 0b - Select Standard Entry Table Condition encoding scheme. 1b - Select Alternate Entry Table Condition encoding scheme.
23-21 —	Reserved
20-16 CFS	Channel Function Select. This field defines the function to be performed by the channel (see Functions and threads). The Function assigned to the channel has to be compatible with the channel condition encoding scheme, selected by field ETCS.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15 ODIS	Output Disable. This bit enables the channel to have its output forced to the value opposite to OPOL when the output disable input signal corresponding to the channel group that it belongs is active (see eTPU channel output disable signals and OBE - Output Buffer Enable control latch). 0b - Turns off the output disable feature for the channel. 1b - Turns on the output disable feature for the channel.
14 OPOL	Output Polarity. Determines the output signal polarity. The activation of the output disable signal forces, when enabled by the ODIS bit, the channel output signal to the opposite of this polarity (see OBE - Output Buffer Enable control latch). 0b - Output active low (output disable drives output to high). 1b - output active high (output disable drives output to low).
13-11 —	Reserved
10-0 CPBA	Channel n Parameter Base Address. The value of this field times 8 specifies the SDM parameter base host (byte) address for channel n (2-parameter granularity; see SDM organization). As seen by the Host, the channel parameter base (byte) address is (without parameter sign extension) eTPU_Base + 0x8000 + CPBA * 8 or (with parameter sign extension), eTPU_Base + 0xC000 + CPBA*8.

67.13.1.6 eTPU Channel n Status Control Register for Engine 2 (C0SCR_ENG2 - C31SCR_ENG2)

Offset

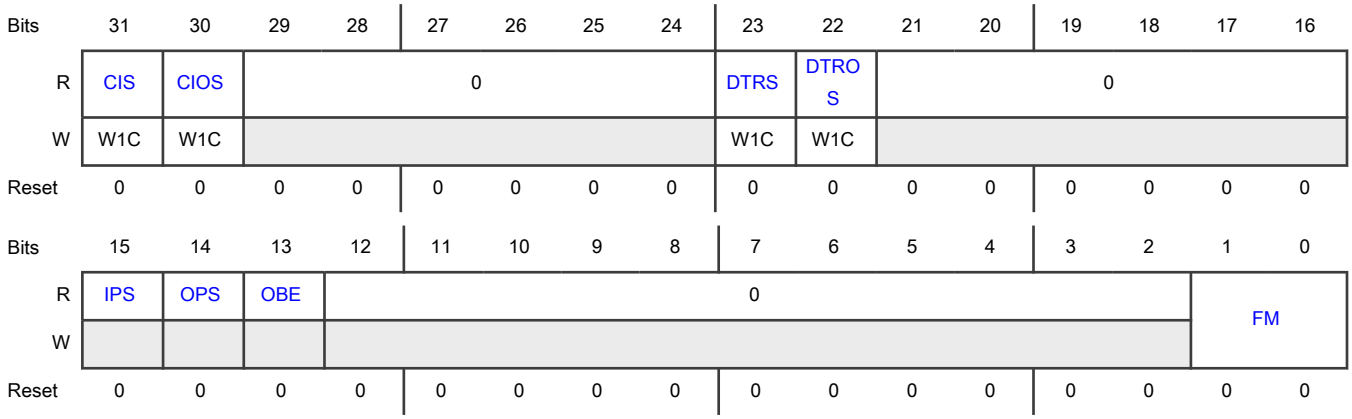
For a = 0 to 31:

Register	Offset
CaSCR_ENG2	804h + (a × 10h)

Function

This register gathers the interrupt status bits of the channel and the Function Mode definition (read-write). Bits CIS, CIOS, and DTRS for each channel can be also accessed from eTPU Channel Interrupt Status Register for Engine 2 (CISR_ENG2), eTPU Channel Interrupt Overflow Status Register for Engine 2 (CIOSR_ENG2), and eTPU Channel Data Transfer Request Status Register for Engine 2 (CDTRSR_ENG2). Host must write 1 to clear a status bit.

Diagram



Fields

Field	Function
31 CIS	Channel Interrupt Status. These bits are mirrored in eTPU Channel Interrupt Status Register for Engine 2 (CISR_ENG2). Also, see Channel Interrupt and Data Transfer Requests. When read: 0.....Channel has no pending interrupt to the Host CPU. 1.....Channel has a pending interrupt to the Host CPU. When written: 0.....Keep interrupt status bit unaltered. 1.....Clear interrupt status bit.
30 CIOS	Channel Interrupt Overflow Status. These bits are mirrored in eTPU Channel Interrupt Overflow Status Register for Engine 2 (CIOSR_ENG2). Also, see Interrupt and Data Transfer Request overflow. When read: 0.....Interrupt overflow negated for this channel. 1.....Interrupt overflow asserted for this channel. When written: 0.....Keep status bit unaltered. 1.....Clear status bit.
29-24 —	Reserved
23 DTRS	Data Transfer Request Status. These bits are mirrored in eTPU Channel Interrupt Status Register for Engine 2 (CISR_ENG2). Also, see Channel Interrupt and Data Transfer Requests.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When read: 0.....Channel has no pending data transfer request. 1.....Channel has a pending data transfer request. When written: 0.....Keep status bit unaltered. 1.....Clear status bit.
22 DTROS	Data Transfer Request Overflow Status. These bits are mirrored in eTPU Channel Data Transfer Request Overflow Status Register for Engine 2 (CDTROSR_ENG2). Also, see Channel Interrupt and Data Transfer Requests. When read: 0.....Data transfer request overflow negated for this channel. 1.....Data transfer request overflow asserted for this channel. When written: 0.....Keep status bit unaltered. 1.....Clear status bit.
21-16 —	Reserved
15 IPS	Channel Input Pin State. This bit shows the current value of the filtered channel input signal state.
14 OPS	Channel Output Pin State. This bit shows the current value driven in the channel output signal, including the effect of the external output disable feature (see eTPU channel output disable signals). If the channel input and output signals are connected to the same pad, OPS reflects the value driven to the pad (if OBE=1). This is not necessarily the actual pad value, which drives the value in the bit IPS.
13 OBE	Output Buffer Enable. This bit shows the state of the channel output buffer enable signal, controlled by microcode.
12-2 —	Reserved
1-0 FM	Channel Function Mode. Each function uses this field for a specific configuration. These bits can be tested by microengine code (see Conditional/unconditional branch).

67.13.1.7 eTPU Channel n Host Service Request Register for Engine 2 (C0HSRR_ENG2 - C31HSRR_ENG2)

Offset

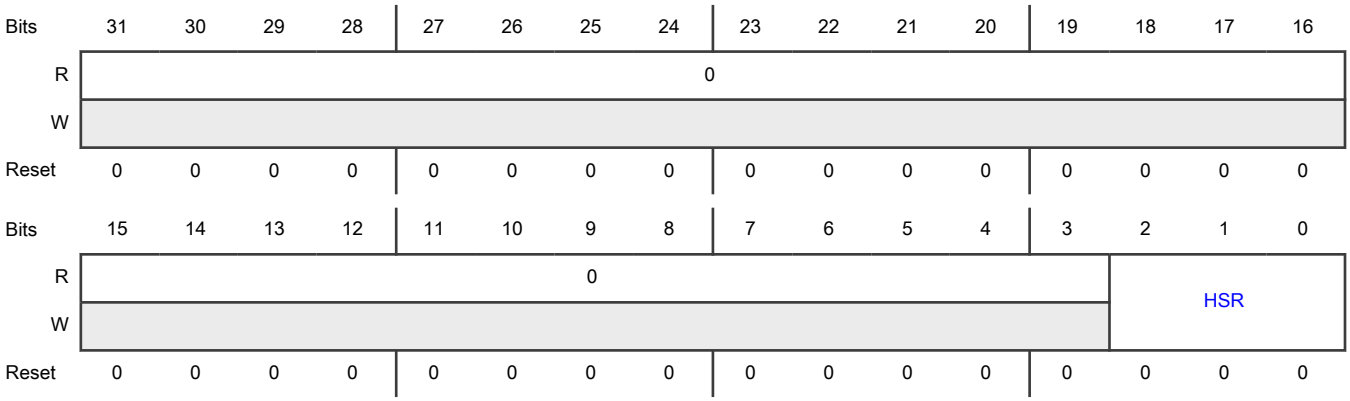
For a = 0 to 31:

Register	Offset
CaHSRR_ENG2	808h + (a × 10h)

Function

This register is used by the Host to issue service requests to the channel.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 HSR	Host Service Request This field is used by the Host CPU to request service to the channel (see Host Service Requests). HSR value turns to 000 automatically at the end of microengine service for that channel, but only if the thread started due to an HSR. Host should write HSR greater than 0 only when HSR=0. Writing HSR=000 withdraws a pending request if scheduler did not begin to resolve the Entry Point yet, but it does not abort the service thread from that point on. For more details, see Entry Points and Host Service Requests. 000b - No Host Service Request pending. 001b - Function-dependent Host Service Request pending. 111b - Function-dependent Host Service Request pending.

67.14 Shared Subsystem Integration memory map and registers

67.14.1 eTPU_SSIR register descriptions

Shared Subsystems Integration Registers configure aspects of how the shared modules interface with the eTPU. There is one integration register for each subsystem unit, which can be, depending on the specific subsystem, a whole IP module, a sub-module, or a channel within a module. For more details, see Shared subsystems support .

67.14.1.1 eTPU_SSIR memory map

eTPU_5 base address: 4068_0000h

67.15 Glossary

channel	The dedicated hardware that, with a selected timebase, performs input signal processing and output signal generation for a specific I/O signal pair.
function	A set of microengine routines that implement a specific channel application. See Functions and threads.
microengine	A single eTPU internal processing core. Also called an eTPU engine. Typically, there are two microengines in an eTPU module.
SCM	Shared code memory
SDM	Shared data memory
SSS	Shared Subsystem area. A memory map region used by both the host and eTPU to access registers of a reaction channel, giving you the option to control them by the host, the eTPU code, or a combination of both.
STAC bus	Shared time and counter bus. Used for sharing real-time data between multiple peripherals.
thread	A service routine of a function, or its execution. See Functions and threads.

Chapter 68
Sine Wave Generator (SGEN)

68.1 Chip-specific SGEN information

68.1.1 SGEN configuration

This device has 2 sine wave generators modules: SGEN_0 and SGEN_1.

The 2 sine wave generators modules share dedicated Power and ground pads.

NOTE

Each instance have one trigger signal which comes through TRGMUX.

68.2 Introduction

The Sine Wave Generator (SGEN) generates a high-quality sinusoidal voltage signal. It can be programmed with the desired oscillation frequency and amplitude voltage. A wide frequency range (1 kHz–50 kHz in 16 Hz steps) is easily programmable through a simple register interface. The linearity and noise performance are carefully optimized through digital processing.

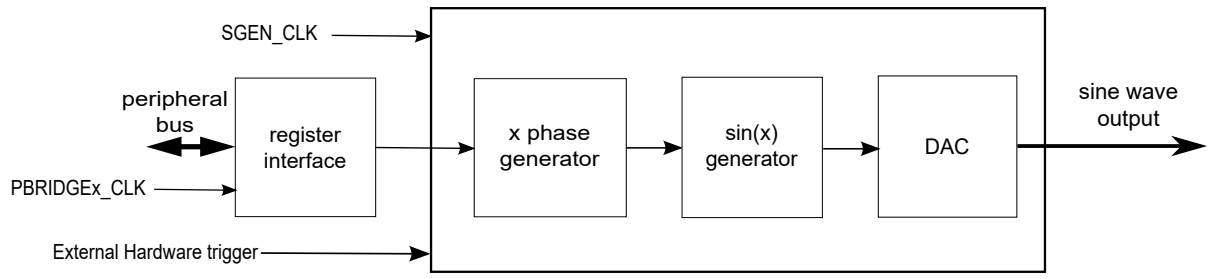


Figure 495. SGEN block diagram

68.3 Features

- Input clock frequency range: 12 MHz–20 MHz
- Output sinusoidal signal:
  - Frequency range: 1 kHz–50 kHz
  - Peak-to-peak amplitude: user adjustable. See Output sine wave amplitude

68.4 SGEN register descriptions

68.4.1 SGEN memory map

SGEN_0 base address: 406C_8000h

SGEN_1 base address: 406C_C000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Control Register (CTRL)	32	RW	0001_0000h
4h	Status Register (STAT)	32	RW	0000_0000h

68.4.2 Control Register (CTRL)

Offset

Register	Offset
CTRL	0h

Function

This register enables the following operations:

- Control and read the output sine wave frequency.
- Control and read the output sine wave amplitude.
- Input phase align trigger mode selection for the sine wave output.
- Control acceptance window width.
- Select the input trigger mode to align the phase of the sine wave output.

NOTE

Changes made to the SGEN_CTRL register must be preserved for at least 50 SGEN clock cycles. Failure to do so might cause unexpected output from the SGEN

Diagram

Fields

Field	Function
31	Load sine wave frequency

Table continues on the next page...

Table continued from the previous page...

Field	Function
LDOS	CTRL[IOFREQ] is loaded by waiting until LDOS = 0 and then setting LDOS to 1. **NOTE** LDOS bit toggling to be done before the Power Down bit is cleared. 0b - Wait for I/O sine wave frequency 1b - Load I/O sine wave frequency
30 —	Reserved
29-26 IOAMPL	IO sine wave amplitude Controls the sine wave voltage amplitude on the output pin. See Output sine wave amplitude for further information.
25-24 WINDOW	Phase alignement acceptance window width These bits controls the size of the acceptance window for the phase alignment. 00b - +- 1% from the zero crossing 01b - +- 10% from the zero crossing 10b - +- 15% from the zero crossing 11b - +- 25% from the zero crossing
23 SEMASK	Sine wave generator error mask interrupt register 0b - Mask the SGEN error interrupt source 1b - Enable the SGEN error interrupt source
22-20 —	Reserved
19 —	Reserved
18 TRIG_MODE	Input phase align trigger mode selection bit The sine wave appears at the output after the first active trigger occurs. Its frequency is determined by IOFREQ. 0b - Software trigger mode is selected. 1b - Hardware trigger mode is selected.
17 —	Reserved
16	Enter/exit Power Down mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
PDS	0b - Force SGEN to exit Power Down mode. 1b - Force SGEN to enter Power Down mode.
15-0 IOFREQ	Output sine wave frequency See Output sine wave frequency to determine value for this field.

68.4.3 Status Register (STAT)

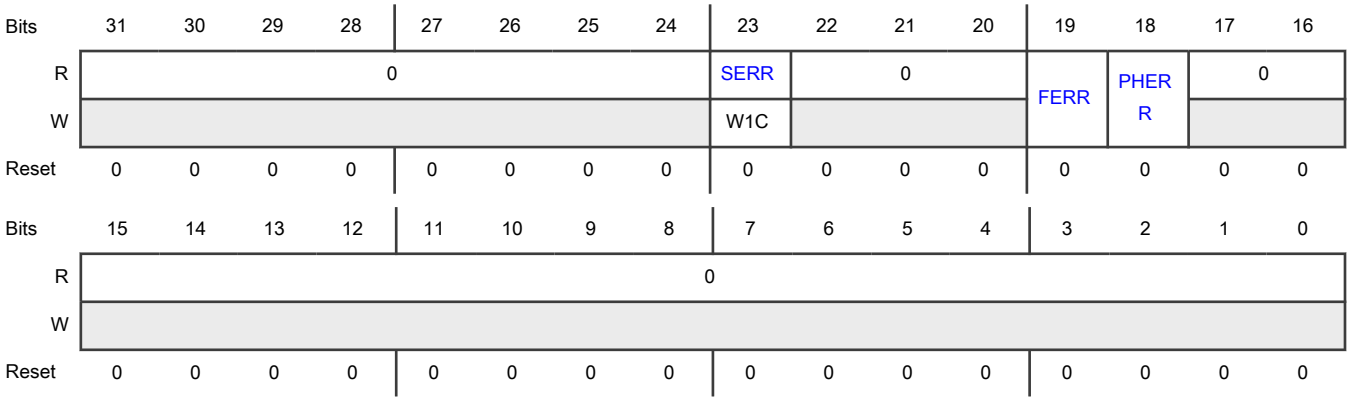
Offset

Register	Offset
STAT	4h

Function

This register provides information about error status.

Diagram



Fields

Field	Function
31-24 —	Reserved
23 SERR	Error interrupt status This field is set by chip and it can be also set by the SGEN_STAT[FERR] or SGEN_STAT[PHERR] field. It can be cleared in software by writing a 1 to it. During an STAT[SERR] clear operation, the hardware set is not allowed to set this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field is set on either of the following conditions: • There is an error in the demodulator block. • The input trigger's phase is out of the acceptance window of the current sine wave output. 0b - No error interrupt pending 1b - Error interrupt pending
22-20 —	Reserved
19 FERR	Software generated demodulator error interrupt **NOTE** Because this field is set in the bus clock domain and the SGEN digital block operates in the SGEN clock domain, both clocks must be present to set the STAT[SERR] field. Also, due to the synchronization between two asynchronous clocks, the setting of STAT[SERR] will occur, at maximum, 4 bus clock and 4 SGEN clock cycles after the setting of STAT[FERR]. 0b - An error interrupt will not be forced. 1b - An error interrupt will be forced.
18 PHERR	Software generated phase error interrupt SERR will be set when this field transistions from 0 to 1. This field can be reset to 0 by software.
17-0 —	Reserved

68.5 Functional description

68.5.1 Operation after a power-on reset

After a power-on reset, the SGEN produces a DC value (no sinusoidal fluctuations).

68.5.2 Output sine wave frequency

The output sine wave frequency *f* is controlled by CTRL[IOFREQ] according to Figure 496 where frequencies *f* and Input frequency are in Hz, and IOFREQ is in decimal format. IOFREQ must be chosen to ensure that *f* remains between 1 kHz and 50 kHz.

$$f = \frac{\text{InputFrequency}}{16777216} \times \text{IOFREQ}$$

Figure 496. Equation 1: Output sine wave frequency

68.5.3 Output sine wave amplitude

The amplitude of the output sine wave is controlled by CTRL[IOAMPL] as described in the following table.

Table 484. Resulting sine wave amplitude for each IOAMPL value

IOAMPL value (decimal)	Sine wave amplitude (V)	Sine wave amplitude step (V)
0	0.423	0.064
1	0.487	0.064
2	0.550	0.063
3	0.613	0.063
4	0.675	0.062
5	0.737	0.062
6	0.797	0.060
7	0.857	0.060
8	0.987	0.130
9	1.136	0.149
10	1.284	0.148
11	1.430	0.146
12	1.575	0.145
13	1.719	0.144
14	1.861	0.142
15	2.00	0.139

68.6 Software trigger mode

The software trigger mode is selected when the SGEN_CTRL[TRIG_MODE] is set to 0. It is possible to update the output signal every time when the new frequency is programmed into the SGEN_CTRL and the bit SGEN_CTRL[LDOS] is toggled (software trigger - see section Initialization and application information for correct sequence of steps).

The figure below shows how the SGEN works in software trigger mode. The software trigger signal is generated by the toggle of the SGEN_CTRL[LDOS] bit. The SGEN OUT signal is not generated until the first software trigger comes.

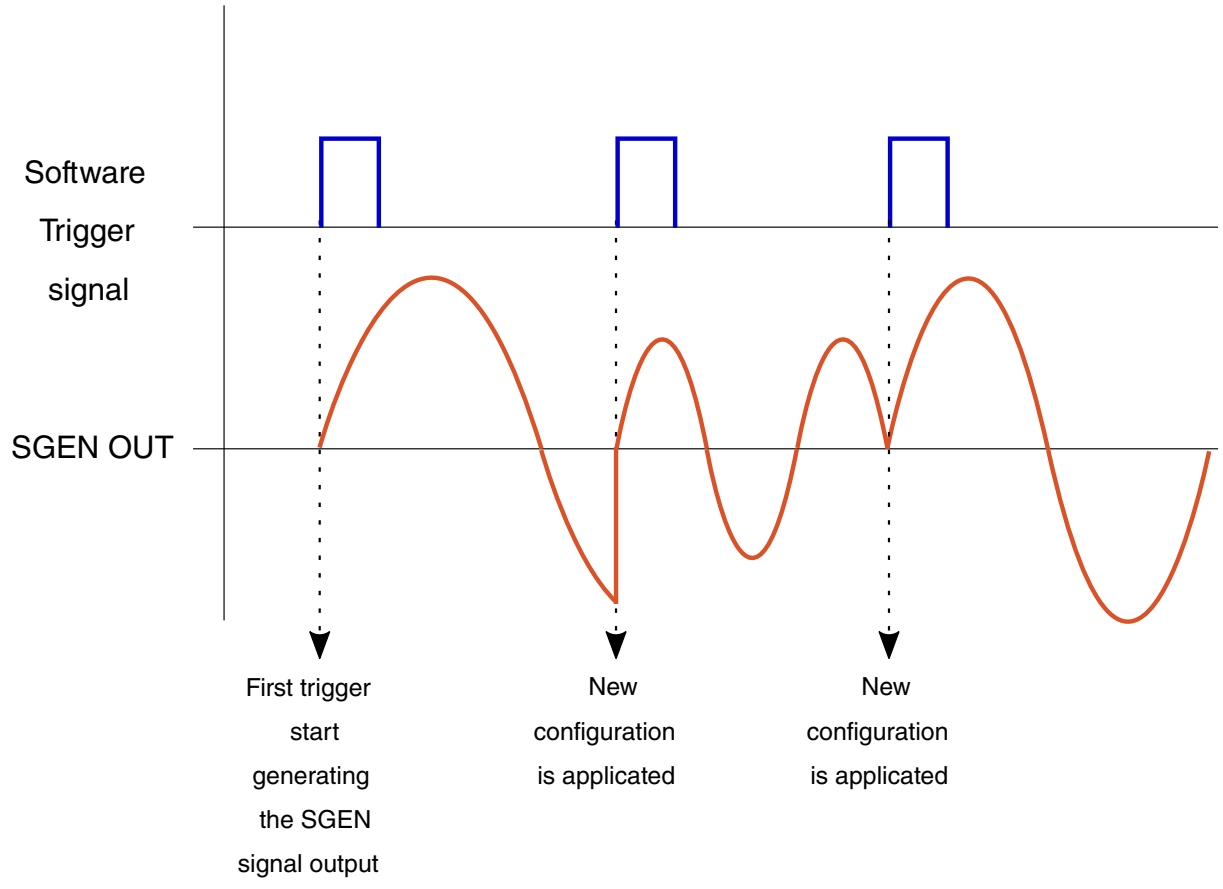


Figure 497. Software trigger mode

68.6.1 Initialization and application information

Bring SWG out of power down by making PDS = 0.

NOTE

A glitch can be observed on the SWG output during the initialization before the output settles on the common voltage level (CV). This glitch is not affecting the SWG functionality.

68.6.2 Change the output frequency

To change the output frequency do the following steps:

1. Determine the required value of the output frequency by using Figure 496.
2. Ensure that CTRL[LDOS] = 0.
3. Write the new value of the CTRL[IOFREQ] field.
4. Set CTRL[LDOS].

The SGEN will begin producing the new sine wave frequency two SGEN clock cycles after this procedure is completed.

68.6.3 Change the output amplitude

Write the new value of the amplitude into SGEN_CTRL[IOAMPL] field using Equation 1Output sine wave amplitude. The amplitude is updated immediately.

68.6.4 Phase control of the sine wave output

To align the SGEN OUT phase with some internal process it is needed to generate the software trigger which will start the SGEN from phase 0 by the following steps:

1. Clear the SGEN_CTRL[LDOS] field.
2. Set SGEN_CTRL[LDOS].

68.7 Hardware trigger mode

The hardware trigger mode is selected when the SGEN_CTRL[TRIG_MODE] is set to 1.

The SGEN OUT signal is not generated until the first hardware trigger arrives.

The SGEN OUT signal frequency and phase are updated when the hardware trigger is inside the acceptance window, which is configurable by the SGEN_CTRL[WINDOW] to +/-1%, +/-10%, +/- 15%, and +/-25%. When the trigger is out of the acceptance window the phase error is generated SGEN_STAT[SERR] = 1.

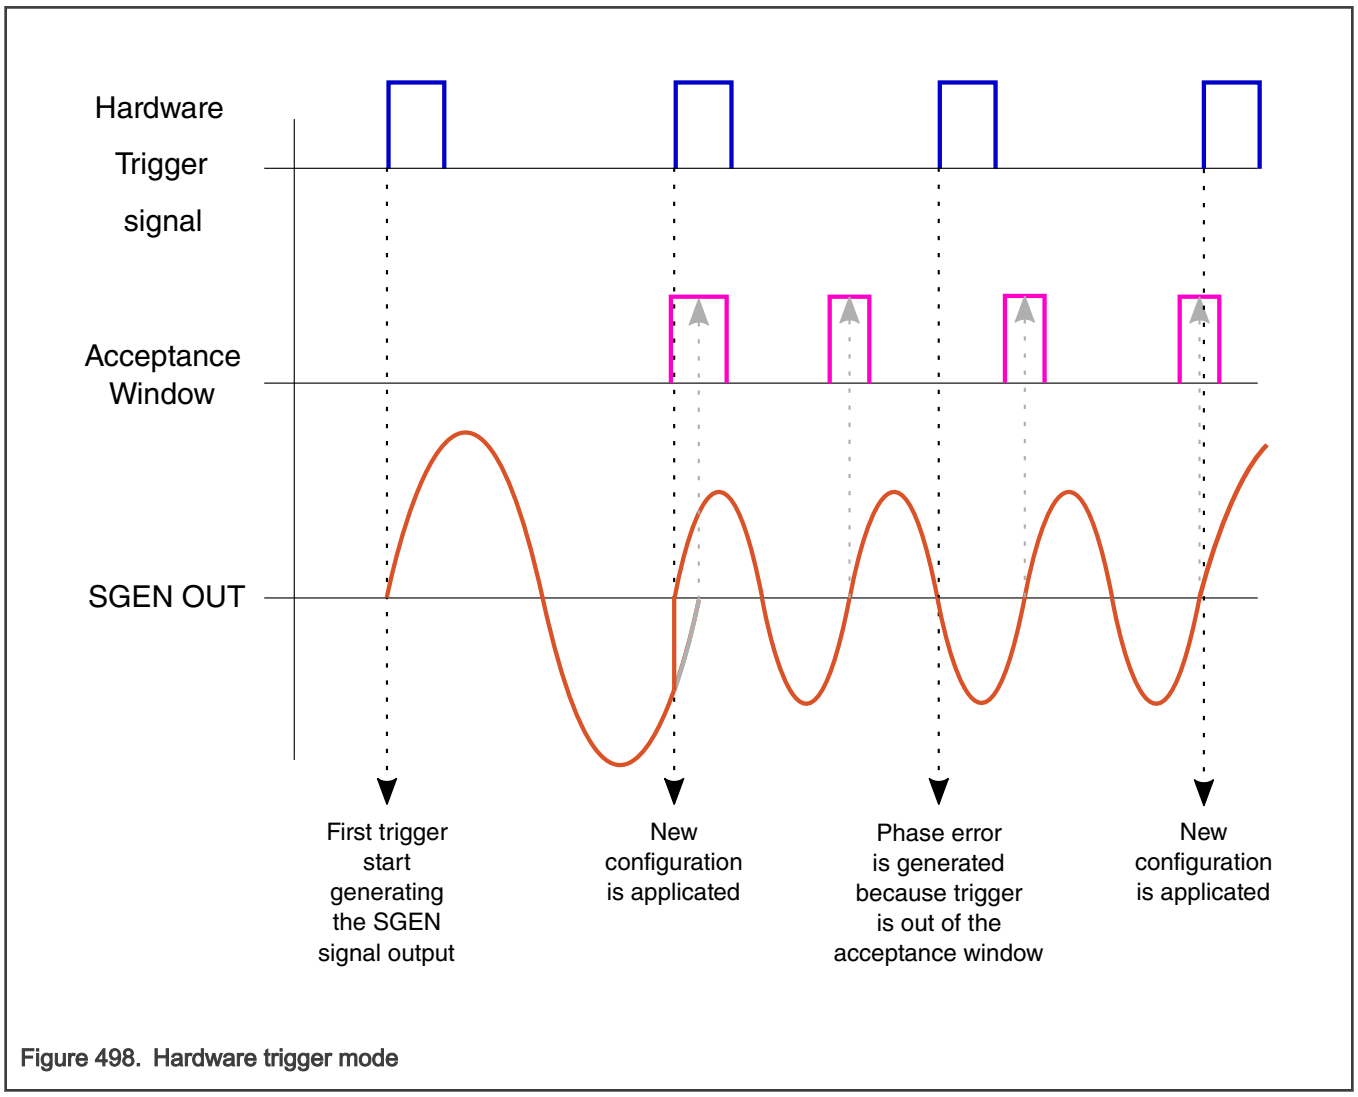

Figure 498. Hardware trigger mode

68.7.1 Acceptance window generation

It is done in the digital part of the SGEN module. When the hardware trigger for reconfiguration is generated (received) the IP checks the value of the pointer which show sample of the SGEN that is sent to the DAC. When the pointer is in the acceptance window (+/-1%, +/-10%, +/-15%, or +/-25%) the trigger is applied, if not the phase error is generated (SGEN_STA[SERR] = 1).

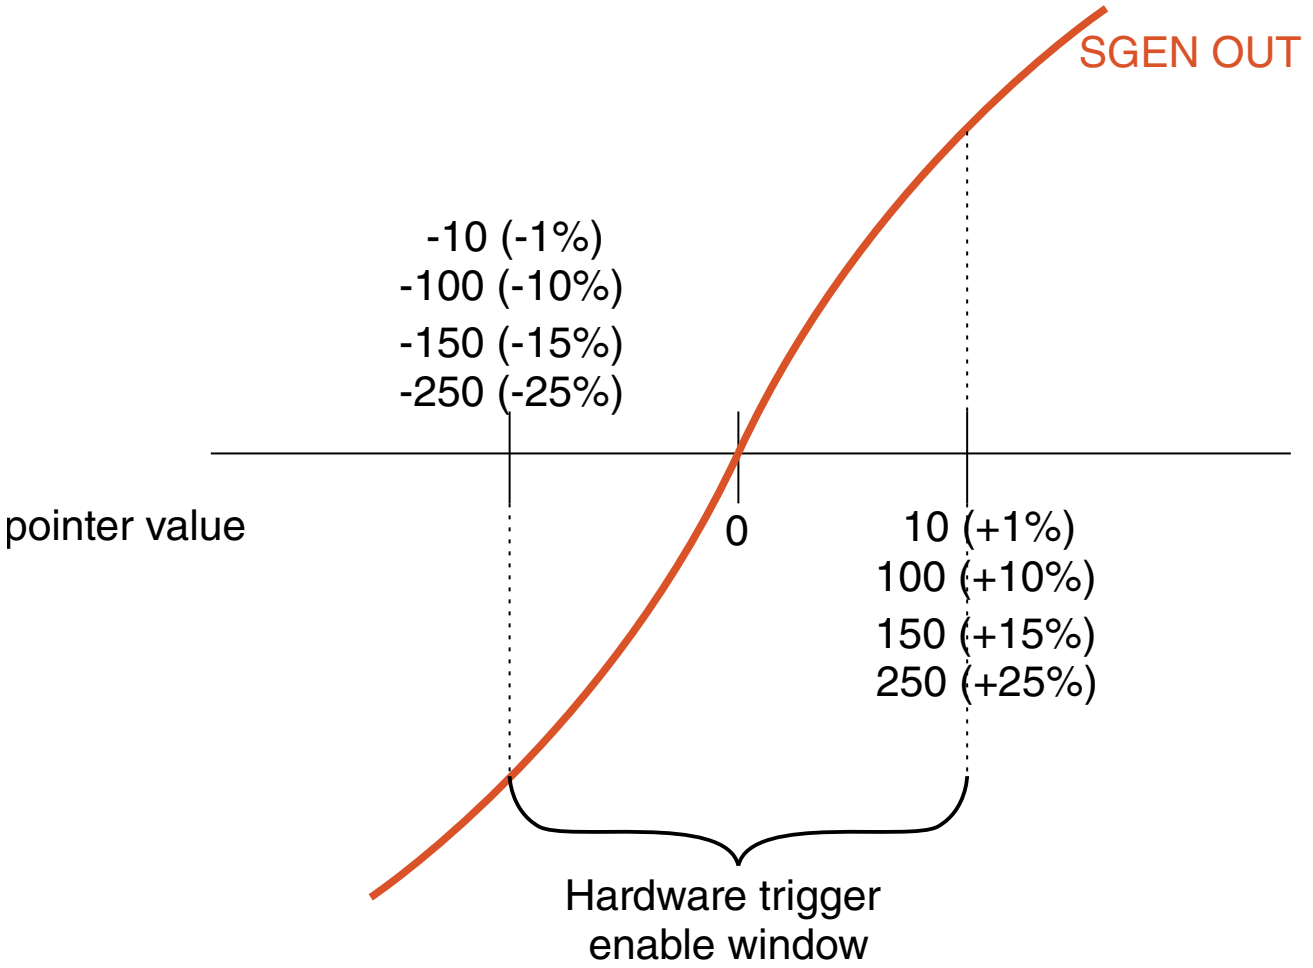

Figure 499. Hardware trigger acceptance window

68.7.2 Initialization and application information

Bring SWG out of power down by making PDS = 0.

NOTE

A glitch can be observed on the SWG output during the initialization before the output settles on the common voltage level (CV). This glitch is not affecting the SWG functionality.

68.7.3 Change the output frequency

To change the output frequency:

1. Determine the required value of the output frequency by using equation 1. Figure 496.
2. Write the new value of the SGEN_CTRL[IOFREQ] field.
3. Generate hardware trigger in the configured acceptance window.
4. When the HW trigger is in the acceptance window the new value of the frequency is applied to SGEN OUT.

68.7.4 Change the output amplitude

Write the new value of the amplitude into the SGEN_CTRL[IOAMPL] field using Output sine wave amplitude. The amplitude is updated immediately.

68.7.5 Phase/Frequency control of the sine wave output

The normal output of the sine wave generator is a free-running sine wave with the amplitude and frequency determined by the SGEN_CTRL register settings.

SGEN_CTRL[TRIG_MODE] selects the hardware phase/frequency align of the sine wave output

The trigger input is a periodic signal which has the same frequency as the sine wave output but might have a different phase (either leading or lagging) or periodical signal with similar frequency as sine wave output which is not reachable by SGEN (this is a limitation by equation Figure 496).

When the HW trigger arrives within the acceptance window the output signal is restarted. If the HW trigger arrives outside of the acceptance window a phase error is generated (SGEN_STAT[SERR] is set).

For additional details refer to the figure below:

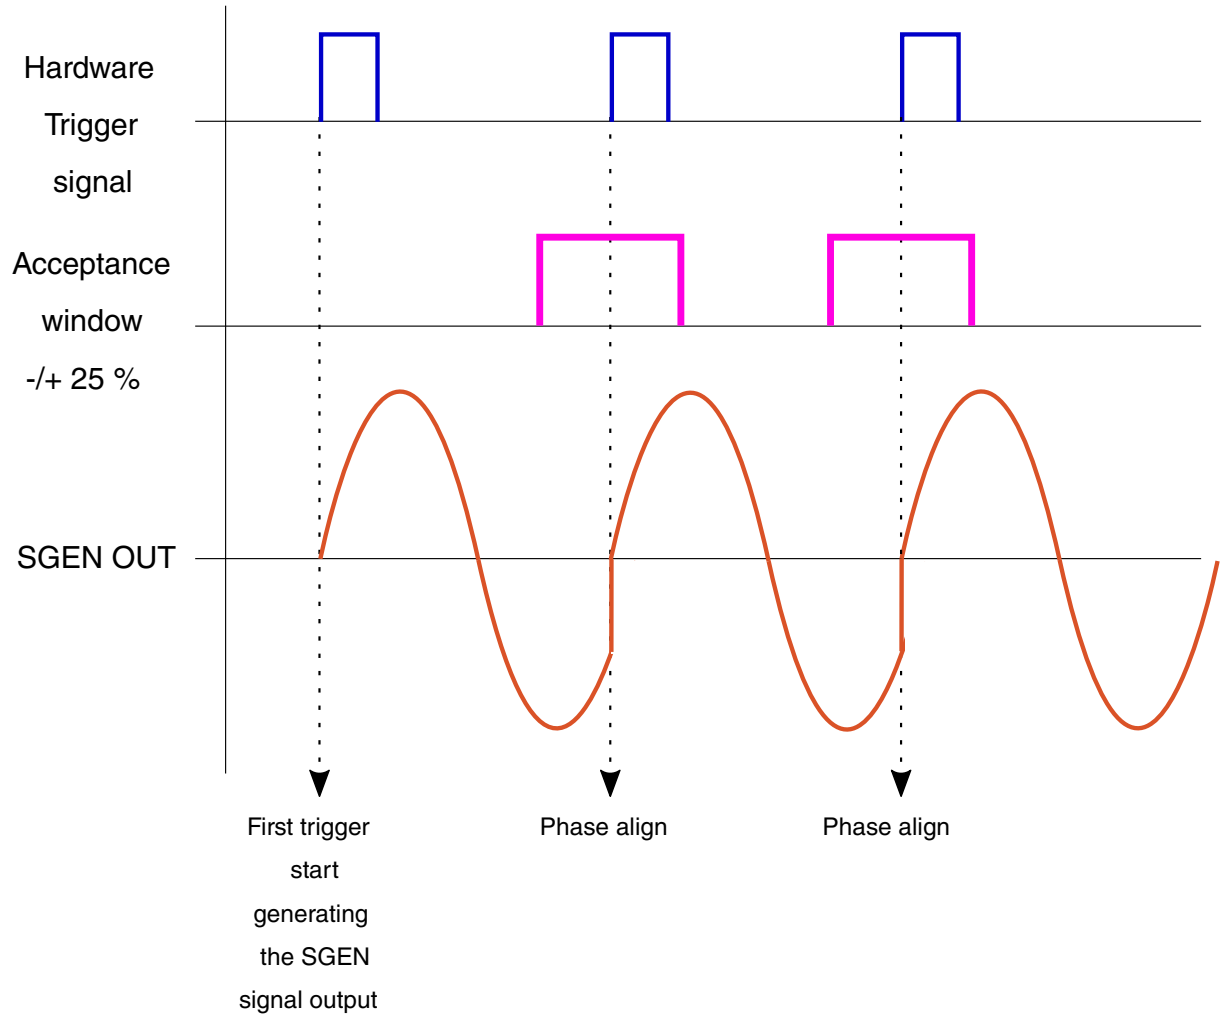

Figure 500. Phase/Frequency control of the sine wave output

NOTE

Because the trigger input is an asynchronous signal, it must be held high for at least 2 SGEN clock cycles to capture the input trigger.

This requirement must be guaranteed by the module generating the trigger input signal. If this requirement is not met, the phase alignment will not function as expected.

Chapter 69
Software Watchdog Timer (SWT)

69.1 Chip-specific SWT information

69.1.1 SWT instances and configuration

This chip supports 3 instances of SWT, one for each Cortex-M7 core.

Table 485. SWT configuration

Instance	Core	Reset type	Clock Source	SWT_MIN_TO (100µs)	SWT_TO_RST (25ms)
SWT_0[1]	Cortex-M7_0	Functional Reset - RAM retention	SIRC (32K)	3	320h
SWT_1	Cortex-M7_1	Functional Reset - RAM retention	SIRC (32K)	3	320h
SWT_2	Cortex-M7_2	Functional Reset - RAM retention	SIRC (32K)	3	320h

1. SWT_0 supports operation in STANDBY mode.

NOTE

When using SWT as a wakeup source from standby, software should ensure proper value of timeout such that SWT timeout doesn't get expired again (after wakeup till standby exit is completed). The timeout should be programmed to a value greater than the time till standby exit is complete (sum of standby exit time and the time till software disables padkeeping).

NOTE

The "Reset only the SWT" feature using SWT_RRR[RRF] is supported only when SWT reset reaction is demoted to interrupt within MC_RGM.

Protect SWT from service by non-core masters

You must program protection for the SWT registers so that only core masters can service SWT.

When an SWT timeout takes place, the logic generating a reset to the system runs off the slow internal RC oscillator (32KHz). It could therefore take the SWT almost 31.25µs to reset the system, after timeout, leaving more time for runaway code to execute. The register interface clock of SWT is running from AIPS_SLOW_CLK, see Clocking chapter for more details. The register interface clock is responsible for generating the abort for invalid access while the counter clock is responsible for generating the SWT reset request. Since there is a synchronization happening between the register interface clock and counter clock domains before generating the SWT reset request, thus the generation of the reset request can take a number of register interface clock cycles after an invalid access is done.

Clock source

SWT is clocked by SIRC only.

69.2 Overview

The Software Watchdog Timer (SWT) is a 32-bit window watchdog timer that enables the system to recover from situations such as:

- Software trapped in a loop

- A bus transaction failing to terminate

In regular operation, SWT requires periodic execution of a watchdog servicing operation. The servicing operation resets the timer to a specified timeout period. If this servicing action does not occur before the timer expires, SWT generates an interrupt or a hardware reset request.

You can configure SWT to generate a reset request or an interrupt on the initial timeout. SWT always generates a reset request on a second consecutive timeout.

69.2.1 Block diagram

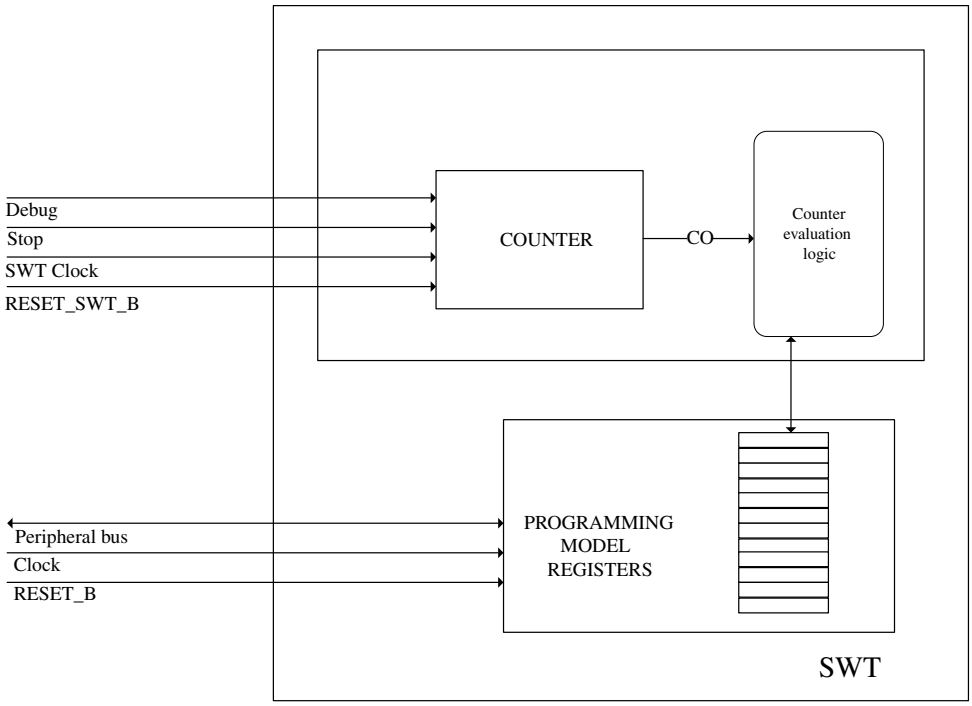

Figure 501. SWT block diagram

69.2.2 Features

SWT has the following features:

- 32-bit countdown timer
- Selection of regular or window servicing
- Selection of reset request or interrupt on an initial timeout
- Selection of fixed or keyed service sequence
- Master access protection
- Hard and soft configuration lock bits

69.3 Functional description

69.3.1 Behavior in different chip and core modes

SWT supports the core modes of operation as follows:

Core mode	SWT behavior
Normal	When SWT is enabled (CR[WEN] = 1), the SWT timer counts down continuously.
Debug	If CR[FRZ] = 1, SWT stops the timer; otherwise, the timer continues to run.
Stop or Standby	If CR[STP] = 1, SWT stops the timer; otherwise, the timer continues to run.

69.3.2 Register access latency

Accesses to SWT registers occur with no peripheral bus wait states. The peripheral bus bridge may add 1 or more system wait states. However, due to synchronization logic in the SWT design, recognition of the service sequence or configuration changes may require up to three system clock cycles plus seven counter clock cycles.

69.3.3 Service key generation

SWT generates service keys with the pseudorandom key generator defined by the following equation.

$$SK_{n+1} = (17 \times SK_n + 3) \bmod 2^{16}$$

Figure 502. Pseudorandom key generator

This algorithm generates a sequence of 2^{16} different key values before repeating. In keyed service sequence mode, each time you write a valid key to SR[WSC], SWT updates SK[SK] with the next key.

For example, if the previous service key (SK[SK]) is 100h, then the next service sequence keys are 1103h followed by 2136h.

69.3.4 Clocking

The SWT has two clock domains, one for the IPS interface and the other for the counter and reset request logic. The two clocks can be asynchronous to each other and have independent resets.

69.3.5 Reset

The following table describes the SWT resets:

Table 486. SWT resets

Reset	Description
RESET_B	It is used to reset the programming model registers.
RESET_SWT_B	It is used to reset the functional domain of the SWT.

69.3.6 Interrupts

The SWT generates one interrupt:

- Timeout interrupt: it is asserted when the watchdog timer count exceeds the timeout period in the TO register.

69.3.7 Reset only the SWT

When a timeout triggers a reset request and the application does not require a system reset, you can make the SWT instance reset itself rather than the whole system.

To make a timeout reset request trigger only an SWT reset (rather than the whole system), write 1 to the Reset Request Flag (RRR[RRF]).

This action causes SWT to:

- Clear the reset request.
- If an interrupt request also occurred, clear the interrupt request (IR[TIF]).
- Reset and restart the SWT.

For systems with multiple SWT instances, this feature allows you to reset an individual SWT instance, avoiding the widespread impact of a system reset.

69.3.8 Test SWT operation

When you disable SWT, it loads the current countdown timer into CO[CNT]. When you enable SWT, it clears this register. You can use CO[CNT] to perform a software self-test of SWT.

To test SWT operation:

1. Enable the SWT (CR[WEN] = 1).
2. Do not service SWT for a fixed period of time that is less than the timeout value.
3. Disable the SWT (CR[WEN] = 0).
4. Read the value in CO[CNT] to determine whether the internal countdown timer is working properly.

NOTE

The value shown in CO[CNT] can lag behind the actual internal timer up to six system clock cycles plus eight counter clock cycles.

69.4 External signals

This module has no external signals.

69.5 Initialization

69.5.1 Initialize the SWT

To initialize the SWT, you must do the following:

- Select the clock source (if there are more than one possible sources).
- Set the timeout period.
- Control timeout behavior. There are two options:
  - Select reset request on timeout, or
  - Select interrupt on initial timeout.

You must initialize all registers before enabling SWT (CR[WEN]). You can initialize the registers in any sequence.

69.5.1.1 Select the clock source

See the chip-specific SWT information to find the clock source that drives the countdown timer.

69.5.1.2 Set the timeout period

When you enable SWT, it loads the greater of the specified watchdog timeout period or the minimum timeout period into an internal 32-bit countdown timer every time you perform a valid service operation.

To set the watchdog timeout period:

- Write the desired timeout period to TO[WTO].

The minimum timeout period is 3 clock cycles.

69.5.1.3 Control timeout behavior

SWT can respond to a timeout in one of two ways:

- Generate an immediate reset request on any timeout.
- Generate an interrupt and load the countdown timer on an initial timeout, then generate a reset request on a subsequent timeout.

69.5.1.3.1 Select reset request on timeout

To configure SWT to generate an immediate reset request on any timeout:

- Write 0 to CR[ITR].

69.5.1.3.2 Select interrupt on initial timeout

To configure SWT to generate an interrupt on an initial timeout:

- Write 1 to CR[ITR].

In this configuration, on the initial timeout:

- SWT loads the countdown timer with the timeout period (TO[WTO]).
- SWT indicates the interrupt with the timeout interrupt flag (IR[TIF]).
- If a second consecutive timeout occurs before writing the service sequence for the first timeout, SWT generates a reset request.

You clear the interrupt flag by writing 1 to IR[TIF].

69.5.1.4 Configure locking and unlocking

You can lock the SWT configuration with either a hard lock or a soft lock. When either lock is in effect, CR, TO, WN, and SK are read-only.

69.5.1.4.1 Enable the hard lock

To enable the hard lock:

- Write 1 to CR[HLK].

Hard lock is disabled only by a reset.

69.5.1.4.2 Enable the soft lock

To enable the soft lock:

- Write 1 to CR[SLK].

69.5.1.4.3 Unlock the soft lock

To unlock the soft lock:

1. Write C520h to SR[WSC].
2. Write D928h to SR[WSC].

This unlock sequence:

- Ignores service sequence writes.
- Recognizes the unlock sequence regardless of previous writes.
- Recognizes the unlock sequence regardless of the time between writes.
- Does not require CR[WEN] to be 1.

You can write this unlock sequence at any time.

NOTE

It is possible for a keyed service sequence to unlock soft lock. See Avoid soft unlock for the procedure to handle this situation.

69.5.1.4.4 Avoid soft unlock

When SWT operates in keyed sequence service, the sequence of service keys generated by the pseudorandom generator includes the unlock keys for soft lock. If one or more service routines use both unlock keys in the proper order, 0xC520 followed at any future time by 0xD928, SWT unlocks soft lock (CR[SLK] = 0). The unlock sequence logic ignores any service keys other than the unlock keys, so the unlock keys don't have to be inserted consecutively. If the second unlock key is also the second key of a service operation, unlock occurs before the service operation completes.

To avoid unlock:

If the service routine writes a key value of C520h to SR[WSC] as a key of the service operation, then do the following:

1. Complete the service operation.
2. Complete the unlock sequence by writing the second unlock key, D928h, to SR[WSC].
3. Reinitiate the soft lock (CR[SLK] = 1).

69.5.1.5 Select behavior on an invalid access

SWT can respond to an invalid access one of two ways:

- Generate a bus error.
- Generate a bus error and, if SWT is enabled, a reset request.

To select how SWT responds to an invalid access:

- Write the appropriate value to CR[RIA].

69.5.2 Initiate service operations

When enabled, SWT requires periodic execution of a servicing operation.

SWT can operate in one of the following service sequence modes:

- Fixed service sequence
- Keyed service sequence

69.5.2.1 Initiate a fixed service sequence

To initiate the fixed service sequence:

1. Select the fixed servicing mode (write 00b to CR[SMD]).
2. Write A602h to SR[WSC].
3. Write B480h to SR[WSC].

There is no timing requirement between the two writes. The service sequence logic ignores unlock-sequence writes.

69.5.2.2 Initiate a keyed service sequence

To initiate the keyed service sequence:

1. Select the keyed servicing mode (write 01b to CR[SMD]).
2. Read the initial service key from SK[SK].

3. Calculate the next service key using the provided equation.
4. Write that service key to SR[WSC].
5. Repeat steps 2 through 4 one time.

See Service key generation for information about service keys.

69.5.2.3 Select window service mode

In window service mode, you must write the service sequence only when the watchdog timer is less than the window start value (WN[WST]). If you write the service sequence outside of this window, the access is invalid and generates a bus error or reset request depending on the Reset on Invalid Access setting (CR[RIA]).

For example, if the timeout period is 5000 and the window start value is 1000, you must write the service sequence during the last 20% of the timeout period.

Synchronization logic in SWT causes a slight delay in the opening of the window. This delay can be up to three system clock cycles plus four counter clock cycles.

To select window service mode:

- Write 1 to (CR[WND]).

69.6 SWT register descriptions

The SWT programming model allows only 32-bit (word) accesses.

Any of the following attempted accesses are invalid:

- Non-32-bit accesses
- Writes to read-only registers
- Writes of incorrect values to SR when SWT is enabled
- Accesses to reserved addresses
- Accesses by masters without permission

You control how SWT responds to an invalid access with CR[RIA].

Chapter 70
System Timer Module (STM)

70.1 Chip-specific STM information

70.1.1 STM instances and configuration

This chip has 3 instances of STM, one for each Cortex-M7 core. The STM counter increments at the STM module clock frequency divided by a pre-scaled value.

Table 487. STM instances and configuration

Instance	Description	Number of Channels	Number of Registers (32-bit)
STM_0	Intended for Cortex-M7_0 core	4	14
STM_1	Intended for Cortex-M7_1 core	4	14
STM_2	Intended for Cortex-M7_2 core	4	14

70.2 Overview

STM supports commonly required system and application software timing functions. STM includes a 32-bit count-up timer and four 32-bit compare channels with a separate interrupt source for each channel. The timer is driven by the STM module clock divided by an 8-bit prescale value (1 to 256).

70.2.1 Block diagram

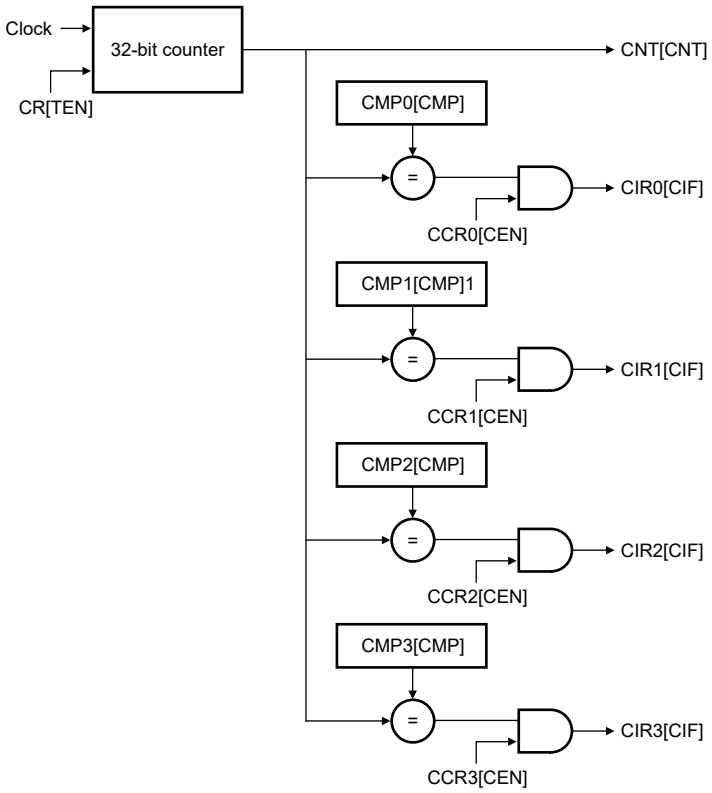

Figure 503. Block diagram

70.2.2 Features

STM has the following features:

- One 32-bit count-up timer with an 8-bit prescaler
- Four 32-bit compare channels
- An independent interrupt source for each channel
- Ability to stop the timer in Debug mode

70.3 Functional description

70.3.1 Count-up timer

STM has one 32-bit count-up timer that serves as the time base for four compare channels. When enabled, the counter increments at the module clock frequency divided by a prescaler value in the range from 1 to 256. When enabled in Normal mode, the timer increments continuously. The counter rolls over at FFFF_FFFFh to 0000_0000h with no restrictions at this boundary.

70.3.2 Compare channels

STM has four identical compare channels. Each channel includes a channel control register (CCR*n*), a channel interrupt register (CCR*n*), and a channel compare register (CMP*n*). When the channel is enabled and its channel compare value matches the timer count, STM sets the channel interrupt flag and generates an IRQ on that channel.

70.3.3 Behavior in different chip modes

STM supports the chip modes of operation as follows:

Chip mode	STM behavior
Normal	When the timer is enabled (CR[TEN] = 1), the timer counts up continuously.
Debug	If CR[FRZ] = 1, STM stops the timer. Otherwise, when the timer is enabled (CR[TEN] = 1), the timer counts up continuously.

70.3.4 Clocking

This module has no clocking considerations.

70.3.5 Interrupts

STM can generate a channel interrupt. For information, see:

- Compare channels
- Respond to compare channel events
- Channel Interrupt (CIR0 - CIR3)

70.4 External signals

This module has no external signals.

70.5 Initialization

This module does not require initialization.

70.6 Application information

70.6.1 Configure the timer

1. Set the initial timer count (CNT[CNT]).
2. Specify STM behavior in chip Debug mode (CNT[FRZ]).
3. Set the counter prescaler (CR[CPS]).
4. Start the timer (CR[TEN]).

70.6.2 Configure the compare channels

For each compare channel:

1. Set the channel compare value (CMP*n*[CMP]).
2. Enable the compare channel (CCR*n*[CEN]).

70.6.3 Respond to compare channel events

For each compare channel:

1. Check the channel interrupt flag (CIR*n*[CIF]).
2. If the channel interrupt flag is set, respond to the interrupt request.
3. When the channel interrupt has been handled, clear the channel interrupt flag (CIR*n*[CIF]).

70.7 STM register descriptions

The STM programming model allows only 32-bit (word) accesses. An attempted reference using a different size or to a reserved address generates a bus error termination.

70.7.1 STM memory map

STM_0 base address: 4027_4000h

70.7.5 Channel Interrupt (CIR0 - CIR3)

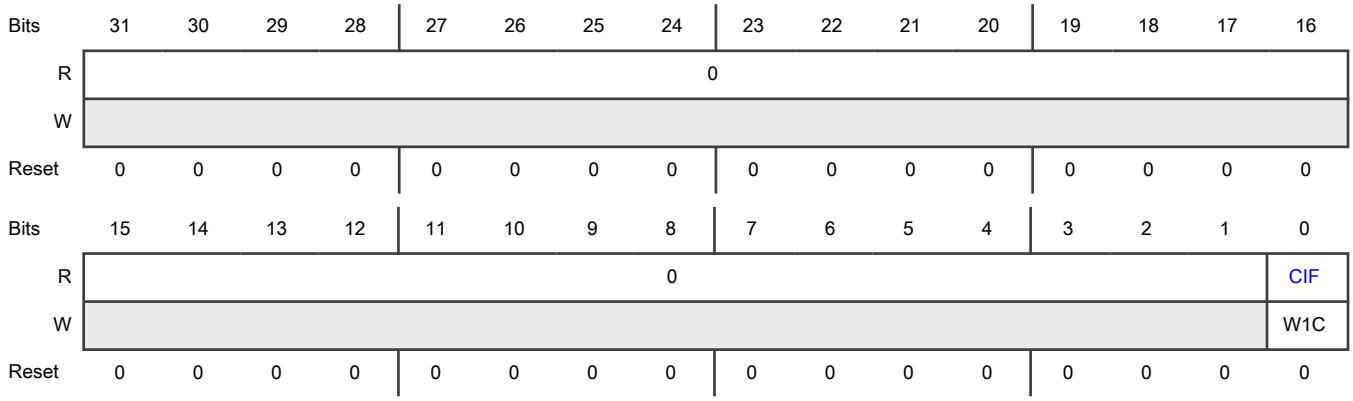
Offset

Register	Offset
CIR0	14h
CIR1	24h
CIR2	34h
CIR3	44h

Function

Indicates and clears the interrupt flag for channel n of the timer.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 CIF	Channel Interrupt Flag Indicates the channel IRQ is asserted due to a match on the channel. 0b - Read: IRQ is not asserted. Write: No effect. 1b - Read: IRQ is asserted. Write: Clear the flag.

70.7.6 Channel Compare (CMP0 - CMP3)

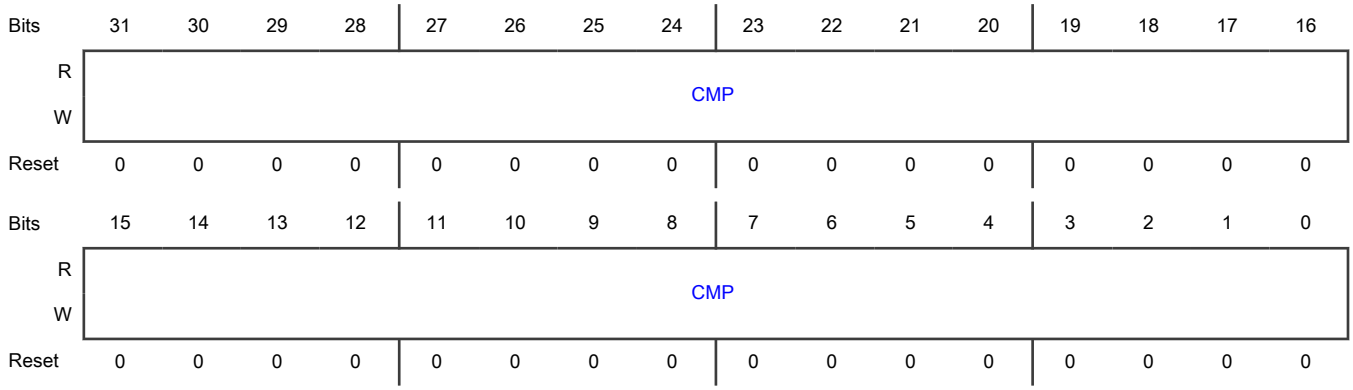
Offset

Register	Offset
CMP0	18h
CMP1	28h
CMP2	38h
CMP3	48h

Function

The compare value for channel n.

Diagram



Fields

Field	Function
31-0 CMP	Channel Compare If the channel is enabled (CCR*n*[CEN]), when the timer count (CNT) matches this value, STM asserts the channel IRQ and sets the channel interrupt flag (CIR*n*[CIF]).

70.8 Glossary

IRQ Interrupt request

Chapter 71
Periodic Interrupt Timer (PIT)

71.1 Chip-specific PIT information

71.1.1 PIT instances and configuration

This chip has 3 instances of the PIT each with 4 PIT timers/channels, each channel being 32 bits in length.

Table 488. PIT instances and features

Feature	PIT_0	PIT_1	PIT_2
Real time interrupt (RTI)	Yes (32-bit)[1]	No	No
Lifetime Timer	Yes	No	No
Timer chaining to create a 64-bit timer	Yes	No	No
Number of 32-bit timer channels	4	4	4
Timer value unchanged by a non-destructive reset	No	No	No

1. The RTI on PIT_0 supports operation in STANDBY mode

The RTI shall be possible to set the timer resolution to 1us independently to other timers. The interrupt can be generated by programming LDVAL0, LDVAL1, LDVAL2 and LDVAL3 to 48 in case of 48 MHz FIRC as system clock and 40 in case of 40 MHz system clock to generate an interrupt after 1us.

71.1.2 Input Output

All the PIT instances are capable of generating periodic triggers. PIT triggers are routed to motor control IPs such as eMIOS, LCU, BCTU, ADC etc. via TRGMUX. See the TRGMUX connectivity file attached to this document for details.

71.2 Overview

PIT includes:

- An array of timers that can be used to raise interrupts and triggers.
- A dedicated RTI timer that runs on a separate oscillator clock and can be used for system wakeup

71.2.1 Block diagram

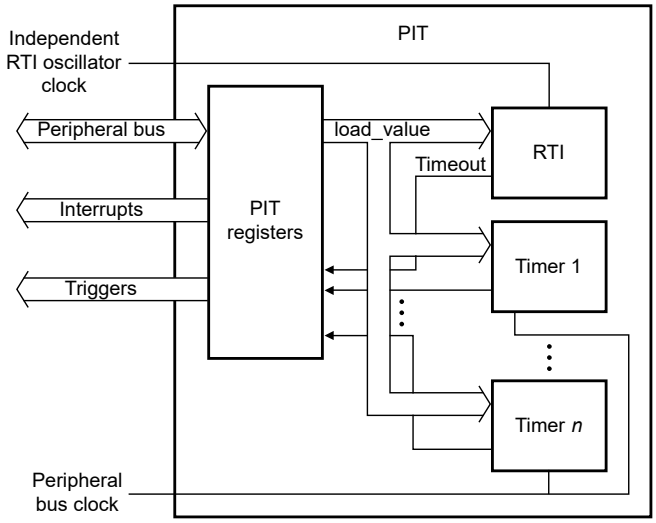


Figure 504. Block diagram

71.2.2 Features

The key features of the module are:

- 4 32-bit countdown timers
- Independent timeout periods for each timer
- Ability to chain two timers into a 64-bit lifetimer
- Ability of timers to generate interrupts
- Ability of timers to generate trigger pulses
- Maskable interrupts
- One RTI countdown timer to wake up the CPU
- Option to generate the RTI even when the bus clock is off
- Power saving with a separate input clock for the RTI timer. All other timers share a common core clock.

71.3 Functional description

71.3.1 Modes of operation

Mode	Description
Run	All functional parts of the PIT operate normally.
Debug	Timers run or stop depending on the Freeze setting (MCR[FRZ]). See Debug mode.

71.3.2 Timer operation

When you enable a timer (write 1 to TCTRL*n*[TEN] or RTI_TCTRL[TEN]), the timer counts down (one count per clock cycle) from its initial start value (LDVAL*n*[TSV] or RTI_LDVAL[TSV]). When the timer period expires (CVAL*n*[TVL] or RTI_CVAL[TVL] reaches

0), PIT sets the Timer Interrupt Flag (writes 1 to TFLG*n*[TIE] or RTI_TFLG[TIE]). It then reloads the timer start value and starts the timer counting down again.

If the timer interrupt is enabled (TCTRL*n*[TIE] or RTI_TCTRL[TIE] = 1), it generates an interrupt when it sets the Timer Interrupt Flag. The timer cannot generate a new interrupt until you clear the flag from the previous interrupt. Because clearing the RTI crosses clock domains, you should use a minimum RTI timer load value of 32.

You can read the current counter value of any timer (CVAL*n*[TVL] or RTI_CVAL[TVL]). Because the RTI timer is synchronized to the RTI clock domain, the value of the RTI counter may be several cycles old when read.

See these related topics:

- Stop and start a timer
- Change timer period
- Change timer period dynamically

NOTE

- If Freeze is enabled (MCR[FRZ] = 1) when the timer nears 0, the Debug mode command may not reach PIT before the timer expires and generates a trigger.
- If a timer is at zero when Debug mode is asserted, the interrupt trigger remains asserted until the device exits Debug mode. Clear the Timer Interrupt Flag (write 1 to TFLG*n*[TIF] or RTI_TFLG[TIF]) upon Debug exit.
- If Freeze is enabled (MCR[FRZ] = 1), sufficient time must be ensured for the IP to react.

71.3.2.1 Stop and start a timer

To restart a running timer:

1. Disable the timer (write 0 to TCTRL*n*[TEN] or RTI_TCTRL[TEN]).
2. Enable the timer (write 1 to TCTRL*n*[TEN] or RTI_TCTRL[TEN]).

   Enabling the timer reloads the start value and starts the timer counting down again. See Stop and start a timer timing.

71.3.2.2 Stop and start a timer timing

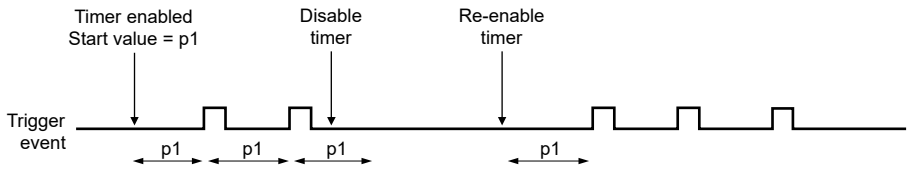

Figure 505. Stop and start a timer

71.3.2.3 Change timer period

To change the counter period of a running timer:

1. Disable the timer (write 0 to TCTRL*n*[TEN] or RTI_TCTRL[TEN]).
2. Specify a new start value (LDVAL*n*[TSV] or RTI_LDVAL[TSV]).
3. Enable the timer (write 1 to TCTRL*n*[TEN] or RTI_TCTRL[TEN]).

   Enabling the timer loads the new start value and starts the timer counting down again. See Change timer period timing.

71.3.2.4 Change timer period timing

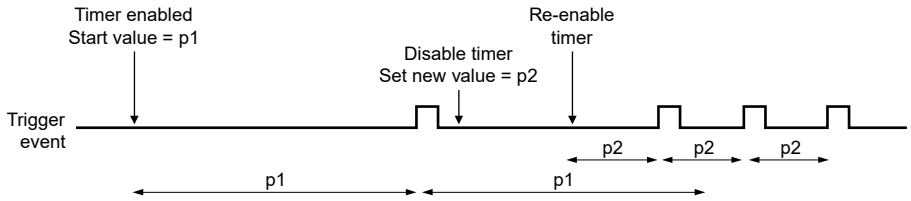

Figure 506. Change timer period dynamically timing

71.3.2.5 Change timer period dynamically

To change the counter period of a running timer:

- Specify a new start value (LDVAL*n*[TSV] or RTI_LDVAL[TSV])

  The next time the timer expires, it loads the new start value. See Change timer period dynamically timing.

71.3.2.6 Change timer period dynamically timing

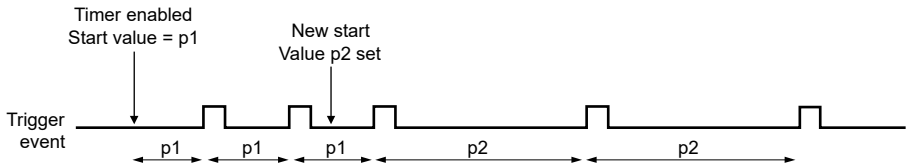

Figure 507. Change timer period dynamically timing

71.3.3 Chained timers

PIT supports chaining two timers together to support timer periods greater than FFFFFFFFh. When a timer *n* has chain mode enabled, it decrements each time timer *n* - 1 expires. The chained timer sets its Timer Interrupt Flag when it expires (CVAL*n* - 0).

For example, assume you need to configure a timer period of 6,000,000,000 cycles. You could specify a start value of 10 for timer *n* and 599,999,999 for timer *n* - 1. With these values, the chained timer expires after timer *n* - 1 has expired ten times.

You cannot chain timer 0 or the RTI timer to another timer.

For an example configuration of a chained timer, see Example configuration using chained timers.

71.3.4 Lifetimer

PIT supports a 64-bit lifetimer. You configure the lifetimer by chaining timer 1 to timer 0 and populating the start values for both timers with the maximum value of FFFFFFFFh. You read the lifetimer in the LTMR64H and LTMR64L registers. LTMR64H returns the upper 32 bits of the lifetimer value and LMTR64L returns the lower 32 bits. When a timer 1 has chain mode enabled, it decrements each time timer 0 expires. The lifetimer expires when CVAL1 expires.

When you chain timer 1 to timer 0, timer 1 decrements every time timer 0 expires. To obtain the correct lifetimer value, read LTMR64H first and then read LTMR64L. When you read LTMR64H, it returns the value in CVAL1 (the chained timer value), and immediately latches the value from CVAL0 into LTMR64L. This latching eliminates the carryover effects of the running counter.

For an example configuration of the lifetimer, see Example configuration using the lifetimer.

71.3.5 Debug mode

If Freeze is enabled (MCR[FRZ] = 1), the timers stop if the device enters Debug mode. This freeze allows the software developer to halt the processor, investigate the current state of the system, including the PIT timer values, and then continue operation.

71.3.6 Clocking

The PIT general-purpose timers are driven by the peripheral bus clock.

The RTI timer is driven by an independent oscillator clock. This clock input continues running when the device is in Stop mode. Driving the RTI timer with an independent clock allows the RTI to trigger periodic wake-up from Stop mode.

71.3.7 Interrupts

All of the timers support interrupt generation.

You enable interrupt generation for each individual timer (TCTRL*n*[TIE]). Each interrupt is available on a separate interrupt output.

When a timer expires (CVAL*n*[TVL] = 0), it sets the Timer Interrupt Flag (TFLG*n*[TIF]) regardless of whether the interrupt is enabled. To enable generation of an interrupt when the Timer Interrupt Flag is set, write 1 to TCTRL*n*[TIE]. To clear the Timer Interrupt Flag, write 1 to it.

When the RTI timer expires (RTI_CVAL*n*[TVL] = 0), PIT sets the RTI Timer Interrupt Flag (RTI_TFLG*n*[TIF]) regardless of whether the RTI is enabled. To enable generation of an RTI when the RTI Timer Interrupt Flag is set, write 1 to TCTRL*n*[TIE]. To clear the RTI Timer Interrupt Flag, write 1 to it.

The RTI is typically used for periodic wake-up from Standby mode, but it can also be used to generate a general-purpose interrupt.

71.4 External signals

PIT has no external inputs.

71.5 Initialization

To initialize PIT:

1. For each timer *n* you plan to use:
    a. Specify the timer period (LDVAL*n*[TSV]).

       To calculate the load value for a timer:

       Start value = (timer period / clock period) - 1

    b. If you want the timer to generate an interrupt each time it expires, enable the timer interrupt (write 1 to TCTRL*n*[TIE]).
    c. If you want to use this timer as the divisor of a pair of chained timers, chain this timer to the next lower-numbered timer (write 1 to TCTRL*n*[CHN]). You cannot chain timer 0. If you want to use the lifetimer, chain timer 1 to timer 0.
    d. Enable the timer (write 1 to TCTRL*n*[TEN]).
2. If you want to use the RTI feature:
    a. Specify the RTI timer period (RTI_LDVAL*n*[TSV]).
    b. Enable the RTI timer interrupt (write 1 to RTI_TCTRL*n*[TIE]).
    c. Enable the RTI timer (write 1 to RTI_TCTRL*n*[TEN]).
3. Activate, or enable, PIT (write 0 to MCR[MDIS]).

   All enabled timers load their start values and begin counting down.

For example configurations, see Application information.

71.6 Application information

71.6.1 Example configuration for general timers

In this example configuration:

- The PIT clock frequency is 50 MHz, which equates to a clock cycle of 20 ns.
- The RTI clock frequency is 10 MHz, which equates to a clock cycle of 100 ns.
- The RTI timer needs to generate a wake-up interrupt every 500 ms.
- Timer 1 needs to generate an interrupt every 5.12 ms.
- Timer 3 needs to generate a trigger event every 30 ms.

To configure PIT for this example:

1. Disable PIT (write 1 to MCR[MDIS]).
2. Use the formula in Initialization to calculate the load value for the RTI timer:

   (500 ms/100 ns) - 1 = 4,999,999 cycles, or 004C4B3Fh.
3. Specify the RTI timer load value (write 004C4B3Fh to RTI_LDVAL[TSV]).
4. Enable the RTI (write 1 to RTI_TCTRL[TIE])
5. Enable the RTI timer (write 1 to RTI_TCTRL*n*[TEN]).
6. Use the formula in Initialization to calculate the load value for timer 1:

   (5.12 ms/20 ns) - 1 = 255,999 cycles, or 0003E7FFh.
7. Disable timer 1 (write 0 to TCTRL1[TEN]).
8. Specify the timer 1 value (write 0003E7FFh to LDVAL1[TSV]).
9. Enable the timer 1 interrupt (write 1 to TCTRL1[TIE])
10. Enable timer 1 (write 1 to TCTRL1[TEN]).
11. Calculate the load value for timer 3:

    (30 ms/20 ns) - 1 = 1,499,999 cycles, or 0016E35Fh.
12. Disable timer 3 (write 0 to TCTRL3[TEN]).
13. Specify the timer 3 value (write 0016E35Fh to LDVAL3[TSV]).
14. Enable timer 3 (write 1 to TCTRL3[TEN]).
15. Activate, or enable, PIT (write 0 to MCR[MDIS]).

NOTE

You can configure timers without first disabling PIT or the timer itself. However, if PIT is running, be aware that when a timer begins using a new start value depends on whether the timer is running or disabled when you specify the new start value. For more information, see Timer operation.

The following example code provides the described configuration:

```
// Disable PIT (see note above)
PIT_MCR = 0x01;
```

```
// RTI
PIT_RTI_LDVAL = 0x004C4B3F; // Configure RTI for 5000000 cycles
```

```
PIT_RTI_TCTRL = PIT_TIE;    // Enable RTI
PIT_RTI_TCTRL |= PIT_TEN;   // Start RTI timer
```

```
// Timer 1
PIT_LDVAL1 = 0x0003E7FF;    // Configure timer 1 for 256000 cycles
PIT_TCTRL1 = TIE;           // Enable Timer 1 interrupts
PIT_TCTRL1 |= TEN;          // Start Timer 1
```

```
// Timer 3
PIT_LDVAL3 = 0x0016E35F;    // Configure timer 3 for 1500000 cycles
PIT_TCTRL3 = TEN;           // Enable Timer 3
```

```
 // Enable PIT
 PIT_MCR = 0x00;
```

71.6.2 Example configuration using chained timers

In this example configuration:

- The PIT clock is frequency 100 MHz, which equates to a clock cycle of 10 ns.
- Timers 1 and 2 are available.
- An interrupt is needed every minute. Using the formula in Initialization, a 1 minute timer period requires:

  (60 s/100 ns) - 1 = 5,999,999,999 cycles, or 165A0BBFFh

  This value requires more than 32 bits.

To configure PIT for this example:

1. Disable PIT (write 1 to MCR[MDIS]).
2. Disable timer 1 (write 0 to TCTRL1[TEN]).
3. Disable timer 2 (write 0 to TCTRL2[TEN]).
4. Chain timer 2 to timer 1 (write 1 to TCTRL2[CHN]).
5. For the timer 2 start value, select a value that divides evenly into the desired period. For this example, we are using 10. For the timer 1 value, divide the full timer period by the selected divisor: 6,000,000,000/10 = 600,000,000.
6. Specify the timer 2 value as the selected divisor (write 0000000Ah to LDVAL2[TSV]).
7. Specify the timer 1 value as the quotient minus 1, or 599,999,999 (write 0003E7FFh to LDVAL1[TSV]).
8. Enable the timer 2 interrupt (write 1 to TCTRL2[TIE])
9. Enable timer 2 (write 1 to TCTRL2[TEN]).
10. Enable timer 1 (write 1 to TCTRL1[TEN]).
11. Activate, or enable, PIT (write 0 to MCR[MDIS]).

The following example code matches the described configuration:

```
// Disable PIT
PIT_MCR = 0x01;
```

```
// Timer 2
PIT_LDVAL2 = 0x0000000A; // Configure Timer 2 to the divisor (10)
PIT_TCTRL2 = TIE;        // Enable Timer 2 interrupt
PIT_TCTRL2 |= CHN;       // Chain Timer 2 to Timer 1
PIT_TCTRL2 |= TEN;       // Enable Timer 2
```

```
// Timer 1
PIT_LDVAL1 = 0x23C345FF; // Configure Timer 1 to 600,000,000 cycles
PIT_TCTRL1 = TEN;        // Enable Timer 1
```

```
 // Enable PIT
 PIT_MCR = 0x00;
```

71.6.3 Example configuration using the lifetimer

To configure the lifetimer:

1. Disable PIT (write 1 to MCR[MDIS]).
2. Disable timer 0 (write 0 to TCTRL0[TEN]).
3. Disable timer 1 (write 0 to TCTRL1[TEN]).
4. Chain timer 1 to timer 0 (write 1 to TCTRL1[CHN]).
5. Specify the maximum start value for timer 1 (write FFFFFFFFh to LDVAL1[TSV]).
6. Specify the maximum start value for timer 0 (write FFFFFFFFh to LDVAL0[TSV]).
7. Enable timer 1 (write 1 to TCTRL1[TEN]).
8. Enable timer 0 (write 1 to TCTRL0[TEN]).
9. Activate, or enable, PIT (write 0 to MCR[MDIS]).

To access the lifetimer, first read LTMR64H and then LTMR64L. For more information, see Lifetimer.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;
```

```
// Timer 1
PIT_LDVAL1 = 0xFFFFFFFF; // setup timer 1 for maximum counting period
PIT_TCTRL1 = 0x0; // disable timer 1 interrupts
PIT_TCTRL1 |= CHN; // chain timer 1 to timer 0
PIT_TCTRL1 |= TEN; // start timer 1
```

```
// Timer 0
```

```
PIT_LDVAL0 = 0xFFFFFFFF; // setup timer 0 for maximum counting period
PIT_TCTRL0 = TEN; // start timer 0
```

```
// Read lifetimer
current_uptime = PIT_LTMR64H<<32;
current_uptime = current_uptime + PIT_LTMR64L;
```

71.7 PIT register descriptions

This section provides a detailed description of all registers accessible in the PIT_RTI module.

- See the chip-specific PIT information for the number of PIT channels used in this MCU.
- Program RTI registers only when the RTI clock is running.

71.7.1 PIT memory map

PIT_0 base address: 400B_0000h

PIT_1 base address: 400B_4000h

PIT_2 base address: 402F_C000h

Offset	Register	Width (In bits)	Access	Reset value

71.7.2 PIT Module Control (MCR)

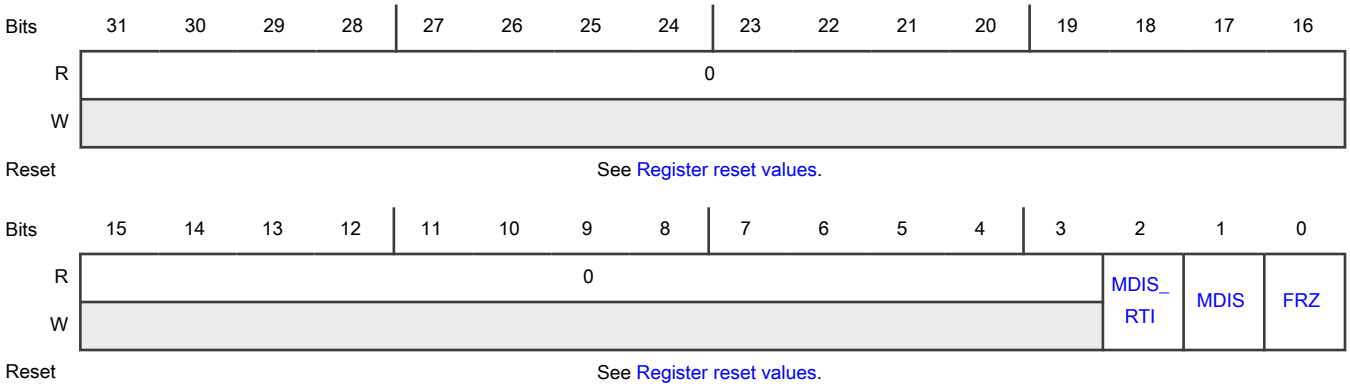
Offset

Register	Offset
MCR	0h

Function

Enables the PIT timer clocks and specifies the behavior of the timers when PIT enters Debug mode.

Diagram



Register reset values

Register	Reset value
MCR	PIT_0: 0000_0006h PIT_1,PIT_2: 0000_0002h

Fields

Field	Function
31-3 —	Reserved
2 MDIS_RTI	Module Disable for RTI Disables the RTI timer. You must write 1 to this field before setting up an RTI. **NOTE** This field is not supported in every instance. The following table includes only supported registers. 0b - Enables 1b - Disables
1 MDIS	Module Disable for PIT Disables the standard timers. This field does not affect the RTI timer. You must disable the clock (write 1 to MDIS) before configuring PIT. After configuration, you must enable the clock (write 0 to MDIS). 0b - Enables 1b - Disables
0 FRZ	Freeze Stops the timers when the device enters Debug mode. 0b - Timers run in Debug mode 1b - Timers stop in Debug mode

Instance	Field supported in	Field not supported in
PIT_0	MCR	—
PIT_1	—	MCR
PIT_2	—	MCR

71.7.3 PIT Upper Lifetimer (LTMR64H)

Offset

Register	Offset
LTMR64H	E0h

Function

Combined with LTMR64L, provides a 64-bit lifetimer constructed from the values in two chained PIT timers.

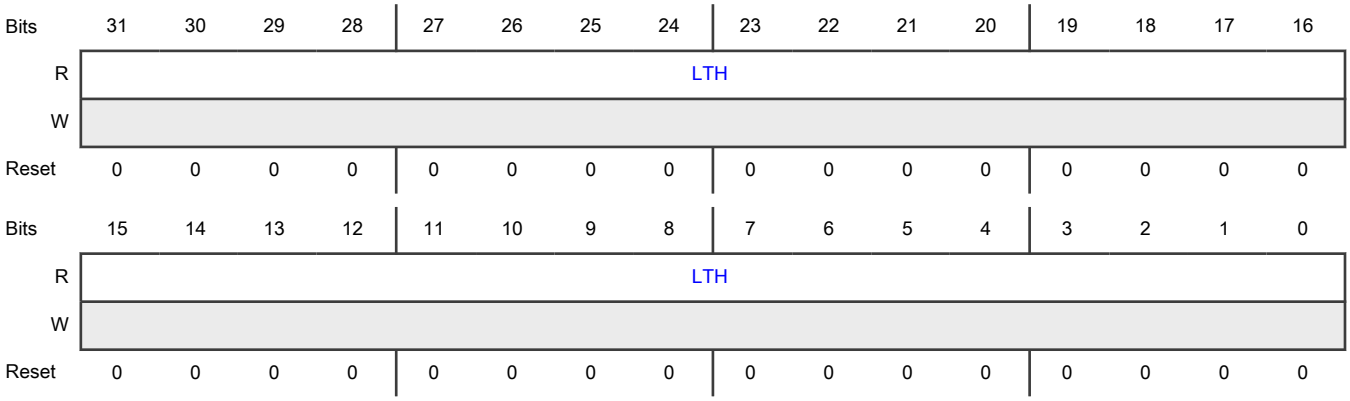
For more information, see Lifetimer.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
PIT_0	LTMR64H	—
PIT_1	—	LTMR64H
PIT_2	—	LTMR64H

Diagram



Fields

Field	Function
31-0 LTH	Lifetimer Value Indicates the timer value of timer 1. This value is the upper 32 bits of the 64-bit lifetimer value. When you read this register at t1, the value of timer 0 at t1 is latched into LTMR64L.

71.7.4 PIT Lower Lifetimer (LTMR64L)

Offset

Register	Offset
LTMR64L	E4h

Function

Combined with LTMR64H, provides a 64-bit lifetimer.

For more information, see Lifetimer.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
PIT_0	LTMR64L	—
PIT_1	—	LTMR64L
PIT_2	—	LTMR64L

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 LTL	Lifetimer Value Indicates the timer value of timer 0 at the moment LTMR64H was last read. This value is the lower 32 bits of the 64-bit lifetimer value. This field updates only when LTMR64H is read.

71.7.5 RTI Timer Load Value Sync Status (RTI_LDVAL_STAT)

Offset

Register	Offset
RTI_LDVAL_STAT	ECh

Function

Indicates whether the RTI timer start value has been loaded (RTI_LDVAL). This status is necessary because it takes several cycles for the RTI start value to synchronize into the RTI clock domain.

NOTE

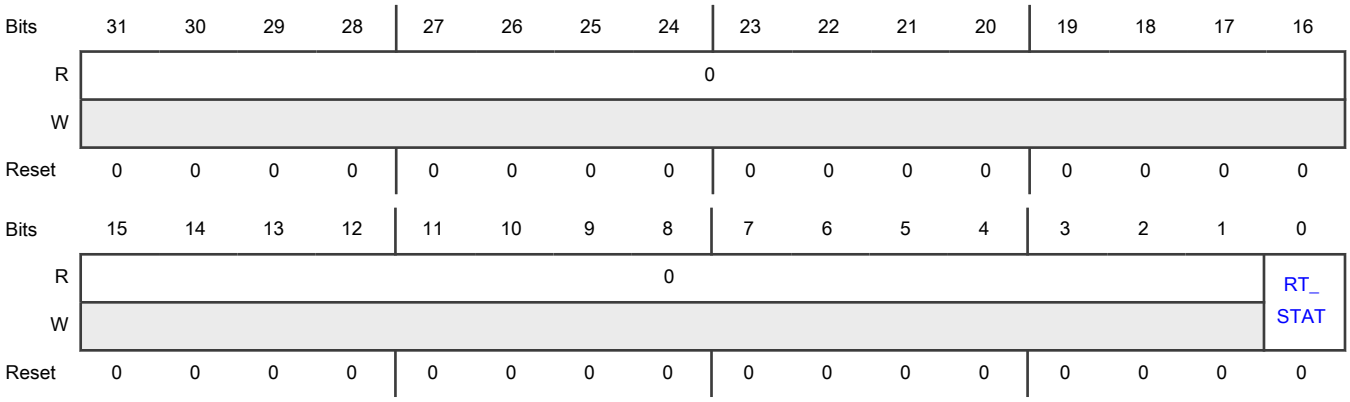
In the case of dynamic loading (Figure 507) of the RTI timer, this status may be unreliable .

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
PIT_0	RTI_LDVAL_STAT	—
PIT_1	—	RTI_LDVAL_STAT
PIT_2	—	RTI_LDVAL_STAT

Diagram



Fields

Field	Function
31-1 —	Reserved
0 RT_STAT	Sync Status Indicates whether the RTI start value is loaded. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not loaded 1b - Loaded When writing 0b - Clears status 1b - Clears status

71.7.6 RTI Timer Load Value (RTI_LDVAL)

Offset

Register	Offset
RTI_LDVAL	F0h

Function

Specifies the length of the RTI timeout period in clock cycles.

It takes several cycles for this value to synchronize into the RTI clock domain.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
PIT_0	RTI_LDVAL	—
PIT_1	—	RTI_LDVAL
PIT_2	—	RTI_LDVAL

Diagram

R	TSV															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TSV	Timer Start Value Specifies the starting RTI timer value. The timer counts down until it reaches 0, then sets the interrupt flag and reloads this value. When you write a new value to this register, the timer does not restart with the new value until the current timing period expires. To terminate the current period and start a new period with the new value, you must disable the timer (write 0 to RTI_TCTRL*n*[TEN]) and then enable it again (write 1 to RTI_TCTRL*n*[TEN]).

Table continues on the next page...

Field	Function
	NOTE Because it may take several cycles to clear the RTI interrupt, setting the value to something less than 32 cycles may result in a lost interrupt.

71.7.7 Current RTI Timer Value (RTI_CVAL)

Offset

Register	Offset
RTI_CVAL	F4h

Function

Indicates the current RTI timer value. Because this timer might be driven from a different clock domain from the other timers, the value may be several cycles old.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
PIT_0	RTI_CVAL	—
PIT_1	—	RTI_CVAL
PIT_2	—	RTI_CVAL

Fields

Field	Function
31-0 TVL	Current Timer Value Indicates the current RTI timer value. **NOTE** • If the timer is disabled (RTI_TCTRL*n*[TEN] = 0), this value has no meaning. • If PIT is frozen in Debug mode (MCR[FRZ] = 1), timer values are frozen when the device is in Debug mode.

71.7.8 RTI Timer Control (RTI_TCTRL)

Offset

Register	Offset
RTI_TCTRL	F8h

Function

Controls RTI timer behavior.

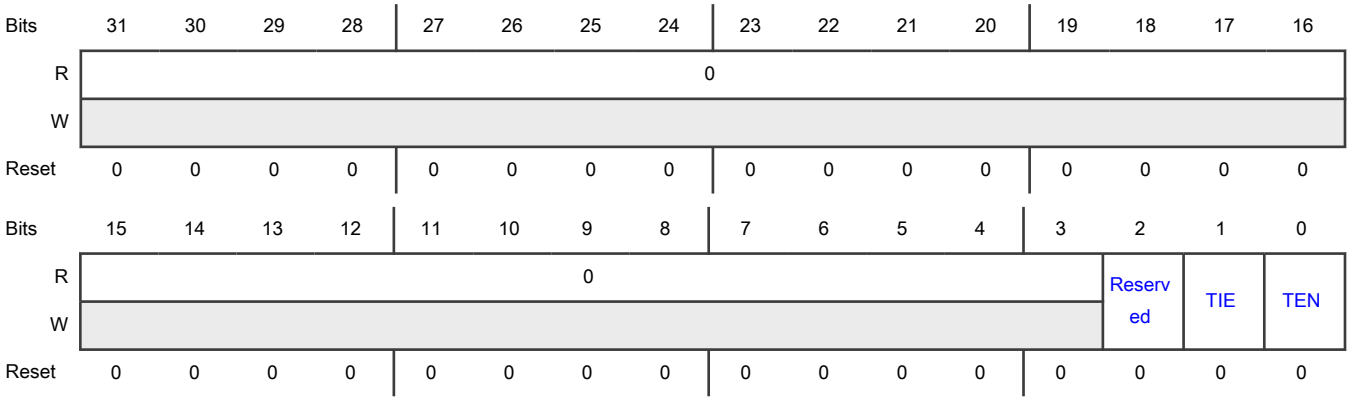
The RTI may take several RTI clock cycles to enable or update. Therefore, you must wait for at least three RTI clock cycles after RTI configuration before relying on the RTI timer.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
PIT_0	RTI_TCTRL	—
PIT_1	—	RTI_TCTRL
PIT_2	—	RTI_TCTRL

Diagram



Fields

Field	Function
31-3 —	Reserved
2 —	Reserved
1 TIE	Timer Interrupt Enable Enables the RTI timer interrupt. If the interrupt is enabled, when an interrupt is pending or the Timer Interrupt Flag is set (RTI_TFLG*n*[TIF] = 1), PIT generates an interrupt. To avoid an interrupt when you first enable the interrupt, clear the Timer Interrupt Flag (write 1 to RTI_TFLG*n*[TIF]) before you enable the interrupt. 0b - Disables 1b - Enables
0 TEN	Timer Enable Bit Enables the RTI timer. 0b - Disables 1b - Enables. The RTI timer begins counting down.

71.7.9 RTI Timer Interrupt Flag (RTI_TFLG)

Offset

Register	Offset
RTI_TFLG	FCh

Function

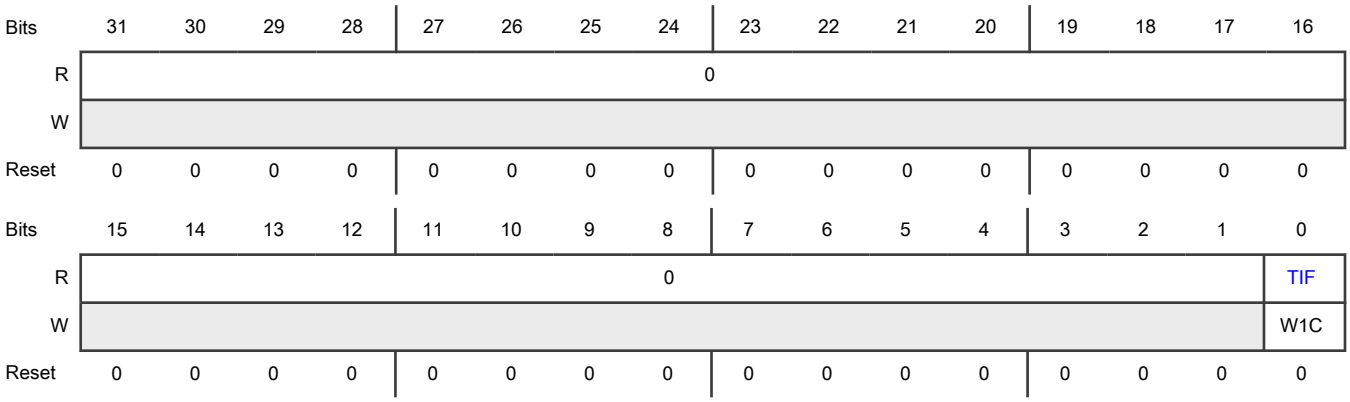
Indicates the RTI timer has expired.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
PIT_0	RTI_TFLG	—
PIT_1	—	RTI_TFLG
PIT_2	—	RTI_TFLG

Diagram



Fields

Field	Function
31-1 —	Reserved
0 TIF	Timer Interrupt Flag Indicates the RTI timer period has expired (CVAL*n*[TVL] = 0). If interrupts are enabled (RTI_TCTRL*n*[TIE] = 1), TIF triggers an interrupt request. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Timer still counting down 1b - Timer has expired When writing 0b - No effect 1b - Clears the flag

71.7.10 Timer Load Value (LDVAL0 - LDVAL3)

Offset

Register	Offset
LDVAL0	100h
LDVAL1	110h
LDVAL2	120h
LDVAL3	130h

Function

Specifies the length of the timeout period in clock cycles.

The value change is visible immediately. The synchronization mechanism allows 0 wait states in this case.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TSV	Timer Start Value Specifies the starting timer value. The timer counts down until it reaches 0, then sets the interrupt flag and reloads this value. When you write a new value to this register, the timer does not restart with the new value until the current timing period expires. To terminate the current period and start a new period with the new value, you must disable the timer (write 0 to TCTRL*n*[TEN]) and then enable it again (write 1 to TCTRL*n*[TEN]). **NOTE** Because the CPU requires several cycles to service an interrupt, there is a practical limit to the lowest start value for a timer. Setting the value too low may result in a lost interrupt.

71.7.11 Current Timer Value (CVAL0 - CVAL3)

Offset

Register	Offset
CVAL0	104h
CVAL1	114h
CVAL2	124h
CVAL3	134h

Function

Indicates the current timer value.

71.8 Glossary

RTI Real-time interrupt

Chapter 72
Real Time Clock (RTC)

72.1 RTC instances and configuration

The chip contains one instance of RTC (Real Time Clock) timer and API (Autonomous Periodic Interrupt) timer, where both can perform 32-bit comparisons.

The RTC is present in always ON domain, hence available in RUN mode as well as in STANDBY mode. Both RTC and API timers can generate interrupts as well as wakeup from low power modes.

RTC supports a resolution of 1µs with high speed internal oscillator clock (1/48MHz (FIRC) * 48 (RTC counter) = 1µs)

This chip supports seamless RTC operation across functional reset with the clock sources SIRC.

API has the capability to change the Timer compare value (APIVAL) independently without stopping the timer.

API can also be used in conjunction with the Comparator module. In STANDBY mode configuration, the API is configured to generate a START / NEXT type signal to inform the Comparator module that a 'compare' must be carried out.

72.2 Overview

The Real-Time Clock (RTC) is a free-running counter used for time keeping applications. The RTC can be configured to generate an interrupt at a pre-defined interval independent of the mode of operation (run mode or low power mode). If in a low power mode, the RTC interval is reached, the RTC first generates a wakeup and then asserts the interrupt request. The RTC also supports an API function used to generate a periodic wakeup request to exit a low-power mode or an interrupt request.

72.2.1 Block diagram

The following figure shows clock gating for RTC clocks.

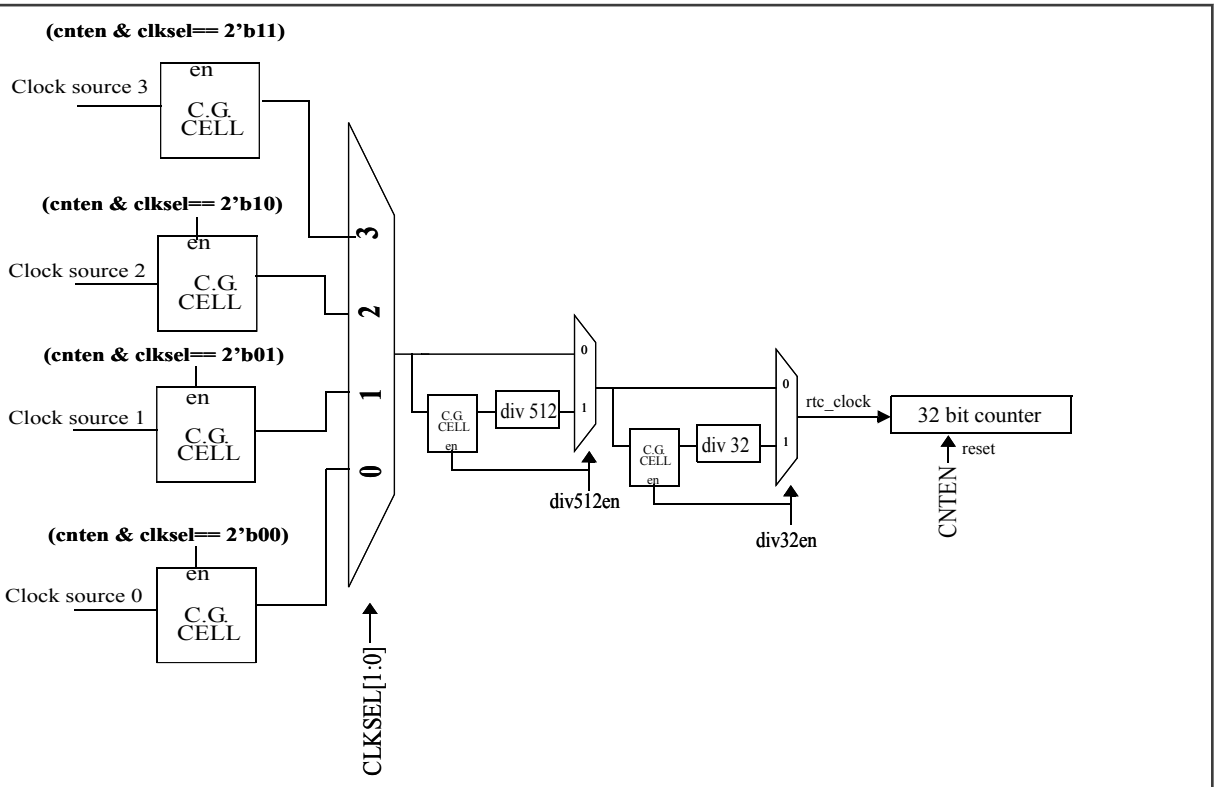

Figure 508. Clock gating for RTC clocks

The following figure shows the block diagram of RTC.

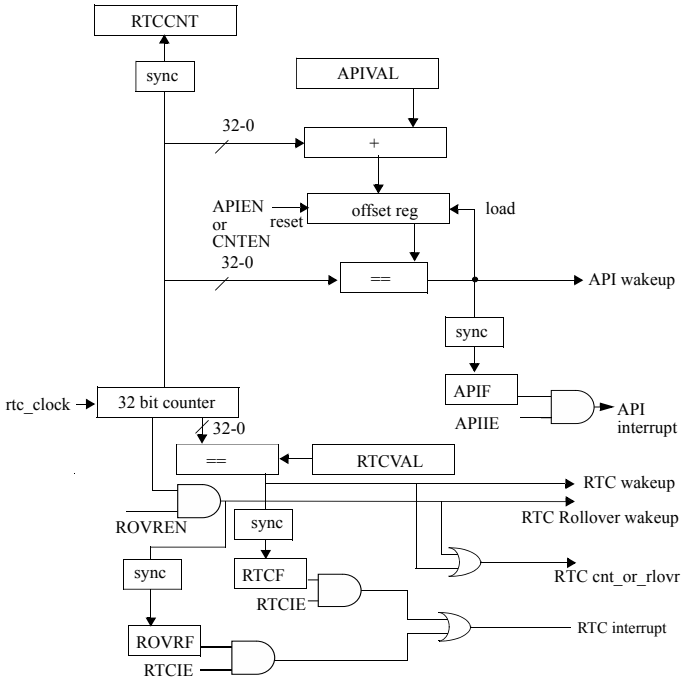

Figure 509. Block diagram

72.2.2 Features

RTC features include:

- 32-bit counter
- Selectable counter clock sources (IRCs and OSCs)
  - Clock source 0
  - Clock source 1
  - Clock source 2
  - Clock source 3
- Optional 512 prescaler and optional 32 prescaler to run the 32 bit counter.
- RTC interrupt with interrupt enable.
- Counter runs in all modes of operation.
- RTC counter is reset when the counter is disabled by software and by reset to RTC block.
- Autonomous periodic interrupt support includes:
  - 32-bit compare value to support range of wakeup intervals/interrupts
  - API logic has a separate enable to support changing compare value while RTC is running
  - API interrupt with interrupt enable
  - Operates in all modes
  - API compare value can be modified while RTC is running
- Optional interrupt for RTC match, API match, and RTC rollover.

72.3 Functional description

72.3.1 RTC

The RTC consists of a 32-bit free running counter enabled with the CNTEN bit (CNTEN, when negated, asynchronously resets the counter and synchronously enables the counter when enabled). After disabling CNTEN, RTCVAL, APIVAL, needs to be written again for desired functionality. The value of the counter may be read via the RTC Counter register (RTCCNT) register. Note that because of clock synchronization, the RTC Counter register (RTCCNT) value may represent a previous counter value. The difference between the counter and the read value depends on the ratio of counter clock and bus clock. Maximum possible difference between the two is 6 count values.

The clock source to the counter is selected with the CLKSEL field, which gives four options for clocking the RTC/API. The four clock sources are assumed to be on these:Clock source 0, Clock source 1, Clock source 2, and Clock source 3. The output of the clock mux can be optionally divided by a combination of 512 and 32 to give various count periods for different clock sources. Note that the CNTEN bit should be disabled when the RTC/API clock source is switched.

When the RTC Counter register (RTCCNT) counter value for counter bits 31-0 match the 32-bit value in the RTCVAL field, then the RTCF interrupt flag bit is set (after proper clock synchronization). If the RTCIE interrupt enable bit is set, then the RTC interrupt request is generated. RTC Compare value register (RTCVAL) register can be written only when INV_RTC bit is clear. Initially INV_RTC=0, and hence RTC Compare value register (RTCVAL) can be written once and hence INV_RTC gets set. This bit can now be cleared only by enabling the RTC counter. After the counter is enabled, RTC Compare value register (RTCVAL) can be written anytime, until RTC is disabled again. RTC Compare value register (RTCVAL) is first synchronized to the RTC clock domain, therefore, if RTC Compare value register (RTCVAL) is updated at the point where a counter match is due to happen in the next 2-3 RTC clocks because of previous RTC Compare value register (RTCVAL), the RTCF flag is set. However, if the RTC Compare value register (RTCVAL) is updated at the point where no counter match is due as per the previous RTC Compare value register (RTCVAL), the RTCF flag is set when the counter matches the new RTC Compare value register (RTCVAL). If there is a match when in the low-power mode, then the RTC first generates a wakeup request to force a wakeup to run mode,and then the RTCF flag is set.

If RTC Compare value register (RTCVAL) is updated just after counter match, new RTC Compare value register (RTCVAL) value should not be within next 6 RTC counter values.

A rollover wakeup and/or interrupt can be generated when the RTC transitions from a count of 0xFFFF_FFFF to 0x0000_0000. The rollover flag is enabled by setting the ROVREN bit. If RTCIE is enabled, an interrupt request is generated for an RTC counter rollover. If system is in low power mode, RTC counter rollover with this bit causes a wakeup from the low-power mode.

Both rollover wakeup and RTC wakeup gets asynchronously de-asserted with disabling of CNTEN.

All the flags and counter values are synchronized with the Bus clock. It is assumed that the Bus clock and RTC clock selected through CLKSEL follows the below relation:

Bus clock >= (1.5 * RTC clock)/(div_factor)

- if both DIV32EN and DIV512EN bits are disabled, div_factor = 1
- if DIV32EN=1 and DIV512EN=0, div_factor = 32
- if DIV32EN=0 and DIV512EN=1, div_factor = 512
- if both DIV32EN and DIV512EN bits are enabled, div_factor = 512*32 = 16384

In case, RTC wakeup's are used as a wakeup source, bus clock (system clock or register interface clock of RTC) should be disabled (to save power in standby mode) after enabling the required wakeup and ensuring sufficient time gap (3-6 bus clock or RTC clock (rtc_clock) cycles, whichever is slower) between bus clock disabling and wakeup event. To ensure writing the register to enable the wakeup, the bus clock must be active, hence it should not be disabled before enabling wakeup. Correct operation is not guaranteed if the specification is not followed.

72.3.2 API functional description

Setting APIEN bit enables the autonomous interrupt function. The 32-bit APIVAL field selects the time interval for triggering an interrupt and/or wakeup event. Because the RTC is a free-running counter, the APIVAL is added to the current count to calculate

an offset. When the counter reaches the offset count, an interrupt and/or wakeup request is generated. Then the offset value is recalculated and again re-triggers a new request when the new value is reached. API function is enabled only when CNTEN and APIEN bits are asserted and APIVAL is non-zero. Also APIVAL can be updated anytime. After APIVAL is updated, the first API interrupt is generated according to the previous value. From the second interrupt onwards, the API interrupt is generated with the new APIVAL. When a compare is reached, the APIF interrupt flag bit is set (after proper clock synchronization). If the APIIE interrupt enable bit is set, then the API interrupt request is generated. If there is a match while being in the low-power mode, then the API first generates a wakeup request to force a wakeup into normal operation, and then the APIF flag is set.

When the CNTEN is de-asserted, the API function is reset , though wakeup API is not asynchronously de-asserted with CNTEN. If APIEN is disabled when counter matches the offset APIF can be missed.

72.3.3 Modes of operation

72.3.3.1 Functional mode

There are two functional modes of operation for RTC, normal operation and low-power mode. In normal operation, all RTC registers can be read or written . The RTC/API and associated interrupts are optionally enabled. In low-power mode, the bus interface is disabled. The RTC/API is enabled (if enabled prior to entry into low-power mode).

72.3.3.2 Debug mode

On entering into the debug mode, the RTC counter freezes on the last valid count if the FRZEN is set. On exit from debug mode, counter continues from the frozen value.

72.4 Initialization

Recommended programming flow as follow

1. Program RTCVAL register with the value greater than 4 if RTCF related functionality is required.
2. Program APIVAL register with the value greater than 4 if API functionality is required.
3. Program all fields (as required) of RTC Control register (RTCC) register with CNTEN=1. After setting CNTEN field, counter starts running and RTC/API functionality will be active as per the configurations.
4. If RTCVAL or APIVAL needs to be updated during run, check corresponding INV_RTC or INV_API bit is cleared before writing and do meet all the restrictions of the corresponding register.
5. If CLKSEL or DIV32EN or DIV512EN needs to be updated, first update RTC Control register (RTCC) register with CNTEN=0 (when all INV_RTC or INV_API are 0) keeping other field values same. Wait for minimum 3 RTC clock cycles so that CNTEN will be synchronized to RTC clock domain. Then write the RTC Control register (RTCC) register with new configuration required with CNTEN=1.

72.5 RTC register descriptions

The RTC registers are listed in this section.

NOTE

Address offset - 0x18h should not be accessed by application as corresponding feature/s are not available. Therefore, transfer error will not be generated at this offset.

NOTE

XFR error will be generated when RTCSUPV is accessed in user mode, any other register is accessed in user mode when SUPV bit is set, write attempt is made for RTCCNT register and any register accessed out of address range.

72.5.1 RTC memory map

RTC base address: 4028_8000h

Offset	Register	Width (In bits)	Access	Reset value
0h	RTC Supervisor control register (RTCSUPV)	32	RW	8000_0000h

8h	RTC Status register (RTCS)	32	RW	0000_0000h
Ch	RTC Counter register (RTCCNT)	32	R	0000_0000h
10h	API Compare value register (APIVAL)	32	RW	0000_0000h
14h	RTC Compare value register (RTCVAL)	32	RW	0000_0000h

72.5.2 RTC Supervisor control register (RTCSUPV)

Offset

Register	Offset
RTCSUPV	0h

Function

The RTCSUPV register contains the SUPV bit that determines whether other registers are accessible in supervisor mode or user mode.

NOTE

You can access this register only in Supervisor mode, and you must write a value only to the SUPV field of the register.

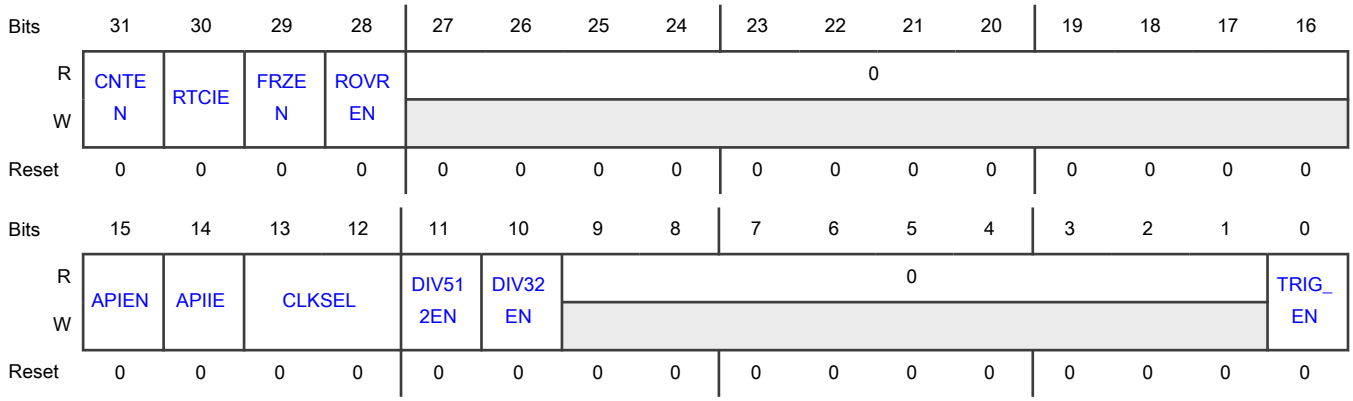
72.5.3 RTC Control register (RTCC)

Offset

Register	Offset
RTCC	4h

Diagram



Fields

Field	Function
31 CNTEN	Counter Enable The CNTEN bit enables the RTC counter. Setting CNTEN bit to 0b has the effect of asynchronously resetting (synchronous reset negation) all the RTC and API logic. This allows RTC configuration and clock source selection to be updated without causing synchronization issues. **NOTE** CNTEN should be disabled when INV_RTC, INV_API are cleared. 0b - Counter disabled 1b - Counter enabled
30	RTC Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
RTCIE	The RTCIE bit enables interrupts requests to the system if RTCF is asserted. 0b - RTC interrupts disabled 1b - RTC interrupts enabled
29 FRZEN	Freeze Enable Bit The counter freezes on entering the debug mode on the last valid count value if the FRZEN bit is set. After passing of the debug mode counter starts from the frozen value. This bit should not be changed when debug mode is enabled. 0b - Counter does not freeze in debug mode 1b - Counter freezes in debug mode
28 ROVREN	Counter Roll Over wakeup/Interrupt Enable The ROVREN bit enables wakeup and interrupt requests when the RTC has rolled over from 0xFFFF_FFFF to 0x0000_0000. The RTCIE bit must also be set in order to generate an interrupt from a counter rollover. 0b - RTC rollover wakeup/interrupt disabled 1b - RTC rollover wakeup/interrupt enabled
27-16 —	Reserved
15 APIEN	Autonomous Periodic Interrupt Enable The APIEN bit enables the autonomous periodic interrupt function. Setting this bit to 0b, asynchronously disables API wakeup output of RTC as well. 0b - API disabled 1b - API enabled
14 APIIE	API Interrupt Enable The APIIE bit enables interrupts requests to the system if APIF is asserted. 0b - API interrupts disabled 1b - API interrupts enabled
13-12 CLKSEL	Clock select The CLKSEL[1:0] bits select the clock source for the RTC. CLKSEL may only be updated when CNTEN is 0. The user should ensure that oscillator is enabled before selecting it as a clock source for RTC. **NOTE** Refer the RTC clocking section in the Clocking chapter of this document. 00b - Clock source 0 01b - Clock source 1

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - Clock source 2 11b - Clock source 3
11 DIV512EN	Divide by 512 enable The DIV512EN bit enables the 512 clock divider. DIV512EN may only be updated when CNTEN is 0. 0b - Divide by 512 is disabled 1b - Divide by 512 is enabled
10 DIV32EN	Divide by 32 enable The DIV32EN bit enables the 32 clock divider. DIV32EN may only be updated when CNTEN is 0. 0b - Divide by 32 is disabled 1b - Divide by 32 is enabled
9-1 —	Reserved
0 TRIG_EN	Trigger enable for Analog Comparator This bit (TRIG_EN) when set will de-assert the wakeup_api on the next RTC clock (required for CMP when bus clock is disabled). **NOTE** If API wakeup is asserted with TRIG_EN set, and bus clock enabled, setting of RTCS[APIF] may be missed.

72.5.4 RTC Status register (RTCS)

Offset

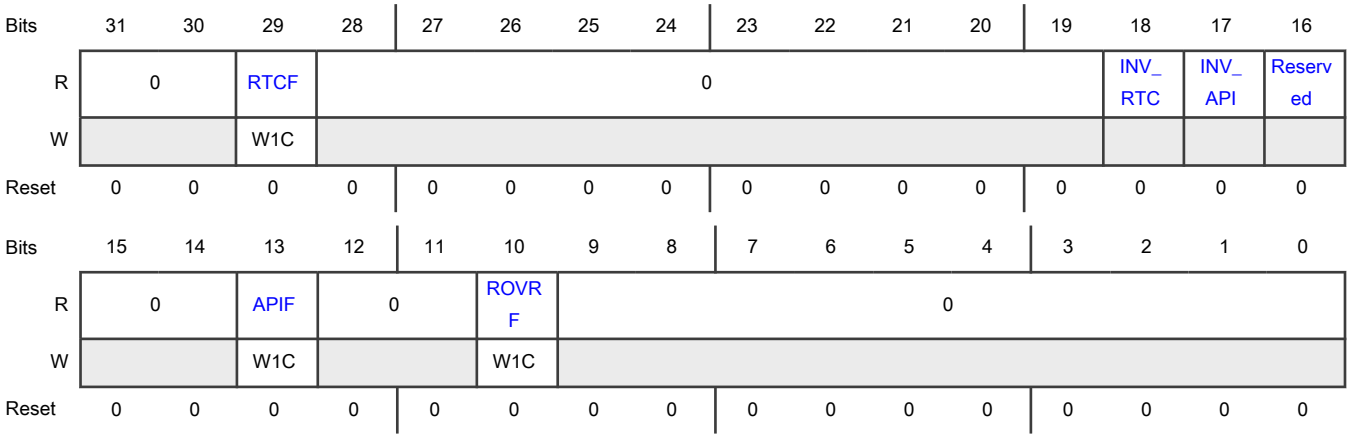
Register	Offset
RTCS	8h

Function

NOTE

W1C has priority over setting of the RTCF, APIF and ROVRF bits, in case both clearing and setting occurs at the same time.

Diagram



Fields

Field	Function
31-30 —	Reserved
29 RTCF	RTC Interrupt Flag The RTCF bit indicates that the RTC counter has reached the counter value matching RTC Compare value register (RTCVAL). RTCF is cleared by writing a 1 to RTCF. Writing a 0 to RTCF has no effect. 0b - RTC counter is not equal to RTCVAL 1b - RTC counter matches RTCVAL
28-19 —	Reserved
18 INV_RTC	Invalid RTC write This bit returns value 1 after a value is written to the RTCVAL register and the synchronization process is in progress. During this synchronization period, any attempt to write to the RTCVAL register again is ignored. Synchronization will complete only when CNTEN is set.
17 INV_API	Invalid APIVAL write This bit returns value 1 after a value is written to the APIVAL register and the synchronization process is in progress. During this synchronization period, any attempt to write to the APIVAL register again is ignored. Synchronization will complete only when CNTEN is set.
16 —	Reserved
15-14 —	Reserved
13	API Interrupt Flag

Chapter 73
Low Power Serial Peripheral Interface (LPSPI)

73.1 Chip-specific LPSPI information

73.1.1 LPSPI instances and configuration

This chip supports 6 instances of LPSPI.

Table 489. LPSPI instances configuration

Instances	TX FIFO Size	RX FIFO Size	Chip Selects
LPSPI0	4x32 bit	4x32 bit	8
LPSPI1	4x32 bit	4x32 bit	6
LPSPI2	4x32 bit	4x32 bit	4
LPSPI3	4x32 bit	4x32 bit	4
LPSPI4	4x32 bit	4x32 bit	4
LPSPI5	4x32 bit	4x32 bit	4

- S32K396 support data rate up to 20 Mbps. Only one LPSPI instance support 20 MHz in loopback mode that is LPSPI0
- All LPSPIs supports a minimum a 10 MHz data rate on standard plus pads and 7.5 MHz on standard pads.
- Low leakage and Wait modes are not supported in this device.

The number of chip selects that each LPSPI instance supports varies. Because of that, in the Configuration Register 1 (CFGR1), the Peripheral Chip Select (PCS) field and the Peripheral Chip Select Polarity (PCSPOL) field also vary. See the next 2 tables.

Table 490. LPSPI instances mapped against Peripheral Chip Select (PCS) field support

73.1.2 LPSPI HREQ considerations

It is recommended that the HREQ pin (when PCS[1] is used as HREQ) should get de-asserted before the completion of frame transfer. In case if the HREQ state is still asserted and LPSPI returns to idle state after frame transfer completion, the HREQ state is internally latched and the next data is written to the transmit FIFO without waiting for the next HREQ assertion.

This limitation is present only while using PCS[1] as HREQ and HREQ remains asserted throughout frame transfer. In case of using trigger input as HREQ, there is no issue.

73.2 Overview

LPSPI provides an efficient interface (either as a master or slave) to an SPI bus, which is a synchronous serial communication interface used in embedded systems. It is typically used to perform short distance communications between microcontrollers and peripheral devices, on printed circuit boards. Typical applications include interfacing with secure digital cards and LCD displays.

73.2.1 Block diagram

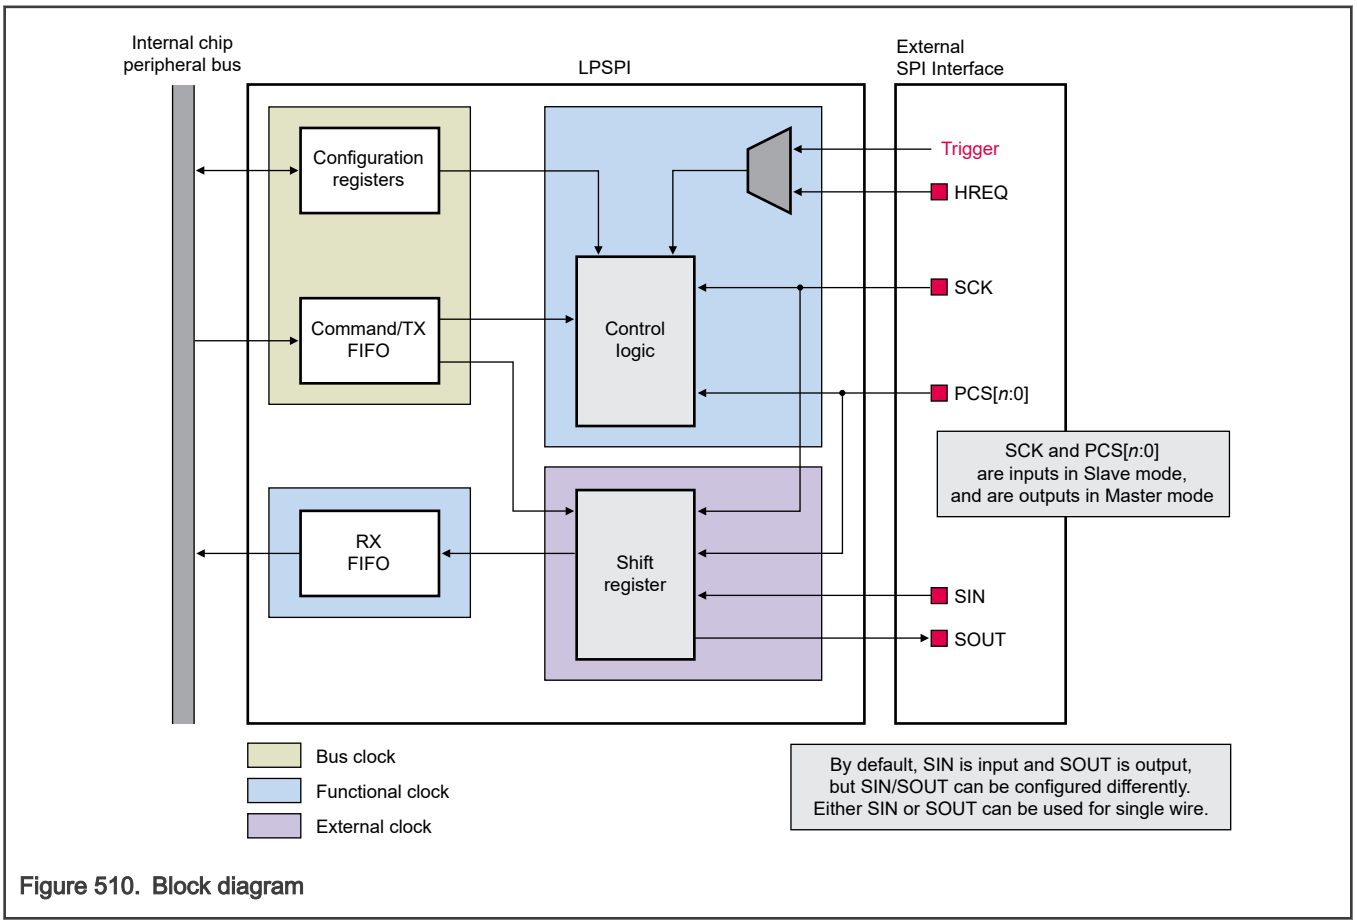

Figure 510. Block diagram

73.2.2 Features

- Minimal CPU overhead, with DMA transmit and receive requests supporting FIFO register accesses

- Support available for 32-bit word size
- Configurable clock polarity and phase
- Support available for 8 peripheral chip selects in Master mode
- Support available for Slave mode
- 4-word transmit and command FIFO
- 4-word receive FIFO
- Flexible timing parameters in Master mode, including SCK frequency and duty cycle, and delays between PCS and SCK edges
- Continuous transfer option to keep PCS asserted across multiple frames
- Full-duplex transfers that support 1-bit transmit and receive on each clock edge
- Half-duplex transfers that support:
  - 1-bit transmit or receive on each clock edge
  - 2-bit transmit or receive on each clock edge
  - 4-bit transmit or receive on each clock edge
  - 8-bit transmit or receive on each clock edge
- Option to use host request to control the start of an SPI bus transfer

73.3 Functional description

73.3.1 Master mode

73.3.1.1 Transmit and command FIFO commands

The transmit and command FIFO is a combined FIFO that includes both transmit data words and command words. You store:

- Transmit data words in the transmit and command FIFO, by writing to Transmit Data (TDR).
- Command words in the transmit and command FIFO, by writing to Transmit Command (TCR).

When a command word is at the top of the transmit and command FIFO, the actions that can occur depend on whether LPSPI is busy or between frames (see TCR[CONT] and TCR[CONTC]). See Table 492 for conditions and possible corresponding actions when a command word is at the top of the transmit and command FIFO.

Table 492. Possible actions when a command word is at the top of the transmit and command FIFO

Condition	Action
LPSPI is enabled and idle.	The command word is pulled from the FIFO, and this command word controls all subsequent transfers.
LPSPI is busy and TCR[CONTC] is 0.	The SPI frame completes at the end of the existing word, ignoring TCR[FRAMESZ]. The command word is then pulled from the FIFO and that command word controls all subsequent transfers (or until the next update to the command word). Note that a command word with TCR[CONTC] = 0 always terminates the existing transfer regardless of the previous TCR[CONT] value.
LPSPI is busy; the existing TCR[CONT] value is 1 and the new TCR[CONTC] value is 1.	The command word must be updated at the frame boundary. The command word is pulled from the FIFO during the last SCK pulse of the existing frame (based on the value of FRAMESZ), and the frame continues using the new command value for the rest of the frame (or until the next update to the command word). When

Table continues on the next page...

Table 492. Possible actions when a command word is at the top of the transmit and command FIFO (continued)

Condition	Action
	TCR[CONTC] = 1, only the lower 24 bits of the command word are updated. If the command word is updated at a word boundary, then the transfer halts (stops) after that word. TCR[CONTC] is ignored when not at a frame boundary, so the frame ends prematurely.

TCR[CONT] = 1 keeps PCS asserted at end of frame, allowing the transfer to continue.

TCR[CONTC] = 1 specifies that this command word must not terminate the existing frame, and the transfer can continue using the new command word.

TCR[CONTC] = 1 is restricted in the sense that the new command must load on a frame boundary, and the only way for a transfer to continue from a frame boundary is when the previous command has TCR[CONT] = 1.

You can read the current state of the existing command word from Transmit Command (TCR). It requires at least three LPSPI functional clock cycles for Transmit Command (TCR) to update after you write to it (assuming an empty FIFO), and LPSPI must be enabled (CR[MEN] = 1).

Writing to Transmit Command (TCR) does not initiate an SPI bus transfer, unless TCR[TXMSK] = 1. When TCR[TXMSK] = 1, a new command word is not loaded until the end of the existing frame (based on the value of TCR[FRAMESZ]); at the end of the transfer, TCR[TXMSK] transitions to 0.

In Master mode, the LPSPI command word in Transmit Command (TCR) controls SPI attributes based on the selections in register fields. See Table 493 for TCR fields and associated functionality related to data transfer.

Table 493. Command word in Master mode

Transmit Command (TCR)		Description	Can this field be modified during a data transfer?
Field	Name		
CPOL	Clock polarity	Specifies the polarity of the SCK pin. Any change of CPOL value causes a transition on the SCK pin.	N
CPHA	Clock phase	Specifies the clock phase of the transfer.	N
PRESCALE	Prescaler value	Specifies a prescaler used to divide the LPSPI functional clock, to generate the timing parameters of the SPI bus transfer. Changing PRESCALE in conjunction with PCS enables LPSPI to connect to different slave devices at different frequencies.	N
PCS	Peripheral chip select	Specifies which PCS pin asserts for the transfer; the polarity of PCS is static and specified by CFGR1[PCSPOL]. If CFGR1[PCSCFG] = 1, do not select PCS[3:2].	N
LSBF	LSB first	Specifies whether LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.	Y
BYSW	Byte swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing with devices that organize data as big-endian.	Y
CONT	Continuous transfer	Configures LPSPI for a continuous transfer that keeps PCS asserted between frames (as specified by FRAMESZ). You must write a new	Y

Table continues on the next page...

Table 493. Command word in Master mode (continued)

Transmit Command (TCR)		Description	Can this field be modified during a data transfer?
Field	Name		
		command word to cause PCS to negate. Also, this field supports changing the command word at frame size boundaries.	
CONTC	Continuing command	Indicates that this is a new command word for the existing continuous transfer. When CONTC = 1, the command word must only be written to the transmit and command FIFO on a frame boundary.	Y
RXMSK	Receive data mask	Masks the receive data and does not store the masked receive data in the receive FIFO or perform receive data matching. This option is useful for half-duplex transfers or to specify which fields are compared during receive data matching.	Y
TXMSK	Transmit data mask	Masks the transmit data; masked transmit data is not pulled from the transmit FIFO, and the output data pin is 3-stated (unless otherwise configured by CFGR1[OUTCFG]). This option is useful for half-duplex transfers.	Y
WIDTH	Transfer width	Specifies the number of bits shifted on each SCK pulse: • 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats. • 2-bit and 4-bit half-duplex transfers are useful for interfacing with QuadSPI memory devices, and either TXMSK or RXMSK must also be 1. • 8-bit half-duplex transfers are useful for interfacing with OctelSPI memory devices, and either TXMSK or RXMSK must also be 1.	Y
FRAMESZ	Frame size	Configures the frame size in number of bits equal to (FRAMESZ + 1): • The minimum frame size is 8 bits, or 16 bits for an 8-bit transfer. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contains the remaining bits. For example, a 72-bit transfer consists of three words: the first and second words are 32 bits, and the third word is 8 bits.	Y

73.3.1.1.1 SPI bus transfers

LPSPI initiates an SPI bus transfer when all these conditions are true:

- Data is written to the transmit FIFO.
- The HREQ pin is asserted (or the HREQ function is disabled).
- LPSPI is enabled.

To perform the SPI bus transfer, LPSPI uses the attributes configured in Transmit Command (TCR) and the timing parameters defined in Clock Configuration (CCR).

The SPI bus transfer ends after the number of bits indicated by the value of FRAMESZ have been transferred (provided CONT = 0), or at the end of a word when a new transmit command word is at the top of the transmit and command FIFO. When LPSPI is disabled, the SPI bus transfers end after the transmit FIFO is empty and LPSPI is idle.

The HREQ input is only checked when PCS is negated.

73.3.1.1.2 Circular FIFO

The transmit and command FIFO supports a circular FIFO feature. This feature enables the LPSPI master to (periodically) repeat a short data transfer that fits within the transmit and command FIFO, without requiring additional FIFO accesses. When the circular FIFO is enabled (CFGR0[CIRFIFO] = 1), the current state of the FIFO read pointer is saved and the status flags are not updated. After the FIFO is empty and LPSPI is idle, the FIFO read pointer is restored with the saved version, so the contents of the transmit and command FIFO are not permanently pulled from the FIFO when Circular FIFO mode is enabled.

73.3.1.2 Receive FIFO and data match

The receive FIFO stores received data during SPI bus transfers. When TCR[RXMSK] = 1, the received data is discarded instead of being stored in the receive FIFO:

- Received data is written to the receive FIFO when the last bit of the word is sampled.
- If the transmit FIFO is empty during a multiple-word or continuous transfer, then the receive data is written to the receive FIFO before the transfer stalls (assuming CFGR1[NOSTALL] = 0) while waiting for new transmit data or for a command word to be written.

LPSPI provides a receive data match function that can match received data against one of the two words in DMR0 and DMR1, or against a masked data word. You can also configure the received data match function to compare only the first one or two received data words since the start of the frame:

- Received data that is already discarded because of TCR[RXMSK] cannot cause the data match flag to set, and delays the receive data match on the first received data word, until all discarded data is received.
- You can configure the receive data match function to discard all received data until a data match is detected, using CFGR0[RDMO].
- After a receive data match, to allow all subsequent data to be received, write 0 to CFGR0[RDMO], and then write 0 to SR[DMF].

73.3.1.3 Timing parameters

The timing parameters that are used for all SPI bus transfers are relative to the LPSPI functional clock divided by the selection specified in TCR[PRESCALE]. Although you cannot change Clock Configuration (CCR) when LPSPI is busy, to support interfacing with different slave devices at different frequencies, you can change the TCR[PRESCALE] selection between SPI bus transfers by using Transmit Command (TCR).

NOTE

The minimum value shown in Table 494 is the minimum counter value, but the values of Clock Configuration (CCR) must also satisfy the data sheet specs based on the LPSPI functional clock frequency and prescaler value.

Table 494. Timing parameters

Clock Configuration (CCR) Clock Configuration 1 (CCR1)		Description	Minimum value	Maximum value
Field	Name			
SCKSET	SCK setup phase	Configures the SCK setup phase to (SCKSET + 1) cycles. The setup phase is the SCK high period	0 (1 cycle)	255 (256 cycles)

Table continues on the next page...

Table 494. Timing parameters (continued)

Clock Configuration (CCR) Clock Configuration 1 (CCR1)		Description	Minimum value	Maximum value
Field	Name			
		when either CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. Otherwise, it is the SCK low period. The SCK period is defined as (SCKSET + SCKHLD + 2) and the duty cycle is the difference between SCKSET and SCKHLD.		
SCKHLD	SCK hold phase	Configures the SCK hold phase to (SCKHLD + 1) cycles. The hold phase is the SCK low period when either CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. Otherwise, it is the SCK high period. The SCK period is defined as (SCKSET + SCKHLD + 2) and the duty cycle is the difference between SCKSET and SCKHLD.	0 (1 cycle)	255 (256 cycles)
PCSPCS	PCS-to-PCS delay	Configures the minimum delay between PCS negation and the next PCS assertion to (PCSPCS + PCSPCS + 2) cycles. When the command word is updated between transfers, there is a minimum of (PCSPCS + 1) cycles between the command word update and any change on PCS pins.	0 (2 cycles)	255 (512 cycles)
SCKSCK	SCK-to-SCK delay	Configures the delay during a continuous transfer between the last SCK edge of a frame and the first SCK edge of the continuing frame to (SCKSCK + 1) cycles. This is useful when the external slave requires a large delay between different words of an SPI bus transfer.	0 (1 cycle)	255 (256 cycles)
PCSSCK	PCS-to-SCK delay	Configures the minimum delay between PCS assertion and the first SCK edge to (PCSSCK + 1) cycles.	0 (1 cycle)	255 (256 cycles)
SCKPCS	SCK-to-PCS delay	Configures the minimum delay between the last SCK edge and the PCS negation to (SCKPCS + 1) cycles.	0 (1 cycle)	255 (256 cycles)

Figure 511 shows the timing settings controlled by:

- TCR[CPHA]
- TCR[CPOL]
- CCR[SCKPCS]
- CCR[PCSSCK]
- CCR1[SCKSET]
- CCR1[SCKHLD]

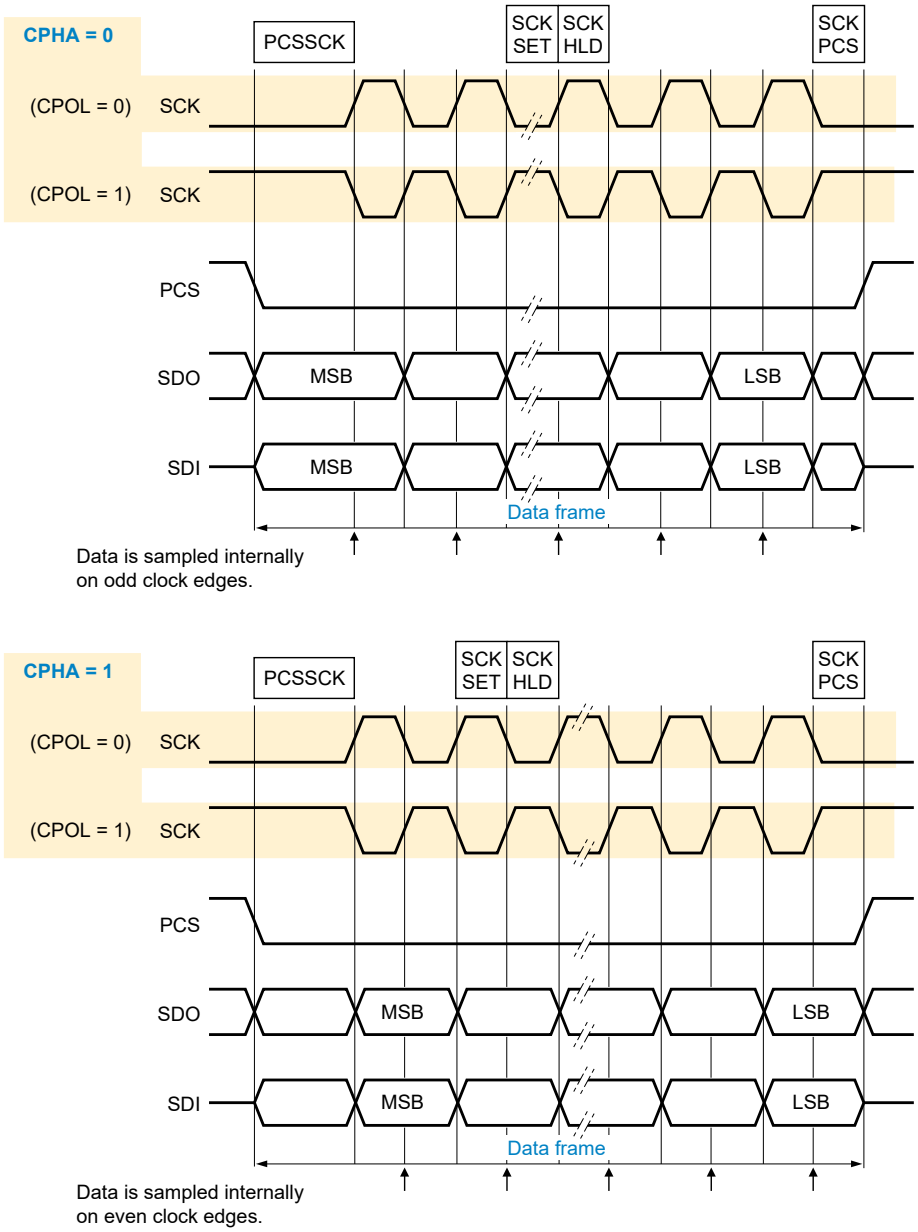

Figure 511. Clock phase (TCR[CPHA]) timing diagram example

To configure for a baud rate of 10 MHz with 50/50 duty cycle and with a functional clock frequency of 100 MHz, use the following settings:

- CCR1[SCKSET] = 0x4 (5 cycles)
- CCR1[SCKHLD] = 0x4 (5 cycles)
- CCR1[PCSPCS] = 0x8 (10 cycles)
- CCR1[SCKSCK] = 0x4 (5 cycles)
- CRR[PCSSCK] = 0x4 (5 cycles)
- CRR[SCKPCS] = 0x4 (5 cycles)
- TCR[PRESCALE] = 0x0 (divide by 1)

73.3.1.4 Pin configuration

Following are the pin configuration settings for half-duplex transfers:

- To swap directions or to support half-duplex transfers on the same pin, you can configure the SIN and SOUT pins using CFGR1[PINCFG].
- To specify whether an output data pin (SOUT, for example) 3-states when PCS is negated, or if the output data pin retains the last value, use CFGR1[OUTCFG].
- When configuring half-duplex transfers, you must configure the output data pins to 3-state when PCS is negated (CFGR1[OUTCFG] = 1).
- When performing half-duplex 2-bit transfers, you can write any value to CFGR1[PCSCFG].
- When performing half-duplex 4-bit transfers, you must write 1h to CFGR1[PCSCFG].

73.3.1.5 Clock loopback

Configure the LPSPI master to use one of the following clocks to sample the input data:

- The SCK output clock
- A delayed version of the SCK output clock

The delayed version of the SCK is chosen by the SCK pin output delay, plus the SCK pin input delay, and is selected by writing 1 to CFGR1[SAMPLE]. Enabling the loopback version of the SCK pin can improve the setup time of the input data from the slave.

See the chip data sheet for the specific input setup time in Master Loopback mode.

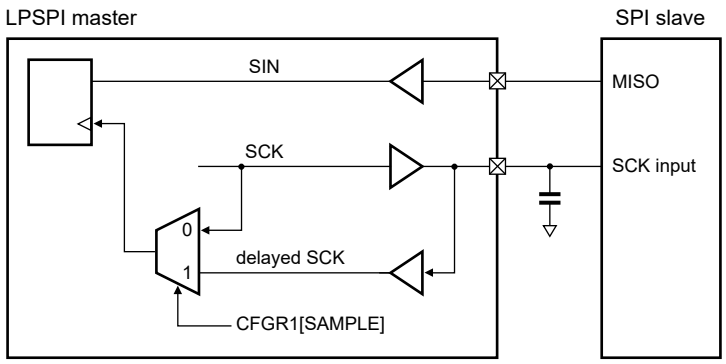

Figure 512. Clock loopback

73.3.2 Slave mode

LPSPI Slave mode:

- Uses the same shift register and logic that Master mode uses.
- Does not use Clock Configuration (CCR).
- Requires Transmit Command (TCR) to remain static (unchanged) during SPI bus transfers.

73.3.2.1 Transmit and command FIFO commands

You must initialize Transmit Command (TCR) before enabling LPSPI in Slave mode, although this register is not updated until after LPSPI is enabled. After LPSPI is enabled, you must make changes to this register only when LPSPI is idle. In Slave mode, the LPSPI command word in this register controls SPI attributes. Before the PCS input asserts, the transmit FIFO must be filled with transmit data, or the transmit error flag sets.

Table 495. Command word in Slave mode

Transmit Command (TCR)		Description
Field	Name	
CPOL	Clock polarity	Specifies the polarity of the external SCK input.
CPHA	Clock phase	Specifies the clock phase of transfer.
PRESCALE	Prescaler value	Specifies the LPSPI functional clock prescaler.
PCS	Peripheral chip select	Specifies which PCS is used. The polarity of PCS is static and configured by CFGR1[PCSPOL]. If CFGR1[PCSCFG] is not equal to zero, then do not select the PCS[3:2] pins.
LSBF	LSB first	Specifies whether LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.
BYSW	Byte swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing with devices that organize data as big-endian.
CONT	Continuous transfer	When continuous transfer is selected in Slave mode, after the number of bits indicated by FRAMESZ are transferred, LPSPI passes through and transmits the received data until the next PCS negation. Whatever is shifted in on the receive data is shifted out as transmit data considering that there is a 32-bit shift register.
CONTC	Continuing command	When the continuing command is enabled in Slave mode, after the number of bits indicated by FRAMESZ are transferred, RXMSK is considered equal to 1 and TXMSK is considered equal to 0 until the next PCS negation. CONTC can be used to change the direction of a transfer after the number of bits indicated by FRAMESZ.
RXMSK	Receive data mask	Masks the receive data; LPSPI does not store masked receive data in the receive FIFO or perform receive data matching. This option is useful for half-duplex transfers or to specify which fields are compared during receive data matching.
TXMSK	Transmit data mask	Masks the transmit data so that the masked transmit data is not pulled from transmit FIFO, and the output data pin is 3-stated (unless otherwise specified in CFGR1[OUTCFG]). This option is useful for half-duplex transfers.
WIDTH	Transfer width	Specifies the number of bits shifted on each SCK pulse: • 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats. • 2-bit and 4-bit half-duplex transfers are useful for interfacing with QuadSPI memory devices, and at least either TCR[TXMSK] or TCR[RXMSK] must be 1. • 8-bit half-duplex transfers are useful for interfacing with OctelSPI memory devices, and at least either TCR[TXMSK] or TCR[RXMSK] must also be 1.
FRAMESZ	Frame size	Specifies the frame size in number of bits equal to (FRAMESZ + 1): • The minimum frame size is 8 bits, or 16 bits for an 8-bit parallel transfer. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contain the remainder bits. For example, a 72-bit transfer consists of three words: the first and second words are 32 bits, and the third word is 8 bits.

73.3.2.2 Receive FIFO and data match

The receive FIFO stores receive data during SPI bus transfers. When TCR[RXMSK] = 1, the received data is discarded instead of storing the received data in the receive FIFO.

Receive data supports a receive data match function that can match received data against one of the two words in DMR0 and DMR1 or against a masked data word. You can also configure the data match function to compare only the first one or two received data words since the start of the frame:

- Received data that is already discarded because TCR[RXMSK] = 1 cannot cause the data match to set, and delays the match on the first received data word, until all discarded data is received.
- By using CFGR0[RDMO], you can also configure the receiver match function to discard all received data until a data match is detected.
- After a receive data match, to allow all subsequent data to be received, first write 0 to CFGR0[RDMO], then clear SR[DMF].

73.3.2.3 Partial received word

When the PCS pin deasserts and the receive shift register shifts in a partial word, you can configure the receive shift register to either discard the partial word or to store it in the receive FIFO. You must specify this using CFGR1[PARTIAL].

A partial word is defined as less than TCR[FRAMESZ] bits (when TCR[FRAMESZ] is equal or less than 32 bits, or it is the last word in a multi-word frame) or less than 32 bits (when TCR[FRAMESZ] is greater than 32 bits and not the last word in a multi-word frame).

A single-bit frame is not supported. A partial received word of 1 bit is supported, but a partial received frame of 1 bit is not supported.

73.3.2.4 Clocked interface

LPSPI supports interfacing with external masters that provide only clock and data pins (PCS is not required). This interface requires:

- Writing 1 to TCR[CPHA] (data is changed on the leading edge of SCK and captured on the following edge).
- Configuring the PCS input to be always asserted (CFGR1[PCSPOL*n*] = 1). For example, to configure PCS[0] to be always asserted, write 1 to PCSPOL[0], and do not configure PCS[0] in the pin muxing. The chip-level drives PCS to a certain value (ideally 1); you could use CFGR1[PCSPOL*n*] to invert that value.
- Writing 1 to CFGR1[AUTOPCS] to enable automatic PCS generation. When CFGR1[AUTOPCS] = 1, a minimum of four LPSPI functional clock cycles (divided by the selection specified in TCR[PRESCALE]) is required between the last SCK edge of one word and the first SCK edge of the next word.

73.3.3 Low-power modes

Table 496. Low-power modes

Chip mode	LPSPI operation
Run	Normal operation

73.3.4 Debug mode

Table 497. Debug mode

Chip mode	LPSPI operation
Debug (the core is in Debug or Halted mode)	Can continue operating in Debug mode, if CR[DBGEN] = 1

73.3.5 Clocking

Table 498. LPSPI clocks

Type of clock	Description
Functional	• Asynchronous to the bus clock. • If the LPSPI functional clock remains enabled in low-power modes, then LPSPI can perform SPI bus transfers and low-power wakeups in both Master and Slave modes. • LPSPI divides the functional clock by a prescaler; the resulting frequency must be at least two times faster than the SPI external clock frequency (SCK).
External	• The LPSPI shift register is clocked directly by the SCK clock. • How the SCK clock is generated or supplied depends on the mode (Master or Slave): — In Master mode, the SCK clock is generated internally. — In Slave mode, the SCK clock is supplied externally.
Bus	The bus clock is only used for bus accesses to the LPSPI control and configuration registers. The bus clock frequency must be high enough to support the data bandwidth requirements of the LPSPI registers, including the FIFOs.

See the chip-specific LPSPI information for more.

73.3.6 Reset

Table 499. LPSPI resets

Type of reset	Description
Chip	Resets the LPSPI logic and registers to their default states.
Software	• Resets the LPSPI logic and registers to their default states, except for the Control register. • The LPSPI software reset is controlled using CR[RST].
FIFO	• Resets the transmit and command FIFO and the receive FIFO. • CR[RTF] and CR[RRF] are write-only. • After being reset, FIFO is empty.

73.3.7 Interrupts and DMA requests

The following table lists Slave mode sources (status flags) that can generate LPSPI interrupts and LPSPI slave transmit and receive DMA requests.

Table 500. Interrupts and DMA requests

Status (SR)		Description	Can generate		
Status flag	Name		Interrupt?	DMA request?	Low-power wake-up?
TDF	Transmit data flag	Indicates that data can be written to transmit FIFO, as configured by the transmit FIFO watermark, FCR[TXWATER].	Y	TX	Y

Table continues on the next page...

Table 500. Interrupts and DMA requests (continued)

Status (SR)		Description	Can generate		
Status flag	Name		Interrupt?	DMA request?	Low-power wake-up?
RDF	Receive data flag	Indicates that data can be read from the receive FIFO, as configured by the receive FIFO watermark, FCR[RXWATER].	Y	RX	Y
WCF	Word complete flag	Indicates that the word is complete and the last bit of the word has been sampled.	Y	N	Y
FCF	Frame complete flag	Indicates that the frame is complete and PCS is deasserted.	Y	N	Y
TCF	Transfer complete flag	Indicates that transfer is complete, PCS is deasserted, and the transmit and command FIFO is empty.	Y	N	Y
TEF	Transmit error flag	Indicates a transmit and command FIFO underrun. In Master mode, when CFGR1[NOSTALL] = 0 (transfers stall when transmit FIFO is empty), TEF cannot be set.	Y	N	Y
REF	Receive error flag	Indicates a receive FIFO overflow. In Master mode, when CFGR1[NOSTALL] = 0 (transfers stall when receive FIFO is full), REF cannot be set.	Y	N	Y
DMF	Data match flag	Indicates that the received data matches the configured data match value.	Y	N	Y
MBF	Module busy flag	Indicates that LPSPI is busy performing an SPI bus transfer.	N	N	N

73.3.8 Peripheral triggers

The connection of the LPSPI peripheral triggers with other peripherals depends on the device that is used.

Table 501. Peripheral triggers

Type of trigger	Description	Additional information
Frame output	The frame output trigger: • Asserts at the end of each frame (when PCS deasserts). • Remains asserted for one cycle of the LPSPI functional clock divided by the configuration defined in TCR[PRESCALE].	LPSPI generates two output triggers that can be connected to other peripherals on the chip.
Word output	The word output trigger: • Asserts at the end of each received word. • Remains asserted for one cycle of the LPSPI functional clock divided by the configuration defined in TCR[PRESCALE].	

Table continues on the next page...

Table 501. Peripheral triggers (continued)

Type of trigger	Description	Additional information
Input	To control the start of an LPSPI bus transfer, the LPSPI input trigger can be selected instead of the HREQ input: • The LPSPI input trigger is synchronized, and must assert for at least two cycles of the LPSPI functional clock divided by the configuration defined in TCR[PRESCALE] so that the input trigger can be detected. • When LPSPI is busy, the HREQ input (and therefore the LPSPI input trigger) is ignored. • When LPSPI is busy, both the HREQ and LPSPI input triggers are ignored. They are used to start a new transfer when LPSPI is idle.	

73.4 External signals

Table 502. External signals

Signal	Name	Description	I/O
SCK	Serial clock	• Input in Slave mode • Output in Master mode	I/O
PCS[0]	Peripheral chip select	• Input in Slave mode • Output in Master mode	I/O
PCS[1]/HREQ	Peripheral chip select or host request	Host request pin is selected when CFGR0[HREN] = 1 and CFGR0[HRSEL] = 0: • Input in either Slave mode or when used as master host request • Output in either Master mode or when used as slave host request	I/O
PCS[2]/DATA[2]	Peripheral chip select or data pin 2 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Slave mode • Output in Master mode When CFGR1[PCSCFG] = 1: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
PCS[3]/DATA[3]	Peripheral chip select or data pin 3 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Slave mode • Output in Master mode When CFGR1[PCSCFG] = 1:	I/O

Table continues on the next page...

Table 502. External signals (continued)

Signal	Name	Description	I/O
		• Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	
PCS[4]/DATA[4]	Peripheral chip select or data pin 4 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Slave mode • Output in Master mode When CFGR1[PCSCFG] = 11b: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
PCS[5]/DATA[5]	Peripheral chip select or data pin 5 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Slave mode • Output in Master mode When CFGR1[PCSCFG] = 11b: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
PCS[6]/DATA[6]	Peripheral chip select or data pin 6 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Slave mode • Output in Master mode When CFGR1[PCSCFG] = 11b: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
PCS[7]/DATA[7]	Peripheral chip select or data pin 7 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Slave mode • Output in Master mode When CFGR1[PCSCFG] = 11b: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O

Table continues on the next page...

Table 502. External signals (continued)

Signal	Name	Description	I/O
SOUT/DATA[0]	Serial data output	Can be configured as serial data input signal (used as data pin 0 in half-duplex parallel data transfers)	I/O
SIN/DATA[1]	Serial data input	Can be configured as serial data output signal (used as data pin 1 in half-duplex parallel data transfers)	I/O

73.5 Initialization

This module does not require initialization.

73.6 Memory map and registers

NOTE

- Writing to a read-only register or reading a write-only register can cause bus errors.
- LPSPI does not check values programmed in registers for validity, so you must take care to write valid values only.

73.6.1 LPSPI register descriptions

LPSPI provides an efficient interface to an SPI bus, either as a master or slave. An SPI bus is a synchronous serial communication interface used in embedded systems. It is typically used to perform short distance communications between microcontrollers and peripheral devices, on printed circuit boards. Typical applications include interfacing with secure digital cards and LCD displays.

73.6.1.1 LPSPI memory map

LPSPI_0 base address: 4035_8000h

LPSPI_1 base address: 4035_C000h

LPSPI_2 base address: 4036_0000h

LPSPI_3 base address: 4036_4000h

73.6.1.2 Version ID (VERID)

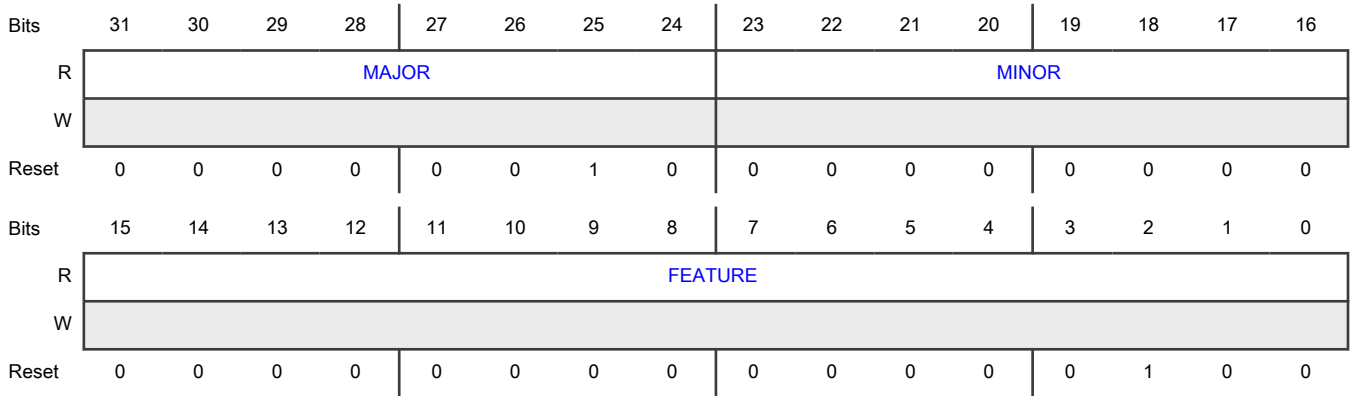
Offset

Register	Offset
VERID	0h

Function

Contains version numbers for the module design and feature set.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number Indicates the major version number of the module specification.
23-16 MINOR	Minor Version Number Indicates the minor version number of the module specification.
15-0 FEATURE	Module Identification Number Indicates the feature set number 0000_0000_0000_0100b - Standard feature set supporting a 32-bit shift register. All other values are reserved.

73.6.1.3 Parameter (PARAM)

Offset

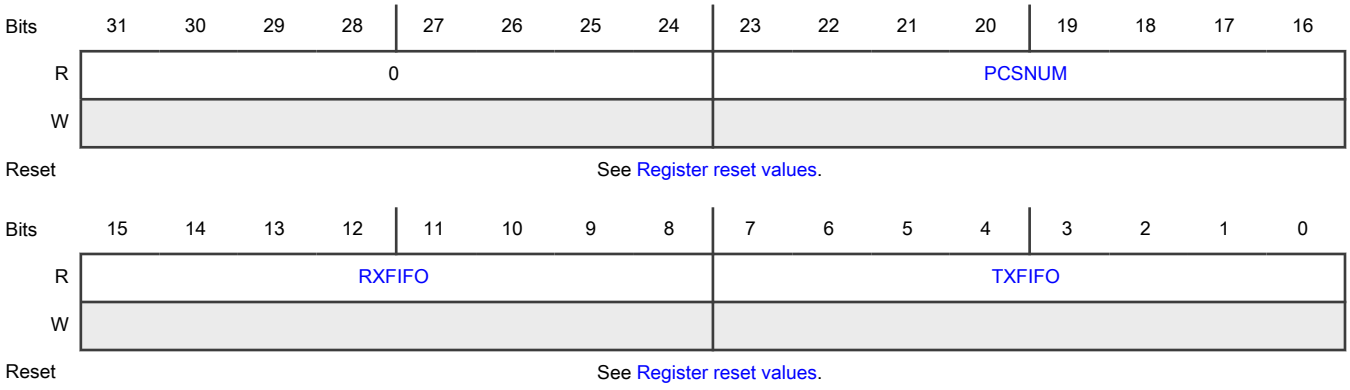
Register	Offset
PARAM	4h

Function

Contains:

- Number of PCS pins.
- Receive FIFO size.
- Transmit FIFO size.

Diagram



Register reset values

Register	Reset value
PARAM	LPSPI_0: 0008_0202h LPSPI_1: 0006_0202h LPSPI_2–LPSPI_5: 0004_0202h

Fields

Field	Function
31-24 —	Reserved
23-16 PCSNUM	PCS Number Indicates the number of PCS pins supported.
15-8 RXFIFO	Receive FIFO Size Indicates the maximum number of words in the receive FIFO. The maximum number of words is 2^{RXFIFO}.
7-0 TXFIFO	Transmit FIFO Size Indicates the maximum number of words in the transmit FIFO. The maximum number of words is 2^{TXFIFO}.

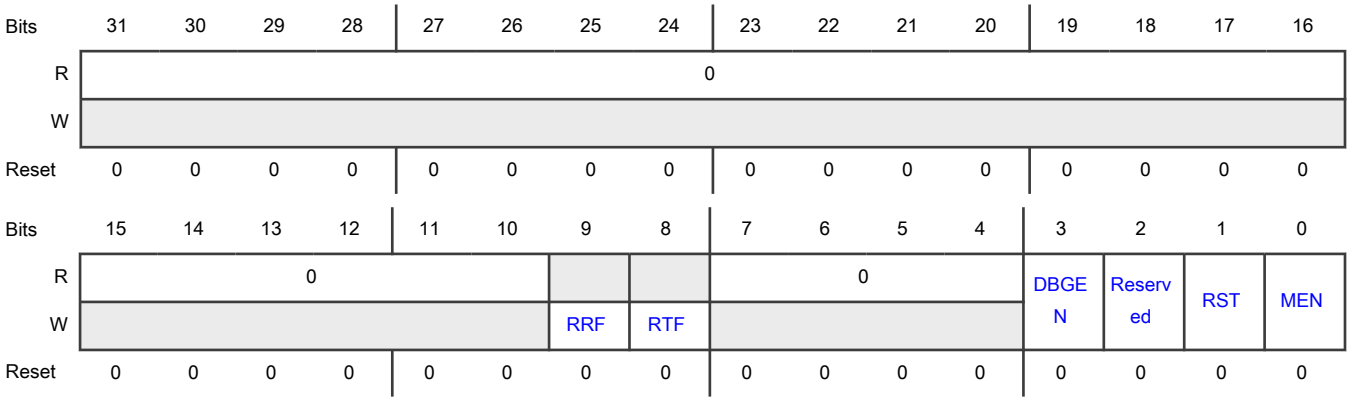
73.6.1.4 Control (CR)

Offset

Register	Offset
CR	10h

Function
Contains fields that control the module operation.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 RRF	Reset Receive FIFO Deletes all entries in the receive FIFO. This field always reads 0. 0b - No effect 1b - Reset
8 RTF	Reset Transmit FIFO Deletes all entries in the transmit FIFO. This field always reads 0. 0b - No effect 1b - Reset
7-4 —	Reserved
3 DBGEN	Debug Enable Enables LPSPI when the CPU is in Debug mode. If this field is 0, LPSPI is disabled when the CPU is halted; the PCS pin is deasserted after the transmit FIFO is empty regardless of the state of Transmit Command (TCR). You must update this field only when LPSPI is disabled (MEN = 0). 0b - Disable 1b - Enable
2 —	Reserved
1 RST	Software Reset Resets all internal logic and registers, except Control (CR). The reset takes effect immediately and remains asserted until you write 0 to it. There is no minimum delay required before clearing the software reset by writing 0. 0b - Not reset 1b - Reset
0 MEN	Module Enable Enables the module. After writing 0, MEN remains set until LPSPI has completed the current transfer and is idle. 0b - Disable 1b - Enable

73.6.1.5 Status (SR)

Offset

Register	Offset
SR	14h

Function
Contains data flow status.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Fields

Field	Function
31-25 —	Reserved
24 MBF	Module Busy Flag Indicates, in Master mode, whether there is data to transmit and LPSPI is able to transmit (for example, the HREQ pin is asserted). The HREQ pin deasserts after the PCS pin deasserts and the LPSPI master has waited for half the time specified in CCR[DBT] with no new data to transmit. Slave mode sets this flag when LPSPI is enabled and PCS is asserted. 0b - LPSPI is idle 1b - LPSPI is busy
23-14 —	Reserved
13 DMF	Data Match Flag Indicates whether the received data matches DMR0[MATCH0] and/or DMR1[MATCH1] (as configured by CFGR1[MATCFG]).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - No match 1b - Match When writing 0b - No effect 1b - Clear the flag
12 REF	Receive Error Flag Indicates a receive FIFO overflow error. When this flag is set: 1. End the transfer. 2. Empty the receive FIFO. 3. Clear this flag. 4. Restart the transfer from the beginning. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No overflow 1b - Overflow When writing 0b - No effect 1b - Clear the flag
11 TEF	Transmit Error Flag Indicates a transmit FIFO underrun error. When this flag is set: 1. End the transfer. 2. Clear this flag. 3. Restart the transfer from the beginning. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No underrun 1b - Underrun

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When writing 0b - No effect 1b - Clear the flag
10 TCF	Transfer Complete Flag Indicates, in Master mode, whether all transfers are complete and LPSPI has returned to the Idle state and the transmit FIFO is empty. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clear the flag
9 FCF	Frame Complete Flag Indicates whether a frame transfer is complete after PCS deasserts. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clear the flag
8 WCF	Word Complete Flag Indicates whether the last bit of a received word is sampled. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not complete 1b - Complete When writing

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No effect 1b - Clear the flag
7-2 —	Reserved
1 RDF	Receive Data Flag Indicates whether the number of words in the receive FIFO is greater than the value in FCR[RXWATER]. 0b - Receive data not ready 1b - Receive data ready
0 TDF	Transmit Data Flag Indicates whether the number of words in the transmit FIFO is equal to or less than the value in FCR[TXWATER]. 0b - Transmit data not requested 1b - Transmit data requested

73.6.1.6 Interrupt Enable (IER)

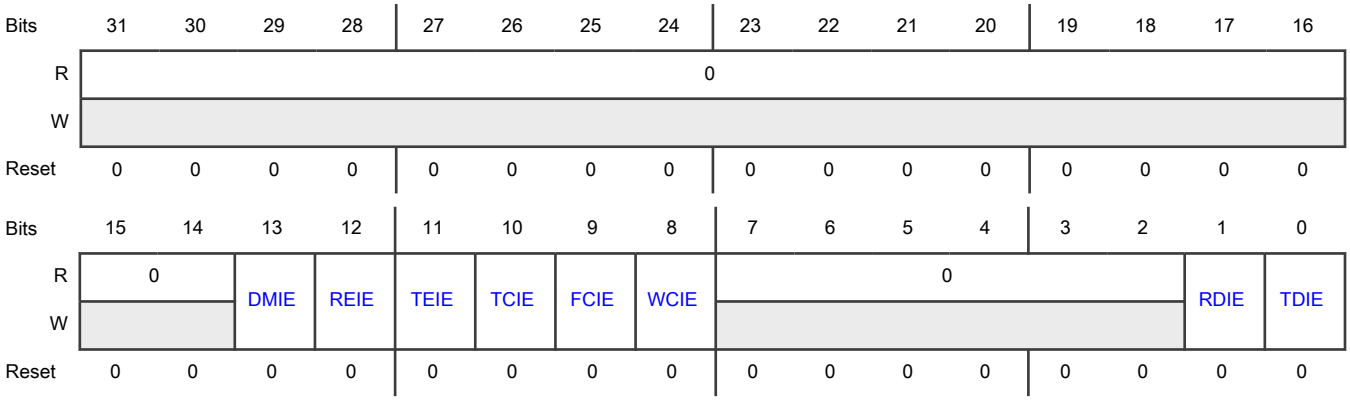
Offset

Register	Offset
IER	18h

Function

Enables interrupts based on data flow and errors.

Diagram



Fields

Field	Function
31-14 —	Reserved
13 DMIE	Data Match Interrupt Enable Enables the data match interrupt. 0b - Disable 1b - Enable
12 REIE	Receive Error Interrupt Enable Enables the receive complete interrupt. 0b - Disable 1b - Enable
11 TEIE	Transmit Error Interrupt Enable Enables the transmit complete interrupt. 0b - Disable 1b - Enable
10 TCIE	Transfer Complete Interrupt Enable Enables the transfer complete interrupt. 0b - Disable 1b - Enable
9 FCIE	Frame Complete Interrupt Enable Enables the frame complete interrupt. 0b - Disable 1b - Enable
8 WCIE	Word Complete Interrupt Enable Enables the word complete interrupt. 0b - Disable 1b - Enable
7-2 —	Reserved
1 RDIE	Receive Data Interrupt Enable Enables the receive data interrupt.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
0 TDIE	Transmit Data Interrupt Enable Enables the transmit data interrupt. 0b - Disable 1b - Enable

73.6.1.7 DMA Enable (DER)

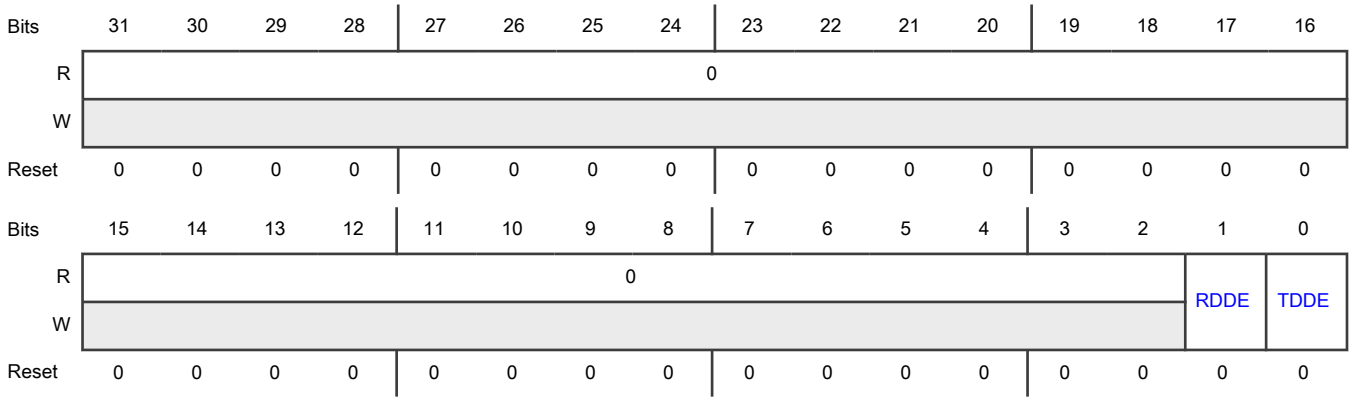
Offset

Register	Offset
DER	1Ch

Function

Enables the DMA data flow.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 RDDE	Receive Data DMA Enable Enables the receive data DMA.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
0 TDDE	Transmit Data DMA Enable Enables the transmit data DMA. 0b - Disable 1b - Enable

73.6.1.8 Configuration 0 (CFGR0)

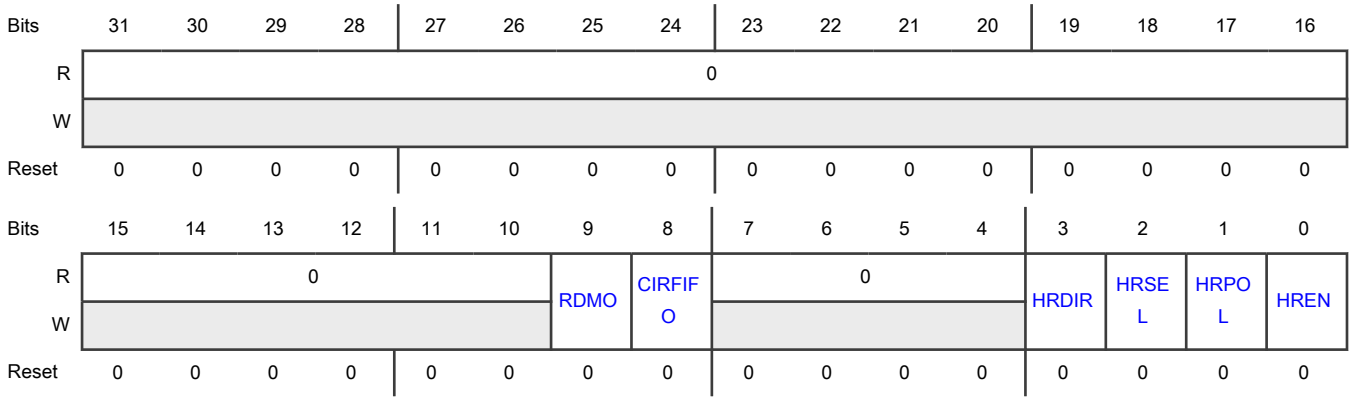
Offset

Register	Offset
CFGR0	20h

Function

Includes fields to configure LPSPI.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 RDMO	Receive Data Match Only Enables receive data match.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When enabled, all received data that does not cause SR[DMF] to assert is discarded: • Write 1 to this field when LPSPI is idle and SR[DMF] = 0. • After SR[DMF] = 1, this field is ignored. • To ensure that no receive data is lost when disabling RDMO, write 0 to this field before clearing SR[DMF]. See CFGR1[MATCFG] for the received data matching options. When disabled, all received data is stored in the receive FIFO. 0b - Disable 1b - Enable
8 CIRFIFO	Circular FIFO Enable Enables circular FIFO. When enabled, the transmit FIFO read pointer is saved to a temporary register. The transmit FIFO is emptied as in normal operation, but when LPSPI is idle and the transmit FIFO is empty, the read pointer value is restored from the temporary register. This restoring of the read pointer causes the contents of the transmit FIFO to be cycled through repeatedly. **NOTE** The read pointer is restored for as long as this field is 1. Writing additional words to the FIFO when this field is 1 adds them to the end of the FIFO, up to the size of the transmit FIFO. 0b - Disable 1b - Enable
7-4 —	Reserved
3 HRDIR	Host Request Direction Specifies the direction of the HREQ pin. You must configure the HREQ pin only as an output when LPSPI is in Slave mode. The HREQ pin direction must be an input for Master mode. 0b - Input 1b - Output
2 HRSEL	Host Request Select Specifies the source of the host request input. When the host request function is enabled with the HREQ pin, the PCS[1] function is disabled. 0b - HREQ pin 1b - Input trigger
1 HRPOL	Host Request Polarity Specifies the polarity of the HREQ pin or input trigger.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Active high 1b - Active low
0 HREN	Host Request Enable Enables LPSPI, in Master mode, to start a new SPI bus transfer only if the host request input is asserted. When LPSPI is busy, the host request input is ignored. In Slave mode, causes the HREQ output pin to assert when data is available to be transmitted. 0b - Disable 1b - Enable

73.6.1.9 Configuration 1 (CFGR1)

Offset

Register	Offset
CFGR1	24h

Function

Includes fields to configure LPSPI. You must write to this register only when LPSPI is disabled.

In addition to pin and output configurations, this register contains match configuration details; the following table shows match conditions specified in MATCFG.

Table 503. Match conditions for CFGR1[MATCFG]

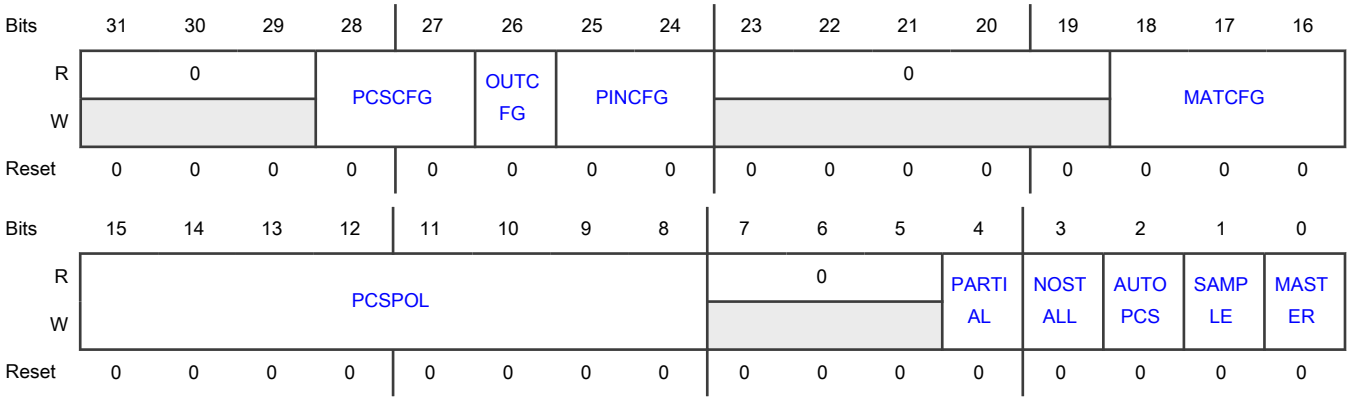
Condition	Description
Match first data word with compare word	Match if first data word equals MATCH0 logically ORed with MATCH1 first_data_word == (MATCH0 || MATCH1)
Match any data word with compare word	Match if any data word equals MATCH0 logically ORed with MATCH1 any_data_word == (MATCH0 || MATCH1)
Sequential match, first data word	Match if first data word equals MATCH0, and second data word equals MATCH1 (first_data_word == MATCH0) && (second_data_word == MATCH1)
Sequential match, any data word	Match if any data word equals MATCH0, and the next data word equals MATCH1 (any_data_word == MATCH0) && (next_data_word == MATCH1)
Match first data word (masked) with compare word (masked)	Match if first data word logically ANDed with MATCH1 equals MATCH0 logically ANDed with MATCH1 (first_data_word && MATCH1) == (MATCH0 && MATCH1)

Table continues on the next page...

Table 503. Match conditions for CFGR1[MATCFG] (continued)

Condition	Description
Match any data word (masked) with compare word (masked)	Match if any data word logically ANDed with MATCH1 equals MATCH0 logically ANDed with MATCH1 (any_data_word && MATCH1) == (MATCH0 && MATCH1)

Diagram



Fields

Field	Function
31-29 —	Reserved
28-27 PCSCFG	Peripheral Chip Select Configuration Specifies PCS pin configuration. When performing parallel transfers, you must configure this field to enable the desired transfer. **NOTE** This field is not supported in every instance. The following table includes only supported registers.

Instance	Field supported in	Field not supported in
LPSPI_0	CFGR1	—
LPSPI_1	CFGR1[27]	CFGR1[28]
LPSPI_2	CFGR1[27]	CFGR1[28]
LPSPI_3	CFGR1[27]	CFGR1[28]
LPSPI_4	CFGR1[27]	CFGR1[28]
LPSPI_5	CFGR1[27]	CFGR1[28]

Table continued from the previous page...

Field	Function
	<table><tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr></table> **NOTE** The descriptions of the field settings vary by module instance. <table><tr><th>Instance</th><th>Field value and description</th></tr><tr><td>LPSPI_0</td><td>00b - PCS[7:2] configured for chip select function 01b - PCS[3:2] configured for half-duplex 4-bit transfers (PCS[3:2] = DATA[3:2]) 11b - PCS[7:2] configured for half-duplex 4-bit and 8-bit transfers (PCS[7:2] = DATA[7:2])</td></tr><tr><td>LPSPI_1</td><td>0b - PCS[5:2] configured for chip select function 1b - PCS[3:2] configured for half-duplex 4-bit transfers (PCS[3:2] = DATA[3:2])</td></tr><tr><td>LPSPI_2</td><td>0b - PCS[3:2] configured for chip select function 1b - PCS[3:2] configured for half-duplex 4-bit transfers (PCS[3:2] = DATA[3:2])</td></tr><tr><td>LPSPI_3</td><td>0b - PCS[3:2] configured for chip select function 1b - PCS[3:2] configured for half-duplex 4-bit transfers (PCS[3:2] = DATA[3:2])</td></tr><tr><td>LPSPI_4</td><td>0b - PCS[3:2] configured for chip select function 1b - PCS[3:2] configured for half-duplex 4-bit transfers (PCS[3:2] = DATA[3:2])</td></tr><tr><td>LPSPI_5</td><td>0b - PCS[3:2] configured for chip select function 1b - PCS[3:2] configured for half-duplex 4-bit transfers (PCS[3:2] = DATA[3:2])</td></tr></table>
26 OUTCFG	Output Configuration Specifies whether the output data is 3-stated between accesses (when PCS is deasserted). When performing half-duplex transfers, this field must be 1. 0b - Retain last value 1b - 3-stated
25-24 PINCFG	Pin Configuration

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Specifies the pins used for input and output data during serial transfers. This field is ignored when performing parallel transfers. 00b - SIN is used for input data; SOUT is used for output data 01b - SIN is used for both input and output data; only half-duplex serial transfers are supported 10b - SOUT is used for both input and output data; only half-duplex serial transfers are supported 11b - SOUT is used for input data; SIN is used for output data
23-19 —	Reserved
18-16 MATCFG	Match Configuration Specifies the condition that causes SR[DMF] to assert. See the match conditions listed in Table 1 for more information. **NOTE** When writing to this field, either the old value or new value must be in the disabled state (0). You cannot transition from a nonzero value to another nonzero value. 000b - Match is disabled 001b - Reserved 010b - Match first data word with compare word 011b - Match any data word with compare word 100b - Sequential match, first data word 101b - Sequential match, any data word 110b - Match first data word (masked) with compare word (masked) 111b - Match any data word (masked) with compare word (masked)
15-8 PCSPOL	Peripheral Chip Select Polarity Specifies the polarity of each PCS pin. Bit *n* in this field (the least-significant bit is bit 0) corresponds to PCS[*n*]. **NOTE** The entire PCSPOL field is not fully supported in every LPSPI module instance. See the LPSPI chip-specific information. **NOTE** This field is not supported in every instance. The following table includes only supported registers.

Instance	Field supported in	Field not supported in
LPSPI_0	CFGR1	—

Table continues on the next page...

Table continued from the previous page...

Field	Function
	<table><tr><th>Instance</th><th>Field supported in</th><th>Field not supported in</th></tr><tr><td>LPSPI_1</td><td>CFGR1[13–8]</td><td>CFGR1[15–14]</td></tr><tr><td>LPSPI_2</td><td>CFGR1[11–8]</td><td>CFGR1[15–12]</td></tr><tr><td>LPSPI_3</td><td>CFGR1[11–8]</td><td>CFGR1[15–12]</td></tr><tr><td>LPSPI_4</td><td>CFGR1[11–8]</td><td>CFGR1[15–12]</td></tr><tr><td>LPSPI_5</td><td>CFGR1[11–8]</td><td>CFGR1[15–12]</td></tr></table> **NOTE** The descriptions of the field settings vary by module instance. <table><tr><th>Instance</th><th>Field value and description</th></tr><tr><td>LPSPI_0</td><td>0000_0000b - Active low 0000_0001b - Active high</td></tr><tr><td>LPSPI_1</td><td>00_0000b - Active low 00_0001b - Active high</td></tr><tr><td>LPSPI_2</td><td>0000b - Active low 0001b - Active high</td></tr><tr><td>LPSPI_3</td><td>0000b - Active low 0001b - Active high</td></tr><tr><td>LPSPI_4</td><td>0000b - Active low 0001b - Active high</td></tr><tr><td>LPSPI_5</td><td>0000b - Active low 0001b - Active high</td></tr></table>
7-5 —	Reserved
4 PARTIAL	Partial Enable Specifies whether LPSPI, when in Slave mode, stores a partial received word in the receive FIFO, or discards it, when PCS deasserts. See Partial received word for more information.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Discard 1b - Store
3 NOSTALL	No Stall Disables a normal operating feature that causes LPSPI, when in Master mode, to stall transfers when the transmit FIFO is empty or when the receive FIFO is full. This feature prevents transmit FIFO underruns and receive FIFO overruns. Writing 1 to this field disables this functionality. 0b - Disable 1b - Enable
2 AUTOPCS	Automatic PCS Enables automatic PCS generation. For correct operation in Slave mode, LPSPI requires the PCS signal to deassert between frames. Writing 1 to this field generates an internal PCS signal at the end of each transfer word when TCR[CPHA] = 1. When this field is 1, SCK must remain idle for at least four LPSPI functional clock cycles, divided by the prescaler (see TCR[PRESCALE]) selected between each word to ensure correct operation. This field is ignored in Master mode. 0b - Disable 1b - Enable
1 SAMPLE	Sample Point Specifies the SCK clock edge on which LPSPI, when in Master mode, samples input data. Writing 1 to this field causes LPSPI to sample input data on a delayed loopback SCK clock edge, which improves the setup time when sampling data (see Clock loopback). In this configuration, the input data setup time in Master mode is equal to the input data setup time in Slave mode. In Slave mode, this field is ignored. **NOTE** When SAMPLE = 1, both the input and output buffers must be enabled for the SCK pin. 0b - SCK edge 1b - Delayed SCK edge
0 MASTER	Master Mode Specifies the LPSPI operating mode, Master or Slave. This field directly controls the direction of the SCK and PCS pins. 0b - Slave mode 1b - Master mode

73.6.1.10 Data Match 0 (DMR0)

Offset

Register	Offset
DMR0	30h

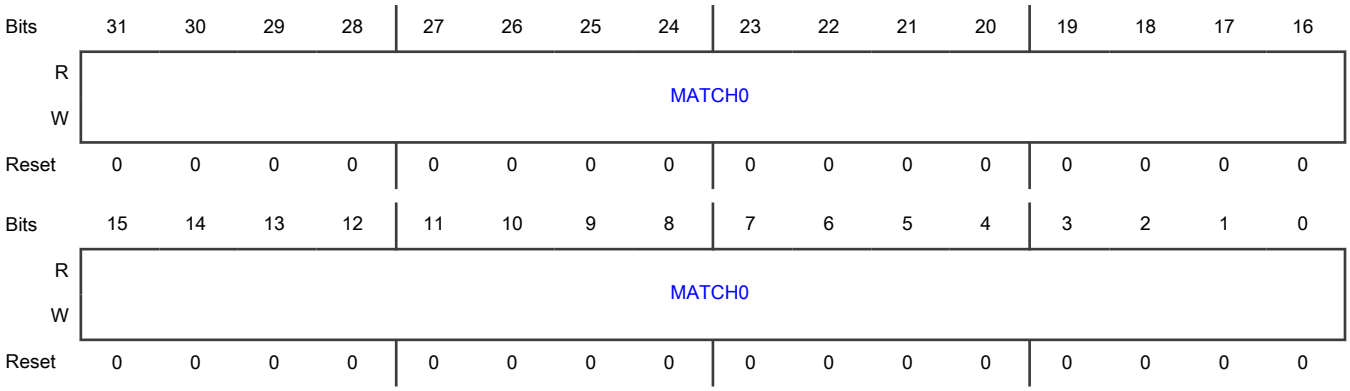
Function

Specifies the match data to be used when data matching is enabled. See CFGR1[MATCFG] for the received data matching options.

NOTE

Do not change the value in this register when CFGR1[MATCFG] > 0.

Diagram



Fields

Field	Function
31-0 MATCH0	Match 0 Value Specifies the MATCH0 value to be compared against received data.

73.6.1.11 Data Match 1 (DMR1)

Offset

Register	Offset
DMR1	34h

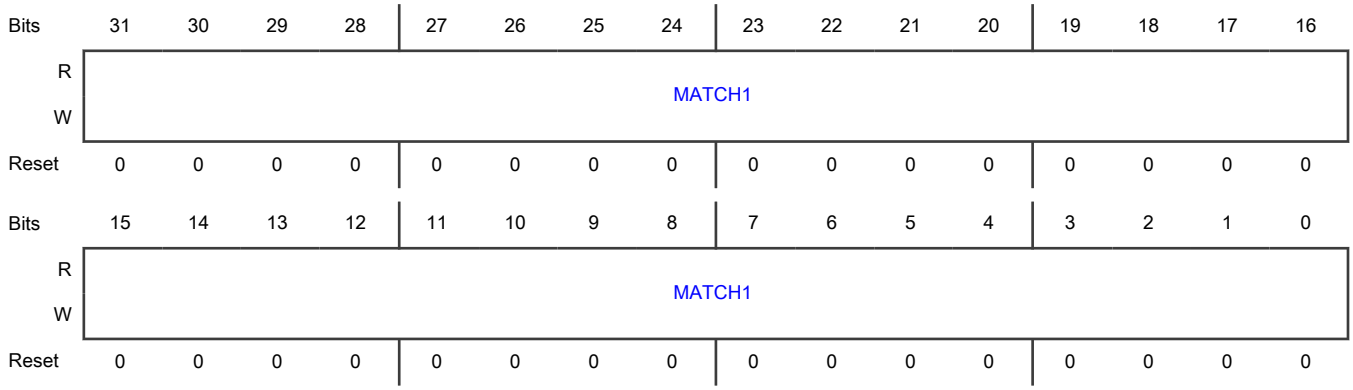
Function

Specifies the match data to be used when data matching is enabled. See CFGR1[MATCFG] for the received data matching options.

NOTE

Do not change the value in this register while CFGR1[MATCFG] > 0.

Diagram



Fields

Field	Function
31-0 MATCH1	Match 1 Value Specifies the MATCH1 value to be compared against received data.

73.6.1.12 Clock Configuration (CCR)

Offset

Register	Offset
CCR	40h

Function

Contains clock configuration fields that are used only in Master mode; you can only change them when LPSPI is disabled (CR[MEN] = 0).

Warning

Writing a 32-bit value to this register overwrites Clock Configuration 1 (CCR1); DBT and SCKDIV always read 0.

To avoid overwriting CCR1, do one of the following:

- Write to all four fields in Clock Configuration (CCR) simultaneously and only once in a 32-bit data.
- Modify the values of CCR[SCKPCS] and/or CCR[PCSSCK]; write only these two upper bytes in a 16-bit data or one of them in an 8-bit data.
- Modify CCR1[PCSPCS] and CCR1[SCKSCK] only or CCR1[SCKSET] and CCR1[SCKHLD] only, write respectively to CCR[DBT] or CCR[SCKDIV] in 8-bit data.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	SCKPCS								PCSSCK							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0								0							
W	DBT								SCKDIV							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 SCKPCS	SCK-to-PCS Delay Configures SCK-to-PCS delay. In Master mode, this field helps you configure the delay from the last SCK edge to PCS negation: • The delay is equal to (SCKPCS + 1) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The minimum delay is one cycle. See Figure 511 for more information.
23-16 PCSSCK	PCS-to-SCK Delay Configures PCS-to-SCK delay. In Master mode, this field helps you configure the delay from PCS assertion to the first SCK edge: • The delay is equal to (PCSSCK + 1) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The minimum delay is one cycle. See Figure 511 for more information.
15-8 DBT	Delay Between Transfers Configures the delay between transfers. Writing to this field updates the contents of CCR1[PCSPCS] and CCR1[SCKSCK].
7-0 SCKDIV	SCK Divider Updates the contents of CCR1[SCKSET] and CCR1[SCKHLD]. Baud rate = function clock ÷ (2^PRESCALE × (SCKSET + SCKHLD + 2))

73.6.1.13 Clock Configuration 1 (CCR1)

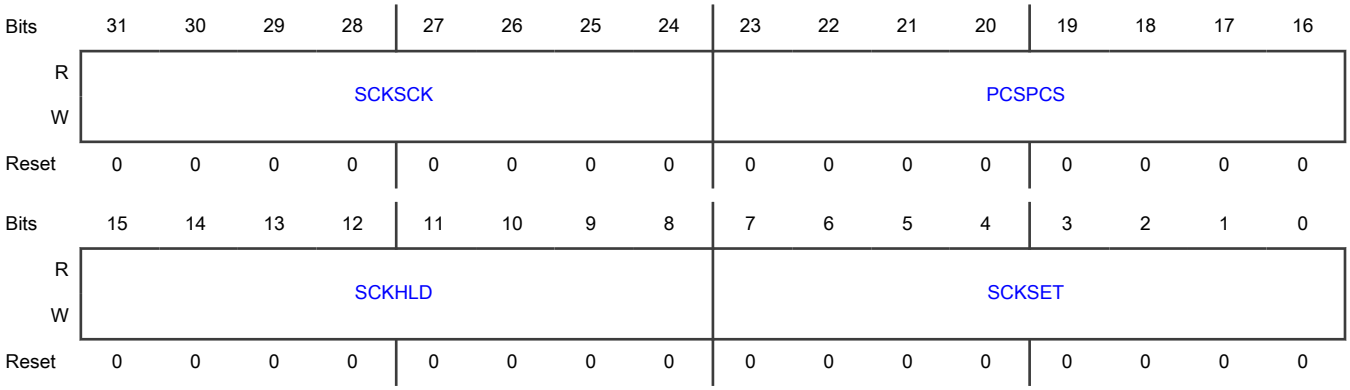
Offset

Register	Offset
CCR1	44h

Function

Contains clock configuration fields, which are used only in Master mode. You can change them only when LPSPI is disabled (CR[MEN] = 0).

Diagram



Fields

Field	Function
31-24 SCKSCK	SCK Inter-Frame Delay Configures SCK inter-frame delay in Master mode: • This field helps you configure the delay from the last SCK pulse of a frame and the first SCK pulse of the following frame, in a continuous transfer. • The delay is equal to (SCKSCK + 1) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The minimum delay is one cycle. **NOTE** For backward compatibility, writing to CCR[DBT] updates this field with the value written.
23-16 PCSPCS	PCS to PCS Delay Configures PCS to PCS delay in Master mode: • This field helps you configure the delay from the PCS negation to the next PCS assertion. • The delay is equal to (PCSPCS + PCSPCS + 2) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• The minimum delay is two cycles. • Half of the delay (PCSPCS + 1) occurs before PCS assertion and the other half of the delay (PCSPCS + 1) occurs after PCS negation. If the command word is updated between two transfers, then the command word is updated halfway between the PCS negation of the last transfer and PCS assertion of the next transfer. • The command word specifies which PCS signal is used, the polarity and phase of the SCK signal, and the selected prescaler. **NOTE** For backward compatibility, writing to CCR[DBT] updates this field with (DBT÷2) rounded up.
15-8 SCKHLD	SCK Hold Configures the hold phase of the SCK pin in Master mode: • The hold phase is the delay between the SCK edge that samples the receive data and the SCK edge that drives the transmit data. • It is the SCK low period when CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. It is the SCK high period when CPHA = 0, CPOL = 0 and CPHA = 1, CPOL = 1. • The SCK hold phase delay is equal to (SCKHLD + 1) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The minimum delay is one cycle. • The SCK period is equal to (SCKSET + SCKHLD + 2) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The SCK duty cycle is based on the difference between SCKSET and SCKHLD. You must configure both these fields to the same value for a 50/50 duty cycle. See Figure 511 for more information. **NOTE** For backward compatibility, writing to CCR[SCKDIV] updates this field with (SCKDIV ÷ 2) rounded down.
7-0 SCKSET	SCK Setup Configures the setup phase of the SCK pin in Master mode: • The setup phase is the delay between the SCK edge that drives the transmit data and the SCK edge that samples the receive data. • It is the SCK high period when CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. It is the SCK low period when CPHA = 0 and CPOL = 0, or CPHA = 1 and CPOL = 1. • The SCK setup phase delay is equal to (SCKSET + 1) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The minimum delay is one cycle.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• The SCK period is equal to (SCKSET + SCKHLD + 2) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The SCK duty cycle is based on the difference between SCKSET and SCKHLD. You must configure both these fields to the same value for a 50/50 duty cycle. See Figure 511 for more information. **NOTE** For backward compatibility, writing to CCR[SCKDIV] updates this field with (SCKDIV ÷ 2) rounded up.

73.6.1.14 FIFO Control (FCR)

Offset

Register	Offset
FCR	58h

Function

Contains the receive FIFO and transmit FIFO watermark values.

Diagram

23-19 —	Reserved
18-16 RXCOUNT	Receive FIFO Count Indicates the number of words currently stored in the receive FIFO.
15-8 —	Reserved
7-3 —	Reserved
2-0 TXCOUNT	Transmit FIFO Count Indicates the number of words currently stored in the transmit FIFO.

73.6.1.16 Transmit Command (TCR)

Offset

Register	Offset
TCR	60h

Function

Pushes the data into the transmit FIFO, in the same order as written.

When you write to either this register or to Transmit Data (TDR), each write pushes data into the transmit FIFO. You must write to this register only using 32-bit writes, which are tagged and cause the command register to update; after that the entry reaches the top of the FIFO and LPSPI is enabled. This allows changes to the command word and the transmit data itself to be interleaved. That is, writes to the two registers can be interleaved (write command word, then data word, then command word, and so on). Changing the command word causes all subsequent SPI bus transfers to be performed using the new command word:

- In Master mode, writing a new command word does not initiate a new transfer, unless TXMSK is 1. Transfers are initiated by transmit data in the transmit FIFO, or by a new command word (with TXMSK = 1). Hardware writes 0 to TXMSK when PCS deasserts.
- In Master mode, if the command word is changed before an existing frame has completed, then the existing frame terminates and the command word updates. The command word can be changed during a continuous transfer, if CONTC of the new command word is 1 and the command word is written on a frame size boundary.
- In Slave mode, the command word must be changed only when LPSPI is idle and there is no SPI bus transfer.

Avoid resetting the transmit FIFO after writing to this register; wait for the command register to update from the FIFO first.

Avoid register reading problems: Reading this register returns the current state of the register. Reading this register at the same time that it is loaded from the transmit FIFO can return an incorrect register value. It is recommended to:

- Read this register when the transmit FIFO is empty.
- Read this register more than once and then compare the returned values.

23 LSBF	LSB First Indicates whether data is transferred with MSB first or LSB first. 0b - MSB first 1b - LSB first
22	Byte Swap

Table continues on the next page...

Table continued from the previous page...

Field	Function
BYSW	Swaps the contents of [31:24] with [7:0] and [23:16] with [15:8] for each transmit data word read from the FIFO and for each received data word stored to the FIFO (or compared with match registers). 0b - Disable byte swap 1b - Enable byte swap
21 CONT	Continuous Transfer Enables continuous transfer: • In Master mode, this field keeps PCS asserted at the end of the frame size until a command word is received that starts a new frame. • In Slave mode, when this field is enabled, LPSPI only transmits the first FRAMESZ bits, after which LPSPI transmits received data (assuming a 32-bit shift register) until the next PCS negation. 0b - Disable 1b - Enable
20 CONTC	Continuing Command Enables the command word to be changed within a continuous transfer in Master mode: • The initial command word must enable continuous transfer (CONT = 1). • The continuing command must have CONTC = 1. • The continuing command word must be loaded on a frame size boundary. For example, if the continuous transfer has a frame size of 64 bits, then a continuing command word must be loaded on a 64-bit boundary. In Slave mode, this field modifies the internal RXMSK and TXMSK configuration after the first FRAMESZ bits and until PCS negation: • Receive data is discarded after the first FRAMESZ bits. If CONT is also 1, this does not block the transmission of received data. • Transmit data is not masked after the first FRAMESZ bits. This allows the first FRAMESZ bits to be received and a response transmitted. 0b - Command word for start of new transfer 1b - Command word for continuing transfer
19 RXMSK	Receive Data Mask Masks receive data (receive data is not stored in the receive FIFO). 0b - Normal transfer 1b - Mask receive data
18 TXMSK	Transmit Data Mask Masks transmit data (no data is loaded from the transmit FIFO and the output pin is 3-stated). In Master mode, TXMSK initiates a new transfer that cannot be aborted by another command word. TXMSK automatically transitions to 0 at the end of the transfer.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Normal transfer 1b - Mask transmit data
17-16 WIDTH	Transfer Width Configures serial (1-bit) or parallel transfers. For half-duplex parallel transfers, either RXMSK or TXMSK must be 1. **NOTE** The descriptions of the field settings vary by module instance.

Instance	Field value and description
LPSPI_0	00b - 1-bit transfer 01b - 2-bit transfer 10b - 4-bit transfer 11b - 8-bit transfer
LPSPI_1	00b - 1-bit transfer 01b - 2-bit transfer 10b - 4-bit transfer 11b - Reserved
LPSPI_2	00b - 1-bit transfer 01b - 2-bit transfer 10b - 4-bit transfer 11b - Reserved
LPSPI_3	00b - 1-bit transfer 01b - 2-bit transfer 10b - 4-bit transfer 11b - Reserved
LPSPI_4	00b - 1-bit transfer 01b - 2-bit transfer 10b - 4-bit transfer 11b - Reserved
LPSPI_5	00b - 1-bit transfer 01b - 2-bit transfer

Table continues on the next page...

Table continued from the previous page...

Field	Function
	<table><tr><th>Instance</th><th>Field value and description</th></tr><tr><td></td><td>10b - 4-bit transfer 11b - Reserved</td></tr></table>
15-12 —	Reserved
11-0 FRAMESZ	Frame Size Configures the frame size in number of bits equal to (FRAMESZ + 1): • The minimum frame size is 8 bits, or 16 bits for an 8-bit transfer. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contains the remainder bits. For example, a 72-bit transfer consists of three words: the first and second words are 32 bits, and the third word is 8 bits.

73.6.1.17 Transmit Data (TDR)

Offset

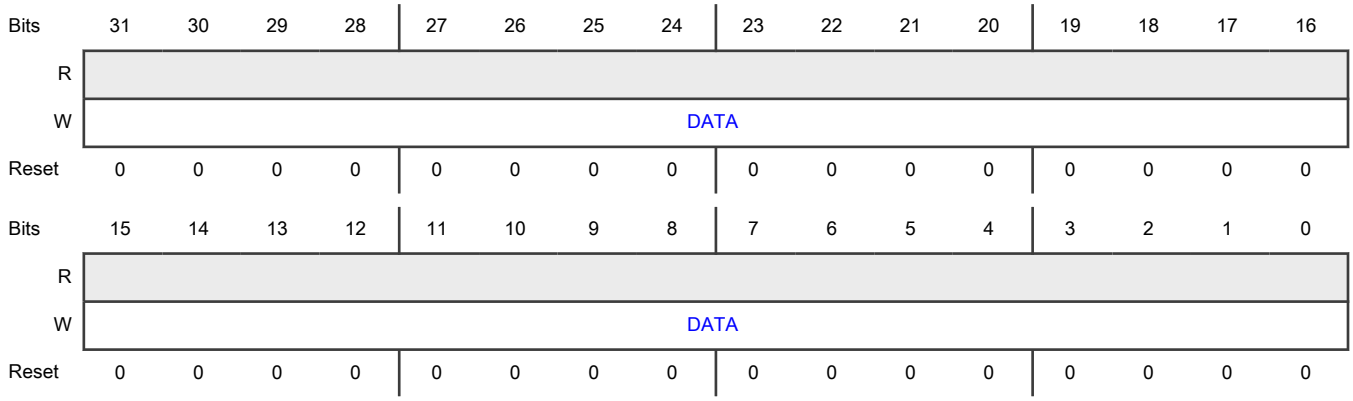
Register	Offset
TDR	64h

Function

Pushes the data into the transmit FIFO, in the same order that the data is written. You can write to this register using 32-, 16-, or 8-bit writes.

When you write to this register or to Transmit Command (TCR), each write pushes data into the FIFO with zero pushed in unwritten bytes.

Diagram



Fields

Field	Function
31-0 DATA	Transmit Data Indicates transmit data. Both 8-bit and 16-bit writes of transmit data zero-extend the data written and push the data into the transmit FIFO. To zero-extend 8-bit and 16-bit writes (to 32 bits) means that the higher order (most significant) empty parts of the 8-bit and 16-bit writes are filled with zeroes.

73.6.1.18 Receive Status (RSR)

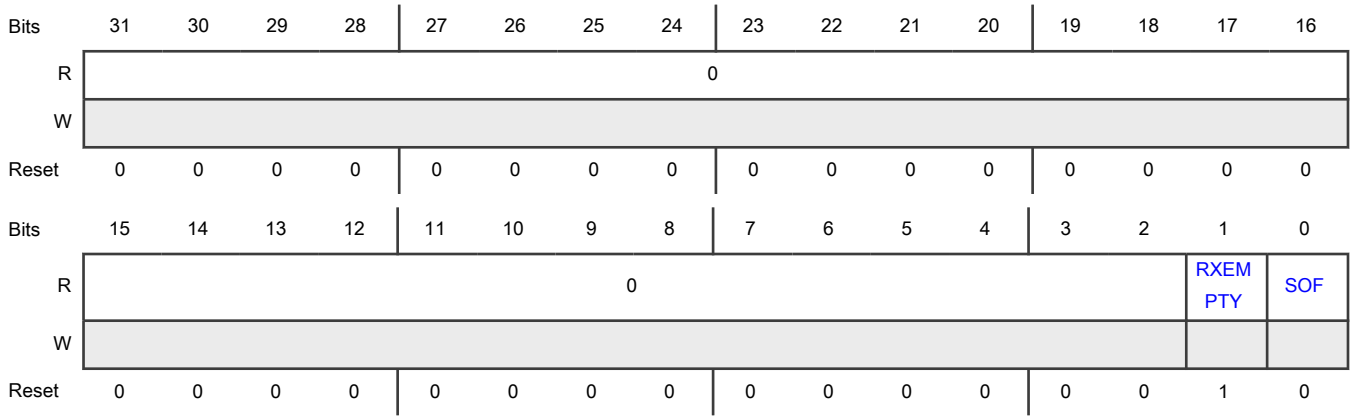
Offset

Register	Offset
RSR	70h

Function

Contains data flow status fields for receive FIFO.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 RXEMPTY	RX FIFO Empty Indicates whether the receive FIFO is empty. 0b - Not empty 1b - Empty
0 SOF	Start of Frame Indicates whether this is the first data word received after PCS assertion. 0b - Subsequent data word 1b - First data word

73.6.1.19 Receive Data (RDR)

Chapter 74
Low Power Inter-Integrated Circuit (LPI2C)

74.1 Chip-specific LPI2C information

74.1.1 LPI2C instances and configuration

This chip has two instances of LPI2C. active="1'd0">[end]

Table 504. LPI2C configuration

Instances	TX FIFO Size	RX FIFO Size	SMBus[1]	Slave Mode Enable
LPI2C_0	4x11 bit	4x8 bit	Yes	Yes
LPI2C_1	4x11 bit	4x8 bit	Yes	Yes

1. System Management Bus

- LPI2C slave mode operation supports up to high speed mode = 3.4MHz (3.4 Mbps data rate; effective data rate reduces according to I2C protocol).
- LPI2C master mode operation supports up to fast Mode = 400KHz (400 kbps data rate; effective data rate reduces according to I2C protocol).
- The LPI2C module includes SMBus (System Management Bus) support and DMA support.
- LPI2C RX FIFO is 8-bit and TX FIFO is 11-bit (8bit data + 3bit command)
- LPI2C supports fast data communication as per I2C standard v3.0.

74.2 Overview

LPI2C supports an efficient interface to an I2C bus as a controller and target:

- Implements logic support for Standard, Fast, Fast+, HS-mode (target only) and Ultra-Fast modes of operation
- Uses little CPU overhead, with DMA offloading of FIFO register accesses

LPI2C also complies with the System Management Bus (SMBus) Specification, version 3. The SMBus is a single-ended simple two-wire bus, which is typically used for low-bandwidth communications.

The Inter-Integrated Circuit (I^2C) serial bus is multi-controller, multi-target, packet-switched, and single-ended, and is often used to attach microcontroller ICs to lower-speed peripheral ICs.

NOTE

Terminology in this chapter has been updated to align with I^2C-bus specification, Rev. 7.0, as shown in Table 505.

Table 505. Updated terms

Updated term	Deprecated term
Controller	Master
Target	Slave

74.2.1 Block diagram

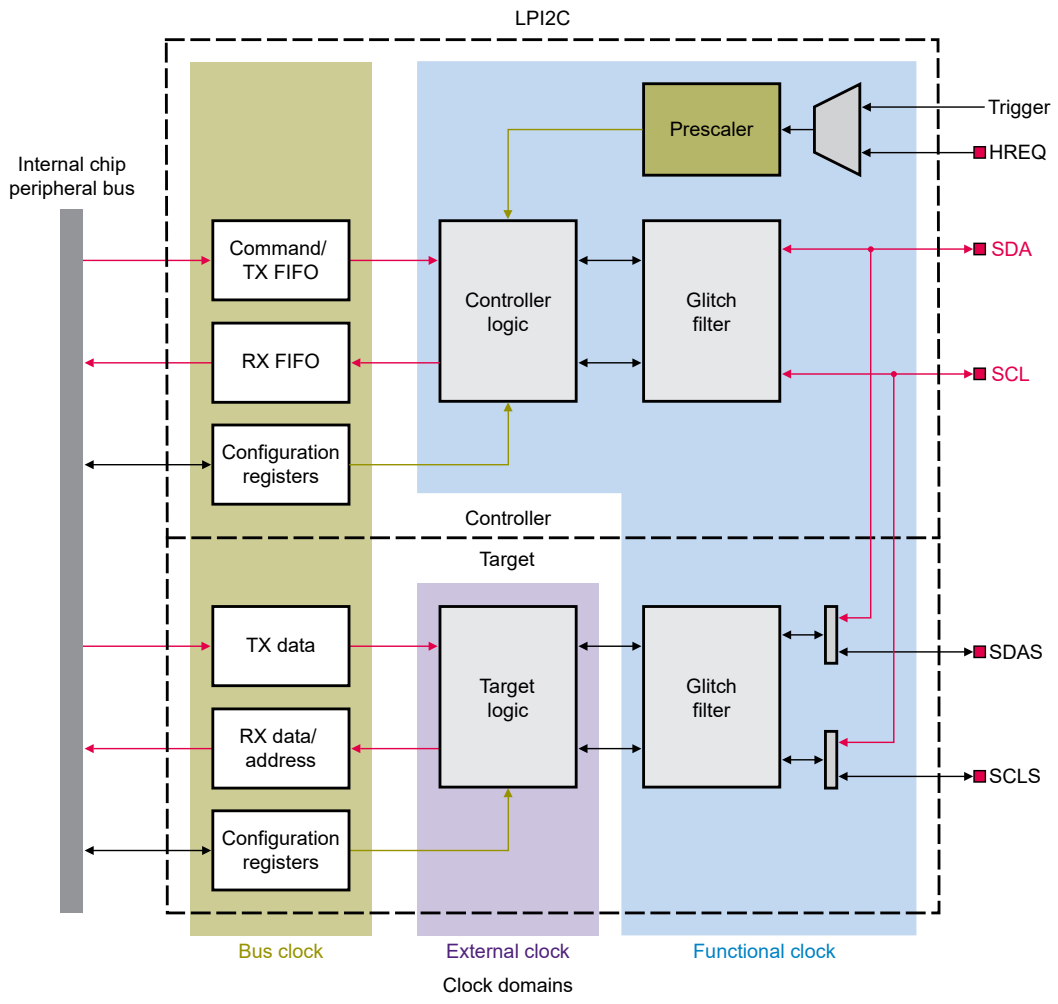

Figure 513. Block diagram

74.2.2 Features

LPI2C supports:

- Standard, Fast, Fast+ and Ultra Fast modes
- HS mode in target mode
- Multicontroller, including synchronization and arbitration, means that any number of controller nodes can be present. Also, controller and target roles can be changed between messages (after a Stop signal is sent).
- Clock stretching. Used on the SCL line, as an I2C flow control mechanism.
- Arbitration for when the system has more than one controller. When used on the SDA line, ensures that there is only one I2C transmitter at a time.
- General call, seven-bit addressing, and ten-bit addressing
- Software reset, Start byte, and device ID (also require software support)

The LPI2C controller supports:

- Command and transmit FIFO of 4 words (8-bit transmit data + 3-bit command)

- Receive FIFO of 4 words (8-bit receive data).
- Command FIFO waiting for an I2C idle bus before initiating a transfer
- Initiation of repeated Start and Stop conditions and one or more controller-receiver transfers by command FIFO
- Stop condition generation from command FIFO, or automatic generation of Stop condition when the transmit FIFO is empty
- Host request input to control the start time of an I2C bus transfer
- Interrupt generation on data match and unwanted data rejection, via flexible receive data match
- Flags and optional interrupt signals at repeated Start condition, Stop condition, loss of arbitration, unexpected NACK, and command word errors
- Configurable bus idle timeout and pin-stuck-low timeout

The LPI2C target supports:

- Separate I2C target registers to minimize software overhead because of controller or target switching
- 7-bit or 10-bit addressing, address range, SMBus alert, and general call address.
- Transmit data register that supports interrupt or DMA requests
- Receive data register that supports interrupt or DMA requests
- Software-controllable ACK or NACK, with optional clock stretching on ACK or NACK field
- Configurable clock stretching, to avoid transmit-FIFO-underrun and receive-FIFO-overrun errors
- Flags and optional interrupt at end of packet, Stop condition, or bit error detection

74.3 Memory map and registers

74.3.1 LPI2C register descriptions

Writing to a read-only register or reading from a write-only register can cause bus errors. This module does not check whether programmed values in the registers are correct; you must ensure that valid programmed values are written to the registers.

74.3.1.1 LPI2C memory map

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Fields

Field	Function
31-26 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
25 BBF	Bus Busy Flag Specifies whether the I2C bus is busy. 0b - Idle 1b - Busy
24 MBF	Controller Busy Flag Specifies whether the I2C controller is busy. 0b - Idle 1b - Busy
23-16 —	Reserved
15 —	Reserved
14 DMF	Data Match Flag Indicates whether the received data matches MDMR[MATCH0] or MDMR[MATCH1] (as configured by MCFGR1[MATCFG]). Received data discarded due to MTDR[CMD] does not cause this flag to set. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Matching data not received 1b - Matching data received When writing 0b - No effect 1b - Clear the flag
13 PLTF	Pin Low Timeout Flag Indicates whether pin low timeout has occurred. Sets when the SCL or SDA input is low for more than the number of PINLOW cycles defined by MCFGR3[PINLOW], even when the LPI2C controller is idle. You must resolve the pin low condition via software. PLTF cannot be cleared as long as the pin low timeout continues. Before LPI2C can initiate a Start condition, you must clear this flag. See MCFGR1[TIMECFG] for the SCL and/or SDA timeout settings. **NOTE** This field behaves differently for register reads and writes. When reading

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Pin low timeout did not occur 1b - Pin low timeout occurred When writing 0b - No effect 1b - Clear the flag
12 FEF	FIFO Error Flag Detects the LPI2C controller's attempt to send or receive data without first generating a (repeated) Start condition. This error can occur when the transmit FIFO underflows when MCFGR1[AUTOSTOP] = 1. When this flag is set, the LPI2C controller sends a Stop condition (if busy). The controller does not initiate a new Start condition until the flag is cleared. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No FIFO error 1b - FIFO error When writing 0b - No effect 1b - Clear the flag
11 ALF	Arbitration Lost Flag Indicates whether arbitration is lost. Either of these conditions sets this flag: • The LPI2C controller transmits a logic 1 and detects a logic 0 on the I2C bus. • The LPI2C controller detects a Start or Stop condition when the LPI2C controller is transmitting data. When ALF is set, the LPI2C controller releases the I2C bus (goes idle), and the LPI2C controller does not initiate a new Start condition until the ALF is cleared. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Controller did not lose arbitration 1b - Controller lost arbitration When writing 0b - No effect 1b - Clear the flag
10	NACK Detect Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
NDF	Indicates whether an unexpected NACK has been detected. This flag is set when the LPI2C controller detects a NACK it was not expecting when transmitting an address or data. When set, the controller does not initiate a new Start condition until this flag is cleared. If a NACK is expected for a given address (as configured by the command word), this flag is set if a NACK is not generated. When this flag is set, the LPI2C controller automatically transmits a Stop condition if MCFGR1[AUTOSTOP] = 1, or if the transmit FIFO is not empty. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No unexpected NACK detected 1b - Unexpected NACK detected When writing 0b - No effect 1b - Clear the flag
9 SDF	Stop Detect Flag Indicates whether the LPI2C controller has generated a Stop condition. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No Stop condition generated 1b - Stop condition generated When writing 0b - No effect 1b - Clear the flag
8 EPF	End Packet Flag Indicates whether the LPI2C controller has generated a repeated Start condition or a Stop condition. When the controller first generates a Start condition, this flag is not set. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No Stop or repeated Start generated 1b - Stop or repeated Start generated When writing

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No effect 1b - Clear the flag
7-2 —	Reserved
1 RDF	Receive Data Flag Indicates whether the receive data is ready. This flag is set when the number of words in the receive FIFO is greater than MFCR[RXWATER]. 0b - Receive data not ready 1b - Receive data ready
0 TDF	Transmit Data Flag Indicates whether transmit data is requested. This flag is set when the number of words in the transmit FIFO is equal or less than MFCR[TXWATER]. 0b - Transmit data not requested 1b - Transmit data requested

74.3.1.6 Controller Interrupt Enable (MIER)

Offset

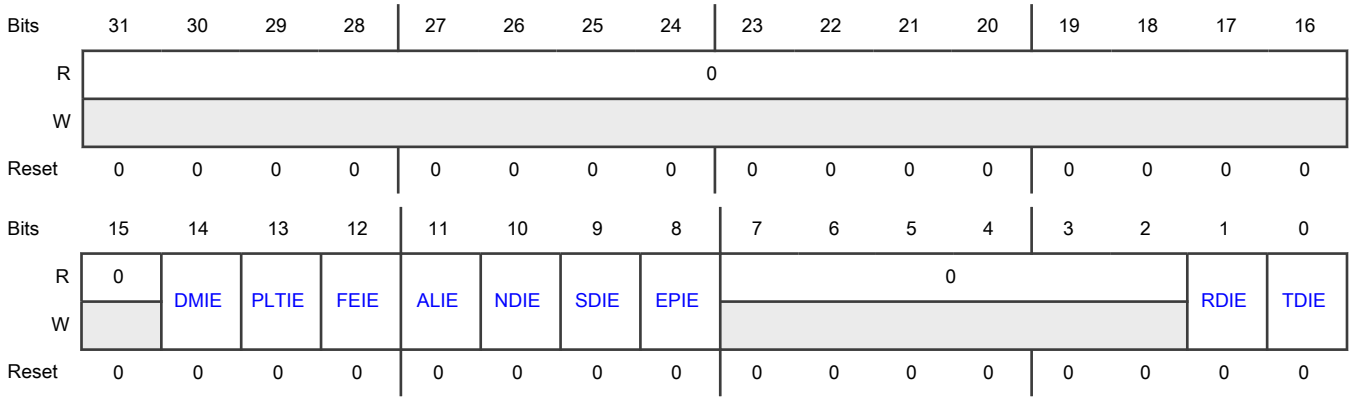
Register	Offset
MIER	18h

Function

Contains enables for:

- Transmit and receive data interrupts
- Start, Stop, and NACK detection interrupts
- DMA interrupts

Diagram



Fields

Field	Function
31-16 —	Reserved
15 —	Reserved
14 DMIE	Data Match Interrupt Enable Enables interrupt for data match. 0b - Disable 1b - Enable
13 PLTIE	Pin Low Timeout Interrupt Enable Enables interrupt for pin-low timeout. 0b - Disable 1b - Enable
12 FEIE	FIFO Error Interrupt Enable Enables interrupt for FIFO error. 0b - Disable 1b - Enable
11 ALIE	Arbitration Lost Interrupt Enable Enables interrupt for arbitration lost. 0b - Disable 1b - Enable
10	NACK Detect Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
NDIE	Enables interrupt for NACK detection. 0b - Disable 1b - Enable
9 SDIE	Stop Detect Interrupt Enable Enables interrupt for Stop detection. 0b - Disable 1b - Enable
8 EPIE	End Packet Interrupt Enable Enables interrupt for end packet. 0b - Disable 1b - Enable
7-2 —	Reserved
1 RDIE	Receive Data Interrupt Enable Enables interrupt for receive data. 0b - Disable 1b - Enable
0 TDIE	Transmit Data Interrupt Enable Enables interrupt for transmit data. 0b - Disable 1b - Enable

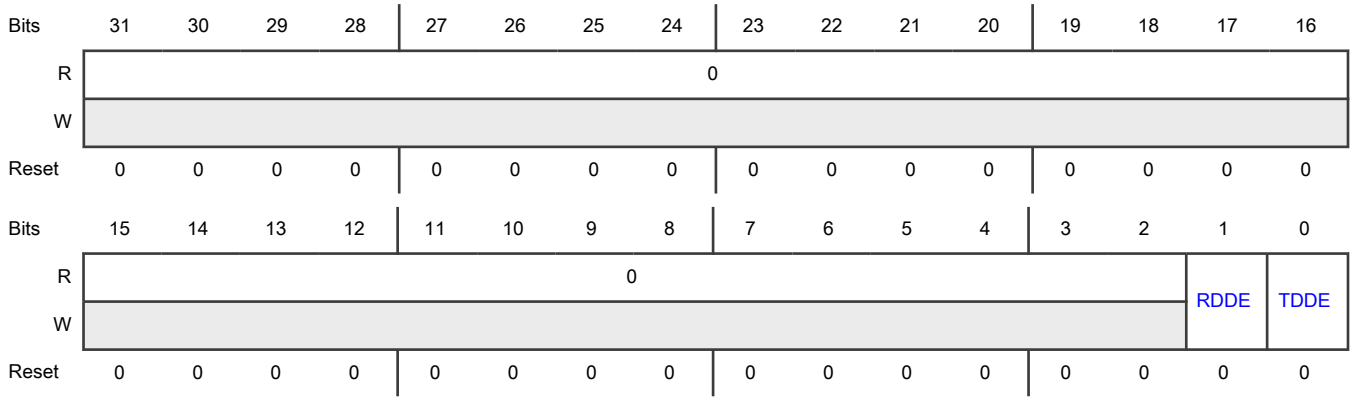
74.3.1.7 Controller DMA Enable (MDER)

Offset

Register	Offset
MDER	1Ch

Function
Contains DMA transmit, request, and receive enables.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 RDDE	Receive Data DMA Enable Enables DMA receive data. 0b - Disable 1b - Enable
0 TDDE	Transmit Data DMA Enable Enables DMA transmit data. 0b - Disable 1b - Enable

74.3.1.8 Controller Configuration 0 (MCFGR0)

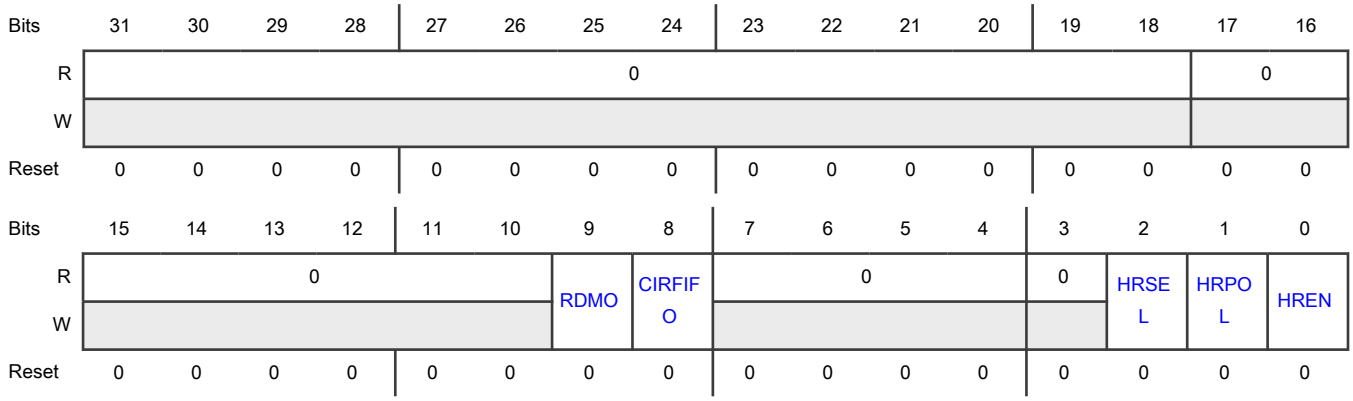
Offset

Register	Offset
MCFGR0	20h

Function

Contains host settings and other receive and transfer settings.

Diagram



Fields

Field	Function
31-18 —	Reserved
17-16 —	Reserved
15-10 —	Reserved
9 RDMO	Receive Data Match Only Determines whether all received data that does not set MSR[DMF] is discarded. After MSR[DMF] is set, the RDMO configuration is ignored. When disabling RDMO, write 0 to this field before writing 0 to MSR[DMF] to ensure that no receive data is lost. 0b - Received data is stored in the receive FIFO 1b - Received data is discarded unless MSR[DMF] is set
8 CIRFIFO	Circular FIFO Enable Enables the transmit FIFO read pointer to be saved to a temporary register. The transmit FIFO empties as normal. After the LPI2C controller is idle and the transmit FIFO is empty, the read pointer value is restored from the temporary register. This setting causes the contents of the transmit FIFO to be cycled through repeatedly. If MCFGR1[AUTOSTOP] is 1, then a Stop condition is sent whenever the transmit FIFO is empty and the read pointer is restored. 0b - Disable 1b - Enable
7-4 —	Reserved
3	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
2 HRSEL	Host Request Select Selects the source of the host request input. When host request is enabled, this field must not change. 0b - Host request input is pin HREQ 1b - Host request input is input trigger
1 HRPOL	Host Request Polarity Configures the polarity of the host request input. When host request is enabled, this field must not change. HRPOL sets the polarity for both the HREQ pin and the input trigger. • When HRPOL=0, the polarity is configured for active low, so host request is asserted if the HREQ pin or input trigger are logic 0. • When HRPOL=1, the polarity is configured for active high, so host request is asserted if the HREQ pin or input trigger are logic 1. 0b - Active low 1b - Active high
0 HREN	Host Request Enable Enables host request. When enabled, the LPI2C controller only initiates a Start condition if the host request input is asserted and the bus is idle. A repeated Start condition is not affected by the host request. 0b - Disable 1b - Enable

74.3.1.9 Controller Configuration 1 (MCFGR1)

Offset

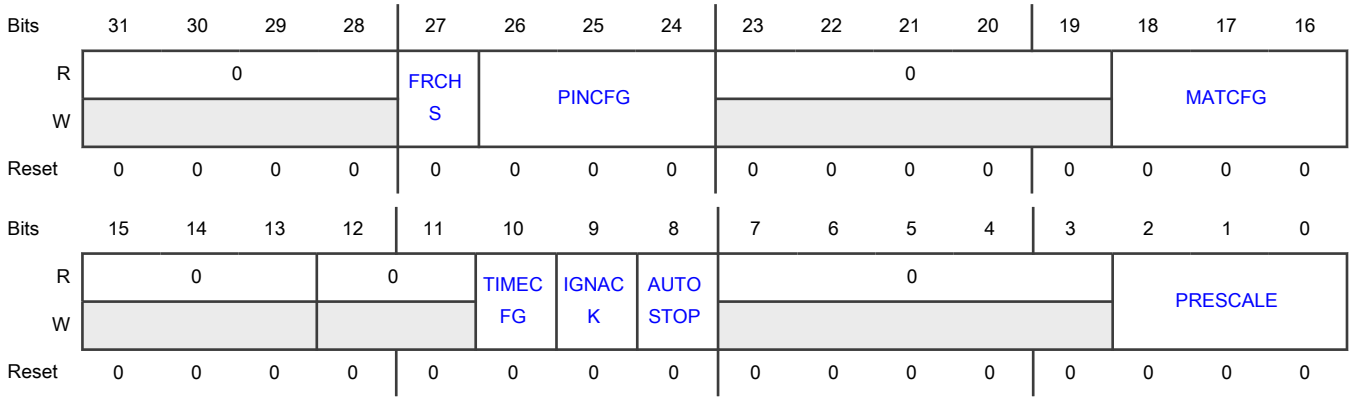
Register	Offset
MCFGR1	24h

Function

Contains controls for pin configuration, clock prescaler, and various other control settings.

Write to this register only when the I2C controller is disabled.

Diagram



Fields

Field	Function
31-28 —	Reserved
27 FRCHS	Force HS Mode Forces the LPI2C pin state into HS mode. Writing 1 to this field does not impact the digital filter configuration or digital timing parameters. **NOTE** This field is not supported in every instance. The following table includes only supported registers. 0b - No effect 1b - LPI2C pin state forced into HS mode
26-24 PINCFG	Pin Configuration Configures the pin mode for LPI2C. 000b - Two-pin open drain mode. SCL/SDA pins: Bidirectional open drain for controller and target. SCLS/SDAS pins: Not used. 001b - Two-pin output only mode (Ultra-Fast mode). SCL/SDA pins: Output-only (Ultra-Fast mode) open drain for controller and target. SCLS/SDAS pins: Not used. 010b - Two-pin push-pull mode. SCL/SDA pins: Bidirectional push-pull for controller and target. SCLS/SDAS pins: Not used. 011b - Four-pin push-pull mode. SCL/SDA pins: Input only for controller and target. SCLS/SDAS pins: Output-only push-pull for controller and target.

Instance	Field supported in	Field not supported in
LPI2C_0	—	MCFGR1
LPI2C_1	MCFGR1	—

Table continues on the next page...

Table continued from the previous page...

Field	Function
	100b - Two-pin open-drain mode with separate LPI2C target. SCL/SDA pins: Bidirectional open drain for controller. SCLS/SDAS pins: Bidirectional open drain for target. 101b - Two-pin output only mode (Ultra-Fast mode) with separate LPI2C target. SCL/SDA pins: Output-only (Ultra-Fast mode) open drain for controller. SCLS/SDAS pins: Output-only open drain for target. 110b - Two-pin push-pull mode with separate LPI2C target. SCL/SDA pins: Bidirectional push-pull for controller. SCLS/SDAS pins: Bidirectional push-pull for target. 111b - Four-pin push-pull mode (inverted outputs). SCL/SDA pins: Input only for controller and target. SCLS/SDAS pins: Inverted output-only push-pull for controller and target.
23-19 —	Reserved
18-16 MATCFG	Match Configuration Configures the condition that sets MSR[DMF]. See Controller Data Match (MDMR). 000b - Match is disabled 001b - Reserved 010b - Match is enabled: first data word equals MDMR[MATCH0] OR MDMR[MATCH1] 011b - Match is enabled: any data word equals MDMR[MATCH0] OR MDMR[MATCH1] 100b - Match is enabled: (first data word equals MDMR[MATCH0]) AND (second data word equals MDMR[MATCH1) 101b - Match is enabled: (any data word equals MDMR[MATCH0]) AND (next data word equals MDMR[MATCH1) 110b - Match is enabled: (first data word AND MDMR[MATCH1]) equals (MDMR[MATCH0] AND MDMR[MATCH1]) 111b - Match is enabled: (any data word AND MDMR[MATCH1]) equals (MDMR[MATCH0] AND MDMR[MATCH1])
15-13 —	Reserved
12-11 —	Reserved
10 TIMECFG	Timeout Configuration Configures which signals must be low for longer than the configured timeout to set MSR[PLTF]. When this field is 0, MSR[PLTF] is set when SCL is low for longer than the configured timeout. 0b - SCL 1b - SCL or SDA

Table continues on the next page...

Table continued from the previous page...

Field	Function
9 IGNACK	Ignore NACK Determines whether the LPI2C controller ignores a received NACK and treats it as an ACK. This field must be 1 in Ultra-Fast mode. 0b - No effect 1b - Treat a received NACK as an ACK
8 AUTOSTOP	Automatic Stop Generation Determines whether a Stop condition is generated when the LPI2C controller is busy and the transmit FIFO is empty. A Stop condition can also be generated using a transmit FIFO command. When this field is 1, a Stop condition is automatically generated when the transmit FIFO is empty and the LPI2C controller is busy. 0b - No effect 1b - Stop automatically generated
7-3 —	Reserved
2-0 PRESCALE	Prescaler Configures the clock prescaler used for all LPI2C controller logic except the digital glitch filters. 000b - Divide by 1 001b - Divide by 2 010b - Divide by 4 011b - Divide by 8 100b - Divide by 16 101b - Divide by 32 110b - Divide by 64 111b - Divide by 128

74.3.1.10 Controller Configuration 2 (MCFGR2)

Offset

Register	Offset
MCFGR2	28h

Function

Contains the configuration for the bus idle timeout and glitch filters for SDA and SCL.

Write to this register only when the I2C controller is disabled.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-28 —	Reserved
27-24 FILTSDA	Glitch Filter SDA Configures the I2C controller digital glitch filters for the SDA input. The latency through the glitch filter is equal to the number of cycles defined by this field. The value of this field must be less than the minimum SCL low or high period. Glitches equal to or less than the number of cycles defined by this field are filtered out and ignored. Writing 0 to this field disables the glitch filter. MCFGR1[PRESCALE] does not affect the glitch filter cycle count. It is automatically bypassed in HS mode.
23-20 —	Reserved
19-16 FILTSCL	Glitch Filter SCL Configures the I2C controller digital glitch filters for SCL input. The latency through the glitch filter is equal to the number of cycles defined by this field. The value of this field must be less than the minimum SCL low or high period. Glitches equal to or less than the number of cycles defined by this field are filtered out and ignored. These cycles are based on the functional clock. Writing 0 to this field disables the glitch filter. MCFGR1[PRESCALE] does not affect the glitch filter cycle count. It is automatically bypassed in HS mode.
15-12 —	Reserved
11-0 BUSIDLE	Bus Idle Timeout Configures the bus idle timeout period, in clock cycles.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If both SCL and SDA are high for longer than the number of cycles defined by this field, the I2C bus is assumed to be idle and the controller can generate a Start condition. Writing 0 to this field disables the bus idle timeout.

74.3.1.11 Controller Configuration 3 (MCFGR3)

Offset

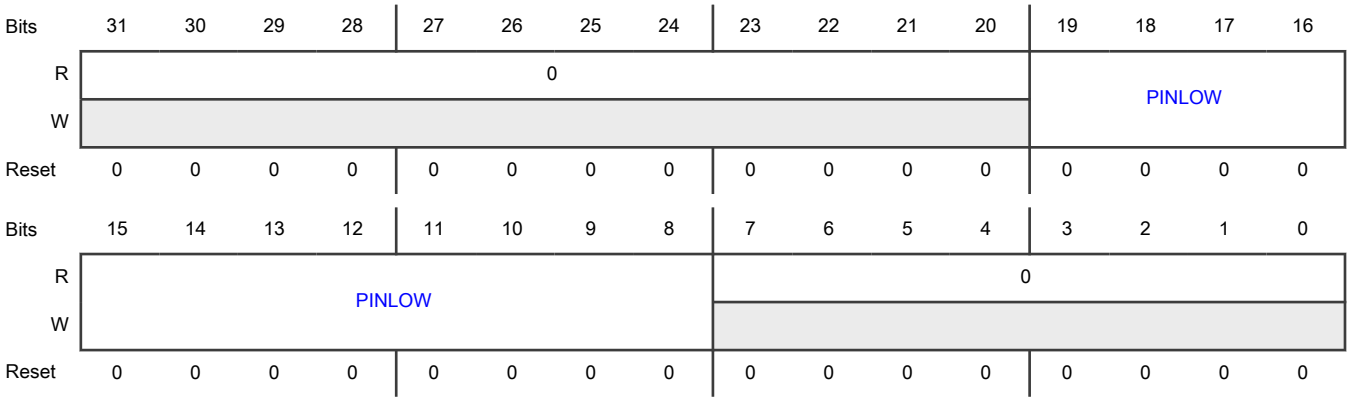
Register	Offset
MCFGR3	2Ch

Function

Configures the threshold value for the pin low timeout flag.

Write to this register only when the I2C controller is disabled.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-8 PINLOW	Pin Low Timeout Configures the threshold value, in clock cycles, that sets MSR[PLTF]. If SCL or SDA (selected by MCFGR1[TIMECFG]) is low for longer than (PINLOW × 256) cycles, MSR[PLTF] is set. When this field is 0, the pin low timeout feature is disabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-0 —	Reserved

74.3.1.12 Controller Data Match (MDMR)

Offset

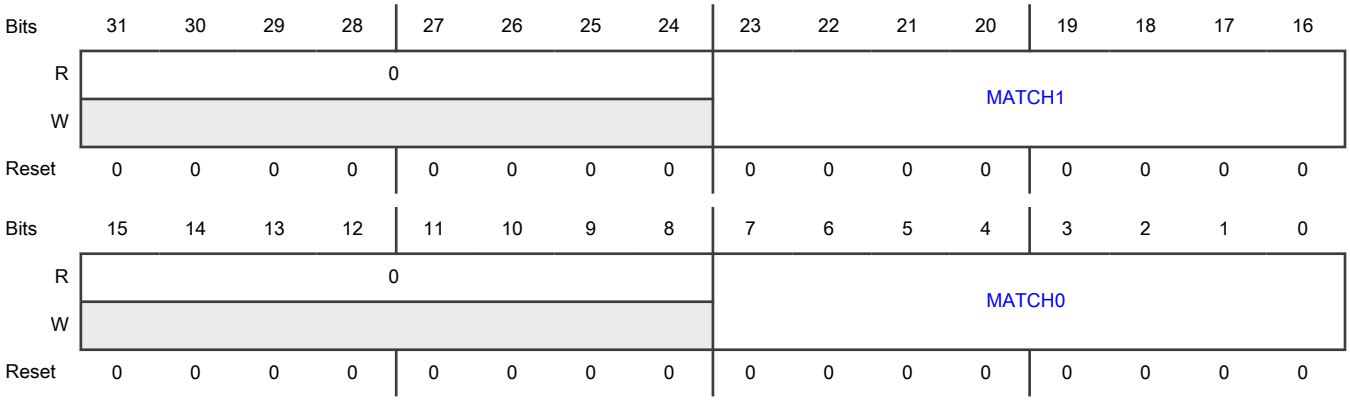
Register	Offset
MDMR	40h

Function

Contains data match values.

Write to this register only when the I2C controller is disabled or idle.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 MATCH1	Match 1 Value Specifies match 1 value that is compared to the received data when receive data match is enabled.
15-8 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-0 MATCH0	Match 0 Value Specifies match 0 value that is compared to the received data when receive data match is enabled.

74.3.1.13 Controller Clock Configuration 0 (MCCR0)

Offset

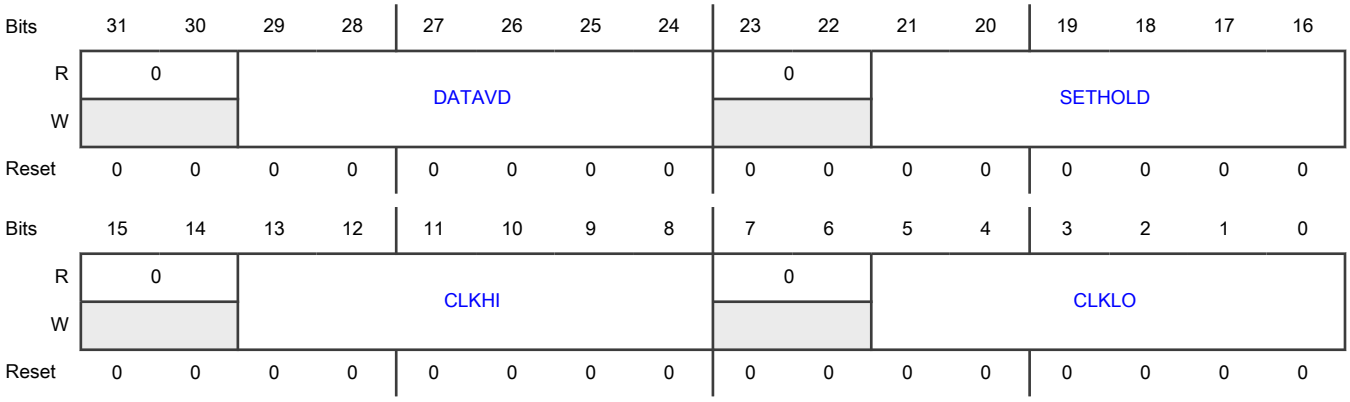
Register	Offset
MCCR0	48h

Function

Configures various clock controls.

You cannot make changes to this register when the I2C controller is enabled and is used for standard, fast, fast-mode plus, and ultra-fast transfers.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-24 DATAVD	Data Valid Delay Specifies the minimum number of cycles (minus one) used as the data hold time for SDA. This value must be less than the minimum SCL low period.
23-22	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
21-16 SETHOLD	Setup Hold Delay Specifies the minimum number of cycles (minus one) used by the controller for these conditions: • Hold time for a Start • Setup and hold time for a repeated Start • Setup time for a Stop The setup time is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.
15-14 —	Reserved
13-8 CLKHI	Clock High Period Specifies the minimum number of cycles (minus one) that the controller drives the SCL clock high. The SCL high time is extended by the time needed to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.
7-6 —	Reserved
5-0 CLKLO	Clock Low Period Specifies the minimum number of cycles (minus one) that the controller drives the SCL clock low. This value is also used for the minimum bus free time between a Stop and a Start condition. This period is extended by the time needed to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.

74.3.1.14 Controller Clock Configuration 1 (MCCR1)

Offset

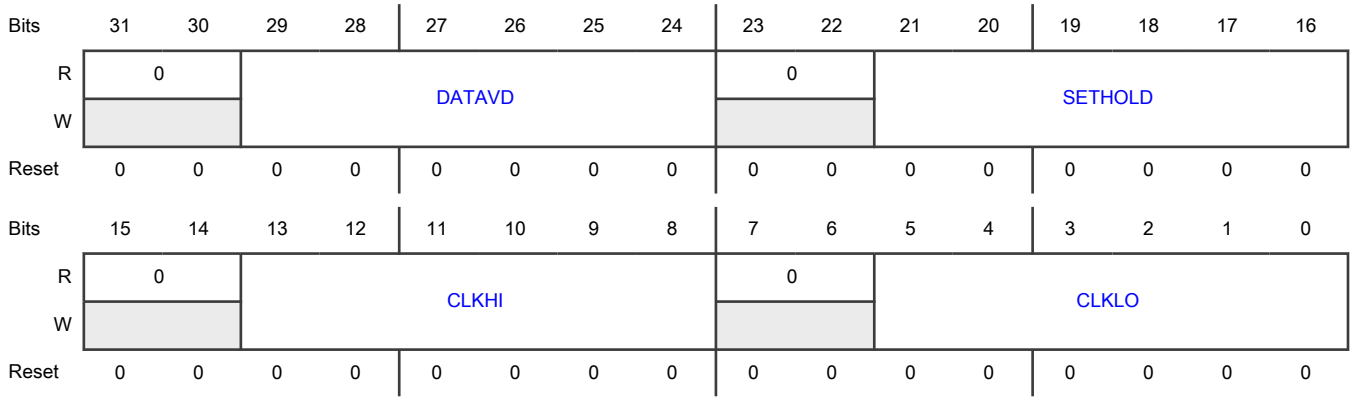
Register	Offset
MCCR1	50h

Function

Configures various clock controls.

You cannot makes changes to this register when the I2C controller is enabled and is used for HS mode transfers. The separate clock configuration for HS mode allows arbitration to take place in Fast mode (with timing configured by Controller Clock Configuration 0 (MCCR0)), before switching to HS mode (with timing configured by MCCR1).

Diagram



Fields

Field	Function
31-26 —	Reserved
25 BBF	Bus Busy Flag Indicates whether an I2C bus is idle or busy. 0b - Idle 1b - Busy
24 SBF	Target Busy Flag Indicates whether an I2C target is idle or busy. 0b - Idle

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Busy
23-16 —	Reserved
15 SARF	SMBus Alert Response Flag Indicates whether an SMBus alert response has been detected. You can clear this flag by reading Target Address Status (SASR). This flag cannot generate an asynchronous wakeup. 0b - Disabled or not detected 1b - Enabled and detected
14 GCF	General Call Flag Indicates whether a target has detected the general call address. You can clear this flag by reading Target Address Status (SASR). This flag cannot generate an asynchronous wakeup. 0b - General call address disabled or not detected 1b - General call address detected
13 AM1F	Address Match 1 Flag Indicates whether the received address matches the value in ADDR1, or it falls within the ADDR0 to ADDR1 range as configured by SCFGR1[ADDRCFG]. This flag is cleared by reading Target Address Status (SASR). This flag cannot generate an asynchronous wakeup. 0b - Matching address not received 1b - Matching address received
12 AM0F	Address Match 0 Flag Indicates whether the received address matches the ADDR0 field, as configured by SCFGR1[ADDRCFG]. This flag is cleared by reading Target Address Status (SASR). This flag cannot generate an asynchronous wakeup. 0b - ADDR0 matching address not received 1b - ADDR0 matching address received
11 FEF	FIFO Error Flag Indicates whether there is a FIFO error. This flag can only be set when clock stretching is disabled. **NOTE** This field behaves differently for register reads and writes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When reading 0b - No FIFO error 1b - FIFO error When writing 0b - No effect 1b - Clear the flag
10 BEF	Bit Error Flag Indicates whether the LPI2C target has transmitted a logic 1 and detects a logic 0 on the I2C bus. The target ignores the rest of the transfer until the next (repeated) Start condition. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No bit error occurred 1b - Bit error occurred When writing 0b - No effect 1b - Clear the flag
9 SDF	Stop Detect Flag Indicates whether the LPI2C target detects a Stop condition, and if the LPI2C target matched the last address byte. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No Stop detected 1b - Stop detected When writing 0b - No effect 1b - Clear the flag
8 RSF	Repeated Start Flag Indicates whether the LPI2C target detects a repeated Start condition and if the LPI2C target matched the last address byte. This flag is not set when the target first detects a Start condition. **NOTE** This field behaves differently for register reads and writes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When reading 0b - No repeated Start detected 1b - Repeated Start detected When writing 0b - No effect 1b - Clear the flag
7-4 —	Reserved
3 TAF	Transmit ACK Flag Indicates whether a transmit ACK or NACK is required. You can clear this flag by writing to Target Transmit ACK (STAR). 0b - Not required 1b - Required
2 AVF	Address Valid Flag Indicates whether the contents of Target Address Status (SASR) are valid. You can clear this flag by reading SASR. When SCFGR1[RXCFG] = 1, this flag is also cleared by reading Target Receive Data (SRDR). 0b - Not valid 1b - Valid
1 RDF	Receive Data Flag Indicates whether receive data is ready. You can clear this flag by reading Target Receive Data (SRDR). When SCFGR1[RXCFG] = 1, this flag is not cleared when reading Target Receive Data (SRDR) if SSR[AVF] = 1. 0b - Not ready 1b - Ready
0 TDF	Transmit Data Flag Indicates whether transmit data has been requested. This flag is cleared by writing to Target Transmit Data (STDR). When SCFGR1[TXCFG] = 0, if a NACK, repeated Start, or Stop condition is detected, this flag is also cleared. 0b - Transmit data not requested 1b - Transmit data is requested

74.3.1.21 Target Interrupt Enable (SIER)

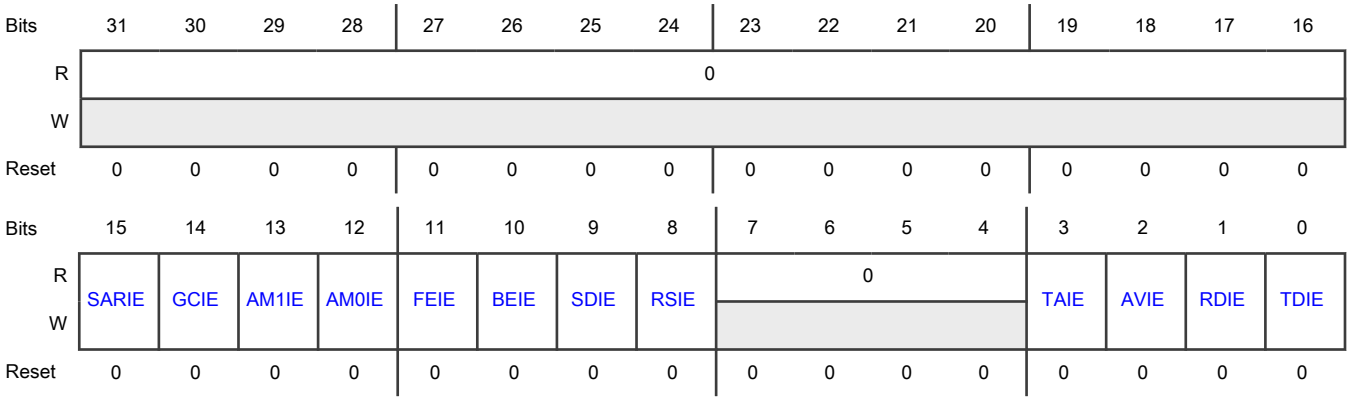
Offset

Register	Offset
SIER	118h

Function

Contains transmit and receive data interrupt enables, start and stop detect interrupt enables, and other target interrupt enables.

Diagram



Fields

Field	Function
31-16 —	Reserved
15 SARIE	SMBus Alert Response Interrupt Enable Enables interrupt for SMBus alert response. 0b - Disable 1b - Enable
14 GCIE	General Call Interrupt Enable Enables interrupt for general call. 0b - Disabled 1b - Enabled

74.3.1.22 Target DMA Enable (SDER)

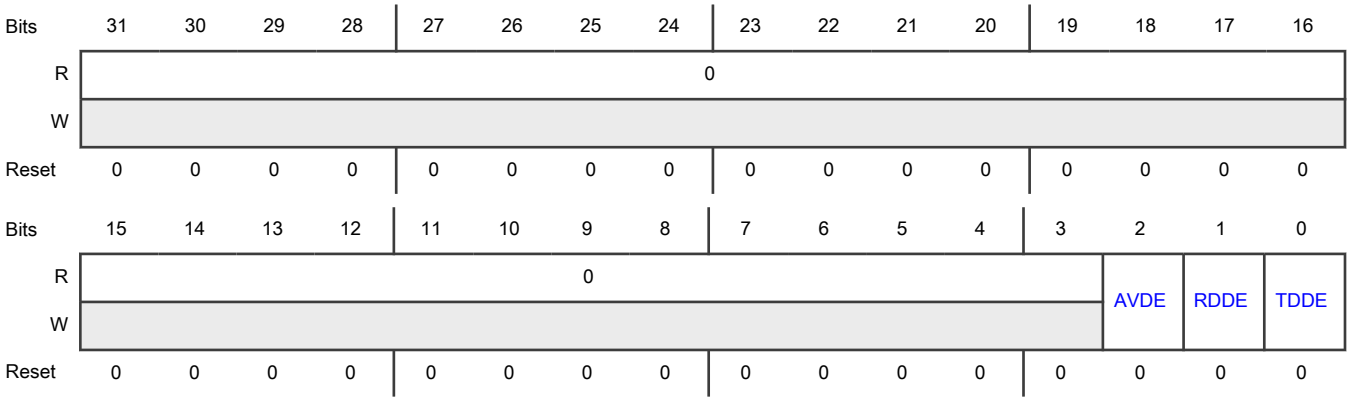
Offset

Register	Offset
SDER	11Ch

Function

Contains the transmit, request, and receive enables for DMA.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 AVDE	Address Valid DMA Enable Enables address valid DMA request. The address valid DMA request is shared with the receive data DMA request. If both are enabled, write 1 to SCFGR1[RXCFG] to allow the DMA to read the address from Target Receive Data (SRDR). 0b - Disable 1b - Enable
1 RDDE	Receive Data DMA Enable Enables receive data for DMA. 0b - Disable DMA request 1b - Enable DMA request
0 TDDE	Transmit Data DMA Enable Enables transmit data for DMA. 0b - Disable 1b - Enable

74.3.1.23 Target Configuration 1 (SCFGR1)

Offset

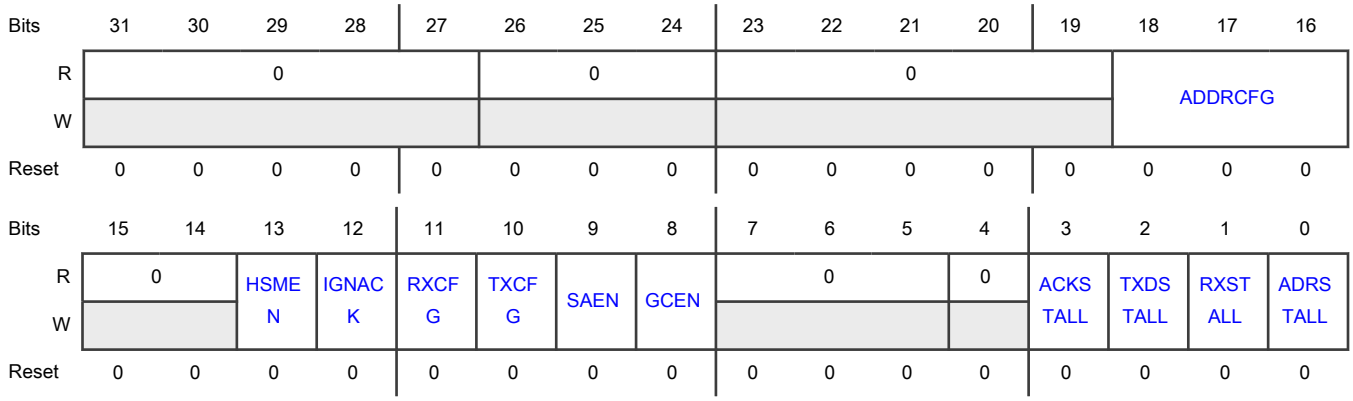
Register	Offset
SCFGR1	124h

Function

Configures various aspects of the target.

Write to this register only when the I2C target is disabled.

Diagram



Fields

Field	Function
31-27 —	Reserved
26-24 —	Reserved
23-19 —	Reserved
18-16 ADDRCFG	Address Configuration Configures the condition that causes an address to match. 000b - Address match 0 (7-bit) 001b - Address match 0 (10-bit) 010b - Address match 0 (7-bit) or address match 1 (7-bit) 011b - Address match 0 (10-bit) or address match 1 (10-bit) 100b - Address match 0 (7-bit) or address match 1 (10-bit) 101b - Address match 0 (10-bit) or address match 1 (7-bit) 110b - From address match 0 (7-bit) to address match 1 (7-bit) 111b - From address match 0 (10-bit) to address match 1 (10-bit)
15-14 —	Reserved
13 HSMEN	HS Mode Enable Enables detection of the HS mode controller code of target address 0000_1XX, but does not cause an address match on this code. When this field is 1 and any HS mode controller code is detected, SCR[FILTEN] and SCFGR1[ACKSTALL] are ignored until the next Stop condition is detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
12 IGNACK	Ignore NACK Determines whether the target ends transfer when a NACK condition is detected. When this field is 1, the LPI2C target continues transfers after a NACK is detected. This field is required to be 1 in Ultra-Fast mode. 0b - End transfer on NACK 1b - Do not end transfer on NACK
11 RXCFG	Receive Data Configuration Configures which data is returned and which flags are cleared when reading Target Receive Data (SRDR). When this field is 0, reading SRDR returns received data and clears MSR[RDF]. When this field is 1, reading SRDR: • Returns the value of Target Address Status (SASR) and clears SSR[AVF] when SSR[AVF] is set. • Returns received data and clears MSR[RDF] when SSR[AVF] is not set. 0b - Return received data, clear MSR[RDF] 1b - Return SASR and clear SSR[AVF] when SSR[AVF] is set, return received data and clear MSR[RDF] when SSR[AFV] is not set
10 TXCFG	Transmit Flag Configuration Determines which conditions set MSR[TDF]. This field always becomes 1 before a NACK is detected at the end of a target-transmit transfer. This change can cause an extra word to be written to the transmit data FIFO. When this field is 0, Target Transmit Data (STDR) is automatically emptied when a target-transmit transfer is detected. MSR[TDF] is set when a target-transmit transfer is detected, and MSR[TDF] is cleared at the end of the target-transmit transfer. When this field is 1, MSR[TDF] is set when STDR is empty, and MSR[TDF] is cleared when STDR is full. This setting allows STDR to be filled before a target-transmit transfer is detected. However, it can cause STDR to be written before a NACK is detected on the last byte of a target-transmit transfer. 0b - MSR[TDF] is set only during a target-transmit transfer when STDR is empty 1b - MSR[TDF] is set whenever STDR is empty
9 SAEN	SMBus Alert Enable Enables a match on an SMBus alert. 0b - Disable 1b - Enable
8	General Call Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
GCEN	Enables a general call address. 0b - Disable 1b - Enable
7-5 —	Reserved
4 —	Reserved
3 ACKSTALL	ACK SCL Stall Enables SCL clock stretching during target-transmit address bytes and target-receiver address and data bytes, so you can write to Target Transmit ACK (STAR) before the ACK or NACK is transmitted. Clock stretching occurs when transmitting the ninth bit, and is therefore not compatible with HS mode. If this field is 1: • You do not need to write 1 to SCFGR1[RXSTALL] or SCFGR1[ADRSTALL]. • When there is an address match on the first byte of a 10-bit address, SSR[AVF] is set, allowing you to read the received address before writing to Target Transmit ACK (STAR). 0b - Disable 1b - Enable
2 TXDSTALL	Transmit Data SCL Stall Enables SCL clock stretching when SSR[TDF] = 1 during a target-transmit transfer. Clock stretching occurs following the ninth bit, and is therefore compatible with HS mode. 0b - Disable 1b - Enable
1 RXSTALL	RX SCL Stall Enables SCL clock stretching when SSR[RDF] = 1 during a target-receive transfer. Clock stretching occurs following the ninth bit, and is therefore compatible with HS mode. 0b - Disable 1b - Enable
0 ADRSTALL	Address SCL Stall Enables SCL clock stretching when SSR[AVF] = 1. Clock stretching only occurs following the ninth bit, and is therefore compatible with HS mode. 0b - Disable 1b - Enable

74.3.1.24 Target Configuration 2 (SCFGR2)

Offset

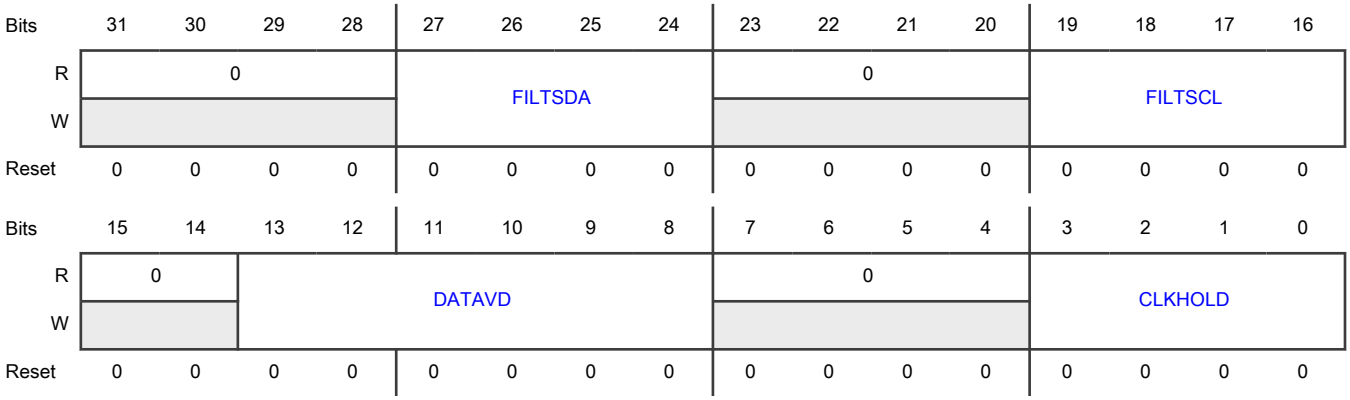
Register	Offset
SCFGR2	128h

Function

Configures data valid delay, clock hold time, and glitch filters for SDA and SCL.

Write to this register only when the I2C target is disabled.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24 FILTSDA	Glitch Filter SDA Configures the I2C target digital glitch filters for SDA input. Writing 0 to this field disables the glitch filter. Glitches equal to or less than the number of cycles defined by this field are filtered out and ignored. The latency through the glitch filter is equal to the number of cycles defined by this field + 3. The latency must be configured to be less than the minimum SCL low or high period. MCFGR1[PRESCALE] does not affect the glitch filter cycle count, and the glitch filter cycle count is disabled in HS mode.
23-20 —	Reserved
19-16	Glitch Filter SCL

Table continues on the next page...

Table continued from the previous page...

Field	Function
FILTSCL	Configures the I2C target digital glitch filters for SCL input. Writing 0 to this field disables the glitch filter. Glitches equal to or less than the number of cycles defined by this field are filtered out and ignored. The latency through the glitch filter is equal to the number of cycles defined by this field + 3. The latency must be configured to be less than the minimum SCL low or high period. MCFGR1[PRESCALE] does not affect the glitch filter cycle count, and the glitch filter cycle count is disabled in HS mode.
15-14 —	Reserved
13-8 DATAVD	Data Valid Delay Configures the SDA data valid delay time for the I2C target, which is equal to FILTSCL + DATAVD + 3 cycles. The data valid delay must be configured to be less than the minimum SCL low period. MCFGR1[PRESCALE] does not affect the I2C target data valid delay time, and the I2C target data valid delay time is disabled in HS mode.
7-4 —	Reserved
3-0 CLKHOLD	Clock Hold Time Configures the minimum clock hold time for the I2C target, when clock stretching is enabled. The minimum hold time is equal to the number of cycles defined by this field + 3. MCFGR1[PRESCALE] does not affect the I2C target clock hold time, and the I2C target clock hold time is disabled in HS mode.

74.3.1.25 Target Address Match (SAMR)

Offset

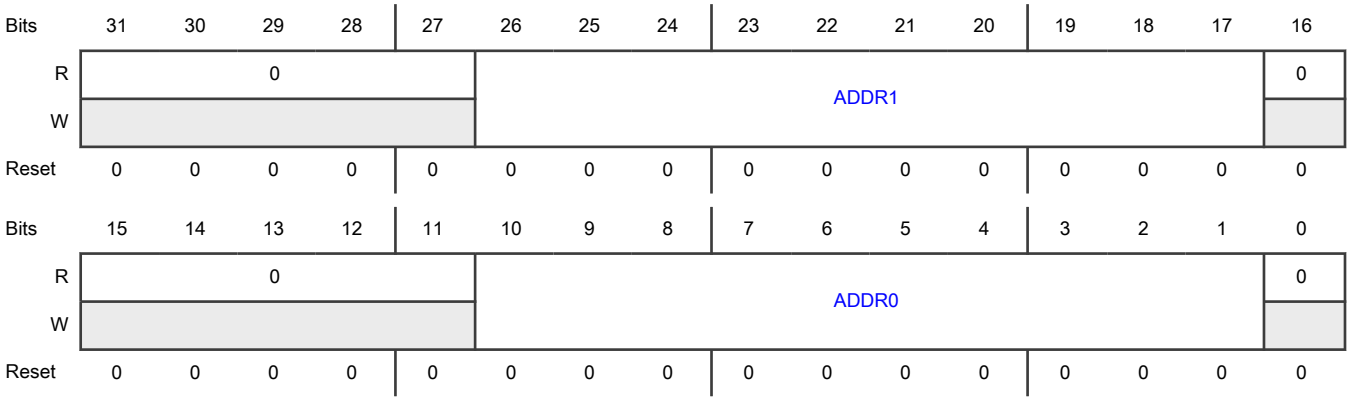
Register	Offset
SAMR	140h

Function

Contains address values for received target match comparison.

Write to this register only when the I2C target is disabled.

Diagram



Fields

Field	Function
31-27 —	Reserved
26-17 ADDR1	Address 1 Value Contains the value of address 1, which is compared to the received address to detect the target address. In 10-bit mode, the first address byte is compared to {11110, ADDR1[26:25]} and the second address byte is compared to ADDR1[24:17]. In 7-bit mode, the address is compared to ADDR1[23:17].
16-11 —	Reserved
10-1 ADDR0	Address 0 Value Contains the value of address 0, which is compared to the received address to detect the target address. In 10-bit mode, the first address byte is compared to {11110, ADDR0[10:9]} and the second address byte is compared to ADDR0[8:1]. In 7-bit mode, the address is compared to ADDR0[7:1].
0 —	Reserved

74.3.1.26 Target Address Status (SASR)

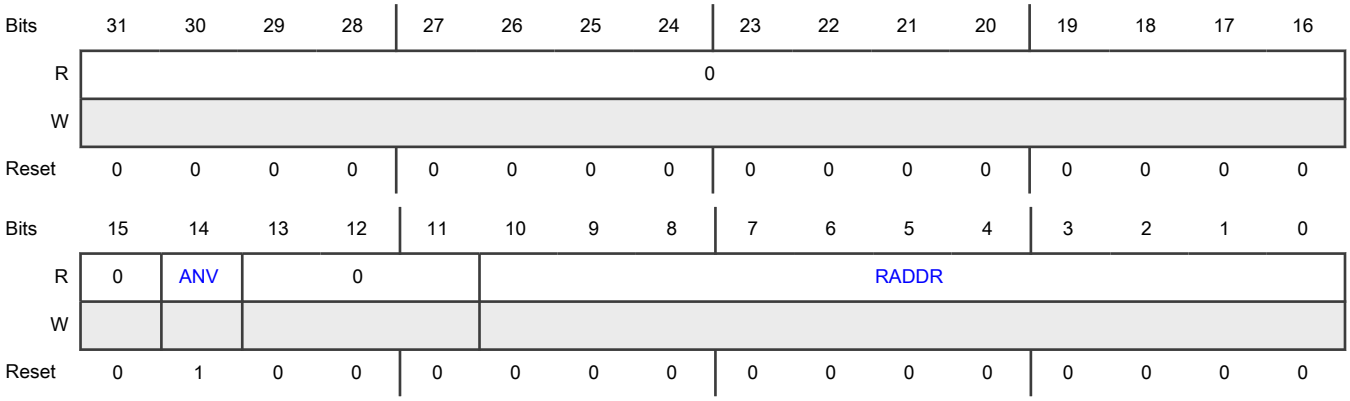
Offset

Register	Offset
SASR	150h

Function

Contains the received address and its validity.

Diagram



Fields

Field	Function
31-15 —	Reserved
14 ANV	Address Not Valid Indicates whether SASR[RADDR] is valid. 0b - Valid 1b - Not valid
13-11 —	Reserved
10-0 RADDR	Received Address Contains the received address. Updates whenever SSR[AM0F] or SSR[AM1F] is set. Reading Target Address Status (SASR) clears SSR[AM0F] and SSR[AM1F]. In 7-bit mode, the address byte is stored in RADDR[7:0]. In 10-bit mode, the first address byte is {11110, RADDR[10:9], RADDR[0]} and the second address byte is RADDR[8:1]. The Read-or-Write bit is therefore always stored in RADDR[0]. When SCFGR1[ACKSTALL] = 1, if the first address byte matches in 10-bit mode, the first address byte is stored in RADDR[7:0] so you can read this field before writing the Transmit ACK. If the second address byte matches, this field is then updated with the full 10-bit address.

74.3.1.27 Target Transmit ACK (STAR)

Offset

Register	Offset
STAR	154h

Function

Configures choice of ACK or NACK on each received word.

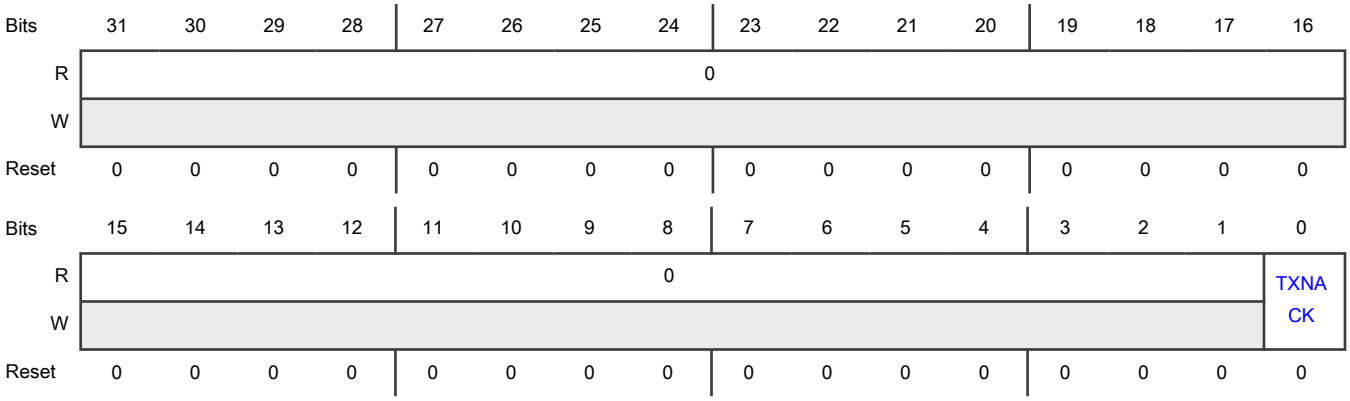
You can write to this register only when SCFGR1[ACKSTALL] = 1.

SCFGR1[ACKSTALL] enables clock stretching during the ACK-or-NACK bit slot. During this time, you can write to this register.

The logic ensures that the clock stretching continues for at least one bus clock cycle after this register is updated.

This clock stretching time can be extended via SCFGR2[CLKHOLD].

Diagram



Fields

Field	Function
31-1 —	Reserved
0 TXNACK	Transmit NACK Selects whether transmit ACK (logic 0) or NACK (logic 1) is returned on the bus by the I2C target after receiving each word. • When SCFGR1[ACKSTALL] = 1, a transmit NACK signal must be written once for each matching address byte and each received word. SCFGR1[ACKSTALL] must be 1, because that setting stalls the data transfer until software reads the received word (and determines whether to respond with an ACK or NACK). • To configure the default (ACK or NACK), you can write to this field when LPI2C target is disabled or idle. 0b - Transmit ACK 1b - Transmit NACK

74.3.1.28 Target Transmit Data (STDR)

Offset

Register	Offset
STDR	160h

Function

Contains the I2C target data to transmit.

Clock stretching (enabled or disabled) affects when the transmit data is transferred. SCFGR1[TXDSTALL] enables clock stretching during the first data bit of a target-transmit transfer.

If clock stretching is enabled (SCFGR1[TXDSTALL] = 1), the transmit data transfer is stalled until this register is updated. Clock stretching is extended by at least 1 bus clock cycle after this register is updated. Clock stretching can be delayed further by using SCFGR2[CLKHOLD].

If clock stretching is disabled (SCFGR1[TXDSTALL] = 0), the transmit data must be written before the start of the target-transmit transfer, otherwise SSR[FEF] is set.

Diagram

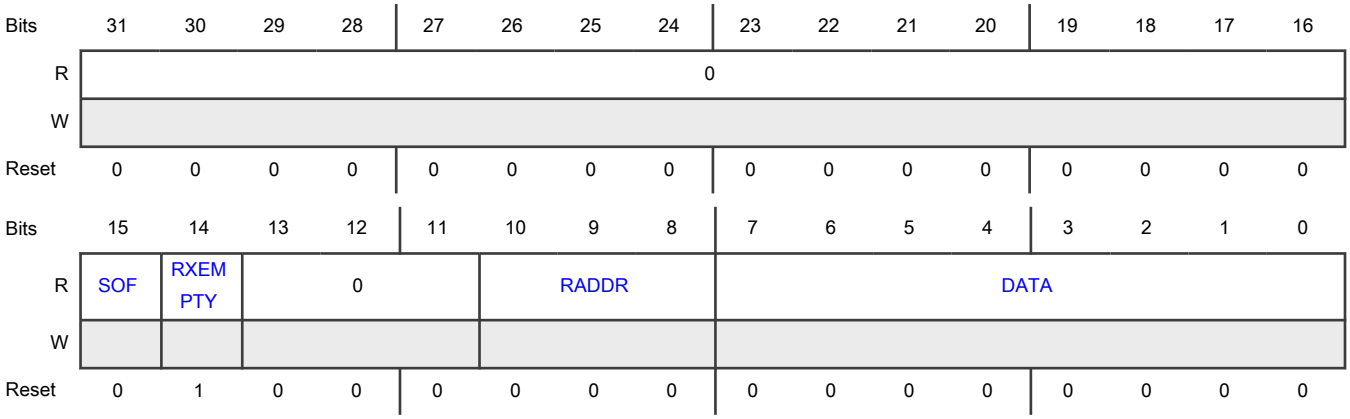
74.3.1.29 Target Receive Data (SRDR)

Offset

Register	Offset
SRDR	170h

Function
Contains status of target receive data transfer.

Diagram



Fields

Field	Function
31-16 —	Reserved
15 SOF	Start of Frame Indicates whether this data word is the first data word since a (repeated) Start or Stop condition. 0b - Not first 1b - First
14 RXEMPTY	Receive Empty Indicates whether this register is empty. 0b - Not empty 1b - Empty
13-11 —	Reserved
10-8	Received Address

Table continues on the next page...

Table continued from the previous page...

Field	Function
RADDR	Contains the address received by the IC2 target. When both SCFGR1[RXCFG] and SSR[AVF] are 1, bits [10:8] of SASR[RADDR] are returned. Otherwise, this field returns zero.
7-0 DATA	Received Data Contains the data received by the I2C target. When both SCFGR1[RXCFG] and SSR[AVF] are 1, bits [7:0] of SASR[RADDR] are returned.

74.4 Functional description

74.4.1 Controller mode

The LPI2C controller logic operates independently from the target logic to perform all controller-mode transfers on the I2C bus.

74.4.1.1 Transmit and Command FIFO commands

The transmit FIFO stores command data to initiate various I2C operations. The following operations can be initiated through commands in the transmit FIFO:

- Start or repeated Start condition with address byte, expecting ACK or NACK.
- Transmit data. This operation is the default for zero-extended-byte writes to the transmit FIFO.
- Receive 1-256 bytes of data. You can configure this operation to discard received data and not to store it in the receive FIFO.
- Stop condition. You can configure this operation to send a Stop condition when the transmit FIFO is empty.

Multiple transmit and receive commands can be inserted between the Start and Stop conditions. To comply with the I2C specification, transmit and receive commands must not be interleaved. The receive data command and the receive data and discard commands can be interleaved. This interleaving ensures that only the desired received data is stored in the receive FIFO (or compared with the data match logic).

The LPI2C controller automatically transmits a NACK on the last byte of a receive data command. It transmits the NACK unless the next command in the FIFO is also a receive data command. If the transmit FIFO is empty when a receive data command completes, a NACK is also automatically transmitted.

The LPI2C controller supports 10-bit addressing via a (repeated) Start condition, followed by a transmit data byte containing the second address byte, followed by any number of data bytes with the controller transmit data.

A Start or repeated Start condition expecting a NACK (for example, HS mode controller code) must be followed by a Stop or (repeated) Start condition.

74.4.1.2 Controller operations

When LPI2C is enabled, it monitors the I2C bus to detect when the I2C is idle (MSR[BBF]). If either SCL or SDA are low, the I2C bus is no longer considered idle. The bus becomes idle if a Stop condition is detected or if a bus idle timeout is detected (as configured by MCFGR2[BUSIDLE]). After the bus is idle, if the transmit FIFO is not empty and the host request is asserted or disabled, the LPI2C controller initiates a transfer on the bus. This transfer involves the following steps:

1. Wait the bus idle time equal to (MCCR0[CLKLO] + 1) multiplied by the prescaler (MCFGR1[PRESCALE]).
2. Transmit a Start condition and address byte using the timing configuration in Controller Clock Configuration 0 (MCCR0). If an HS mode transfer is configured, the timing configuration from Controller Clock Configuration 1 (MCCR1) is used instead.
3. Perform controller transmit or controller receive transfers, as configured by the transmit FIFO.

4. Transmit NACK on the last byte of a controller receive transfer. This action is performed unless the next command in the transmit FIFO is also a receive data command and the transmit FIFO is not empty.
5. Transmit a repeated Start or Stop condition as configured by the transmit FIFO or MCFGR1[AUTOSTOP]. A repeated Start can change which timing configuration register is used.

When the LPI2C controller is disabled, LPI2C continues emptying the transmit FIFO until a Stop condition is transmitted. (The controller could be disabled due to MCR[MEN] being 0, or automatically due to mode entry.) However, LPI2C no longer stalls the I2C bus by waiting for the transmit or receive FIFO. After the transmit FIFO is empty, LPI2C generates a Stop condition automatically.

The LPI2C controller can stall the I2C bus under certain conditions. This stalling results in SCL pulled low continuously on the first bit of a byte, until these conditions change:

- The LPI2C controller is enabled and busy, the transmit FIFO is empty, and MCFGR1[AUTOSTOP] is 0. The LPI2C controller continues to stall the bus until the transmit FIFO is loaded with more data.
- The LPI2C controller is enabled and receiving data, receive data is not being discarded (due to command or receive data match), and the receive FIFO is full. The LPI2C controller continues to stall the I2C bus until the receive FIFO is emptied.

74.4.1.3 Receive FIFO and data matching

The receive FIFO stores receive data during controller-receiver transfers. You can configure the LPI2C controller to discard received data instead of storing it in the receive FIFO. This option is configured via the command word in the transmit FIFO.

Received data supports a receive data match function that can match received data against one of two bytes, or against a masked data byte. You can configure the data match function to compare only the first one or two data words received since the last (repeated) Start condition. Received data that is already discarded due to the command word cannot cause a data match. It delays the match on the first data word received until after the discarded data is received.

You can configure the receiver match function to discard all received data until a data match is detected, using MCFGR0[RDMO]. Following a data match, write 0 to MCFGR0[RDMO] before writing 0 to MSR[DMF] to allow all subsequent data to be received.

74.4.1.4 Timing parameters

The LPI2C controller can configure the following timing parameters. Parameters are configured separately for HS mode (Controller Clock Configuration 1 (MCCR1)) and other modes (Controller Clock Configuration 0 (MCCR0)). This separation allows the HS mode controller code to be sent using regular timing parameters. Then it allows a switch to HS mode timing (following a repeated Start) until the next STOP condition.

Configure the LPI2C controller timing parameters, measured in LPI2C functional clock cycles, as shown in Table 506. You must configure these parameters to meet the I2C timing specification for the required mode.

Table 506. Timing parameters

I2C specification timing parameter	I2C specification timing symbol	LPI2C timing parameter (in LPI2C functional clock cycles)
SCL clock period	tSCL	(CLKHI + CLKLO + 2 + SCL_LATENCY) × (2 ^ PRESCALE)
Hold time (repeated) Start condition	tHD:STA	(SETHOLD +1) × (2 ^ PRESCALE)
Low period of the SCL clock	tLOW	(CLKLO + 1) × (2 ^ PRESCALE)
High period of the SCL clock	tHIGH	(CLKHI + 1 + SCL_LATENCY) × (2 ^ PRESCALE)
Setup time for a repeated Start condition or Stop condition	tSU:STA, tSU:STO	(SETHOLD + 1 + SCL_LATENCY) × (2 ^ PRESCALE)

Table continues on the next page...

Table 506. Timing parameters (continued)

I2C specification timing parameter	I2C specification timing symbol	LPI2C timing parameter (in LPI2C functional clock cycles)
Data hold time	tHD:DAT	(DATAVD + 1) × (2 ^ PRESCALE)
Data setup time	tSU:DAT	(SDA_LATENCY + 1) × (2 ^ PRESCALE)
Bus free time between a Stop and Start condition	tBUF	(CLKLO + 1 + SDA_LATENCY) × (2 ^ PRESCALE)
Data valid time, data valid acknowledge time	tVD:DAT, tVD:ACK	(DATAVD + 1) × (2 ^ PRESCALE)

Table 507 defines the latency parameters. These parameters assume that the risetime is less than one LPI2C functional clock cycle. The risetime depends on a number of factors, including the I/O propagation delay, the I2C bus loading, and the external pullup resistor sizing. A larger risetime increases the number of cycles that the signal takes to propagate through the synchronizer (and glitch filter), which increases the latency.

Table 507. Synchronization latency

Timing parameter	Timing definition
SCL_LATENCY	ROUNDDOWN ((2 + FILTSCL + SCL_RISETIME) ÷ (2 ^ PRESCALE))
SDA_LATENCY	ROUNDDOWN ((2 + FILTSDA + SDA_RISETIME) ÷ (2 ^ PRESCALE))

The following timing restrictions must be enforced to avoid unexpected Start or Stop conditions on the I2C bus. These restrictions also avoid unexpected Start or Stop conditions detected by the LPI2C controller. The timing restrictions can be summarized as "SDA cannot change when SCL is high outside a transmitted (repeated) Start or Stop condition."

Table 508. LPI2C timing parameter restrictions

Timing parameter	Minimum	Maximum	Comment
CLKLO	03h	—	CLKLO x (2 ^ PRESCALE) > SCL_LATENCY
CLKHI	01h	—	Configure CLKHI to meet the duty cycle requirements in the I2C specification
SETHOLD	02h	—	SETHOLD × (2 ^ PRESCALE) > SDA_LATENCY
DATAVD	01h	CLKLO – SDA_LATENCY – 1	Configure DATAVD to meet the data hold requirement in the I2C specification
FILTSCL	00h	[CLKLO × (2 ^ PRESCALE)] – 3	FILTSCL and FILTSDA are the only parameters not multiplied by (2 ^ PRESCALE)
FILTSDA	FILTSCL	[CLKLO × (2 ^ PRESCALE)] – 3	Configuring FILTSDA greater than FILTSCL can delay the SDA input to compensate for board level skew
BUSIDLE	(CLKLO + SETHOLD + 2) × 2	—	Must also be greater than (CLKHI + 1)

See the UM10204, *I2C-bus specification and user manual*.

See Application information for example LPI2C timing configurations.

74.4.1.5 Error conditions

The LPI2C controller monitors errors while it is active. The following conditions generate an error flag and block a new Start condition from being sent, until the flag is cleared by software:

- A Start or Stop condition is detected and is not generated by the LPI2C controller (MSR[ALF] becomes 1).
- Transmitting data on SDA and different values are received (MSR[ALF] becomes 1).
- NACK is detected when transmitting data, and MCFGR1[IGNACK] is 0 (MSR[NDF] becomes 1).
- NACK is detected and is expecting ACK for the address byte, and MCFGR1[IGNACK] is 0 (MSR[NDF] becomes 1).
- ACK is detected and is expecting NACK for the address byte, and MCFGR1[IGNACK] is 0 (MSR[NDF] becomes 1).
- Transmit FIFO is requesting to transmit or receive data without a Start condition (MSR[FEF] becomes 1).
- SCL (or SDA if MCFGR1[TIMECFG] is 1) is low for (MCFGR2[TIMELOW] × 256) prescaler cycles without a pin transition (MSR[PLTF] becomes 1).

You must respond to MSR[PLTF] to terminate the existing command. You can terminate the command cleanly by writing 0 to MCR[MEN], or you can terminate it abruptly by writing 1 to MCR[RST].

You can use MCFGR2[BUSIDLE] to force the I2C bus to be considered idle when SCL and SDA remain high for (BUSIDLE + 1) prescaler cycles. The bus is considered idle when the LPI2C controller is first enabled. When BUSIDLE is configured greater than zero, then SCL or SDA must be high for (BUSIDLE + 1) prescaler cycles before the I2C bus is considered idle.

74.4.1.6 Pin configuration

Configuration	Description
Open-drain support	The LPI2C controller defaults to open-drain configuration of the SDA and SCL pins. Support for true open drain depends on the specific device, and requires the pins where LPI2C pins are muxed to support true open drain.
HS mode support	Support for HS mode depends on the specific device. This mode requires the SCL pin to support the current source pullup required in the I2C specification.
Ultra-Fast mode support	The LPI2C controller supports the output-only push-pull function required for I2C Ultra-Fast mode using the SDA and SCL pins. Support for Ultra-Fast mode also requires MCFGR1[IGNACK] to be 1.
Push-pull two-wire support	A push-pull two-wire configuration is available to the LPI2C controller. If LPI2C is the only controller and all I2C pins on the bus are at the same voltage, this configuration may support a partial HS mode. A partial HS mode, not a full HS mode, because this configuration actively drives high rather than enabling a current service pull-up. This configuration sets the SCL pin as push-pull for every clock except the ninth clock pulse, to allow HS-mode-compatible targets to perform clock stretching. In this mode, the SDA pin is tristated for controller-receive data bits and controller-transmit ACK/NACK bits, and is configured as push-pull at other times. To avoid the risk of contention when SDA is push-pull, configure the pin for open-drain operation, as part of the device-specific configuration.
Push-pull four-wire support	The push-pull four-wire configuration separates the SCL input data and output data into separate pins. It also separates the SDA input data and output data into separate pins. The SCL/SDA pins are used for input data; the SCLS/SDAS pins are used for output data, with configurable polarity. This configuration simplifies external connections when connecting the LPI2C to the I2C bus through external level shifters or discrete components. When using this four-wire configuration, the LPI2C controller logic and LPI2C target logic cannot connect to separate I2C buses.

74.4.2 Target mode

To perform all target mode transfers on the I2C bus, the LPI2C target logic operates independently from the LPI2C controller logic.

74.4.2.1 Address matching

You can configure the LPI2C target:

- To match one of two addresses, using either 7-bit or 10-bit addressing modes for each address.
- To match a range of addresses in either 7-bit or 10-bit addressing modes.
- To match the general call address and generate appropriate flags.
- To match the SMBus alert address and generate appropriate flags.
- To detect the HS mode controller code address, and to disable the digital filters and output valid delay time until the next Stop condition is detected.

After a valid address is matched, the LPI2C target automatically performs target-transmit or target-receive transfers until:

- A NACK is detected (unless SCFGR1[IGNACK] becomes 1).
- A bit error is detected (the LPI2C target is driving SDA, but a different value is sampled).
- A (repeated) Start or Stop condition is detected.

74.4.2.2 Transmit and receive data

Target Transmit Data (STDR) and Target Receive Data (SRDR) are double-buffered and only update during a target-transmit and target-receive transfer, respectively.

You can configure the target address that was received to be read from SRDR (for example, when using DMA to transfer data) or from Target Address Status (SASR).

You can configure STDR to request data only after a target-transmit transfer is detected. You can also configure it to request new data whenever STDR is empty.

Write to STDR only when SSR[TDF] is set.

Read SRDR only when SSR[RDF] is set, or when SSR[AVF] is set and SCFGR1[RXCFG] = 1.

Read SASR only when SSR[AVF] is set.

74.4.2.3 Clock stretching

The LPI2C target supports many configurable options for clock stretching. You can configure these conditions to perform clock stretching:

- SSR[AVF] is set during the ninth clock pulse of the address byte.
- SSR[TDF] is set during the ninth clock pulse of a target-transmit transfer.
- SSR[RDF] is set during the ninth clock pulse of a target-receive transfer.
- SSR[TAF] is set during the eighth clock pulse of an address byte or a target-receive transfer. In HS mode, this option is disabled.
- Clock stretching can be extended for a number of cycles equal to the value of SCFGR2[CLKHOLD] cycles. This stretching allows additional setup time to sample the SDA pin externally. In HS mode, this option is disabled.

When clock stretching is enabled, clock stretching extends for one peripheral bus clock cycle after SDA updates, unless extended by the SCFGR2[CLKHOLD] configuration.

74.4.2.4 Timing parameters

The LPI2C target can configure the following timing parameters:

- SDA data valid time from SCL negation to SDA update
- SCL hold time when clock stretching is enabled to increase setup time when sampling SDA externally
- SCL glitch filter time
- SDA glitch filter time

These parameters are disabled when SCR[FILTEN] is 0, when SCR[FILTDZ] is 1 in Doze mode, and when LPI2C target detects HS mode. When disabled, the LPI2C target is clocked directly from the I2C bus. In this case, the target may not satisfy all timing requirements of the I2C specification (such as SDA minimum hold time in Standard/Fast mode).

The LPI2C target places the following restrictions on the timing parameters:

- You must configure SCFGR2[FILTSDA] to be greater than or equal to SCFGR2[FILTSCL] (unless compensating for board level skew between SDA and SCL).
- You must configure SCFGR2[DATAVD] to be less than the minimum SCL low period.

74.4.2.5 Error conditions

The LPI2C target can flag the following error conditions:

- SSR[BEF] is set when the LPI2C target is driving SDA but it samples a different value than what is expected.
- SSR[FEF] is set due to a transmit data underrun or a receive data overrun. To eliminate the possibility of underrun and overrun, enable clock stretching.
- SSR[FEF] is also set due to an address overrun, but only when SCFGR1[RXCFG] is 1. To eliminate the possibility of overrun, enable clock stretching.

The LPI2C target does not implement a timeout due to SCL or SDA being stuck low. If this detection is required, use the LPI2C controller logic so you can reset the LPI2C target when this condition is detected.

74.4.3 Low-power modes

LPI2C remains functional during low-power modes, if MCR[DOZEN] = 0 and LPI2C uses an external or internal clock source that remains enabled. LPI2C can generate an interrupt or DMA request to cause a wake-up from low-power modes.

You can configure LPI2C to be disabled in low-power modes when MCR[DOZEN] = 1. In this case, LPI2C waits for the current transfer to complete any pending operation.

NOTE

See the chip-specific information for low-power modes available on your chip.

74.4.4 Debug mode

Table 509. Debug mode

Mode	LPI2C operation
Debug	If MCR[DBGEN] = 1, can continue operating in Debug mode.

74.4.5 Peripheral triggers

The connection of the LPI2C peripheral triggers to other peripherals depends upon the specific device being used.

Table 510. LPI2C triggers

Trigger	Description
Controller output trigger	Generates an output trigger that can be connected to other peripherals on the device. The controller output trigger asserts on either a repeated Start or a Stop condition. The trigger remains asserted for one cycle of the LPI2C functional clock divided by MCFGR1[PRESCALE].
Target output trigger	Generates an output trigger that can be connected to other peripherals on the device. The target output trigger asserts on either a repeated Start or a Stop condition that occurs after a target address match. The target output trigger remains asserted until the next target SCL pin negation.
Input trigger	To control the start of a LPI2C bus transfer, the LPI2C input trigger can be selected instead of the HREQ input. The input trigger is synchronized. To be detected, the input trigger must assert for at least two cycles of the LPI2C functional clock divided by the value of MCFGR1[PRESCALE]. When LPI2C is busy, the HREQ input (and therefore the input trigger) is ignored.

74.4.6 Clocking

Table 511. LPI2C clocks

Clock	Description
LPI2C functional clock	The LPI2C functional clock is asynchronous to the bus clock. It can remain enabled in low-power modes to support I2C bus transfers by the LPI2C controller. The functional clock is also used by the LPI2C target to support digital filter and data hold time configurations. The LPI2C controller divides the functional clock by a prescaler (MCFGR1[PRESCALE]) and the resulting frequency must be at least eight times faster than the I2C bus bandwidth.
External clock	The LPI2C target logic is clocked directly from the external pins. These pins are SCL and SDA, or SCLS and SDAS if the controller and target are implemented on separate pins). This clocking allows the LPI2C target to remain operational, even when the LPI2C functional clock is disabled. **NOTE** If the LPI2C functional clock is disabled, the LPI2C target digital filter must be disabled. This condition can affect compliance with some timing parameters of the I2C specification, such as data hold time.
Bus clock	The bus clock is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPI2C controller and target registers.

For chip-specific clocking information, see the Clocking chapter.

74.4.7 Reset

Table 512. LPI2C resets

Reset	Description
Chip reset	The logic and registers for the LPI2C controller and target are reset to their default states after a chip reset.
Software reset	The LPI2C controller implements a software reset field in its control register. MCR[RST] resets all controller logic and registers to their default states, except for Controller Control (MCR) itself.

Table continues on the next page...

Table 512. LPI2C resets (continued)

Reset	Description
	The LPI2C target implements a software reset field in its control register. SCR[RST] resets all target logic and registers to their default states, except for Target Control (SCR) itself.
FIFO reset	The LPI2C controller implements write-only control fields that reset the transmit FIFO (MCR[RTF]) and receive FIFO (MCR[RRF]). After a FIFO is reset, that FIFO is empty. The LPI2C target implements write-only control fields that reset the transmit data register (SCR[RTF]) and receive data register (SCR[RRF]). After a data register is reset, that data register is empty.

74.4.8 Interrupts and DMA requests

Depending on the configuration, interrupts and DMA requests can be combined:

- LPI2C controller and target interrupts
- LPI2C controller and target transmit DMA requests
- LPI2C controller and target receive DMA requests

74.4.8.1 Controller mode

Table 513 lists the Controller mode sources that can generate LPI2C controller interrupts and LPI2C controller transmit and receive DMA requests.

Table 513. Controller interrupts and DMA requests

Status flag	Description	Can generate		
		Interrupt?	DMA request?	Low-power wake-up?
Transmit Data Flag (MSR[TDF])	Data can be written to transmit FIFO, as configured by MFCR[TXWATER].	Y	TX	Y
Receive Data Flag (MSR[RDF])	Data can be read from the receive FIFO, as configured by MFCR[RXWATER].	Y	RX	Y
End Packet Flag (MSR[EPF])	Controller has transmitted a repeated Start or Stop condition.	Y	N	Y
Stop Detect Flag (MSR[SDF])	Controller has transmitted a Stop condition .	Y	N	Y
NACK Detect Flag (MSR[NDF])	During an address byte, the controller expects an ACK but detects a NACK. During an address byte, the controller expects a NACK but detects an ACK. During a controller-transmitter data byte, the controller detects a NACK.	Y	N	Y
Arbitration Lost Flag (MSR[ALF])	The controller lost arbitration due to a Start or Stop condition detected at the wrong time, or the controller was transmitting data but received data different from the data that was transmitted.	Y	N	Y

Table continues on the next page...

Table 513. Controller interrupts and DMA requests (continued)

Status flag	Description	Can generate		
		Interrupt?	DMA request?	Low-power wake-up?
FIFO Error Flag (MSR[FEF])	The controller expects a Start condition in the command FIFO, but the next entry in the command FIFO is not a Start condition.	Y	N	Y
Pin Low Timeout Flag (MSR[PLTF])	Pin low timeout is enabled and SCL (or SDA, if configured) is low for longer than the configured timeout.	Y	N	Y
Data Match Flag (MSR[DMF])	The received data matches the configured data match, but the received data is not discarded due to a command FIFO entry.	Y	N	Y
Controller Busy Flag (MSR[MBF])	LPI2C controller is busy transmitting or receiving data.	N	N	N
Bus Busy Flag (MSR[BBF])	LPI2C controller is enabled and activity is detected on the I2C bus, but no Stop condition is detected and no bus idle timeout (if enabled) occurred.	N	N	N

74.4.8.2 Target mode

Table 514 lists the target mode sources that can generate LPI2C target interrupts and LPI2C target transmit and receive DMA requests.

Table 514. Target interrupts and DMA requests

Status flag	Description	Can generate		
		Interrupt?	DMA request?	Low-power wake-up?
Transmit Data Flag (SSR[TDF])	Data can be written to Target Transmit Data (STDR).	Y	TX	Y
Receive Data Flag (SSR[RDF])	Data can be read from Target Receive Data (SRDR).	Y	RX	Y
Address Valid Flag (SSR[AVF])	Address can be read from Target Address Status (SASR).	Y	RX	Y
Transmit ACK Flag (SSR[TAF])	ACK or NACK can be written to Target Transmit ACK (STAR).	Y	N	Y
Repeated Start Flag (SSR[RSF])	Target has detected an address match followed by a repeated Start condition.	Y	N	Y
Stop Detect Flag (SSR[SDF])	Target has detected an address match followed by a Stop condition.	Y	N	Y
Bit Error Flag (SSR[BEF])	Target was transmitting data, but received data is different from what was transmitted.	Y	N	Y

Table continues on the next page...

Table 514. Target interrupts and DMA requests (continued)

Status flag	Description	Can generate		
		Interrupt?	DMA request?	Low-power wake-up?
FIFO Error Flag (SSR[FEF])	This flag is set by: • Transmit data underrun • Receive data overrun • Address status overrun when SCFGR1[RXCFG] = 1 This flag can only be set when clock stretching is disabled.	Y	N	Y
Address Match 0 Flag (SSR[AM0F])	Target detected an address match SAMR[ADDR0].	Y	N	N
Address Match 1 Flag (SSR[AM1F])	Target detected an address match with SAMR[ADDR1] or using an address range.	Y	N	N
General Call Flag (SSR[GCF])	Target detected an address match with the general call address.	Y	N	N
SMBus Alert Response Flag (SSR[SARF])	Target detected an address match with the SMBus alert address.	Y	N	N
Target Busy Flag (SSR[SBF])	LPI2C target is busy receiving an address byte or is transmitting or receiving data.	N	N	N
Bus Busy Flag (SSR[BBF])	LPI2C target is enabled and a Start condition is detected on I2C bus, but no Stop condition detected.	N	N	N

74.5 External signals

Table 515. External signals

Signal	Name	Two-wire scheme	Four-wire scheme	Direction
SCL	LPI2C clock line	SCL	In Four-Wire mode, this pin is the SCL input pin.	Input or output
SDA	LPI2C data line	SDA	In Four-Wire mode, this pin is the SDA input pin.	Input or output
SCLS	Secondary I2C clock line	Not used	In Four-Wire mode, this pin is the SCLS output pin. If LPI2C controller/target are configured to use separate pins, then this pin is the LPI2C target SCL pin.	Input or output
SDAS	Secondary I2C data line	Not used	In Four-Wire mode, this pin is the SDAS output pin. If LPI2C controller/target are configured to use separate pins, then this pin is the LPI2C target SDA pin.	Input or output

Table continues on the next page...

Table 515. External signals (continued)

Signal	Name	Two-wire scheme	Four-wire scheme	Direction
HREQ	Host request	If host request is asserted and the I2C bus is idle, then it initiates an LPI2C controller transfer. HREQ is an additional pin separate from the two-wire or four-wire scheme.		Input

Figure 514 shows the two-signal connection.

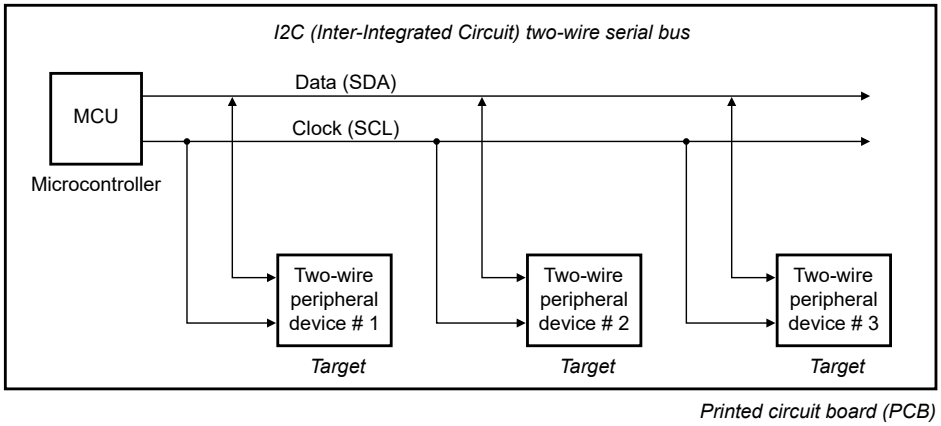


Figure 514. I²C two-wire serial bus

Figure 515 shows a possible four-signal connection.

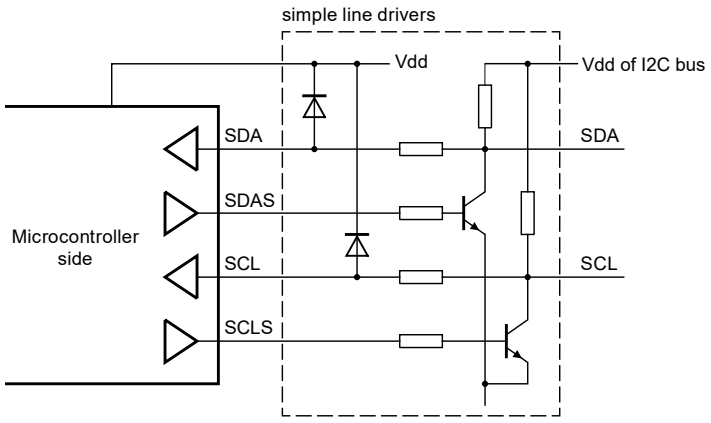

Figure 515. I²C four-wire serial bus

74.6 Initialization

To initialize the LPI2C controller:

1. Configure Controller Configuration 0 (MCFGR0)–Controller Configuration 3 (MCFGR3) as required by the application.
2. Configure Controller Clock Configuration 0 (MCCR0) and Controller Clock Configuration 1 (MCCR1) to satisfy the timing requirements of the I2C mode supported by the application.
3. Enable controller interrupts and DMA requests as required by the application.

4. Enable the LPI2C controller by writing 1 to MCR[MEN].

To initialize the LPI2C target:

1. Configure Target Address Match (SAMR) with the I2C address of the target location on the I2C bus.
2. Configure Target Configuration 1 (SCFGR1) as required by the application.
3. Configure Target Configuration 2 (SCFGR2) to satisfy the timing requirements of the I2C mode supported by the application.
4. Enable target interrupts and DMA requests as required by the application.
5. Enable the LPI2C target by writing 1 to SCR[SEN].

74.7 Application information

Configure the I2C timing parameters to meet the requirements of the I2C specification. This configuration depends on the supported mode and LPI2C functional clock frequency. When switching between two modes using different clock configuration registers (for example, Fast mode and HS mode), MCFGR1[PRESCALE] must remain constant between the modes.

Table 516. Example timing configurations

I2C mode	Clock frequency	Baud rate	PRESCALE	FILTSCL / FILTSDA	SETHOLD	CLKLO	CLKHI	DATAVD
Standard	8 MHz	100 kbit/s	0h	0h/0h	24h	28h	24h	02h
Standard	48 MHz	100 kbit/s	2h	1h/1h	37h	3Fh	37h	03h
Standard	60 MHz	100 kbit/s	2h	1h/1h	45h	50h	44h	04h
Fast	8 MHz	400 kbit/s	0h	0h/0h	04h	0Bh	05h	02h
Fast+	8 MHz	1 Mbit/s	0h	0h/0h	02h	03h	01h	01h
Fast	48 MHz	400 kbit/s	0h	1h/1h	1Dh	3Eh	35h	0Fh
Fast	48 MHz	400 kbit/s	2h	1h/1h	07h	11h	0Bh	03h
Fast+	48 MHz	1 Mbit/s	2h	1h/1h	03h	06h	04h	04h
HS	48 MHz	3.2 Mbit/s	0h	0h/0h	07h	08h	03h	01h
Fast	60 MHz	400 kbit/s	1h	2h/2h	11h	28h	1Fh	08h
Fast+	60 MHz	1 Mbit/s	1h	2h/2h	07h	0Fh	0Bh	01h
HS	60 MHz	3.33 Mbit/s	1h	0h/0h	04h	04h	02h	01h

SCL	Serial clock line
SCLS	Secondary serial clock line
SDA	Serial data line
SDAS	Secondary serial data line

Chapter 75
Flexible I/O (FlexIO)

75.1 Chip-specific FlexIO information

75.1.1 FlexIO instances and configuration

The device contains one instance of FlexIO.

FlexIO is a highly configurable module providing a wide range of functionality including:

- Emulation of a variety of serial communication protocols like UART, I2C, SPI. It can work either as master or slave.
- Flexible 16-bit timers with support for a variety of trigger, reset, enable and disable conditions.

Table 517. FlexIO configuration

No. of pins	No. of timers	No. of shift registers	No. of bits in counter
32	8	8	16

Table 518. Data rate limitation

FlexIO operation	Data rate limitation
Master Tx	FlexIO_clk/4
Slave Tx	FlexIO_clk/10
Master Rx	FlexIO_clk/8
Slave Rx	FlexIO_clk/6

NOTE

FlexIO supports 32 bit accesses only.

75.2 Overview

FLEXIO is a highly configurable module that provides:

- Emulation of various serial or parallel communication protocols.
- Flexible 16-bit timers with support for various trigger, reset, enable, and disable conditions.
- Programmable logic blocks that allow the implementation of digital logic functions on-chip and configurable interaction of internal and external modules.
- Programmable state machine for offloading basic system control functions from the CPU.

75.2.1 Block diagram

The following diagram provides a high-level overview of the FLEXIO timer and shifter configuration.

FLEXIO uses shifters, timers, and external triggers to shift data into or out of FLEXIO. As shown in the block diagram, timers control the timing of this data shift. You can configure the timers to use generic timer functions, external triggers, or various other conditions to determine the control.

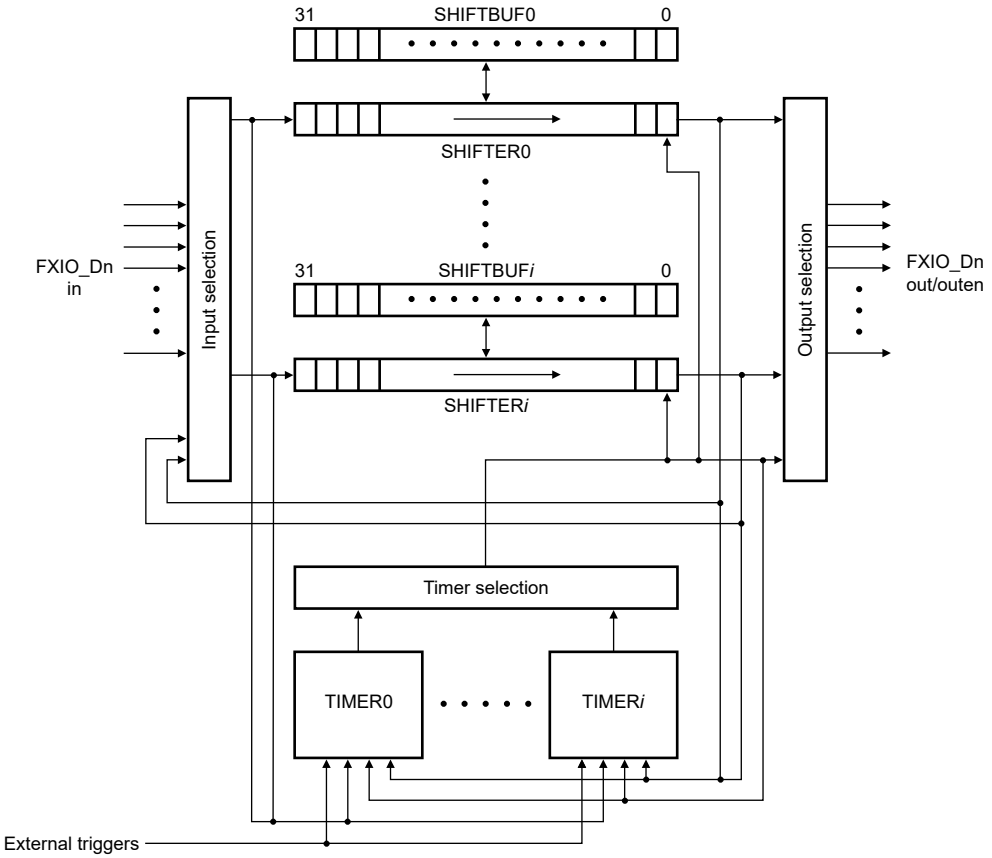

Figure 516. Block diagram

75.2.2 Features

- Array of 32-bit shift registers with transmit, receive, data match, logic, and state modes:
  - Double-buffered shifter operation for continuous data transfer
  - Shifter concatenation to support large transfer sizes
  - Automatic start and stop bit generation
  - 1, 2, 4, 8, 16, or 32 multi-bit shift widths for parallel interface support
  - Interrupt, DMA, or polled transmit and receive operation
- Highly flexible 16-bit timers with support for various internal or external triggers, reset, enable, and disable conditions:
  - Programmable baud rates independent of bus clock frequency
  - Programmable logic mode for integrating external digital logic functions on-chip, or combining pin, shifter, or timer functions to generate complex outputs
  - Programmable state machine for offloading basic system control functions from CPU, with support for up to eight states, eight outputs, and three selectable inputs per state
- Integrated general-purpose I/O registers and pin rising or falling edge interrupts to simplify software support
- Support for a wide range of protocols, including but not limited to:
  - UART
  - I2C

— SPI

— I2S

— Camera IF

— Motorola 68K or Intel 8080 bus

— PWM or waveform generation

— Input-capture (pulse-edge interval measurement), such as SENT

75.3 Functional description

75.3.1 Shifter operation

Shifters are responsible for buffering and shifting data into or out of FLEXIO. The timer assigned to the shifter controls the timing of shift, load, and store events via SHIFTCTL*n*[TIMSEL]. Shifters are designed to support either DMA, interrupt, or polled operations. The following figure provides a detailed view of the shifter microarchitecture.

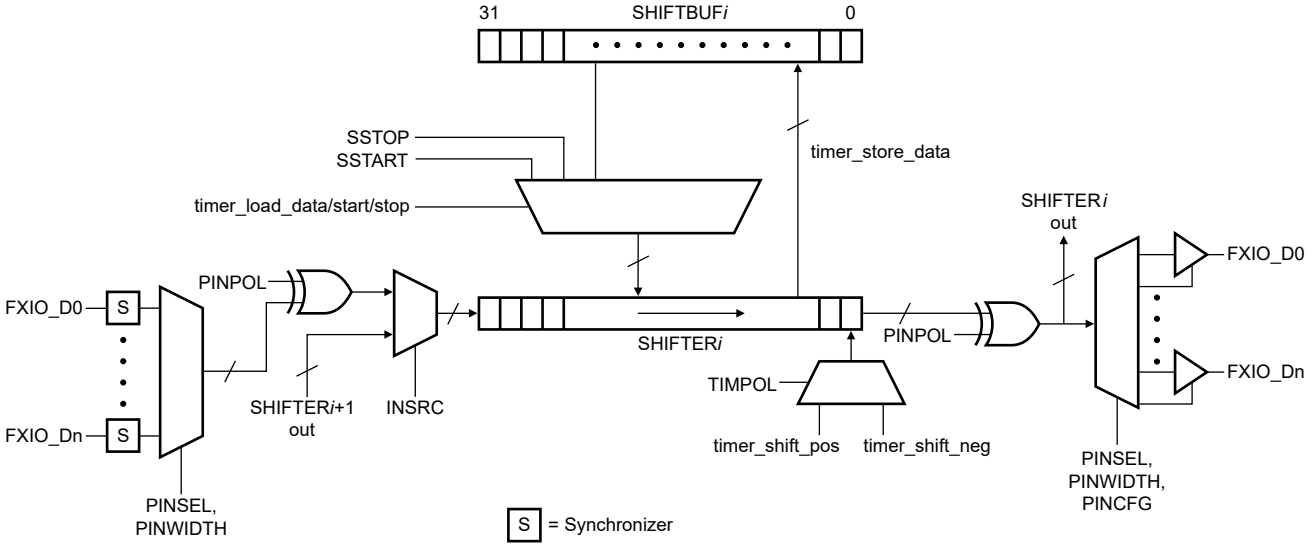

Figure 517. Shifter microarchitecture

75.3.1.1 Transmit mode

In Transmit mode (SHIFTCTL*n*[SMOD] = 010b), the shifter loads data from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) and shifts data out when the assigned timer signals a load event. An optional start and stop bit can be automatically loaded before or after SHIFTBUF register data by configuring either SHIFTCFG[SSTART] and TIMCFG[TSTART], or SHIFTCFG[SSTOP] and TIMCFG[TSTOP] in the shifter and timer.

NOTE

If a stop bit is enabled, the shifter immediately loads a stop bit when it is initially configured for Transmit mode.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when data has either been loaded from the SHIFTBUF register into the shifter or when the shifter is initially configured for Transmit mode. To clear the flag, write 1 or write new data to SHIFTBUF. In Transmit mode, write any value to the SHIFTBUF register to clear the corresponding shifter status flag, which is cleared regardless of what is writing to the register (DMA or interrupt), or the state of the DMA or interrupt enables. See the functional description of SHIFTSTAT[SSF] for information on how the flag is set and cleared for each mode.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to load data from an empty SHIFTBUF register occurs (buffer underrun). Clear the flag by writing 1.

75.3.1.2 Receive mode

When the assigned timer signals a store event in Receive mode (SHIFTCTL*n*[SMOD] = 001b), the shifter shifts and stores data in Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). You can check for a start and stop bit before or after the shifter data is sampled by configuring either SHIFTCFG[SSTART] and TIMCFG[TSTART], or SHIFTCFG[SSTOP] and TIMCFG[TSTOP] in the shifter and timer.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when data is stored in the SHIFTBUF register from the shifter. To clear the flag, write 1 to or read the data from SHIFTBUF. Any read of the SHIFTBUF register clears the corresponding shifter status flag when the shifter is in Receive mode. The flag is cleared regardless of what is reading the register (DMA or interrupt) or the state of the DMA or interrupt enables. See the functional description of SHIFTSTAT[SSF] for information on how the flag is set or cleared for each mode.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set either when an attempt to store data into a full SHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start or stop bit check. Write 1 to clear the flag.

75.3.1.3 Match Store mode

In Match Store mode (SHIFTCTL*n*[SMOD] = 100b), the shifter shifts data in, checks for a match result, and stores matched data in Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) when the assigned timer signals a store event. By configuring either SHIFTCFG[SSTART], TIMCFG[TSTART], and SHIFTCFG[SSTOP], or TIMCFG[TSTOP] in the shifter and timer, you can check for a start and stop bit before or after the shifter data is sampled. You can compare up to 16 bits of data using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when a match occurs and the matched data is stored in the SHIFTBUF register from the shifter. To clear the flag, read the matched data from the SHIFTBUF register or write 1 to the flag. Any read of the SHIFTBUF register clears the corresponding shifter status flag when the shifter is configured in Match Store mode. The flag is cleared regardless of what is reading the register (DMA or interrupt) or the state of the DMA or interrupt enables. See the functional description for SHIFTSTAT[SSF] to know how the flag is set or cleared for each mode.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to store matched data into a full SHIFTBUF register occurs (buffer overrun), or when a mismatch occurs on a start or stop bit check. Write 1 to clear the flag.

75.3.1.4 Match Continuous mode

In Match Continuous mode (SHIFTCTL*n*[SMOD] = 101b), the shifter shifts data in and continuously checks for a match result whenever a shift event is signaled by the assigned timer. You can compare up to 16 bits of data using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when a match occurs. The flag clears automatically as soon as no match exists between the shifter data and Shifter Buffer (SHIFTBUF0 - SHIFTBUF7).

You cannot clear the flag by reading the SHIFTBUF register.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when a match occurs. To clear the flag, write 1 or perform a read from the SHIFTBUF register.

75.3.1.5 State mode

State mode enables you to implement any state machine with up to eight states, eight outputs, and three selectable inputs per state. This feature allows basic control functions to be offloaded from the CPU.

In State mode (SHIFTCTL*n*[SMOD] = 110b), when the shifter is selected by the current state pointer (SHIFTSTATE[STATE]), use the SHIFTBUF register to drive the output and compute the next state values. The following figure provides a detailed view of the shifter microarchitecture when configured for State mode.

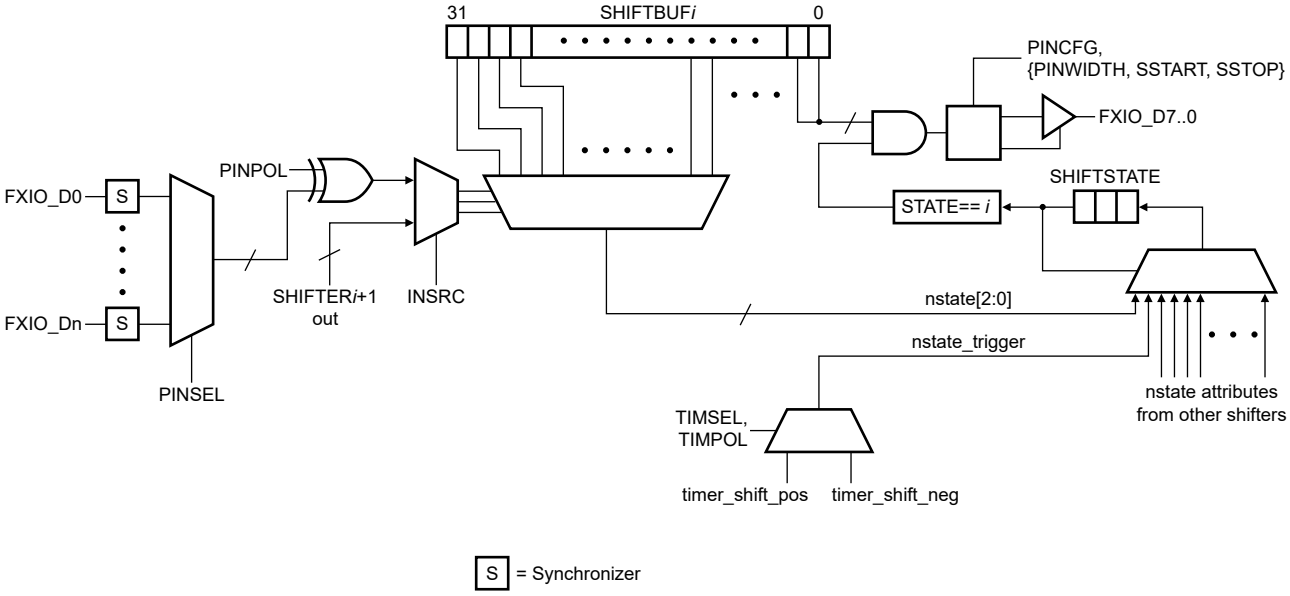

Figure 518. State microarchitecture

When the current state pointer selects a specific shifter (shifter *n*), output pins FXIO_D[7:0] are driven by SHIFTBUF*n*[31:24]; the configuration is defined by SHIFTCTL*n*[PINCFG]. Write 1 to Shifter Configuration (SHIFTCFG0 - SHIFTCFG7) {PWIDTH[3:0],SSTOP[1:0],SSTART[1:0]} to disable the output drive on pins FXIO_D[7:0] for state machine applications that require less than eight output pins.

Use the three input pins selected by SHIFTCTL*n*[PINSEL] and SHIFTBUF*n*[23:0] to compute the next state value.

NOTE

Each state can use a different set of three input pins.

The following table shows how the next state value is computed when the current state pointer is pointing to shifter *n*.

Table 519. Next state computation for SHIFTSTATE[STATE] = *n*

FXIO_D[PINSEL + 2]	FXIO_D[PINSEL + 1]	FXIO_D[PINSEL]	Next state value
0	0	0	SHIFTBUF*n*[2:0]
0	0	1	SHIFTBUF*n*[5:3]
0	1	0	SHIFTBUF*n*[8:6]
0	1	1	SHIFTBUF*n*[11:9]
...	...	...	...
1	1	1	SHIFTBUF*n*[23:21]

NOTE

You can configure other shifters and timers to drive the input pins of a given state, allowing you to create complex combinations of shifters and timers as needed. For example, the output of a shifter configured for Logic mode can be used to drive a state machine input.

The next state transition is triggered using the timer output selected by SHIFTCTL*n*[TIMSEL], with polarity controlled by SHIFTCTL*n*[TIMPOL].

NOTE

Each state can use a different timer to trigger each next state transition, allowing various internal or external trigger sources and clocking configurations to be used. See Timer section for more information.

The current state pointer defaults to shifter 0 at reset; however, you can write to select a different shifter for the initial state. If the current state pointer selects a shifter that is not configured for State mode, then outputs are not driven and the next state transition is never triggered.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when the shifter is selected by the current state pointer. The flag is cleared when the current state pointer is updated to a different shifter.

75.3.1.6 Logic mode

Logic mode enables you to implement a small amount of programmable digital logic within a FLEXIO shifter.

In Logic mode (SHIFTCTL*n*[SMOD] = 111b), use Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) to implement a 5-input, 32-bit programmable logic lookup table. The following figure provides a detailed view of shifter microarchitecture when configured for Logic mode.

Use the SHIFTBUF register to configure the lookup table for the four pin inputs. You can also use SHIFTER*n* to configure a feedback or delayed pin source as the fifth input to the lookup table.

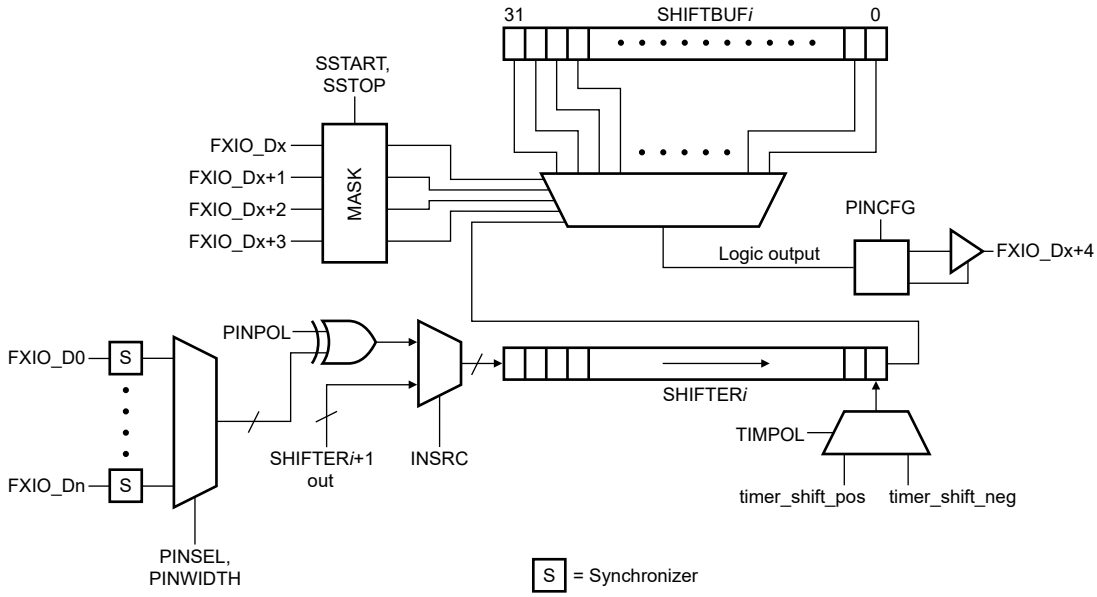

Figure 519. Logic microarchitecture

The lookup table is driven using four pin inputs (maskable using SHIFTCFG[SSTOP] and SHIFTCFG[SSTART]), plus one input from the internal shifter. It can be configured to drive an output pin using SHIFTCTL[PINCFG]. Pin inputs and outputs are fixed for each logic lookup table and are not selectable. The following table lists the logic output value selected by the lookup table for shifter *n*.

Table 520. Logic lookup table for shifter *n*

SHIFTER*n*[0]	FXIO_D[*x* + 3][1]	FXIO_D[*x* + 2]	FXIO_D[*x* + 1]	FXIO_D[*x*]	Logic output to FXIO_D[*x* + 4]
0	0	0	0	0	SHIFTBUF*n*[0]
0	0	0	0	1	SHIFTBUF*n*[1]

Table continues on the next page...

Table 520. Logic lookup table for shifter *n* (continued)

SHIFTER*n*[0]	FXIO_D[*x* + 3][1]	FXIO_D[*x* + 2]	FXIO_D[*x* + 1]	FXIO_D[*x*]	Logic output to FXIO_D[*x* + 4]
0	0	0	1	0	SHIFTBUF*n*[2]
0	0	0	1	1	SHIFTBUF*n*[3]
...	...	...	...	...	...
1	1	1	1	1	SHIFTBUF*n*[31]

1. for shifters *n* = 0...3, *x* = *n*

   for shifter *n* = 4...7, *x* = *n* + 4

To minimize output glitches, use SHIFTCFG*n*[SSTOP] and SHIFTCFG*n*[SSTART] to mask unused input pins. When these fields are 1, {SSTOP[1:0] and SSTART[1:0]} mask FXIO_D[*x* + 3]...FXIO_D[*x*] inputs respectively so that any transitions on these pins do not cause the logic output to glitch.

NOTE

You can configure other shifters and timers to drive the input pins of a given lookup table, allowing you to concatenate lookup tables or create complex combinations of shifters and timers as needed.

SHIFTCFG[PWIDTH] controls the number of delay stages introduced by the internal shifter input (SHIFTER*n*[0]). For example, when configured for a 1-bit shift (SHIFTCFG[PWIDTH] = 0), the internal shifter introduces a 32-shift clock delay before passing its input (selected by SHIFTCTL[PINSEL]) to the lookup table. When configured for a 32-bit shift (SHIFTCFG[PWIDTH] = 16...31), the internal shifter introduces a 1-shift clock delay to its input.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set whenever the output pin allocated to the logic lookup table has a value of 1 after being synchronized with the FLEXIO clock. The flag clears when the output pin has a value of 0. This also allows SHIFTSTAT[SSF] to be used as a trigger to a timer if needed.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when the output pin allocated to the logic lookup table is asserted. Clear the flag by writing 1 to it.

The Logic mode input pins, including pins driven by other shifters and timers, are synchronized with the FLEXIO functional clock before they are input to the programmable logic lookup table.

75.3.2 Timer operation

The FLEXIO 16-bit timers control the loading, shifting, and storing of the shift registers. The counters load the contents of the compare register and decrement down to zero on the FLEXIO clock. The counters can perform generic timer functions such as generating a clock, select output, or a PWM waveform. You can configure these timers to perform any of the following functions:

- Enable in response to a trigger, pin, or shifter condition.
- Decrement always or only on a trigger or pin edge.
- Reset in response to a trigger or pin condition.
- Disable on a trigger or pin condition or on a timer compare.

Timers can optionally include a start condition and a stop condition.

Although each timer operates independently, you can configure a timer to enable or disable at the same time as the previous timer (for example, timer 1 can enable or disable at the same time as timer 0) and a timer output can be used to trigger any other timer. The trigger used by each timer is configured independently as a timer output, shifter status flag, pin input, or an external trigger input. The trigger configuration is separate from pin configuration; you can perform it to configure input, output data, or output enable. See the chip-specific FLEXIO information for information on external trigger connections.

You must configure Timer Configuration (TIMCFG0 - TIMCFG7) before writing 1 to TIMCTL*n*[TIMOD].

75.3.2.1 Timer 8-bit Baud Counter mode

In 8-bit Baud Counter mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the baud rate of the shift clock and the upper 8 bits are used to configure the number of shift clock edges in the transfer. When the lower 8 bits decrement to zero, the timer output is toggled and the lower 8 bits reload from the compare register. The upper 8 bits decrement when the lower 8 bits become zero and decrement.

NOTE

A timer reset event in 8-bit Baud Counter mode only resets the lower 8-bit counter. The upper 8-bit counter is not affected and can decrement if the timer reset is configured to update the state of the timer output, which toggles as a result of the timer reset event.

A timer compare event occurs when the upper 8 bits equal zero and decrement. The timer status flag is set on a timer compare event.

75.3.2.2 Timer 8-bit High PWM mode

In 8-bit High PWM mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the timer output high period and the upper 8 bits are used to configure the timer output low period. The lower 8 bits decrement when the output is high. When the lower 8 bits become zero and decrement, the timer output is cleared and the lower 8 bits are reloaded from the compare register. The upper 8 bits decrement when the output is low. When the upper 8 bits become zero and decrement, the timer output is set and the upper 8 bits are reloaded from the compare register.

A timer compare event occurs when the upper 8 bits become zero and decrement. The timer status flag is set on a timer compare event.

75.3.2.3 Timer 16-bit Counter mode

In 16-bit Counter mode, you can use the 16-bit counter to configure either the baud rate of the shift clock (for example, TIMDEC[1:0] ≠ 10 or 11) or the number of shift clock edges in the transfer (for example, TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer compare event.

75.3.2.4 Timer 16-bit Counter Disable mode

In 16-bit Counter Disable mode, the 16-bit counter can be used to configure either the baud rate of the shift clock (for example, TIMDEC[1:0] ≠ 10 or 11) or the number of shift clock edges in the transfer (for example, TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer disable event.

75.3.2.5 Timer 8-bit Word Counter mode

In 8-bit Word Counter mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the number of shift clock edges in each word and the upper 8 bits are used to configure the number of words in the transfer. When the lower 8 bits decrement to zero, the timer output is toggled and the lower 8 bits reload from the compare register. The upper 8 bits only decrement when the lower 8 bits become zero and decrement.

A timer compare event occurs when the lower 8 bits become zero and decrement. The timer status flag is set when the upper 8 bits become zero and decrement.

75.3.2.6 Timer 8-bit Low PWM mode

In 8-bit Low PWM mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the timer output low period and the upper 8 bits are used to configure the timer output high period. The lower 8 bits decrement when the output is low. When the lower 8 bits become zero and decrement, the timer output is set and the lower 8 bits are reloaded from the compare

register. The upper 8 bits decrement when the output is high. When the upper 8 bits become zero and decrement, the timer output is cleared and the upper 8 bits are reloaded from the compare register.

A timer compare event occurs when the upper 8 bits become zero and decrement. The timer status flag is set on a timer compare event.

75.3.2.7 Timer enable and start functions

The following events occur when you configure TIMCTL*n*[TIMOD] for the desired mode and the condition configured by the timer enable (TIMCFG*n*[TIMENA]) is detected. When TIMCTL*n*[ONETIM] is 1, the timer status flag must be clear to generate a timer enable event; otherwise, the timer enable event is blocked. You can use this to enforce software intervention after each timer iteration:

- The timer counter loads the current value of the compare register and starts decrementing, as configured by TIMCFG*n*[TIMDEC].
- The timer output may update to its initial state depending on the configuration of TIMCFG*n*[TIMOUT]. Shifters that are controlled by this timer do not see this as a rising edge on the timer shift clock.
- Transmit shifters controlled by this timer either output their start bit value or load the shift register from the shift buffer and output the first bit, as configured by SHIFTCFG*n*[SSTART].

If the timer start bit is enabled, the timer counter reloads with the compare register on the first rising edge of the shift clock after the timer starts decrementing. If there is no falling edge on the shift clock before the first rising edge (for example, when TIMCFG*n*[TIMOUT] = 1), a shifter that is configured to shift on the falling edge and load on the first shift does not load correctly.

75.3.2.8 Timer decrement and reset functions

The timer generates the timer output and timer shift clock depending on the fields, TIMCTL*n*[TIMOD] and TIMCFG*n*[TIMDEC]. The shifter clock is either equal to the timer output (when TIMCFG*n*[TIMDEC] ≠ 10 or 11) or equal to the decrement clock (when TIMCFG*n*[TIMDEC] = 10 or 11). If you configure TIMCFG*n*[TIMDEC] to decrement from a pin or trigger, the timer decrements on both rising and falling edges.

If a timer is configured to decrement on the FLEXIO functional clock divided by 16 or 256 (when TIMCFG*n*[TIMDEC] = 100 or 101), then a common prescaler that is shared by all timers is used to generate the two divide ratios. This prescaler is reset when all timers are either idle or configured not to use the prescaler (TIMCFG*n*[TIMDEC] ≠ 100 or 101).

If you configure the timer to reset as determined by TIMCFG*n*[TIMRST], then the timer counter loads the current value of the compare register again. You can configure the timer output and timer shift clock to update on timer reset, as configured by TIMCFG*n*[TIMOUT]. If the time output toggles as a result of the timer reset, this can result in a timer shift clock edge. In 8-bit Baud Counter mode, this also decrements the upper 8 bits of the counter.

In general, when the timer counter decrements to zero, a timer compare event is triggered. The timer compare event causes:

- The timer counter to load the contents of the timer compare register.
- The timer output to toggle.
- Any configured transmit shift registers to load.
- Any configured receive shift registers to store.

Depending on the timer mode, the timer status flag may also be set.

75.3.2.9 Timer disable and stop functions

When the timer is configured to add a stop bit on each compare, the following additional events occur:

- Transmit shifters controlled by this timer output their stop bit value (if configured by SHIFTCFG*n*[SSTOP]).
- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by SHIFTCFG*n*[SSTOP].

- The timer counter reloads the current value of the compare register on the first rising edge of the shifter clock after the compare.

If you configure the timer to insert a stop bit on each compare, you must configure the transmit shifters to load on the first shift.

When the condition configured by timer disable (TIMCFG*n*[TIMDIS]) is detected, the following events occur:

- Timer counter reloads the current value of the compare register and starts decrementing as configured by TIMCFG*n*[TIMDEC].
- Timer output clears. Shifters that are controlled by this timer do not see this as a falling edge on the timer shift clock, but can generate a shift event if the timer shift clock otherwise generates one.
- Transmit shifters controlled by this timer output their stop bit value (if configured by SHIFTCFG*n*[SSTOP]).
- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by SHIFTCFG*n*[SSTOP].

If the timer stop bit is enabled, the timer counter continues decrementing until the next rising edge of the shift clock is detected, at which point it finishes decrementing. Although the timer output is forced low during the stop bit, the timer shift clock can toggle during the stop bit. The timer output does not generate shift events during the stop bit.

A timer enable condition can be detected in the same cycle as a timer disable condition (if timer stop bit is disabled), or on the first rising edge of the shift clock after the disable condition (if stop bit is enabled). When TIMCTL*n*[ONETIM] is 1, the timer status flag must be clear before the next timer enable condition is detected. When the timer is in the stop state condition, receive shift registers with stop bit enabled store the contents of the shift register into the shift buffer and verify the state of the input data on the configured shift edge. If there is no configured edge between the timer disable and the next rising edge of the shift clock, then the final store and verify do not occur.

75.3.3 Pin operation

The pin configuration for each timer and shifter can be set to use any FLEXIO pin with either polarity. You can configure each timer and shifter as an input, output data, output enable, or bidirectional output. A pin configured for output enable can be used as an open drain (with inverted polarity because the output enable assertion causes logic zero to be output on the pin) or to control the enable on the bidirectional output. You can configure any timer or shifter to control the output enable for a pin where the bidirectional output data is driven by another timer or shifter.

75.3.3.1 Parallel interface

You can configure shifters to use multiple FLEXIO pins simultaneously by using SHIFTCFG*n*[PWIDTH], which is used to configure the following settings of a shifter:

1. Number of bits shifted per shift clock.
2. Number of pins driven by the shifter per shift clock (only on shifters supporting parallel transmit—that is, SHIFTER0 and SHIFTER4.)
3. Number of pins sampled by the shifter per shift clock (only on shifters supporting parallel receive—that is, SHIFTER3 and SHIFTER7.)

When configured for parallel shift, either 4, 8, 16, or 32 bits can be shifted on every shift clock. If an adjacent shifter is selected as the input source (SHIFTCFG*n*[INSRC] = 1), the least significant 4, 8, 16, or 32 bits from the adjacent shifter are sampled on each shift clock.

For shifters supporting parallel receive (SHIFTER3, SHIFTER7), you can configure the shifter to sample multiple pins (INSRC = 0), with PWIDTH and PINSEL selecting the pins as FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL].

NOTE

If PWIDTH is less than the number of bits being shifted on each shift clock, then the most significant bits are masked with 0. For example, if PINSEL = 7 and PWIDTH = 6, then SHIFTER[31:24] samples {0,0,FXIO_D[12:7]} on each shift clock.

For shifters supporting parallel transmit (SHIFTER0, SHIFTER4), you can configure the shifter to drive multiple pins using SHIFTCTL*n*[PINCFG], with PWIDTH and PINSEL selecting the pins as follows: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL].

NOTE

If PWIDTH is less than the number of bits being shifted on each shift clock, then the most significant pins are not driven. For example, if PINSEL = 7 and PWIDTH = 6, then SHIFTER[5:0] drives only FXIO_D[12:7] on each shift clock.

75.3.3.2 Pin synchronization

When you configure a pin as an input (this includes a timer trigger configured as a pin input), the input signal is first synchronized with the FLEXIO clock before a timer or shifter could use the signal. This introduces a small latency of 0.5–1.5 FLEXIO clock cycles when using an external pin input to generate an output or control a shifter. This sets the maximum setup time at 1.5 FLEXIO clock cycles.

If an input is used by more than one timer or shifter, then the synchronization occurs once to ensure any edge is seen on the same cycle by all timers and shifters using that input.

NOTE

FLEXIO pins are also connected internally. Configuring a FLEXIO shifter or timer to output data on an unused pin makes an internal connection that allows other shifters and timers to use this pin as an input. This allows a shifter output to trigger a timer or a timer output to be shifted into a shifter. This path is also synchronized with the FLEXIO clock and therefore incurs a one-cycle latency.

When using a pin input as a timer trigger, timer clock, or shifter data input, the following synchronization delays occur:

- 0.5–1.5 FLEXIO clock cycles for an external pin
- One FLEXIO clock cycle for an internally driven pin

See Application information for timing considerations such as output valid time and input setup time for specific applications (SPI controller, SPI target, I2C controller, I2S controller, and I2S target).

75.3.3.3 Pin override

You can change the state of any FLEXIO pin at any time. Pin Output Enable (PINOUTE) configures any pin as an output and drives that pin with the value in Pin Output Data (PINOUTD).

Alias registers for PINOUTE and data registers also exist. Writing a logic 1 to an alias register updates the corresponding register fields in both PINOUTE and PINOUTD as follows:

- Pin Output Disable (PINOUTDIS) clears Pin Output Enable (PINOUTE) and Pin Output Data (PINOUTD).
- Pin Output Clear (PINOUTCLR) sets Pin Output Enable (PINOUTE) and clears Pin Output Data (PINOUTD).
- Pin Output Set (PINOUTSET) sets Pin Output Enable (PINOUTE) and Pin Output Data (PINOUTD).
- Pin Output Toggle (PINOUTTOG) sets Pin Output Enable (PINOUTE) and toggles Pin Output Data (PINOUTD).

75.3.3.4 Pin interrupt

You can read the state of any FLEXIO pin at any time and also configure any pin to set a status flag when either a rising or falling edge is detected on that pin. Additionally, you can configure the pin status flag to generate an interrupt.

75.3.4 Low-power modes

FLEXIO remains functional during low-power modes, if the FLEXIO functional clock remains enabled.

75.3.5 Debug mode

FLEXIO remains functional in Debug mode, provided the value of CTRL[DBGE] is 1.

75.3.6 Clocking

Table 521. FLEXIO clocks

Clock	Description
Functional clock	Is asynchronous to the bus clock and can remain enabled in low-power modes. You must enable the FLEXIO functional clock before accessing any of the FLEXIO registers. Provided the FLEXIO functional clock is at least equal to the bus clock, you can configure CTRL[FASTACC] to support fast register accesses.
Bus clock	Is used only for bus accesses to the control and configuration registers.

75.3.7 Reset

Table 522. FLEXIO reset types

Reset	Description
Chip reset	Resets the FLEXIO logic and registers to their default states on chip reset.
Software reset	Resets, using CTRL[SWRST], all logic and registers to their default states, except for the Control register.

75.3.8 Interrupts and DMA requests

The following table shows the status flags that generate the FLEXIO interrupt and DMA requests.

Table 523. FLEXIO interrupts and DMA requests

Flag	Description	Interrupt	DMA request	Low-power wake-up
SHIFTSTAT[SSF]	Shifter status flag	Y	Y	Y
SHIFTERR[SEF]	Shifter error flag	Y	N	Y
TIMSTAT[TSF]	Timer status flag	Y	Y	Y
PINSTAT[PSF]	Pin status flag	Y	N	Y
TRGSTAT[ETSF]	External trigger status flag	Y	N	Y

75.3.9 Peripheral triggers

The connection between FLEXIO peripheral triggers and other peripherals is device-specific.

75.3.9.1 Output triggers

Each FLEXIO timer generates an output trigger equal to the timer output. The output trigger is not affected by the timer pin polarity configuration.

75.3.9.2 Input trigger

FLEXIO supports multiple external trigger inputs that can be used to trigger one or more FLEXIO timers. If a rising edge is detected on an external trigger when FLEXIO is enabled, then the external trigger status flag is set. The external triggers are synchronized to the FLEXIO functional clock and must assert for at least two cycles of the FLEXIO functional clock to be sampled correctly.

75.4 External signals

Table 524. External signals

Signal	Description	Direction
FXIO_D*n* (*n* = 0...31)	Bidirectional FLEXIO shifter and timer pin	Input or output

75.5 Initialization

Perform the following procedure to initialize FLEXIO registers:

1. Enable FLEXIO by writing 1 to CTRL[FLEXEN].
2. Configure shift registers for the given application. It is recommended to write to Shifter Configuration (SHIFTCFG0 - SHIFTCFG7) before writing to the corresponding register, Shifter Control (SHIFTCTL0 - SHIFTCTL7).
3. Configure timer registers for the given application. It is recommended to write to Timer Compare (TIMCMP0 - TIMCMP7) and Timer Configuration (TIMCFG0 - TIMCFG7) before writing to the corresponding register, Timer Control (TIMCTL0 - TIMCTL7).
4. Enable interrupts and/or DMA requests, as appropriate, for the given application.
5. Write transmit data to initiate a transfer (depending on the given application).

75.6 Application information

This section provides examples for a variety of FLEXIO module applications. See FLEXIO register descriptions for more information.

75.6.1 UART transmit

UART transmit can be supported using one timer, one shifter, and one pin (two pins, if supporting CTS). The start and stop bit insertion is handled automatically, and multiple transfers are supported using the DMA controller. The timer status flag is used to indicate when the stop bit of each word is transmitted.

Break and idle characters require software intervention. Before transmitting a break or idle character, you must modify SHIFTCFG*n*[SSTART] and SHIFTCFG*n*[SSTOP] to transmit the required state, and the data to transmit must equal FFh or 00h. Supporting a second stop bit requires the stop bit to be inserted into the data stream using software (and increasing the number of bits to transmit). When performing byte writes to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) (or Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) for transmitting MSB first), the rest of the register remains unaltered. This allows an address mark bit or additional stop bit to remain undisturbed.

NOTE

FLEXIO does not support automatic insertion of parity bits.

Table 525. UART transmit configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTL*n*	0003_0002h	Configure transmit using timer 0 on the positive edge of clock with output data on pin 0. You can configure the PINPOL field to invert output data, or support open-drain by writing 1h to the PINPOL and PINCFG fields.

Table continues on the next page...

Table 525. UART transmit configuration (continued)

Register	Value	Configuration
TIMCMP*n*	0000_0F01h	Configure 8-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0000_2222h	Configure start bit, stop bit, enable on trigger asserted and disable on compare. You can support CTS by configuring the TIMENA field as 3h.
TIMCTL*n*	01C0_0001h	Configure the dual 8-bit counter using the shifter 0 status flag as an inverted internal trigger source. To support CTS, configure the PINSEL (for pin 1) and PINPOL fields as 1h.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer. Use the shifter status flag to indicate when data can be written using an interrupt or a DMA request. Write to SHIFTBUFBBS[7:0] instead to support MSB first transfer.

The following table shows an alternative configuration that supports slower baud rates. This configuration requires two timers.

Table 526. UART transmit configuration for slow baud rate

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTL*n*	0003_0002h	Configure transmit using timer 0 on the positive edge of clock with output data on pin 0. Invert output data by writing 1 to the PINPOL field. Support open-drain by configuring the PINPOL and PINCFG fields as 1h.
TIMCMP*n*	0000_000Fh	Configure for 8-bit transfer, and configure TIMCMP[15:0] as (number of bits × 2) - 1.
TIMCFG*n*	0030_2622h	Configure start bit, stop bit, enable on trigger rising edge, decrement on trigger and disable on compare.
TIMCTL*n*	0740_0003h	Configure the 16-bit counter using the timer 1 output as an internal trigger source.
TIMCMP(*n* + 1)	0000_0001h	Configure baud rate of divide by 4 of the FLEXIO clock, and configure

Table continues on the next page...

Table 526. UART transmit configuration for slow baud rate (continued)

Register	Value	Configuration
		TIMCMP[15:0] as (baud rate divider ÷ 2) - 1.
TIMCFG(*n* + 1)	0000_1200h	Configure enable on trigger asserted and disable on timer 0 disable. You can configure the TIMEN field as 3h to support CTS.
TIMCTL(*n* + 1)	01C0_0003h	Configure the 16-bit counter using the shifter 0 status flag as an inverted internal trigger source. You can support CTS by configuring the PINSEL (for pin 1) and PINPOL fields as 1h.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer. Use the shifter status flag to indicate when data can be written using an interrupt or a DMA request. Write to SHIFTBUFBBS[7:0] instead to support MSB first transfer.

75.6.2 UART receive

UART receive can be supported using one timer, one shifter, and one pin (two timers and two pins, if supporting RTS). The start and stop bit verification is handled automatically and multiple transfers are supported using the DMA controller. The timer status flag is used to indicate when the stop bit of each word is received.

FLEXIO does not support triple voting of the received data, which is sampled only once in the middle of each bit. You can use a timer to implement a glitch filter on the incoming data and a different timer to detect an idle line of programmable length. Break characters cause the error flag to set, and the shifter buffer register returns 00h.

NOTE

FLEXIO does not support automatic verification of parity bits.

Table 527. UART receiver configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTL*n*	0080_0001h	Configure receive using timer 0 on the negative edge of clock with input data on pin 0. You can invert input data by writing 1 to the PINPOL field.
TIMCMP*n*	0000_0F01h	Configure 8-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0204_2422h	Configure start bit, stop bit, enable on pin positive edge and disable on

Table continues on the next page...

Table 527. UART receiver configuration (continued)

Register	Value	Configuration
		compare. Enable resynchronization to received data with TIMOUT = 2h and TIMRST = 4h.
TIMCTL*n*	0000_0081h	Configure the dual 8-bit counter using the inverted pin 0 input.
SHIFTBUF*n*	Data to receive	You can read received data from SHIFTBUFBYS[7:0]. Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from SHIFTBUFBIS[7:0] instead to support MSB first transfer.

The UART receiver with RTS configuration uses a second timer to generate the RTS output. RTS asserts when the start bit is detected and negates when the data is read from the shifter buffer register. If no start bit is detected when the RTS is asserted, the received data is ignored.

Table 528. UART receiver with RTS configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTL*n*	0080_0001h	Configure receive using timer 0 on the negative edge of clock with input data on pin 0. Invert input data by writing 1 to the PINPOL field.
TIMCMP*n*	0000_0F01h	Configure 8-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0204_2522h	Configure start bit, stop bit, enable on pin positive edge with trigger asserted and disable on compare. Enable resynchronization to received data with TIMOUT = 2h and TIMRST = 4h.
TIMCTL*n*	02C0_0081h	Configure dual 8-bit counter using the inverted pin 0 input. Trigger is internal using the inverted pin 1 input.
TIMCMP(*n* + 1)	0000_FFFFh	Never compare.
TIMCFG(*n* + 1)	0030_6100h	Enable on timer *n* enable and disable on the trigger falling edge. Decrement on trigger to ensure no compare.
TIMCTL(*n* + 1)	0143_0003h	Configure 16-bit counter and output on pin 1. Trigger is internal using the shifter 0 flag.

Register	Value	Configuration
SHIFTBUF*n*	Data to receive	You can read received data using SHIFTBUFBYS[7:0]. Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from SHIFTBUFBIS[7:0] instead to support MSB first transfer.

75.6.3 SPI controller

SPI Controller mode can be supported using two timers, two shifters, and four pins. Using the DMA controller, either CPHA = 0 or CPHA = 1 and transfers can be supported. For CPHA = 1, the chip select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The stop bit is used to guarantee a minimum of one clock cycle between the target chip select negating and before the next transfer. To initiate each transfer, either the core or DMA writes to the transmit buffer.

NOTE

Because of synchronization delays, the setup time for the serial input data is 1.5 FLEXIO clock cycles. This means the maximum baud rate is divide by 4 of the FLEXIO clock frequency.

Table 529. SPI controller (CPHA = 0) configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0000h	Start and stop bit disabled.
SHIFTCTL*n*	0083_0002h	Configure transmit using timer 0 on the negative edge of clock with output data on pin 0.
SHIFTCFG(*n* + 1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n* + 1)	0000_0101h	Configure receive using timer 0 on the positive edge of clock with input data on pin 1.
TIMCMP*n*	0000_3F01h	Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0100_2222h	Configure start bit, stop bit, enable on trigger high and disable on compare; initial clock state is logic 0.
TIMCTL*n*	01C3_0201h	Configure dual 8-bit counter using the pin 2 output (shift clock), with shifter 0 flag as the inverted trigger. Write 1 to the PINPOL field to invert the output shift clock.
TIMCMP(*n* + 1)	0000_FFFFh	Never compare.

Register	Value	Configuration
		PINPOL field to invert the output shift clock, and set the TIMDIS field as 3 to keep target select asserted for as long as there is data in the transmit buffer.
TIMCMP(*n* + 1)	0000_FFFFh	Never compare.
TIMCFG(*n* + 1)	0000_1100h	Enable when timer 0 is enabled and disable when timer 0 is disabled.
TIMCTL(*n* + 1)	0003_0383h	Configure 16-bit counter (never compare) using inverted pin 3 output (as target select).
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUF. Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.

75.6.4 SPI target

SPI Target mode can be supported using one timer, two shifters, and four pins. Either CPHA = 0 or CPHA = 1 can be supported and transfers can be supported using the DMA controller. For CPHA = 1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

You must write the transmit data to the transmit buffer register before the external target select asserts; otherwise, the shifter error flag is set.

NOTE

Because of synchronization delays, the output valid time for the serial output data is 2.5 FLEXIO clock cycles. This means the maximum baud rate is divide by 6 of the FLEXIO clock frequency.

Table 531. SPI target (CPHA = 0) configuration

Read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.

75.6.5 I2C controller

I2C Controller mode can be supported using two timers, two shifters, and two pins. One timer is used to generate the SCL output and another one is used to control the shifters. The two shifters that are used to transmit and receive for every word, when receiving the transmitter, must transmit FFh to 3-state the output. FLEXIO inserts a stop bit after every word to generate and verify the ACK or NACK. FLEXIO waits for the first write to the transmit data buffer before enabling SCL generation. Data transfers can be supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The first timer generates the bit clock for the entire packet (start to repeated start or stop condition), so you must program the compare register with the total number of clock edges in the packet (minus one). The timer supports clock stretching using the reset counter when pin is equal to output. However, this increases both the clock high and clock low periods by at least one FLEXIO clock cycle each. The second timer uses the SCL input pin to control the transmit and receive shift registers. This enforces an SDA data hold time by an extra two FLEXIO clock cycles.

Both the transmit and receive shifters must be serviced for each word in the transfer. The transmit shifter must transmit FFh when receiving, and the receive shifter returns the data present on the SDA pin. The transmit shifter loads one additional word on the last falling edge of the SCL pin. When generating a stop condition or a repeated start condition, this word must be 00h and FFh, respectively. During the last word of a controller-receiver transfer, you must set the transmit SHIFTCFG*n*[SSTOP] field to generate a NACK.

The receive shift register asserts an error interrupt if a NACK is detected, but you are responsible for generating the stop or repeated start condition. If a NACK is detected during controller-transmit, the interrupt routine must immediately write 00h (when generating a stop condition) or FFh (when generating a repeated start condition) to the transmit shifter register. You must wait for

the next rising edge on SCL before disabling both timers. The transmit shifter must be disabled after the setup delay for a repeated start or stop condition.

NOTE

Because of synchronization delays, the data valid time for the transmit output is two FLEXIO clock cycles. This means the maximum baud rate is divide by 6 of the FLEXIO clock frequency.

To guarantee SDA hold time, the I2C controller data valid is delayed by two cycles because the clock output is passed through a synchronizer before clocking the transmit or receive shifter. Because the SCL output is synchronous with FLEXIO clock, the synchronization delay is one cycle, and then an additional cycle is involved to generate the output.

Table 533. I2C controller configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Start bit enabled (logic 0) and stop bit enabled (logic 1).
SHIFTCTL*n*	0101_0082h	Configure transmit using timer 1 on the rising edge of clock with inverted output enable (open-drain output) on pin 0.
SHIFTCFG(*n* + 1)	0000_0020h	Start bit disabled and stop bit enabled (logic 0) for ACK or NACK detection.
SHIFTCTL(*n* + 1)	0180_0001h	Configure receive using timer 1 on the falling edge of clock with input data on pin 0.
TIMCMP*n*	0000_2501h	Configure 2 word transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of words × 18) + 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0102_2222h	Configure start bit, stop bit, enable on trigger high, disable on compare, reset if output equals pin. Initial clock state is logic 0 and is not affected by reset.
TIMCTL*n*	01C1_0101h	Configure dual 8-bit counter using pin 1 output enable (SCL open-drain), with the shifter 0 flag as the inverted trigger.
TIMCMP(*n* + 1)	0000_000Fh	Configure 8-bit transfer. Set TIMCMP[15:0] as (number of bits x 2) - 1.
TIMCFG(*n* + 1)	0020_1112h	Enable when timer 0 is enabled; disable when timer 0 is disabled. Enable start bit and stop bit at the end of each word and decrement on pin input.
TIMCTL(*n* + 1)	01C0_0183h	Configure 16-bit counter using inverted pin 1 input (SCL).
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUFBBS[7:0]. Use the shifter

		status flag to indicate when data can be written using interrupt or DMA request.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from SHIFTBUFBIS[7:0]. Use the shifter status flag to indicate when data can be read using interrupt or DMA request.

75.6.6 I2S controller

I2S Controller mode can be supported using two timers, two shifters, and four pins. One timer is used to generate the bit clock and control the shifters and another timer is used to generate the frame sync. FLEXIO waits for the first write to the transmit data buffer before enabling bit clock and frame sync generation. Data transfers are supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The bit clock frequency is an even integer divide of the FLEXIO clock frequency. The initial frame sync assertion occurs at the same time as the first bit clock edge. The timer uses the start bit to ensure that the frame sync is generated one clock cycle before the first output data.

NOTE

Because of synchronization delays, the setup time for the receiver input is 1.5 FLEXIO clock cycles. This means that the maximum baud rate is divide by 4 of the FLEXIO clock frequency.

Table 534. I2S controller configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0001h	Load transmit data on first shift and stop bit disabled.
SHIFTCTL*n*	0003_0002h	Configure transmit using timer 0 on the rising edge of clock with output data on pin 0.
SHIFTCFG(*n* + 1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n* + 1)	0080_0101h	Configure receive using timer 0 on the falling edge of clock with input data on pin 1.
TIMCMP*n*	0000_3F01h	Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0000_0202h	Configure start bit, enable on trigger high and never disable. Initial clock state is logic 1.
TIMCTL*n*	01C3_0281h	Configure dual 8-bit counter using inverted pin 2 output (bit clock), with shifter 0 flag as the inverted trigger.

Table continues on the next page...

Table 534. I2S controller configuration (continued)

Register	Value	Configuration
		Write 0 to the PINPOL field to invert the polarity of the output shift clock.
TIMCMP(*n* + 1)	0000_007Fh	Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:0] as (number of bits × baud rate divider) ÷ 1.
TIMCFG(*n* + 1)	0000_0100h	Enable when timer 0 is enabled and never disable.
TIMCTL(*n* + 1)	0003_0383h	Configure 16-bit counter using inverted pin 3 output (as frame sync). Write 0 to the PINPOL field to invert the polarity of the output frame sync.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) instead to support LSB first transfer.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) instead to support LSB first transfer.

75.6.7 I2S target

I2S Target mode can be supported using three timers, two shifters, and four pins. For single transmit and single receive, other combinations of transmit and receive are possible.

The transmit data must be written to the transmit buffer register before the external frame sync asserts, otherwise the shifter error flag is set.

NOTE

Because of synchronization delays, the output valid time for the serial output data is 2.5 FLEXIO clock cycles. This means the maximum baud rate is divide by 6 of the FLEXIO clock frequency.

The output valid time of I2S target is maximum 2.5 cycles because there is a maximum 1.5 cycle delay on the clock synchronization, plus one cycle to output the data.

Timer 2 detects the falling edge of frame sync (start of new frame) and asserts output until the rising edge of bit clock (when the frame sync is normally sampled). Timer 0 detects the rising edge of bit clock with timer 2 output asserted and asserts output for length of frame. Timer 1 detects the falling edge of bit clock with timer 0 output asserted and controls shift registers for 32-bit transfers.

Table 535. I2S target configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0000h	Start and stop bit disabled.
SHIFTCTL*n*	0103_0002h	Configure transmit using timer 1 on the rising edge of shift clock with output data on pin 0.
SHIFTCFG(*n* + 1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n* + 1)	0180_0101h	Configure receive using timer 1 on the falling edge of shift clock with input data on pin 1.
TIMCMP*n*	0000_007Fh	Configure two 32-bit transfers per frame. Set TIMCMP[15:0] as (number of bits × 4) - 1.
TIMCFG*n*	0020_2500h	Configure enable on pin rising edge (inverted bit clock) with trigger high (timer 2) and disable on compare. Initial clock state is logic 1 and decrements on pin input (bit clock).
TIMCTL*n*	0B40_0203h	Configure 16-bit counter using pin 2 input (bit clock), with timer 2 output as the trigger.
TIMCMP(*n* + 1)	0000_003Fh	Configure 32-bit transfers. Set TIMCMP[15:0] as (number of bits × 2) - 1.
TIMCFG(*n* + 1)	0020_2500h	Configure enable on pin (bit clock) rising edge with trigger (timer 0) high and disable on compare. Initial clock state is logic 1 and decrement on pin input (bit clock).
TIMCTL(*n* + 1)	0340_0283h	Configure 16-bit counter using inverted pin 2 input (bit clock), with timer 0 output as the trigger.
TIMCMP(*n* + 2)	0000_0000h	Compare on zero (first edge).
TIMCFG(*n* + 2)	0020_6400h	Configure enable on inverted pin (frame sync) rising edge and disable on trigger falling edge (bit clock). Initial clock state is logic 1 and decrement on inverted pin input (frame sync).
TIMCTL(*n* + 2)	04C0_0383h	Configure 16-bit counter using inverted pin 3 input (frame sync), with pin 2 inverted input (bit clock) as the trigger.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be written

Table continues on the next page...

Register	Value	Configuration
		using interrupt or DMA request. Write to the SHIFTBUF register instead to support LSB first transfer.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from the SHIFTBUF register instead to support LSB first transfer.

75.6.8 SENT receiver

The SENT receiver can be supported by using one timer and one pin. The timer is configured as Input-Capture mode, and captures the counter value at the falling edge of the pin input. After the counter value is captured, the counter is automatically restarted from counter value 0. Therefore, the captured value always indicates the period between the previous falling edge and current falling edge. You can configure the CPU interrupt or DMA trigger at each capture of the counter. The CPU software performs the entire SENT frame decoding with the latest tick width adjustment.

Table 536. SENT receiver configuration

Register	Value	Configuration
TIMCMP*n*	—	Stores counter value at the falling edge of the pin.
TIMCFG*n*	0000_6000h	Timer is always enabled. It is disabled on trigger falling edge, decrement counter on FLEXIO clock.
TIMCTL*n*	0040_0007h	Single 16-bit input capture mode. The PINSEL field selects the timer pin input and output. Timer pin output disabled, internal trigger selected, select pin 0 as trigger.

75.6.9 Camera interface

Camera interface can be supported using one timer, one or more shifters, and multiple pins. Multiple transfers can be supported using the DMA controller.

The example configuration shown in the following table describes the FLEXIO configuration for interfacing with an 8-bit CMOS sensor with PCLK, VSYNC, HREF, and D[7:0] outputs. The example uses a 128-bit buffer to capture 16 pixels of image data before an interrupt or DMA transfer. You can use a bigger or smaller buffer depending on system DMA performance and FLEXIO resource usage by other applications.

NOTE

You can use additional timers to track the number of pixels per row and number of rows per frame, or HREF or VSYNC can be assigned as GPIO interrupts for software tracking.

Table 537. Camera interface configuration for 8-bit CMOS sensor

Register	Value	Configuration
SHIFTCFG*n*...*n*+2[1]	0007_0100h	Configure 8-bit parallel shift in from adjacent shifter.
SHIFTCFG*n*+3	0007_0000h	Configure 8-bit parallel shift in from pins FXIO_D[7:0] (D[7:0]).
SHIFTCTL*n*...*n*+3	0080_0001h	Configure receive using timer 0 on the negative edge of clock.
TIMCMP*n*	0000_001Fh	Configure 16 pixel (8 bits/pixel × 16 pixels = 128 bits) transfer. Set TIMCMP[15:0] as (number of pixels × 2) - 1.
TIMCFG*n*	0120_6600h	Configure enable on trigger (HREF) rising edge and disable on trigger falling edge. Initial shift clock state is logic 0 and decrement on PCLK input.
TIMCTL*n*	12C0_0803h	Configure 16-bit counter using FXIO_D[8] input (PCLK), with FXIO_D[9] input (HREF) as the inverted trigger.
SHIFTBUF*n*...*n*+3	Data to receive	Received data can be read from SHIFTBUF*n*...*n*+3. Use the shifter status flag to indicate when data can be read using interrupt or DMA request.

1. *n* = 0 or 4

75.6.10 Motorola 68K and Intel 8080 bus interface

Motorola 68K and Intel 8080 bus are two parallel interfaces commonly used by smart and asynchronous LCD controllers. With GPIO, FLEXIO can drive these interfaces using one timer and one shifter. Additional shifters can be used to support large transfers via the DMA controller.

The following table provides an example of how to drive a 16-bit 68K or 8080 bus. For an 8080 bus, two GPIOs are used to drive the nCS and RS pins. For a 68K bus, an additional GPIO is required to drive the RDWR pin.

Table 538. Motorola 68K and Intel 8080 write configuration

Register	Value	Configuration
SHIFTCFG0...3	000F_0100h	Configure 16-bit parallel shift in from the adjacent shifter.
SHIFTCFG0	000F_0000h	Configure 16-bit parallel shift in from pin.
SHIFTCTL0...0	0080_0001h	Configure receive using timer 0 on the negative edge of clock with data input from FXIO_D[15:0].
TIMCMP0	0000_0101h (1 beat) 0000_1F01h (16 beats)	Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] = (number of beats × 2) - 1, and set TIMCMP[7:0] = (baud rate divider ÷ 2) - 1.
TIMCFG0	0000_2220h	Configure stop_bit. Enable on trigger high and disable on compare. Timer output high on enable.
TIMCTL0	1DC3_1001h (Motorola 68K, 1 beat) 01C3_1001h (Motorola 68K, 16 beats) 1DC3_1181h (Intel 8080, 1 beat) 01C3_1181h (Intel 8080, 16 beats)	Configure dual 8-bit counter using either FXIO_D[16] output (EN pin for 68K) or FXIO_D[17] output (nRD pin for 8080), with shifter 0 flag (1-beat) or shifter 0 flag (16 beats) as the inverted trigger.
SHIFTBUF0...0	Data received	Received data can be read from SHIFTBUF0 (1 beat) or SHIFTBUF0...0

Table continues on the next page...

Table 539. Motorola 68K and Intel 8080 read configuration (continued)

Register	Value	Configuration
		(16 beats). Use the shifter status flag to indicate when data can be read using interrupt or DMA request.

In general, any operation to a 68K or 8080 bus target begins with a register write cycle followed by one or more data read or write cycles. To accomplish this, perform the following procedure:

1. Configure FLEXIO with 1-beat write configuration.
2. Configure GPIO to assert the nCS and RS pins (and deassert the RDWR pin for 68K).
3. Write register index data to SHIFTBUF0[15:0].
4. Configure GPIO to deassert the RS pin (and assert the RDWR pin for 68K data read).
5. Configure FLEXIO with the desired read or write configuration (1 or 16 beats).
6. Use the shifter status flag to trigger interrupt or DMA driven data transfers to and from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7).
7. Configure GPIO to deassert the nCS pin.

75.6.11 Low-power state machine

Table 540 shows an example of a hypothetical state machine to illustrate the flexibility allowed in Shifter State mode.

In this example, FLEXIO waits for the FXIO_D[2] pin to assert and then drives a complementary square wave output at a frequency of FLEXIO_CLK/131072 on the FXIO_D[1:0] pins while the comparator output is asserted. This assumes that the comparator is connected to external trigger 15. See the chip-specific FLEXIO information for actual FLEXIO trigger mappings. Figure 520 shows the states and transitions implemented by this example.

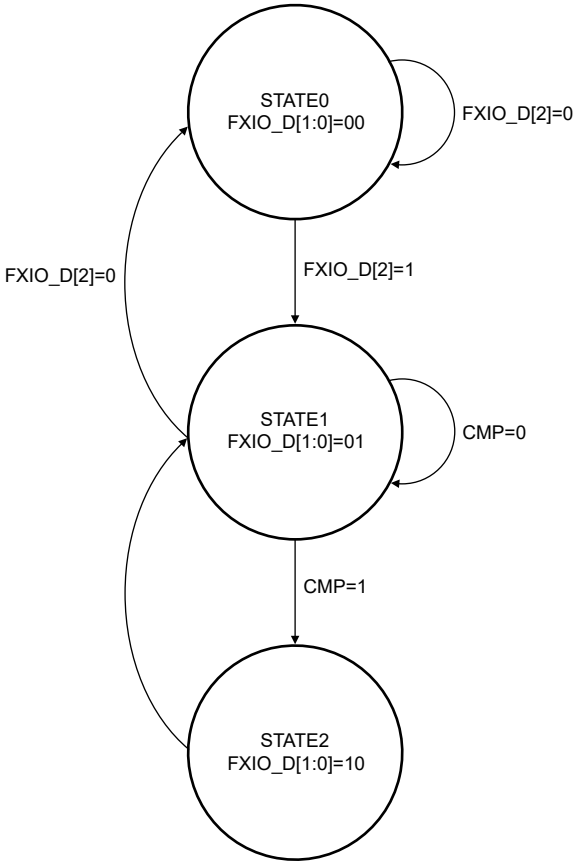

Figure 520. State diagram

Table 540. State machine configuration

Register	Value	Configuration
SHIFTCFG0...2	0000_0003h	Enable FXIO_D[1:0] as outputs.
SHIFTCTL0	0080_0206h	Configure for State mode using FXIO_D[4:2] as inputs to select next state and timer 0 output low to trigger next state.
SHIFTBUF0	0020_8208h	State0: Drive FXIO_D[1:0] = 00; transition to state0 if FXIO_D[2] = 0, state1 if FXIO_D[2] = 1.
SHIFTCTL1	0000_0206h	Configure for State mode using FXIO_D[4:2] as inputs to select next state and timer 0 output high to trigger next state.
SHIFTBUF1	0140_8408h	State1: Drive FXIO_D[1:0]=01; transition to state0 if FXIO_D[2]=0, state1 if CMP = 0, state2 if CMP = 1 (FXIO_D[3]=1).

Table continues on the next page...

Table 540. State machine configuration (continued)

Register	Value	Configuration
SHIFTCTL2	0080_0206h	Configure for State mode using FXIO_D[4:2] as inputs to select next state and timer 0 output low to trigger next state.
SHIFTBUF2	0224_9249h	State2: Drive FXIO_D[1:0] = 10, transition to state1 with timer 0 output low.
TIMCMP0	0000_FFFFh	Configure baud rate of divide by 131072 of the FLEXIO clock. Set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG0	0000_0000h	Configure timer always enabled.
TIMCTL0	0000_0003h	Configure single 16-bit counter.
TIMCFG1	0010_7600h	Configure timer enabled on trigger rising edge, disabled on trigger falling edge, decrement on trigger edge.
TIMCTL1	0F03_0303h	Configure timer output enabled on FXIO_D[3], external trigger 15 (comparator output) selected.

75.6.12 Keypad interface

The keypad interface can support a 3 × 4 keypad matrix using three timers and three shifters, although a larger matrix can be supported using additional shifters. The configuration is designed for four columns configured as active low open-drain pins and three rows configured as input pins with pull-up resistors enabled.

One shifter is configured in Logic mode to assert its output when any of the row inputs are low, indicating a key is pressed. Use a timer to filter the shifter output to ensure that the key is pressed for a minimum amount of time before performing the column scan.

A different shifter is configured for parallel transmit. Use this shifter to scan each column when a keypress is detected. When not scanning, the shifter output is configured to assert all active low open-drain column outputs to detect any keypress. Use a dedicated timer to control the transmit shifter.

The last shifter is configured for parallel receive. Use this shifter to capture the result of the column scanning so that you can decode which key (or keys) was pressed. This configuration captures the state of both row and column pins for each scan, although the row state can also be deduced by the shift order. Use a dedicated timer to control the receive shifter, which shifts at half the frequency of the transmit shifter.

When the result of the key scan is available in the receive shifter register, FLEXIO continues to monitor the row inputs and can trigger multiple scans from a single keypress. To support debouncing, you can decide how many consecutive scans must be considered as a single keypress.

NOTE

Because the pins used in Logic mode are fixed per shifter and the shifters that support parallel shifts are limited, this configuration is restricted to what pins and shifters it can use. Increasing the matrix beyond four-row inputs requires multiple shifters in Logic mode. Increasing beyond four-column outputs requires concatenating transmit shifters to create a larger shift register.

Table 541. Keypad interface configuration

Register	Value	Configuration
SHIFTCFG0	0003_0032h	Start bit enabled (logic 0) and stop bit enabled (logic 1), configured for 4-bit shift.
SHIFTCTL0	0101_0402h	Configure transmit using timer 1 on the rising edge of clock generating open-drain output on pins[7:4] (column outputs).
SHIFTBUF0	0804_0201h	Static data containing the column scan pattern; each column is scanned one-hot with dead time in between.
SHIFTCFG1	0000_0020h	In Logic mode, mask input 3.
SHIFTCTL1	0000_0007h	Configure Logic mode.
SHIFTBUF1	07FF_07FFh	Static data configuring Logic mode LUT. Output asserts if pins [3:1] are logic 0.
SHIFTCFG3	0007_0000h	Configured for 8-bit shift.
SHIFTCTL3	0280_0001h	Configure receive using timer 2 on falling edge of clock with input data on pins [7:0] (both rows and columns; pin 0 is don't care).
TIMCMP0	0000_00ffh	Configure prescanning glitch filter to 256 FLEXIO clock cycles. For different filter cycles, configure TIMCMP[15:0] as (filter cycles) - 1.
TIMCFG0	0103_6600h	Configure enable on trigger rising edge and disable on trigger falling edge. Initial clock state is logic 0 and is not affected by reset.
TIMCTL0	0540_0003h	Configure 16-bit counter using the shifter 1 flag (logic state) as trigger.
TIMCMP1	0000_0F3Fh	Configure eight shifts (twice for each column) at column scan rate of divide by 128. For a different scan frequency, define TIMCMP[7:0] as (scan divider ÷ 2) - 1.
TIMCFG1	0020_2622h	Enable on trigger rising edge, disable on compare. Start and stop bits are enabled.
TIMCTL1	0340_0001h	Configure dual 8-bit counter using timer 0 output as the trigger.
TIMCMP2	0000_0801h	Configure four shifts at half the frequency of the timer 1 trigger.

Table continues on the next page...

Table 541. Keypad interface configuration (continued)

Register	Value	Configuration
TIMCFG2	0110_2100h	Enable on timer 1 enable, disable on compare, decrement on trigger input with output initially negated, and not affected by reset.
TIMCTL2	0740_0001h	Configure dual 8-bit counter using timer 1 output as the trigger.
SHIFTBUF3	Keypad scan result	Keypad scan result can be read from SHIFTBUF3. Each byte is the result of one scan with both row and column pin state from the scan (pin 0 is not used). Use the shifter status flag to indicate when data can be written using interrupt or DMA request.

75.7 Memory map and registers

75.7.1 FLEXIO register descriptions

NOTE

Invalid register accesses, which include reading a write-only register, writing to a read-only register, or accessing an invalid address, result in a bus error.

31-0 PDI	Pin Data Input Indicates the input data on each of the FLEXIO pins.

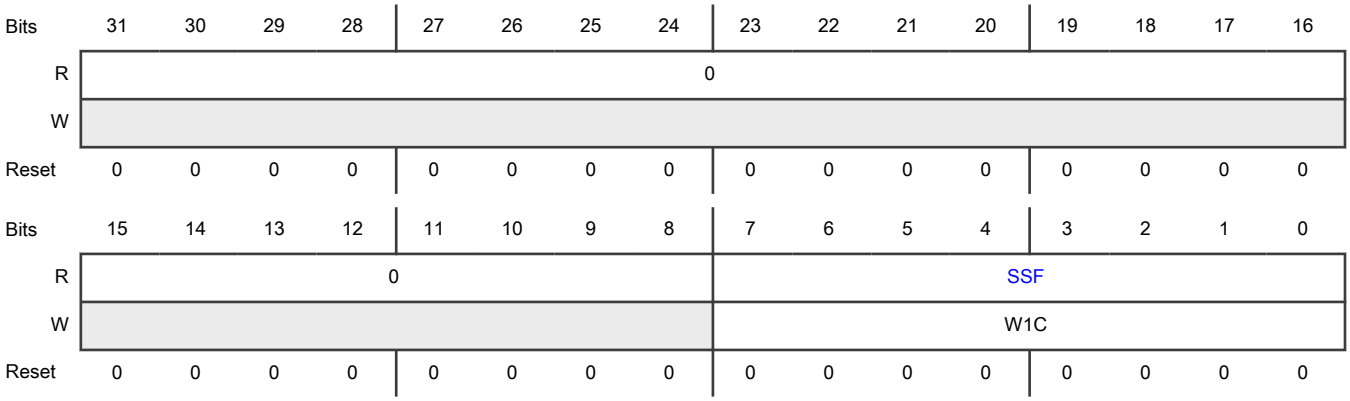
75.7.1.6 Shifter Status (SHIFTSTAT)

Offset

Register	Offset
SHIFTSTAT	10h

Function
Contains shifter status flags.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SSF	Shifter Status Flag Indicates the shifter status. This flag is updated in one of the following cases: • If SHIFTCTL*n*[SMOD] = 001b (Receive mode), the status flag is set when SHIFTBUF is loaded with data from the shifter (SHIFTBUF is full). The status flag is cleared when you read Shifter Buffer (SHIFTBUF0 - SHIFTBUF7).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If SHIFTCTL*n*[SMOD] = 010b (Transmit mode), the status flag is set when SHIFTBUF data is transferred to the shifter (SHIFTBUF is empty) or when SHIFTCTL*n*[SMOD] is initially configured as 010b (Transmit mode). The status flag is cleared when you write to the SHIFTBUF register. • If SHIFTCTL*n*[SMOD] = 100b (Match Store mode), the status flag is set when a match occurs between SHIFTBUF and the shifter. The status flag is cleared when you read the SHIFTBUF register. • If SHIFTCTL*n*[SMOD] = 101b (Match Continuous mode), the status flag returns the current match result between SHIFTBUF and the shifter. You cannot clear the status flag by reading the SHIFTBUF register. • If SHIFTCTL*n*[SMOD] = 110b (State mode), the status flag for a shifter sets when it is selected by the current state pointer. • If SHIFTCTL*n*[SMOD] = 111b (Logic mode), the status flag returns the current value of the programmable logic block output. You can clear this status flag by writing a logic one to the flag for all modes except Match Continuous mode, State mode, and Logic mode. **NOTE** This field behaves differently for register reads and writes. When reading 0000_0000b - Clear 0000_0001b - Set When writing 0000_0000b - No effect 0000_0001b - Clear the flag

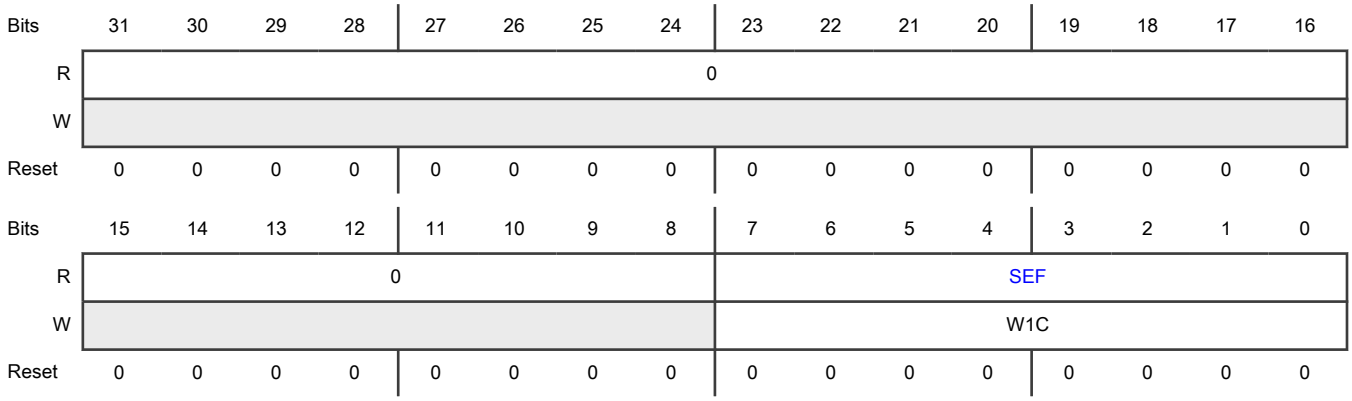
75.7.1.7 Shifter Error (SHIFTERR)

Offset

Register	Offset
SHIFTERR	14h

Function
Reports shifter errors.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SEF	Shifter Error Flag Indicates shifter error flag status. This flag is set when one of the following events occurs: • If SHIFTCTL*n*[SMOD] = 001b (Receive mode), it indicates that either the shifter is ready to store new data into SHIFTBUF before the previous data is read from SHIFTBUF (SHIFTBUF overrun), or the received start or stop bit does not match the expected value. • If SHIFTCTL*n*[SMOD] = 010b (Transmit mode), it indicates that the shifter is ready to load new data from SHIFTBUF before new data is written into SHIFTBUF (SHIFTBUF underrun). • If SHIFTCTL*n*[SMOD] = 100b (Match Store mode), it indicates the occurrence of a match event before the previous match data is read from SHIFTBUF (SHIFTBUF overrun). • If SHIFTCTL*n*[SMOD] = 101b (Match Continuous mode), the error flag is set when a match occurs between SHIFTBUF and the shifter. • If SHIFTCTL*n*[SMOD] = 111b (Logic mode), the error flag is set when the output of the programmable logic block is asserted. For SHIFTCTL*n*[SMOD] = 101b (Match Continuous mode), the flag can also be cleared when you read Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). **NOTE** This field behaves differently for register reads and writes. When reading 0000_0000b - Clear 0000_0001b - Set When writing 0000_0000b - No effect 0000_0001b - Clear the flag

75.7.1.8 Timer Status Flag (TIMSTAT)

Offset

Register	Offset
TIMSTAT	18h

Function
Reports timer status.

Fields

Field	Function
31-0 PSF	Pin Status Flag Indicates whether the pin status flag is set when a rising edge or falling edge (if configured) is detected on the corresponding pin, as configured by the pin. **NOTE** This field behaves differently for register reads and writes. When reading 0000_0000_0000_0000_0000_0000_0000_0000b - Clear 0000_0000_0000_0000_0000_0000_0000_0001b - Set When writing 0000_0000_0000_0000_0000_0000_0000_0000b - No effect 0000_0000_0000_0000_0000_0000_0000_0001b - Clear the flag

75.7.1.18 Pin Interrupt Enable (PINIEN)

Offset

Register	Offset
PINIEN	54h

Function

Enables pin status interrupts.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 PSIE	Pin Status Interrupt Enable Enables interrupt generation when the corresponding PINSTAT[PSF] flag is set. If you write 0 to this field, PINSTAT[PSF] is disabled, and if you write 1 to this field, PINSTAT[PSF] is enabled. 0b - Disable 1b - Enable

75.7.1.19 Pin Rising Edge Enable (PINREN)

Offset

Register	Offset
PINREN	58h

Function
Enables the pin status flag on a rising edge.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 PRE	Pin Rising Edge Specifies whether the pin status flag is set whenever a rising edge is detected on the pin. 0b - Not set 1b - Set

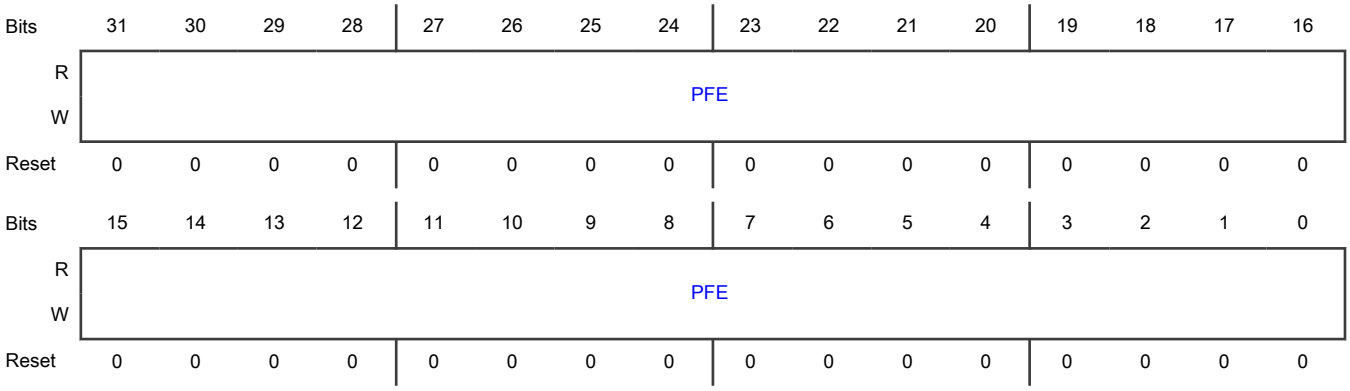
75.7.1.20 Pin Falling Edge Enable (PINFEN)

Offset

Register	Offset
PINFEN	5Ch

Function
Enables the pin status flag on a falling edge.

Diagram



Fields

Field	Function
31-0 PFE	Pin Falling Edge Specifies whether the pin status flag is set whenever a falling edge is detected on the pin. 0b - Not set 1b - Set

75.7.1.21 Pin Output Data (PINOUTD)

Offset

Register	Offset
PINOUTD	60h

Function
Contains data output when direct pin output is enabled.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	OUTE															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 OUTE	Output Enable Enables direct output on the corresponding pin. If this field is 0, the pin is controlled by timer/shifter configuration, and if this field is 1, pin is an output and driven with the value of Pin Output Data (PINOUTD). 0b - Controlled by timer/shifter configuration 1b - Output; driven with value of PINOUTD

75.7.1.23 Pin Output Disable (PINOUTDIS)

Offset

Register	Offset
PINOUTDIS	68h

Function
Disables pin output.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0															
W	OUTDIS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 OUTDIS	Output Disable Configures the corresponding pins to disable direct output. If this field is 1, the corresponding fields in Pin Output Data (PINOUTD) and Pin Output Enable (PINOUTE) become 0. 0b - No effect 1b - Corresponding fields become 0

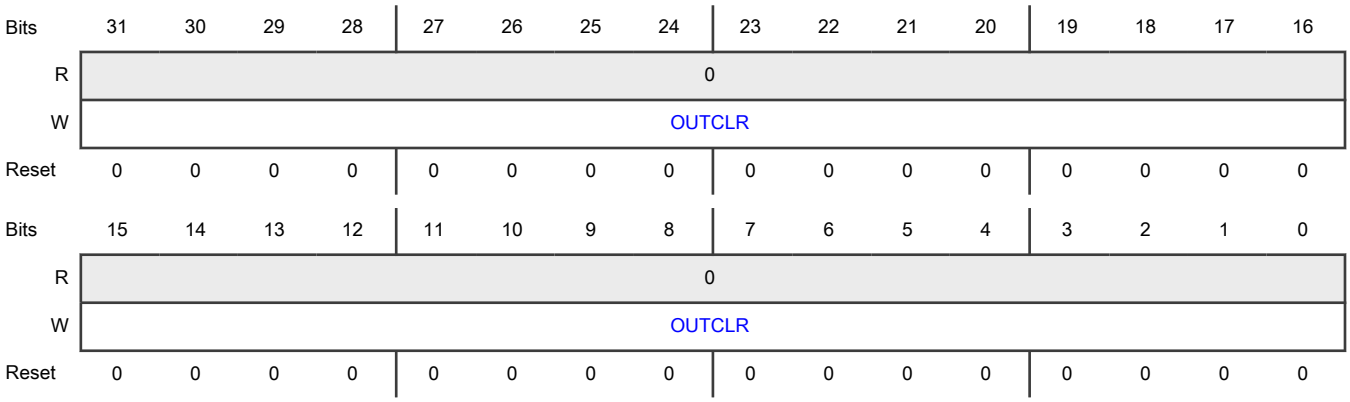
75.7.1.24 Pin Output Clear (PINOUTCLR)

Offset

Register	Offset
PINOUTCLR	6Ch

Function
Clears pin output.

Diagram



Fields

Field	Function
31-0 OUTCLR	Output Clear Configures the corresponding pins to output zero. If this field is 1, the corresponding field in Pin Output Data (PINOUTD) becomes 0 and the one in Pin Output Enable (PINOUTE) becomes 1. 0b - No effect 1b - Corresponding field in PINOUTD becomes 0; corresponding field in PINOUTE becomes 1

75.7.1.25 Pin Output Set (PINOUTSET)

Offset

Register	Offset
PINOUTSET	70h

Function
Sets pin output.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0															
W	OUTTOG															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 OUTTOG	Output Toggle Configures the corresponding pins to toggle. If this field is 1, the corresponding field in Pin Output Data (PINOUTD) is inverted and the one in Pin Output Enable (PINOUTE) becomes 1. 0b - No effect 1b - Corresponding field in PINOUTD is inverted; corresponding field in PINOUTE becomes 1

75.7.1.27 Shifter Control (SHIFTCTL0 - SHIFTCTL7)

Offset

For n = 0 to 7:

Register	Offset
SHIFTCTLn	80h + (n × 4h)

Function

Provides shifter controls.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0				TIMSEL				TIMPOL	0			PINCFG			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0			PINSEL					PINPOL	0			SMOD			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-27 —	Reserved
26-24 TIMSEL	Timer Select Selects which timer is used for controlling the logic or shift register and generating the shift clock. TIMSEL = i selects TIMERi.
23 TIMPOL	Timer Polarity Determines whether the shift occurs on the positive edge or negative edge of the shift clock. 0b - Positive edge 1b - Negative edge
22-18 —	Reserved
17-16 PINCFG	Shifter Pin Configuration Specifies shifter pin configuration. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register. **NOTE** When initially configuring PINCFG as 11b, FLEXIO may briefly drive the pin low. To avoid this, you can configure PINCFG as 10b along with the rest of the Control register and then perform a subsequent write to set PINCFG as 11b. Likewise, when changing the value of PINCFG from 11b to 00b, you must perform an initial write to set PINCFG as 10b and then perform a subsequent write to update the rest of the Control register with the value of PINCFG as 00b. 00b - Shifter pin output disabled 01b - Shifter pin open-drain or bidirectional output enable 10b - Shifter pin bidirectional output data 11b - Shifter pin output
15-13 —	Reserved
12-8 PINSEL	Shifter Pin Select Selects the pin that is used by the shifter input or output. PINSEL = i selects the FXIO_Di pin. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register.
7 PINPOL	Shifter Pin Polarity Specifies the shifter pin polarity. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to this register.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Active high 1b - Active low
6-3 —	Reserved
2-0 SMOD	Shifter Mode Configures the mode of the shifter. 000b - Disable 001b - Receive mode; capture the current shifter content into SHIFTBUF on expiration of the timer 010b - Transmit mode; load SHIFTBUF contents into the shifter on expiration of the timer 011b - Reserved 100b - Match Store mode; shifter data is compared to SHIFTBUF content on expiration of the timer 101b - Match Continuous mode; shifter data is continuously compared to SHIFTBUF contents 110b - State mode; SHIFTBUF contents store programmable state attributes 111b - Logic mode; SHIFTBUF contents implement programmable logic lookup table

75.7.1.28 Shifter Configuration (SHIFTCFG0 - SHIFTCFG7)

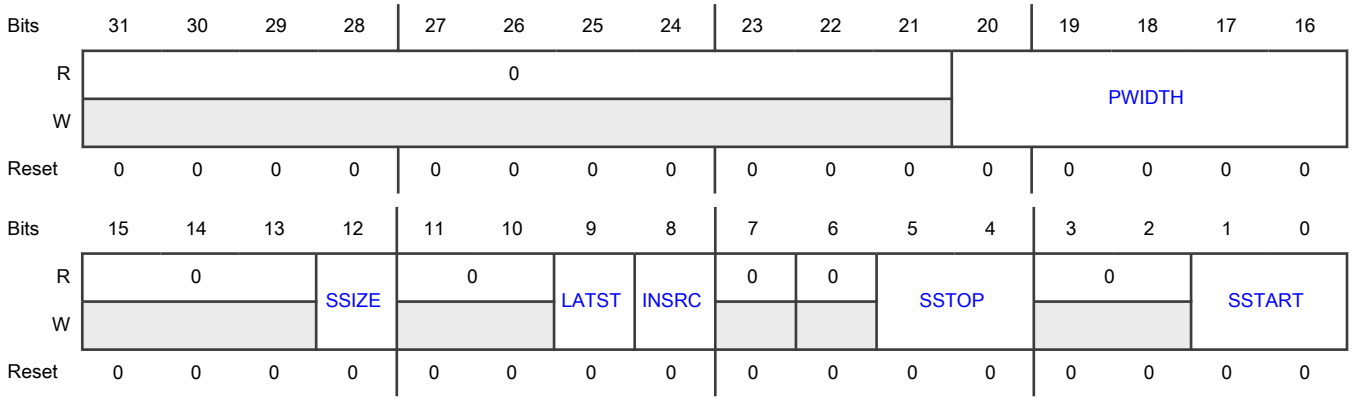
Offset

For n = 0 to 7:

Register	Offset
SHIFTCFGn	100h + (n × 4h)

Function
Provides fields for shifter configuration.

Diagram



Fields

Field	Function
31-21 —	Reserved
20-16 PWIDTH	Parallel Width Configures the number of bits to be shifted on each shift clock for all shifters: • 1-bit shift for PWIDTH = 0 • 2-bit shift for PWIDTH = 1 • 4-bit shift for PWIDTH = 2...3 • 8-bit shift for PWIDTH = 4...7 • 16-bit shift for PWIDTH = 8...15 • 32-bit shift for PWIDTH = 16...31 For shifters that support parallel transmit (SHIFTER0, SHIFTER4, ...) or parallel receive (SHIFTER3, SHIFTER7, ...), this field, together with PINSEL, also selects the pins to be driven or sampled on each shift clock: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL]. Shifters that do not support parallel transmit or parallel receive only support parallel shift when SHIFTCFG*n*[INSRC] = 1. If SHIFTCTL*n*[SMOD] = 110b (State mode), use this field to disable state outputs (see State mode).
15-13 —	Reserved
12 SSIZE	Shifter Size Configures the size of the Shift registers. A 24-bit Shift register shifts data only into bits [23:0] and does not update bits [31:24] during shift operations. When the Shift register is configured for a 24-bit shift, configuring PWIDTH as 8..15 performs a 12-bit shift and PWIDTH as 16..31 performs a 24-bit shift.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - 32-bit 1b - 24-bit
11-10 —	Reserved
9 LATST	Late Store Configures what happens when a receive or match Shift register is configured to both shift and store on the same cycle. 0b - Store the pre-shift register state 1b - Store the post-shift register state
8 INSRC	Input Source Selects the input source for the shifter. Configuring this field as 1 is not supported for the last shifter. 0b - Pin 1b - Shifter n+1 output
7 —	Reserved
6 —	Reserved
5-4 SSTOP	Shifter Stop Allows automatic stop bit insertion, if the selected timer has also enabled a stop bit, when SHIFTCTL*n*[SMOD] is 10b (Transmit mode). If SHIFTCTL*n*[SMOD] is 1b or 100b (Receive mode or Match Store mode), this field allows automatic stop bit checking if the selected timer has also enabled a stop bit. If SHIFTCTL*n*[SMOD] is 110b (State mode), this field disables state outputs (see State mode). If SHIFTCTL*n*[SMOD] is 111b (Logic mode), this field masks logic pin inputs (see Logic mode). 00b - Stop bit disabled for Transmitter, Receiver, and Match Store modes 01b - Stop bit disabled for Transmitter, Receiver, and Match Store modes; when timer is in stop condition, Receiver and Match Store modes store receive data on the configured shift edge 10b - Transmitter mode outputs stop bit value 0 in Match Store mode; if stop bit is not 0, Receiver and Match Store modes set error flag (when timer is in stop condition, these modes also store receive data on the configured shift edge) 11b - Transmitter mode outputs stop bit value 1 in Match Store mode; if stop bit is not 1, Receiver and Match Store modes set error flag (when timer is in stop condition, these modes also store receive data on the configured shift edge)
3-2	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
1-0 SSTART	Shifter Start Allows automatic start bit insertion, if the selected timer has also enabled a start bit, when SHIFTCTL*n*[SMOD] is 10b (Transmit mode). If SHIFTCTL*n*[SMOD] = 1b (Receive mode) or 100b (Match Store mode), this field allows automatic start bit checking if the selected timer has also enabled a start bit. If SHIFTCTL*n*[SMOD] is 110b (State mode), this field disables state outputs (see State mode). If SHIFTCTL*n*[SMOD] = 111b (Logic mode), this field masks logic pin inputs (see Logic mode). 00b - Start bit disabled for Transmitter, Receiver, and Match Store modes; Transmitter mode loads data on enable 01b - Start bit disabled for Transmitter, Receiver, and Match Store modes; Transmitter mode loads data on first shift 10b - Transmitter mode outputs start bit value 0 before loading data on first shift; if start bit is not 0, Receiver and Match Store modes set error flag 11b - Transmitter mode outputs start bit value 1 before loading data on first shift; if start bit is not 1, Receiver and Match Store modes set error flag

75.7.1.29 Shifter Buffer (SHIFTBUF0 - SHIFTBUF7)

Offset

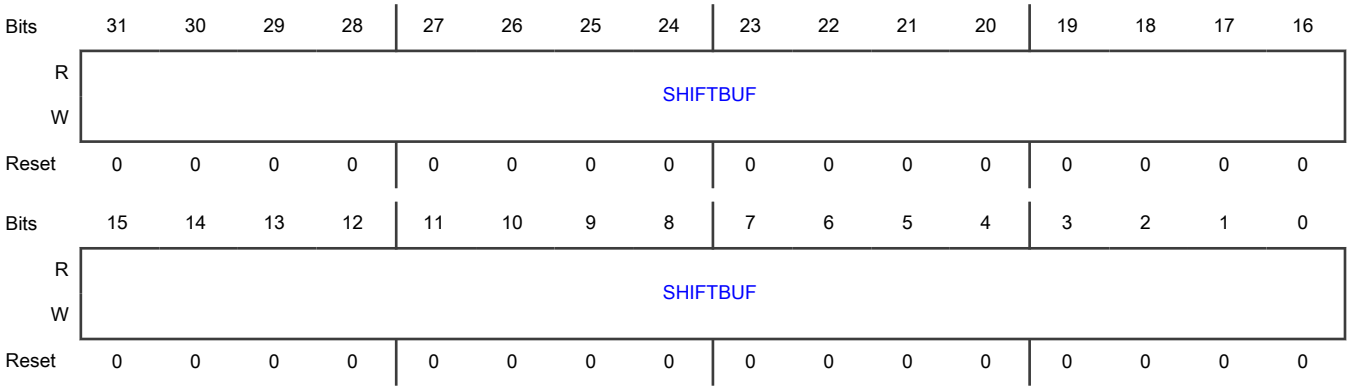
For n = 0 to 7:

Register	Offset
SHIFTBUFn	200h + (n × 4h)

Function

Contains shift buffer data.

Diagram



Fields

Field	Function
31-0 SHIFTBUF	Shift Buffer Contains the data to be matched with the shifter contents and is used for various other functions, depending on the setting of SHIFTCTL*n*[SMOD]: • If SHIFTCTL0[SMOD] is 1b (Receive mode), shifter data is transferred into SHIFTBUF at the expiration of the timer. You must read this register only when the corresponding SHIFTSTAT[SSF] flag is set, indicating that new shifter data is available. • If SHIFTCTL0[SMOD] is 10b (Transmit mode), SHIFTBUF data is transferred into the shifter before the timer begins. • If SHIFTCTL0[SMOD] is 100b (Match Store mode), SHIFTBUF[31:16] contains the data to be matched with the shifter contents and SHIFTBUF[15:0] can be used to mask the match result (1 = mask, 0 = no mask). The match is checked when the timer expires. Shifter data [31:16] is written to SHIFTBUF[31:16] whenever a match event occurs. You must read this register only when the corresponding shifter status flag is set, indicating that new shifter data is available. • If SHIFTCTL0[SMOD] is 101b (Match Continuous mode), SHIFTBUF[31:16] contains the data to be matched with the shifter contents, and SHIFTBUF[15:0] can be used to mask the match result (1 = mask, 0 = no mask). • If SHIFTCTL0[SMOD] is 111b (Logic mode), SHIFTBUF[31:0] implements a 5-input, 32-bit programmable logic lookup table (see Logic mode). • If SHIFTCTL0[SMOD] is 110b (State mode), use SHIFTBUF[31:24] to drive the output value when this shifter is selected by the current state pointer and use SHIFTBUF[23:0] to configure the value of the next state transition (see State mode).

75.7.1.30 Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7)

Offset

For n = 0 to 7:

Register	Offset
SHIFTBUFBISn	280h + (n × 4h)

Function

Contains Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) content, but it is bit-swapped.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	SHIFTBUFBIS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 SHIFTBUFBIS	Shift Buffer Acts as an alias to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), but reads or writes to this register are bit-swapped. Reads return SHIFTBUF[0:31].

75.7.1.31 Shifter Buffer Byte Swapped (SHIFTBUFBYS0 - SHIFTBUFBYS7)

Offset

For n = 0 to 7:

Register	Offset
SHIFTBUFBYSn	300h + (n × 4h)

Function

Contains Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) content, but it is byte-swapped.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	SHIFTBUFBYS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 SHIFTBUFBYS	Shift Buffer Acts as an alias to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), but reads or writes to this register are byte-swapped. Reads return {SHIFTBUF[7:0], SHIFTBUF[15:8], SHIFTBUF[23:16], SHIFTBUF[31:24]}.

75.7.1.32 Shifter Buffer Bit Byte Swapped (SHIFTBUFBBS0 - SHIFTBUFBBS7)

Offset

For n = 0 to 7:

Register	Offset
SHIFTBUFBBSn	380h + (n × 4h)

Function

Contains the register data for Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), but it is bit-swapped within each byte.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	SHIFTBUFBBS

R W	SHIFTBUFBBS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 SHIFTBUFBBS	Shift Buffer Acts as an alias to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), except that reads or writes to this register are bit-swapped within each byte. Reads return {SHIFTBUF[24:31], SHIFTBUF[16:23], SHIFTBUF[8:15], SHIFTBUF[0:7]}.

75.7.1.33 Timer Control (TIMCTL0 - TIMCTL7)

Offset

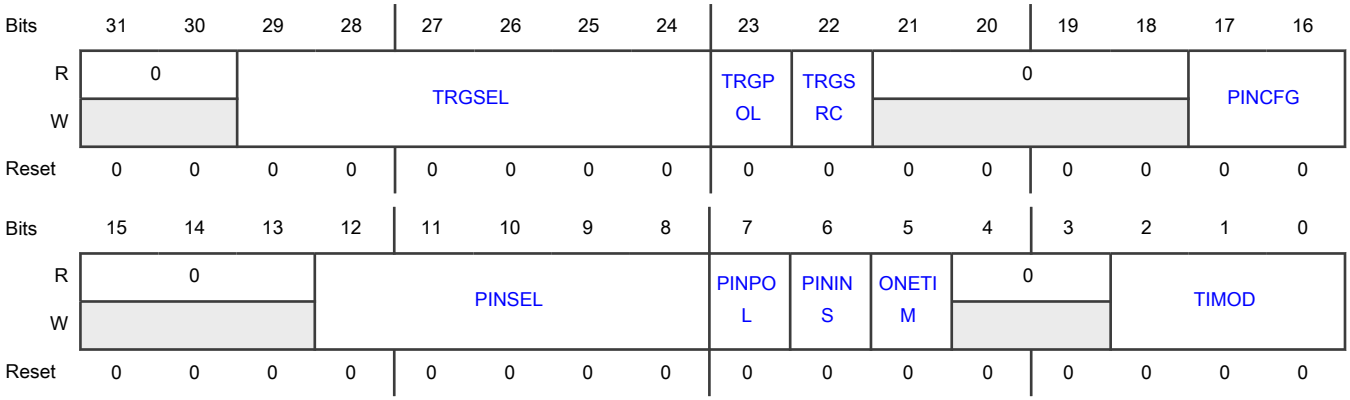
For n = 0 to 7:

Register	Offset
TIMCTLn	400h + (n × 4h)

Function

Controls various settings for timer *n*.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-24 TRGSEL	Trigger Select Selects the trigger. The valid values for TRGSEL depend on the configuration of Parameter (PARAM): • If TRGSRC = 1, the valid values for *n* depend on the settings of PARAM[PIN], PARAM[TIMER], and PARAM[SHIFTER]. • If TRGSRC = 0, the valid values for *n* depend on PARAM[TRIGGER]. See the chip-specific FLEXIO information for external trigger selection. **NOTE** For a pin, *n* = 0 to 31, for a shifter, *n* = 0 to 7, and for a timer, *n* = 0 to 7. If TRGSRC = 0, configure the trigger selection as *n* = external trigger *n* input. If TRGSRC = 1, you can configure the internal trigger to select an input pin as 2×*n* = pin *n* input. If TRGSRC = 1, you can configure the internal trigger to select a shifter or timer signal as: • 4×*n* + 1 = shifter *n* status flag • 4×*n* + 3 = timer *n* trigger output Following are the values for expanded internal trigger selection (TRGSRC = 1):

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• 0000 = Pin 0 • 0001 = Shifter 0 flag • 0010 = Pin 1 • 0011 = Timer 0 trigger • 0100 = Pin 2 • 0101 = Shifter 1 flag • 0110 = Pin 3 • 0111 = Timer 1 trigger • ... • This continues up to pin 31, shifter 7, and timer 7.
23 TRGPOL	Trigger Polarity Specifies whether the trigger is active high or active low. 0b - Active high 1b - Active low
22 TRGSRC	Trigger Source Specifies whether the selected trigger source is external or internal. 0b - External 1b - Internal
21-18 —	Reserved
17-16 PINCFG	Timer Pin Configuration Configures the direction of the timer pin. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register. **NOTE** When you initially configure PINCFG as 11b, FLEXIO may briefly drive the pin low. To avoid this, configure PINCFG as 10b along with the rest of the Control register and then perform a subsequent write to set the value of PINCFG as 11b. Likewise, when changing the value of PINCFG from 11b to 00b, you must perform an initial write to set PINCFG as 10b, and then perform a subsequent write to update the rest of the Control register with PINCFG as 00b. 00b - Timer pin output disabled 01b - Timer pin open-drain or bidirectional output enable 10b - Timer pin bidirectional output data 11b - Timer pin output

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-13 —	Reserved
12-8 PINSEL	Timer Pin Select Selects the pin that is used by the timer input or output. PINSEL = i selects the FXIO_Di pin. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register.
7 PINPOL	Timer Pin Polarity Specifies the timer pin polarity. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register. 0b - Active high 1b - Active low
6 PININS	Timer Pin Input Select Specifies what selects the timer pin input. If this field is 1, the timer input pin is different from the timer output pin. PINSEL must select an even-numbered pin when this field is 1, which means that the output pin is even-numbered and input pin is odd-numbered. 0b - PINSEL selects timer pin input and output 1b - PINSEL + 1 selects the timer pin input; timer pin output remains selected by PINSEL
5 ONETIM	Timer One Time Operation Configures the timer to perform a single enable or disable iteration. Clear the timer status flag for the timer to be enabled again. 0b - Generate the timer enable event as normal 1b - Block the timer enable event unless the timer status flag is clear
4-3 —	Reserved
2-0 TIMOD	Timer Mode Specifies the timer mode: • In 8-bit baud counter mode, the lower 8 bits of the counter and compare register are used to configure the baud rate of the timer shift clock. The upper 8 bits are used to configure the shifter bit count. • In 8-bit PWM high mode, the lower 8 bits of the counter and compare register are used to configure the high period of the timer shift clock. The upper 8 bits are used to configure the low period of the timer shift clock. The shifter bit count is configured using another timer or external signal. • In 16-bit counter mode, the full 16 bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count. • In 16-bit counter disable mode, the full 16 bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• In 8-bit word counter mode, the lower 8 bits of the counter and compare register are used to configure the shifter bit count. The upper 8 bits are used to configure the shifter word count. • In 8-bit PWM low mode, the lower 8 bits of the counter and compare register are used to configure the low period of the timer shift clock. The upper 8 bits are used to configure the high period of the timer shift clock. Use another timer or external signal to configure the shifter bit count. • In 16-bit input capture mode, the inverted value of the 16-bit counter is latched into the compare register when a timer counter disable condition is detected (as configured by TIMCFG*n*[TIMDIS]). This also sets the timer status flag. The timer counter is immediately restarted from FFFFh. 000b - Timer disabled 001b - Dual 8-bit counters baud mode 010b - Dual 8-bit counters PWM high mode 011b - Single 16-bit counter mode 100b - Single 16-bit counter disable mode 101b - Dual 8-bit counters word mode 110b - Dual 8-bit counters PWM low mode 111b - Single 16-bit input capture mode

75.7.1.34 Timer Configuration (TIMCFG0 - TIMCFG7)

Offset

For n = 0 to 7:

Register	Offset
TIMCFGn	480h + (n × 4h)

Function

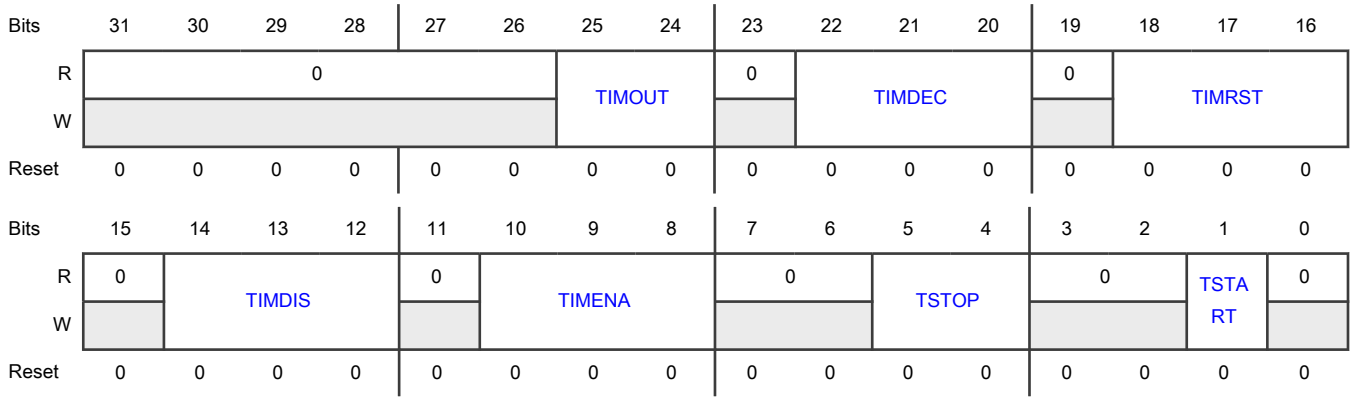
Controls various aspects of timer configuration.

The options to enable or disable the timer using the timer *n* - 1 enable or disable are reserved when *n* is evenly divisible by 4 (timer 0, for example).

NOTE

The pin and trigger level and edges specified in this register refer to the signal state after being modified by the settings of TIMCTL*n*[PINPOL] and TIMCTL*n*[TRGPOL]. For example, "trigger low" means that a trigger is actually at logic level 1 if TIMCTL*n*[TRGPOL] is 1 (active low).

Diagram



Fields

Field	Function
31-26 —	Reserved
25-24 TIMOUT	Timer Output Configures the initial state of the timer output and whether it is affected by the timer reset. 00b - Logic one when enabled; not affected by timer reset 01b - Logic zero when enabled; not affected by timer reset 10b - Logic one when enabled and on timer reset 11b - Logic zero when enabled and on timer reset
23 —	Reserved
22-20 TIMDEC	Timer Decrement Configures the source of the timer decrement and that of the shift clock. 000b - Decrement counter on FLEXIO clock; shift clock equals timer output 001b - Decrement counter on trigger input (both edges); shift clock equals timer output 010b - Decrement counter on pin input (both edges); shift clock equals pin input 011b - Decrement counter on trigger input (both edges); shift clock equals trigger input 100b - Decrement counter on FLEXIO clock divided by 16; shift clock equals timer output 101b - Decrement counter on FLEXIO clock divided by 256; shift clock equals timer output 110b - Decrement counter on pin input (rising edge); shift clock equals pin input 111b - Decrement counter on trigger input (rising edge); shift clock equals trigger input
19 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
18-16 TIMRST	Timer Reset Configures the condition that causes the timer counter (and optionally the timer output) to be reset. In 8-bit counter mode, the timer reset only resets the lower 8 bits that configure the baud rate. In all other modes, the timer reset resets full 16 bits of the counter. 000b - Never reset timer 001b - Timer reset on timer output high. 010b - Timer reset on timer pin equal to timer output 011b - Timer reset on timer trigger equal to timer output 100b - Timer reset on timer pin rising edge 101b - Reserved 110b - Timer reset on trigger rising edge 111b - Timer reset on trigger rising or falling edge
15 —	Reserved
14-12 TIMDIS	Timer Disable Configures the condition that causes the timer to be disabled and stop decrementing. 000b - Timer never disabled 001b - Timer disabled on timer n-1 disable 010b - Timer disabled on timer compare (upper 8 bits match and decrement) 011b - Timer disabled on timer compare (upper 8 bits match and decrement) and trigger low 100b - Timer disabled on pin rising or falling edge 101b - Timer disabled on pin rising or falling edge provided trigger is high 110b - Timer disabled on trigger falling edge 111b - Reserved
11 —	Reserved
10-8 TIMENA	Timer Enable Configures the condition that causes the timer to be enabled and start decrementing. 000b - Timer always enabled 001b - Timer enabled on timer n-1 enable 010b - Timer enabled on trigger high 011b - Timer enabled on trigger high and pin high

Table continues on the next page...

Table continued from the previous page...

Field	Function
	100b - Timer enabled on pin rising edge 101b - Timer enabled on pin rising edge and trigger high 110b - Timer enabled on trigger rising edge 111b - Timer enabled on trigger rising or falling edge
7-6 —	Reserved
5-4 TSTOP	Timer Stop Specifies whether the stop bit is enabled. The stop bit can be added on a timer compare (between each word) or on a timer disable. When stop bit is enabled, configured shifters output the contents of the stop bit when the timer is disabled. When stop bit is enabled on timer disable, the timer remains disabled until the next rising edge of the shift clock. If configured for both timer compare and timer disable, only one stop bit is inserted on timer disable. 00b - Disabled 01b - Enabled on timer compare 10b - Enabled on timer disable 11b - Enabled on timer compare and timer disable
3-2 —	Reserved
1 TSTART	Timer Start Specifies whether the start bit is enabled. If it is enabled, configured shifters output the contents of the start bit when the timer is enabled. The timer counter reloads from the compare register on the first rising edge of the shift clock. 0b - Disabled 1b - Enabled
0 —	Reserved

75.7.1.35 Timer Compare (TIMCMP0 - TIMCMP7)

Offset

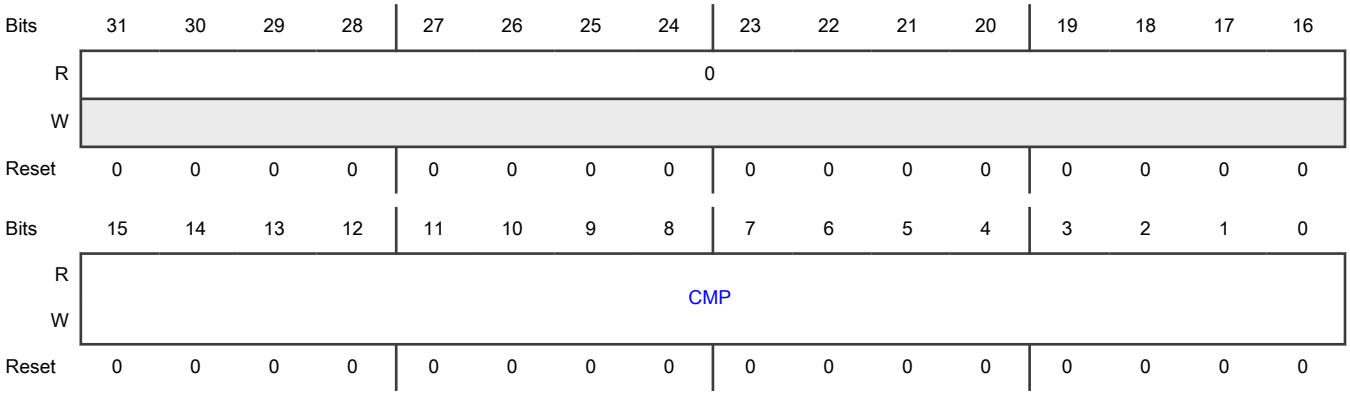
For n = 0 to 7:

Register	Offset
TIMCMPn	500h + (n × 4h)

Function

Contains the timer compare value.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 CMP	Timer Compare Value Loads into the timer counter when the timer is first enabled, when the timer is reset, and when the timer decrements down to zero. In 8-bit baud counter mode, the lower 8 bits configure the baud rate divider as (CMP[7:0] + 1) × 2. The upper 8 bits configure the number of bits in each word as (CMP[15:8] + 1) ÷ 2. In 8-bit PWM high mode, the lower 8 bits configure the high period of the output to (CMP[7:0] + 1) and the upper 8 bits configure the low period of the output to (CMP[15:8] + 1). In 16-bit counter mode, the compare value can be used to generate the baud rate divider (if shift clock source is timer output) as (CMP[15:0] + 1) × 2. When the shift clock source is a pin or trigger input, the compare register is used to set the number of bits in each word as (CMP[15:0] + 1) ÷ 2. In 16-bit counter disable mode, the compare value can be used to generate the baud rate divider (if shift clock source is timer output) as (CMP[15:0] + 1) × 2. When the shift clock source is a pin or trigger input, the compare register is used to set the number of bits in each word as (CMP[15:0] + 1) ÷ 2. In 8-bit word counter mode, the lower 8 bits configure the number of bits in each word as (CMP[7:0] + 1) ÷ 2. The upper 8 bits configure the number of words to transfer equal to (CMP[15:8] + 1) ÷ 2. In 8-bit PWM low mode, the lower 8 bits configure the low period of the output to (CMP[7:0] + 1) and the upper 8 bits configure the high period of the output to (CMP[15:8] + 1). In 16-bit input capture mode, the compare register is updated with the inverse of the timer counter value whenever the timer status flag is set. You must read this register only when the timer status flag is set.

75.7.1.36 Shifter Buffer Nibble Byte Swapped (SHIFTBUFNBS0 - SHIFTBUFNBS7)

Offset

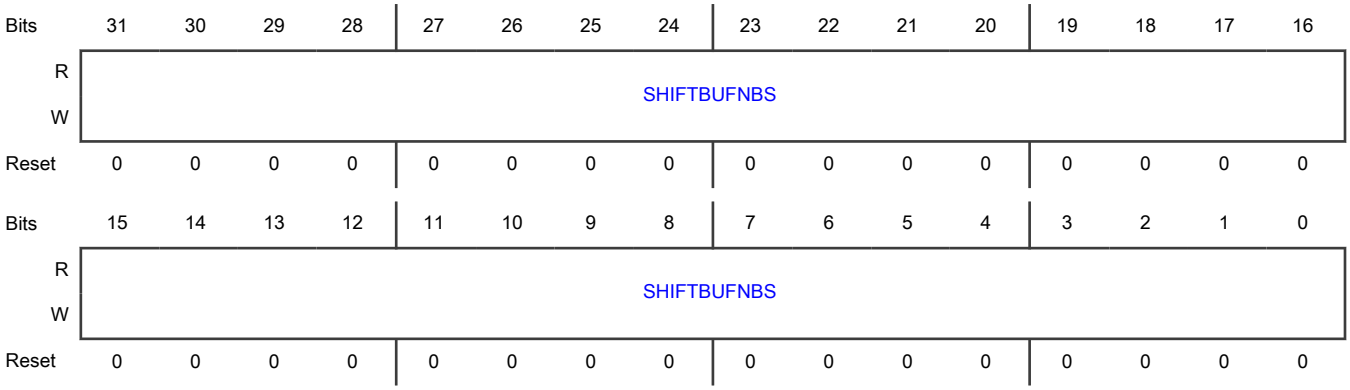
For n = 0 to 7:

Register	Offset
SHIFTBUFNBSn	680h + (n × 4h)

Function

Contains Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) content, but it is nibble-swapped within each byte.

Diagram



Fields

Field	Function

75.8 Glossary

Baud rate	Number of bits that LPUART transmits or receives per second
Break character	Break character is generated when the transmitter is holding the data line at the space level for at least 1 character time
Idle character	Idle character is generated when the transmitter is holding the data line at logic 1 for at least 1 character time
PWM	Pulse width modulation

Chapter 76
CAN (FlexCAN)

76.1 Chip-specific FlexCAN information

76.1.1 FlexCAN instances and configuration

This chip contains up to 6 instances of FlexCAN:

- FlexCAN_0
- FlexCAN_1
- FlexCAN_2
- FlexCAN_3
- FlexCAN_4
- FlexCAN_5

NOTE

Message buffer, Enhanced RX FIFO, and Legacy RXFIFO structure of Flexcan is big endian whereas Cortex-M7 cores support little endian format. So, to align with the IP, there is an extra software overhead for endianness correction.

Table 542. FlexCAN modules instantiation

Feature	FlexCAN0	FlexCAN1	FlexCAN2	FlexCAN3	FlexCAN4	FlexCAN5
Flexible Data Rate (CAN FD) protocol specification and CAN protocol.	Yes	Yes	Yes	Yes	Yes	Yes
Number of message buffers.	96	96	96	64	64	64
Rx FIFO Filtering	Yes	Yes	Yes	Yes	Yes	Yes
ECC	Yes	Yes	Yes	Yes	Yes	Yes
PNET	No	No	No	No	No	No
External Tick Time	Yes, Supported by PIT_RTI_2 Trigger[0]					
DMA	Yes	Yes	Yes	Yes	Yes	Yes
Enhanced RX FIFO Feature	Yes	Yes	Yes	No	No	No

NOTE

See attached interrupt map file for the vector numbers for the CAN instances and their corresponding interrupt sources.

76.1.2 FlexCAN error injection

Error injection address mapping

Use the following table to convert from the memory map address to the location in the physical FlexCAN RAM (where pairs of values are provided, the first is the address for MCR[FDEN] negated, the second is for MCR[FDEN] asserted):

RAM contents	Memory map	Injection address	
—	—	FlexCAN0/1/2	FlexCAN3/4/5
FlexCAN Registers	—	Not mapped	Not mapped
MBs	0080h	0000h	0000h
RXIMRs	0880h	600h	400h
RXIFR_0	0A80h	780h	500h
RXIFR_1	0A84h	784h	504h
RXIFR_2	0A88h	788h	508h
RXIFR_3	0A8Ch	78Ch	50Ch
RXIFR_4	0A90h	790h	510h
RXIFR_5	0A94h	794h	514h
Reserved	0A98h	—	—
RXMGMASK	0AA0h	7A0h	520h
RXFGMASK	0AA4h	7A4h	524h
RX14MASK	0AA8h	7A8h	528h
RX15MASK	0AACh	7ACh	52Ch
Tx_SMB	0AB0h/0F28h	7B0h	530h
Rx_SMB0	0AC0h/0F70h	7C0h/7F8h	540h/578h
Rx_SMB1	0AD0h/0FB8h	7D0h/840h	550h/5C0h
Rx_SMB0_TIME_STAMP	0C20h	888h	608h
Rx_SMB1_TIME_STAMP	0C24h	88Ch	60Ch
HR_TIME_STAMP	0C30h	890h	610h
Enhanced RX FIFO	2000h	A10h	—
ERFFEL	3000h	1050h	—

FlexCAN memory initialization

All FlexCAN memory must be initialized before starting its operation in order to have the parity bits in memory properly updated. CTRL2[WRMFRZ] grants write access to all memory positions that require initialization.

These locations are as listed in this table:

from 080h–ADFh and from C20h–31FFh.

Instance	Offset address ranges to be initialized
FlexCAN0/1/2	080h–ADFh; C20h–31FFh
FlexCAN3/4/5	080h–ADFh; C20h–FFFh

76.1.3 Reset value of MDIS bit

The CAN_MCR[MDIS] bit is set to 1 when the module is reset. Therefore, FlexCAN module is disabled following a reset. For details of CAN_MCR[MDIS] register refer to "CAN register description" section.

76.1.4 CAN Timestamp Implementation

FlexCAN uses Ethernet Media Access Controller (EMAC) and System Timer Module (STM_0) counters as time source. For details see 'FlexCAN timestamp implementation' section in Clocking chapter.

76.1.4.1 Considerations while using FlexCAN timestamp in S32K396

While using FlexCAN timestamp feature, the message buffers should be unlocked within each 20 CAN bits. A failure to do so while using FlexCAN timestamp feature along with FlexCAN RX FIFO or enhanced RX FIFO might result in timestamp information being missed.

76.1.5 CAN clock setup

For clock setup, see Clocking chapter.

76.2 Overview

FlexCAN is a communication controller implementing the CAN protocol according to the ISO 11898-1:2015 standard and CAN 2.0 Part B protocol specifications.

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific real-time processing and reliable operation requirements in the electromagnetic interference (EMI) environment of a vehicle. FlexCAN is a full implementation of the CAN protocol specification, the CAN with flexible data rate (CAN FD) protocol, and the CAN version 2.0 Part B protocol. It supports both standard and extended message frames and long payloads.

NOTE

Legacy Receive (RX) FIFO cannot be used in Flexible Data (FD) mode.

NOTE

In CAN FD mode, use the Enhanced Receive FIFO feature instead of the Legacy Receive FIFO.

76.2.1 Block diagram

Figure 521 shows the main submodules implemented in FlexCAN.

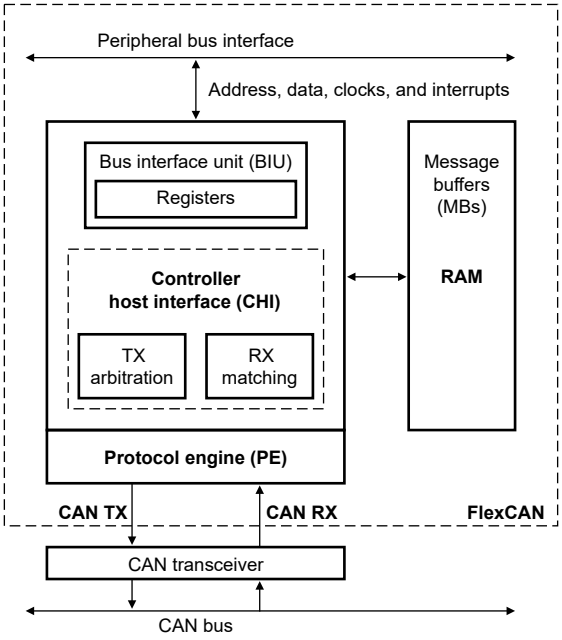

Figure 521. Block diagram

The Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- RAM access for receiving and transmitting message frames
- Receive message validation
- Error handling.
- CAN FD message detection

The Controller Host Interface (CHI) submodule manages:

- Message buffer (MB) selection for reception and transmission
- Arbitration and ID matching algorithms for both CAN FD and non-CAN FD message formats

The Bus Interface Unit (BIU) submodule controls access to and from the internal interface bus to establish connection to the CPU and to other blocks. The BIU manages access to:

- Clocks
- Address and data buses
- Interrupt outputs
- DMA
- Test signals

76.2.2 Features

- Full implementation of *CAN with Flexible data rate (CAN FD) protocol specification* and *CAN Specification Version 2.0, Part B*
  - Standard data frames
  - Extended data frames
  - Data length of 0–64 bytes
  - Programmable bit rate (see chip-specific FlexCAN information for specific maximum rate configuration)

  - Content-related addressing
- Compliance with ISO 11898-1:2015 standard
- Flexible message buffers that can be configured to store a payload of 0, 8, 16, 32, or 64 bytes
  - Increasing the payload size decreases the number of supported message buffers (see FlexCAN memory partition for CAN FD).
  - Message buffers are configurable as receive or transmit, supporting standard and extended messages.
- Individual Receive Mask registers for each message buffer
- Full-featured Legacy RX FIFO with storage capacity for six frames and automatic internal pointer handling with DMA support
- Full-featured Enhanced RX FIFO with storage capacity of 20 CAN FD frames and automatic internal pointer handling with DMA support
- Transmission abort capability
- Optional general purpose RAM space, using RAM not used by reception or transmission structures
- Listen-Only mode
- Programmable loopback mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Timestamp based on 32-bit free-running timer, with optional external time tick
- Global network time, synchronized by specific message
- Maskable interrupts
- Independence from transmission medium (external transceiver is assumed)
- Short latency time due to arbitration scheme for high-priority messages
- Low-power mode
- Transceiver delay compensation when transmitting CAN FD messages at faster data rates
- Management of remote request frames, automatically or by software
- Restriction only to write CAN bit time settings and configuration bits in Freeze mode
- Transmit message buffer status (lowest-priority buffer or empty buffer)
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- ESR1[SYNCH] to indicate module is synchronous with CAN bus
- CRC status for transmitted message
- Legacy RX FIFO Global Mask register
- Selectable priority between message buffers and receive FIFO during matching process
- Powerful Legacy RX FIFO ID filtering, capable of matching incoming IDs against either 128 extended IDs, 256 standard IDs, or 512 partial (8-bit) IDs, with 32 individual masking capability
- Powerful Enhanced RX FIFO ID filtering, capable of matching incoming IDs against either 64 extended or 128 standard ID filter elements with three filtering schemes: mask plus filter, range, and two filters without mask.
- Complete backward compatibility with previous FlexCAN version
- Detection and correction of errors in memory read accesses.
  - Each byte of FlexCAN memory is associated to five parity bits.
  - The error correction mechanism ensures that errors in one bit of this 13-bit word can be corrected (correctable errors).

— Errors in two bits can be detected but not corrected (noncorrectable errors).

76.3 Functional description

FlexCAN is a CAN protocol engine with a flexible message buffer system for transmitting and receiving CAN frames. The system is a set of message buffers (MBs) that stores configuration and control data, timestamp, message ID, and data (see Message buffer structure). The memory corresponding to the first 38 message buffers can be configured to support a Legacy FIFO reception scheme with a powerful ID filtering mechanism. This scheme can check incoming frames against a table of IDs (up to 128 extended IDs or 256 standard IDs or 512 8-bit ID slices), with an individual mask register for up to 32 ID filter table elements.

For classical CAN frames, FlexCAN supports simultaneous reception through Legacy FIFO and message buffer. For CAN FD frames, FlexCAN supports reception through message buffer and enhanced receive FIFO.

For message buffer reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed in the ID field. A masking scheme makes it possible to match the ID programmed on the message buffer with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of message buffers to be transmitted based on the message ID (optionally augmented by three local priority bits) or the message buffer ordering.

A message buffer is active at a given time if it can participate in both the matching and arbitration processes. A receive message buffer with a 0b code is inactive (see Table 579). A transmit message buffer with a 1000b or 1001b code is also inactive (see Table 580).

FlexCAN can receive and transmit messages in CAN FD format. The message buffers are sized to store the quantity of data bytes selected by FDCTRL[MBDSRn]. The quantity of FD message buffers available for a given quantity of data bytes is described in the CAN FD Control (FDCTRL) register. See also FlexCAN memory partition for CAN FD.

76.3.1 Modes of operation

FlexCAN has these functional modes:

Table 543. Functional modes

Mode	Description
Normal (User or Supervisor)	In Normal mode, FlexCAN receives and transmits message frames, manages errors normally, and enables all CAN Protocol functions. User and Supervisor modes differ in the access to some restricted control registers.
Freeze	Freeze mode is enabled when MCR[FRZ] = 1. If enabled, FlexCAN enters Freeze mode when MCR[HALT] is 1 or when is requested at chip level and FlexCAN writes 1 to MCR[FRZACK]. In this mode, no transmission or reception of frames is done, and synchronicity to the CAN bus is lost. See Freeze mode.
Loopback	FlexCAN enters this mode when CTRL1[LPB] becomes 1. In this mode, FlexCAN performs an internal loopback that can be used for self-test. The bit stream output of the transmitter is internally fed back to the receiver input. The receiving CAN input pin is ignored and the transmitting CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. To ensure proper reception of its own message, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field. Both transmit and receive interrupts are generated.
Listen-Only	FlexCAN enters this mode when CTRL1[LOM] becomes 1. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station are received. If FlexCAN detects an unacknowledged message, it flags a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.
CAN FD Active	In this mode, FlexCAN can transmit and receive all messages formatted according to the CAN FD Standard (2.0) and 2.0B Protocol in an interleaved fashion. The CPU can put FlexCAN into CAN FD Active mode by configuring MCR[FDEN] in Freeze mode.

Some features available in classical CAN are unavailable in CAN FD mode.

Table 544. Differences between classical CAN and CAN FD

Feature	Classical CAN	CAN FD
Legacy RX FIFO DMA	Yes	No
Legacy RX FIFO	Yes	No
Enhanced RX FIFO DMA	Yes	Yes
Enhanced RX FIFO	Yes	Yes

FlexCAN can operate in these low-power modes:

Table 545. Low-power modes

Mode	Description
Module Disable	FlexCAN enters this mode when the CPU writes 1 to MCR[MDIS] and FlexCAN writes 1 to MCR[LPMACK]. After FlexCAN is disabled, it issues a request to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Writing 0 to MCR[MDIS] exits this mode. See Module Disable mode.

76.3.1.1 Modes of operation details

FlexCAN has functional modes and low-power modes. See Modes of operation for an introductory description of all the modes of operation. The following subsections contain functional details about Freeze mode and low-power modes.

CAUTION

FlexCAN does not support "Permanent Dominant" failure on the CAN bus line. If a Low-Power request or Freeze mode request occurs during a "Permanent Dominant" condition, the corresponding acknowledgment field can never be 1.

76.3.1.1.1 Freeze mode

This mode is requested either by the CPU writing 1 to MCR[HALT] or when the chip is put into Debug mode. MCR[FRZ] must be 1 and the module must not be in a low-power mode.

When MECR[NCEFAFRZ] becomes 1 and a noncorrectable error is detected in a memory read access performed by FlexCAN internal processes (see Error response), FlexCAN also requests Freeze mode. This request occurs via both MCR[HALT] and MCR[FRZ] automatically becoming 1.

To obtain acknowledgment, FlexCAN writes 1 to MCR[FRZACK]. The CPU must only consider FlexCAN to be in Freeze mode when both request and acknowledgment conditions are satisfied.

When Freeze mode is requested, FlexCAN:

1. Waits to be in either Intermission, Error Passive, Bus Off, or Idle state.
2. Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in does not prevent entering Freeze mode.
3. Ignores the receive input pin and drives the transmit pin as recessive.
4. Stops the prescaler, halting all CAN protocol activities.
5. Grants write access to the Error Counters register, which is read-only in other modes.
6. Writes 1 to MCR[NOTRDY] and MCR[FRZACK].

After requesting Freeze mode, you must wait for MCR[FRZACK] to become 1 before executing any other action, otherwise FlexCAN may operate unpredictably. In Freeze mode, all memory-mapped registers are accessible.

Freeze mode is exited in one of these conditions:

- CPU writes 0 to MCR[FRZ].
- The chip is removed from Debug mode or the MCR[HALT] becomes 0.

MCR[FRZACK] becomes 0 after the protocol engine recognizes the negation of the freeze request. After leaving Freeze mode, FlexCAN tries to resynchronize to the CAN bus by waiting for 11 consecutive recessive bits.

76.3.1.1.2 Module Disable mode

This low-power mode is normally used to disable a complete FlexCAN block temporarily, with no power consumption. The CPU requests this mode by writing 1 to MCR[MDIS], and FlexCAN acknowledges the request by writing 1 to MCR[LPMACK]. The CPU must only consider FlexCAN to be in Disable mode when both the request and acknowledgment conditions are satisfied.

If FlexCAN is disabled during Freeze mode, the module requests to disable the clocks to the PE and CHI submodules, writes 1 to MCR[LPMACK] and writes 0 to MCR[FRZACK].

If the module is disabled during transmission or reception, FlexCAN:

1. Waits to be in either Idle or Bus Off state, or waits for the third bit of Intermission and then checks that it is recessive.
2. Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. FlexCAN does not take a pending move-in into account.
3. Ignores its receive input pin and drives its transmit pin as recessive.
4. Shuts down the clocks to the PE and CHI submodules.
5. Writes 1 to MCR[NOTRDY] and MCR[LPMACK].

In this mode, the Bus Interface Unit continues to operate, enabling the CPU to access memory-mapped registers, except for:

- The Receive Message Buffers Global Mask registers
- The Receive Buffer 14 Mask register
- The Receive Buffer 15 Mask register
- The Legacy Receive FIFO Global Mask register

When in Disable mode, these items may not be accessed:

- The Legacy Receive FIFO Information register
- The message buffers
- The Receive Individual Mask registers
- The reserved words within RAM

To exit this mode, the CPU writes 0 to MCR[MDIS], causing FlexCAN to request to resume the clocks and write 0 to MCR[LPMACK]. This write occurs after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

76.3.2 Transmission process

NOTE

Instances of MB_CS in this topic refer to items in message buffers. See Message buffer structure for details.

To transmit a CAN frame, the CPU must prepare a message buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt flag is set, and clear it if necessary.
2. If the message buffer is active (transmission pending), request an abort of the transmission. Write the ABORT code (1001b) to the CODE field of the Control and Status word.
3. Poll the IFLAG register until the corresponding IFLAG flag is set, or wait for the interrupt request (if enabled by the respective IMASK field).

4. Read the CODE field to identify whether the transmission was aborted or transmitted (see Transmission abort mechanism).
5. Clear the corresponding interrupt flag.
6. Write the ID register (containing the local priority if enabled via MCR[LPRIOEN]).
7. Write payload data bytes.
8. Configure the Control and Status word as needed.
    a. Set ID type via MB_CS[IDE].
    b. Set Remote Transmission Request (if needed) via MB_CS[RTR].
    c. If MCR[FDEN] = 1, configure MB_CS[EDL] and MB_CS[BRS]. For details about the relationship between the written value and transmitted value of MB_CS[ESI], see Table 556.[35]
    d. Configure Data Length Code in bytes via MB_CS[DLC]. See Table 583 for detailed information.
    e. To transmit the CAN frame, activate the message buffer by writing Ch to MB_CS[CODE].

NOTE

To maximize software performance, configure all the fields in the MB_CS word in a single 32-bit write operation. If the fields are configured in separate writes, MB_CS[CODE] must be the last write in the Control and Status word.

When the MB is activated, it participates in the arbitration process and its contents are eventually transmitted according to its priority. When the DLC value stored in the MB selected for transmission exceeds the MB payload size, FlexCAN completes the expected DLC by adding a constant CCh pattern.

After a successful transmission:

1. The value of the free-running timer is written into the timestamp field.
2. The CODE field in the Control and Status word is updated.
3. Both Cyclic Redundancy Check (CRCR) and CAN FD CRC (FDCRC) are updated.
4. A status flag is set in the Interrupt Flag register.
5. If allowed by the corresponding Interrupt Mask Register field, an interrupt is generated.

After transmission, the new CODE field depends on the code used to activate the message buffer (see Table 579 and Table 580 in Message buffer structure).

When the Abort feature is enabled (MCR[AEN] is 1), after the Interrupt flag is set for an MB configured as transmit buffer, the message buffer is blocked. The CPU cannot update the message buffer until the Interrupt Flag is cleared by the CPU. The CPU must clear the corresponding IFLAG flag before preparing this MB for a new transmission or reception.

NOTE

For backward compatibility (MCR[AEN] is 0), write the INACTIVE code (1000b) to the CODE field to deactivate the MB. In this case, the pending frame may be transmitted without notification (see Message buffer inactivation).

76.3.3 Arbitration process

The arbitration process scans the message buffers, searching for the transmission MB that holds the message to be sent at the next opportunity. This MB is called the arbitration winner. The scan starts from the lowest number MB and continues to the higher ones.

The arbitration process is triggered when at least one of the following occur:

- CRC field of the CAN frame arrives. The starting point depends on the value of CTRL2[TASD].

[35] There is no need to write the ESI field; it is automatically transmitted as dominant by error active nodes and as recessive by error passive nodes. If FlexCAN is operating as a network gateway, however, the CPU writes MB_CS[ESI] according to the error status of the node that sent the message.

- Error Delimiter field of a CAN frame is in progress.
- Overload Delimiter field of a CAN frame is in progress.
- The winner of the arbitration is deactivated, and the CAN bus has not reached the first bit of the Intermission field.
- CPU writes to the Control and Status word of a winner MB, and the CAN bus has not reached the first bit of the Intermission field.
- CHI is in the Idle state and the CPU writes to the Control and Status word of any message buffer.
- FlexCAN exits Bus Off state.
- FlexCAN leaves Freeze mode or a low-power mode.

If the arbitration process does not evaluate all message buffers before the CAN bus reaches the first bit of the Intermission field, the temporary arbitration winner is invalidated. FlexCAN will not compete for the CAN bus at the next opportunity.

The arbitration process selects the winner among the active transmission message buffers at the end of the scan according to the values of CTRL1[LBUF] and MCR[LPRIOEN].

See Arbitration process (continued) for more information about this process.

76.3.3.1 Lowest-number message buffer first

If CTRL1[LBUF] is 1, the first (lowest number) active transmission message buffer found is the arbitration winner. MCR[LPRIOEN] has no effect when CTRL1[LBUF] is 1.

76.3.3.2 Highest-priority message buffer first

If CTRL1[LBUF] is 0, the arbitration process searches for the active transmission message buffer with the highest priority. The frame of this message buffer has a higher probability of winning the arbitration on the CAN bus when multiple external nodes compete for the bus simultaneously.

The sequence of bits considered for this arbitration is called the arbitration value of the message buffer. The transmission message buffer with the lowest arbitration value among all transmission message buffers has the highest priority.

If two or more message buffers have equivalent arbitration values, the message buffer with the lowest number is the arbitration winner.

The composition of the arbitration value depends on MCR[LPRIOEN].

76.3.3.2.1 Local priority disabled

If MCR[LPRIOEN] = 0, the arbitration value is built using the exact sequence of bits that would be transmitted in a CAN frame where local priority is disabled.

Table 546. Composition of the arbitration value when local priority is disabled

Format	Message buffer arbitration value (32 bits)				
Standard (IDE = 0)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	— (18 bits)	— (1 bit)
Extended (IDE = 1)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

76.3.3.2.2 Local priority enabled

To enable local priority, MCR[LPRIOEN] must be 1. In this case, the message buffer PRIO field (see Message buffer structure) is included at the very left of the arbitration value.

Table 547. Composition of the arbitration value when local priority is enabled

Format	Message buffer arbitration value (35 bits)					
Standard (IDE = 0)	PRIO (3 bits)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	— (18 bits)	— (1 bit)
Extended (IDE = 1)	PRIO (3 bits)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

Because the PRIO field is the most significant part of the arbitration value, message buffers with low PRIO values have higher priority than message buffers with high PRIO values. This priority is maintained regardless of the rest of their arbitration values.

The PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

76.3.3.3 Arbitration process (continued)

After the arbitration winner is found (see Arbitration process), its content is copied to a hidden auxiliary message buffer called a transmit serial message buffer (TX SMB). The TX SMB has the same structure as a normal message buffer, but is not user-accessible. This copy operation is called move-out. After it is done, write access to the Control and Status word of the corresponding MB is blocked (if MCR[AEN] = 1). Write access is restored in one of the following events:

- The CPU clears the corresponding IFLAG flag after the message buffer is transmitted.
- FlexCAN enters Freeze mode or Bus Off state.
- FlexCAN loses the bus arbitration, or there is an error during the transmission.

At the first opportunity window on the CAN bus, the message on the TX SMB is transmitted according to the CAN protocol rules.

The arbitration process can be triggered under the following conditions:

- During RX and TX frames from CAN CRC field to end of frame. The value of CTRL2[TASD] may be changed to optimize the arbitration start point.
- During CAN Bus Off state from TX_ERR_CNT = 124 to 128. The value of CTRL2[TASD] may be changed to optimize the arbitration start point.
- During Control and Status write by CPU in Bus Idle. The first Control and Status write starts the arbitration process, and a second Control and Status write during this same arbitration restarts the process. If other Control and Status writes are performed, the transmission arbitration process is pending. If there is no arbitration winner after the arbitration process has finished, then the TX arbitration machine begins a new arbitration process. If there is a pending arbitration and Bus Idle state starts, then an arbitration process is triggered. In this case, the first and second Control and Status writes in Bus Idle do not restart the arbitration process. If there is not enough time to finish arbitration in the Wait For Bus Idle state and the next state is Idle, the scan is not interrupted. That scan is completed during Bus Idle state. During this arbitration, a Control and Status write does not cause an arbitration restart.
- Deactivation of an arbitration winner during a valid arbitration window.
- Upon exiting Freeze mode (first bit of the Wait For Bus Idle state). If a resynchronization occurs during Wait For Bus Idle, the arbitration process is restarted.

The arbitration process stops when:

- All message buffers are scanned.
- A transmission message buffer is found (if lowest buffer feature is enabled).
- An arbitration winner deactivates or aborts during any arbitration process.
- There is not enough time to finish the transmission arbitration process (for instance, when a deactivation is performed near the end of frame). In this case, the arbitration process is pending.
- An error or overload flag occurs in the bus.

- A low-power or Freeze mode request occurs in Idle state.

Arbitration is considered pending when:

- It is not possible to finish arbitration process in time.
- A Control and Status write occurs during arbitration, when that write is performed in an MB whose number is lower than the transmission arbitration pointer.
- Any Control and Status write occurs when there is no transmission arbitration process in progress.
- RX Match has updated an RX code to TX code.
- FlexCAN enters the Bus Off state.

If a Control and Status write is performed in the arbitration winner, a new process is restarted immediately.

If a Control and Status write is performed in an MB whose number is higher than the transmission arbitration pointer, the ongoing arbitration process scans this MB as normal.

76.3.4 Receive process

To be able to receive CAN frames into a message buffer, the CPU must prepare it for reception by executing the following steps:

1. If the message buffer is active (either TX or RX), deactivate it (see Message buffer inactivation), preferably with a safe deactivation (see Transmission abort mechanism).
2. Write the ID word into the message buffer.
3. To activate the message buffer, write the EMPTY code (0100b) to the CODE field of the Control and Status word. No setup is required for EDL, BRS, and ESI fields. The respective fields in the received message overwrite these fields.

After the MB is activated, it can receive frames that match the programmed filter. At the end of a successful reception, the move-in process updates the message buffer (see Move-in) as follows:

1. The received data field (up to eight bytes for Classical CAN message format and up to 64 bytes for CAN FD message format) is stored.
2. The received Identifier field is stored.
3. The value of the free-running timer when the second bit of the Identifier field of the frame is written into the Timestamp field of the MB.
4. The received SRR, IDE, RTR, EDL, BRS, ESI, and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see Table 579 and Table 580 in Section Message buffer structure).
6. If allowed by the corresponding Interrupt Mask field, a status flag is set in the Interrupt Flag register and an interrupt is generated.

The recommended way for the CPU to service (read) the frame received in a message buffer is:

1. Read the Control and Status word of that message buffer.
2. Verify that the BUSY bit is 0, indicating that the message buffer is locked. If it is not 0, repeat step 1 until it becomes 0. See Message buffer lock mechanism.
3. Read the contents of the message buffer. After the message buffer is locked, FlexCAN move-in processes do not modify its contents. See Move-in.
4. Acknowledge the proper flag in the IFLAG registers.
5. Unlock the message buffer by reading the free-running timer.

To verify frame reception, the CPU should poll the status flag bit for that specific message buffer in one of the IFLAG registers, not the CODE field of that message buffer. Polling the CODE field does not work in this case. After a frame is received and the CPU services the message buffer (by reading the Control and Status word and unlocking the message buffer), the CODE field does not return to EMPTY. It remains FULL, as explained in Table 579. If the CPU tries to work around this behavior by writing to

the Control and Status word to force an EMPTY code after reading the message buffer without a prior safe deactivation, a newly received frame matching the filter of that message buffer may be lost.

CAUTION

In summary: never poll by reading the Control and Status word of the message buffers directly. Instead, read the IFLAG registers.

The Identifier field of the received frame is always stored in the matching message buffer. If the match was due to masking, the contents of the ID field in a message buffer may change. When MCR[SRXDIS] becomes 1, FlexCAN does not store frames transmitted by itself in any MB, even if it contains a matching receive MB. Also, no interrupt flag or interrupt signal is generated. Otherwise, when MCR[SRXDIS] becomes 0, if a matching receive MB exists, FlexCAN can receive frames transmitted by itself.

To be able to receive CAN frames through the Legacy RX FIFO, the CPU must enable and configure the Legacy RX FIFO during Freeze mode (see Legacy RX FIFO). Upon receiving the Frames Available in the Legacy RX FIFO interrupt (see MCR[BUF5I]), the CPU must service the received frame using the following procedure:

1. If a mask was used for IDE and RTR bits, read the Control and Status word.
2. If a mask was used, read the ID field.
3. Read the data field.
4. If the Identifier Acceptance Filter Hit Indicator (IDHIT) is required in the application, read Legacy RX FIFO Information (RXFIR).
5. Clear the Frames Available in Legacy RX FIFO interrupt by writing one to IFLAG1[BUF5I]. This step is mandatory; it releases the MB and allows the CPU to read the next RX FIFO entry.

When MCR[DMA]) becomes 1, upon receiving a frame in the Legacy FIFO, IFLAG1[BUF5I] generates a DMA request and does not generate a CPU interrupt (see Legacy RX FIFO in DMA Operation). The IMASK1 fields in the Legacy RX FIFO region are not used.

The DMA controller must service the received frame using the following procedure:

1. Read the Control and Status word (read 80h address, optional).
2. Read the ID field (read 84h address, optional).
3. Read all data bytes (start read at 88h address, optional).
4. Read the last data bytes (read 8Ch address, mandatory).

76.3.5 Matching process

The matching process scans the message buffer memory for RX MBs programmed with the same ID as the one received from the CAN bus. If the Legacy RX or Enhanced RX FIFO is enabled, the priority of scanning can be selected between MBs and FIFO filters. The matching starts from the lowest number message buffer and continues toward the higher-numbered ones. If no match is found within the first structure, the other is scanned afterward. If the FIFO is full, the matching algorithm always looks for a matching MB outside the FIFO region.

For enhanced RX FIFO, see Enhanced RX FIFO.

For legacy RX FIFO, see Legacy RX FIFO.

As the frame is received, it is stored in a hidden auxiliary MB called Receive Serial Message Buffer (RX SMB).

The starting point of the matching process depends on the following conditions:

- If the received frame is a remote frame, the starting point is the CRC field of the frame.
- If the received frame is a data frame with DLC field equal to zero, the starting point is the CRC field of the frame.
- If the received frame is a data frame and the DLC field has a nonzero value, the starting point is the DATA field of the frame.

If a matching ID is found in the FIFO table or in one of the message buffers, the move-in process transfers the contents of the RX SMB to the FIFO or to the matched MB. If any CAN protocol error is detected, no match results are transferred to the FIFO or to the matched MB at the end of reception.

The matching process scans all matching elements of the RX FIFO (if enabled) and the active receive MBs (CODE is EMPTY, FULL, OVERRUN, or RANSWER). The process searches for a successful comparison to the matching elements of the RX SMB that is receiving the frame on the CAN bus. The RX SMB has the same structure as a message buffer. The reception structures (RX FIFO or message buffers) associated with the matching elements that had a successful comparison are the matched structures. The matching winner is selected at the end of the scan among those matched structures. The matching winner depends on conditions described in Table 548.

Table 548. Matching architecture

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EACEN]	MB[IDE]	MB[RTR]	MB[ID[1]]	MB[CODE]
Message buffer	0	—	0	cmp[2]	no_cmp[3]	cmp_msk[4]	EMPTY, FULL, or OVERRUN
Message buffer	0	—	1	cmp_msk	cmp_msk	cmp_msk	EMPTY, FULL, or OVERRUN
Message buffer	1	0	—	cmp	no_cmp	cmp	RANSWER
Message buffer	1	1	0	cmp	no_cmp	cmp_msk	EMPTY, FULL, or OVERRUN
Message buffer	1	1	1	cmp_msk	cmp_msk	cmp_msk	EMPTY, FULL, or OVERRUN
Legacy RX FIFO[5]	—	—	—	cmp_msk	cmp_msk	cmp_msk	—

1. For message buffer structure, if SMB[IDE] is 1, the ID is 29 bits (ID Standard plus ID Extended). If SMB[IDE] is 0, the ID is 11 bits (ID Standard). For Legacy RX FIFO structure, the ID depends on IDAM.
2. cmp: Compares the RX SMB contents to the MB contents regardless of masks.
3. no_cmp: The RX SMB contents are not compared to the MB contents.
4. cmp_msk: Compares the RX SMB contents to MB contents, accounting for masks.
5. SMB[IDE] and SMB[RTR] are not considered when IDAM is type C.

NOTE

For Enhanced RX FIFO, see Enhanced RX FIFO matching process.

A reception structure is free-to-receive when any of the following conditions is satisfied:

- The CODE field of the message buffer is EMPTY.
- The CODE field of the message buffer is either FULL or OVERRUN, and it has already been serviced (the CPU has read the Control and Status word and unlocked it as described in Message buffer lock mechanism).
- The CODE field of the message buffer is either FULL or OVERRUN and an inactivation (see Message buffer inactivation) is performed.
- The Legacy RX FIFO or Enhanced RX FIFO is not full.

The scan order for message buffers and Legacy Receive FIFO is from the matching element with the lowest number to the higher ones.

76.3.5.1 Matching priority

MCR[IRMQ] affects the matching winner search for MBs. If the field is 0, the matching winner is the first matched MB whether it is free-to-receive or not. If it is 1, the matching winner is selected according to this priority:

1. The first free-to-receive matched message buffer
2. The last non-free-to-receive matched message buffer

It is possible to select the priority of scan between MBs and Legacy RX FIFO or Enhanced RX FIFO with CTRL2[MRP].

If the selected priority is RX FIFO first:

- If the RX FIFO is a matched structure and is free-to-receive, the RX FIFO is the matching winner regardless of the scan for MBs.
- Otherwise, the matching winner is searched for among MBs as described above.

If the selected priority is MBs first:

- If a free-to-receive matched MB is found, it is the matching winner regardless of the scan for RX FIFO.
- If no matched MB is found, then the matching winner is searched for in the scan for the RX FIFO.
- If both conditions above are not satisfied and a non-free-to-receive matched MB is found, then the matching winner depends on the value of MCR[IRMQ]:
  - If MCR[IRMQ] = 0, the matching winner is the first matched MB.
  - If MCR[IRMQ] = 1, the matching winner is the RX FIFO if it is a free-to-receive matched structure. Otherwise, the matching winner is the last non-free-to-receive matched MB.

Table 549. Matching possibilities and resulting reception structures

RFEN or ERFEN	IRMQ	MRP	Matched in MB	Matched in FIFO	Reception structure	Description
No FIFO, only MB, match is always MB first						
0	0	X[1]	None[2]	—[3]	None	Frame lost by no match
0	0	X	Free[4]	—	First MB	—
0	1	X	None	—	None	Frame lost by no match
0	1	X	Free	—	First MB	—
0	1	X	Not free	—	Last MB	Overrun
FIFO enabled, no match in FIFO; is as if FIFO does not exist						
1	0	X	None	None[5]	None	Frame lost by no match
1	0	X	Free	None	First MB	—
1	1	X	None	None	None	Frame lost by no match
1	1	X	Free	None	First message buffer	—
1	1	X	Not free	None	Last message buffer	Overrun

Table continues on the next page...

Table 549. Matching possibilities and resulting reception structures (continued)

RFEN or ERFEN	IRMQ	MRP	Matched in MB	Matched in FIFO	Reception structure	Description
FIFO enabled, queue disabled						
1	0	0	X	Not full[6]	FIFO	—
1	0	0	None	Full[7]	None	Frame lost by FIFO full (FIFO overflow)
1	0	0	Free	Full	First MB	—
1	0	0	Not free	Full	First MB	
1	0	1	None	Not full	FIFO	
1	0	1	None	Full	None	Frame lost by FIFO full (FIFO overflow)
1	0	1	Free	X	First message buffer	—
1	0	1	Not free	X	First message buffer	Overrun
FIFO enabled, queue enabled						
1	1	0	X	Not full	FIFO	—
1	1	0	None	Full	None	Frame lost by FIFO full (FIFO overflow)
1	1	0	Free	Full	First message buffer	—
1	1	0	Not free	Full	Last message buffer	Overrun
1	1	1	None	Not full	FIFO	—
1	1	1	Free	X	First message buffer	—
1	1	1	Not free	Not full	FIFO	—
1	1	1	Not free	Full	Last message buffer	Overrun

1. Indicates a don't care condition.
2. Matched in message buffer "None" means that the frame has not matched any message buffer (free-to-receive or non-free-to-receive).
3. This condition is forbidden.
4. Matched in message buffer "Free" means that the frame matched at least one message buffer free-to-receive regardless of whether it has matched MBs that are non-free-to-receive.
5. Matched in FIFO, "None" means that the frame has not matched any filter in FIFO. It is as if the FIFO did not exist (CTRL2[RFFN] = 0 and ERFCR[ERFEN] = 0).
6. Matched in FIFO, "Not full" means that the frame has matched a FIFO filter and has empty slots to receive it.
7. Matched in FIFO, "Full" means that the frame matched a FIFO filter but could not store it, because it has no empty slots to receive it.

76.3.5.2 Special cases

If a non-safe MB inactivation (see Message buffer inactivation) occurs during the matching process and the inactivated MB is the temporary matching winner, the temporary matching winner is invalidated. The matching elements scan is not stopped and not restarted; it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist. In this case, a message may be lost.

Consider an example where:

- The FIFO is disabled.
- MCR[IRMQ] is 1.
- There are two message buffers with the same ID: the second and fifth MBs in the array.
- FlexCAN starts receiving messages with that ID.

When the first message arrives, the matching algorithm finds the first match in message buffer number 2. The code of this message buffer is EMPTY, so the message is stored in that MB. When the second message arrives, the matching algorithm finds MB number 2 again, but it is not "free-to-receive." It continues looking, finds MB number 5, and stores the message in that MB. If yet another message with the same ID arrives, the matching algorithm finds no matching free-to-receive MBs, so it overwrites the last matched message buffer (MB number 5). In doing so, it updates the CODE field of the message buffer to OVERRUN.

The ability to match the same ID in more than one MB can be used to implement a reception queue (in addition to the full-featured FIFO) to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages are queued into the message buffers. The CPU can examine the Timestamp field of the message buffers to determine the order in which the messages arrived.

Matching a range of IDs is possible via ID acceptance masks. FlexCAN supports individual masking per message buffer (see Receive Individual Mask (RXIMR0 - RXIMR95)). During the matching algorithm, if a mask field is 1, the corresponding ID bit is compared. If the mask field is 0, the corresponding ID bit is a "don't care". Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed when the module is in Freeze mode; otherwise, the module blocks them.

FlexCAN also supports an alternate masking scheme with only Legacy RX FIFO Global Mask (RXFGMASK), RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), and Receive 15 Mask (RX15MASK) for backward compatibility with legacy applications. This alternate masking scheme is enabled when the MCR[IRMQ] = 0.

76.3.6 Move process

There are two types of move process: move-in and move-out.

76.3.6.1 Move-in

The move-in process is the copying of a message received by an RX SMB to an RX message buffer or FIFO that has matched it. If the move destination is the Legacy RX FIFO, attributes of the message are also copied to the CAN_RXFIR FIFO. Each RX SMB has its own move-in process, but only one is performed at a given time. The move-in starts only when the message held by the RX SMB has a corresponding match (see Matching process) and all of the following conditions are true:

- The CAN bus has reached or already gone past:
  - The second bit of Intermission field next to the frame that carried the message that is in the RX SMB.
  - The first bit of an overload frame next to the frame that carried the message in the RX SMB.
- There is no ongoing matching process.
- The CPU is not locking the destination message buffer.
- No move-in process from another RX SMB is ongoing. If more than one move-in process is to be started at the same time, both are performed and the newest process substitutes for the oldest.

The term "pending move-in" is used throughout the documentation and stands for a move-to-be that does not satisfy all of the above conditions.

If any of the following conditions is satisfied, the move-in is canceled and the RX SMB is able to receive another message:

- The destination message buffer is inactivated after the CAN bus has reached the first bit of the Intermission field next to the frame that carried the message. Also, its matching process has finished.
- There is a previous pending move-in to the same destination message buffer.
- The RX SMB is receiving a frame transmitted by FlexCAN itself and self-reception is disabled (MCR[SRXDIS] = 1).
- Any CAN protocol error is detected.

If the module enters Freeze or Low-Power mode, the pending move-in is not canceled. It remains on hold, waiting for Freeze and Low-Power mode to be exited and for the module to be unlocked. If a message buffer is unlocked during Freeze mode, the move-in occurs immediately.

The move-in process is FlexCAN executing the following steps:

1. Push IDHIT into the RXFIR FIFO if the message is destined for the Legacy RX FIFO.
2. Read all data words from the RX SMB in accordance with the selected payload size for the RX storage element.
3. Write all data words to the RX message buffer according to the selected payload size for the RX storage element. If the data size of the storage element is smaller than the original payload size described in the DLC field of the message, the payload is truncated. The high-order bytes that do not fit the destination size are lost.
4. Read the Control and Status and ID words from the RX SMB.
5. Write the Control and Status and ID words to the RX message buffer, and update the CODE field.

The move-in process is not atomic; the inactivation of the destination message buffer immediately cancels it (see Message buffer inactivation). In this case, the message buffer may remain partially updated, and therefore incoherent. When the move-in destination is a Legacy or Enhanced RX FIFO message buffer, however, the process cannot be canceled.

To alert the CPU that the message buffer content is temporarily incoherent, the BUSY Bit (least significant bit of the CODE field) of the destination message buffer becomes 1 during move-in.

76.3.6.2 Move-out

The move-out process is the copying of content from a TX message buffer to the TX SMB when a message for transmission is available (see Arbitration process). The move-out occurs in the following conditions:

- In the first bit of Intermission field
- During the Bus Off state, when TX Error Counter is in the 124 to 128 range
- During the Bus Idle state
- During the Wait For Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently outside the Bus Idle state. In Bus Idle, the move-out has the lowest priority of the concurrent memory accesses.

76.3.7 Data coherence

In order to maintain data coherency and proper FlexCAN operation, the CPU must obey the rules described in Transmission process and Receive process.

76.3.7.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform the CPU whether the transmission was aborted or the frame could not be aborted and was transmitted instead.

These primary conditions must be fulfilled in order to abort a transmission:

- MCR[AEN] must be 1.
- The first CPU action must be the writing of abort code (1001b) into the CODE field of the Control and Status word.

Active message buffers configured for transmission must be aborted before they can be updated. The write operation is blocked and the transmission is not disturbed when the abort code is written to:

- A message buffer currently being transmitted.
- A message buffer that was already loaded into the TX SMB for transmission.

In this case, the abort request is captured and kept pending until one of the following conditions is satisfied:

- The module loses the bus arbitration.
- There is an error during the transmission.
- The module is put into Freeze mode.
- The module enters the Bus Off state.
- There is an overload frame.

If none of the conditions above are reached:

1. The message buffer is transmitted correctly.
2. The interrupt flag is set in the proper IFLAG register.
3. If enabled, an interrupt to the CPU is generated.

The abort request is automatically cleared when the interrupt flag is set. If only one of the above conditions is reached, the frame is not transmitted. In this case:

1. The abort code is written into the CODE field.
2. The interrupt flag is set in the proper IFLAG register.
3. Optionally, an interrupt is generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, the write operation is not blocked. The MB is updated and the interrupt flag is set. In this way, the CPU only needs to read the abort code to verify that the active MB was safely inactivated. In this case, although MCR[AEN] = 1 and the CPU wrote the abort code, the MB is inactivated and not aborted, because the transmission did not start yet. A message buffer is aborted only when the abort request is captured and kept pending until one of the previous conditions is satisfied.

76.3.7.2 Message buffer inactivation

Inactivation protects the message buffer against updates by FlexCAN internal processes. It allows the CPU to rely on message buffer data coherence after having updated it, even in Normal mode.

Inactivation of transmission message buffers must be performed only when MCR[AEN] = 0.

If a message buffer is inactivated, it does not participate in the arbitration process or the matching process until it is reactivated. See Transmission process and Receive process for detailed instructions on how to inactivate and reactivate a message buffer.

To inactivate a message buffer, the CPU must update its CODE field to INACTIVE (either 0b or 1000b).

Because you cannot synchronize the CODE field update with FlexCAN internal processes, an inactivation can have the following consequences:

- A frame in the bus that matches the filtering of an inactivated RX message buffer may be lost without notice. This loss can occur even if there are other message buffers with the same filter.
- A frame containing the message within an inactivated TX message buffer may be transmitted without setting the respective IFLAG flag.

To perform a safe inactivation and avoid the above consequences for TX message buffers, the CPU must use the transmission abort mechanism (see Transmission abort mechanism).

The inactivation automatically unlocks the message buffer (see Message buffer lock mechanism).

NOTE

Message buffers that are part of the Legacy RX FIFO or Enhanced RX FIFO cannot be inactivated. There is no write protection on the Legacy FIFO region by FlexCAN. The CPU must maintain data coherency in the Legacy FIFO region when MCR[RFEN] = 1.

76.3.7.3 Message buffer lock mechanism

In addition to message buffer inactivation, FlexCAN uses a message buffer lock mechanism to maintain data coherence for the receive process. When the CPU reads the Control and Status word of an RX message buffer with codes FULL or OVERRUN, FlexCAN is configured to allow the CPU to read the whole message buffer in an atomic operation. FlexCAN sets an internal lock flag for that message buffer.

The lock is released in any of the following events:

- The CPU reads the free-running timer (global unlock operation).
- The CPU reads the Control and Status word of another message buffer, regardless of its code.
- The CPU writes into the Control and Status word. This procedure is not recommended for normal unlocking, because it cancels a pending move and may lose a received message.

The message buffer lock prevents a new frame from being written into the message buffer when the CPU is reading it.

NOTE

The locking mechanism applies only to RX message buffers that are not part of the Legacy RX FIFO and have a code other than INACTIVE (0b) or EMPTY[1] (0100b). TX message buffers cannot be locked.

Consider an example where:

- The Legacy RX FIFO is disabled.
- The second and the fifth message buffers of the array are programmed with the same ID.
- FlexCAN has already received and stored messages into these two message buffers.
- The CPU reads message buffer number 5 while another message with the same ID is arriving.

When the CPU reads the Control and Status word of message buffer number 5, this message buffer is locked. The new message arrives and the matching algorithm finds no free-to-receive message buffers, so it overrides message buffer number 5. This message buffer is locked, so the new message cannot be written to it. The message remains in the RX SMB until the message buffer is unlocked, and only then is it written to the message buffer.

If the message buffer remains locked and another new message with the same ID arrives, the new message overwrites the one in the RX SMB. There is no indication of lost messages in the CODE field of the message buffer or in Error and Status 1 (ESR1).

When the message is moved from the RX SMB to the message buffer, the BUSY bit on the CODE field becomes 1. If the CPU reads the Control and Status word and identifies that the BUSY bit is 1, it must wait until the BUSY bit becomes 0 to access the MB.

NOTE

If the BUSY bit is 1 or the message buffer is empty, reading the Control and Status word does not lock the message buffer.

Inactivation takes precedence over locking. If the CPU inactivates a locked receive message buffer, then its lock status is negated and the message buffer is marked as invalid for the current matching round. Any pending message on the RX SMB is not transferred to the message buffer. A message buffer is unlocked when the CPU reads Free-Running Timer (TIMER) or the Control and Status word of another message buffer.

The lock and unlock mechanisms have the same functionality in Normal and Freeze modes.

[1] In previous FlexCAN versions, reading the Control and Status word locked the message buffer even when CODE indicates it is EMPTY. This behavior is maintained when the IRMQ bit is 0.

An unlock during Normal or Freeze mode results in the move-in of the pending message. If unlocking occurs during a low-power mode, however, the move-in is postponed (see Modes of operation). Move-in takes place only when the module returns to Normal or Freeze mode.

76.3.8 Enhanced RX FIFO

FlexCAN supports an enhanced RX FIFO engine which can store up to 20 CAN FD messages. The region 2000h–204Fh contains the output of the FIFO, which the CPU should read. To enable the enhanced RX FIFO, write 1 to ERFCR[ERFEN]. FlexCAN has two FIFO options, Legacy RX FIFO and Enhanced RX FIFO, but both options cannot be enabled at the same time. See Legacy RX FIFO for additional information.

To configure the enhanced RX FIFO watermark, write a value to ERFCR[ERFWM]. If ERFCR[ERFWM] is configured, the CPU is notified only if a minimum number of messages is stored in the FIFO. When the number of stored messages is greater than the value in ERFCR[ERFWM], the module sets ERFSR[ERFWMI]. Optionally, if MCR[DMA] or ERFIER[ERFWMIIE] are enabled, a DMA transfer or an interrupt can be triggered, respectively.

For the enhanced RX FIFO to receive, the CPU must execute the configuration procedure below. If the CPU must change any configurations of the Enhanced RX FIFO, the same procedure must be followed.

Prerequisites

MCR[RFEN] must be 0.

Procedure

Step	Purpose	Programming	Notes
1	Enter Freeze mode.	See Freeze mode.	—
2	If enhanced RX FIFO is not already enabled, enable it.	Write 1 to ERFCR[ERFEN].	—
3	Reset enhanced RX FIFO engine.	Write 1 to ERFSR[ERFCLR].	—
4	If the enhanced RX FIFO error flags are set, clear them.	Write 1 to these flags: • ERFSR[ERFUFW] • ERFSR[ERFOVF] • ERFSR[ERFWMI] • ERFSR[ERFDA]	—
5	Specify the total number of enhanced RX FIFO filter elements to be used in Enhanced RX FIFO reception.	Write the number to ERFCR[NFE].	—
6	Specify the number of extended ID and standard ID filter elements to be used in Enhanced RX FIFO reception.	Write the number to ERFCR[NEXIF].	ERFCR[NEXIF] ≤ ERFCR[NFE] + 1.
7	If you are using DMA, enable DMA.	Write 1 to MCR[DMA].	—
8	If you are using DMA, specify the number of words to transfer for each Enhanced RX FIFO data element.	Write the number to ERFCR[DMALW].	—
9	Specify the Enhanced RX FIFO watermark.	Write the number to ERFCR[ERFWM].	If MCR[DMA] = 1, ERFCR[ERFWM] should be 0h.

Table continues on the next page...

Table continued from the previous page...

Step	Purpose	Programming	Notes
10	If you are using interrupts, enable the interrupts.	Write 1 to the interrupt enables in Enhanced RX FIFO Interrupt Enable (ERFIER).	—
11	Configure the filter elements.	Write to the ERFFEL*n* registers.	ERFFEL*n* registers are implemented in RAM; you must explicitly initialize them before prior any reception.
12	Exit Freeze mode.	See Freeze mode.	—

There are two types of enhanced RX FIFO filter elements that can be stored in ERFFEL*n* registers: extended-ID filter elements and standard-ID filter elements. Each extended-ID filter element is stored in two ERFFEL*n* registers, and each standard-ID filter element is stored in one ERFFEL*n* register. ERFCR[NFE] defines the total number of Enhanced RX FIFO filter elements.

In addition, the filter memory space can be split into two regions: one for extended-ID filter elements and another for standard-ID filter elements, according to ERFCR[NEXIF]. Figure 522 shows how the enhanced RX filter elements are defined. See Enhanced RX FIFO matching process for information about the Enhanced RX FIFO matching process and filter element formats.

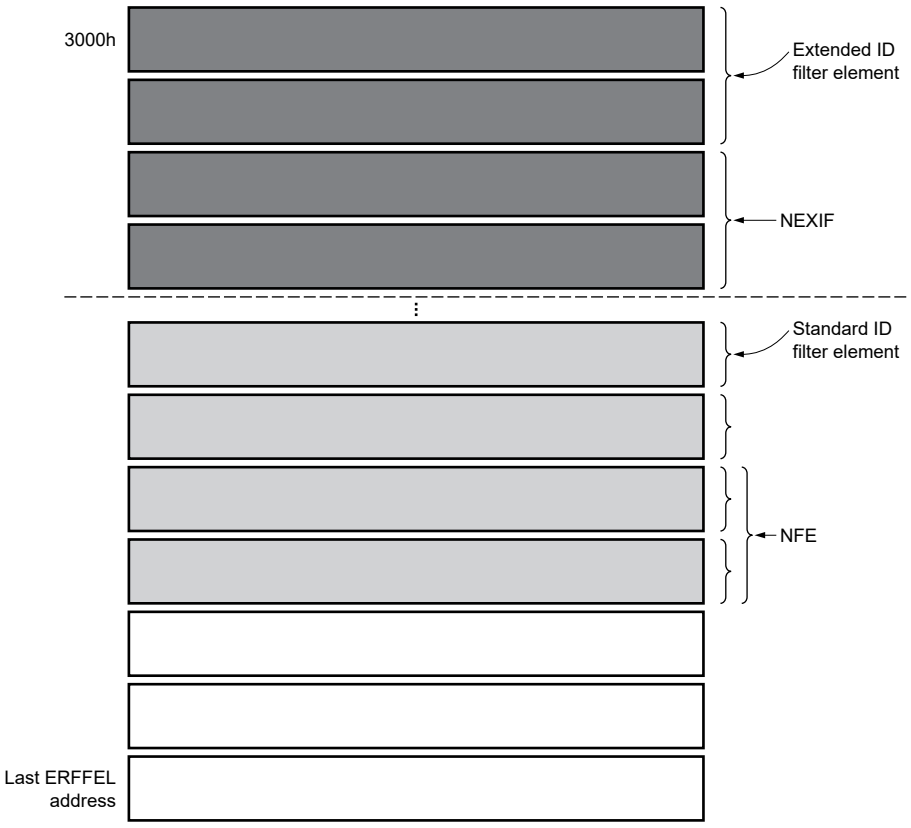

Figure 522. Number of enhanced RX FIFO filter elements

76.3.8.1 Enhanced RX FIFO matching process

When ERFCR[ERFEN] = 1, FlexCAN scans the ERFFEL*n* memory region. If at least one filter element satisfies the matching criteria, the CAN message content is transferred to the enhanced RX FIFO memory. If multiple filters match the incoming message ID, the first matching filter found by the matching process must be indicated in IDHIT.

Each ERFFEL*n* register can store one standard filter element. ERFFEL*n*[FEL][31:30], also called FSCH, determines the matching criteria in this way:

- If FSCH = b00, the filter scheme is based on mask and filter. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base-frame format (IDE = 0).
  2. (ID[*n*] = STD ID filter [*n*]) or (STD ID Mask[*n*] = 0) for each bit *n* from 0 to 10.
  3. (RTR = RTR Filter) or (RTR MASK = 0).

In this explanation, RTR and ID are the Remote Transmit Request field and the ID from a CAN message, respectively.

If FSCH = b00, the filters and masks are defined as shown in Table 550.

Table 550. Standard ID filter element with filter and mask scheme (FSCH = b00)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH = b00		Reserved		RTR filter	STD ID filter		Reserved		RTR mask	STD ID mask	

- If FSCH = b01, the filter scheme is based on range. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0).
  2. ID ≥ STD ID Filter1.
  3. ID ≤ STD ID Filter2.
  4. (RTR = RTR filter) or (RTR MASK = 0).

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If FSCH = b01, the filters and mask are defined as shown in Table 551.

Table 551. Standard ID filter element with range scheme (FSCH = b01)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH = b01		Reserved		RTRfilter	STD ID Filter2		Reserved		RTR mask	STD ID Filter1	

- If FSCH = b10, the filter scheme is based on two filters without masks. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0).
  2. (ID[*n*] = STD ID Filter1[*n*]) or (ID[*n*] = STD ID Filter2[*n*]) for each bit *n* from 0 to 10.
  3. (RTR = RTR Filter1) or (RTR = RTR Filter2).

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If FSCH = b10, the filters are defined as shown in Table 552.

Table 552. Standard ID filter element with two-filter scheme (FSCH = b10)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH = b10		Reserved		RTR Filter 2	STD ID Filter2		Reserved		RTR Filter 1	STD ID Filter1	

Each pair of ERFFEL*n* registers can store one extended filter element. ERFFEL*n*[FSCH] determines the matching criteria in this way:

- If FSCH = b00, the filter scheme is based on mask and filter. A CAN message matches an extended ID filter element only if these criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. (ID[*n*] = EXT ID filter [*n*]) or (EXT ID Mask[*n*] = 0) for each bit *n* from 0 to 28.
  3. (RTR = RTR Filter) or (RTR MASK = 0).

If FSCH = b00, the filters and masks are defined as shown in Table 553.

Table 553. Extended ID filter element with filter + mask scheme (FSCH = b00)

31	30	29	28	0
FSCH		RTR filter	EXT ID filter	
Reserved		RTR mask	EXT ID mask	

- If FSCH = b01, the filter scheme is based on range. A CAN message matches an extended ID filter element only if the following criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. ID ≥ EXT ID Filter1.
  3. ID ≤ EXT ID Filter2.
  4. (RTR = RTR Filter) or (RTR MASK = 0).

If FSCH = b01, the filters and masks are defined as shown in Table 554.

Table 554. Extended ID filter element with range scheme (FSCH = b01)

31	30	29	28	0
FSCH		RTR filter	EXT ID Filter2	
Reserved		RTR mask	EXT ID filter 1	

- If FSCH = b10, the filter scheme is based on two filters without masks. A CAN message matches an extended ID filter element only if these criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. (ID[*n*] = EXT ID Filter1[*n*]) or (ID[*n*] = EXT ID Filter2[*n*]) for each bit *n* from 0 to 28.
  3. (RTR = RTR Filter1) or (RTR = RTR Filter2).

If FSCH = b10, the filters are defined as shown in Table 555.

Table 555. Extended ID filter element with two-filter scheme (FSCH = b10)

31	30	29	28	0
FSCH		RTR Filter2	EXT ID Filter2	
Reserved		RTR Filter1	EXT ID filter 1	

76.3.8.2 Enhanced RX FIFO under DMA operation

You can enable the DMA feature by writing 1 to both ERFCR[ERFEN] and MCR[DMA]. The DMA controller can read the received message by reading a message buffer structure at the enhanced FIFO output port at the address range defined in Enhanced RX FIFO structure.

NOTE

FlexCAN supports 32-bit access only for DMA transfers.

For proper FIFO engine operation, the CPU should not access the Enhanced FIFO output port address range during DMA operation. Before writing 1 to MCR[DMA], the CPU must service Enhanced RX FIFO status bits. Otherwise, these bits may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before writing 0 to MCR[DMA], the CPU must first clear the ERFSR[ERFUFW], ERFSR[ERFOVF], ERFSR[ERFWMI], and ERFSR[ERFDA] flags. It must then clear the enhanced RX FIFO engine by writing one to ERFSR[ERFCLR].

When there is one frame available to be read from the Enhanced RX FIFO, FlexCAN sets ERFSR[ERFDA]. Upon receiving the request, the DMA controller can read the message in the Enhanced RX FIFO output. Each message reading process must end by the address defined in ERFCR[DMALW].

Follow these rules for Enhanced RX FIFO DMA operation:

- Because a DMA transfer cannot be changed dynamically, program ERFCR[DMALW] so the enhanced RX FIFO element can store the largest CAN message present on the CAN bus.
- Data bytes are valid according to the DLC field. See Table 583.

Each time the DMA controller reads one message from the FIFO, FlexCAN clears ERFSR[ERFDA]. If there is at least one message stored in the FIFO, FlexCAN sets it again.

Consider an example where the maximum number of bytes in the data field of a CAN frame for a certain application is eight, and high-resolution timestamp is enabled. In that case, the last enhanced RX FIFO address offset can be found in Table 593 and Table 594. Using this address offset, ERFCR[DMALW] can be determined in this way:

- Maximum number of data bytes = 8
- HR_TIME_STAMP enabled
- Last address offset = TS_OFF = 2014h
- DMALW = 5

76.3.8.3 Enhanced RX FIFO clear operation

When ERFCR[ERFEN] is 1, the CPU can clear the Enhanced RX FIFO by writing 1 to ERFSR[ERFCLR]. The clear operation resets the internal FIFO pointers, but the FIFO content stored in RAM is not changed. This operation can only be performed in Freeze mode; the module blocks the operation in other modes. This operation does not clear ERFSR[ERFUFW], ERFSR[ERFOVF], ERFSR[ERFDA], or ERFSR[ERFWMI]. The CPU must service all these fields before executing the clear FIFO operation.

76.3.9 Legacy RX FIFO

The Legacy RX FIFO is receive-only. To enable it, write 1 to MCR[RFEN]. To maintain software backward compatibility with previous versions of FlexCAN that did not have the Legacy FIFO feature, the reset value of this field is zero.

CAUTION

Do not enable Legacy RX FIFO when the CAN FD feature is enabled.

The Legacy FIFO is six messages deep. The memory region the Legacy FIFO structure occupies (both message buffers and Legacy FIFO engine) is described in Legacy RX FIFO structure. The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a message buffer structure at the output of the Legacy FIFO.

IFLAG1[BUF5I] (Frames Available in Legacy RX FIFO) is set when at least one frame is available to be read from the Legacy FIFO. If the corresponding mask bit enables it, an interrupt is generated. Upon receiving the interrupt, the CPU can read the message (accessing the output of the Legacy FIFO as a message buffer) and Legacy RX FIFO Information (RXFIR), then clear the interrupt. If there are more messages in the Legacy FIFO, clearing the interrupt:

1. Updates the output of the Legacy FIFO with the next message.
2. Updates RXFIR with the attributes of that message.
3. Reissues the interrupt to the CPU.

Otherwise, the flag remains cleared. The output of the Legacy FIFO is valid only when IFLAG1[BUF5I] is set.

IFLAG1[BUF6I] (Legacy RX FIFO Warning) is set when the Legacy RX FIFO receives a new message that increases the number of unread messages from four to five. This change means that the Legacy RX FIFO is almost full. The flag remains set until the CPU clears it.

IFLAG1[BUF7I] (Legacy RX FIFO Overflow) is set when an incoming message is lost because the Legacy RX FIFO is full. The flag is not set when the Legacy RX FIFO is full and a message buffer captures the message. The flag remains set until the CPU clears it.

Clearing one of the three flags above does not affect the state of the other two.

If an IFLAG flag is set and the corresponding mask bit is 1, an interrupt is generated.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing workload. The filtering criteria are specified by programming a table of up to 128 32-bit registers, according to CTRL2[RFFN]. This table can be configured to one of the following formats (see also Legacy RX FIFO structure):

- Format A: 128 Identifier Acceptance Filters (IDAFs) — extended or standard IDs including IDE and RTR
- Format B: 256 IDAFs — standard IDs or extended 14-bit ID slices including IDE and RTR
- Format C: 512 IDAFs — standard or extended 8-bit ID slices

NOTE

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the Legacy RX FIFO has a corresponding Identifier Acceptance Filter Hit Indicator (IDHIT). The IDHIT can be read in the IDHIT field in the Control and Status word, as shown in the Legacy RX FIFO Structure description. The CPU can also obtain this information by accessing Legacy RX FIFO Information (RXFIR). RXFIR[IDHIT] refers to the message at the output of the Legacy FIFO, and is valid when IFLAG1[BUF5I] is set. RXFIR must be read only before clearing the flag, guaranteeing that the information refers to the correct frame within the Legacy FIFO.

The Individual Mask Registers (RXIMR*n*) individually affect up to 32 elements of the filter table, according to the value of CTRL2[RFFN]. This configuration allows very powerful filtering criteria to be defined. If MCR[IRMQ] is 0, the Legacy RX FIFO filter table is affected by Legacy RX FIFO Global Mask (RXFGMASK).

NOTE

See Table 544 for information about the difference between FD and non-FD regarding this feature.

76.3.9.1 Legacy RX FIFO in DMA Operation

The receive-only Legacy FIFO can support DMA. To enable this feature, write 1 to both MCR[RFEN] and MCR[DMA]. To maintain backward compatibility with previous versions of the module that did not have the DMA feature, the reset value of MCR[DMA] is zero.

The DMA controller can read the received message by reading a message buffer structure at the Legacy FIFO output port in the 80h–8Ch address range.

NOTE

FlexCAN supports 32-bit access only for DMA transfers.

When MCR[DMA] = 1, the CPU must not access the Legacy FIFO output port address range. Before writing 1 to MCR[DMA], the CPU must service the IFLAG flags set in the Legacy RX FIFO region. Otherwise, these flags may indicate that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before writing 0 to MCR[DMA], the CPU must perform a clear Legacy FIFO operation.

When at least one frame available to be read from the FIFO, IFLAG1[BUF5I] (Frames available in Legacy RX FIFO) is set. A DMA request is generated simultaneously. Upon receiving the request, the DMA controller can read the message (accessing the output of the Legacy FIFO as a message buffer). The DMA reading process must end by reading address 8Ch. This read operation:

- Clears IFLAG1[BUF5I].
- Updates the FIFO output with the next message (if the FIFO is not empty).
- Updates Legacy RX FIFO Information (RXFIR) with the attributes of the new message.

If there are more messages stored in the FIFO, IFLAG1[BUF5I] is reasserted and another DMA request is issued. Otherwise, the flag remains cleared.

NOTE

RXFIR contents cannot be read after DMA completes the Legacy FIFO read. The IDHIT information is also available in the Control and Status word at address 080h (see Legacy RX FIFO structure).

IFLAG1[BUF6I] and IFLAG1[BUF7I] are not used when the DMA feature is enabled.

When FlexCAN is working with DMA, the CPU does not receive any Legacy RX FIFO interruption and must not clear the related IFLAG flags. The related IMASK bits are not used to mask the generation of DMA requests.

NOTE

See Table 544 for information about the difference between FD and non-FD regarding this feature.

76.3.9.2 Clear Legacy FIFO

When MCR[RFEN] = 1, you can use the clear Legacy FIFO operation to empty Legacy FIFO contents. When the CPU writes 1 to IFLAG1[BUF0I], the clear FIFO operation occurs. This operation can only be performed in Freeze mode; FlexCAN blocks it in other modes. This operation does not clear the FIFO IFLAG flags; the CPU must service all FIFO IFLAG flags before executing the clear FIFO operation.

When Legacy RX FIFO is working with DMA, the clear FIFO operation clears IFLAG1[BUF5I], and the DMA request is canceled.

CAUTION

The clear Legacy FIFO operation does not clear IFLAG flags, except when MCR[DMA] = 1; in this case, only IFLAG1[BUF5I] is cleared.

76.3.10 CAN protocol-related features

76.3.10.1 CAN FD ISO compliance

The CAN FD protocol has been improved to increase the failure-detection capability that was in the original CAN FD protocol. This original protocol is also called non-ISO CAN FD, by CAN in Automation (CiA). A three-bit stuff counter and a parity bit have been introduced in the improved CAN FD protocol, now called ISO CAN FD. The CRC calculation has also been modified. All these improvements make the ISO CAN FD protocol incompatible with the non-ISO CAN FD protocol. FlexCAN still supports non-ISO CAN FD, so it can be used during an intermediate phase, for evaluation and development purposes.

It is recommended that you configure FlexCAN with the ISO CAN FD protocol by writing 1 to CTRL2[ISOCANFDEN].

76.3.10.2 CAN FD frames

ISO 11898-1:2015 specifies the Classical Frame format compliant to ISO 11898-1:2003 (2003) and introduces the CAN Flexible Data Rate Frame format (CAN FD). The Classical Frame format allows bit rates up to one Mbit/s and payloads up to eight bytes per frame. The Flexible Data Rate Frame format allows bit rates faster than one Mbit/s and payloads longer than eight bytes per frame. FlexCAN can receive and transmit CAN FD messages interleaved with Classical CAN messages.

There are additional control bits in the CAN FD frame:

- The Extended Data Length (EDL) bit enables a longer data payload with different data length coding.
- The Bit Rate Switch (BRS) bit decides whether the bit rate is switched inside a CAN FD format frame.
- The Error State Indicator (ESI) flag is transmitted dominant by error active nodes, and recessive by error passive nodes.

There are no Remote Frames (see Remote frames) in the CAN FD format. A message configured to transmit a Remote Frame is always sent out in Classical CAN format. When an FD frame is received and matches a message buffer, the RTR bit in the receiving message buffer becomes 0. The RTR bit must be considered in classical frames only.

76.3.10.2.1 CAN FD messages

CAN FD messages may be formatted as long frames where the data field exceeds eight bytes, and may range from 12 up to 64 bytes. They can also be configured to support bit rate switching. In this case, the control field, data field, and CRC field of a CAN frame are transmitted with a higher bit rate than the beginning and end of the frame. Messages in Classical CAN format are limited to transport a maximum payload of eight bytes at nominal rate. Figure 523 illustrates the message formats for Classical and FD frames with either standard or extended ID.

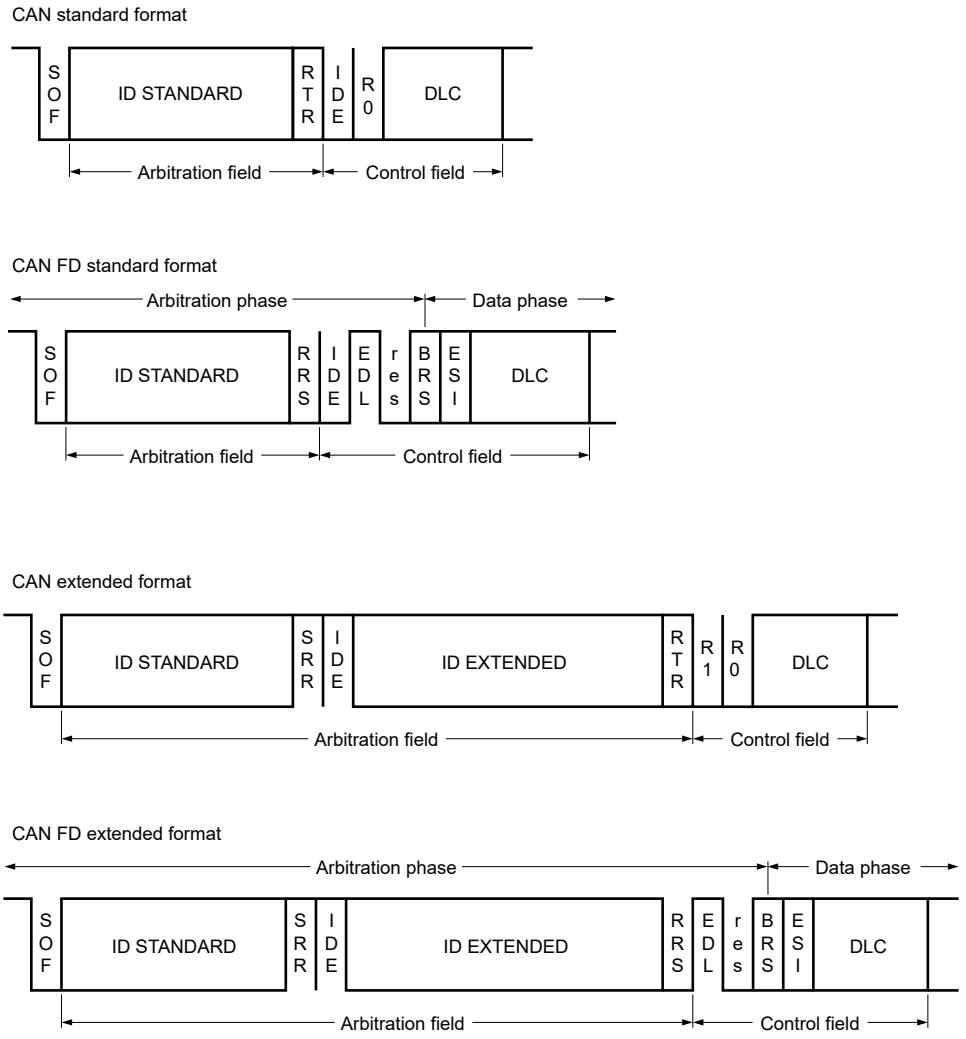

Figure 523. CAN message formats

MCR[FDEN] enables the ability to receive and transmit CAN FD messages. A recessive R0 bit in CAN frames with 11-bit identifiers, or a recessive R1 bit in CAN frames with 29-bit identifiers, is decoded as an EDL bit (not a reserved one). A recessive EDL bit identifies a CAN FD frame, and a dominant EDL bit identifies a Classical CAN frame. The BRS bit specifies whether this frame switches the bit rate in its data phase. A long frame is decoded according to the DLC field value (see DLC definition in Message buffer structure).

CAN FD messages can be transmitted with two different bit rates. The first part of a CAN FD frame, from the Start of Frame (SOF) bit until the Bit Rate Switch (BRS) bit is called the arbitration phase. This part is transmitted with the nominal bit rate based on a set of nominal CAN bit timing configuration values. The second part, from the BRS bit until the CRC Delimiter bit, is called the data phase. When this second part is transmitted, a second set of CAN data bit timing configuration values determines the data bit rate. Finally, from the CRC delimiter until the Intermission bits, the transmission returns to nominal bit rate.

76.3.10.2.2 BRS in CAN FD

In CAN FD frames with bit rate switching, the bit timing changes inside the frame at the sample point of the BRS bit if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by CAN Bit Timing (CBT). (Control 1 (CTRL1) also defines this timing for backward compatibility.) Upon detecting a recessive BRS bit, the CAN data bit timing is used as defined by CAN FD Bit Timing (FDCBT).

NOTE

If the time quantum length in nominal bit timing and in the data bit timing are not identical, a quantization error of up to one time quantum of the arbitration phase may be present as a phase error. This situation can occur after the switch from arbitration to data phase, and it lasts until the next synchronization event. The length of the time quantum should be the same in nominal and data bit timing. This configuration minimizes the chance of error frames on the CAN bus, and optimizes the clock tolerance in networks that use FD frames.

If BRS = 1 in the selected TX MB, FDCTRL[FDRATE] enables the transmission of all frames with bit rate switching. If FDCTRL[FDRATE] = 0, the transmission is performed at nominal rate regardless of the BRS bit value. FDCTRL[FDRATE] can be written at any time but takes effect only for the next message transmitted or received.

Nominal bit timing is resumed at the sample point of the CRC Delimiter bit or when an error is detected, whichever occurs first. Figure 524 describes the mechanism for entering and leaving the data phase when the BRS bit is recessive.

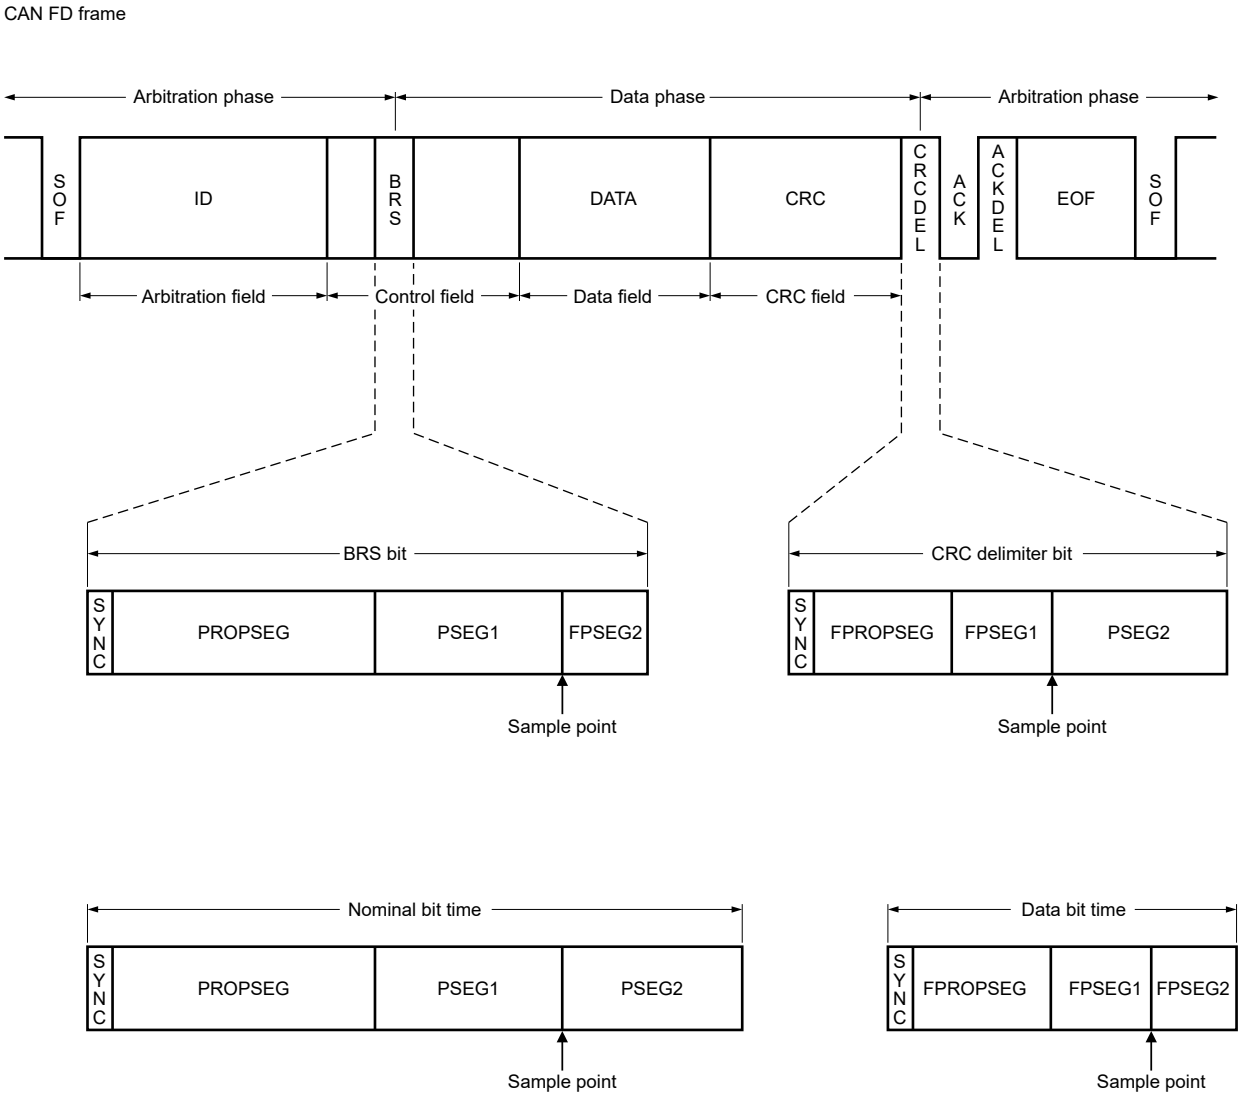

Figure 524. Bit rate switching mechanism for CAN FD messages

NOTE

In Classical CAN frames, the CRC delimiter is one recessive bit. In CAN FD frames, the CRC delimiter may consist of one or two recessive bits. FlexCAN sends only one recessive bit as the CRC delimiter. It accepts two recessive bits before the recessive-to-dominant edge that starts the acknowledge slot. As a receiver, FlexCAN sends its acknowledge bit after the first CRC delimiter bit. In CAN FD frames, FlexCAN accepts a two-bit dominant ACK slot as a valid ACK to compensate for phase shifts between the receivers.

The maximum configurable bit rate in the CAN FD data phase depends on the clock frequency of the CAN_PE subblock. For example, for a CAN_PE clock frequency of 40 MHz and the shortest configurable bit time of 5 time quanta, the bit rate in the data phase is 8 Mbit/s.

NOTE

The frequency used in this example may not be supported on this chip. It is shown only to demonstrate how the maximum configurable bit rate is calculated.

76.3.10.2.3 ESI in CAN FD

The value of the ESI bit is determined:

- By the error state of the transmitter at the start of the transmission, if the frame is originated in the FlexCAN node,
- Or by the original transmitting node when FlexCAN is acting as a gateway for the message.

If the transmitter is error-passive, ESI is transmitted recessive; otherwise, it is transmitted dominant. The permutations of the relationship between the written value and the transmitted value of the ESI are shown in Table 556.

Table 556. Written versus transmitted values of ESI field

FlexCAN fault confinement status at start of frame	ESI bit of TX MB	Transmitted ESI
Error active	0	0 (Error Active)
Error passive	0	1 (Error Passive)
Error active	1	1 (Error Passive)
Error passive	1	1 (Error Passive)

76.3.10.2.4 CRC calculations in CAN FD

Different CAN frame formats have different CRC polynomials. The first polynomial, CRC_15, is used for all frames in Classical CAN format. The second, CRC_17, is used for frames in CAN FD format with a data field up to 16 bytes long. The third, CRC_21, is used for frames in CAN FD format with a data field longer than 16 bytes. Each polynomial results in a Hamming distance of 6. At the start of the frame, all three CRC polynomials are calculated concurrently. The values of the EDL bit and the DLC field select the CRC sequence to be transmitted. When receiving a message, FlexCAN decodes EDL and DLC to select the adequate CRC polynomial to check for a CRC error.

In CAN FD format frames, stuff bits are included in the bit stream for CRC calculation. In Classical CAN format frames, stuff bits are not included. After the transmission of the last bit relevant to the CRC calculation, CAN FD CRC (FDCRC) stores the calculated CRC for the transmitted message. This storage is performed with adequate length for the type of message, for CAN FD and non-FD messages. Cyclic Redundancy Check (CRCR) reports a valid CRC for Classical CAN messages only.

In CAN FD format frames, the CAN bit stuffing method changes for the CRC sequence, so the stuff bits are inserted at fixed positions. When FlexCAN is transmitting a CAN FD frame, a fixed stuff bit is inserted just before the first bit of the CRC sequence. This insertion occurs even if the last bits of the preceding field do not fulfill the CAN stuff condition. Additional stuff bits are inserted after each fourth bit of the CRC sequence. The value of any fixed stuff bit is the inverse value of its preceding bit. When FlexCAN receives a CAN FD frame, it discards the fixed stuff bits from the bit stream for the CRC check. A stuff error is detected if the fixed stuff bit has the same value as its preceding bit.

76.3.10.2.5 CAN FD errors

FlexCAN detects errors in CAN FD frames the same way as in Classical CAN frames. The error counters ECR[RXERRCNT] and ECR[TXERRCNT] accumulate the counts of RX and TX errors, respectively, for both FD and non-FD frames indiscriminately. Two extra error counters, ECR[RXERRCNT_FAST] and ECR[TXERRCNT_FAST], accumulate RX and TX errors occurring in the data phase of CAN FD frames with BRS = 1 only. The rules for updating the error counters are the same for both CAN FD and non-FD frames (see Error Counter (ECR)).

These error flags report errors in both CAN FD and non-FD frames:

- ESR1[BIT1ERR]
- ESR1[BIT0ERR]
- ESR1[ACKERR]
- ESR1[CRCERR]
- ESR1[FRMERR]
- ESR1[STFERR]

If CTRL1[ERRMSK] = 1, they also generate the ERRINT interrupt.

These additional error flags indicate the occurrence of errors in the data phase of CAN FD frames with BRS = 1:

- ESR1[BIT1ERR_FAST]
- ESR1[BIT0ERR_FAST]
- ESR1[CRCERR_FAST]
- ESR1[FRMERR_FAST]
- ESR1[STFERR_FAST]

No ACKERR is detected in the data phase of a CAN FD frame. Fault confinement status reported in ESR1[FLTCONF] is the same for both CAN FD and Classical CAN frames, and is based on ECR[RXERRCNT] and ECR[TXERRCNT] only. Information in ECR[RXERRCNT_FAST] and ECR[TXERRCNT_FAST] may be considered as status to help detect the error nature related to the bit rate value.

When FlexCAN detects an error while transmitting or receiving a CAN FD message in the data phase, it immediately switches:

- Back to the arbitration phase, and
- Back to the nominal rate to start an error flag.

76.3.10.2.6 CAN FD synchronization

Resynchronization and hard synchronization occur in CAN FD frames in the same way as in Classical CAN ones. A hard synchronization is also performed at the recessive-to-dominant edge from EDL to R0 in CAN FD format frames. FlexCAN does not resynchronize when transmitting in the CAN FD data phase.

76.3.10.3 Transceiver delay compensation

The CAN FD protocol allows the transmission and reception of data at a higher bit rate than the nominal rate used in the arbitration phase, when BRS = 1 in the message. This feature enables the use of rates up to 8 Mbit/s.

During the data phase of a CAN FD frame, if the transmitter cannot receive its own latest transmitted bit at the sample point of that bit, it detects a bit error. When bit rate switching is enabled (BRS = 1), the CAN bit time in the data phase can become shorter than the loop delay of the transceiver. This condition impedes the correct comparison between the transmitted bit and the received bit within the current CAN bit time interval.

The transceiver delay compensation (TDC) process defines a secondary sample point where the transmitted bit is correctly compared to the received bit to check for bit errors.

You can enable the TDC mechanism via FDCTRL[TDCEN] or ETDC[ETDCEN]. The TDC mechanism is effective only during the data phase of FD frames with BRS = 1. It has no effect on either non-FD frames or FD frames transmitted at the normal bit rate. When the transmitted message has BRS = 1, TDC is active from the sample point of the BRS bit until the sample point of the CRC Delimiter bit. When TDC is active, the real received bit is compared to the delayed transmitted bit, where the delay is calculated based on the measured transceiver loop delay.

NOTE

The transmitters using TDC disregard the value of the CRC delimiter bit. A global error at the end of the CRC field causes the receivers to send error frames that the transmitter detects during Acknowledge or End of Frame.

For every transmitted FD frame with BRS = 1, the transition from the recessive EDL bit to the dominant R0 bit triggers the delay measurement (as shown in Figure 525). The loop delay is measured in Protocol Engine (PE) clock periods (CANCLK, see Protocol timing), from the transmitted EDL-R0 edge to the received EDL-R0 edge. The measured loop delay time added to an offset value specified in FDCTRL[TDCOFF] or ETDC[ETDCOFF] determines the position of the secondary sample point. FDCTRL[TDCVAL] or ETDC[ETDCVAL] stores the result of this calculation. The TDCVAL and ETDCVAL value saturates at its maximum value of 63 CANCLK and 255 CANCLK when the delay measurement is too long.

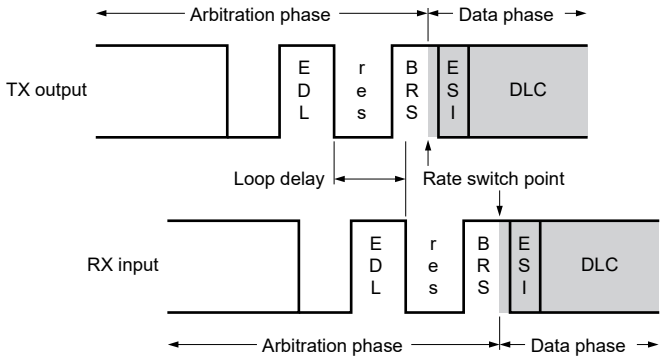

Figure 525. Transceiver loop delay measurement

The measured loop delay is not enough to define the secondary sample point, because it relates to the CAN bit edges. The transceiver delay compensation offset FDCTRL[TDCOFF] or ETDC[ETDCOFF] is used to shift the secondary sample point to an intermediate point inside the bit time, far away from its edges. The value of FDCTRL[TDCOFF] or ETDC[ETDCOFF] cannot be larger than the CAN bit duration in the data phase.

If the secondary sample point is set very near the CAN bit edge (SYNC field), problems may occur during the bit sampling in the data phase. For the TDC to work reliably, the offset must use optimal settings. To ensure that bit sampling is performed in the best region, configure the TDC offset as shown in this equation:

$$Offset = (FPSEG1 + FPROPSEG + 2) \times (FPRESDIV + 1)$$
or
$$Offset = (DTSEG1 + 2) \times (EDPRESDIV + 1), \textit{ if ETDCEN}$$

Equation 13. TDC offset calculation

Figure 526 shows the SSP position when these settings are used.

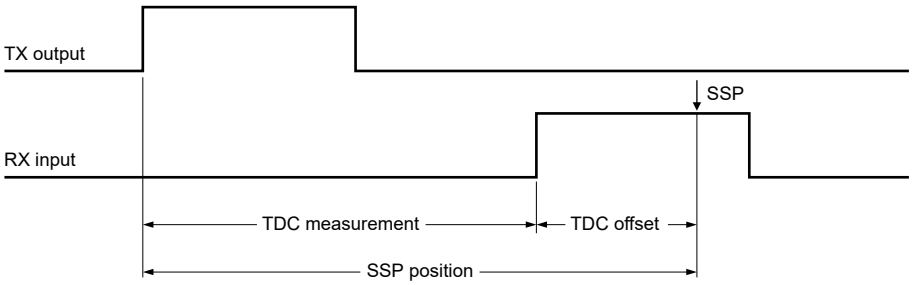

Figure 526. SSP position with optimal values

Alternatively, if CTRL2[BTE] and ETDC[ETDCEN] are 1, you can write 1 to ETDC[TDMDIS] to disable the transceiver delay measurement. In this case, only ETDC[ETDCOFF] defines the SSP position. Figure 527 shows the secondary sample point position when the transceiver delay measurement is disabled.

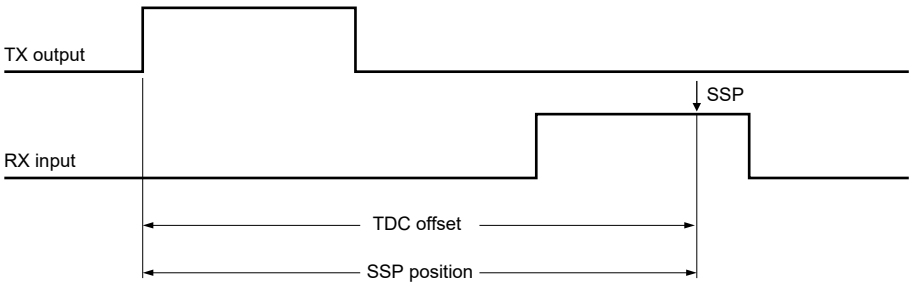

Figure 527. SSP position with TDC measurement disabled by ETDCEN and TDMDIS

During the data phase of CAN FD frames with bit rate switching enabled, at the onset of every TX CAN bit:

- The transmitted TX bit value is temporarily stored in a buffer.
- A time countdown based on FDCTRL[TDCVAL] or ETDC[ETDCVAL] is started. This countdown ends with the comparison of the received RX bit (delayed by the external loop delay plus the specified offset) to the stored TX bit.

If a bit error is detected at the secondary sample point, FlexCAN issues an error flag to the CAN bus at the next sample point.

During the arbitration phase, delay compensation is always disabled. During the data phase, the TDC mechanism of FlexCAN can compensate a maximum delay of 3 CAN bit times − 2 Tq. Beyond this limit, the FDCTRL[TDCFAIL] or ETDC[ETDCFAIL] flag is set. The flag indicates when the TDC mechanism is out of range and is unable to compensate the transceiver loop delay.

76.3.10.4 Remote frames

A remote frame is a special type of frame. You can program a message buffer to be a remote request frame by configuring the message buffer as Transmit with the RTR = 1. After the remote request frame is transmitted successfully, the message buffer becomes a receive message buffer, with the same ID as before.

When FlexCAN receives a remote request frame, the frame can be treated in different ways, depending on remote request storing (CTRL2[RRS]) and RX FIFO Enable (MCR[RFEN]):

- If RRS = 0, the ID of the frame is compared to the IDs of the transmit message buffers with the CODE field 1010b. If a matching ID exists, this message buffer frame is transmitted. If the matching message buffer has the RTR = 1, FlexCAN transmits a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response.

  The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. If a remote request frame is received and matches a message buffer, this message buffer immediately enters the internal arbitration process. However, it is considered a normal TX message buffer, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.

- If CTRL2[RRS] = 1, the ID of the frame is compared to the IDs of the receive message buffers with the CODE field 0100b, 0010b, or 0110b. If a matching ID exists, this message buffer stores the remote frame in the same fashion as a data frame. No automatic remote response frame is generated. The mask registers are used in the matching process.
- If MCR[RFEN] = 1, FlexCAN does not generate an automatic response for remote request frames that match the Legacy FIFO filtering criteria. If the remote frame matches one of the target IDs, it is stored in the Legacy FIFO and presented to the CPU.

  For filtering formats A and B (see Legacy RX FIFO structure), it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted if they match the ID. Remote request frames are considered as normal frames. They generate a Legacy FIFO overflow when a successful reception occurs and the Legacy FIFO is already full.
- If ERFCR[ERFEN] = 1, FlexCAN does not generate an automatic response for remote request frames that match the Enhanced RX FIFO filtering criteria. Remote Request Frames are considered normal frames. They generate an Enhanced RX FIFO overflow when a successful reception occurs and the enhanced RX FIFO is already full.

NOTE

There is no remote frame in the CAN FD format. A fixed dominant RRS bit replaces the RTR bit. FlexCAN receives and transmits remote frames in the Classical CAN format.

76.3.10.5 Overload frames

When a dominant bit is detected on the CAN bus in these locations, FlexCAN transmits overload frames:

- The first or second bit of Intermission.
- The seventh bit (last) of End of Frame field (RX frames).
- The eighth bit (last) of Error Frame Delimiter or Overload Frame Delimiter.

76.3.10.6 Message buffer timestamp

The value of the free-running timer is sampled at the beginning of the Identifier field on the CAN bus. This value is stored at the end of move-in in the TIME_STAMP field of a message buffer, providing network behavior regarding time.

When CTRL2[TIMER_SRC] = 1, an external time tick continuously clocks the free-running timer.

When CTRL2[TIMER_SRC] = 0, the FlexCAN bit clock clocks the free-running timer, which defines the baud rate on the CAN bus. During a message transmission or reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate.

The free-running timer is not incremented during Disable and Freeze modes. It can be reset upon a specific frame reception, enabling network time synchronization. See CTRL1[TSYN].

Alternatively, by configuring CTRL2[MBTSBASE], the timestamp of the message buffer can capture the lower or higher 16 bits of the high-resolution dedicated counter.

76.3.10.7 High-resolution timestamp

The high-resolution timestamp (HR_TIME_STAMP) uses a dedicated timer with a 32-bit counter operating in free-running mode. CTRL2[TSTAMPCAP] enables the high-resolution timestamp. When this field is not zero, the dedicated 32-bit counter value is captured during a valid CAN frame and stored in an HR_TIME_STAMP*n* register.

Each HR_TIME_STAMP*n* corresponds to a specific message buffer. For example, HR_TIME_STAMP0 stores the 32-bit timestamp associated with message buffer 0. HR_TIME_STAMP1 stores the 32-bit timestamp associated with message buffer 1, and so on.

The counter value is captured according to CTRL2[TSTAMPCAP]. For classical CAN frames, the capture points can be the start of frame bit or the point in time a CAN frame is considered valid. This valid point is the seventh bit of end of frame for transmission and the sixth bit of end of frame for reception.

For CAN FD frames, the capture points can be:

- The start of frame

- The point in time a CAN FD frame is considered valid
- The res bit of a CAN FD frame

The 16-bit timestamp of the message buffer can be configured to capture the lower or higher 16 bits of the high-resolution timer. This configuration is made by CTRL2[MBTSBASE].

76.3.10.8 Protocol timing

Figure 528 shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule.

NOTE

To identify the proper clock source, see the clock distribution chapter (module clocks table).

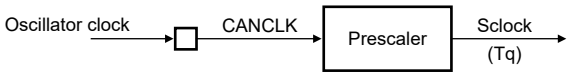

Figure 528. CAN engine clocking scheme

76.3.10.8.1 Bit timing configuration

FlexCAN supports various means to configure bit timing parameters required by the CAN protocol. Control 1 (CTRL1) has various fields to control bit timing parameters:

- CTRL1[PRESDIV]
- CTRL1[PROPSEG]
- CTRL1[PSEG1]
- CTRL1[PSEG2]
- CTRL1[RJW]

CAN Bit Timing (CBT) extends the range of the CAN bit timing variables in CTRL1. Enhanced Data Phase CAN Bit Timing (EDCBT) provides a second set of CAN bit timing variables to be applied at the data phase of CAN FD frames with the Bit Rate Switch (BRS) = 1.

Enhanced Nominal CAN Bit Timing (ENCBT) extends the range of CAN bit timing variables in CBT. Enhanced Nominal CAN Bit Timing (ENCBT) extends the range of CAN bit timing variables in FDCBT. When using ENCBT and EDCBT, you must program the nominal bit timing and data phase serial clock (Sclock) dividers in Enhanced CAN Bit Timing Prescalers (EPRS).

NOTE

When the CAN FD feature is enabled, always write 1 to CBT[BTF] or CTRL2[BTE] and specify the CAN bit timing variables in CBT or ENCBT. See CAN Bit Timing (CBT) or Enhanced Nominal CAN Bit Timing (ENCBT).

CTRL1[PRESDIV], and its extended range CBT[EPRESDIV] (or EPRS[ENPRESDIV]) and FDCBT[FPRESDIV] (or EPRS[EDPRESDIV]) for the data phase bits of CAN FD messages, defines the prescaler value that generates the serial clock (Sclock). (See Equation 14.) The period of Sclock defines the time quantum used to compose the CAN waveform. A time quantum (Tq) is the atomic unit of time managed by the CAN engine. It is the smallest time unit for all configuration values.

$$Tq = \frac{(PRESDIV + 1)}{f_{CANCLK}}$$

Equation 14. Time quantum

The bit rate, which defines the rate the CAN message is received or transmitted, is calculated with the formula:

$$CAN\ bit\ time = (Number\ of\ time\ quanta\ in\ 1\ bit\ time) \times Tq$$

$$Bit\ rate = \frac{1}{CAN\ bit\ time}$$

Equation 15. CAN bit time and baud rate

76.3.10.8.2 Bit time segments

A bit time is subdivided into three segments as shown in Figure 529. See also Figure 530 , Figure 531, and Table 557.

NOTE

For further explanation of the underlying concepts, see ISO 11898-1:2015. See also *CAN Specification Version 2.0, Part A and Part B* for bit timing.

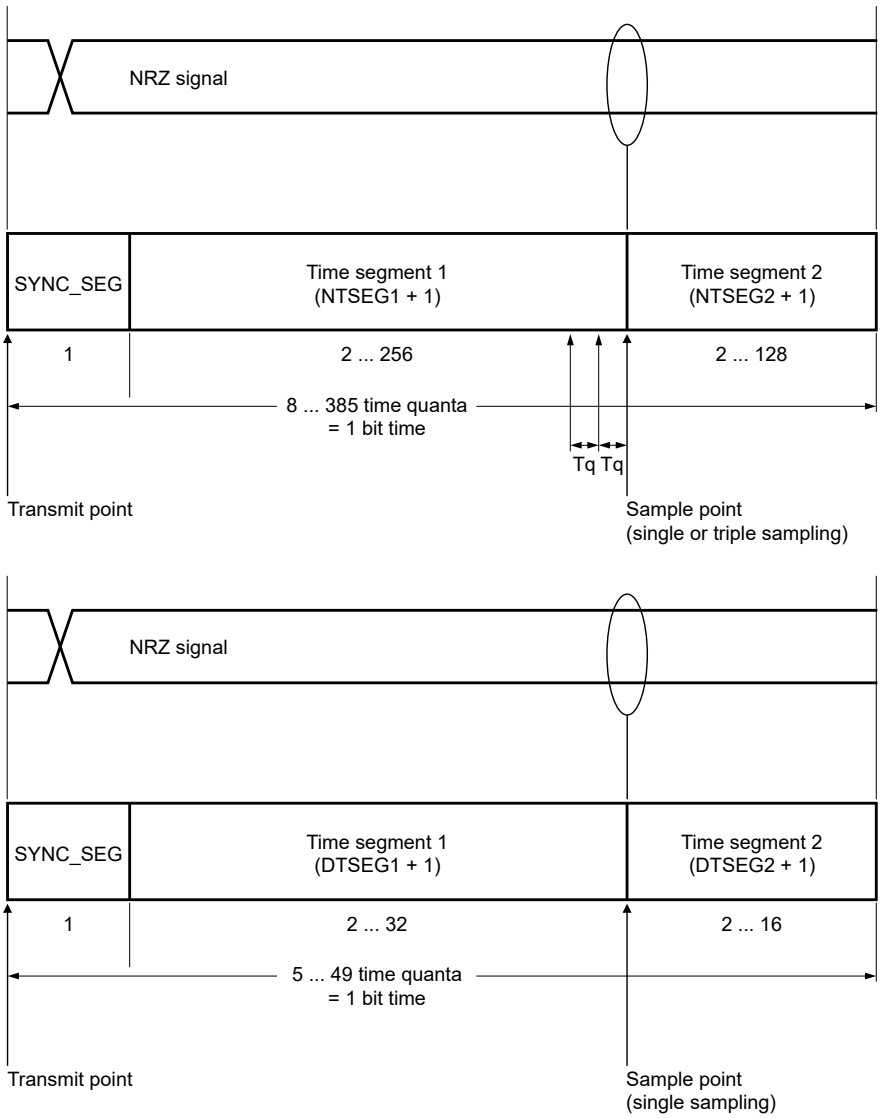

Figure 529. Segments within the bit timing (example using ENCBT and EDCBT bit timing variables)

The three bit time segments are:

- SYNC_SEG—this segment has a fixed length of one time quantum. Signal edges are expected to occur within this section.
- Time Segment 1—this segment includes the propagation segment and the phase segment 1 of the CAN standard.

  It can be programmed by configuring CTRL1[PROPSEG] and CTRL1[PSEG1] so that the sum (plus 2) is 2–16 time quanta. When CBT[BTF] = 1, FlexCAN uses CBT[EPROPSEG] and CBT[EPSEG1] so that the sum (plus 2) is 2–96 time quanta. For messages in CAN FD format with the BRS = 1, FlexCAN uses FDCBT[FPROPSEG] and FDCBT[FPSEG1] so that the sum (plus 1) is 2–39 time quanta.

  If CTRL2[BTE] = 1, FlexCAN uses ENCBT[NTSEG1] to configure time segment 1 to 2–256 time quanta. For the data phase in CAN FD messages with BRS = 1, EDCBT[DTSEG1] must be used for configuring time segment 1 to 2–32 time quanta.
- Time Segment 2—this segment represents the phase segment 2 of the CAN standard.

  It can be programmed by configuring CTRL1[PSEG2] (plus 1) to be 2–8 time quanta. When CBT[BTF] = 1, FlexCAN uses CBT[EPSEG2] so that its value (plus 1) is 2–32 time quanta. For messages in CAN FD format with the BRS = 1, FlexCAN uses FDCBT[FPSEG2] instead, so that its value (plus 1) is 2–8 time quanta. Time segment 2 cannot be smaller than the Information Processing Time (IPT), which is 2 time quanta in FlexCAN.

  If CTRL2[BTE] = 1, FlexCAN uses ENCBT[NTSEG2] to configure time segment 2 to 2–128 time quanta. For the data phase in CAN FD messages with BRS = 1, EDCBT[DTSEG2] must configure time segment 2 to 2–16 time quanta.

NOTE

The bit time defined by the above time segments must not be smaller than five time quanta. For bit time calculations, use an Information Processing Time (IPT) of two, which is the value implemented in the FlexCAN module.

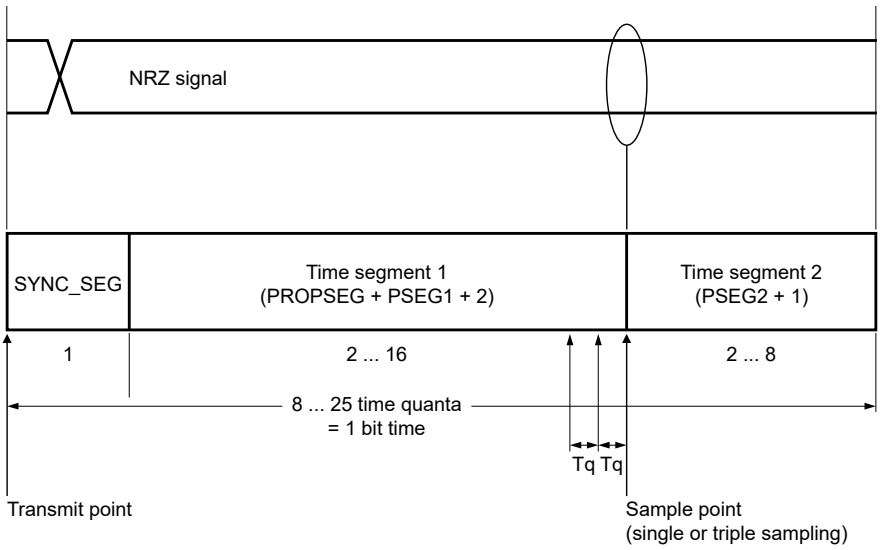

Figure 530. Segments within the bit time (example using CTRL1 bit timing variables for Classical CAN format)

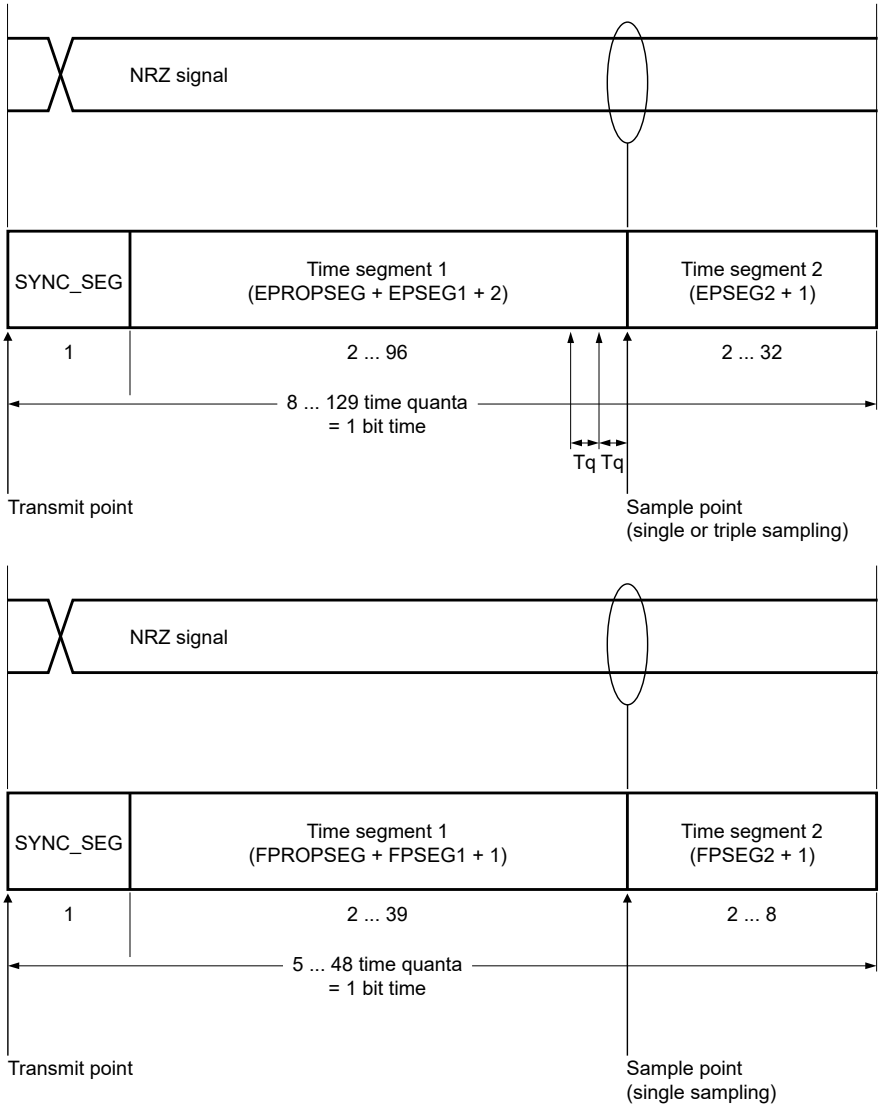

Figure 531. Segments within the bit time (example using CBT and FDCBT bit timing variables for CAN FD format)

Table 557. Time segment syntax

Syntax	Description
SYNC_SEG	Period during which the system expects transitions to occur on the bus
TSEG1	Period corresponding to the sum of PROPSEG and PSEG1
TSEG2	Period corresponding to the PSEG2 value
Transmit point	Point at which a node in Transmit mode transfers a new value to the CAN bus
Sample point	Point at which a node samples the bus. If the option of three samples per bit is selected, this point marks the position of the third sample.

Table 558 gives some examples of the CAN-compliant segment settings for Classical CAN format (Bosch CAN 2.0B) (non-FD) messages.

Table 558. Bosch CAN 2.0B standard compliant bit time segment settings

Time segment 1	Time segment 2	Resynchronization jump width
5 to 10	2	1 to 2
4 to 11	3	1 to 3
5 to 12	4	1 to 4
6 to 13	5	1 to 4
7 to 14	6	1 to 4
8 to 15	7	1 to 4
9 to 16	8	1 to 4

NOTE

You must ensure the bit time settings comply with the CAN Protocol standard (ISO 11898-1:2015).

76.3.10.8.3 Calculating peripheral clocks

A CAN bit can be used as a measure of duration (for example, estimating the occurrence of a CAN bit event in a message). When a CAN bit is used in this way, the number of peripheral clocks in one CAN bit (NumClkBit) can be calculated as:

$$NumClkBit = \frac{f_{SYS}}{f_{CANCLK}} \times (PRESDIV + 1) \times (PROPSEG + PSEG1 + PSEG2 + 4)$$

Equation 16. Number of peripheral clocks per CAN bit when CTRL2[BTE] = 0

Or, if CTRL2[BTE] = 1:

$$NumClkBit = \frac{f_{SYS}}{f_{CANCLK}} \times (ENPRESDIV + 1) \times (NTSEG1 + NTSEG2 + 3)$$

Equation 17. Number of peripheral clocks per CAN bit when CTRL2[BTE] = 1

Where:

- NumClkBit is the number of peripheral clocks in one CAN bit.
- f_{CANCLK} is the Protocol Engine (PE) Clock (see Figure 528), in Hz.
- f_{SYS} is the frequency of operation of the system (CHI) clock, in Hz.
- PSEG1 is the value of CTRL1[PSEG1].
- PSEG2 is the value of CTRL1[PSEG2].
- PROPSEG is the value of CTRL1[PROPSEG].
- PRESDIV is the value in CTRL1[PRESDIV].
- ENPRESDIV is the value of EPRS[ENPRESDIV].
- NTSEG1 is the value of ENCBT[NTSEG1].
- NTSEG2 is the value of ENCBT[NTSEG2].

The formula above is also applicable to the alternative CAN bit timing variables described in:

- CAN Bit Timing (CBT)

- Enhanced Nominal CAN Bit Timing (ENCBT)
- CAN FD Bit Timing (FDCBT)
- Enhanced Nominal CAN Bit Timing (ENCBT)

For example, 180 CAN bits = (180 × NumClkBit) peripheral clock periods.

76.3.10.9 Arbitration and matching timing

During normal reception and transmission, the matching, arbitration, move-in, and move-out processes are executed during certain time windows inside the CAN frame. These windows are shown in the following figures.

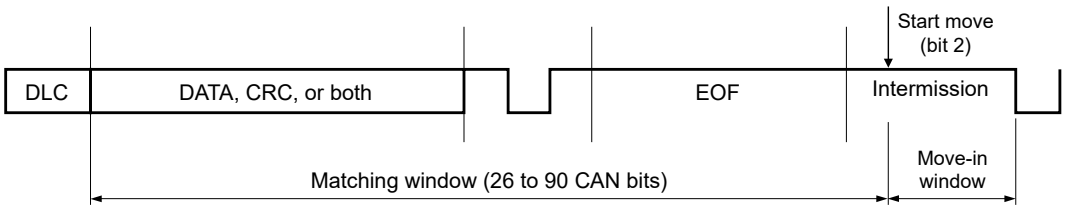

Figure 532. Matching and move-in time windows

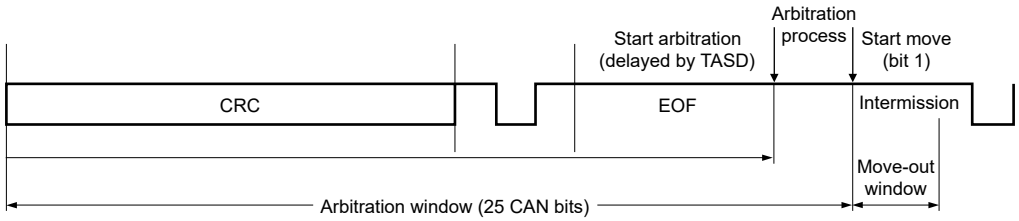

Figure 533. Arbitration and move-out time windows

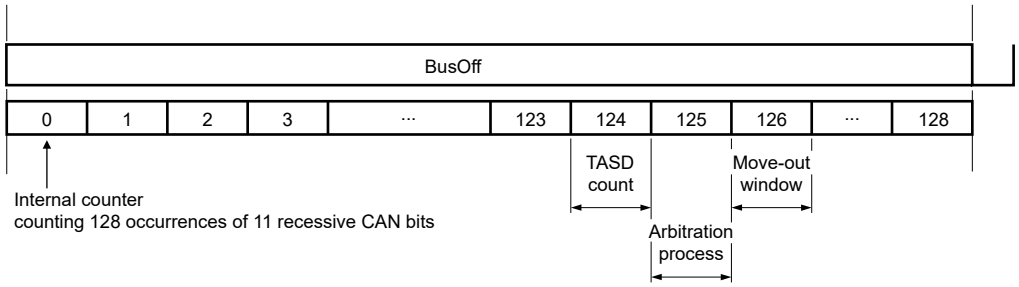

Figure 534. Arbitration at the end of bus off and move-out time windows

NOTE

In these figures, the matching and arbitration timing do not consider delays caused by concurrent memory access due to the CPU or other internal FlexCAN subblocks.

76.3.10.10 TX arbitration start delay

TX Arbitration Start Delay (CTRL2[TASD]) indicates the number of CAN bits that FlexCAN uses to delay the TX arbitration process starting point from the first bit of the CRC field of the current frame. This variable can be written only in Freeze mode; FlexCAN blocks it in other modes.

The ability of the CPU to reconfigure message buffers for transmission after the end of the internal arbitration process impacts transmission performance. In the arbitration process, FlexCAN finds the winner MB for transmission (see Arbitration process). If

the arbitration ends too early (before the first bit of the Intermission field) the CPU may reconfigure some TX message buffers. It is possible that the winning message buffer is no longer the best candidate to be transmitted.

TASD can optimize the transmission performance by defining the arbitration start point, as shown in Figure 535, based on factors such as:

- Peripheral-to-oscillator clock ratio
- CAN bit timing variables that determine the CAN bit rate
- Number of message buffers in use by the matching and arbitration processes

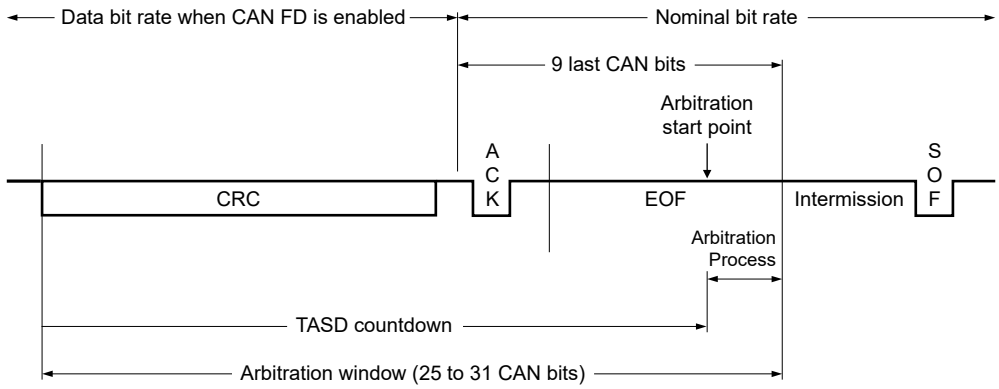

Figure 535. Optimal TX arbitration start point

The duration of an arbitration process, in terms of CAN bits, is:

- Directly proportional to the number of available message buffers
- Directly proportional to the CAN bit rate
- Inversely proportional to the peripheral clock frequency

The optimal arbitration timing occurs when the last message buffer is scanned immediately before the first bit of the Intermission field of a CAN frame. For instance, if the following are true:

- There are few message buffers.
- The peripheral-to-oscillator clock ratio is high.
- The CAN baud rate is low.

Then the arbitration can be placed closer to the end of the frame, adding more delay to its starting point, and vice versa.

If CTRL2[TASD] = 0, the arbitration start is not delayed, and more time is reserved for arbitration. Alternatively, if CTRL2[TASD] is close to 24, the CPU can configure a TX message buffer later, and less time is reserved for arbitration. If too little time is reserved for arbitration, FlexCAN may not be able to find a winner MB in time. The transmitted arbitration winner may not have the best chance to win the bus arbitration against external nodes on the CAN bus.

The optimal TASD value can be calculated as follows:

For CAN FD frames and (MAXMB + 1) ≤ NMB_{END}

$$TASD = 31 - \frac{2 * (MAXMB + 1) + 4}{CPCB_N}$$

For CAN FD frames and (MAXMB + 1) > NMB_{END}

$$TASD = 22 - \frac{2 * (MAXMB + 1) - NMB_{END}}{CPCB_F}$$

For non-FD frames

$$TASD = 25 - \frac{2 * (MAXMB + 1) + 4}{CPCB}$$

Equation 18. Optimal value for TASD

Where:

$$NMB_{END} = \frac{(9 \times CPCB_N) - 4}{2}$$

$$BITRATE_N = \left(\frac{f_{CANCLK}}{[1 + (EPSEG1 + 1) + (EPSEG2 + 1) + (EPROPSEG + 1)] \times (EPRESDIV + 1)} \right)$$

$$BITRATE_F = \left(\frac{f_{CANCLK}}{[1 + (FPSEG1 + 1) + (FPSEG2 + 1) + FPROPSEG] \times (FPRESDIV + 1)} \right)$$

$$CPCB_N = \frac{f_{SYS}}{BITRATE_N}$$

$$CPCB_F = \frac{f_{SYS}}{BITRATE_F}$$

$$CPCB = CPCB_N$$

Equation 19. Variables used in TASD calculation

- MAXMB is the value in MCR[MAXMB].
- NMB_{END} is the number of message buffers that the arbitration process can scan during the last nine CAN bits at the end of a frame. (See Equation 19.)
- $BITRATE_N$ is the CAN bit rate in bits per second calculated by the nominal CAN bit time variables.
- $BITRATE_F$ is the CAN bit rate in bits per second calculated by the data CAN bit time variables.
- $CPCB_N$ is the number of peripheral clocks per CAN bit in nominal bit rate for CAN FD frames.
- $CPCB_F$ is the number of peripheral clocks per CAN bit in data bit rate for CAN FD frames.
- CPCB is the number of peripheral clocks per CAN bit for non-FD frames.
- f_{CANCLK} is the oscillator clock, in Hz.
- f_{SYS} is the peripheral clock, in Hz.
- EPSEG1 is the value in CBT[EPSEG1] (CTRL1[PSEG1] can also be used).
- EPSEG2 is the value in CBT[EPSEG2] (CTRL1[PSEG2] can also be used).
- EPROPSEG is the value in CBT[EPROPSEG] (CTRL1[PROPSEG] can also be used).
- EPRESDIV is the value in CBT[EPRESDIV] (CTRL1[PRESDIV] can also be used).
- FPSEG1 is the value in FDCBT[FPSEG1].

- FPSEG2 is the value in FDCBT[FPSEG2].
- FPROPSEG is the value in FDCBT[FPROPSEG].
- FPRESDIV is the value in FDCBT[FPRESDIV].
- NTSEG1 is the value in ENCBT[NTSEG1].
- NTSEG2 is the value in ENCBT[NTSEG2].
- ENPRESDIV is the value in EPRS[ENPRESDIV].
- DTSEG1 is the value in EDCBT[DTSEG1].
- DTSEG2 is the value in EDCBT[DTSEG2].
- EDPRESDIV is the value in EPRS[EDPRESDIV].

If CTRL2[BTE] = 1, then:

$$BITRATE_N = \frac{f_{CANCLK}}{[1 + (NTSEG1 + 1) + (NTSEG2 + 1)] \times (ENPRESDIV + 1)}$$

Equation 20. Nominal baud rate when CTRL2[BTE] = 1

$$BITRATE_F = \frac{f_{CANCLK}}{[1 + (DTSEG1 + 1) + (DTSEG2 + 1)] \times (EDPRESDIV + 1)}$$

Equation 21. Fast baud rate when CTRL2[BTE] = 1

See also Protocol timing for more details.

76.3.10.10.1 TASD configuration examples

The following tables show the TASD value calculated for some configuration cases.

Case 1:

- Clock ratio = 2:1 (for example, peripheral clock 80 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 559. TASD values in Case 1

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	24	8.0
64	23	8.0
96	22	8.0

Case 2:

- Clock ratio = 1:1 (for example, peripheral clock 40 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 560. TASD values in Case 2

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid

Table continues on the next page...

Table 560. TASD values in Case 2 (continued)

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
32	23	6.67
54	22	5.0
64	21	3.33
96	20	1.6

Case 3:

- Clock ratio = 2:1 (for example, peripheral clock 40 MHz and oscillator clock 20 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 561. TASD values in Case 3

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	23	4.0
54	22	4.0
64	21	3.33
96	20	1.54

76.3.11 Clocks

The following table describes the clock sources for FlexCAN. See the chip clocking chapter for clock setting, configuration, and gating information.

Table 562. FlexCAN clocks

Clock name	Description
MODULE_CLK (system_clk)	Peripheral clock
MODULE_CLK_CHI (host_clock)	Control Host Interface (CHI) clock
MODULE_CLK_PE (protocol_engine_clock)	Protocol Engine (PE) clock
MODULE_CLK_PE_NOGATE (protocol_engine_clock_nogate)	Protocol Engine clock (no gating)
MODULE_CLK_S (system_clock_nogate)	Peripheral access clock

76.3.11.1 Clock domains and restrictions

FlexCAN has two clock domains asynchronous to each other:

- The bus domain feeds the Control Host Interface (CHI) submodule.
- The oscillator domain feeds the CAN Protocol Engine (PE) submodule.

When the two domains are connected to clocks with different frequencies or phases, the frequency relationship between the two clock domains is restricted. In asynchronous operation, the bus domain clock frequency must always be greater than the oscillator domain clock frequency.

NOTE

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

When performing matching and arbitration, FlexCAN must scan the whole message buffer memory during the time slot of one CAN frame, comprised of a number of CAN bits. To provide sufficient time for the scan, observe the following requirements:

- The peripheral clock frequency cannot be less than the oscillator clock frequency.
- There must be a minimum number of peripheral clocks per CAN bit, as specified in Table 563.

Table 563. Minimum number of peripheral clocks per CAN bit for Classical CAN format

Number of message buffers	Value of MCR[RFEN]	Value of ERFCR[ERFEN]	Minimum number of peripheral clocks per CAN bit
16	0	0	16
32	0	0	16
64	0	0	25
96	0	0	37
16	1	0	16
32	1	0	17
64	1	0	30
96	1	0	42
16	0	1	16
32	0	1	19
64	0	1	31
96	0	1	42

For classical frame format, the minimum number of peripheral clocks per CAN bit specified in Table 563 determines the minimum peripheral clock frequency for a given number of message buffers and for an expected CAN bit rate. The CAN bit rate depends on the number of time quanta in a CAN bit. This number can be defined by adjusting one or more of the bit timing values contained in:

- Control 1 (CTRL1)
- CAN Bit Timing (CBT)
- Enhanced Nominal CAN Bit Timing (ENCBT)

The time quantum (Tq) is defined in Protocol timing. The minimum number of time quanta per CAN bit must be eight, so the oscillator clock frequency should be at least eight times the CAN bit rate.

76.3.11.1.1 Clock restrictions for CAN FD

For CAN FD frame format, some constraints must be satisfied. The equation below calculates the number of peripheral clocks per CAN bit in nominal bit rate (NumClkNomBit).

$$NumClkNomBit = \frac{f_{SYS}}{f_{CANCLK}} \times (PRESDIV + 1) \times (PROPSEG + PSEG1 + PSEG2 + 4)$$

$$= \frac{f_{SYS}}{NomBitRate}$$

Equation 22. Number of peripheral clocks per nominal CAN bit

Where PRESDIV, PSEG1, and PSEG2 are CAN bit time values in Control 1 (CTRL1). Alternatively, EPRESDIV, EPSEG1, and EPSEG2 values in CAN Bit Timing (CBT) or the values of EPRS[ENPRESDIV], ENCBT[NTSEG1], and ENCBT[NTSEG2] can be used instead. NumClkNomBit can also be calculated as a function of the expected nominal bit rate used in the arbitration phase (NomBitRate), as shown in the equation above.

The number of CAN bits in the data phase of an FD frame with BRS = 1 (fast CAN bits) depends on the number of data bytes in the payload. The number of fast CAN bits (NumOfFastBits) can be determined in Table 564. Having fewer data bytes means having fewer fast CAN bits. It also means that less time is available for FlexCAN to scan the whole message buffer memory during the internal matching and arbitration processes.

Table 564. Number of fast CAN bits in a CAN FD frame

Minimum number of data bytes	DLC field	NumOfFastBits
0	0h	21
1	1h	29
2	2h	37
3	3h	45
4	4h	53
5	5h	61
6	6h	69
7	7h	77
8	8h	85
12	9h	117
16	Ah	149
20	Bh	186
24	Ch	218
32	Dh	282
48	Eh	410
64	Fh	538

The critical part of a CAN FD frame is during the data phase, where the CAN bit rate is faster than in the arbitration phase. The minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated to guarantee that enough time is available for FlexCAN to scan the message buffer memory during reception and transmission. The equation below calculates this constraint.

$$MinNumClkFastBit_A = \frac{(8.5 \times MaxNumOfMb) + [ERFEN \times (2 \times NFE + 4)] + 64 - (9 \times NumClkNomBit)}{NumOfFastBits}$$

Equation 23. Minimum number of peripheral clocks per fast CAN bit for FlexCAN scan process

Where MaxNumOfMb is the maximum number of available message buffers defined in MCR[MAXMB]. NFE and ERFEN are the fields defined in Enhanced RX FIFO Control (ERFCR).

The clock-domain-crossing circuit between the CHI and PE subblocks also imposes a minimum number of peripheral clocks per fast CAN bit. This minimum is required for the handshake mechanism to work properly without losing status information through the interface, as shown in the equation below.

$$MinNumClkFastBit_B = 3 \times \left(1 + \frac{f_{SYS}}{f_{CANCLK}}\right)$$

Equation 24. Minimum number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface

Therefore, the larger of the two values calculated above determines the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit).

$$MinNumClkFastBit = Maximum\ (MinNumClkFastBitA, MinNumClkFastBitB)$$

Equation 25. Minimum number of peripheral clocks per fast CAN bit

Then, the maximum CAN bit rate in the data phase of CAN FD frames (DataBitRateMAX) can be calculated as below.

$$DataBitrate_{MAX} = \frac{f_{CANCLK}}{ROUNDUP\left(\frac{MinNumClkFastBit \times f_{CANCLK}}{f_{SYS}}\right)}$$

Equation 26. Maximum achievable baud rate for data phase

These factors affect the maximum data bit rate attainable by FlexCAN in CAN FD mode:

- The peripheral and oscillator clock frequencies
- The maximum number of message buffers
- The expected nominal bit rate

Also, the data bit rate depends on the minimum payload size of FD frames used in a given application.

To illustrate how the configuration of FlexCAN variables affects the CAN FD bit rate, consider this application example:

- The peripheral clock frequency is set to 50 MHz
- The oscillator clock frequency is set to 40 MHz

1. Considering the nominal bit rate as 1 Mbit/s, the number of peripheral clocks per CAN bit in nominal bit rate is calculated as below.

   $$NumClkNomBit = \frac{50 \times 10^6}{1 \times 10^6} = 50$$

   Equation 27. Calculation example for number of peripheral clocks per nominal CAN bit

2. The number of fast CAN bits (NumOfFastBits) is determined in Table 564. For example, if the minimum payload in FD frames is 8 bytes, there are 85 CAN bits in the data phase.
3. Assuming the maximum number of message buffers is 96, and Enhanced RX FIFO is disabled, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated.

   $$MinNumClkFastBit_A = \frac{(8.5 \times 96) + 64 - (9 \times 50)}{85} = 5.06$$

   Equation 28. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN scan process

$$MinNumClkFastBit_B = 3 \times \left(1 + \frac{50}{40}\right) = 6.75$$

Equation 29. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface

$$MinNumClkFastBit = Maximum\ (\ 5.06, 6.75\ ) = 6.75$$

Equation 30. Calculation example for number of peripheral clocks per fast CAN bit

4. The maximum CAN bit rate in the data phase can finally be found.

$$DataBitRate_{MAX} = \frac{40 \times 10^6}{ROUNDUP\left(\frac{6.75 \times 40 \times 10^6}{50 \times 10^6}\right)} = 6.667\ Mbps$$

Equation 31. Calculation example for maximum achievable baud rate

Even though the oscillator clock frequency (40 MHz) is adequate to generate a data rate of 8 Mbit/s in CAN FD mode, the specific FlexCAN configuration limits this rate to 6.667 Mbit/s. This limitation is mainly due to the low peripheral clock frequency that imposes the MinNumClkFastBitB bound.

Table 565 shows the maximum data rate for CAN FD with Enhanced RX FIFO disabled according to clock frequencies, payload size, and number of available message buffers. For some cases, if the number of available message buffers is reduced, FlexCAN can then achieve a data rate up to 8 Mbit/s.

Table 565. Maximum CAN bit rate in data phase on CAN FD frames with Enhanced RX FIFO disabled

Peripheral clock frequency (MHz)	Payload size	Number of available message buffers	Maximum data rate (Mbit/s)
40	8	94	6.667
40	8	114	>5.0
40	12	>117	6.667
40	12	128	5.714
50	12–64	128	6.667
60	8	126	8.0
60	12	128	8.0
67	6	128	8.0
80	3	128	8.0
100	0	128	8.0

76.3.12 Reset

You can reset FlexCAN in the following ways:

- Chip-level hard reset, which resets all memory-mapped registers asynchronously.
- Soft reset, in one of two ways:
  - MCR[SOFTRST], which resets some of the memory-mapped registers synchronously. To see which registers soft reset affects, see Table 568.

Soft reset is synchronous and must follow an internal request-and-acknowledge procedure across clock domains. Therefore, it may take some time to propagate its effects fully. MCR[SOFTRST] remains 1 when soft reset is pending, so software can poll this field to identify when the reset has completed. Soft reset cannot be applied when clocks are shut down in a low-power mode. The low-power mode should be exited and the clocks resumed before applying soft reset.

When the module is enabled (MCR[MDIS] becomes 0), FlexCAN automatically enters Freeze mode. In Freeze mode:

1. FlexCAN is unsynchronized to the CAN bus.
2. MCR[HALT] and MCR[FRZ] become 1.
3. The internal state machines are disabled.
4. MCR[FRZACK] and MCR[NOTRDY] become 1.

The TX pin is in the recessive state and FlexCAN does not initiate any transmission or reception of CAN frames. Reset does not affect the message buffers and the RX Individual Mask registers, so they are not automatically initialized.

76.3.13 Interrupts

FlexCAN has many interrupt sources:

- Interrupts due to message buffers
- Interrupts due to interrupts combined via an OR operator from:
  - Message buffers
  - Bus Off
  - Bus Off Done
  - Error
  - Error Fast (errors detected in the data phase of CAN FD format messages with BRS = 1)
  - TX Warning
  - RX Warning

If its corresponding IMASK bit is 1, each message buffer can be an interrupt source. There is no distinction between TX and RX interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each buffer has an assigned flag bit in the IFLAG registers. When the corresponding buffer completes a successful transfer, the flag is set. When the CPU writes 1 to it, the flag is cleared (unless another interrupt is generated at the same time).

NOTE

The CPU must clear only the bit causing the current interrupt. For this reason, do not use bit manipulation instructions (BSET) to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt handler.

If the Legacy RX FIFO is enabled (MCR[RFEN] = 1) and DMA is disabled (MCR[DMA] = 0), the interrupts corresponding to message buffers 0–7 have different meanings.

- Bit 7 of Interrupt Flags 1 (IFLAG1) becomes the Legacy FIFO Overflow flag
- Bit 6 becomes the Legacy FIFO Warning flag
- Bit 5 becomes the Frames Available in Legacy FIFO flag
- Bits 4–0 are unused.

See Interrupt Flags 1 (IFLAG1) for more information.

If both Legacy RX FIFO and DMA are enabled (MCR[RFEN] = 1 and MCR[DMA] = 1), FlexCAN does not generate any Legacy FIFO interrupt. Bit 5 of IFLAG1 still indicates Frames Available in Legacy FIFO and generates a DMA request. Bits 7, 6, and 4–0 are unused.

CAUTION

Legacy FIFO cannot be enabled when CAN FD is enabled.

When multiple message buffer interrupt sources are combined via an OR operator into a single interrupt, the interrupt is generated when any associated message buffer (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the IFLAG registers to determine which message buffer or FIFO source caused the interrupt.

These interrupt sources generate interrupts like the message buffer interrupt sources, and can be read from Error and Status 1 (ESR1):

- Bus Off
- Bus Off Done
- Error
- Error Fast
- TX Warning
- RX Warning

The Bus Off, Error, TX Warning, and RX Warning interrupt masks are located in Control 1 (CTRL1).

76.3.14 Bus interface

CPU access to FlexCAN registers is subject to the following rules:

- Unrestricted read and write access to supervisor registers results in an access error. In Table 568, supervisor registers are registers identified with an S, and registers that are identified with S/U that are in Supervisor Mode
- Read and write access to implemented reserved address space results in an access error.
- Write access to positions whose bits are all currently read-only results in an access error. If at least one of the bits is not read-only, no access error is issued. Write permission to specific positions or some of their bits can change depending on the mode of operation or transitory state. See register and field descriptions for details.
- Read and write access to unimplemented address space results in an access error.
- Read and write access to RAM-located positions during Low-Power mode results in an access error.
- The RXIMR memory region can be considered as general-purpose memory and available for access via these methods:
  - If you write 0 to MCR[IRMQ], the individual masks (RXIMR) are disabled. In this case, the RXIMR memory region is considered general-purpose memory.
  - If MCR[MAXMB] is programmed with a value smaller than the available number of message buffers, the unused memory space can be used as general-purpose RAM space. Reserved words within RAM cannot be used.
    For example, suppose the RAM in FlexCAN can support up to 16 message buffers, CTRL2[RFFN] = 0h, and MCR[MAXMB] = 0.
    - In this case, the maximum number of message buffers becomes one.
    - The RAM starts at 0080h, and the space 0080h–008Fh is used by the one message buffer.
    - The memory space 0090h–017Fh is available.
    - The space 0180h–087Fh is reserved.
    - The space 0880h–0883h is used by the one individual mask and the available memory in the mask register space is 0884h–08BFh.
    - In the space from 08C0h–09DFh, there are reserved words for internal use which cannot be used as general-purpose RAM.

    As a rule, free memory space for general purpose depends only on MCR[MAXMB].
  - If MCR[FDEN] = 1, general-purpose memory can be used only outside Freeze mode.

1. Access in low power is only possible if RAM_clk and MODULE_CLK are enabled.
2. If MCR[RFEN] = 1, see Legacy FIFO access rules in the rows below.
3. Write operation has no effect.
4. If MCR[RFEN] = 1, do not access Enhanced RX FIFO.

76.3.15 Detection and correction of memory errors

To update the parity bits in memory properly, all FlexCAN memory must be initialized before starting its operation. CTRL2[WRMFRZ] grants write access to all memory positions that require initialization, from 080h–ADFh and from C20h–31FFh. You must also initialize these registers:

- RX Message Buffers Global Mask (RXMGMASK)
- Receive 14 Mask (RX14MASK)
- Receive 15 Mask (RX15MASK)
- Legacy RX FIFO Global Mask (RXFGMASK)

MCR[RFEN] and ERFCR[ERFEN] must not be 1 during memory initialization.

FlexCAN supports detection and correction of errors in memory read accesses. Each byte of FlexCAN memory is associated with five parity bits that ensure a Hamming distance of 4. The error correction mechanism ensures that in this 13-bit word, errors in one bit can be corrected (correctable errors). Errors in two bits can be detected but not corrected (uncorrectable errors). Errors in more than two bits may not be detected. For uncorrectable errors, the error correction logic does not change the corrupted data. When a read access is performed, the parity bits are used to calculate a syndrome, which indicates the error in each byte.

When an all-zeroes or an all-ones read occurs, FlexCAN detects an uncorrectable error. See Error Report Syndrome (RERRSYNR).

Memory errors are indicated to the host via status register (Error Status (ERRSR)) and bus transfer errors. Memory errors are reported via these report registers:

- Error Report Address (RERRAR)
- Error Report Data (RERRDR)

- Error Report Syndrome (RERRSYNR)

MECR[ECCDIS] determines whether the error detection and correction mechanism can be activated. When disabled, updates on indications and reporting registers are stopped. To ensure that memory has consistent parity bits associated with the data, the parity bits are still calculated and written with data in memory write operations.

To avoid accidentally changing the critical error correction configuration, follow this protocol to enable the update of Memory Error Control (MECR):

1. Write 1 to CTRL2[ECRWRE]. (By default, CTRL2[ECRWRE] is 0 and MECR[ECRWRDIS] is 1.)
2. Write 0 to MECR[ECRWRDIS].
3. All writes to Memory Error Control (MECR) must keep MECR[ECRWRDIS] = 0.
4. After configuration is done, lock MECR by writing 1 to MECR[ECRWRDIS] or writing 0 to CTRL2[ECRWRE].

76.3.15.1 Sources of memory access

These major sources (or requestors) can access FlexCAN memory:

- Host (CPU). The largest word accessed is 32-bit.
- FlexCAN internal processes:
  - RX matching
  - TX arbitration
  - Move-in on reception
  - Move-out on transmission

  The largest word accessed is 64-bit.

The source of access determines the way that uncorrectable errors are indicated and reported.

76.3.15.2 Error indication

These flags indicate memory errors:

- ERRSR[HANCEIF]
- ERRSR[FANCEIF]
- ERRSR[CEIF]

Uncorrectable errors detected in memory reads requested by the host are indicated separately from the errors detected in requests by FlexCAN internal processes. When correctable errors are detected, FlexCAN makes no distinction of the source of the access. There are three independent flags for these three cases, and each flag raises an interrupt unless a mask in Memory Error Control (MECR) masks it. If both uncorrectable and correctable errors are found in different bytes in the same read operation, both flags are set.

An uncorrectable error detected in host access is also indicated as a bus transfer error. A bus wait request may be asserted to extend the memory transaction to the moment the report registers are updated. This indication cannot be masked. If ERRSR[HANCEIF] is not masked, the same uncorrectable error raises a bus transfer error and an interrupt request.

Each indication flag has one overrun flag in Error Status (ERRSR). The overrun flags do not request interrupts. Overrun flags for uncorrectable errors indicate that other errors of the same nature were detected after the current error being treated. Overrun flags for correctable errors indicate that other errors of the same nature were detected before the current error being treated.

The recommended handling sequence for error indication is:

1. Get error report information from report registers.
2. Use this information to take proper measures in the application.
3. Clear the ERRSR[HANCEIF], ERRSR[FANCEIF], and ERRSR[CEIF] flags.

4. If the overrun flag is active:
    a. Alert the application that at least one error could not be managed.
    b. Clear the overrun flag.

FlexCAN internal processes can access memory in transactions larger than 32 bits. For the indication, this kind of access is considered a consecutive sequence of 32-bit accesses. If errors are found in two or more 32-bit words, the interrupt and overrun flags are set simultaneously.

76.3.15.3 Error reporting

The error report registers provide detailed information about the address read, raw data, and syndrome read with error. The flags described in Error indication indicate these report registers:

- Error Report Address (RERRAR)
- Error Report Data (RERRDR)
- Error Report Syndrome (RERRSYNR)

The address, data, and syndrome registers are updated simultaneously with the error flags, according to these rules:

1. If either of the uncorrectable error flags is set, the report registers are not updated. The previous uncorrectable error reporting is preserved.
2. Otherwise, either no error flag is set or only the correctable error flag is set. The report registers are updated according to the new error, or according to the most severe new error, if uncorrectable and correctable errors are simultaneously detected.

Reporting of errors detected in accesses larger than 32 bits follows the rules described in Error indication and in the description of Error Report Address (RERRAR).

The addresses reported in RERRAR and defined in ERRIAR are not the same as the addresses listed in the module memory map. The relation between the reported addresses and the respective ones in the module memory map is shown in the description of Error Injection Address (ERRIAR).

Addresses reported when reading memory portions organized as FIFOs refer to the address of the specific entry accessed in the FIFO, not to the FIFO base address. Such memory portions include:

- Legacy RX FIFO Structure
- Enhanced RX FIFO Structure
- Legacy RX FIFO Information (RXFIR)

To ensure coherence of error report registers, disable the report update by writing 1 to MECR[RERRDIS] before reading the report registers.

76.3.15.4 Error response

Correctable errors have no consequence to FlexCAN operation because the host or FlexCAN internal processes corrects affected data before its use.

For host-initiated reads, an uncorrectable error may affect the host, but does not affect FlexCAN operation.

Uncorrectable errors detected on memory read operations requested by FlexCAN internal processes may result in incorrect operation depending on the state of MECR[NCEFAFRZ], as follows:

- During reception (either matching or move-in process), when an uncorrectable error occurs:
    — An incorrect destination may be selected to store the incoming frame.
    — A corrupted frame may be stored in the correct destination.
    — Both of these events may occur.

If MECR[NCEFAFRZ] = 1, FlexCAN stops operation automatically and enters Freeze mode to prevent corrupted data from being treated as valid by FlexCAN internal processes. If MECR[NCEFAFRZ] = 0, FlexCAN continues working, and a corrupted frame is received.

- During arbitration, when an uncorrectable error occurs:
  - A non-highest-priority TX message buffer may be mistakenly selected for transmission.
  - Its data may be corrupted.

  If MECR[NCEFAFRZ] = 1, FlexCAN stops operation automatically and enters Freeze mode before starting the move-out. If MECR[NCEFAFRZ] = 0, FlexCAN proceeds to move-out with a corrupted frame that will be transmitted on the CAN bus.
- During move-out, when an uncorrectable error occurs, a corrupted frame is copied from the selected TX MB that won the arbitration to the TX SMB for transmission. If MECR[NCEFAFRZ] = 1, FlexCAN stops operation automatically and enters Freeze mode before starting the transmission. When MECR[NCEFAFRZ] = 0, the corrupted frame is transferred from the TX SMB to the Protocol Engine (PE) subblock and is transmitted on the CAN bus.
- An uncorrectable error can also be detected beyond move-out, when TX data is read from TX SMB (buffer located in RAM) to be transferred to the PE subblock for transmission. In this case, a frame with corrupted ID or data is transmitted on the CAN bus.

  To prevent the external nodes from successfully receiving the frame, FlexCAN inverts all bits in the CRC field (CRC sequence plus CRC delimiter). Also, it transmits an error flag just after CRC delimiter due to self-detecting a Bit1 error and a form error due to the CRC field inversion. When MECR[NCEFAFRZ] = 1, FlexCAN stops operation automatically and enters Freeze mode just after the error frame. When MECR[NCEFAFRZ] = 0, FlexCAN may attempt to retransmit the same frame, as long as no other higher-priority TX MB is configured for transmission after.

  If the uncorrectable error persists, FlexCAN eventually reaches the Bus Off state due to consecutive error detections. ECR[TXERRCNT] is updated every time FlexCAN inverts the CRC field, causing errors as described above.

When MECR[NCEFAFRZ] = 1 and FlexCAN enters Freeze mode, only the CPU can cause FlexCAN to exit Freeze mode and resume Normal mode. MECR[NCEFAFRZ] becoming 1 is the only way to prevent corrupted frames from being transmitted on the CAN bus to the move-out internal process.

The error report registers can provide information to the application for customized management of these situations.

76.3.15.5 Error injection

These error injection registers are used to inject errors in memory reads to force errors and update the indication and reporting registers:

- Error Injection Address (ERRIAR)
- Error Injection Data Pattern (ERRIDPR)
- Error Injection Parity Pattern (ERRIPPR)

The relation between the error injection addresses and the corresponding addresses in the module memory map is shown in Error Injection Address (ERRIAR).

The injection is done by flipping the data and parity bits corresponding to the bits set to 1 in ERRIDPR and ERRIPPR. You can select injection specifically for memory accesses requested by the host or by FlexCAN internal processes.

For accesses larger than 32 bits, MECR[EXTERRIE] extends the injection pattern, replicating it in 32-bit words to fill the width of the access.

NOTE

It is possible, but very unlikely, for error injection to correct a bit with error. This correction does not raise the error flags and reports as expected.

To ensure coherence among error injection registers and avoid spurious error injections, you must clear MECR[HAERRIE] and MECR[FAERRIE] when configuring the memory injection registers.

76.4 External signal descriptions

FlexCAN has two I/O signals connected to the external chip pins. These signals are summarized in Table 567 and described in the following subsections.

Table 567. FlexCAN signal descriptions

Signal	Description	I/O
CAN RX	CAN receive pin	Input
CAN TX	CAN transmit pin	Output

76.4.1 CAN RX

This pin is the receive pin from the CAN bus transceiver. Logic level 0 represents its dominant state. Logic level 1 represents its recessive state.

76.4.2 CAN TX

This pin is the transmit pin to the CAN bus transceiver. Logic level 0 represents its dominant state. Logic level 1 represents its recessive state.

76.5 Initialization and application information

76.5.1 FlexCAN initialization sequence

For any configuration change or initialization, you must put FlexCAN into Freeze mode (see Freeze mode). The module must be initialized after every reset. FlexCAN memory must be initialized before switching to functional mode.

The following is a generic initialization sequence applicable to FlexCAN:

1. Initialize Module Configuration (MCR).
    a. Enable the individual filtering per message buffer and reception queue features by writing 1 to MCR[IRMQ].
    b. Enable the warning interrupts by writing 1 to MCR[WRNEN].
    c. If required, disable frame self-reception by writing 1 to MCR[SRXDIS].
    d. Enable the Legacy RX FIFO by writing 1 to MCR[RFEN] or enable the Enhanced RX FIFO by writing 1 to ERFCR[ERFEN].
    e. If Legacy RX FIFO or Enhanced RX FIFO is enabled and DMA is required, write 1 to MCR[DMA].
    f. Enable the abort mechanism by writing 1 to MCR[AEN].
    g. Enable the local priority feature by writing 1 to MCR[LPRIOEN].
2. Initialize Control 1 (CTRL1) and CAN FD Bit Timing (FDCBT). Optionally initialize CAN Bit Timing (CBT).
    a. Determine the bit timing parameters: CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW].
    b. Optionally determine the bit timing parameters: CBT[EPROPSEG], CBT[EPSEG1], CBT[EPSEG2], and CBT[ERJW].
    c. Determine the CAN FD bit timing parameters: FDCBT[FPROPSEG], FDCBT[FPSEG1], FDCBT[FPSEG2], and FDCBT[FRJW].
    d. Determine the bit rate by programming CTRL1[PRESDIV] and optionally programming CBT[EPRESDIV].
    e. Determine the CAN FD bit rate by programming FDCBT[FPRESDIV].
    f. Determine the internal arbitration mode by programming CTRL1[LBUF].

3. If Error Code Correction (ECC) is enabled, you must initialize all FlexCAN memory. See Detection and correction of memory errors.
4. Initialize the message buffers. (See Message buffer structure for message buffer details.)
    a. The control and status word of all message buffers must be initialized.
    b. If RX FIFO is enabled, the ID filter table must be initialized.
    c. Other entries in each message buffer should be initialized as required.
5. Initialize Receive Individual Mask (RXIMR0 - RXIMR95).
6. Write 1 to required interrupt mask bits in:
    - IMASK registers (for all message buffer interrupts)
    - Control 1 (CTRL1) and Control 2 (CTRL2) (for Bus Off and Error interrupts)
7. Write 0 to MCR[HALT].

After the last step listed above, FlexCAN attempts to synchronize to the CAN bus.

76.6 Memory map and register definition

This section describes the registers and data structures in FlexCAN. The base address of the module depends on the particular memory map of the chip.

76.6.1 FlexCAN memory mapping

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address offset 0080h.

Each individual register is identified by its complete name and corresponding mnemonic. The access type can be Supervisor (S) or Unrestricted (U). Most registers can be configured to have either Supervisor or Unrestricted access by programming MCR[SUPV]. These registers are identified as S/U in the Access column of Table 568.

NOTE

An invalid register access results in a bus error. Invalid accesses include reading a write-only register, writing a read-only register, and accessing an invalid address.

NOTE

To update the parity bits in memory properly, all FlexCAN memory must be initialized before reading registers which are implemented in memory. CTRL2[WRMFRZ] grants write access to all memory positions that require initialization, from 080h–ADFh and from C20h–31FFh. You must also initialize RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), Receive 15 Mask (RX15MASK) and Legacy RX FIFO Global Mask (RXFGMASK). MCR[RFEN] and ERFCR[ERFEN] must not be 1 during memory initialization.

Table 568. Register access and reset information

Register	Access type	Affected by hard reset	Affected by soft reset
Module Configuration (MCR)	S	Yes	Yes
Control 1 (CTRL1)	S/U	Yes	No
Free-Running Timer (TIMER)	S/U	Yes	Yes
RX Message buffers Global Mask (RXMGMASK)	S/U	No	No

Table continues on the next page...

Table 568. Register access and reset information (continued)

Register	Access type	Affected by hard reset	Affected by soft reset
RX Buffer 14 Mask (RX14MASK)	S/U	No	No
RX Buffer 15 Mask (RX15MASK)	S/U	No	No
Error Counter (ECR)	S/U	Yes	Yes
Error and Status 1 (ESR1)	S/U	Yes	Yes
Interrupt Masks 2 (IMASK2)	S/U	Yes	Yes
Interrupt Masks 1 (IMASK1)	S/U	Yes	Yes
Interrupt Flags 2 (IFLAG2)	S/U	Yes	Yes
Interrupt Flags 1 (IFLAG1)	S/U	Yes	Yes
Control 2 (CTRL2)	S/U	Yes	No
Error and Status 2 (ESR2)	S/U	Yes	Yes

Interrupt Flags 3 (IFLAG3)	S/U	Yes	Yes
Message buffers	S/U	No	No
RX Individual Masks	S/U	No	No
Memory Error Control (MECR)	S/U	Yes	Yes
Error Injection Address (ERRIAR)	S/U	Yes	Yes
Error Injection Data Pattern (ERRIDPR)	S/U	Yes	Yes
Error Injection Parity Pattern (ERRIPPR)	S/U	Yes	Yes
Error Report Address (RERRAR)	S/U	Yes	Yes
Error Report Data (RERRDR)	S/U	Yes	Yes
Error Report Syndrome (RERRSYNR)	S/U	Yes	Yes

Table continues on the next page...

Table 568. Register access and reset information (continued)

Register	Access type	Affected by hard reset	Affected by soft reset
Error Status (ERRSR)	S/U	Yes	Yes
Enhanced CAN Bit Timing Prescalers (EPRS)	S/U	Yes	No
Enhanced Nominal CAN Bit Timing (ENCBT)	S/U	Yes	No
Enhanced Data Phase CAN bit Timing (EDCBT)	S/U	Yes	No
Enhanced Transceiver Delay Compensation (ETDC)	S/U	Yes	No
CAN FD Control (FDCTRL)	S/U	Yes	No
CAN FD Bit Timing (FDCBT)	S/U	Yes	No
CAN FD CRC (FDCRC)	S/U	Yes	Yes
Enhanced RX FIFO Control (ERFCR)	S/U	Yes	Yes
Enhanced RX FIFO Interrupt Enable (ERFIER)	S/U	Yes	Yes
Enhanced RX FIFO Status (ERFSR)	S/U	Yes	Yes
High-Resolution Timestamp (HR_TIME_STAMP)	S/U	No	No
Enhanced RX FIFO	S/U	No	No
Enhanced RX FIFO Filter Element (ERFFEL)	S/U	No	No

FlexCAN can store CAN messages for transmission and reception using message buffers and RX FIFO structures.

76.6.2 CAN register descriptions

The table below shows the FlexCAN memory map.

The address range from offset 80h–67Fh allocates the ninety-six 128-bit message buffers. The memory maps for the message buffers are in FlexCAN message buffer memory map.

The address range from offset 2000h–204Ch allocates the Enhanced RX FIFO output, and the address range from offset 2050h–263Ch allocates the rest of Enhanced RX FIFO 19 elements. The memory map for the Enhanced RX FIFO is in Enhanced RX FIFO structure.

76.6.2.1 CAN memory map

CAN_0 base address: 4030_4000h

CAN_1 base address: 4030_8000h

CAN_2 base address: 4030_C000h

CAN_3 base address: 4031_0000h

CAN_4 base address: 4031_4000h

CAN_5 base address: 4031_8000h

Offset	Register	Width (In bits)	Access	Reset value

Fields

Field	Function
31 MDIS	Module Disable Disables FlexCAN. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Soft reset does not affect this field. 0b - Enable 1b - Disable
30 FRZ	Freeze Enable Specifies FlexCAN behavior when MCR[HALT] = 1 or when Debug mode is requested at chip level. When this field becomes 1, FlexCAN can enter Freeze mode. Writing 0 to this field causes FlexCAN to exit from Freeze mode. The chip writes 1 to this field when a noncorrectable error is detected (MECR[NCEFAFRZ] becomes 1). 0b - Disable 1b - Enable
29 RFEN	Legacy RX FIFO Enable Enables the Legacy RX FIFO feature. When this field is 1, message buffers 0–5 cannot be used for normal reception and transmission. The corresponding memory region (80h–DCh) is used by the FIFO engine and additional message buffers (up to 32, depending on CTRL2[RFFN]). These message buffers are used as Legacy RX FIFO ID filter table elements. This field also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table 563. This field can be written in Freeze mode only; the module blocks it in other modes. **NOTE** When CAN FD operation is enabled (see MCR[FDEN]), you cannot write 1 to this field. **NOTE** This field must not be 1 if ERFCR[ERFEN] = 1. 0b - Disable 1b - Enable
28 HALT	Halt FlexCAN Puts FlexCAN into Freeze mode. The CPU should write 0 to this field after initializing the message buffers and Control 1 (CTRL1) and Control 2 (CTRL2). FlexCAN performs no reception or transmission before this field becomes 0. Freeze mode cannot be entered when FlexCAN is in a low-power mode. The module writes 1 to this field when a noncorrectable error is detected and MECR[NCEFAFRZ] = 1. 0b - No request 1b - Enter Freeze mode, if MCR[FRZ] = 1.
27 NOTRDY	FlexCAN Not Ready Indicates whether FlexCAN is in Disable mode or Freeze mode. When FlexCAN has exited these modes, this field becomes 0. Soft reset does not affect this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - FlexCAN is in Normal mode, Listen-Only mode, or Loopback mode. 1b - FlexCAN is in Disable mode or Freeze mode.
26 —	Reserved When writing to this field, always write the reset value.
25 SOFTRST	Soft Reset Resets internal state machines of FlexCAN and some memory-mapped registers. The CPU can write 1 to this field directly.. Because soft reset is synchronous and must follow a request-and-acknowledge procedure across clock domains, it may take some time to propagate its effect fully. When reset is pending, this field remains 1; it automatically becomes 0 when reset completes. You can poll this field to know when the soft reset has completed. Soft reset cannot be applied when clocks are shut down in a low-power mode. Transfer the module out of the low-power mode before applying soft reset. Soft reset does not affect this field. **NOTE** This field becomes 0 within 2 CAN bits after assertion of this bit. 0b - No reset 1b - Soft reset affects reset registers
24 FRZACK	Freeze Mode Acknowledge Indicates whether FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished. Therefore you can poll this field to know when FlexCAN has entered Freeze mode. If the Freeze mode request is negated, this field becomes 0 after the FlexCAN prescaler is running again. If Freeze mode is requested when FlexCAN is in a low-power mode, this field becomes 1 only when the low-power mode is exited. See Freeze mode. Soft reset does not affect this field. **NOTE** FRZACK becomes 1 within 178 CAN bits following the Freeze mode request by the CPU. This field becomes 0 within 2 CAN bits after the Freeze mode request removal (see Protocol timing). 0b - Not in Freeze mode, prescaler running. 1b - In Freeze mode, prescaler stopped.
23 SUPV	Supervisor Mode Configures FlexCAN to be either in Supervisor or User mode. The registers that this field affects are marked as S/U in the Access type column of Table 568. The affected registers start with Supervisor access allowance only. In User mode, affected registers allow both Supervisor and Unrestricted accesses. In Supervisor mode, affected registers allow only Supervisor access. Unrestricted access behaves as though the access is performed on an unimplemented register location. This field can be written only in Freeze mode; the module blocks it in other modes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - User mode 1b - Supervisor mode
22 —	Reserved When writing to this field, always write the reset value.
21 WRNEN	Warning Interrupt Enable Enables the generation of the flags ESR1[TWRNINT] and ESR1[RWRNINT]. When this field is 1, TWRNINT and RWRNINT flags are set when the respective error counter transitions from less than 96 to greater than or equal to 96. When this field is 0, the TWRNINT and RWRNINT flags are always zero, independent of the values of the error counters. No warning interrupt is generated. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Disable 1b - Enable
20 LPMACK	Low-Power Mode Acknowledge Indicates whether FlexCAN is in a low-power mode (Disable mode). A low-power mode cannot be entered until all current transmission and reception processes have finished. The CPU can poll this field to know when FlexCAN has entered low-power mode. Soft reset does not affect this field. **NOTE** This field becomes 1 within 180 CAN bits after the low-power mode request by the CPU. This field becomes 0 within 2 CAN bits after the low-power mode request removal (see Protocol timing). 0b - Not in a low-power mode 1b - In a low-power mode
19 —	Reserved When writing to this field, always write the reset value.
18 —	Reserved When writing to this field, always write the reset value.
17 SRXDIS	Self-Reception Disable Determines whether FlexCAN can receive frames transmitted by itself. If 1, frames transmitted by the module are not stored in any MB, regardless of whether the MB is programmed with an ID that matches the transmitted frame. No interrupt flag or interrupt signal is generated due to the frame reception. This field can be written only in Freeze mode; the module blocks it in other modes. 0b - Enable 1b - Disable
16	Individual RX Masking and Queue Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
IRMQ	Indicates whether RX matching process is based on individual masking and queue, or based on a masking scheme with RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), Receive 15 Mask (RX15MASK), and Legacy RX FIFO Global Mask (RXFGMASK). When this field is disabled, for backward compatibility with legacy applications, reading the Control and Status word locks the MB even if it is empty. This field can be written in Freeze mode only. The module blocks it in other modes. 0b - Disable 1b - Enable
15 DMA	DMA Enable Enables DMA. The DMA feature can only be used in Legacy RX FIFO or Enhanced RX FIFO, so MCR[RFEN] or ERFCR[ERFEN] must be 1. When DMA and RFEN are 1, IFLAG1[BUF5I] generates the DMA request, and no RX FIFO interrupt is generated. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Disable 1b - Enable
14 —	Reserved
13 LPRIOEN	Local Priority Enable Enables the local priority feature. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word. However, the actual transmitted ID is 11 bits for standard frames and 29 bits for extended frames. This field can be written only in Freeze mode; the module blocks it in other modes. This bit is provided for backward compatibility with legacy applications. 0b - Disable 1b - Enable
12 AEN	Abort Enable Enables the TX abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This field can be written only in Freeze mode; the module blocks it in other modes. **NOTE** When this field is 1, only use the abort mechanism (see Transmission abort mechanism) to update message buffers configured for transmission. **CAUTION** Writing the abort code into RX message buffers can cause unpredictable results when this field is 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
11 FDEN	CAN FD Operation Enable Enables the CAN with flexible data rate (CAN FD) operation. This field can be written in Freeze mode only. FlexCAN can receive and transmit messages in CAN 2.0 format. If this field is enabled, FlexCAN can also receive and transmit messages in CAN FD format. FlexCAN can transmit FD frame format according to ISO 11898-1:2015. **NOTE** If the value of this field is 1, the Legacy RX FIFO Enable (MCR[RFEN]) field cannot be 1. 0b - Disable 1b - Enable
10 —	Reserved
9-8 IDAM	ID Acceptance Mode Identifies the format of the Legacy RX FIFO ID filter table elements. This field configures all elements of the table at the same time; they are all the same format. See Legacy RX FIFO structure. This field can be written only in Freeze mode; the module blocks it in other modes. 00b - Format A: One full ID (standard and extended) per ID filter table element. 01b - Format B: Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID filter table element. 10b - Format C: Four partial 8-bit standard IDs per ID filter table element. 11b - Format D: All frames rejected.
7 —	Reserved
6-0 MAXMB	Number of the Last Message Buffer Defines the number of the last message buffer that takes part in the matching and arbitration processes. The reset value (0Fh) is equivalent to a 16-MB configuration. This field can be written only in Freeze mode; the module blocks it in other modes. **NOTE** You must write a value smaller than or equal to the number of available message buffers to this field, as described in FlexCAN memory partition for CAN FD. Additionally, the MAXMB value must consider the region of message buffers occupied by Legacy RX FIFO and its ID filters table space defined by CTRL2[RFFN]. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit, as described in Table 563.

76.6.2.3 Control 1 (CTRL1)

Offset

Register	Offset
CTRL1	4h

Function

Contains specific FlexCAN control features related to the CAN bus. These features include bit rate, programmable sampling point within an RX bit, Loopback mode, Listen-Only mode, Bus Off recovery behavior, and interrupt enabling (Bus-Off, Error, Warning). It also determines the division factor for the clock prescaler.

The CAN bit timing variables (CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW]) can also be configured in CAN Bit Timing (CBT), which extends the range of all these variables. If CBT[BTF] = 1, CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] become read-only.

If CTRL2[BTE] = 1, CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] are not used by the module. Instead, these fields are read as zero, and a write operation to them has no effect.

NOTE

When the CAN FD feature is enabled, do not use CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] for CAN bit timing. Instead use CBT[EPRESDIV], CBT[ERJW], CBT[EPSEG1], CBT[EPSEG2], and CBT[EPROPSEG].

The CAN bit variables in CTRL1 and in CBT are stored in the same internal register.

Soft reset does not affect the contents of this register.

Fields

Field	Function
31-24 PRESDIV	Prescaler Division Factor Determines the ratio between the PE clock frequency and the serial clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The maximum value of this field is FFh, which gives a minimum Sclock frequency

Table continues on the next page...

Table continued from the previous page...

Field	Function
	equal to the PE clock frequency divided by 256. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. Sclock frequency = PE clock frequency ÷ (PRESDIV + 1).
23-22 RJW	Resync Jump Width Defines the maximum number of time quanta that one resynchronization can change a bit time. One time quantum is equal to one Sclock period. The valid programmable values are 0–3. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. Resync Jump Width = RJW + 1.
21-19 PSEG1	Phase Segment 1 Defines the length of phase segment 1 in the bit time. The valid programmable values are 0–7. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 1 = (PSEG1 + 1) × Time Quanta.
18-16 PSEG2	Phase Segment 2 Defines the length of phase segment 2 in the bit time. The valid programmable values are 1–7. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 2 = (PSEG2 + 1) × Time Quanta.
15 BOFFMSK	Bus Off Interrupt Mask Provides a mask for the Bus Off interrupt ESR1[BOFFINT]. 0b - Interrupt disabled 1b - Interrupt enabled
14 ERRMSK	Error Interrupt Mask Provides a mask for the Error interrupt ESR1[ERRINT]. 0b - Interrupt disabled 1b - Interrupt enabled
13 —	Reserved **NOTE** Writeable only if the module is disabled. Otherwise the access type is read-only.
12 LPB	Loopback Mode Configures FlexCAN to operate in Loopback mode. In this mode, FlexCAN performs an internal loopback that can be used for self-test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The RX CAN input pin is ignored and the TX CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field. It generates an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This field can be written only in Freeze mode; the module blocks it in other modes. **NOTE** In this mode, MCR[SRXDIS] cannot become 1, because it would impede the self-reception of a transmitted message. **NOTE** FDCTRL[TDCEN] and MCR[ETDCEN] must be 0 when this field is 1. 0b - Disabled 1b - Enabled
11 TWRNMSK	TX Warning Interrupt Mask Provides a mask for the TX Warning interrupt associated with the ESR1[TWRNINT] flag. When MCR[WRNEN] = 0, this field is read as 0. This field can be written only if MCR[WRNEN] = 1. 0b - Disabled 1b - Enabled
10 RWRNMSK	RX Warning Interrupt Mask Provides a mask for the RX Warning interrupt associated with the ESR1[RWRNINT] flag. When MCR[WRNEN] = 0, this field is read as 0. This field can be written only if MCR[WRNEN] = 1. 0b - Disabled 1b - Enabled
9 —	Reserved
8 —	Reserved
7 SMP	CAN Bit Sampling Determines the sampling mode of CAN bits at the RX input. This field can be written in Freeze mode only; the module blocks it in other modes. **NOTE** For proper operation, to write 1 to this field, you must guarantee a minimum value of two time quanta in CTRL1[PSEG1] (or CBT[EPSEG1]).This bit cannot become 1 when CAN FD is enabled (MCR[FDEN] = 1). 0b - One sample is used to determine the bit value.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Three samples are used to determine the value of the received bit: the regular one (sample point) and two preceding samples. A majority rule is used.
6 BOFFREC	Bus Off Recovery Determines how FlexCAN recovers from Bus Off state. If 0, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If 1, automatic recovering from Bus Off is disabled. The module remains in Bus Off state until you write 1 to this field. If this field becomes 0 before 128 sequences of 11 recessive bits are detected on the CAN bus, Bus Off recovery happens as if this field had never become 1. If this field becomes 0 after 128 sequences of 11 recessive bits occurred, FlexCAN resynchronizes to the bus. It waits for 11 recessive bits before joining the bus. After this field becomes 0, it can become 1 again during Bus Off, but it will only be effective the next time the module enters Bus Off. If this field becomes 0 when the module is in Bus Off, writing 1 to this field is not effective for the current Bus Off recovery. **NOTE** See Bus Off in the CAN Protocol standard (ISO 11898-1:2015) for details. 0b - Enabled 1b - Disabled
5 TSYN	Timer Sync Enables a mechanism that resets the free-running timer each time a message is received in message buffer 0. This feature provides the means to synchronize multiple FlexCAN stations with a special "SYNC" message (that is, global network time). If MCR[RFEN] = 1 (Legacy RX FIFO enabled), the first available message buffer, according to CTRL2[RFFN], is used for timer synchronization instead of MB0. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Disable 1b - Enable
4 LBUF	Lowest Buffer Transmitted First Determines the ordering mechanism for message buffer transmission. When 1, MCR[LPRIOEN] does not affect the priority arbitration. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Buffer with highest priority is transmitted first. 1b - Lowest number buffer is transmitted first.
3 LOM	Listen-Only Mode Configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters described in Error Counter (ECR) are frozen, and the module operates in CAN Error Passive mode. Only messages acknowledged by another CAN station are received. If FlexCAN detects an unacknowledged message, it flags a BIT0 error without changing the receive error counter (ECR[RXERRCNT]), as if it is trying to acknowledge the message.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	FlexCAN acknowledges Listen-Only mode when ESR1[FLTCONF] = 1, indicating the Error Passive state. There can be some delay between the Listen-Only mode request and its acknowledgment. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Listen-Only mode is deactivated. 1b - FlexCAN module operates in Listen-Only mode.
2-0 PROPSEG	Propagation Segment Defines the length of the propagation segment in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode; the module blocks it in other modes. Propagation segment time = (PROPSEG + 1) × Time Quanta. One Time Quantum = one Sclock period.

76.6.2.4 Free-Running Timer (TIMER)

Offset

Register	Offset
TIMER	8h

Function

Represents a 16-bit free-running counter that the CPU can read and write. The timer starts from 0h after reset, counts linearly to FFFFh, and wraps around.

When CTRL2[TIMER_SRC] = 1, an external time tick continuously increments the timer. The time tick must be synchronous to the peripheral clock, with a minimum pulse width of one clock cycle.

When CTRL2[TIMER_SRC] = 0, the CAN bit clock increments the timer, which defines the baud rate on the CAN bus. During a message transmission or reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable and Freeze modes.

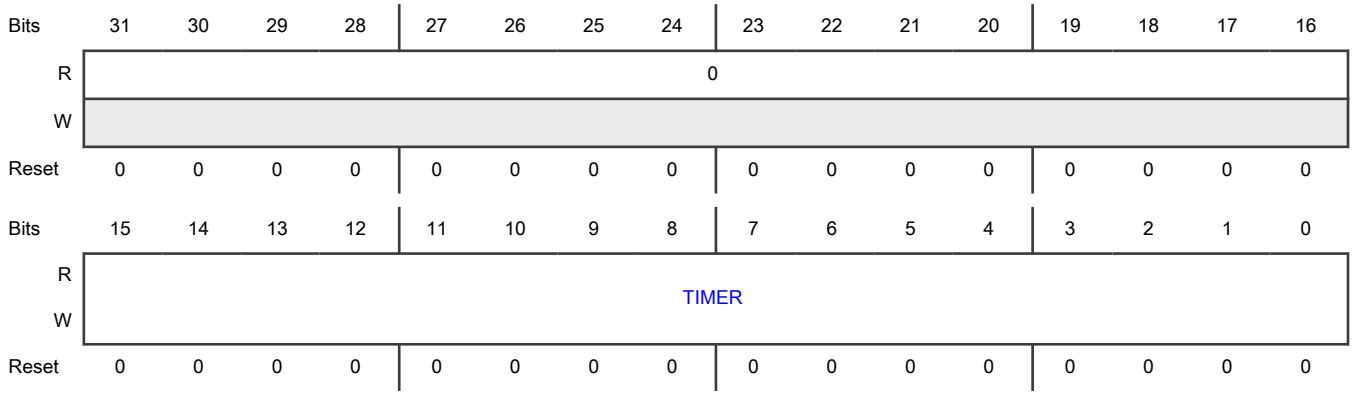
The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the timestamp entry in a message buffer after a successful reception or transmission of a message.

If CTRL1[TSYN] = 1, the timer is reset whenever a message is received in the first available message buffer, according to CTRL2[RFFN].

The CPU can write to this register anytime. However, if the write occurs simultaneously with the timer being reset by a reception in the first message buffer, the write value is discarded.

Reading this register affects the message buffer unlocking procedure (see Message buffer lock mechanism).

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 TIMER	Timer Value Contains the free-running counter value.

76.6.2.5 RX Message Buffers Global Mask (RXMGMASK)

Offset

Register	Offset
RXMGMASK	10h

Function

Masks the filter bits of all RX message buffers, excluding MB14 and MB15, which have individual mask registers.

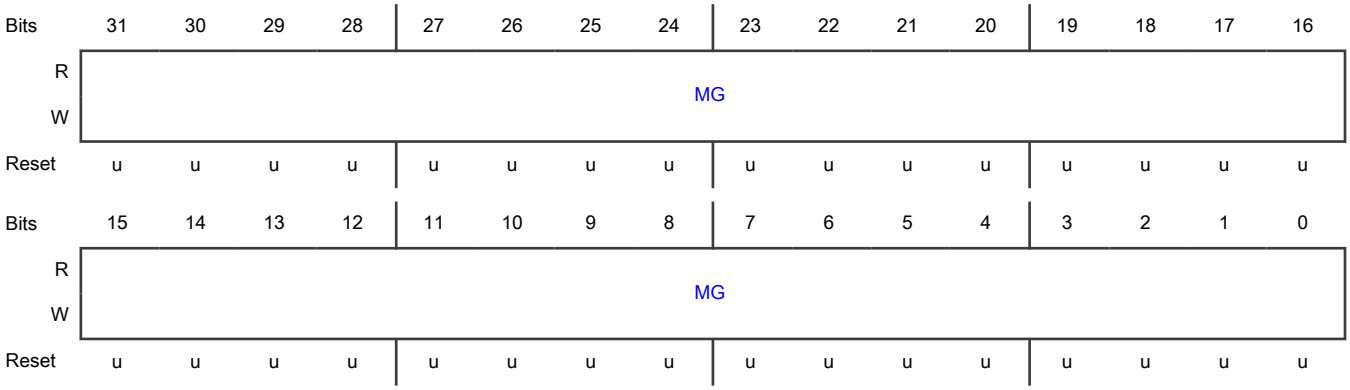
This register is located in RAM.

RXMGMASK is provided for legacy application support.

- When MCR[IRMQ] is 0, RXMGMASK is always in effect. The bits in RXMGMASK[MG] mask the MB filter bits.
- When MCR[IRMQ] is 1, RXMGMASK has no effect. The bits in RXMGMASK[MG] do not mask the MB filter bits.

This register can only be written in Freeze mode; the module blocks it in other modes.

Diagram



Fields

Field	Function
31-0 MG	Global Mask for RX Message Buffers Masks the message buffer filter bits. The alignment with the ID word of the message buffer is imperfect. The two most significant MG bits affect the fields RTR and IDE, which are located in the Control and Status word of the MB. The following table shows which MG bits mask each MB filter field.

SMB[RTR] [1]	CTRL2[RRS]	CTRL2[EACEN]	Message buffer filter fields			
			MB[RTR]	MB[IDE]	MB[ID]	Reserved
0	-	0	Note [2]	Note [3]	MG[28:0]	MG[31:29]
0	-	1	MG[31]	MG[30]	MG[28:0]	MG[29]
1	0	-	-	-	-	MG[31:0]
1	1	0	-	-	MG[28:0]	MG[31:29]
1	1	1	MG[31]	MG[30]	MG[28:0]	MG[29]

1. RTR bit of the incoming frame. It is saved into an auxiliary MB called RX serial message buffer (RX SMB).
2. If CTRL2[EACEN] is 0, the RTR bit of MB is never compared with the RTR bit of the incoming frame.
3. If CTRL2[EACEN] is 0, the IDE bit of MB is always compared with the IDE bit of the incoming frame.

0b - The corresponding bit in the filter is "don't care."

1b - The corresponding bit in the filter is checked.

76.6.2.6 Receive 14 Mask (RX14MASK)

Offset

Register	Offset
RX14MASK	14h

Function

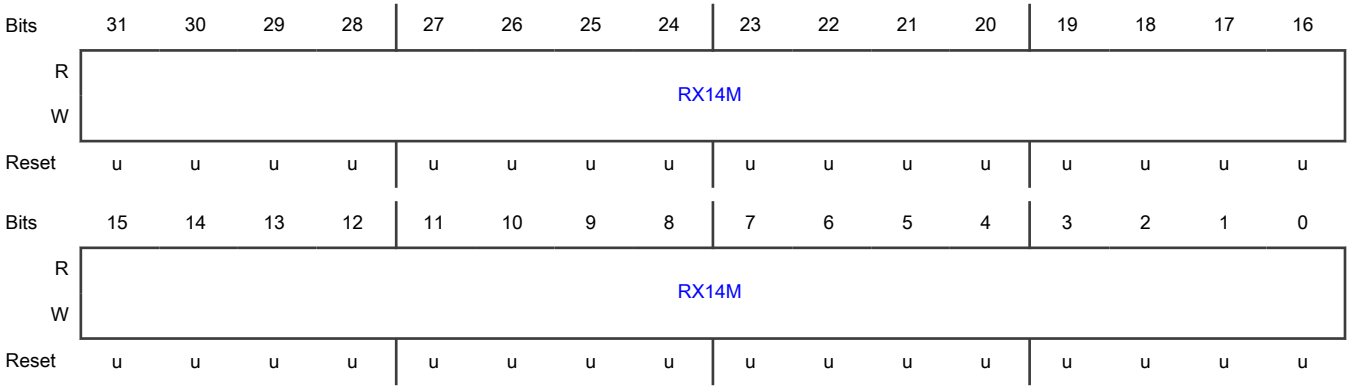
Masks the filter fields of MB14.

This register is located in RAM.

RX14MASK is provided for legacy application support. When MCR[IRMQ] = 1, RX14MASK has no effect.

This register can only be programmed when the module is in Freeze mode; the module blocks it in other modes.

Diagram



Fields

Field	Function
31-0 RX14M	RX Buffer 14 Mask Bits Masks the corresponding MB14 filter field in the same way that RX Message Buffers Global Mask (RXMGMASK) masks the filters of the other message buffers. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

76.6.2.7 Receive 15 Mask (RX15MASK)

Offset

Register	Offset
RX15MASK	18h

Function

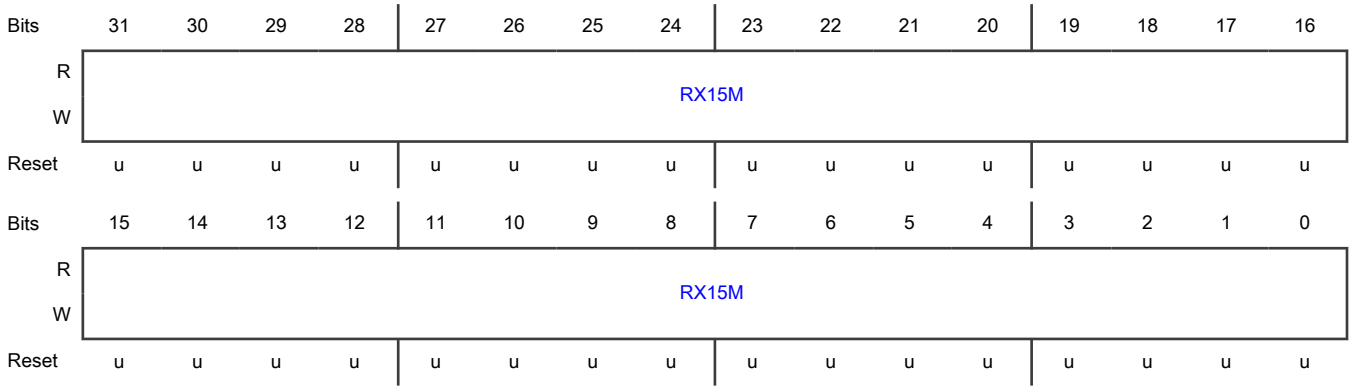
Masks the filter fields of MB15.

This register is located in RAM.

RX15MASK is provided for legacy application support. When MCR[IRMQ] = 1, RX15MASK has no effect.

This register can be programmed only when the module is in Freeze mode; the module blocks it in other modes.

Diagram



Fields

Field	Function
31-0 RX15M	RX Buffer 15 Mask Bits Masks the corresponding MB15 filter field in the same way that RX Message Buffers Global Mask (RXMGMASK) masks the filters of other message buffers. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

76.6.2.8 Error Counter (ECR)

Offset

Register	Offset
ECR	1Ch

Function

Contains error counters for received and transmitted messages.

TXERRCNT and RXERRCNT consider all errors in both CAN FD and non-FD message formats. TXERRCNT_FAST and RXERRCNT_FAST count only the errors that occur in the data phase of CAN FD frames that have BRS = 1.

The Fault Confinement state (ESR1[FLTCONF]) is updated based on TXERRCNT and RXERRCNT counters only. The rules for increasing and decreasing these counters are described in the CAN protocol and are entirely implemented in FlexCAN.

The basic rules for FlexCAN bus state transitions are:

- If the value of TXERRCNT or RXERRCNT becomes greater than or equal to 128, ESR1[FLTCONF] is updated to reflect Error Passive state.
- If the state of FlexCAN is Error Passive, and TXERRCNT or RXERRCNT decrements to a value less than 128 when the other already satisfies this condition, ESR1[FLTCONF] is updated to reflect Error Active state.
- If the value of TXERRCNT becomes greater than 255, ESR1[FLTCONF] is updated to reflect Bus Off state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
- If FlexCAN is in Bus Off, TXERRCNT is cascaded with another internal counter to count the occurrences of 11 consecutive recessive bits on the bus. TXERRCNT is reset to zero. It counts in a manner where the internal counter

counts 11 such bits and then wraps around when incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, ESR1[FLTCONF] is updated to Error Active, and both error counters are reset to zero. Upon any instance of a dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value. The TXERRCNT_FAST counter is frozen during Bus Off.

- If only one node is operating during system startup, its TXERRCNT increases upon each attempted message transmission, as a result of acknowledge errors (indicated by ESR1[ACKERR]). After the transition to Error Passive state, TXERRCNT no longer increments upon acknowledge errors. The chip never goes into the Bus Off state.
- If RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected when being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to return to the Error Active state.
- TXERRCNT_FAST and RXERRCNT_FAST error counter values increment and decrement based on errors detected only in the data phase of CAN FD frames that have BRS = 1. These counters follow the same increment and decrement rules as TXERRCNT and RXERRCNT. These counters do not wrap around and get stuck at their maximum value (255). They stop counting and keep their values frozen when FlexCAN is in the Bus Off state. They are reset when FlexCAN leaves the Bus Off state and resume counting after FlexCAN returns to the Error Active state.

NOTE

See Fault confinement in the CAN Protocol standard (ISO 11898-1:2015) for details.

Fields

Field	Function
31-24 RXERRCNT_FAST	Receive Error Counter for Fast Bits Counts errors detected in the data phase of received CAN FD messages that have BRS = 1. This field is read-only except in Freeze mode, when the CPU can write an 8-bit zero value only.
23-16 TXERRCNT_FAST	Transmit Error Counter for Fast Bits Counts errors detected in the data phase of transmitted CAN FD messages that have BRS = 1. This field is read-only except in Freeze mode, when the CPU can write an 8-bit zero value only.
15-8 RXERRCNT	Receive Error Counter Counts all errors detected in received messages. This field is read-only except in Freeze mode, when the CPU can write to it.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-0 TXERRCNT	Transmit Error Counter Counts all errors detected in transmitted messages. This field is read-only except in Freeze mode, when the CPU can write to it.

76.6.2.9 Error and Status 1 (ESR1)

Offset

Register	Offset
ESR1	20h

Function

Reports various error conditions detected in the reception and transmission of a CAN frame. This register provides status information about the chip, and is the source of some interrupts to the CPU. The reported error conditions are:

NOTE

Reading host can clear these fields.

- Errors detected in CAN frames of any format:
  - BIT1ERR
  - BIT0ERR
  - ACKERR
  - CRCERR
  - FRMERR
  - STFERR
- Errors detected in the data phase of CAN FD frames with the BRS bit set only:
  - BIT1ERR_FAST
  - BIT0ERR_FAST
  - CRCERR_FAST
  - FRMERR_FAST
  - STFERR_FAST

One or more error flags may report an error detected in a single CAN frame. To account for more error events occurring in subsequent frames when the CPU does not attempt to read this register, error reporting is cumulative.

Status flags:

- TXWRN
- RXWRN
- IDLE
- TX

- FLTCONF
- RX
- SYNCH

Interrupt flags:

- BOFFINT
- BOFFDONEINT
- ERRINT
- ERRINT_FAST
- TWRNINT
- RWRNINT

The CPU should follow this procedure when servicing interrupt requests generated by these flags:

1. Read this register to capture all error condition and status flags. This action clears the respective flags that were set since the last read access.
2. Write 1 to clear the interrupt flag that triggered the interrupt request.
3. Write 1 to clear the ERROVR flag, if it is set.

Starting from all error flags cleared, a first error event sets either ERRINT or ERRINT_FAST (provided the corresponding mask bit is 1). If other error events in subsequent frames occur before the CPU serves the interrupt request, the ERROVR flag is set to indicate that errors from different frames have accumulated.

Table 569. CAN bus status

SYNCH	IDLE	TX	RX	FlexCAN state
0	0	0	0	Not synchronized to CAN bus
1	1	X	X	Idle
1	0	1	0	Transmitting
1	0	0	1	Receiving

NOTE

See Fault confinement in the CAN Protocol standard (ISO 11898-1:2015) for details.

Fields

Field	Function
31 BIT1ERR_FAST	Fast Bit1 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames that have BRS = 1. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit transmitted as recessive is received as dominant.
30 BIT0ERR_FAST	Fast Bit0 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames that have BRS = 1. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit transmitted as dominant is received as recessive.
29 —	Reserved
28 CRCERR_FAST	Fast Cyclic Redundancy Check Error Flag Indicates that the receiver node has detected a CRC error in the CRC field of CAN FD frames that have BRS = 1. This error means that the calculated CRC is different from the received CRC. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A CRC error occurred since last read of this register.
27 FRMERR_FAST	Fast Form Error Flag Indicates whether the receiver node has detected a form error in the data phase of CAN FD frames that have BRS = 1. This error means that a fixed-form bit field contains at least one illegal bit. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A form error occurred since last read of this register.
26 STFERR_FAST	Fast Stuffing Error Flag Indicates that a stuffing error has been detected in the data phase of CAN FD frames that have BRS = 1. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A stuffing error occurred since last read of this register.
25-24 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
23 —	Reserved
22 —	Reserved
21 ERROVR	Error Overrun Flag Indicates that an error condition occurred when any error flag is already set. 0b - No overrun 1b - Overrun
20 ERRINT_FAST	Fast Error Interrupt Flag Indicates that at least one error flag detected in the data phase of CAN FD frames that have BRS = 1 (BIT1ERR_FAST, BIT0ERR_FAST, CRCERR_FAST, FRMERR_FAST, or STFERR_FAST) is set. If CTRL2[ERRMSK_FAST] = 1, an interrupt is generated to the CPU. 0b - No such occurrence. 1b - Error flag set in the data phase of CAN FD frames that have BRS = 1.
19 BOFFDONEINT	Bus Off Done Interrupt Flag Indicates whether ECR[TXERRCNT] has finished counting 128 occurrences of 11 consecutive recessive bits on the CAN bus and is ready to leave Bus Off. If CTRL2[BOFFDONEMSK] = 1, an interrupt is generated to the CPU. 0b - No such occurrence 1b - FlexCAN module has completed Bus Off process.
18 SYNCH	CAN Synchronization Status Flag Indicates whether FlexCAN is synchronized to the CAN bus and able to participate in the communication process. FlexCAN sets and clears this flag. See the table in Error and Status 1 (ESR1). 0b - Not synchronized 1b - Synchronized
17 TWRNINT	TX Warning Interrupt Flag Indicates whether TX error counter changed from less than 96 to greater than or equal to 96. If MCR[WRNEN] = 1, this flag is set when the TXWRN flag transitions from 0 to 1, meaning that the TX error counters reached 96. If CTRL1[TWRNMSK] = 1, an interrupt is sent to the CPU. When MCR[WRNEN] = 0, this flag is masked. The CPU must clear this flag before writing 0 to MCR[WRNEN]. Otherwise, this flag is set when MCR[WRNEN] = 1 again. Writing 0 has no effect. This flag is not generated when in the Bus Off state. This flag is not updated during Freeze mode. 0b - No such occurrence 1b - TX error counter changed from less than 96 to greater than or equal to 96.

Table continues on the next page...

Table continued from the previous page...

Field	Function
16 RWRNINT	RX Warning Interrupt Flag Indicates whether the RX error counter changed from less than 96 to greater than or equal to 96. If MCR[WRNEN] = 1, this flag is set when the RXWRN flag transitions from 0 to 1, meaning that the RX error counters reached 96. If CTRL1[RWRNMSK] = 1, an interrupt is sent to the CPU. When MCR[WRNEN] = 0, this flag is masked. The CPU must clear this flag before writing 0 to MCR[WRNEN]. Otherwise, this flag is set when MCR[WRNEN] = 1 again. Writing 0 has no effect. This flag is not updated during Freeze mode. 0b - No such occurrence 1b - RX error counter changed from less than 96 to greater than or equal to 96.
15 BIT1ERR	Bit1 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. **NOTE** A transmitter does not set this flag for an arbitration field or ACK slot. It is not set for a node sending a error passive flag that detects dominant bits. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit sent as recessive is received as dominant.
14 BIT0ERR	Bit0 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit sent as dominant is received as recessive.
13 ACKERR	Acknowledge Error Flag Indicates whether the transmitter node has detected an acknowledge error. This error means that a dominant bit has not been detected during the ACK SLOT. After a read operation, the field's value clears to 0. 0b - No error 1b - Error occurred since last read of this register.
12 CRCERR	Cyclic Redundancy Check Error Flag Indicates whether the receiver node has detected a cyclic redundancy check (CRC) error either in a non-FD message or in the arbitration or data phase of a frame in CAN FD format. This error means that the calculated CRC is different from the received. After a read operation, the field's value clears to 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No error 1b - Error occurred since last read of this register.
11 FRMERR	Form Error Flag Indicates whether a form error has been detected in a non-FD message or in the arbitration or data phase of an FD message by the receiver node. This error means that a fixed-form field contains at least one illegal bit. After a read operation, the field's value clears to 0. 0b - No error 1b - Error occurred since last read of this register.
10 STFERR	Stuffing Error Flag Indicates that a stuffing error has been detected in a non-FD message or in the arbitration or data phase of an FD message by the receiver node. After a read operation, the field's value clears to 0. 0b - No error 1b - Error occurred since last read of this register.
9 TXWRN	TX Error Warning Flag Indicates when repetitive errors occur during message transmission. Only the value of ECR[TXERRCNT] affects this flag. This flag is not updated during Freeze mode. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - TXERRCNT is 96 or greater.
8 RXWRN	RX Error Warning Flag Indicates when repetitive errors occur during message reception. Only the value of ECR[RXERRCNT] affects this flag. This flag is not updated during Freeze mode. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - RXERRCNT is greater than or equal to 96.
7 IDLE	Idle Indicates whether CAN bus is in IDLE state. See Table 569. 0b - Not IDLE 1b - IDLE
6 TX	FlexCAN In Transmission Indicates whether FlexCAN is transmitting a message. See Table 569.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not transmitting 1b - Transmitting
5-4 FLTCONF	Fault Confinement State Indicates the confinement state of FlexCAN. If CTRL1[LOM] = 1, after a delay that depends on the CAN bit timing, this field indicates Error Passive. The same delay affects the way that this field reflects an update to ECR register by the CPU. It may be necessary to wait up to one CAN bit time for coherence to be restored. Soft reset affects this field, but if CTRL1[LOM] = 1, its reset value lasts for only one CAN bit. After that time, this field reports Error Passive. 00b - Error Active 01b - Error Passive 1xb - Bus Off
3 RX	FlexCAN in Reception Flag Indicates whether FlexCAN is receiving a message. See the table in Error and Status 1 (ESR1). 0b - Not receiving 1b - Receiving
2 BOFFINT	Bus Off Interrupt Flag Indicates whether FlexCAN has entered Bus Off state. If CTRL1[BOFFMSK]) = 1, an interrupt is generated to the CPU. Writing 0 to this field has no effect. 0b - No such occurrence. 1b - FlexCAN module entered Bus Off state.
1 ERRINT	Error Interrupt Flag Indicates that at least one of the error flags (ESR1[BIT1ERR], ESR1[BIT0ERR], ESR1[ACKERR], ESR1[CRCERR], ESR1[FRMERR], or ESR1[STFERR]) is set. If the corresponding mask CTRL1[ERRMSK] = 1, an interrupt is generated to the CPU. Writing 0 to this field has no effect. 0b - No such occurrence. 1b - Indicates setting of any error flag in the Error and Status register.
0 —	Reserved

76.6.2.10 Interrupt Masks 2 (IMASK2)

Offset

Register	Offset
IMASK2	24h

Function

Masks interrupt flags. This register allows any of the 32 message buffer interrupts to be enabled or disabled for MB63–MB32. It contains one interrupt mask bit per buffer. This configuration allows the CPU to determine which buffer generates an interrupt after a successful transmission or reception when the corresponding Interrupt Flags 2 (IFLAG2) flag is set.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 BUF63TO32M	Buffer MBi Mask Masks the corresponding FlexCAN message buffer interrupt for MB63–MB32. **NOTE** If the corresponding Interrupt Flags 2 (IFLAG2) flag is set, writing 1 or 0 to a field in IMASK2 can set or clear an interrupt request. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

76.6.2.11 Interrupt Masks 1 (IMASK1)

Offset

Register	Offset
IMASK1	28h

Function

Masks interrupt flags. This register allows any of the 32 message buffer interrupts to be enabled or disabled for MB31–MB0. It contains one interrupt mask bit per buffer. This configuration allows the CPU to determine which buffer generates an interrupt after a successful transmission or reception when the corresponding Interrupt Flags 1 (IFLAG1) flag is set.

Diagram

R W	BUF31TO0M															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 BUF31TO0M	Buffer MBi Mask Enables or disables the corresponding FlexCAN message buffer interrupt for MB31–MB0. **NOTE** If the corresponding Interrupt Flags 1 (IFLAG1) flag is set, writing 1 or 0 to a field in IMASK1 can set or clear an interrupt request. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

76.6.2.12 Interrupt Flags 2 (IFLAG2)

Offset

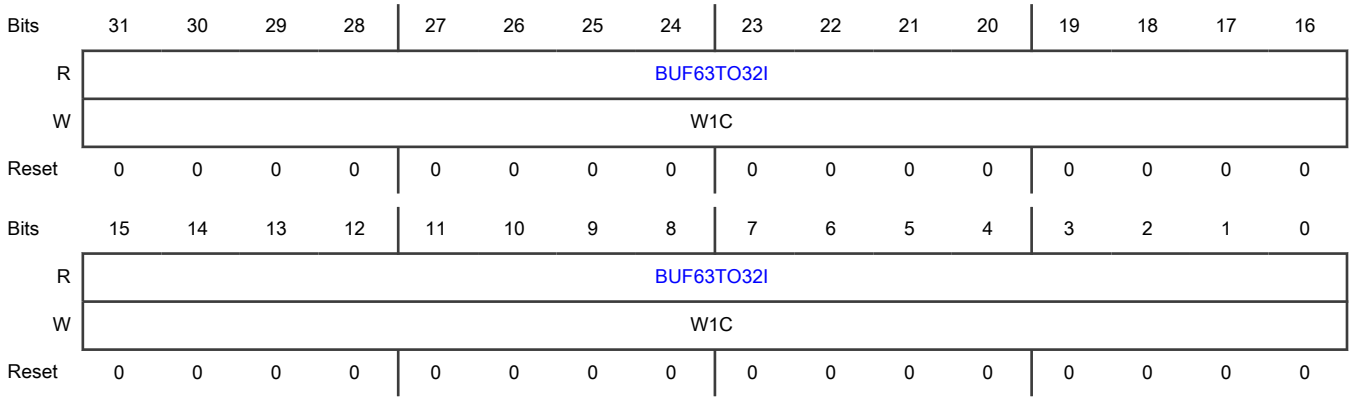
Register	Offset
IFLAG2	2Ch

Function

Contains the flags for the 32 message buffer interrupts for MB63–MB32. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the respective flag in this register. If the corresponding Interrupt Masks 2 (IMASK2) bit is set, an interrupt is generated.

Before updating MCR[MAXMB], the CPU must service the IFLAG2 flags whose MB value is greater than the MAXMB to be updated. Otherwise, those flags remain set and are inconsistent with the number of message buffers available.

Diagram



Fields

Field	Function
31-0 BUF63TO32I	Buffer MBi Interrupt Flags the corresponding FlexCAN message buffer interrupt for MB63–MB32. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.

76.6.2.13 Interrupt Flags 1 (IFLAG1)

Offset

Register	Offset
IFLAG1	30h

Function

Contains the flags for the 32 message buffer interrupts for MB31–MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding Interrupt Masks 1 (IMASK1) bit is set, an interrupt is generated. There is an exception when DMA for Legacy RX FIFO is enabled, as described below.

The BUF7I–BUF5I flags also represent Legacy FIFO interrupts when the Legacy RX FIFO is enabled. When MCR[RFEN] is 1 and MCR[DMA] is 0, the function of the eight least significant interrupt flags changes:

- BUF7I, BUF6I, and BUF5I indicate operating conditions of the Legacy FIFO.
- BUF4I–BUF1I fields are reserved.
- BUF0I empties the Legacy FIFO.

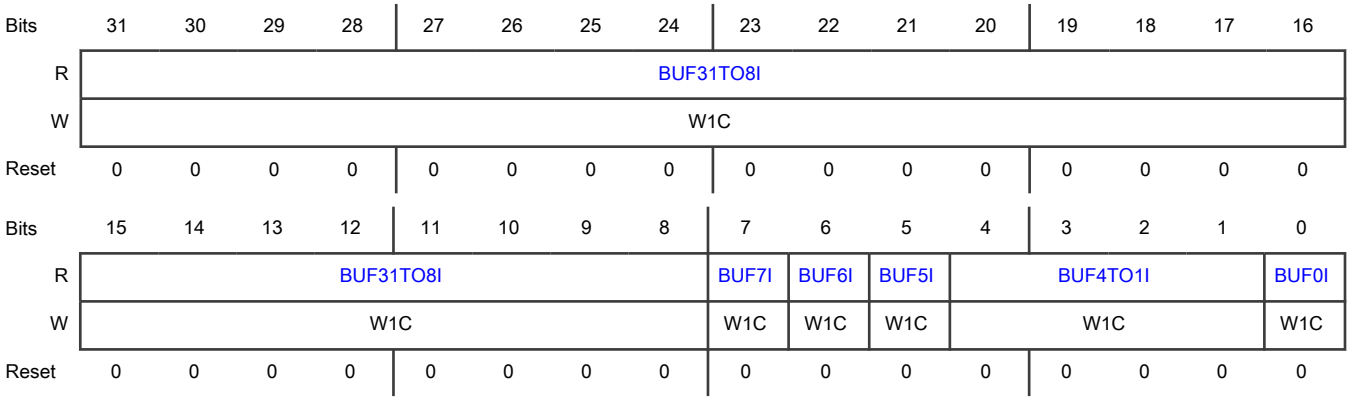
Before writing 1 to MCR[RFEN], the CPU must service the IFLAG flags set in the Legacy RX FIFO region; see Legacy RX FIFO. Otherwise, these IFLAG flags mistakenly show the related message buffers now belonging to Legacy FIFO as having contents to be serviced. When MCR[RFEN] is 0, the Legacy FIFO flags must be cleared. The same care must be taken when a CTRL2[RFFN] value is selected, extending Legacy RX FIFO filters beyond MB7. For example, when RFFN is 8h, Legacy RX FIFO filters occupy the MB23–MB0 range, and related IFLAG flags must be cleared.

When MCR[RFEN] and MCR[DMA] are 1 (DMA feature for Legacy RX FIFO enabled), the function of the eight least significant interrupt flags (BUF7I–BUF0I) changes to support DMA operation. BUF7I, BUF6I, and BUF4I–BUF1I are not used.

BUF5I indicates the operating condition of the Legacy FIFO, and BUF0I empties the Legacy FIFO. Moreover, BUF5I does not generate a CPU interrupt, but it does generate a DMA request. IMASK1 bits in the Legacy RX FIFO region are not considered when bit MCR[DMA] = 1. In addition, the CPU must not clear the BUF5I flag when DMA is enabled. Before writing 1 to MCR[DMA], the CPU must service the IFLAG flags set in the Legacy RX FIFO region. When MCR[DMA] is 0, the Legacy FIFO must be empty. Legacy FIFO must be disabled when MCR[FDEN] = 1.

Before updating MCR[MAXMB], the CPU must service the IFLAG1 flags whose MB value is greater than the MCR[MAXMB] to be updated. Otherwise, those flags remain set and are inconsistent with the number of message buffers available.

Diagram



Fields

Field	Function
31-8 BUF31TO8I	Buffer MBi Interrupt Flags the corresponding FlexCAN message buffer interrupt for MB31–MB8. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.
7 BUF7I	Buffer MB7 Interrupt or Legacy RX FIFO Overflow Flags the interrupt for MB7 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears this flag. When MCR[RFEN] = 1, this flag represents a Legacy RX FIFO overflow. In this case, the flag indicates that a message was lost because the Legacy RX FIFO is full. When the Legacy RX FIFO is full and a message buffer captures the message, this flag is not set. 0b - No occurrence of MB7 completing transmission or reception, or no FIFO overflow. 1b - MB7 completed transmission or reception, or FIFO overflow.
6 BUF6I	Buffer MB6 Interrupt or Legacy RX FIFO Warning Flags the interrupt for MB6 when MCR[RFEN] = 0 (Legacy RX FIFO disabled).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE When a CPU write changes the value of MCR[RFEN], FlexCAN clears this flag. When MCR[RFEN] = 1, this flag represents a Legacy RX FIFO warning. In this case, the flag indicates when the number of unread messages within the Legacy RX FIFO is increased to five from four due to the reception of a new message. In other words, the Legacy RX FIFO is almost full. If this flag is cleared when there are more than four unread messages, it does not set again until the number of unread messages in the Legacy RX FIFO decreases to four or fewer. 0b - No occurrence of MB6 completing transmission or reception, or FIFO not almost full. 1b - MB6 completed transmission or reception, or FIFO almost full.
5 BUF5I	Buffer MB5 Interrupt or Frames available in Legacy RX FIFO Flags the interrupt for MB5 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears this flag. When MCR[RFEN] = 1, the BUF5I flag represents frames available in Legacy RX FIFO. In this case, the flag indicates that at least one frame is available to be read from the Legacy RX FIFO. When MCR[DMA] = 1, this flag generates a DMA request. The CPU must not clear this field by writing 1 to BUF5I. 0b - No occurrence of completed transmission or reception, or no frames available 1b - MB5 completed transmission or reception, or frames available
4-1 BUF4TO1I	Buffer MBi Interrupt or Reserved Flags the interrupts for MB4–MB1 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears these flags. When MCR[RFEN] = 1, the BUF4TO1I flags are reserved. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.
0 BUF0I	Buffer MB0 Interrupt or Clear Legacy FIFO bit Flags the interrupt for MB0 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). If MCR[RFEN] = 1, this field is used to trigger the clear Legacy FIFO operation. This operation empties the Legacy FIFO contents. Before performing this operation, the CPU must service all Legacy FIFO-related IFLAG flags. When MCR[DMA] = 1, this operation also clears the BUF5I flag, aborting the DMA request. The clear Legacy FIFO operation occurs when the CPU writes 1 to BUF0I. This operation is only allowed in Freeze mode; the module blocks it in other conditions.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - MB0 has no occurrence of successfully completed transmission or reception. 1b - MB0 has successfully completed transmission or reception.

76.6.2.14 Control 2 (CTRL2)

Offset

Register	Offset
CTRL2	34h

Function

Complements Control 1 (CTRL1), providing control bits for memory write-access in Freeze mode. This register extends Legacy FIFO filter quantity, and adjusts the operation of internal FlexCAN processes such as matching and arbitration.

Soft reset does not affect the contents of this register.

Table 570 shows how the value of CTRL2[RFFN] determines the Legacy RX FIFO filter structure.

Table 570. Possible Legacy RX FIFO filter structures

RFFN[3:0]	Number of Legacy RX FIFO filter elements	Message buffers occupied by Legacy RX FIFO and ID filter table	Remaining available message buffers	Legacy RX FIFO ID filter table elements affected by RX individual masks	Legacy RX FIFO ID filter table elements affected by Legacy RX FIFO global mask

Fields

Field	Function
31 ERRMSK_FAST	Error Interrupt Mask for Errors Detected in the Data Phase of Fast CAN FD Frames Enables the ESR1[ERRINT_FAST] interrupt. 0b - Disable 1b - Enable
30 BOFFDONEMSK	Bus Off Done Interrupt Mask Enables the Bus Off Done interrupt, ESR1[BOFFDONEINT]. 0b - Disable 1b - Enable
29 ECRWRE	Error Correction Configuration Register Write Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Enables updates for Memory Error Control (MECR). If the protocol described in Detection and correction of memory errors is not followed, this field is automatically 0. 0b - Disable 1b - Enable
28 WRMFRZ	Write Access to Memory in Freeze Mode Enables unrestricted write access to FlexCAN memory in Freeze mode. When this field is 0, write access restrictions are maintained. This field can only be written in Freeze mode, and has no effect out of Freeze mode. **NOTE** Do not write 1 to MCR[RFEN] during FlexCAN memory initialization. 0b - Disable 1b - Enable
27-24 RFFN	Number of Legacy Receive FIFO Filters Defines the number of Receive Legacy FIFO filters, as shown in Table 570. The chip determines the maximum selectable number of filters. Do not program this field with values that cause the number of message buffers occupied by Legacy RX FIFO and Legacy RX FIFO ID Filter to exceed MCR[MAXMB]. MCR[MAXMB] defines the number of message buffers present. This field can only be written in Freeze mode; the module blocks it in other modes. Each group of eight filters occupies a memory space equivalent to two message buffers. The more filters are implemented, the fewer message buffers are available. The Legacy RX FIFO occupies the memory space originally reserved for MB5–MB0. This field should be programmed with a value corresponding to a number of filters less than the number of available memory words. The number of available words can be calculated as follows: (SETUP_MB - 6) × 4 Where SETUP_MB is the smaller of the parameter NUMBER_OF_MB and MCR[MAXMB]. The number of remaining message buffers available is: (SETUP_MB - 8) - (RFFN × 2) If the number of Legacy RX FIFO filters programmed through RFFN exceeds the SETUP_MB value (memory space available), the exceeding ones are not functional. **NOTE** • The number of the last remaining available message buffers is the smaller of (NUMBER_OF_MB - 1) and MCR[MAXMB]. • If RX Individual Mask registers are not enabled, the Legacy RX FIFO Global Mask affects all Legacy RX FIFO filters.
23-19 TASD	Transmission Arbitration Start Delay

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates by how many CAN bits the transmission arbitration process start point can be delayed from the first bit of CRC field on CAN bus. See TX arbitration start delay for details. This field can be written only in Freeze mode; the module blocks it in other modes.
18 MRP	Message Buffers Reception Priority Sets the priority for the matching process. This field can be written only in Freeze mode; the module blocks it in other modes. **NOTE** The descriptions of the field settings vary by module instance.

Instance	Field value and description
CAN_0	0b - Matching starts from Legacy RX FIFO or Enhanced RX FIFO and continues on message buffers. 1b - Matching starts from message buffers and continues on Legacy RX FIFO or Enhanced RX FIFO.
CAN_1	0b - Matching starts from Legacy RX FIFO or Enhanced RX FIFO and continues on message buffers. 1b - Matching starts from message buffers and continues on Legacy RX FIFO or Enhanced RX FIFO.
CAN_2	0b - Matching starts from Legacy RX FIFO or Enhanced RX FIFO and continues on message buffers. 1b - Matching starts from message buffers and continues on Legacy RX FIFO or Enhanced RX FIFO.
CAN_3	0b - Matching starts from RX FIFO and continues on message buffers. 1b - Matching starts from message buffers and continues on RX FIFO.
CAN_4	0b - Matching starts from RX FIFO and continues on message buffers. 1b - Matching starts from message buffers and continues on RX FIFO.
CAN_5	0b - Matching starts from RX FIFO and continues on message buffers. 1b - Matching starts from message buffers and continues on RX FIFO.

17 RRS	Remote Request Storing Determines what the module does with a remote request. The remote request frame is submitted to a matching process. If this field is 1, the frame is stored in the corresponding message buffer in the same fashion as a data frame. No automatic remote response frame is generated.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 0, an automatic remote response frame is generated if a message buffer with CODE = 1010b is found with the same ID. You can only write to this field in Freeze mode. The module blocks it in other modes. 0b - Generated 1b - Stored
16 EACEN	Entire Frame Arbitration Field Comparison Enable for RX Message Buffers Controls the comparison of IDE and RTR fields within RX message buffer filters with their corresponding bits in the incoming frame by the matching process. If enabled, the IDE and RTR fields of the RX message buffer are compared to their corresponding bits within the incoming frame (mask bits apply). If disabled, the IDE field of the RX message buffer filter is always compared and RTR is never compared despite mask bits. This field does not affect matching for Legacy RX FIFO or Enhanced RX FIFO. You can only write to this field in Freeze mode; the module blocks it in other modes. 0b - Disable 1b - Enable
15 TIMER_SRC	Timer Source Selects the time tick source used for incrementing the free-running timer counter. If CAN bit clock is selected, it defines the baud rate on the CAN bus. If External time tick is selected, the period can be adjusted to match the baud rate on the CAN bus. It can also be adjusted to a different value as required. See the chip-specific section for details about the external time tick. You can only write to this field in Freeze mode. 0b - CAN bit clock 1b - External time tick
14 PREXCEN	Protocol Exception Enable Enables the protocol exception feature. You can only write to this field in Freeze mode. **NOTE** See Protocol exception event in the CAN Protocol standard (ISO 11898-1:2015) for details. 0b - Disabled 1b - Enabled
13 BTE	Bit Timing Expansion Enable Enables the use of Enhanced CAN Bit Timing Prescalers (EPRS), Enhanced Data Phase CAN Bit Timing (EDCBT), and Enhanced Nominal CAN Bit Timing (ENCBT) to configure the CAN bit timing segments, instead of using the bit timing fields of CAN Bit Timing (CBT), CAN FD Bit Timing (FDCBT), and Control 1 (CTRL1).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 1: • CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] are read as zero. A write operation to these fields has no effect. • CBT[EPRESDIV], CBT[ERJW], CBT[EPROPSEG], CBT[EPSEG1], and CBT[EPSEG2], and the corresponding fields in CAN FD Bit Timing (FDCBT), are read as zero. A write operation to these fields has no effect. • ETDC[ETDCOFF], ETDC[ETDCEN], ETDC[ETDCFAIL], and ETDC[ETDCVAL] are used by FlexCAN instead of FDCTRL[TDCOFF], FDCTRL[TDCEN], FDCTRL[TDCFAIL], and FDCTRL[TDCVAL]. These fields are read as zero, and a write operation to them has no effect. • ETDC[TDMDIS] can be used to disable transceiver delay measurement. 0b - Disable 1b - Enable
12 ISOCANFDEN	ISO CAN FD Enable Enables the CAN FD protocol according to ISO specification (ISO 11898-1:2015) (see CAN FD ISO compliance). When disabled, FlexCAN operates using the non-ISO CAN FD protocol. You can only write to this field in Freeze mode. **NOTE** FlexCAN is able to transmit FD frame format according to CAN Protocol standard (ISO 11898-1:2015). 0b - Disable 1b - Enable
11 EDFLTDIS	Edge Filter Disable Disables the edge filter used during the Bus Integration state. When the Edge Filter is enabled, two consecutive nominal time quanta with dominant bus states are required to detect an edge that causes synchronization. When synchronization occurs, the counting of the sequence of 11 consecutive recessive bits is restarted. The edge filter prevents dominant pulses that are shorter than a nominal bit time (present during the data phase of an FD frame) from being mistaken for an idle condition. You can only write to this field in Freeze mode. **NOTE** See Bus Integration state in the CAN Protocol standard (ISO 11898-1:2015) for details. 0b - Enabled 1b - Disabled
10 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
9-8 MBTSBASE	Message Buffer Timestamp Base Selects the timebase used for capturing the 16-bit TIME_STAMP field of the message buffer register. This field can be written in Freeze Mode only. 00b - TIMER 01b - Lower 16 bits of high-resolution timer 10b - Upper 16 bits of high-resolution timer 11b - Reserved
7-6 TSTAMPCAP	Timestamp Capture Point Configures the point in time when a 32-bit timebase is captured during a CAN frame. This base is stored in the high-resolution timestamp register (HR_TIME_STAMP). For classical CAN frames, capture points can be the start-of-frame bit or the point when CAN frame is considered valid. This point is the seventh bit of the end-of-frame for transmission and the sixth bit of the end-of-frame for reception. For CAN FD frames, the high-resolution timestamp can be captured at the start of frame, when a CAN FD frame is considered valid, or the res bit. You can only write to this field in Freeze mode. 00b - Disabled 01b - End of the CAN frame 10b - Start of the CAN frame 11b - Start of frame for classical CAN frames; res bit for CAN FD frames
5 —	Reserved
4-2 —	Reserved
1-0 —	Reserved

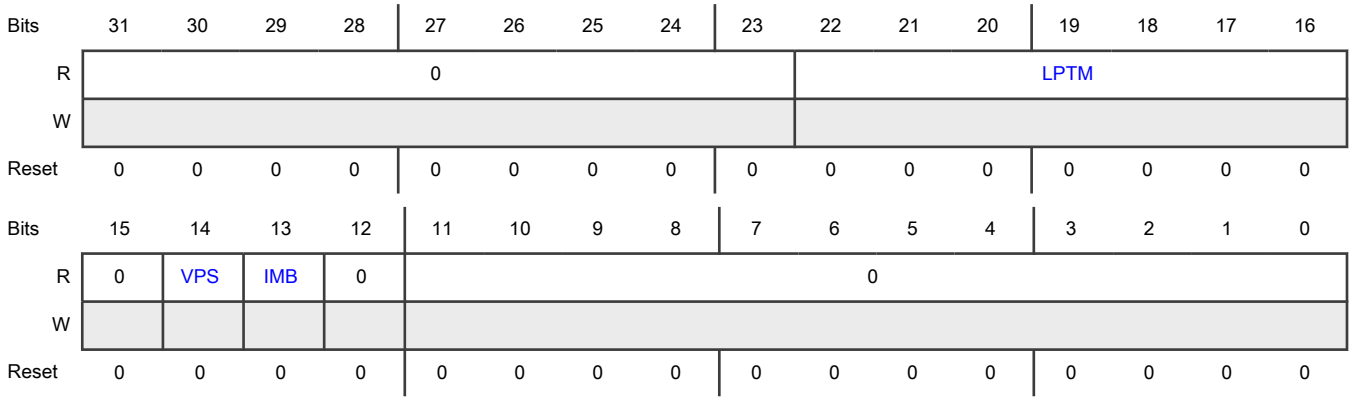
76.6.2.15 Error and Status 2 (ESR2)

Offset

Register	Offset
ESR2	38h

Function
Reports general status information.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-16 LPTM	Lowest Priority TX Message Buffer Indicates the lowest number inactive message buffer when ESR2[VPS] = 1 (see ESR2[IMB]). If no message buffer is inactive, the message buffer indicated depends on the value of CTRL1[LBUF]. If CTRL1[LBUF] = 0, the message buffer indicated is the one with the greatest arbitration value (see Highest-priority message buffer first). If CTRL1[LBUF] = 1, the message buffer indicated is the active TX message buffer with the highest number. If a TX message buffer is being transmitted, it is not considered in the LPTM calculation. If ESR2[IMB] is not 0 and a frame is transmitted successfully, the value of LPTM is updated with its message buffer number.
15 —	Reserved
14 VPS	Valid Priority Status Indicates whether the contents of ESR2[IMB] and ESR2[LPTM] are valid. It becomes 1 upon every complete TX arbitration process, unless the CPU writes to the Control and Status word of a message buffer already scanned. In other words, it is behind the TX Arbitration Pointer, during the TX arbitration process. If there is no inactive message buffer and only one TX message buffer that is being transmitted, this field remains 0. This field becomes 0 upon the start of every TX arbitration process or upon a write to the Control and Status word of any message buffer. **NOTE** No CPU write to the Control and Status of a message buffer that the abort mechanism blocks affects this field. When MCR[AEN] = 1, the abort code write to the Control and Status of an MB being transmitted (pending abort) is blocked. Any write attempt to a TX MB with its IFLAG flag set is also blocked. 0b - Invalid 1b - Valid

Table continues on the next page...

Table continued from the previous page...

Field	Function
13 IMB	Inactive Message Buffer Indicates whether any message buffer is inactive (CODE field is either 1000b or 0b) when ESR2[VPS] = 1. This field becomes 1 when: • A lowest-priority TX message buffer (ESR2[LPTM]) is found and it is inactive during arbitration. • This field is not 1, and a frame is transmitted successfully. This field always becomes 0 at the start of arbitration (see Arbitration process). If a message buffer is successfully transmitted and this field is 0 (no inactive message buffer), ESR2[VPS] and this field both become 1. The index related to the MB transmitted is loaded into ESR2[LPTM]. In this case, the value of ESR2[LPTM] is the number of the first inactive message buffer. 0b - Message buffer indicated by ESR2[LPTM] is not inactive. 1b - At least one message buffer is inactive.
12 —	Reserved
11-0 —	Reserved

76.6.2.16 Cyclic Redundancy Check (CRCR)

Offset

Register	Offset
CRCR	44h

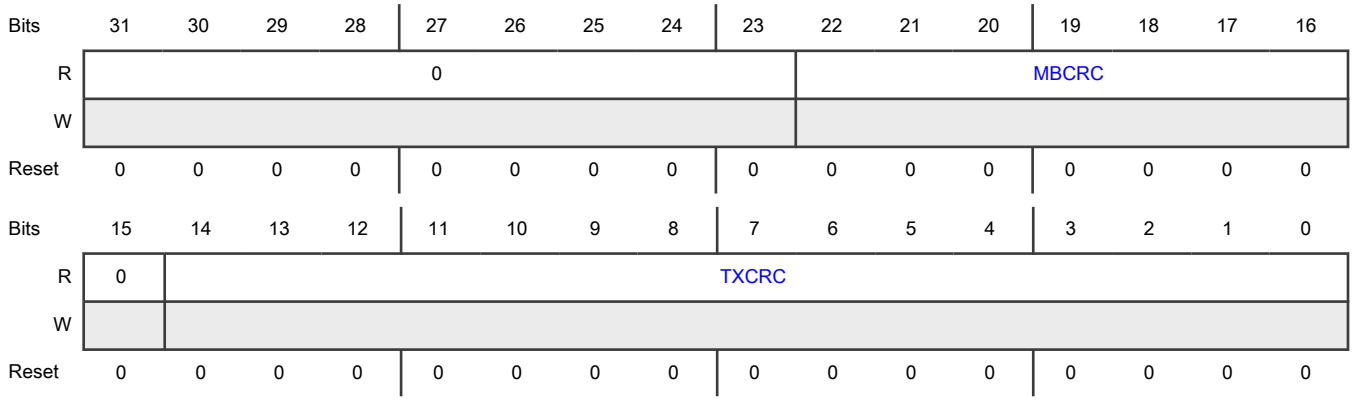
Function

Provides information about the CRC of transmitted messages for non-FD messages. This register only reports the 15 low-order bits of CRC calculations for messages in CAN FD format that require either 17 or 21 bits. For CAN FD format frames, you must use the CAN FD CRC (FDCRC). This register is updated at the same time that the TX interrupt flag is set.

NOTE

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1:2015) for details.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-16 MBCRC	CRC Message Buffer Indicates the number of the message buffer corresponding to the value in CRCR[TXCRC].
15 —	Reserved
14-0 TXCRC	Transmitted CRC value Indicates the CRC value of the last transmitted message for non-FD frames. For FD frames, CRC value is reported in CAN FD CRC (FDCRC).

76.6.2.17 Legacy RX FIFO Global Mask (RXFGMASK)

Offset

Register	Offset
RXFGMASK	48h

Function

Masks the Legacy RX FIFO ID filter table elements that do not have a corresponding RXIMR according to CTRL2[RFFN], when Legacy RX FIFO is enabled.

This register is located in RAM.

You can only write to this register in Freeze mode; the module blocks it in other modes.

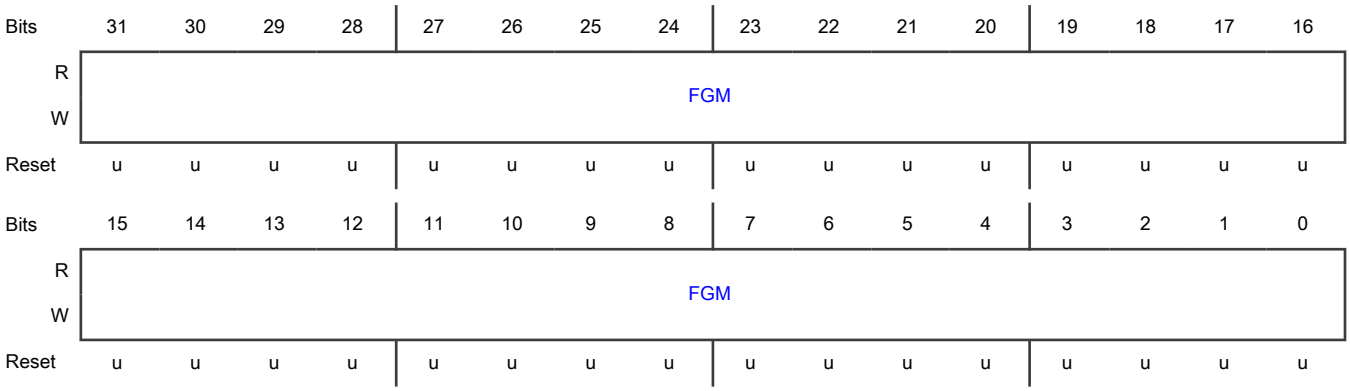
The following table shows how the FGM bits correspond to each IDAF field.

Table 571. Correspondence of Legacy RX FIFO global mask bits to IDF fields

Legacy RX FIFO ID filter table elements format (MCR[IDAM])	Identifier acceptance filter fields					
	RTR	IDE	RXIDA	RXIDB [1]	RXIDC [2]	Reserved
A	FGM[31]	FGM[30]	FGM[29:1]	—	—	FGM[0]
B	FGM[31], FGM[15]	FGM[30], FGM[14]	—	FGM[29:16], FGM[13:0]		—
C	—	—		—	FGM[31:24], FGM[23:16], FGM[15:8], FGM[7:0]	

1. If MCR[IDAM] is equivalent to format B, only the 14 most significant bits of the identifier of the incoming frame are compared with the Legacy RX FIFO filter.
2. If MCR[IDAM] is equivalent to format C, only the eight most significant bits of the identifier of the incoming frame are compared with the Legacy RX FIFO filter.

Diagram



Fields

Field	Function
31-0 FGM	Legacy RX FIFO Global Mask Bits Masks the ID filter table elements bits in a perfect alignment. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

76.6.2.18 Legacy RX FIFO Information (RXFIR)

Offset

Register	Offset
RXFIR	4Ch

Function

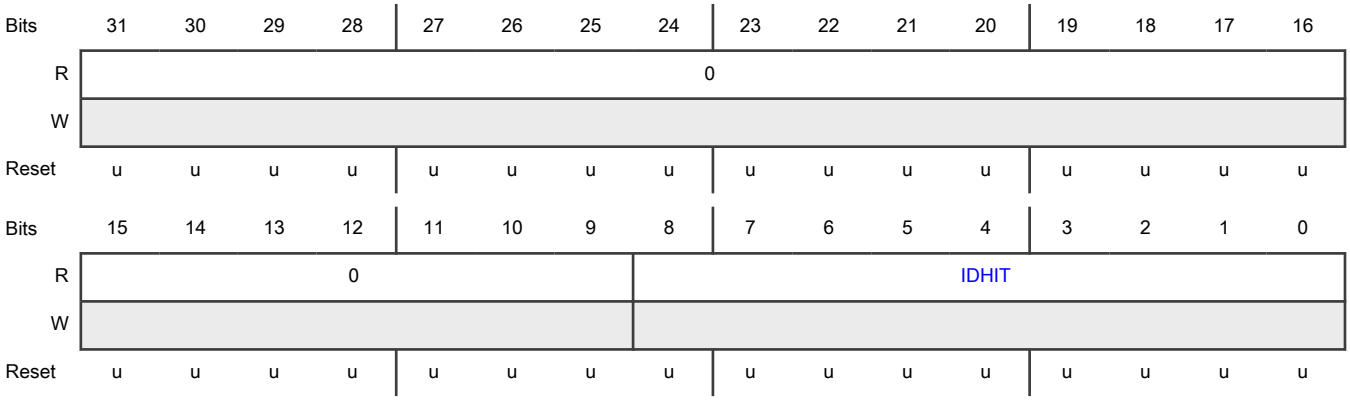
Provides information about Legacy RX FIFO.

This register is the port through which the CPU accesses the output of the Legacy RXFIR FIFO located in RAM. FlexCAN writes to the Legacy RXFIR FIFO when a new message is moved into the Legacy RX FIFO. Also, its output is updated whenever the output of the Legacy RX FIFO is updated with the next message. See Legacy RX FIFO for instructions on reading this register.

NOTE

RXFIR can be written only during memory initialization, due to the error code correction (ECC) feature. In every other case, this register is read-only.

Diagram



Fields

Field	Function
31-9 —	Reserved
8-0 IDHIT	Identifier Acceptance Filter Hit Indicator Indicates which Identifier Acceptance filter that the received message hit in the output of the Legacy RX FIFO. If multiple filters match the incoming message ID, the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only when IFLAG1[BUF5I] is set.

76.6.2.19 CAN Bit Timing (CBT)

Offset

Register	Offset
CBT	50h

Function

Provides an alternative way to store the CAN bit timing variables described in Control 1 (CTRL1). EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW are extended versions of CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] respectively.

NOTE

The CAN bit variables in CTRL1 and in CBT are stored in the same register.

CBT[BTF] selects the use of the timing variables defined in this register.

When the CAN FD feature is enabled (MCR[FDEN] = 1), always write 1 to CBT[BTF].

Soft reset does not affect the contents of this register.

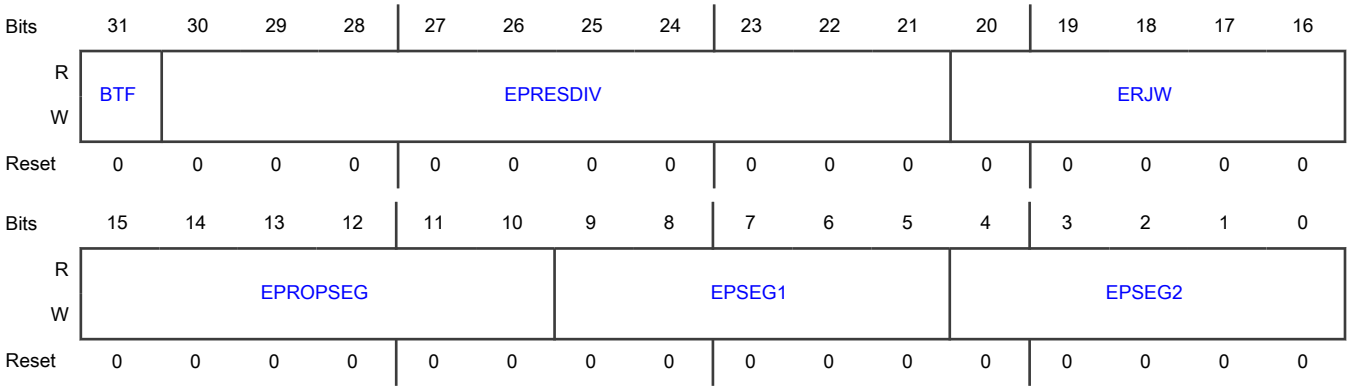
NOTE

Ensure that bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1:2015).

NOTE

If CTRL2[BTE] = 1, EPRESDIV, ERJW, EPROPSEG, EPSEG1, and EPSEG2 are read as zero. A write operation to them has no effect.

Diagram



Fields

Field	Function
31 BTF	Bit Timing Format Enable Enables the use of extended CAN bit timing fields EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW. These fields replace the CAN bit timing variables defined in Control 1 (CTRL1). This field can be written in Freeze mode only. 0b - Disable 1b - Enable
30-21 EPRESDIV	Extended Prescaler Division Factor Defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PRESDIV] value range. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). This field can be written only in Freeze mode; the module blocks it in other modes. Sclock frequency = PE clock frequency ÷ (EPRESDIV + 1)

Table continues on the next page...

Table continued from the previous page...

Field	Function
20-16 ERJW	Extended Resync Jump Width Defines the maximum number of time quanta that one resynchronization can change a bit time when CBT[BTF] = 1. Otherwise, it has no effect. It extends the CTRL1[RJW] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Resync Jump Width = ERJW + 1. One Time Quantum = one Sclock period.
15-10 EPROPSEG	Extended Propagation Segment Defines the length of the propagation segment in the bit time when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PROPSEG] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Propagation Segment Time = (EPROPSEG + 1) × Time Quanta. One Time Quantum = one Sclock period.
9-5 EPSEG1	Extended Phase Segment 1 Defines the length of phase segment 1 in the bit time when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PSEG1] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 1 = (EPSEG1 + 1) × Time Quanta. One Time Quantum = one Sclock period.
4-0 EPSEG2	Extended Phase Segment 2 Defines the length of phase segment 2 in the bit time when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PSEG2] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 1 = (EPSEG2 + 1) × Time Quanta. One Time Quantum = one Sclock period.

76.6.2.20 Interrupt Masks 3 (IMASK3)

Offset

Register	Offset
IMASK3	6Ch

Function

Enables or disables any number of the 32 message buffer interrupts for MB95–MB64. It contains one interrupt mask bit per buffer. This configuration allows the CPU to determine which buffer generates an interrupt after a successful transmission or reception when the corresponding IFLAG3 flag is set.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
CAN_0	IMASK3	—
CAN_1	IMASK3	—
CAN_2	IMASK3	—
CAN_3	—	IMASK3
CAN_4	—	IMASK3
CAN_5	—	IMASK3

Diagram

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 BUF95TO64M	Buffer MBi Mask Enables or disables the corresponding FlexCAN message buffer interrupt for MB95–MB64. When CAN FD is enabled, the MB range is defined in accordance with FDCTRL[MBDSRn]. **NOTE** If the corresponding IFLAG3 flag is set, writing 1 or 0 to a field in IMASK3 can set or clear an interrupt request. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

76.6.2.21 Interrupt Flags 3 (IFLAG3)

Offset

Register	Offset
IFLAG3	74h

Function

Defines the flags for the 32 message buffer interrupts for MB95–MB64. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG3 flag. If the corresponding IMASK3 bit is 1, an interrupt is generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating MCR[MAXMB], the CPU must service the IFLAG3 flags whose MB value is greater than the MAXMB to be updated. Otherwise, they remain set and are inconsistent with the number of message buffers available.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
CAN_0	IFLAG3	—
CAN_1	IFLAG3	—
CAN_2	IFLAG3	—
CAN_3	—	IFLAG3

Fields

Field	Function
31-0 BUF95TO64	Buffer MBi Interrupt Flags the corresponding FlexCAN message buffer interrupt for MB95–MB64.When CAN FD is enabled, the MB range is defined in accordance with FDCTRL[MBDSRn]. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.

76.6.2.22 Receive Individual Mask (RXIMR0 - RXIMR95)

Offset

For n = 0 to 95:

Register	Offset
RXIMRn	880h + (n × 4h)

Function

Stores the acceptance masks for ID filtering in RX message buffers and the Legacy RX FIFO.

When the Legacy RX FIFO is disabled (MCR[RFEN] = 0), an individual mask is provided for each available RX message buffer on a one-to-one correspondence. When the Legacy RX FIFO is enabled (MCR[RFEN] = 1), an individual mask is provided for each Legacy RX FIFO ID filter table element on a one-to-one correspondence. This correspondence depends on the setting of CTRL2[RFFN] (see Legacy RX FIFO).

RXIMR0 stores the individual mask associated with either MB0 or ID filter table element 0. RXIMR1 stores the individual mask associated with either MB1 or ID filter table element 1, and so on.

The CPU can only access the RXIMR registers when the module is in Freeze mode; otherwise, the module blocks them. Reset does not affect these registers. They are located in RAM and must be explicitly initialized prior to any reception.

It is possible for the RXIMR memory region to be accessed as general-purpose memory. See Bus interface for more information.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
CAN_0	RXIMR0–RXIMR95	—
CAN_1	RXIMR0–RXIMR95	—
CAN_2	RXIMR0–RXIMR95	—

Register reset values

Register	Reset value
RXIMR0–RXIMR63	CAN_0–CAN_5: undefined
RXIMR64–RXIMR95	CAN_0–CAN_2: undefined CAN_3–CAN_5: Register not supported

Fields

Field	Function
31-0 MI	Individual Mask Bits Masks the corresponding bit in both the message buffer filter and Legacy RX FIFO ID filter table element in distinct ways. For message buffer filters, see RX Message Buffers Global Mask (RXMGMASK). For Legacy RX FIFO ID filter table elements, see Legacy RX FIFO Global Mask (RXFGMASK). 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

76.6.2.23 Memory Error Control (MECR)

Offset

Register	Offset
MECR	AE0h

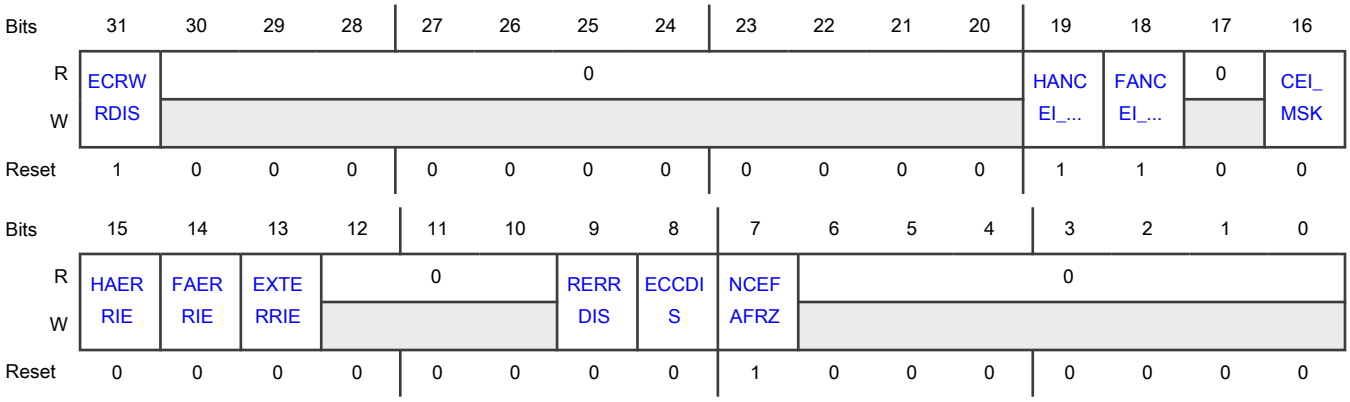
Function

Contains control bits for memory error detection and correction (ECC).

NOTE

When CTRL2[ECRWRE] = 0, writes to this register are blocked, except for MECR[ECRWRDIS].

Diagram



Fields

Field	Function
31 ECRWRDIS	Error Configuration Register Write Disable Disables writes on this register. This field automatically becomes 1 (disabled) when CTRL2[ECRWRE] is 1. The protocol described in Detection and correction of memory errors must be followed. 0b - Enable 1b - Disable
30-20 —	Reserved
19 HANCEI_MSK	Host Access with Noncorrectable Errors Interrupt Mask Enables the interrupt for noncorrectable errors detected in memory reads issued by the host (CPU). 0b - Disable 1b - Enable
18 FANCEI_MSK	FlexCAN Access with Noncorrectable Errors Interrupt Mask Enables the interrupt for noncorrectable errors detected in memory reads issued by FlexCAN internal processes. 0b - Disable 1b - Enable
17	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
16 CEI_MSK	Correctable Errors Interrupt Mask Enables the interrupt for correctable errors detected in memory reads issued by the host or FlexCAN internal processes. 0b - Disable 1b - Enable
15 HAERRIE	Host Access Error Injection Enable Enables the injection of errors only in memory reads issued by the host (CPU). 0b - Disable 1b - Enable
14 FAERRIE	FlexCAN Access Error Injection Enable Enables the injection of errors only in memory reads issued by FlexCAN internal processes. 0b - Disable 1b - Enable
13 EXTERRIE	Extended Error Injection Enable Extends the error injection on 32-bit memory accesses to the complementary 32-bit word. This feature uses the same 32-bit error injection data and parity words used for 64-bit memory accesses performed by internal FlexCAN processes. See Error Injection Data Pattern (ERRIDPR) and Error Injection Parity Pattern (ERRIPPR). 0b - Disable. Apply error injection only to the 32-bit word. 1b - Enable. Apply error injection to the 64-bit word.
12-10 —	Reserved
9 RERRDIS	Error Report Disable Disables the update of the error report registers. The update of error-related flags and the generation of bus transfer errors are still active. **NOTE** When reading the report registers, this field must be 1 to ensure coherence on the consecutive register reads. 0b - Enable 1b - Disable
8 ECCDIS	Error Correction Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Completely disables the memory detection and correction mechanism. Besides disabling the error report mechanism, it also stops the update of the error-related flags and the generation of bus transfer errors. The parity bits continue to be calculated and written into memory on write transactions. 0b - Enable 1b - Disable
7 NCEFAFRZ	Noncorrectable Errors in FlexCAN Access Put Chip in Freeze Mode Determines whether to put FlexCAN into Freeze mode when a noncorrectable error is detected in a memory read performed by FlexCAN internal processes. In this case, entering Freeze mode prevents FlexCAN internal processes from treating corrupted data as valid. See Freeze mode for more information. 0b - Normal operation 1b - Freeze mode
6-0 —	Reserved

76.6.2.24 Error Injection Address (ERRIAR)

Offset

Register	Offset
ERRIAR	AE4h

Function

Contains the address where error is to be injected.

Use the following table to convert from the memory map address to the location in the physical FlexCAN RAM. Where pairs of values are provided, the first is the address for MCR[FDEN] = 0, the second is for MCR[FDEN] = 1.

Table 572. Error injection address for classical CAN format

RAM contents	Injection address	Memory map
FlexCAN registers	Not mapped	—
Message buffers	0000h	0080h
RXIMRs	600h	0880h
RXFIR_0	780h	0A80h
RXFIR_1	784h	0A84h
RXFIR_2	788h	0A88h
RXFIR_3	78Ch	0A8Ch

Table continues on the next page...

Table 572. Error injection address for classical CAN format (continued)

RAM contents	Injection address	Memory map
RXFIR_4	790h	0A90h
RXFIR_5	794h	0A94h
Reserved	—	0A98h
RXMGMASK	7A0h	0AA0h
RXFGMASK	7A4h	0AA4h
RX14MASK	7A8h	0AA8h
RX15MASK	7ACh	0AACh
Tx_SMB	7B0h	0AB0h / 0F28h
Rx_SMB0	7C0h / 7F8h	0AC0h / 0F70h
Rx_SMB1	7D0h / 840h	0AD0h / 0FB8h
Rx_SMB0_TIME_STAMP	888h	0C20h
Rx_SMB1_TIME_STAMP	88Ch	0C24h
HR_TIME_STAMP	890h	0C30h
Enhanced RX FIFO	A10h	2000h
ERFFEL	1050h	3000h

NOTE

For RXFIR, Enhanced RX FIFO, and HR_TIME_STAMP addresses, you must inject ECC errors in host access only.

Field	Function
7-5 —	Reserved
4-0 PFLIP0	Parity Flip Pattern for Byte 0 (Least Significant) Contains the error injection pattern for Byte 0.

76.6.2.27 Error Report Address (RERRAR)

Offset

Register	Offset
RERRAR	AF0h

Function

Reports the address used for an access operation in which an error (correctable or noncorrectable) was detected. Also reports the identification of the source of that access.

This address is always reported using a 32-bit alignment. Non-aligned accesses (ERRADDR[1:0] nonzero) are reported with the address aligned, and data is reported in Error Report Data (RERRDR) shifted accordingly. When errors are detected in accesses larger than 32-bit (as performed by FlexCAN internal processes), the address of the 32-bit word where the error was detected is reported. For errors detected in more than one 32-bit word, only the least significant address is reported.

Table 573. Source of memory access

SAID[2:0]	Error during...
0	Move-out FlexCAN access
1	Move-in
2	TX arbitration
3	RX matching
4	Move-out host access

15-14 —	Reserved
13-0	Address Where Error Detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
ERRADDR	See description of Error Injection Address (ERRIAR).

76.6.2.28 Error Report Data (RERRDR)

Offset

Register	Offset
RERRDR	AF4h

Function

Reports the raw data (unmodified by the correction performed by ECC logic) read from memory with error. The value reported does not represent the transient values of the BUSY bit (see Table 579) when reading a message buffer.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 RDATA	Raw Data Word Read from Memory with Error

76.6.2.29 Error Report Syndrome (RERRSYNR)

Offset

Register	Offset
RERRSYNR	AF8h

Function

Contains the syndrome detected in a memory read with error. It also reports the bytes which were read in this 32-bit read transaction.

Each SYND*n* field indicates the type of error and which bit in byte (*n*) the error affects. SYND3 corresponds to the most significant byte in the data word read from memory; SYND0 corresponds to the least significant.

Table 574. Syndrome definition

SYND*n* (hex)	Type	Bit affected
00	—	None (no error)
01	Code	0
02	Code	1
04	Code	2
07	Data	5
08	Code	3
0E	Data	7
10	Code	4
13	Data	2
15	Data	6
16	Data	1
19	Data	3
1A	Data	4
1C	Data	0
06	—	All-zeroes noncorrectable error
1F	—	All-ones noncorrectable error
All others	—	Noncorrectable error

Each BEn field indicates which byte in the 32-bit word reported was effectively read. The syndrome bits are calculated for all bytes, including the non-read ones. Errors detected in non-read bytes are indicated (see Error indication) and reported (see Error reporting).

15-4 —	Reserved
3 HANCEIOF	Host Access With Noncorrectable Error Interrupt Overrun Flag Indicates that a noncorrectable error was detected in a memory read initiated by host when ERRSR[HANCEIF] was set. No interrupt is associated with this flag. See Error indication. 0b - No errors detected 1b - Error detected
2 FANCEIOF	FlexCAN Access with Noncorrectable Error Interrupt Overrun Flag Indicates that a noncorrectable error was detected in a memory read initiated by FlexCAN internal processes when ERRSR[FANCEIF] was set. No interrupt is associated with this flag. See Error indication. 0b - No errors detected 1b - Error detected
1 —	Reserved
0 CEIOF	Correctable Error Interrupt Overrun Flag Indicates that a correctable error was detected in a memory read when ERRSR[CEIF] was set. No interrupt is associated with this flag. See Error indication. 0b - No errors detected 1b - Error detected

76.6.2.31 Enhanced CAN Bit Timing Prescalers (EPRS)

Offset

Register	Offset
EPRS	BF0h

Function

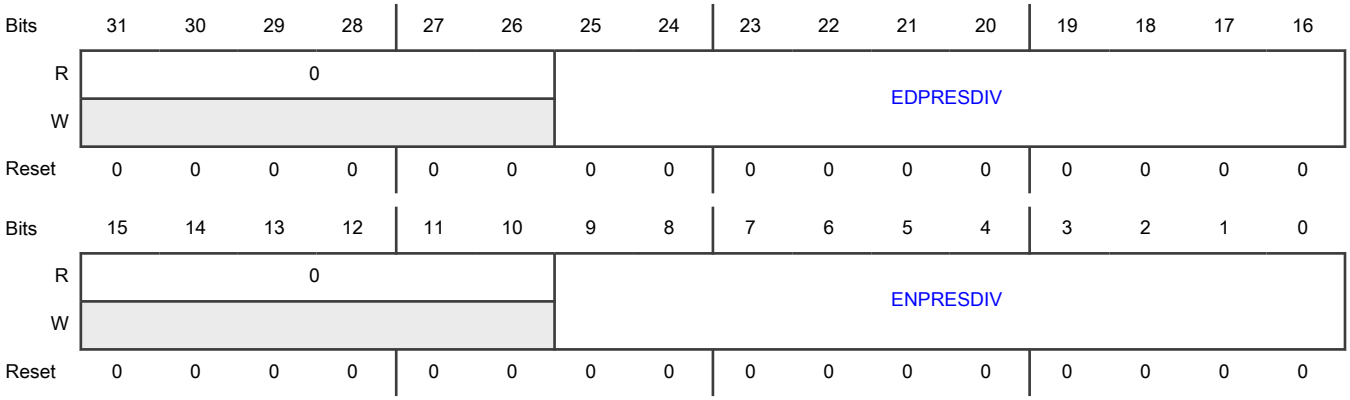
Defines the CAN bit timing prescalers for the nominal phase and data phase when CTRL2[BTE] = 1.

Used by the module only if CTRL2[BTE] = 1; otherwise a write operation has no effect and all fields are read as zero.

This register can be written only in Freeze mode; the module blocks it in other modes.

Soft reset does not affect the contents of this register.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-16 EDPRESDIV	Extended Data Phase Prescaler Division Factor Defines the ratio between the PE clock frequency and the Sclock frequency in the data phase of a CAN FD message when CTRL2[BTE] = 1. The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. Sclock frequency = PE clock frequency ÷ (EDPRESDIV + 1) **NOTE** To minimize errors when processing FD frames, use the same value for this field and for EPRS[ENPRESDIV]. See the first note in CAN FD frames for details.
15-10 —	Reserved
9-0 ENPRESDIV	Extended Nominal Prescaler Division Factor Defines the ratio between the PE clock frequency and the Sclock frequency when CTRL2[BTE] = 1. Otherwise, it reads as 0 and a write operation has no effect. The Sclock period defines the time quantum of the CAN protocol in the nominal phase. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). Sclock frequency = PE clock frequency ÷ (ENPRESDIV + 1)

76.6.2.32 Enhanced Nominal CAN Bit Timing (ENCBT)

Offset

Register	Offset
ENCBT	BF4h

Function

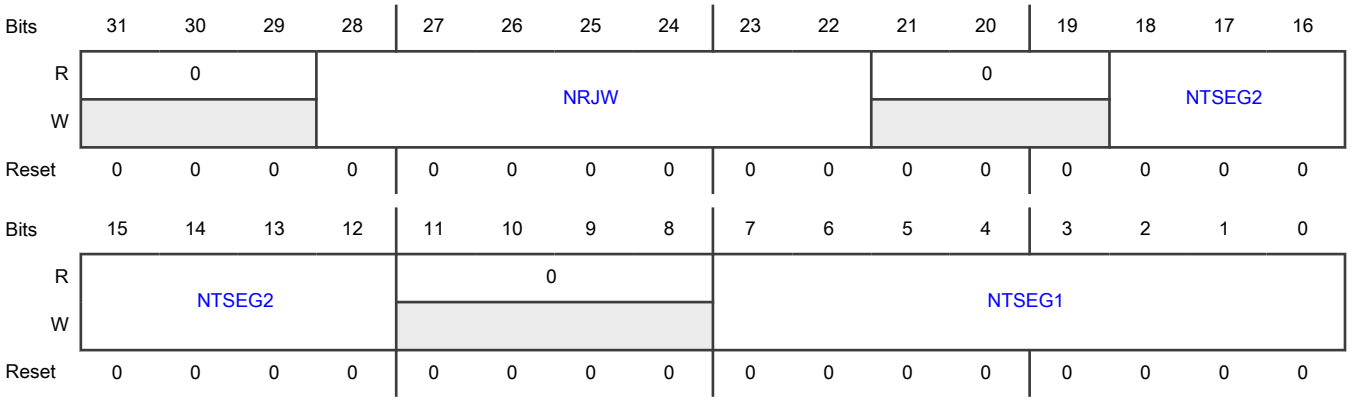
Provides an alternative way to store the CAN bit timing variables described in Control 1 (CTRL1) and CAN Bit Timing (CBT), to get higher CAN bit timing resolution.

This register is used by the module only if CTRL2[BTE] = 1. Otherwise, a write operation has no effect and all fields are read as zero.

Soft reset does not affect the contents of this register.

This register can be written only in Freeze mode; the module blocks it in other modes.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-22 NRJW	Nominal Resynchronization Jump Width Defines the maximum number of time quanta that one resynchronization can change a nominal bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. One time quantum = one Sclock period Nominal Resync Jump Width = NRJW + 1
21-19 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
18-12 NTSEG2	Nominal Time Segment 2 Defines the length of Time Segment 2 in the nominal bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Nominal Time Segment 2 = (NTSEG2 + 1) × Time Quanta One time quantum = one Sclock period
11-8 —	Reserved
7-0 NTSEG1	Nominal Time Segment 1 Defines the length of Time Segment 1 in the bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Nominal Time Segment 1 = (NTSEG1 + 1) × Time Quanta One time quantum = one Sclock period

76.6.2.33 Enhanced Data Phase CAN Bit Timing (EDCBT)

Offset

Register	Offset
EDCBT	BF8h

Function

Provides an alternative way to store the data phase CAN bit timing variables described in CAN FD Bit Timing (FDCBT) to achieve higher CAN bit timing resolution.

This register is used by the module only if CTRL2[BTE] = 1; otherwise a write operation has no effect and all fields are read as zero.

Soft reset does not affect the contents of this register.

This register can be written only in Freeze mode; the module blocks it in other modes.

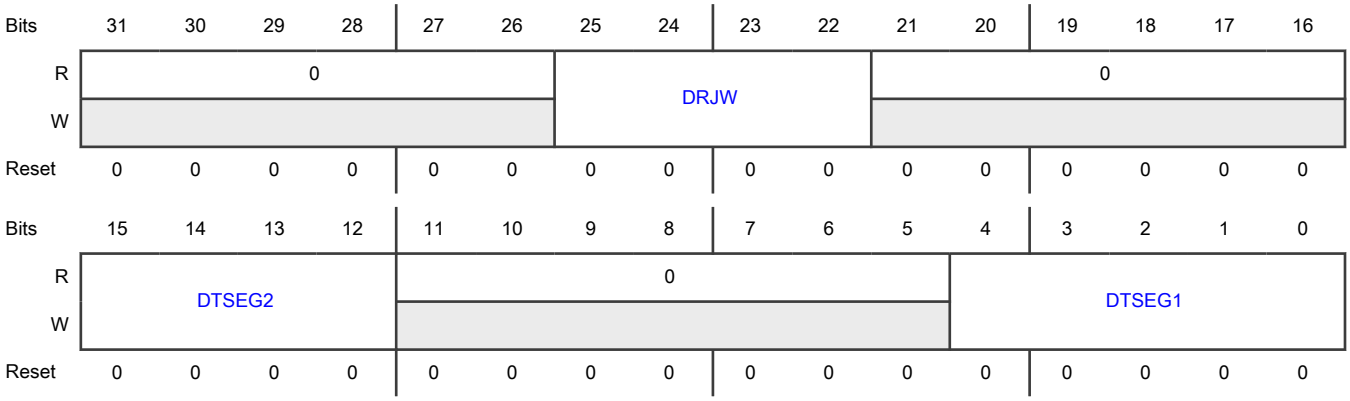
NOTE

Ensure that bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1:2015).

NOTE

DTSEG1 must be at least two time quanta.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-22 DRJW	Data Phase Resynchronization Jump Width Defines the maximum number of time quanta that one resynchronization can change a data phase bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Data Phase Resync Jump Width = DRJW + 1.
21-16 —	Reserved
15-12 DTSEG2	Data Phase Time Segment 2 Defines the length of time segment 2 in the data phase bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Data Phase Time Segment 2 = (DTSEG2 + 1) × Time Quanta. One Time Quantum = one Sclock period.
11-5 —	Reserved
4-0 DTSEG1	Data Phase Segment 1 Defines the length of time segment 1 in the data phase bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Data Phase Time Segment 1 = (NTSEG1 + 1) × Time Quanta. One Time Quantum = one Sclock period.

76.6.2.34 Enhanced Transceiver Delay Compensation (ETDC)

Offset

Register	Offset
ETDC	BFCh

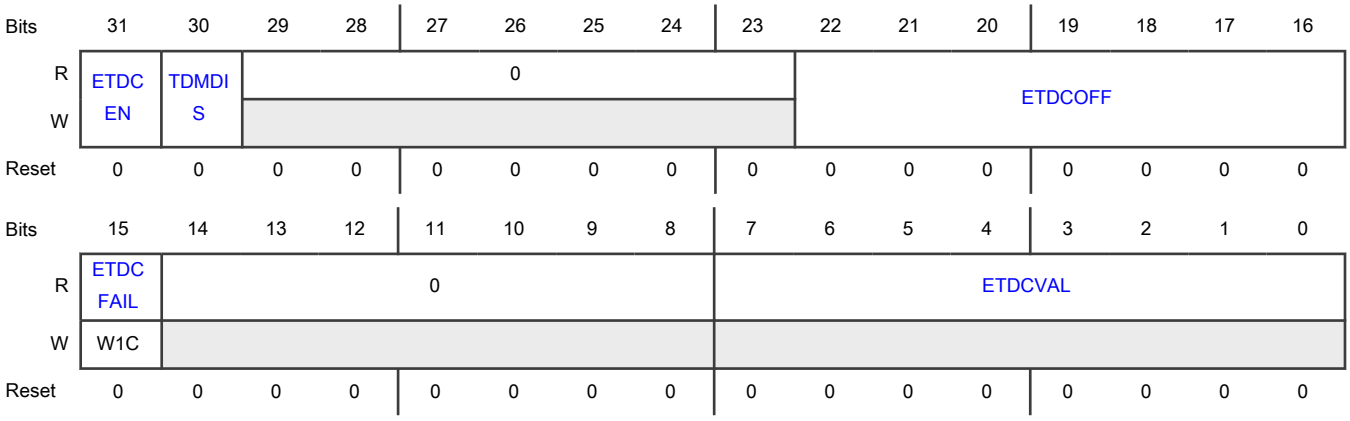
Function

Contains extended versions of FDCTRL[TDCOFF] and FDCTRL[TDCVAL]. This register is used by the module only if CTRL2[BTE] = 1. Otherwise, a write operation has no effect and all fields are read as zero.

NOTE

See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1:2015) for details.

Diagram



Fields

Field	Function
31 ETDCEN	Transceiver Delay Compensation Enable Enables the TDC feature. It can be written in Freeze mode only. **NOTE** See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1:2015) for details. **NOTE** TDC must be disabled when the Loop Back Mode is enabled. See CTRL1[LPB]. 0b - Disable 1b - Enable
30 TDMDIS	Transceiver Delay Measurement Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Disables the transceiver delay measurement. When the TDC measurement is disabled, only ETDC[ETDCOFF] determines the secondary sample point position. If TCD measurement is enabled, the sum of the transceiver delay measurement plus the enhanced TDC offset determines the secondary sample point position. Soft reset does not affect this field. **NOTE** This bit can be enabled only if CTRL2[BTE] = 1. 0b - Enable 1b - Disable
29-23 —	Reserved
22-16 ETDCOFF	Enhanced Transceiver Delay Compensation Offset Contains the offset value to be added to the loop delay of the measured transceiver. This value defines the position of the delayed comparison point when bit rate switching is active. See Transceiver delay compensation for details on how the loop delay measurement is performed. This field can be written in Freeze mode only. Its value can be defined in protocol engine (PE) clock periods (CANCLK, see Protocol timing for more details). It must be smaller than the CAN bit duration in the data bit rate for proper operation. Do not write 0 to this field. **NOTE** If CTRL2[BTE] becomes 1 after a chip-level hard reset, this field is read as 1h.
15 ETDCFAIL	Transceiver Delay Compensation Fail Indicates whether the transceiver delay compensation (TDC) mechanism is out of range. In this case, it is unable to compensate the loop delay of the transceiver and successfully compare the delayed received bits to the transmitted ones. (See Transceiver delay compensation.) This field becomes 0 the first time FlexCAN detects the out of range condition. 0b - In range 1b - Out of range
14-8 —	Reserved
7-0 ETDCVAL	Enhanced Transceiver Delay Compensation Value Contains ETDC[ETDCOFF] added to the measured value of the transceiver loop delay in the latest transmitted CAN FD frame, with BRS = 1. The module only updates this field when ETDC[ETDCEN] = 1. Soft reset affects this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE If ETDC[TDMDIS] = 1, this field stores ETDC[ETDCOFF] only.

76.6.2.35 CAN FD Control (FDCTRL)

Offset

Register	Offset
FDCTRL	C00h

Function

Contains control bits for CAN FD operation. It also defines the data size of message buffers allocated in different partitions of RAM (memory blocks) as described in Table 575.

When an 8-byte payload is selected:

- Block R0 allocates MB0–MB31.
- Block R1 allocates MB32–MB63.
- Block R2 allocates MB64–MB95.

When a payload larger than eight bytes is selected, the maximum number of message buffers in a block is limited as described below.

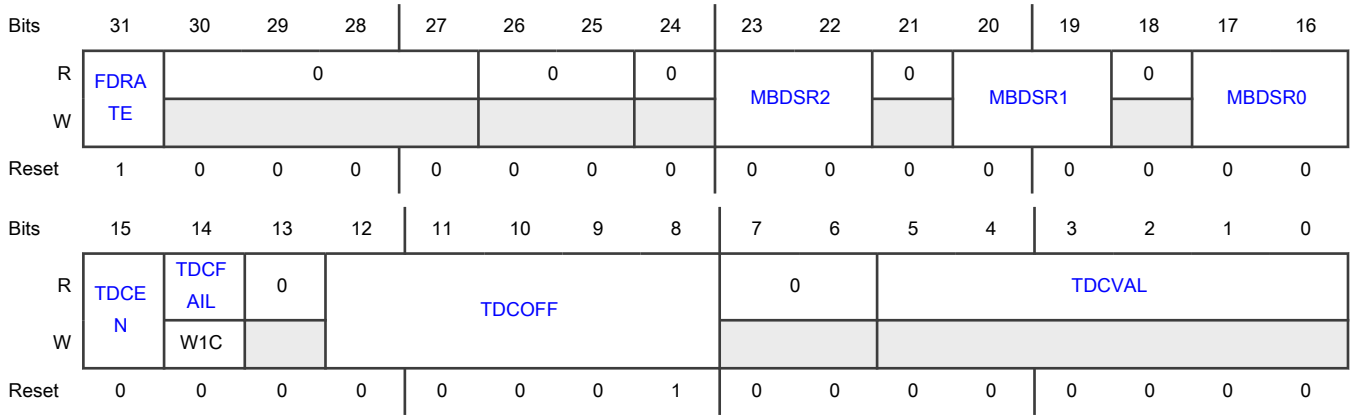
Table 575. Number of message buffers

Payload size	Maximum number of message buffers per RAM block
8 bytes	32
16 bytes	21
32 bytes	12
64 bytes	7

One memory block fits exactly 32 message buffers with an 8-byte payload. For other possible payload sizes, empty memory may exist between the last message buffer in a block and the beginning of the next block. This empty memory corresponds to less than one message buffer, and must not be used.

Soft reset does not affect the contents of this register.

Diagram



Fields

Field	Function
31 FDRATE	Bit Rate Switch Enable Enables the effect of the Bit Rate Switch (BRS bit) during the data phase of TX messages. When 1, if BRS = 1 in the TX message buffer, frames are transmitted with bit rate switching. When 0, frames are transmitted at a nominal rate, and the BRS bit in the TX MB has no effect. The CPU can write to this field at any time. However, its effect becomes active only under one of these conditions: • The CAN bus is in the Wait for Bus Idle state. • The CAN bus is in the Bus Idle state. • The CAN bus is in the Bus Off state. • The current frame under reception or transmission reaches the interframe space. By writing 0 to FDCTRL[FDRATE], the CPU can force all bits in CAN FD messages to be transmitted at nominal bit rate. This transmission occurs regardless of the value in the BRS bit of the TX message buffers. 0b - Disable 1b - Enable
30-27 —	Reserved
26-25 —	Reserved
24 —	Reserved
23-22 MBDSR2	Message Buffer Data Size for Region 2 Selects the data size per message buffer for region R2 of message buffers allocated in RAM. This field can be written in Freeze mode only.

Table continued from the previous page...

15 TDCEN	Transceiver Delay Compensation Enable Enables the TDC feature. It can be written in Freeze mode only. See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1:2015) for details. TDC must be disabled when Loopback mode is enabled (see CTRL1[LPB]). **NOTE** If CTRL2[BTE] = 1, this field is read as 0 and a write operation has no effect. 0b - Disable 1b - Enable
14 TDCFAIL	Transceiver Delay Compensation Fail Indicates whether the Transceiver Delay Compensation (TDC) mechanism is out of range. In this case, the mechanism cannot compensate for the loop delay of the transceiver and successfully compare the delayed received bits to the transmitted ones (see Transceiver delay compensation). The first time that FlexCAN detects the out-of-range condition, this field becomes 1. **NOTE** If CTRL2[BTE] = 1, this field is read as 0 and a write operation has no effect. 0b - In range 1b - Out of range
13 —	Reserved
12-8 TDCOFF	Transceiver Delay Compensation Offset Contains the offset value to be added to the loop delay of the measured transceiver. This value defines the position of the delayed comparison point when bit rate switching is active. See Transceiver delay compensation for details about loop delay measurement. This field can be written in Freeze mode only. Its value can be defined in Protocol Engine Clock periods (CANCLK, see Protocol timing for more details). The value must be smaller than the CAN bit duration in the data bit rate for proper operation. **NOTE** If CTRL2[BTE] = 1, TDCOFF is read as 0 and a write operation has no effect. Do not write 0 to this field.
7-6	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
5-0 TDCVAL	Transceiver Delay Compensation Value Contains the value of the transceiver loop delay measured from the transmitted EDL-to-R0 transition edge to the respective received one added to FDCTRL[TDCOFF]. This value is an integer multiple of the Protocol Engine Clock period (CANCLK). If CTRL2[BTE] = 1, this field is read as 0. See Protocol timing for details on the loop delay measurement.

76.6.2.36 CAN FD Bit Timing (FDCBT)

Offset

Register	Offset
FDCBT	C04h

Function

Stores the CAN bit timing variables used in the data phase of CAN FD messages when the FDCTRL[FDRATE] = 1, compatible with the CAN FD specification. Fields in this register define:

- The time quantum duration
- The number of time quanta per CAN bit
- The sample point position for the data bit rate portion of a CAN FD message with BRS = 1

Soft reset does not affect the contents of this register.

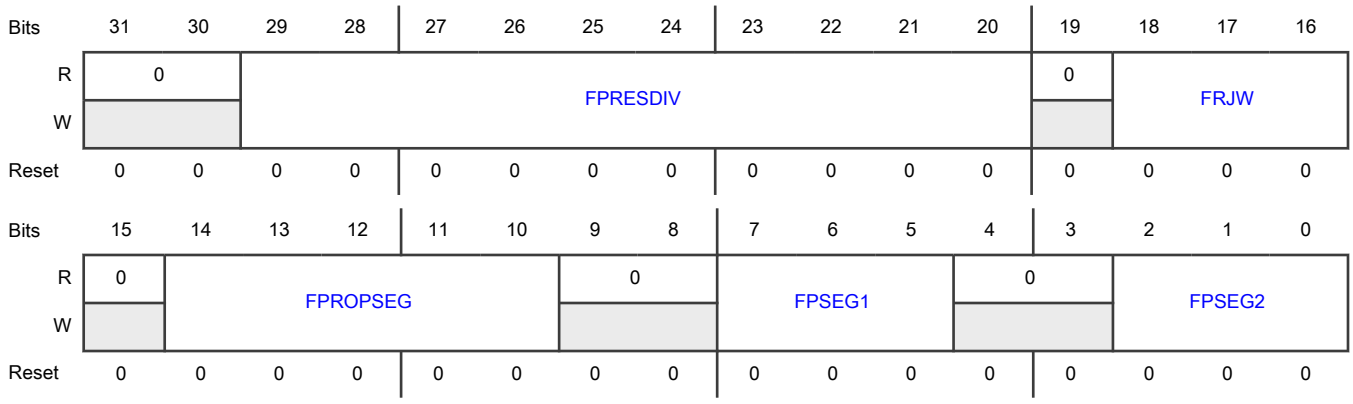
The sum of the Fast Propagation Segment (FPROPSEG) and Fast Phase Segment 1 (FPSEG1) must be at least two time quanta.

Ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1:2015).

NOTE

If CTRL2[BTE] = 1, this register is read as zero and a write operation has no effect.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-20 FPRESDIV	Fast Prescaler Division Factor Defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency in the data bit rate portion of a CAN FD message with BRS = 1. The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. This field can be written only in Freeze mode; the module blocks it in other modes. Sclock frequency = PE clock frequency ÷ (FPRESDIV + 1). **NOTE** To minimize errors when processing FD frames, use the same value for this field and for CTRL1[PRESDIV] or CBT[EPRESDIV]. See the first note in CAN FD frames for details.
19 —	Reserved
18-16 FRJW	Fast Resync Jump Width Defines the maximum number of time quanta that one resynchronization can change a bit time in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Resync Jump Width = FSJW + 1. One Time Quantum = one Sclock period.
15 —	Reserved
14-10 FPROPSEG	Fast Propagation Segment Defines the length of the propagation segment in the bit time in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Propagation Segment Time = FPROPSEG × Time Quanta. One Time Quantum = one Sclock period.
9-8 —	Reserved
7-5 FPSEG1	Fast Phase Segment 1 Defines the length of phase segment 1 in the bit time in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Segment 1 = (FPSEG1 + 1) × Time Quanta. One Time Quantum = one Sclock period.

Table continues on the next page...

Table continued from the previous page...

Field	Function
4-3 —	Reserved
2-0 FPSEG2	Fast Phase Segment 2 Defines the length of phase segment 2 in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Segment 2 = (FPSEG2 + 1) × Time Quanta. One Time Quantum = one Sclock period.

76.6.2.37 CAN FD CRC (FDCRC)

Offset

Register	Offset
FDCRC	C08h

Function

Provides information about the cyclic redundancy check (CRC) of transmitted messages.

FlexCAN uses different CRC polynomials for different frame formats.

- The CRC_15 polynomial is used for all frames in CAN format.
- The CRC_17 polynomial is used for frames in CAN FD format with a DATA FIELD up to 16 bytes.
- The CRC_21 polynomial is used for frames in CAN FD format with a DATA FIELD longer than 16 bytes.

Each polynomial shown below results in a Hamming distance of 6. This register is updated at the same time that the TX Interrupt flag is set.

$$\text{CRC_15} = \text{C599h}: \ (x^{15} + x^{14} + x^{10} + x^{8} + x^{7} + x^{4} + x^{3} + 1)$$

$$\text{CRC_17} = \text{3685Bh}: \ (x^{17} + x^{16} + x^{14} + x^{13} + x^{11} + x^{6} + x^{4} + x^{3} + x^{1} + 1)$$

$$\text{CRC_21} = \text{302899h}: \ (x^{21} + x^{20} + x^{13} + x^{11} + x^{7} + x^{4} + x^{3} + 1)$$

Equation 32. CRC polynomial used on CAN frame

NOTE

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1:2015) for details.

Fields

Field	Function
31 —	Reserved
30-24 FD_MBCRC	CRC Message Buffer Number for FD_TXCRC Indicates the number of the message buffer corresponding to the value in FDCRC[FD_TXCRC], for both FD and non-FD frames. It reports the same information as in CRCR[MBCRC].
23-21 —	Reserved
20-0 FD_TXCRC	Extended Transmitted CRC value Contains the CRC value calculated over the most recent transmitted message. Different CRC polynomials are used for different frame formats. For CRC_15 and CRC_17, the six most significant bits and the four most significant bits are reported as zeroes, respectively. For CRC_15, this field has the same content as Cyclic Redundancy Check (CRCR).

76.6.2.38 Enhanced RX FIFO Control (ERFCR)

Offset

Register	Offset
ERFCR	C0Ch

Function

Defines the Enhanced RX FIFO configuration.

This register can be written only in Freeze mode.

Soft reset does not affect any of the contents of this register.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
CAN_0	ERFCR	—
CAN_1	ERFCR	—

Fields

Field	Function
31 ERFUFW	Enhanced RX FIFO Underflow Flag Indicates whether an underflow condition occurred in the enhanced RX FIFO. If ERFIER[ERFUFWIE] = 1, this field generates an interrupt. 0b - No such occurrence 1b - Underflow
30 ERFOVF	Enhanced RX FIFO Overflow Flag Indicates whether an overflow condition occurred in the Enhanced RX FIFO. If ERFIER[ERFOVFIE] = 1, this field generates an interrupt.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No such occurrence 1b - Overflow
29 ERFWMI	Enhanced RX FIFO Watermark Indication Flag Indicates whether the number of messages available in the Enhanced RX FIFO is greater than the watermark defined in ERFCR[ERFWM]. If ERFIER[ERFWMIIE] = 1, this field generates an interrupt. 0b - No such occurrence 1b - Number of messages in FIFO is greater than the watermark
28 ERFDA	Enhanced RX FIFO Data Available Flag Indicates whether there is at least one message stored in the ERX FIFO. If ERFIER[ERFDAIE] = 1, this field generates an interrupt. 0b - No such occurrence 1b - At least one message stored in Enhanced RX FIFO
27 ERFCLR	Enhanced RX FIFO Clear Writing one to this field during Freeze mode clears Enhanced RX FIFO content. Writing to this field outside Freeze mode, or writing 0 to this field, has no effect. 0b - No effect 1b - Clear enhanced RX FIFO content
26-18 —	Reserved
17 ERFE	Enhanced RX FIFO Empty Flag Indicates whether Enhanced RX FIFO is empty. 0b - Not empty 1b - Empty
16 ERFF	Enhanced RX FIFO Full Flag Indicates whether enhanced RX FIFO is full. 0b - Not full 1b - Full
15 —	Reserved
14-6	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
5-0 ERFEL	Enhanced RX FIFO Elements Indicates the number of CAN messages stored in the Enhanced RX FIFO.

76.6.2.41 High-Resolution Timestamp (HR_TIME_STAMP0 - HR_TIME_STAMP95)

Offset

For n = 0 to 95:

Register	Offset
HR_TIME_STAMPn	C30h + (n × 4h)

Function

Stores a copy of a 32-bit timer at the start or end of a CAN frame.

HR_TIME_STAMP0 stores the 32-bit timestamp associated with MB0, HR_TIME_STAMP1 stores the 32-bit timestamp associated with MB1, and so on.

Reset does not affect these registers.

NOTE

Do not write to these registers outside Freeze mode.

Table 576. High-Resolution Timestamp register operation

TSTAMPCAP	Captured timebase	Capture point
b00	None	None
b01	32 bits of high-resolution on-chip timer	Seventh bit of the end-of-frame field for transmission and sixth bit of the end-of-frame field for reception.
b10	32 bits of high-resolution on-chip timer	Start of frame
b11	32 bits of high-resolution on-chip timer	Start of frame for classical CAN frame format and res bit for CAN FD frame format

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
CAN_0	HR_TIME_STAMP0–HR_TIME_STAMP95	—

HR_TIME_STAMP64–HR_TIME_STAMP95	CAN_0–CAN_2: undefined CAN_3–CAN_5: Register not supported

Fields

Field	Function
31-0 TS	High-Resolution Timestamp Captures the copy of the timestamp of corresponding message buffer. This field always captures a 32-bit timer value.

76.6.2.42 Enhanced RX FIFO Filter Element (ERFFEL0 - ERFFEL127)

Offset

For n = 0 to 127:

Register	Offset
ERFFELn	3000h + (n × 4h)

Function

Stores the filter elements of the Enhanced RX FIFO.

For standard ID filtering, each ERFFEL register stores one filter element. For extended ID filtering, each pair of ERFFEL registers stores one filter element.

ERFFEL registers can be written only in Freeze mode; otherwise, the module blocks them. Reset does not affect these registers. They are located in RAM and must be explicitly initialized prior to any reception.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
CAN_0	ERFFEL0–ERFFEL127	—
CAN_1	ERFFEL0–ERFFEL127	—
CAN_2	ERFFEL0–ERFFEL127	—
CAN_3	—	ERFFEL0–ERFFEL127

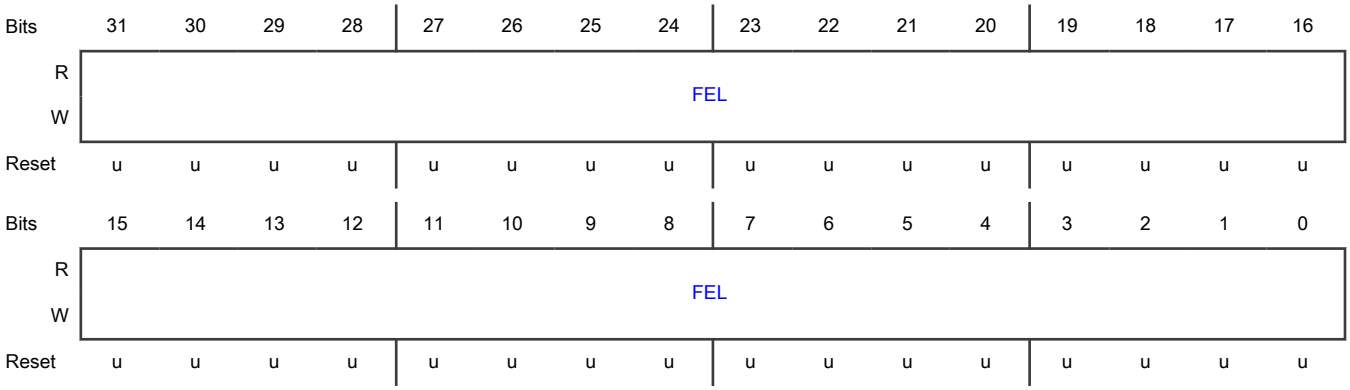
Diagram



Fields

Field	Function
31-0	Filter Element Bits

Table continues on the next page...

Field	Function
FEL	Stores filter elements. Each filter element is used during the match process. If the matching criteria are met, a message is stored in the Enhanced RX FIFO.

76.6.3 Message buffer structure

The message buffer structure used by FlexCAN is represented in the following figure. Both extended (29-bit identifier) and standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual message buffer is 16, 24, 40, or 72 bytes, depending on the quantity of data bytes allocated for the message payload: 8, 16, 32, or 64 data bytes, respectively.

The memory area 80h–67Fh is used by the message buffers. When CAN FD is enabled, the exact address for each message buffer depends on the size of its payload. See FlexCAN memory partition for CAN FD.

Table 577. Message buffer structure example with 64-byte payload

	31	30	29	28	27	24	23	22	21	20	19	18	17	16	15	8	7	0

= Unimplemented or reserved

Table 578. Field descriptions

Mnemonic	Field	Description
EDL	Extended Data Length	Distinguishes between CAN format and CAN FD format frames. EDL must not be 1 for message buffers configured to RANSWER with code field 1010b (see Table 579).
BRS	Bit Rate Switch	Defines whether the bit rate is switched inside a CAN FD format frame.
ESI	Error State Indicator	Indicates whether the transmitting node is error-active or error-passive.
CODE	Message Buffer Code	Can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in Table 579 and Table 580. See Functional description.

Table 579. Message buffer code for RX buffers

CODE description	RX code BEFORE RX new frame	SRV[1]	RX code AFTER successful reception[2]	RRS[3]	Comment
0000b: INACTIVE. Message buffer is not active.	INACTIVE	—	—	—	Message buffer does not participate in the matching process.
0100b: EMPTY. Message buffer is active and empty.	EMPTY	—	FULL	—	When a frame is received successfully (after Move-in), CODE is automatically updated to FULL.
0010b: FULL. Message buffer is full.	FULL	Yes	FULL	—	The act of reading the Control and Status word followed by unlocking the message buffer (SRV) does not make CODE return to EMPTY. It remains FULL. If a new frame is moved to the message buffer after the message buffer is serviced, the code remains FULL. See Matching process for matching details related to FULL code.
		No	OVERRUN	—	If the message buffer is FULL and a new frame is moved to this message buffer before the CPU services it, CODE is automatically updated to OVERRUN. See Matching process for details about overrun behavior.

Table continues on the next page...

Table 579. Message buffer code for RX buffers (continued)

CODE description	RX code BEFORE RX new frame	SRV[1]	RX code AFTER successful reception[2]	RRS[3]	Comment
0110b: OVERRUN. Message buffer is being overwritten into a full buffer.	OVERRUN	Yes	FULL	—	If CODE indicates OVERRUN and the CPU has serviced the message buffer, when a new frame is moved to the message buffer, CODE returns to FULL.
		No	OVERRUN	—	If CODE already indicates OVERRUN, and another new frame must be moved, the message buffer is overwritten again, and CODE remains OVERRUN. See Matching process for details about overrun behavior.
1010b: RANSWER[4]. A frame was configured to recognize a Remote Request frame and transmit a Response frame in return.[5]	RANSWER	—	TANSWER (1110b)	0	A Remote Answer was configured to recognize a Remote Request frame received. After that, a message buffer is set to transmit a response frame. CODE is automatically changed to TANSWER (1110b). See Matching process for details. If CTRL2[RRS] = 0, transmit a response frame when a remote request frame with the same ID is received.
		—	—	1	This code is ignored during matching and arbitration process. See Matching process for details.
CODE[0] = 1: BUSY. FlexCAN is updating the contents of the message buffer. The CPU must not access the message buffer.	BUSY[6]	—	FULL	—	Indicates that the message buffer is being updated. It automatically becomes 0 and does not interfere with the next CODE.
		—	OVERRUN	—	

1. SRV: Serviced message buffer. Message buffer was read and unlocked by reading TIMER or other message buffer.
2. A frame is considered a successful reception after the frame is moved to a message buffer (move-in process). See Move-in.

3. Remote Request Stored field. See Control 2 (CTRL2).
4. Code 1010b is not considered TX and a message buffer with this code should not be aborted.
5. Code 1010b must be used in message buffers configured in CAN FD format, with EDL = 1.
6. For TX message buffers, the BUSY bit should be ignored upon read, except when MCR[AEN] = 1. If this field is 1, the corresponding message buffer does not participate in the matching process.

Table 580. Message buffer code for TX buffers

CODE Description	TX Code BEFORE TX frame	MB RTR	TX Code AFTER successful transmission	Comment
1000b: INACTIVE. Message buffer is not active.	INACTIVE	—	—	Message buffer does not participate in arbitration process.
1001b: ABORT. Message buffer is aborted.	ABORT	—	—	Message buffer does not participate in arbitration process.
1100b: DATA. Message buffer is a TX data frame (MB RTR must be 0).	DATA	0	INACTIVE	Transmit data frame unconditionally once. After transmission, the message buffer automatically returns to the INACTIVE state.
1100b: REMOTE. Message buffer is a Transmit Remote Request frame (MB RTR must be 1).	REMOTE	1	EMPTY	Transmit remote request frame unconditionally once. After transmission, the message buffer automatically becomes an RX Empty message buffer with the same ID.
1110b: TANSWER. Message buffer is a Transmit Response frame from an incoming Remote Request frame.	TANSWER	—	RANSWER	This intermediate code is automatically written to the message buffer by the CHI as a result of a match to a Remote Request frame. The Remote Response frame is transmitted unconditionally once, then the code automatically returns to RANSWER (1010b). The CPU can also write this code with the same effect. The Remote Response frame can be a data frame or another remote request frame, depending on the value of RTR. See Matching process and Arbitration process for details.

Table 581. RX and TX message buffer field descriptions

Mnemonic	Field	Description
SRR	Substitute Remote Request	Fixed recessive bit, used only in extended format. Write 1 to SRR for transmission (TX Buffers). SRR is stored with the value received on the CAN bus for RX receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, it is interpreted as an arbitration loss. 1: Recessive value is compulsory for transmission in extended format frames. 0: Dominant is not a valid value for transmission in extended format frames.
IDE	ID Extended Bit	Identifies whether the frame format is standard or extended. 1: Frame format is extended 0: Frame format is standard
RTR	Remote Transmission Request	Affects the behavior of remote frames and is part of the reception filter. See Table 579, Table 580, and CTRL2[RRS]. If FlexCAN transmits this field as 1 (recessive) and receives it as 0 (dominant), it is interpreted as an arbitration loss. If this field is transmitted as 0 (dominant) and it is received as 1 (recessive), FlexCAN treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission. 1: If message buffer is TX, indicates that the current message buffer may have a Remote Request frame to be transmitted. If the message buffer is RX, incoming remote request frames may be stored. 0: Indicates that the current message buffer has a Data frame to be transmitted. In an RX message buffer, it may be considered in matching processes. **NOTE** When configuring CAN FD frames, this field must be 0.
DLC	Data Length Code	Indicates the length (in bytes) of the RX or TX data, which is located in offset 8h–Fh of the message buffer space (see Table 577). In reception, this field is written by FlexCAN, copied from the DLC field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see Table 583).
TIMESTAMP	Free-Running Counter Timestamp	Provides a copy of the Free-Running Timer, captured for TX and RX frames when the beginning of the Identifier field appears on the CAN bus. See Table 582 for Timestamp operation.
PRIO	Local priority	Used only when MCR[LPRIOEN] = 1, and only makes sense for transmit message buffers. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See Arbitration process.

Table continues on the next page...

Table 581. RX and TX message buffer field descriptions (continued)

Mnemonic	Field	Description
ID	Frame Identifier	In standard frame format, only the 11 most significant bits (28 to 18) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.
DATA BYTE 0–63	Data Field	Up to 64 bytes can be used for a data frame, depending on the size of payload selected for the message buffers. For RX frames, the data is stored as it is received from the CAN bus. DATA BYTE (*n*) is valid only if *n* is less than DLC, as shown in Table 583.

Table 582. Timestamp operation

TSTAMPCAP	MBTSBASE	TIMER_SOURCE	Captured timebase	Capture point
b00	bxx	0	CAN_TIMER incremented by CAN bit clock	Second bit of identifier field
b00	bxx	1	CAN_TIMER incremented by on-chip timer clock	Second bit of identifier field

14	DATA BYTE 0–47
15	DATA BYTE 0–63

76.6.4 FlexCAN memory partition for CAN FD

When CAN FD is enabled, FlexCAN RAM can be partitioned into blocks of 512 bytes each. Each block can accommodate a number of message buffers depending on the configuration provided by FDCTRL[MBDSR*n*] as shown in Table 584.

Table 584. RAM partition

RAM block	Number of MBs with 8 bytes (default range)	Size control field in FDCTRL	Number of MBs of different sizes, per block
0	0 to 31	MBDSR0	MBDSR0 = 00, 32 MBs with 8-byte payload MBDSR0 = 01, 21 MBs with 16-byte payload MBDSR0 = 10, 12 MBs with 32-byte payload MBDSR0 = 11, 7 MBs with 64-byte payload
1	32 to 63	MBDSR1	MBDSR1 = 00, 32 MBs with 8-byte payload MBDSR1 = 01, 21 MBs with 16-byte payload MBDSR1 = 10, 12 MBs with 32-byte payload MBDSR1 = 11, 7 MBs with 64-byte payload
2	64 to 95	MBDSR2	MBDSR2 = 00, 32 MBs with 8-byte payload MBDSR2 = 01, 21 MBs with 16-byte payload

Table continues on the next page...

Table 584. RAM partition (continued)

RAM block	Number of MBs with 8 bytes (default range)	Size control field in FDCTRL	Number of MBs of different sizes, per block
			MBDSR2 = 10, 12 MBs with 32-byte payload MBDSR2 = 11, 7 MBs with 64-byte payload

Payload sizes of 16, 32, or 64 bytes may be configured in some or all of RAM blocks. In those cases, the total number of MBs and their respective number order may differ from the default configuration of 8 bytes. Consider an example where:

- Block0 is configured to an 8-byte payload
- Block1 is configured to a 16-byte payload
- Block2 is configured to 32-byte payload

In this case, Table 585 indicates how the message buffers are arranged in RAM.

Table 585. RAM partition example

RAM block	Payload size	Number of MBs in the RAM block	Message buffer range
0	FDCTRL[MBDSR0] = 00, 8-byte payload	32	0 to 31
1	FDCTRL[MBDSR1] = 01, 16-byte payload	21	32 to 52
2	FDCTRL[MBDSR2] = 10, 32-byte payload	12	53 to 64

76.6.5 FlexCAN message buffer memory map

The FlexCAN memory buffers are allocated in memory according to the tables below.

76.6.6 Legacy RX FIFO structure

When MCR[RFEN] = 1, the memory area 80h–DCh (which is normally occupied by MBs 0–5) is used by the reception Legacy FIFO engine.

The region 80h–8Ch contains the output of the Legacy RX FIFO, which the CPU must read as a message buffer. This output contains the oldest message that has been received but not yet read. The region 90h–DCh is reserved for internal use of the Legacy RX FIFO engine.

An additional memory area, which starts at E0h and may extend up to 2DCh (normally occupied by MBs 6–37) depending on the value of CTRL2[RFFN], contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the Legacy RX FIFO.

Out of reset, the ID filter table flexible memory area defaults to E0h and extends only to FCh, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Legacy RX FIFO data structure.

Table 590. Legacy RX FIFO structure

	31 28 24	23 22 21 20	19 18 17 16	15 8	7 0
80h	IDHIT	SRR IDE RTR	DLC	TIMESTAMP	
84h		ID standard		ID extended	
88h	Data byte 0	Data byte 1		Data byte 2	Data byte 3
8Ch	Data byte 4	Data byte 5		Data byte 6	Data byte 7
90h–DCh	Reserved				
E0h	ID filter table element 0				
E4h	ID filter table element 1				
E8h–2D4h	ID filter table elements 2 to 125				
2D8h	ID filter table element 126				
2DCh	ID filter table element 127				
	= Unimplemented or reserved				

Each ID filter table element occupies an entire 32-bit word. One, two, or four Identifier Acceptance Filters (IDAF) can compound each element, depending on MCR[IDAM]. The following tables show the IDAF indexing.

Table 591 shows the three different formats of the ID table elements. All elements of the table must have the same format. See Legacy RX FIFO for more information.

Table 591. ID table structure

Format	31	30	29 24	23 16	15	14	13 8	7 1	0
A	RTR	IDE	RXIDA (standard = 29–19, extended = 29–1)						
B	RTR	IDE	RXIDB_0 (standard = 29–19, extended = 296–)		RTR	IDE	RXIDB_1 (standard = 13–3, extended = 13–0)

		= Unimplemented or Reserved		

Table 592. Field descriptions

Mnemonic	Field	Description
RTR	Remote Frame	Specifies whether remote frames are accepted into the Legacy FIFO if they match the target ID. 1: Remote frames can be accepted and data frames are rejected. 0: Remote frames are rejected and data frames can be accepted.
IDE	Extended Frame	Specifies whether extended or standard frames are accepted into the Legacy FIFO if they match the target ID. 1: Extended frames can be accepted and standard frames are rejected. 0: Extended frames are rejected and standard frames can be accepted.
RXIDA	RX Frame Identifier (Format A)	Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In the standard frame format, only the 11 most significant bits (29 to 19) are used for frame identification. In the extended frame format, all bits are used.
RXIDB_0, RXIDB_1	RX Frame Identifier (Format B)	Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (29 to 19 and 13 to 3) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.
RXIDC_0, RXIDC_1, RXIDC_2, RXIDC_3	RX Frame Identifier (Format C)	Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.
IDHIT	Identifier Acceptance Filter Hit Indicator	Indicates which identifier acceptance filter the received message in the output of the Legacy RX FIFO hit. See Legacy RX FIFO for more information.

76.6.7 Enhanced RX FIFO structure

When ERFCR[ERFEN] = 1, the Enhanced RX FIFO is enabled. The region 2000h–204Ch contains the output of the Enhanced RX FIFO, which the CPU must read as a message buffer. This output contains the oldest message that has been received but not yet read.

14	2038h	203Ch
15	2048h	204Ch

Table 595. Field descriptions

Mnemonic	Field	Description
EDL	Extended Data Length	Distinguishes between classical CAN format and CAN FD format frames. 0: Classical CAN frame format 1: CAN FD frame format
BRS	Bit Rate Switch	Defines whether the bit rate is switched inside a CAN FD format frame. 0: Bit rate is not switched in a CAN FD frame. 1: Bit rate is switched in a CAN FD frame.
ESI	Error State Indicator	Indicates whether the transmitting node is error-active or error-passive. This field is meaningful only if EDL = 1. 0: Error-active 1: Error-passive
SRR	Substitute Remote Request	Fixed recessive bit, used only in extended format. Transmitting nodes always send it as recessive and receiving nodes can receive it as either recessive or dominant. If FlexCAN receives this bit as dominant, it is interpreted as an arbitration loss.
IDE	ID Extended Bit	Identifies whether the frame format is standard or extended. 0: Standard 1: Extended
RTR	Remote Frame	Identifies whether the current frame is a data frame or a remote request. 0: Data frame 1: Remote request
DLC	Data Length Code	Defines the number of bytes in the data field of a CAN frame (Data byte 0 to Data byte 63). When RTR = 1, the frame is a remote request and does not include the data field, regardless of the DLC field. See Table 583 for more details.
LEGACY TIMESTAMP	16-bit Timestamp	Provides a copy of the Free-Running Timer, captured during the CAN frame. See Table 582 for details about legacy timestamp operation.

Table continues on the next page...

Table 595. Field descriptions (continued)

Mnemonic	Field	Description
ID	Frame Identifier	In base frame format, only the 11 most significant bits are used for frame identification. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification.
DATA BYTE 0–63	Data Field	Up to 64 bytes can be stored in the data field.
IDHIT	Identifier Acceptance Filter Hit Indicator	Indicates which Enhanced RX FIFO Filter Element (ERFFEL0 - ERFFEL127) the received message in the output of the Enhanced RX FIFO hit. For each filter region, standard-ID filter space, and extended-ID filter space, there is an independent index starting from zero. Table 596 shows how FlexCAN writes IDHIT according to each filter element.
HR TIMESTAMP	High-resolution Timestamp	32-bit timebase captured during the CAN frame. When CTRL2[TSTAMPCAP] is not zero, a 32-bit timebase is captured from a dedicated on-chip timer which operates in free-running mode. See CTRL2[TSTAMPCAP] for details about capture point configuration of the high-resolution timestamp.

Table 596. IDHIT for Enhanced RX FIFO

Enhanced RX FIFO filter element - ERFFEL	IDHIT value	Filter element type
ERFFEL0	0	Extended-ID
ERFFEL1	1	Extended-ID
. . .	. . .	Extended-ID
ERFFEL(m-1)	m-1	Extended-ID
ERFFEL(m)	0	Standard-ID
ERFFEL(m+1)	1	Standard-ID
. . .	. . .	Standard-ID
ERFFEL(2n-m+1)	2x(n-m)+1	Standard-ID

NOTE

Where m = NEXIF and n = NFE. If NEXIF = 0, only standard-ID filter elements exist. If NEXIF > NFE, only extended-ID filter elements exist.

76.7 Glossary

Active message buffer A message buffer is active if it can participate in the current matching or arbitration process.

Bus interface unit FlexCAN submodule responsible for the interface to the CPU.

Bus off	See CAN Specification.[36]
CAN	Controller Area Network, a serial communication protocol defined in CAN Specification[36] and ISO International Standard.[37]
CHI	Controller-host interface, a FlexCAN submodule responsible for message buffer matching and arbitration algorithms.
CRC	Cyclic redundancy check
Dominant bit	A dominant bit wins the arbitration on the CAN bus. It is transmitted as 0.
Doze mode	A system low-power mode where the CPU bus remains active and a global Doze mode request is sent to all peripherals asking them to enter low power mode.
Error active	See CAN Specification.[36]
Error frame	See CAN Specification.[36]
Error passive	See CAN Specification.[36]
Form error	See CAN Specification.[36]
Hard reset	A reset coming from an external pin and/or following power-on. It resets everything.
Idle	See CAN Specification.[36]
Information processing time	See CAN Specification.[36]
Intermission	See CAN Specification.[36]
Matching elements	Data used in the matching process, such as ID, filter, mask, etc.
MB	See Message buffer.
Message buffer	Internal FlexCAN data structure containing bytes received from, or to be transmitted to, the CAN line, as well as information about this data.
Overload frame	See CAN Specification.[36]
Phase buffer segment	See CAN Specification.[36]
Recessive bit	A recessive bit loses the arbitration on the CAN bus. It is transmitted as 1.
Sclock	Serial clock. Obtained by dividing the clock feeding the CAN engine (oscillator or bus clock) by a prescaler factor. The Sclock period defines the time quantum for CAN protocol timing.
Soft reset	Global reset typically used by peripherals to reinitialize some of its registers, but not all of them.
Stop mode	A system low-power mode in which all chip clocks are stopped for maximum power savings.
Stuffing error	See CAN Specification.[36]
Time quantum	This is equal to the Sclock period. It is the minimum time period used to compose the CAN protocol bit timing.

[36] Controller Area Network - CAN Specification Version 2.0 Part A, Part B, Robert Bosch GmbH, 1991.
[37] ISO International Standard - ISO 11898 First Edition 1993 Road Vehicles - Interchange of Digital Information - Controller Area Network (CAN) for high-speed Communication.

Chapter 77
De-serial Serial Peripheral Interface (DSPI)

77.1 Chip-specific DSPI information

77.1.1 DSPI instances and configuration

The chip has only one instance of DSPI which can be used to implement MSC (MicroSecond Channel interface)

- MSC timer channel serialization is supported.
- 64 bit mode is supported.
- DSPI Serialization mode is enabled.

The trigger inputs to DSPI should be stable for 1µs

NOTE

- MTO operation is not supported.
- Slave mode is not supported for DSPI.

NOTE

DSPI/MSC interface is supported only at VDD_HV_A = 5V and not at 3.3V.

77.2 Introduction

The DSPI module provides a synchronous serial bus for communication between a chip and an external peripheral device. The module supports chip pin count reduction through serialization and deserialization of chip internal signals transmitted over the DSPI serial link.

77.2.1 Block diagram

The following figure represents the module's block diagram.

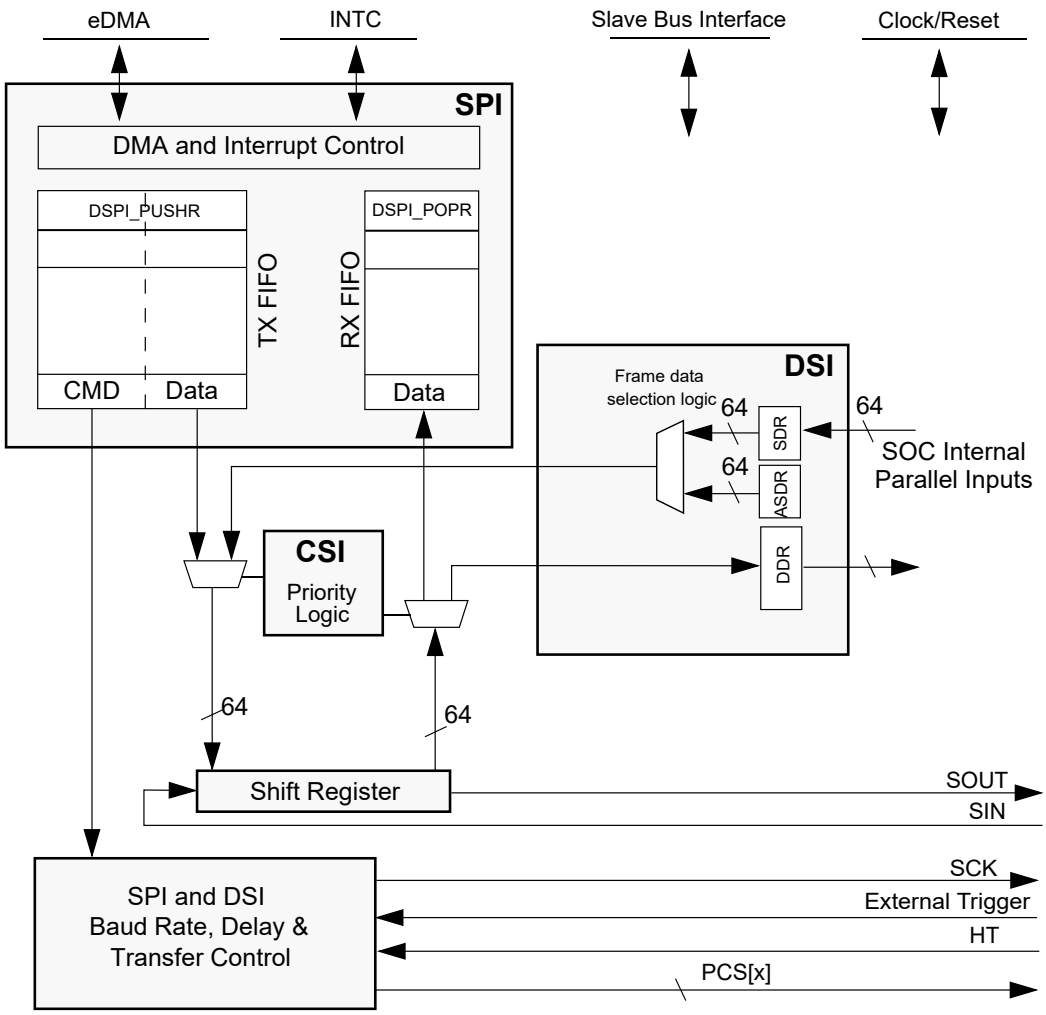

Figure 536. DSPI block diagram

77.2.2 Features

The module supports the following features:

- Full-duplex, three-wire synchronous transfers
- Master mode
- Buffered transmit operation using transmit first in first out (TX FIFO) with a depth of 16 entries
- Buffered receive operation using the Receive FIFO (RX FIFO) with a depth of 16 entries
- TX and RX FIFOs can be disabled individually for low-latency updates to DSPI queues
- Visibility into TX and RX FIFOs for ease of debugging
- Programmable transfer attributes on a per-frame basis:
  - 6 transfer attribute registers
  - 6 extended transfer attribute registers
  - Serial clock (SCK) with programmable polarity and phase
  - Various programmable delays

  - Programmable serial frame size is 4 to 64 bits
    - DSPI frames longer than 32 bits can be supported using the continuous selection format.
  - Continuously held chip-select capability
  - Parity control
- 2 peripheral chip selects (PCSes)
- DMA support for adding entries to TX FIFO and removing entries from RX FIFO when:
  - TX FIFO is not full (TFFF)
  - RX FIFO is not empty (RFDF)
  - Command (CMD) FIFO is not full (CMDFFF)
- Interrupt conditions:
  - End of queue reached (EOQF)
  - TFFF
  - CMDFFF
  - Transfer of current frame complete (TCF)
  - Transfers due from current command frame complete (CMDTCF)
  - Transfer of current DSPI frame complete (SPITCF)
  - RFDF
  - Frame received while RX FIFO is full (RFOF)
  - DSPI Parity Error (SPEF)
  - Data present in TX FIFO while CMD FIFO is empty (TFIWF)
- Global interrupt request line

The DSPI also supports pin reduction through serialization and deserialization, if enabled.

- Two sources of serialized data:
  - Module memory-mapped register
  - Parallel input signals
  - Programmable selection of source data on bit basis
- Deserialized data is provided as parallel output signals and as bits in a memory-mapped register.
- Interrupt conditions and DMA support is provided when:
  - Deserialized data matches pre-programmed pattern (DDIF)
  - Transfer of current DSI frame complete (DSITCF)
  - DSI Parity Error (DPEF)
- Transfer initiation conditions:
  - Continuous
  - Edge-sensitive hardware trigger
  - Change in data
- Pin serialization/deserialization with interleaved DSPI frames for control and diagnostics
- Continuous serial communications clock (SCK)

DSPI supports a combination of DSPI and DSI modes of operation known as the Combined Serial Interface (CSI). It also supports the downstream Micro Second Channel in the Timed Serial Bus (TSB) configuration or Interleaved Frames Configuration; configurable by software.

Both TSB and Interleaved TSB modes have the following common features:

- Transmission of frames is done at frame boundaries
- Frames from DSPI and DSI are identifiable by a bit transmitted at the start of each frame
- Separate interrupts for frame completion from DSPI and DSI

77.2.3 Interface configurations

77.2.3.1 SPI configuration

The SPI configuration allows the module to send and receive serial data. This configuration allows the module to operate as a basic SPI block with internal FIFOs supporting the external queue operation. Transmitted data and received data are included in separate FIFOs. The host CPU or a DMA controller reads the received data from the RX FIFO and writes transmit data to the transmit FIFO.

For queued operations, the SPI queues can be included in system RAM, external to the module. A DMA controller or host CPU accomplishes data transfers between the queues and the module FIFOs. The following figure shows an example with DMA, DSPI, and external queues in system RAM.

NOTE

In the following diagram, SPI is used for both the DSPI and DSI modes.

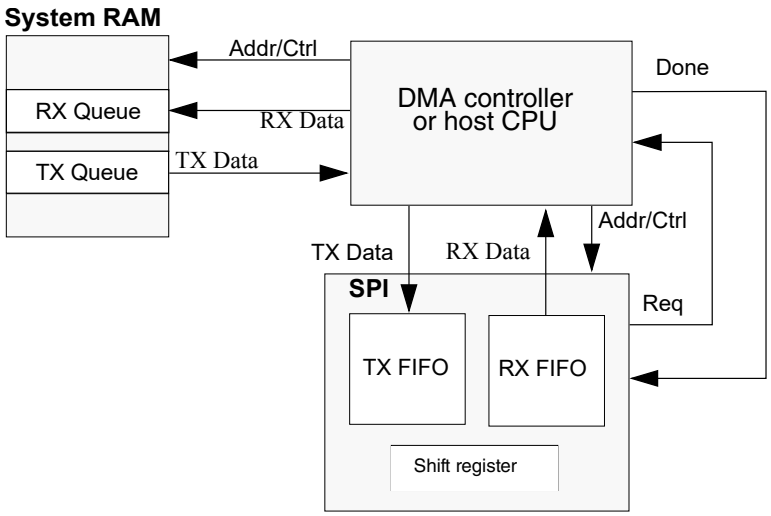

Figure 537. SPI with queues and DMA

77.2.3.2 DSI configuration

In the Deserial Serial Interface (DSI) configuration, DSPI serializes up to 64 parallel input signals or register bits. DSPI also deserializes the received data to parallel output signals or to a memory-mapped register, and transfers the data using SPI-like protocol.

Timed Serial Bus (TSB) mode provides the MicroSecond Channel (MSC) downstream support, serializing from 4 to 64 parallel input signals or register bits. For more information on TSB mode, see Timed serial bus (TSB).

77.2.3.3 CSI configuration

The CSI configuration supports the following modes:

- Normal: It provides a combination of the DSPI and DSI configurations. The DSPI interleaves DSI data frames with SPI data frames, and the interleaving is done on the frame boundaries.
- TSB: Transmission of DSPI data has a higher priority than DSI data.
- Interleaved TSB (ITSB): The frames from DSPI and DSI are interleaved without priority. On every trigger, frames from DSI are sent when there are no frames in the DSPI or the previous transmission was a frame from DSPI. For more information, see Interleaved TSB (ITSB) Mode.

77.3 Module signal descriptions

This table describes the signals on the boundary of the module that may connect off chip (in alphabetical order).

Table 597. Module signal descriptions

Signal	Master mode	I/O
HT	Hardware Trigger	I
PCS0	Peripheral Chip Select 0 (O)	O
PCS1	Peripheral Chip Select 1	O
SCK	Serial Clock (O)	O
SIN	Serial Data In	I
SOUT	Serial Data Out	O

77.3.1 HT

Master mode: Hardware Trigger (I)—

- Is honored only when the module is configured for the DSI or CSI configuration (MCR[DCONF]), the value for DSICR0[TRRE] is 1, and the module is in the Running state (SR[TXRXS])
- Receives hardware triggers that initiate data transfers
- DSICR0[TPOL] specifies whether the module uses the rising or falling edges of HT as hardware triggers

77.3.2 PCS0

Master mode: Peripheral Chip Select 0 (O)—Selects DSPI slave to receive data transmitted from the module

NOTE

Do not tie the DSPI slave select pin to ground. Otherwise, DSPI cannot function properly.

77.3.3 PCS1

Master mode: Peripheral Chip Select 1 (O)—Selects DSPI slave to receive data that the module transmits

77.3.4 SCK

Master mode: Serial Clock (O)—Supplies a clock signal from the module to DSPI slaves

77.3.5 SIN

Master mode: Serial Input (I)—Receives serial data

77.3.6 SOUT

Master mode: Serial Output (O)—Transmits serial data

77.4 Functional description

The module supports full-duplex, synchronous serial communications between chips and peripheral devices. It can also be used to reduce the number of pins that I/O requires, by serializing and deserializing parallel input/output signals. All communications are performed with SPI-like protocol.

The module includes the following configuration:

- SPI configuration in which the module operates as a basic SPI or a queued SPI
- DSI configuration in which the module serializes and deserializes parallel input/output signals or fields from memory-mapped registers
- When the Master mode is enabled, the module also supports CSI configuration, which combines the functionality of the SPI and DSI configurations.

MCR[DCONF] determines the module configuration. See Module Configuration Register (MCR) for the DSPI configuration values.

The CTAR*n* registers hold clock and transfer attributes. The SPI configuration allows to select which CTAR to use, on a frame-by-frame basis, by setting a field in the SPI command. MCR[XSPI] further allows the usage of CTARE*n* registers. This allows you to send multiple data frames using a single command frame.

The DSI configuration statically selects which CTAR to use. In CSI, configuration priority logic determines if SPI data or DSI data is transferred and dictates which CTAR register is used for data transfer.

Typical master-to-slave connections are shown in the following figure. When a data transfer operation is performed, data is serially shifted to a predetermined number of bit positions. Because the modules are linked, data is exchanged between the master and the slave. The data that was included in the master shift register is now in the shift register of the slave, and vice versa. At the end of a transfer, if the value of SR[TCF] is 1, it indicates a completed frame transfer.

NOTE

SPI is used for both the DSPI and DSI modes in the following diagram.

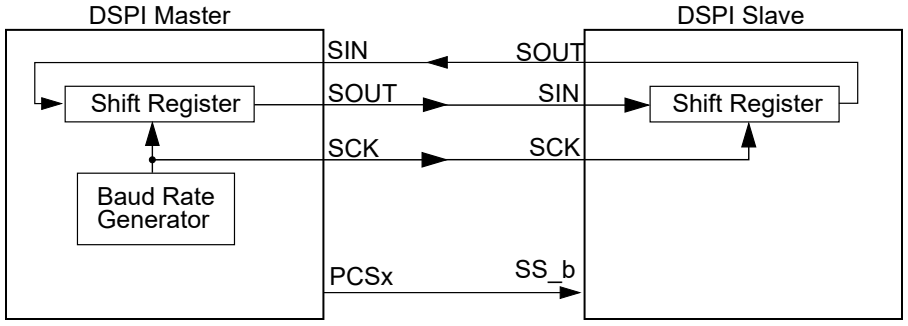

Figure 538. Serial protocol overview

Generally, more than one slave device can be connected to the module master, and 2 PCS signals of the module masters can be used to select which of the slaves to communicate with.

The three DSPI configurations share transfer protocol and timing properties that are described independently of the configuration in Transfer formats. The transfer rate and delay settings are described in Module baud rate and clock delay generation.

77.4.1 Modes of operation

The module supports the following modes of operation that can be divided into two categories:

- Module-specific modes:

- Master mode
- Module Disable mode

- Chip-specific modes:
  - Debug mode

The module enters module-specific modes when the host writes to a module register. The signals external to the module control the chip-specific modes. The chip may enter these modes in parallel to the module-specific modes.

77.4.1.1 Master mode

The Master mode allows the module to initiate and control serial communication. In this mode, the module controls the following signals, which the module configures as outputs:

- SCK
- PCS[*x*]

77.4.1.2 Module Disable mode

The Module Disable mode can be used for chip-power management. In this mode, you can stop the clock to the non-memory mapped logic in the module.

77.4.1.3 Debug mode

The Debug mode is used for system development and debugging. MCR[FRZ] controls module behavior when the chip is in this mode.

- If you write a 1 to this field, the module stops all serial transfers .
- If you write a 0 to the field, this mode has no effect on the module.

77.4.2 Starting and stopping module transfers

The module has two operating states: Stopped and Running. Both the states are independent of their configuration. The default state of the module is Stopped. In this state, the module initiates no serial transfers in the Master mode. The Stopped state is also a safe state for writing to the various configuration registers of the module, without causing undetermined results. In the Running state, serial transfers take place.

SR[TXRXS] indicates the state of the module. The value of this field is 1 if the module is in the Running state.

The module starts or transitions to the Running state when all of the following conditions are true:

- The value of SR[EOQF] = 0.
- The chip is not in the Debug mode or the value of MCR[FRZ] = 0.
- The value of MCR[HALT] = 0.

The module stops or transitions from the Running state to the Stopped state after the current frame, when any one of the following conditions exist:

- The value of SR[EOQF] = 1.
- The chip is in Debug mode and the value of MCR[FRZ] = 1.
- The value of MCR[HALT] = 1.

State transitions from running to stopped occur on the next frame boundary if a transfer is in progress, and occur immediately if no transfers are in progress.

77.4.3 SPI configuration

The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes. The module is in SPI configuration when the value of MCR[DCONF] is 0. The SPI frames can be 32-bit long. The host CPU or a DMA controller transfers the external SPI data to the module RAM queues and to a TX FIFO buffer. The received data is stored in the entries of the RX FIFO buffer. The host CPU or the DMA controller transfers the received data from the RX FIFO to a memory external to the module. The operation of FIFO buffers is described in the following sections:

- TX FIFO buffering mechanism
- CMD FIFO buffering mechanism
- RX FIFO buffering mechanism

The interrupt and DMA request conditions are described in Interrupts/DMA requests.

In the Master mode, the module initiates and controls the transfer according to the fields of the executing SPI command.

77.4.3.1 Master mode

In the DSPI Master mode, the module initiates serial transfers by controlling the SCK and the PCS signals. The executing DSPI command determines which CTARs will be used to set the transfer attributes and which PCS signals to assert. The command field also contains various bits that help with queue management and transfer protocol. See PUSH TX FIFO Register In Master Mode (PUSHR) for details on the DSPI command fields. The data in the executing TX FIFO entry is loaded into the shift register and shifted out on the SOUT pin. In the DSPI Master mode, each SPI frame to be transmitted has a command associated with it, allowing for transfer attribute control on a frame by frame basis. In the Extended SPI Master mode, multiple DSPI frames can have a single command associated with them allowing efficient SPI frame transfers requiring common transfer attributes. In addition, the Extended SPI mode allows larger frame sizes of up to 32 bits.

77.4.3.2 FIFO disable operation

The FIFO disable mechanisms allow DSPI transfers without using the TX FIFO, CMD FIFO, or RX FIFO. The module operates as a double-buffered, simplified DSPI when the FIFOs are disabled. The transmit and receive sides of the FIFOs are disabled separately. Writing a 1 to MCR[DIS_TXF] disables the TX FIFO and CMD FIFO, and writing a 1 to MCR[DIS_RXF] disables the RX FIFO.

The FIFO disable mechanisms are transparent to you and to the host software. Transmit data and commands are written to the PUSHR and received data is read from the POPR.

When the TX FIFO and CMD FIFO are disabled:

- SR[TFFF], SR[CMDFFF], SREX[CMDCTR], and SR[TXCTR] behave as if there is a one-entry FIFO.
- The contents of TXFRs, SR[TXNXTPTR], and SREX[CMDNXTPTR] are undefined.

Similarly, when the RX FIFO is disabled, SR[RFDF], SR[RFOF], and SR[RXCTR] behave as if there is a one-entry FIFO, but the contents of the RXFR registers and SR[POPNXTPTR] are undefined.

77.4.3.3 TX FIFO buffering mechanism

The TX FIFO functions as a buffer of DSPI data for transmission. It holds 16 words, each consisting of DSPI data. The number of entries in the TX FIFO is chip-specific. DSPI data is added to the TX FIFO by writing to the data field of PUSHR. TX FIFO entries can only be removed from the TX FIFO if they are shifted out or by flushing the TX FIFO.

SR[TXCTR] indicates the number of valid entries in the TX FIFO. The field updates every time an 8- or 16-bit write takes place on PUSHR[TXDATA] or SPI data is transferred into the Shift register from the TX FIFO.

SR[TXNXTPTR] indicates the TX FIFO entry that will be transmitted during the next transfer. The TXFR*n* registers are invalid in the Extended SPI mode because the TX FIFO and CMD FIFO can be used independently. The TXNXTPTR field increments every time SPI data is transferred from the TX FIFO to the Shift register. The maximum value of this field is equal to the maximum implemented TXFR number and it rolls over after reaching the maximum.

77.4.3.3.1 Filling the TX FIFO

Host software or other intelligent blocks can add (push) entries to the TX FIFO and CMD FIFO by writing to the PUSHR. When the TX FIFO is not full, the value of DR[TFFF] is set to 1, and the value is set to 0 when TX FIFO is full and the DMA controller indicates that a write to PUSHR is complete. You can also write a 1 to clear the field, which can generate a DMA request or an interrupt request. See Transmit FIFO fill interrupt or DMA request for details.

The module ignores attempts to push data to a full TX FIFO, and the state of the TX FIFO does not change and no error condition occurs.

77.4.3.3.2 Draining the TX FIFO

The module removes (drains) the TX FIFO entries by shifting DSPI data out through the Shift register. It transfers entries from the TX FIFO to the Shift register, and the entries are shifted out as long as there are valid entries in the TX FIFO. Every time an entry is transferred from the TX FIFO to the Shift register, the TX FIFO counter decrements by 1. When the value of MCR[XSPI] is 1, and if the frame size of SPI data to be transmitted is more than 16 bits, then it causes two data entries to be popped from TX FIFO simultaneously. These entries are transferred to the Shift register. The first of the two popped entries forms the 16 least significant bits of the SPI frame to be transmitted. Such an operation also causes the TX FIFO counter to decrement by 2. At the end of a transfer, the value of SR[TCF] is set to indicate the completion of a transfer. The TX FIFO is flushed by writing a 1 to MCR[CLR_TXF].

77.4.3.4 CMD FIFO buffering mechanism

The CMD FIFO functions as a buffer of DSPI command used for SPI data transmission. When Extended SPI Mode (MCR[XSPI]) is disabled, the TX FIFO and CMD FIFO must be filled together, i.e. write enables should be given for both the Data and Command fields while performing a PUSHR operation.When Extended SPI Mode (MCR[XSPI]) is enabled, the TX FIFO and CMD FIFO can be filled independently.

The CMD FIFO holds 16 words, each representing SPI command fields. The number of entries in the CMD FIFO is chip-specific. DSPI command is added to the CMD FIFO by writing to the command field of PUSHR. CMD FIFO entries can only be removed from the CMD FIFO by being shifted out (to help transmit SPI data) or by flushing the CMD FIFO.

When Extended SPI Mode (MCR[XSPI]) is disabled, every CMD FIFO entry has a corresponding single TX FIFO entry attached to it because both these FIFO's are filled simultaneously.

When Extended SPI Mode (MCR[XSPI]) is enabled, every CMD FIFO entry can have multiple TX FIFO entries attached to it. Thus a single CMD FIFO entry can be used to transmit multiple TX FIFO entries. The CTARE[DTCP] field decides the number of SPI Data Frames having frame size as {FMSZE, FMSZ} to be transmitted using the current Command Entry. The CTAR/CTARE registers pointed by the CTAS field in the Command frame gives the FMSZ and FMSZE fields respectively. The time for which a command entry is in use is known as a Command Cycle. The Busy Flag SR[BSYF] is asserted for the duration of the Command Cycle except for the last SPI frame in the Command Cycle.

The CMD FIFO Counter field (CMDCTR) in the DSPI Status Register extended(SREX) indicates the number of valid entries in the CMD FIFO. The CMDCTR field is updated every time a 8- or 16-bit write takes place on the lower half of DSPI_PUSHR or SPI data is transferred into the shift register from the TX FIFO.

The TXFRn Registers are invalid in the Extended SPI Mode, since the TX FIFO and CMD FIFO can be used independently. The CMDNXTPTR field indicates which CMD FIFO Entry will be used during the next command cycle. The CMDNXTPTR field is incremented every time the last SPI data in the command cycle is transferred from the TX FIFO to the shift register and it rolls over after reaching the maximum.

77.4.3.5 RX FIFO buffering mechanism

The RX FIFO functions as a buffer for data received on the SIN pin. The FIFO holds 16 received DSPI data frames. The number of entries in the RX FIFO is chip-specific. DSPI data is added to the RX FIFO at the completion of a transfer when the received data in the Shift register is transferred into the RX FIFO. DSPI data is removed (popped) from the RX FIFO by reading the POPR. RX FIFO entries can only be removed from the RX FIFO by reading the POPR or by flushing the RX FIFO.

SR[RXCTR] indicates the number of valid entries in the RX FIFO. The field is updated every time the POPR is read or DSPI data is copied from the Shift register to the RX FIFO.

SR[POPNXTPTR] points to the RX FIFO entry that is returned when the POPR is read. The field contains the positive offset from RXFR0 in a number of 32-bit registers. For example, POPNXTPTR = 2 means that the RXFR2 contains the received DSPI data that is returned after the POPR is read. The POPNXTPTR field increments every time the POPR is read. The maximum value of the field is equal to the maximum implemented RXFR number and it rolls over after reaching the maximum.

77.4.3.5.1 Filling the RX FIFO

The RX FIFO is filled with the received DSPI data from the Shift register. While the RX FIFO is not full, DSPI frames from the Shift register are transferred to the RX FIFO. Every time a DSPI frame is transferred to the RX FIFO, the RX FIFO counter is incremented by 1.

If the RX FIFO and Shift register are full and a transfer is initiated, the value of SR[RFOF] equals 1, indicating an overflow condition. Depending on the state of MCR[ROOE], the data from the transfer that generated the overflow is either ignored or shifted to the Shift register. If the value of the ROOE field is 1, the incoming data is shifted in to the Shift register. If the value of ROOE is 0, the incoming data is ignored.

77.4.3.5.2 Draining the RX FIFO

Host CPU or a DMA can remove (pop) entries from the RX FIFO by reading the POPR. A read of the POPR decrements the RX FIFO counter by 1. Attempts to pop data from an empty RX FIFO are ignored and the RX FIFO counter remains unchanged. The data, read from the empty RX FIFO, is undetermined.

When the RX FIFO is not empty, the value of SR[RFDF] is 1. The value of the RFDF field turns 0 when the RX FIFO is empty and the DMA controller indicates that a read from POPR is complete or by writing a 1 to it.

77.4.4 DSI configuration

The DSI configuration supports pin count reduction by serializing parallel input signals or register fields and shifting them out in SPI-like protocol. The timing and transfer protocols are described in Transfer formats. The received serial frames are converted to a parallel form (deserialized) and placed on the parallel output signals or in the DDRs. The various features of DSI configuration are available in DSI configuration registers (DSICR0/DSICR1). The DSI frames can range from 4 to 32 bits. This can go up to 64 bits when the value of DSICR1[DSI64E] is 1.

77.4.4.1 DSI Master mode

In DSI Master mode, the DSPI initiates and controls the DSI transfers. The DSI master has different conditions that can initiate a transfer:

- Continuous
- Change in data
- Trigger signal
- Trigger signal combined with a change in data

Transfer attributes are set during initialization. The DSICTAS field in the DSI_EXISTSCR0 determines which of the DSPI_CTAR registers will control the transfer attributes.

77.4.4.2 DSI serialization

In the DSI configuration, up to 64 bits can be serialized using two different sources. DSICR0[TXSS] selects between SDR0–1 and ASDR0–1 as the source of serialized data. SDR0 holds the latest 32 parallel input signal values that are sampled at every rising edge of the bus clock. If the value of DSICR1[DSI64E] is 1, 64-bit DSI frames are supported, and hence, SDR1 holds up to 32 most significant parallel input signal values that are sampled at every rising edge of the bus clock. The ASDR0–1 registers are written by the host software and used as alternate sources of serialized data. ASDR1 is only usable when the value of DSICR1[DSI64E] is 1.

NOTE

The parallel input pin state to be transmitted should be selected by DSICR0[TXSS] or SSR0-1 and the frame size should be higher than the bit position in the preselected frame.

The SSR0–1 register provides an additional way to create the frame for transmission. Each field of this register is OR'd with the TXSS field and controls individual transmitted bit source. This way, the transmitted frame can have any combination of the SDR0–1 and ASDR0–1 fields. This feature allows control over SPI-based chips, requiring control and data fields in the frame. A control field may be a part of the ASDR0–1 registers, configured by the chip's CPU, while a data field can be generated by chip peripheral modules, such as PWM timers.

A copy of the last DSI frame shifted out of the Shift register is stored in the COMPR0–1 registers. These registers provide added visibility for debugging and serve as a reference for transfer initiation control. The following figure shows the DSI serialization logic.

NOTE

SPI is used for both the DSPI and DSI modes in this diagram.

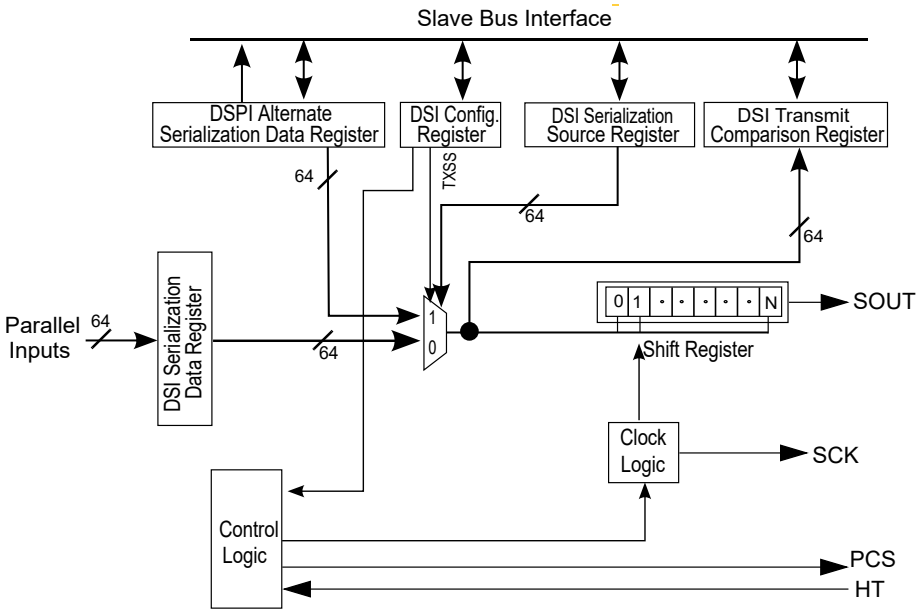

Figure 539. DSI serialization diagram

77.4.4.3 DSI deserialization

When all the bits in a DSI frame are shifted in, the frame is copied to the DDR0/1. This register presents the deserialized data as parallel output signal values. DDR0/1 is memory mapped to allow the host software to read the deserialized data directly.

The received data is compared, bit-wise, to the value of the DPIR0/1, AND'ed with DIMR0/1, and the results OR'ed to produce a DDIF field in the SR. This, in turn, can cause a DDI or DMA request based on RSER[DDIF_RE] and RSER[DDIF_DIRS] and/or stop DSI frame transmissions if the value of DSICR0[DMS] is 1.

The following figure shows the DSI deserialization logic.

NOTE

SPI is used for both DSPI mode and DSI mode in this diagram.

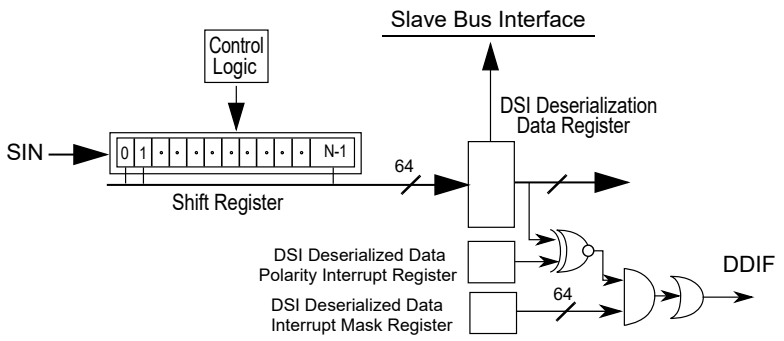

Figure 540. DSI deserialization diagram

77.4.4.4 DSI transfer initiation control

Data transfers for DSPI in DSI configuration are initiated by a condition. DSICR0[TRRE] and DSICR0[CID] select the transfer initiation conditions. The following table lists the four transfer initiation conditions.

Table 598. DSI data transfer initiation control

DSICR0 fields		Transfer initiation control
TRRE	CID	
0	0	Continuous
0	1	Change in data
1	0	Triggered
1	1	Triggered or change in data

77.4.4.4.1 Continuous control

For Continuous control, a new DSI frame shifts out when the previous transfer cycle is compete and the Delay after Transfer (t_{DT}) has elapsed.

77.4.4.4.2 Change in data control

For Change in Data Control, a transfer is initiated when the data to be serialized has changed since the transfer of the last DSI frame. A copy of the previously transferred DSI data is stored in COMPR0/1. When the data selected for the transfer from the SDR0/1 and ASDR0/1 registers is different from the data in COMPR0/1, a new DSI frame is transmitted.

NOTE

It is not advisable to configure a DSPI slave with the combination of DSICR0[DCONT] = 1 and DSICR0[CID] = 1 because the following statement then holds true.

After slave select is asserted, there is a very small window (of up to t module clocks) after every Start of Frame (SOF) during which if a write on ASDR/SDR registers occurs, the next frame to be transmitted is loaded into the Shift register. However, it is not feasible that such a write be initiated and completed within this short span of time; hence, the data transmitted by DSPI slave lags by one data frame.

77.4.4.4.3 Triggered control

For Triggered Control initiation of a transfer is controlled by the Hardware Trigger signal (HT). The TPOL bit in the DSI_EXISTSCR0 selects the active edge of HT. For HT to have any affect, the TRRE bit in the DSI_EXISTSCR0 must be set.

77.4.4.4.4 Triggered or change in data control

For Triggered or Change in Data Control, initiation of a transfer is controlled by the HT signal or by the detection of a change in data to be serialized.

77.4.5 CSI configuration

The CSI Configuration of the DSPI is used to support SPI and DSI functions on a frame by frame basis. CSI Configuration allows interleaving of DSI data frames from the parallel input signals with DSPI data frames from the TX FIFO. The data returned from the bus slave is either used to drive the Parallel Output signals or it is stored in the RX FIFO. The CSI Configuration allows serialized data and configuration or diagnostic data to be transferred to a slave device using only one serial link. The DSPI is in CSI Configuration when the DCONF field in the DSPI_MCR is 0b10. The following figure shows an example of how a DSPI can be used with a deserializing peripheral that supports DSPI control for control and diagnostic frames.

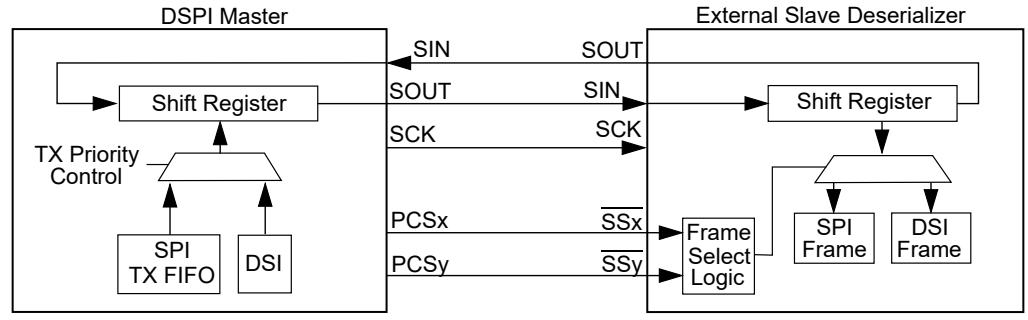

Figure 541. Example of System using DSPI in CSI Configuration

When DSPI commands are in the TX FIFO, the SPI frames have priority over the DSI frames. When the TX FIFO or CMD FIFO is empty, DSI transfer resumes.

Two peripheral chip select signals indicate whether DSI data or DSPI data is transmitted. The user must configure the DSPI so that the two CTAR registers associated with DSI data and DSPI data assert different peripheral chip select signals denoted in the figure as PCSx and PCSy. The CSI Configuration is only supported in master mode.

Data returned from the external slave while a DSI frame is transferred is placed on the Parallel Output signals. Data returned from the external slave while a DSPI frame is transferred is moved to the RX FIFO. The TX FIFO, CMD FIFO and RX FIFO are fully functional in CSI mode.

77.4.5.1 CSI serialization

Serialization in the CSI configuration is similar to serialization in DSI Configuration. The transfer attributes for SPI frames are determined by the DSPI_CTAR register selected by the CTAS field in the SPI command halfword. The transfer attributes for the DSI frames are determined by the DSPI_CTAR register selected by the DSICTAS field in the DSI_EXISTSCR0.

The Parallel Inputs signal states are latched into the DSPI DSI Serialization Data Register (DSPI_SDR0/1) and serialized based on the transfer initiation control settings in the DSI_EXISTSCR0. When SPI frames are written to the TX FIFO (and when CMD FIFO is not empty) they have priority over DSI data from the DSPI_SDR and are transferred at the next frame boundary. A copy of the most recently transferred DSI frame is stored in DSPI_COMPR0/1. The Transfer Priority Logic selects the source of the serialized data and asserts the appropriate PCS signal.

Separate frame completion interrupts are available to indicate frame transmission completion from SPI and DSI frames.

77.4.5.2 CSI deserialization

The deserialized frames in CSI configuration go into the DDR0/1 registers or the RX FIFO based on the transfer priority logic. When DSI frames are transferred, the returned frames are deserialized and latched into the DDR0/1 registers. When SPI frames are transferred, the returned frames are deserialized and written to the RX FIFO.

77.4.6 Module baud rate and clock delay generation

The SCK frequency and the delay values for serial transfer are generated by dividing the system clock frequency by a prescaler and a scaler with the option for doubling the baud rate. The following figure shows conceptually how the SCK signal is generated.

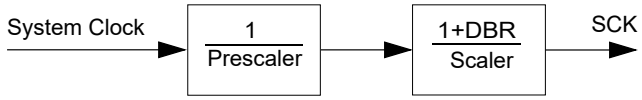

Figure 542. Communications clock prescalers and scalers

77.4.6.1 Baud rate generator

The baud rate is the frequency of the SCK. The protocol clock is divided by a prescaler (PBR) and scaler (BR) to produce SCK with the possibility of halving the scaler division. The DBR, PBR, and BR fields in the CTARs select the frequency of SCK by the formula in the BR field description. The following table shows an example of how to compute the baud rate.

Table 599. Baud rate computation example

f_P	PBR	Prescaler	BR	Scaler	DBR	Baud rate
100 MHz	0b00	2	0b0000	2	0	25 Mb/s
20 MHz	0b00	2	0b0000	2	1	10 Mb/s

NOTE

The clock frequencies mentioned in the preceding table are provided as an example. See the Clocking chapter for the frequency used to drive this module in the chip.

77.4.6.2 PCS to SCK delay (t_{CSC})

The "PCS to SCK delay" is the duration from assertion of the PCS signal to the first SCK edge. See Figure 543 for an illustration of the PCS to SCK delay. The PCSSCK and CSSCK fields in the CTAR*x* registers select the PCS to SCK delay by the formula in the CSSCK field description. The following table shows an example of how to compute the PCS to SCK delay.

Table 600. PCS to SCK delay computation example

f_{SYS}	PCSSCK	Prescaler	CSSCK	Scaler	PCS to SCK Delay
100 MHz	0b01	3	0b0100	32	0.96 µs

PCSCSK and CSSCK fields have no effect in TSB configuration.

NOTE

The clock frequency mentioned in the preceding table is given as an example. See the Clocking chapter for the frequency used to drive this module in the chip.

77.4.6.3 After SCK delay (t_{ASC})

The "After SCK Delay" is the duration between the last edge of SCK and the negation of PCS. See Figure 543 and Figure 544 for illustrations of this type of delay. The PASC and ASC fields in the CTAR*x* registers select the "After SCK Delay" by the formula in the ASC field description. The following table shows an example of how to compute the "After SCK Delay".

Table 601. After SCK Delay computation example

f_P	PASC	Prescaler	ASC	Scaler	After SCK Delay
100 MHz	0b01	3	0b0100	32	0.96 µs

PCASC and ASC fields have no effect in TSB configuration.

NOTE

The clock frequency mentioned in the preceding table is given as an example. See the Clocking chapter for the frequency used to drive this module in the chip.

77.4.6.4 Delay after transfer (t_{DT})

The "Delay after Transfer" is the minimum time between negation of the PCS signal for a frame and the assertion of the PCS signal for the next frame. See Figure 543 for an illustration of this type of delay. The PDT and DT fields in the CTAR*x* registers select the "Delay after Transfer" by the formula in the DT field description. The following table shows an example of how to compute the "Delay after Transfer".

Table 602. "Delay after Transfer" computation example

f_P	PDT	Prescaler	DT	Scaler	Delay after Transfer
100 MHz	0b01	3	0b1110	32768	0.98 ms

NOTE

The clock frequency mentioned in the preceding table is given as an example. See the Clocking chapter for the frequency used to drive this module in the chip.

When in Non-Continuous Clock mode, the t_{DT} delay is configured according to the equation specified in the CTAR[DT] field description. When in Continuous Clock mode and TSB is not enabled, the delay is fixed at 1 SCK period.

In TSB mode, the Delay after Transfer is equal to a number formed by concatenation of PDT and DT fields plus 1 of the SCK clock periods. See detailed information on Timed serial bus (TSB)".

77.4.7 Transfer formats

The DSPI serial communication is controlled by the SCK signal and the PCS signals. The SCK signal provided by the master device synchronizes shifting and sampling of the data on the SIN and SOUT pins. The PCS signals serve as enable signals for the slave devices.

In Master mode, CTAR*n*[CPOL] and CTAR*n*[CPHA] select the polarity and phase of the serial clock, SCK.

- CPOL - Selects the idle state polarity of the SCK
- CPHA - Selects if the data on SOUT is valid before or on the first SCK edge

The module supports two different transfer formats:

- Classic DSPI with CPHA = 0
- Classic DSPI with CPHA = 1

In the interface configurations, the module provides the option of having the PCS signals asserted between frames. See Continuous selection format for details.

77.4.7.1 Classic DSPI transfer format (CPHA = 0)

The transfer format shown in the following figure is used to communicate with peripheral DSPI slave devices where the first data bit is available on the first clock edge. In this format, the master and slave sample their SIN pins on the odd-numbered SCK edges and change the data on their SOUT pins on the even-numbered SCK edges.

NOTE

SPI is used for both DSPI and DSI modes in this diagram.

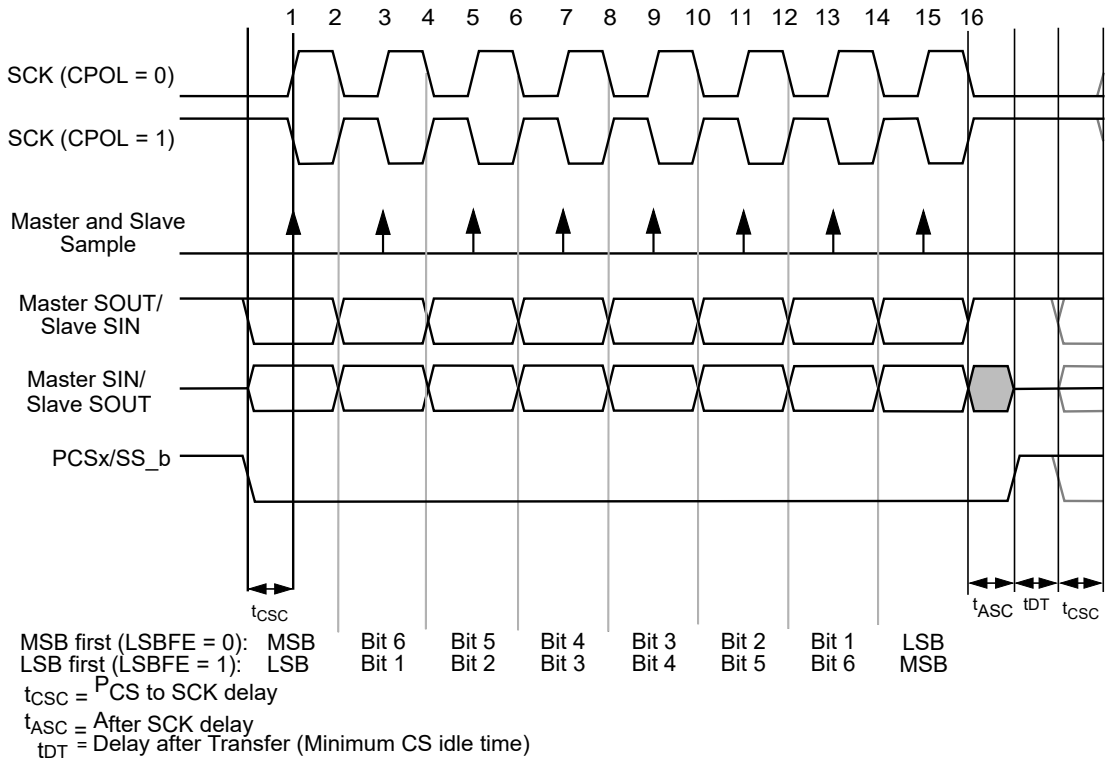

Figure 543. Module transfer timing diagram (CPHA = 0, FMSZ = 8)

The master initiates the transfer by placing its first data bit on the SOUT pin and asserting the appropriate PCS signals to the slave device. The slave responds by placing its first data bit on its SOUT pin. After the t_{CSC} delay elapses, the master outputs the first edge of SCK. The master and slave devices use this edge to sample the first input data bit on their serial data input signals. At the second edge of the SCK, the master and slave devices place their second data bit on their serial data output signals. For the rest of the frame, the master and the slave sample their SIN pins on the odd-numbered clock edges and change the data on their SOUT pins for the even-numbered clock edges. After the last clock edge occurs, a delay of t_{ASC} is inserted before the master negates the PCS signals. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

77.4.7.2 Classic DSPI transfer format (CPHA = 1)

This transfer format shown in the following figure is used to communicate with peripheral DSPI slave devices that require the first SCK edge before the first data bit becomes available on the slave SOUT pin. In this format, the master and slave devices change the data on their SOUT pins on the odd-numbered SCK edges and sample the data on their SIN pins for the even-numbered SCK edges.

NOTE

SPI is used for both DSPI and DSI modes in this diagram.

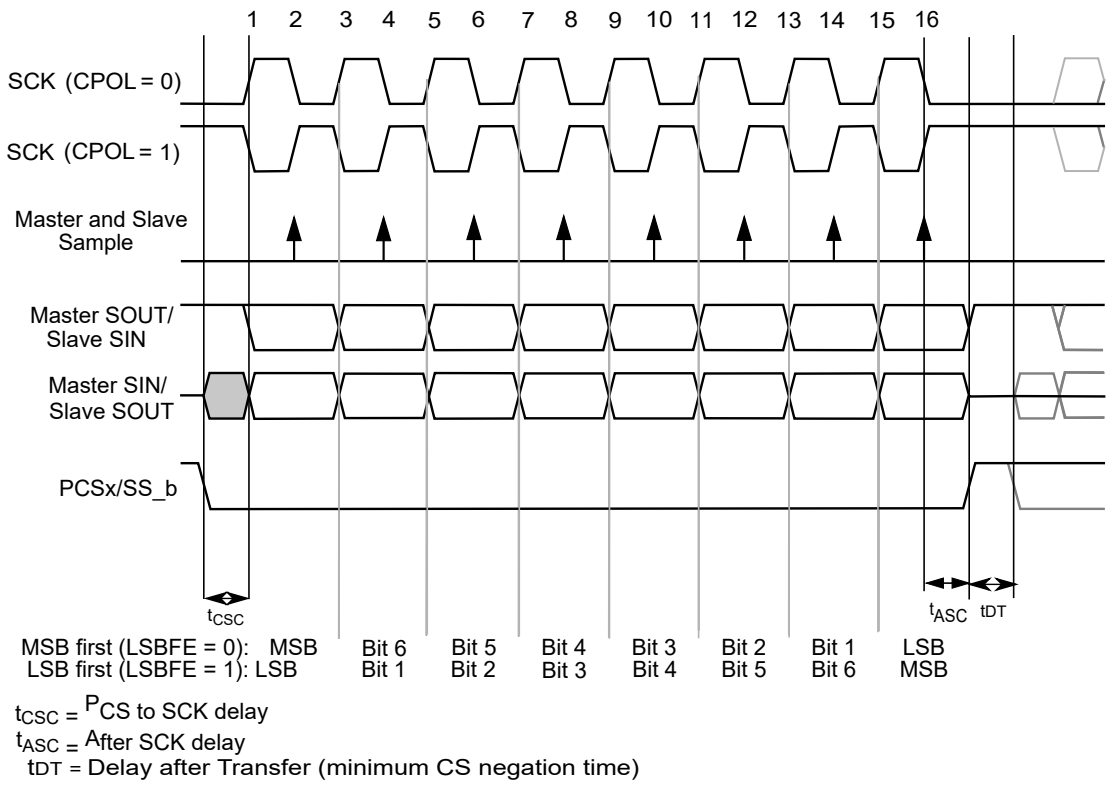

Figure 544. Module transfer timing diagram (CPHA = 1, FMSZ = 8)

The master initiates the transfer by asserting the PCS signal to the slave. After the t_{CSC} delay elapses, the master generates the first SCK edge and at the same time places valid data on the master SOUT pin. The slave responds to the first SCK edge by placing its first data bit on its slave SOUT pin.

At the second edge of the SCK, the master and slave sample their SIN pins. For the rest of the frame, the master and the slave change the data for their SOUT pins on the odd-numbered clock edges and sample their SIN pins on the even-numbered clock edges. After the last clock edge occurs, a delay of t_{ASC} is inserted before the master negates the PCS signal. A delay of t_{DT} is inserted before the master can initiate a new frame transfer.

77.4.7.3 Continuous selection format

Some peripherals must be deselected between every transfer. Other peripherals must remain selected between several sequential serial transfers. The continuous selection format provides the flexibility to handle both the following cases. The format is enabled for the DSPI configuration by setting the CONT bit in the DSPI command. Continuous Selection is enabled for the DSI configuration by setting the DCONT bit in the DSICR0.The behavior of the PCS signals in the two configurations is identical so only SPI configuration will be described.

When the value of CONT is 0, the module drives the asserted Chip Select signals to their idle states in between frames. The idle states of these signals are selected by the PCSIS*n* fields in the MCR. The following figure shows the timing diagram for two 4-bit transfers with CPHA = 1 and CONT = 1.

NOTE

SPI is used for both DSPI Mode and DSI mode in this diagram.

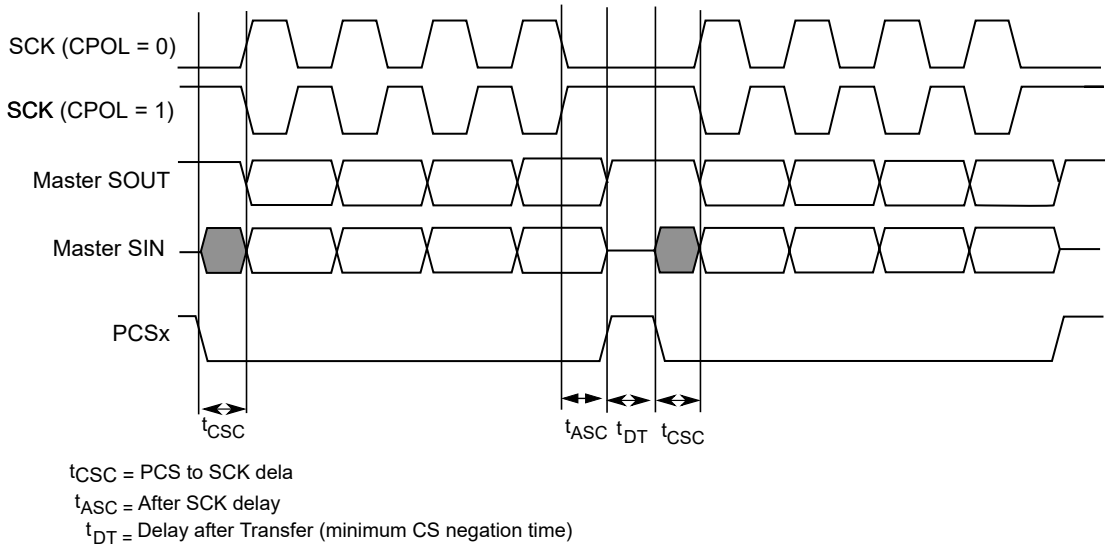

Figure 545. Example of non-continuous format (CPHA=1, CONT=0)

When CONT = 1, the PCS signal remains asserted for the duration of the two transfers. The "Delay between Transfers" (t_{DT}) is not inserted between the transfers. The following figure shows the timing diagram for two 4-bit transfers with CPHA = 1 and CONT = 1.

NOTE

SPI is used for both DSPI Mode and DSI mode in this diagram.

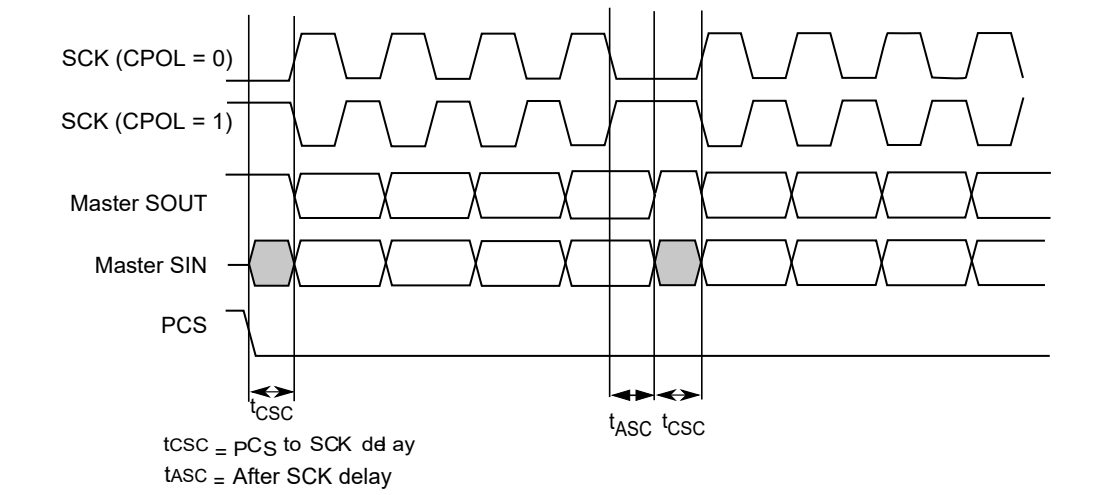

Figure 546. Example of continuous transfer (CPHA=1, CONT=1)

When using the module with continuous selection, follow these rules:

- All transmit commands must have the same PCS*n* field programming.
- The CTARs, selected by transmit commands, must be programmed with the same transfer attributes. Only the FMSZ and LSBFE field can be programmed differently in these CTARs.
- When transmitting multiple frames in this mode, the software must ensure that the last frame has PUSHR[CONT] deasserted in Master mode and the software must provide sufficient frames in the TX_FIFO to be sent out in Slave mode and the master deasserts the PCSn at end of transmission of the last frame.

- PUSHR[CONT] and DSICR0[DCONT] must be deasserted before asserting MCR[HALT] in master mode. This ensures that the PCSn signals are deasserted. Asserting MCR[HALT] during continuous transfer causes the PCSn signals to be in unknown state and hence the slave device cannot transition from Running to Stopped state.

NOTE

You must fill the TX FIFO with the number of entries that are concatenated together under one PCS assertion for both master before the TX FIFO is empty.

77.4.8 Continuous SCK

The module provides the option of generating a Continuous SCK signal for slave peripherals that require a continuous clock.

Continuous SCK is enabled by writing a 1 to MCR[CONT_SCKE]. Enabling this field generates the Continuous SCK only if MCR[HALT] is low. Continuous SCK is valid for all configurations.

Continuous SCK is only supported for CPHA = 1. Clearing CPHA is ignored if the value of the CONT_SCKE field is 1.

Clock and transfer attributes for the Continuous SCK mode are set according to the following rules:

- When the module is in DSPI configuration, CTAR0 is used initially. At the start of each SPI frame transfer, the CTAR specified by the CTAS for the frame is used.
- When the module is in DSI configuration, the CTAR specified by DSICR0[DSICTAS] is used at all times.
- When the module is in CSI configuration, the CTAR selected by the DSICTAS field is used initially.
  - At the start of a DSPI frame transfer, the CTAR specified by the CTAS value for the frame is used.
  - At the start of a DSI frame transfer, the CTAR specified by the DSICTAS field is used.
- In all configurations, the currently selected CTAR remains in use until the start of a frame with a different CTAR specified, or the Continuous SCK mode is terminated.

It is recommended to keep the baud rate the same while using continuous SCK. Switching clock polarity between frames while using continuous SCK can cause errors in the transfer. The Continuous SCK operation is not guaranteed if the module is put into the Module Disable mode.

Enabling continuous SCK disables the PCS to SCK delay, and the Delay after Transfer (t_{DT}) is fixed to one SCK cycle. When TSB configuration is enabled the t_{DT} is programmable from 1 to 64 SCK cycles. The following figure is the timing diagram for the Continuous SCK format with continuous selection disabled.

NOTE

In the Continuous SCK mode, for the DSPI transfer, CTAR0 should always be used and the TX FIFO must be cleared through MCR[CLR_TXF] before initiating a transfer.

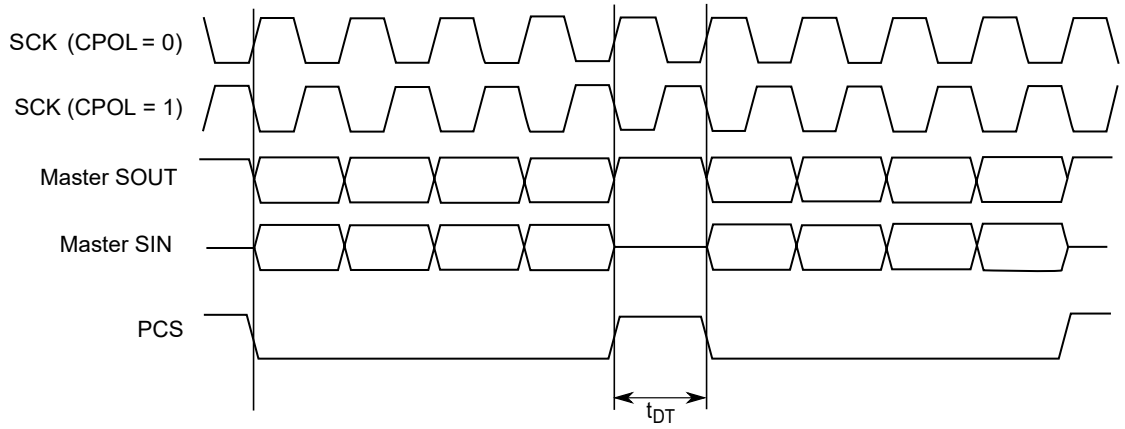

Figure 547. Continuous SCK timing diagram (CONT = 0)

If the CONT bit in the TX FIFO entry is set or the value of DSICR0[DCONT] is 1, PCS remains asserted between the transfers. Under certain conditions, SCK can continue with PCS asserted, but with no data being shifted out of SOUT, which means when SOUT is pulled high. This can cause the slave to receive incorrect data. Those conditions include:

- Continuous SCK with CONT bit set, but no data in the TX FIFO
- Continuous SCK with CONT bit set and entering the Stopped state (see Starting and stopping module transfers)
- Continuous SCK with CONT bit set and entering the Module Disable mode

The following figure shows the timing diagram for the Continuous SCK format with continuous selection enabled.

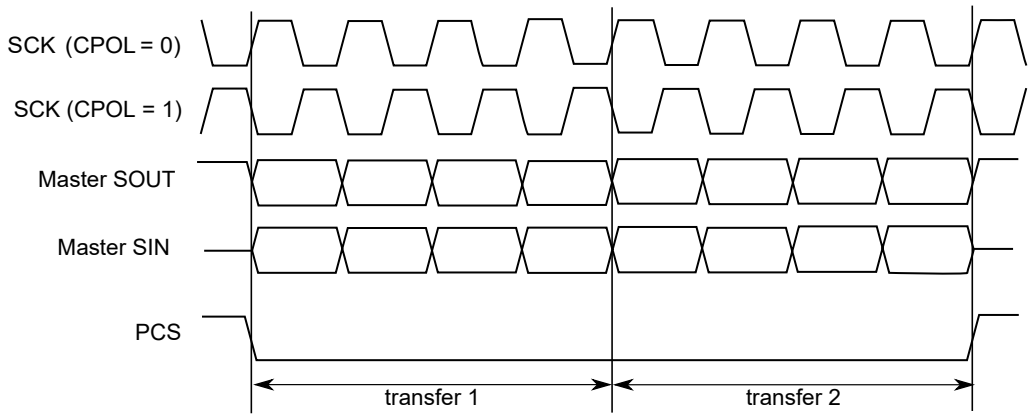

Figure 548. Continuous SCK timing diagram (CONT = 1)

77.4.9 Timed serial bus (TSB)

The DSPI can be programmed in Timed Serial Bus configuration by setting the TSBC bit in the DSI_EXISTSCR0 register. See DSPI DSI Configuration Register 0 (DSI_EXISTSCR0) for details.

TSB configuration provides the Micro Second Channel (MSC) downstream channel support.

The MSC upstream channel is not supported by the DSPI, but can be supported by any available Serial Communication Controller (SCI or UART) in the SoC.

The DSI Continuous Frame Selection Format is not supported by the TSB Mode (DSICR0[DCONT] bit cannot not be asserted).

To work in TSB mode the DSPI must be in master mode and in DSI (DCONF = 0b01) or CSI (DCONF = 0b10) configuration. Both Continuous and Non Continuous Serial Communication Clock (controlled by the DSPI_MCR[CONT_SCKE] bit) are supported in the TSB mode.

The following figure shows the signals used in the TSB interface.

In the TSB configuration the DSPI is able to send from 4 to 66 bits MSC data frames (4 to 64 serialized data bits and up to 2 Data Selection zero bits). The serialized data bits source can be either:

- the DSPI DSI Alternate Serialization Data Register (DSPI_ASDR0/1), written by the host software,
- Parallel Input pin states latched into the DSPI DSI Serialization Data Register (DSPI_SDR0/1).

DSI_EXISTSCR0 TXSS bit or DSPI_SSR0–1 register bits define the source of the data.

The Least Significant Bits of the DSPI_ASDR0 or DSPI_SDR0 registers are selected to be serialized if the data frame is set to less than 32 bits.

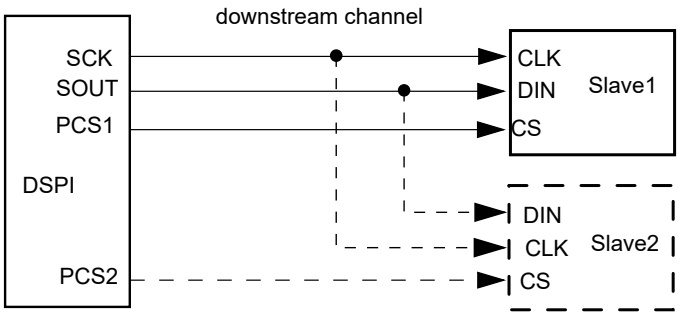

Figure 549. DSPI usage in the TSB Configuration

The PCS signals are driven together with SOUT. The t_{CSC} and t_{ASC} delays are not available. Delay after Transfer (DT) is set in SCK clock periods as a binary number formed by concatenation of the DSPI_CTARn PDT and DT fields plus one, allowing to set DT from 1 to 64 serial clock periods. DT field provides least significant bits and PDT field provides most significant bits of the Delay after Transfer.

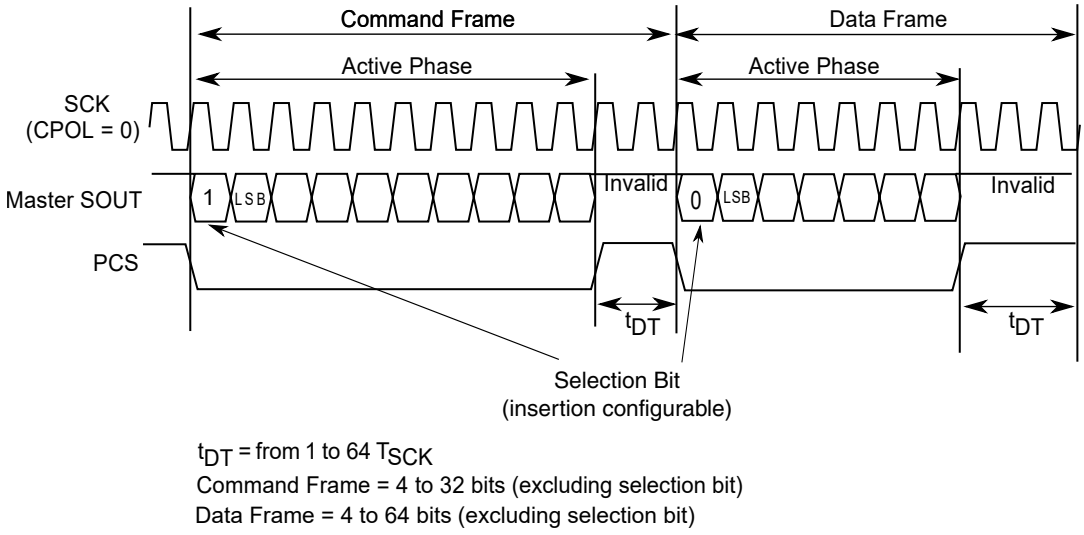

Figure 550. TSB/ITSB Downstream Frames

NOTE

In the above figure, selection bit in the downstream frames may differ in TSB and ITSB modes.

Above figure shows the two types of MSC downstream frames - command frame, and data frame.

The first transmitted bit, called the selection bit, determines the frame type:

- The selection bit "0" indicates a data frame
- The selection bit "1" indicates a command frame

Data frame may contain up to 2 selection bits to support two external slave devices, (so called dual receiver configuration) or no selection bits at all.

The command frame can be written by software, through SPI TX FIFO, using one or two FIFO entries with help of the CONT bit or MCR[XSPI]. The data frame consists of up to 64 bits from the SDR0–1 or ASDR0–1 registers and up to two selection bits (0). Number of data bits in the data frame is defined by the DSCICR1[TSBCNT] field.

The selection bit of the MSC command frames (1) can be implemented by software.

The selection bits in the data frames are enabled by DSI_EXISTSCR1 DSE0 and DSE1 bits. Each DSEn bit set increases the data frame size by one bit.

To comply with MSC specification, set DSPI_CTARn[LSBFE] to transmit least significant bit first.

Regardless the LSBFE bit setting, the Data Frame Selection Bits, if enabled, are always transmitted first, before corresponded data sub frames.

77.4.9.1 MSC dual receiver support with PCS switch over

When in TSB mode it is possible to switch the set of PCS signals that are driven during the first part of the frame to a different set of PCS signals during the second part of the frame. The bit, at which this switch over occurs, is defined by FMSZ field of the DSPI_CTARn register, selected by DSICTAS field of the DSICR0 register. If DSICR1[DSI64E] is enabled, then the bit at which the PCS switch occurs, is defined by the concatenation of {DSICR0[FMSZ4], CTAR[FMSZ]} fields.

Number of the bits, not including the Data Selection Bit, in the first part of the frame is equal to value of the FMSZ field plus one. (This value changes to {FMSZ4,FMSZ} plus one, when DSICR1[DSI64E] is enabled). During this part of the frame the PCS signal levels are controlled by DSI_EXISTSCR0 DPCSn bits, after that by DSI_EXISTSCR1 DPCS1_n bits.

The PCS switch over occurs at driving edge of the SCK clock output.

The second Data Selection Bit is inserted after the PCS switch over if enabled.

Data Frame with PCS switch over is shown in the following figure.

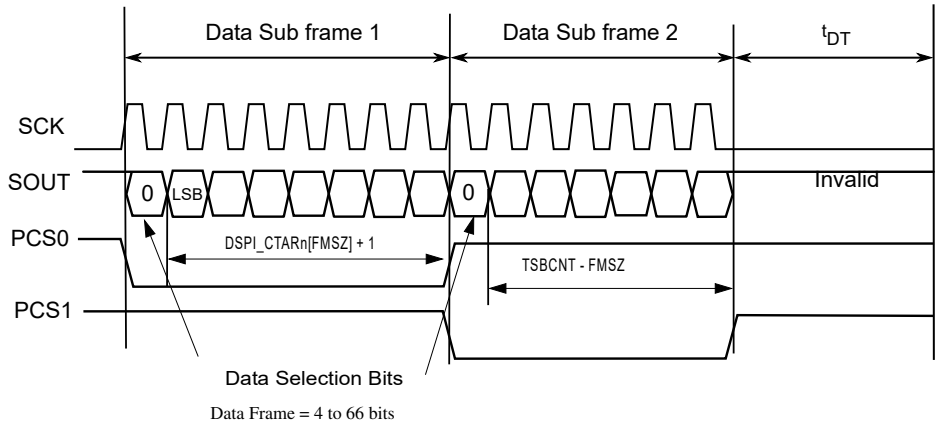

Figure 551. TSB Data Frame Format for MSC Dual Receiver Operation

77.4.10 Interleaved TSB (ITSB) mode

This mode is similar to the TSB mode in some aspects except for the differences mentioned in the table below. The major difference is that the ITSB mode is highly generic in its approach to be compliant with the Downstream operation of the Microsecond Channel Protocol. It includes a triggered time-slot based system with user configurable options for the frames to be transmitted in each time slot. (The time period between any two triggers is known as a time-slot).

The DSPI can be programmed to the ITSB Mode by asserting DSICR0[TSBC], DSICR0[ITSB]. To work in ITSB Mode, the DSPI must be in Master Mode and MCR[DCONF] must be set to CSI mode. (DCONF = 0b10). Both continuous and non-continuous clock serial communication clock (MCR[CONT_SCKE] are supported in this mode.

There are three types of frames which can be transmitted in a time slot i.e. Data Frame, Command Frame and Passive (Idle) frame. Similar to the TSB Mode, SPI frames are used for MSC Command frames, while DSI frames are used for MSC Data frames. A Passive Frame is an Idle frame in which no chip selects are asserted and no data is transmitted. The frame transmission is broadly governed by the following rules:

- Transmission of frames is done on trigger pulses that can be generated internal to the DSPI or externally. This is configured via DSICR0[TRG]. The internal trigger is periodic with a period of 4. Thus there are 4 time-slots which appear periodically in the ITSB mode. The frame rules to be followed during each of the 4 time-slots can be programmed via TS_CONF[TSn] fields.

The length of each time slot can be programmed via TSL[TSx_LEN] fields. The minimum length of a time slot is governed by the following formulae :

— Minimum Length for Time slot X = Frame size of the frame to be transmitted in Time slot X + no. of selection bits, if any + 2 (Inherent time(Delay) changed by baud rate(Fp/n)).

— The above constraint is only true for Data and Command frames. Passive frames do not have a minimum trigger length constraint. The user software shall configure the trigger lengths and trigger source.

- If the previously transmitted frame was a Command (SPI) frame or the TX_FIFO (or CMD FIFO) is empty, the non-passive frame transmitted on a subsequent trigger will not be a command frame.
- If the previously transmitted frame was not a Command (SPI) frame and the TX_FIFO (and CMD FIFO) have sufficient data to allow a SPI frame transmission, the frame transmitted on subsequent trigger can be a Command (SPI) frame.
- A Dual Receiver Frame (DRF) is a single Data (DSI) Frame which is split and transmitted to two different receivers (via occurrence of PCS switchover at the split) - the former part being called DRF1 and the latter part as DRF2 (Dual Receiver Frames 1 & 2). Using TS_CONF[TSn] fields, a time-slot can be programmed to transmit a sole DRF1 or a DRF2 frame. A sole DRF1 frame followed by any other frame is a valid scenario. A DRF2 frame programmed for a time slot is only valid if the immediate previous time-slot was DRF1 - an invalid DRF2 frame, if programmed results in the transmission of a Passive frame (PF).

This mode does not change the way DSI and SPI frame transmissions are done except that ITSB mode interleaves the source (SPI or DSI) with a configurable set of rules based on triggered time-slot system. All features of SPI and DSI mode can be used except for the Continuous Frame Selection format (PUSHR[CONT] and DSICR0[DCONT] bits should not be asserted).

The following table lists the differences between the TSB and ITSB modes:

Table 603. Differences between TSB and ITSB modes

TSB Mode	ITSB Mode
Priority available to frames from SPI. Back to back SPI frames are sent out.	No priority. Messages are interleaved such that there are no back-to-back SPI frames
Selection Bit inserted for DSI frames only. Selection bit for SPI frames is inserted by software.	Selection bit for both DSI and SPI frames inserted automatically. Encoding of selection bit same as TSB mode (0 = DSI; 1 = SPI).
Occasionally triggered transmission (that is trigger is received via hardware trigger input).	Triggered time-slot based transmission (that is frames are transmitted continuously on every trigger).
Gap between frames is configurable. Time between frames is t_{DT} which is configurable from 1 to 64 baud rate clock cycles.	Gap between frames is configurable and can be introduced in any of the two ways - By programming a Passive Frame or by increasing the length of a time-slot. Time t_{DT} is not used in this mode as it can be made part of the trigger period (as passive time).

In both TSB & ITSB mode, separate frame completion interrupts will be available to indicate frame transmission completion from SPI & DSI frames. MSC dual receiver support with PCS switchover is also supported in ITSB mode. See MSC Dual Receiver Support with PCS Switch Over for more details.

The ITSB mode is suitable to implement the Downstream Channel for the MSC Bus because of the above features.

77.4.10.1 Configuring DSPI for ITSB mode

The following steps give the recommended way to initialize the DSPI for the ITSB mode of operation:

- The DSPI should be put in HALT mode (by asserting the MCR[HALT] bit) before programming the registers.
- Set the DSICR0[TSBC] and DSICR0[ITSB] bits. The DSICR0[TRRE] and DSICR0[CID] bits should be cleared. DSICR0[DCONT] and PUSHR[CONT] should not be used in ITSB mode. If DSICR0[ITSB] bit is set without setting DSICR0[TSBC], then the DSPI operates in the Normal Mode depending on MCR[DCONF] bit.

- Configure the Time Slot Length's via TSL register and the frame rules for each time slot via TS_CONF register.
- Based on trigger source requirements, set the values in the DSICR0[TRG] bit.
- Enable frame completion interrupts for either any frame completion (TCF) or separate frame complete (DSITCF and SPITCF) as required by application.
- When remainder configuration of DSPI is complete, clear the MCR[HALT] bit to allow DSPI to start operations.

Once configured and DSPI is brought out of HALT, the ITSB mode shall start sequencing the frames from either DSI or SPI as per the rules mentioned in Interleaved TSB (ITSB) Mode.

77.4.10.2 Variable length time slots

In the Interleaved TSB Mode, the TSL[TSx_LEN] registers are used to configure the time slot length's as required by the application. There are up to 4 time slots named TS0, TS1, TS2 and TS3 respectively, which repeat periodically. To achieve a periodicity less than 4, any time slot length can be programmed as 0 (which eliminates this time slot). The following figures illustrate this concept.

In the figure below, the fields TSL[TSx_LEN] are programmed to be non-zero for x = 0,1,2,3. Hence, the time slots repeat after every 4 trigger pulses as shown.

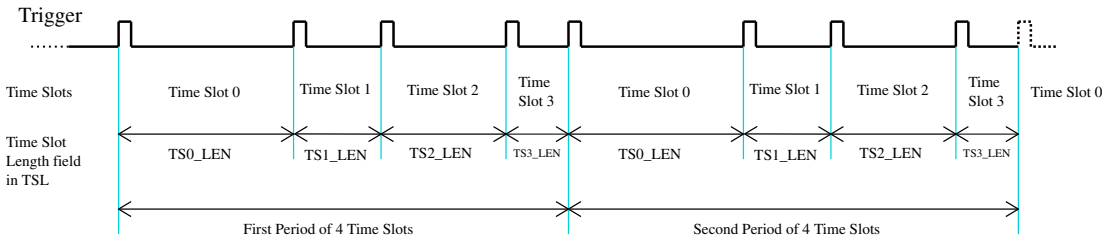

Figure 552. Periodic Time Slots with period = 4

In the figure below, the fields TSL[TSx_LEN] are programmed to be non-zero for x = 0,1,2, while TSL[TS3_LEN] = 0. Hence, the time slots repeat after every 3 trigger pulses as shown.

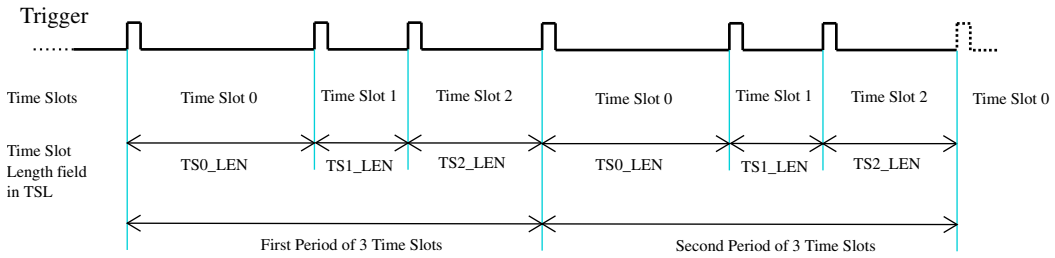

Figure 553. Periodic Time Slots with period = 3

The following figure shows time slots with periodicity of 1. Here the fields TSL[TSx_LEN] are programmed to zero for x = 1,2 and 3 while TSL[TS0_LEN] is non-zero. Hence, the time slots repeat after every trigger as shown.

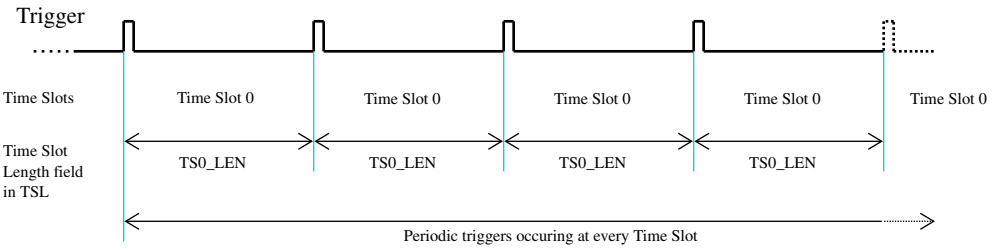

Figure 554. Periodic Time Slots with period = 1

Similarly, any TSL[TSx_LEN] can be made 0 to vary periodicity of time slots, but it is an illegal scenario to have all TSL[TSx_LEN] fields as 0.

NOTE

If external triggering mechanism is enabled (DSICR0[TRG] is set), then it must be ensured that the minimum distance between two trigger pulses is at least 5P, where P is the protocol clock period.

When internal triggering mechanism is enabled (DSICR0[TRG] is zero), the minimum value which can be programmed in the field TSL[TSx_LEN] is given by L = F + 1 + m; where F is the frame size of the frame programmed to be transmitted for the time slot TSx. The variable 'm' equals 1 when maximum baud rate is programmed (i.e. SCK = protocol clock frequency/ 2) and 0 otherwise.

77.4.10.3 Using ITSB mode for MSC downstream channel

MSC Downstream Channel uses three types of frames: command frames, data frames and passive frames. The Downstream operation of these frames require:

- Data frames can be sent back to back.
- Back to back command frames are not a legal scenario.
- Passive frames are used when no activity is desired for any time slot. In a passive frame, chip selects are de-asserted, and no SCK or data is transmitted. For this reason Command Frames cannot be separated by Passive frames as it would still be an illegal scenario.
- In dual MSC ASIC, some bits of the data frame goes to first ASIC and remainder bits to second ASIC. The first part is referred to as DRF1 (Dual Receiver Frame 1) and the second part as DRF2 (Dual Receiver Frame 2).
- A DRF2 programmed for a time slot is only valid if the immediately preceding time slot was DRF1. If DRF2 is valid, it would be transmitted seamlessly after DRF1 without waiting for the trigger pulse for the time slot of DRF2. For that reason, the TSL[TSx_LEN] for DRF1 must be programmed to the minimum possible value. If DRF2 is not valid, a Passive Frame is transmitted instead.

The ITSB mode can help implement the MSC Downstream Channel by allowing the command frames to be sent via the SPI interface and data frames to be sent via the DSI interface. Once the DSPI has been configured to work in ITSB mode the user software can program the DSI and SPI sides to send data and command frames respectively. The programming of frames for transmission via DSI or SPI is same as explained in Combined Serial Interface (CSI) Configuration.

The following figure shows a sample MSC Downstream transmission for the ITSB mode with the following configuration:

- All TSL[LEN] are programmed to be non-zero. Note that the length between triggers are not drawn to scale in the figure. The lengths of all 4 time slots shown are unequal.
- Data and Command selection bits are enabled, i.e. DSICR1[DSE0] and DSICR1[CSE] are set.
- TS_CONF[TS0] = CMD_SRDF
- TS_CONF[TS1] = CMD_SRDF
- TS_CONF[TS2] = CMD_PF
- TS_CONF[TS3] = CMD_SRDF
- PCS0 is used for Data Frames while PCS1 is used for Command Frames. Both chip select's are active low.

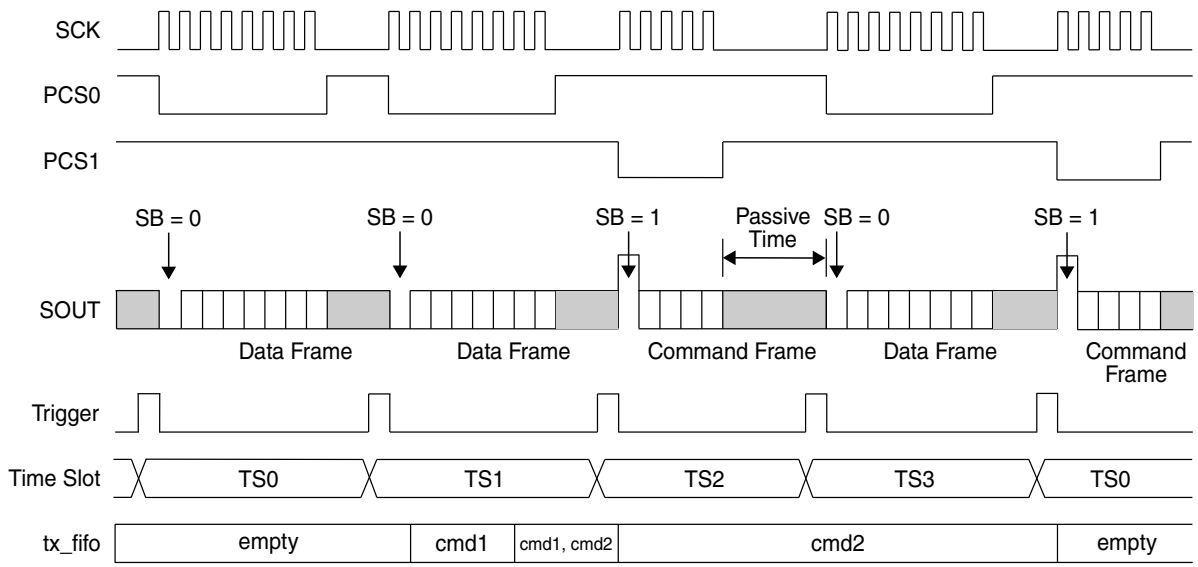

Figure 555. Sample MSC Downstream transmission using ITSB mode

Brief description of operation includes:

- At the first trigger, TS0 is initiated. The frame rule for TS0 is configured as CMD_SRDF (Command if valid, else Single Receiver Data Frame). Since there is no data present in the TXFIFO, a valid command frame is not available to be transmitted. Hence a single receiver data frame is transmitted instead.
- The second trigger initiates TS1. Again a single receiver data frame is transmitted since the frame rule for TS1 is programmed to CMD_SRDF and a command frame is not valid as there is no data present in the TXFIFO when TS1 is initiated.
- During TS1, two frames are pushed into the TX_FIFO.
- At third trigger, TS2 is initiated , the frame rule for which is programmed to CMD_PF (Command if valid. else Passive Frame). A Command frame is transmitted as the TX_FIFO is not empty.
  - Since the frame size of the command frame is less than the trigger length for TS2, no transmission happens till next trigger. This is marked as the “Passive Time”. Such passive time exists in all frames after frame transmission completes and until next trigger pulse is detected.
- For TS3, the frame rule programmed is CMD_SRDF. Since the previous transmission was a command frame, a single receiver data frame is transmitted during TS3.
- The time slot TS0 repeats, and this time a command frame is transmitted during TS0 since the Command Frame is eligible to be transmitted.
- At sixth trigger (not shown), TS1 occurs and the process continues.

The figure below shows another sample MSC Downstream transmission for the ITSB mode with the following configuration:

- All TSL[LEN] are programmed to be non-zero. Note that the length between triggers are not drawn to scale in the figure. The lengths of all 4 time slots shown are unequal.
- Data and Command selection bits are enabled, i.e. DSICR1[DSE0] and DSICR1[CSE] are set.
- TS_CONF[TS0] = CMD_DRF1
- TS_CONF[TS1] = DRF2
- TS_CONF[TS2] = CMD_DRF1
- TS_CONF[TS3] = CMD_DRF2
- PCS0 is used for DRF1 while PCS1 is used for DRF2 or Command Frames. Both chip select's are active low.

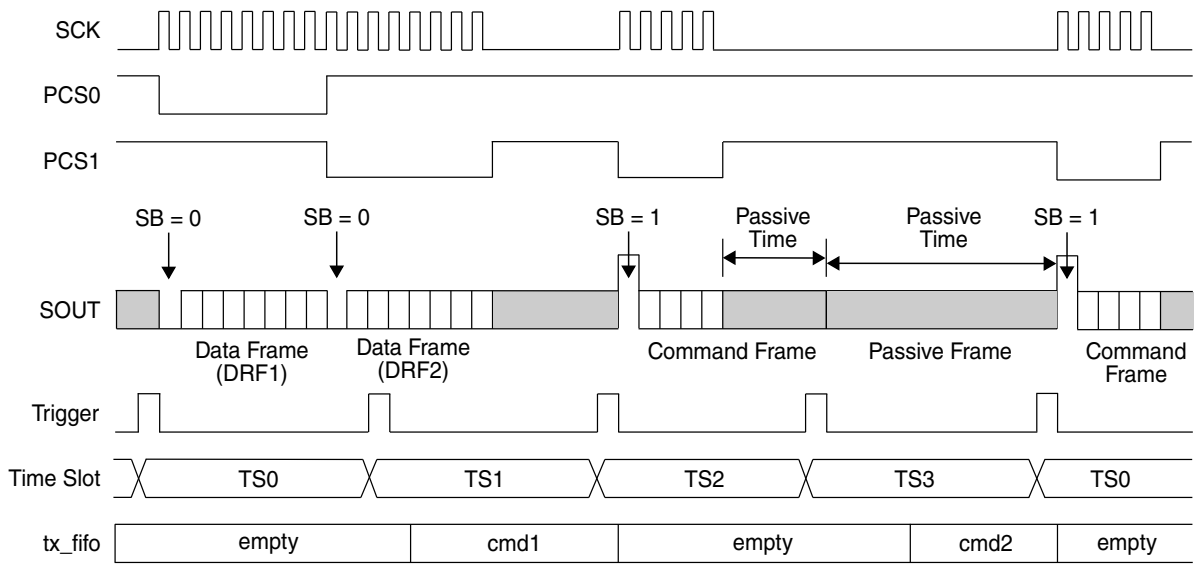

Figure 556. Sample MSC Downstream transmission using ITSB mode

Brief description of operation includes:

- At the first trigger, TS0 is initiated. The frame rule for TS0 is configured as CMD_DRF1 (Command if valid, else Dual Receiver Frame 1). Since there is no data present in the TXFIFO, a valid command frame is not available to be transmitted. Hence DRF1 is selected for transmission. Now it is checked if the next trigger is DRF2 which is true and hence DRF1 and DRF2 are transmitted back-to-back seamlessly with the PCS switch-over occurring in between. Note that this happens independent of the next trigger. If the next trigger were configured to CMD_DRF2 instead, then at the current trigger, the validity of CMD is checked to confirm the presence of DRF2 for next trigger. If presence of DRF2 is confirmed for next trigger, it is transmitted along with DRF1 seamlessly as shown here, otherwise only DRF1 would be transmitted in the current trigger and the CMD frame would be transmitted in the next trigger.
- During TS1, one frame is pushed into the TX_FIFO.
- Since DRF2 is transmitted immediately after DRF1, the occurrence second trigger does not cause any operation. Hence it must be ensured by the user that Trigger Length of TS0 must be programmed to minimum possible value - during which DRF1 can be successfully transmitted. This ensures that trigger for TS1 occurs sometime after the switch-over and not after DRF2 has been transmitted.
- The third trigger initiates TS2, the frame rule for which is configured as CMD_DRF1. A Command frame is transmitted as the data required to transmit a command frame is available (TX_FIFO and CMD_FIFO_DEPTH_PP is not empty) and the previous transmitted frame was not a command frame.
- The fourth trigger initiates TS3, the frame rule for which is configured as CMD_DRF2. Since a CMD frame isn't available and DRF2 is not valid (since DRF1 wasn't transmitted in the previous trigger), a passive frame is transmitted instead.
- The time slot TS0 repeats, and this time a command frame is transmitted during TS0 since the Command Frame is eligible to be transmitted.
- At sixth trigger (not shown), TS1 occurs and the process continues.

NOTE

For a command/data frame to be transmitted on a trigger, they should be available some time before the occurrence of the trigger. A DSI frame must be updated/present "X" time units before the occurrence of the trigger for the time slot in which this data is to be transmitted. This is true for all DSI frames and also implies that when DRF1 and DRF2 are positioned to be transmitted seamlessly, both DRF1 and DRF2 frames must be available 'X' time units before occurrence of trigger pulse for the time slot of DRF1 itself.

Similarly, a command frame must be available "Y" time units before the occurrence of the trigger for the time slot in which this data is to be transmitted.

Here X = 2R + 1P and Y = 1R + 3P; where R = register clock period, P = protocol clock period.

77.4.11 Parity generation and check

The module can generate and check parity in the serial frame. The parity bit replaces the last transmitted bit in the frame. The parity is calculated for all transmitted data bits in frame, not including the last data bit that would be transmitted. The parity generation and control are done on a frame basis. The registers field setting frame size defines the total number of bits in the frame, including the parity bit. Thus, to transmit or receive the same number of data bits with parity check, increase the frame size by one versus the same data size frame without the parity check.

Parity can be selected as odd or even. Parity errors in the received frame set parity error flags in the Status register. The parity error interrupt requests are generated, if enabled. The module can be programmed to stop frame transmission in case of a frame reception with parity error.

77.4.11.1 Parity for SPI frames

When the module is in the master mode the parity generation is controlled by PE and PP bits of the CMD FIFO entries (PUSHR). Setting the PE bit enables parity generation for transmitted DSPI frames and parity check for received frames. The PP bit defines polarity of the parity bit.

When continuous PCS selection is used to transmit DSPI data, two parity generation scenarios are available:

- Generate or check parity for the whole frame
- Generate or check parity for each sub-frame separately

To generate or check parity for the whole frame, set PE bit only in the last command or TX FIFO entry, forming this frame with the PUSHR.

To generate or check parity for each sub-frame, set PE bit in each command or TX FIFO entry, forming this frame.

If the parity error occurs for received DSPI frame, SR[SPEF] is set. If the value of MCR[PES] is 1, the module stops DSPI frames transmission. To resume DSPI operation, clear SR[SPEF] or MCR[PES].

77.4.11.2 Parity for DSI frames

When DSPI is in Master mode, parity generation is controlled by PE and PP bits of the DSI_EXISTSCR0 register similar to the SPI frames. The parity is calculated and checked for each DSI frame. DSI_EXISTSCR0[DCONT] bit has no effect on parity generation. In slave mode the parity is controlled by the PE and PP bits of the CTAR1 register.

If the parity error occurs for received DSI frame, the DSPI_SR[DPEF] bit is set. If DSI_EXISTSCR0[PES] bit is set, the DSPI stops DSI frames transmission. To resume DSI operation clear the DSPI_SR[DPEF] or the DSI_EXISTSCR0[PES] bits.

77.4.12 Clocking

This table describes the clock signals on the boundary of the module:

Table 604. DSPI clocks

Clock	Description
Serial Clock (O)	Supplies a clock signal from the module to DSPI slaves
Serial Clock (I)	Supplies a clock signal to the module from the DSPI master

77.4.13 Interrupts/DMA requests

The module has several conditions that can generate only interrupt requests and three conditions that can generate interrupt or DMA requests. The following table lists these conditions.

Table 605. Interrupt and DMA request conditions

Condition	Flag	Interrupt	DMA
End of Queue (EOQ)	EOQF	Yes	-
TX FIFO Fill	TFFF	Yes	Yes
CMD FIFO Fill	CMDFFF	Yes	Yes
TX FIFO Invalid Write	TFIWF	Yes	-
Transfer Complete	TCF	Yes	-
CMD Transfer Complete	CMDTCF	Yes	-
SPI Transfer Complete	SPITCF	Yes	-
DSI Transfer Complete	DSITCF	Yes	-
RX FIFO Drain	RFDF	Yes	Yes
RX FIFO Overflow	RFOF	Yes	-
SPI Parity Error	SPEF	Yes	-
DSI Parity Error	DPEF	Yes	-
DSI Deserialized Data Match	DDIF	Yes	Yes

Each condition has a corresponding field in the SR and a Request Enable field in the RSER. Certain fields, as shown in the above table, generate interrupt requests or DMA requests depending on the configuration of this register.

The module also provides a global interrupt request line, which is asserted when any of individual interrupt requests lines is asserted.

77.4.13.1 EOQ interrupt request

The EOQ interrupt request indicates that the end of a transmit queue is reached. The module generates the interrupt request when the value of RSER[EOQF_RE] is 1 and the value of the EOQ field in the executing DSPI command is 1.

If the value of MCR[XSPI] is 1 and the value of the EOQ field in the executing SPI command is 1, the module generates the EOQ interrupt request after the last bit of the last data frame in the command cycle is transmitted.

When the value of MCR[XSPI] is 0, the module generates the interrupt request after the last bit of the SPI frame, with the value of EOQ as 1, is transmitted.

77.4.13.2 Transmit FIFO fill interrupt or DMA request

The transmit FIFO fill request indicates that the TX FIFO is not full. This request is generated when the number of entries in the TX FIFO is less than the maximum number of possible entries, and the value of RSER[TFFF_RE] is 1.

RSER[TFFF_DIRS] selects whether a DMA request or an interrupt request is generated.

NOTE

TFFF clears automatically when DMA is used to fill TX FIFO. You must configure the DMA to fill only one FIFO location per transfer.

To clear TFFF when not using DMA, follow these steps for every PUSH performed using CPU to fill TX FIFO:

1. Wait until the value of TFFF is 1.
2. Write data to PUSHR using CPU.
3. Clear TFFF by writing a 1 to its location. If TX FIFO is not full, the flag does not clear.

77.4.13.3 CMD FIFO fill interrupt or DMA request

The CMD FIFO fill request indicates that the CMD FIFO is not full. This request is generated when the number of entries in the CMD FIFO is less than the maximum number of possible entries, and the value of RSER[CMDFFF_RE] is 1. RSER[CMDFFF_DIRS] selects whether a DMA request or an interrupt request is generated.

The request is useful when the value of MCR[XSPI] is 1 because TX FIFO and CMD FIFO can be filled independently. If the value of MCR[XSPI] is 0, the TX FIFO fill interrupt or DMA request suffices to fill both the FIFOs, which must be filled simultaneously.

NOTE

The CMDFFF flag clears automatically when DMA is used to fill CMD FIFO. Configure the DMA to fill only one FIFO location per transfer.

To clear CMDFFF when not using DMA, follow these steps for every PUSH performed using CPU to fill CMD FIFO:

1. Wait until the value of CMDFFF is 1.
2. Write data to PUSHR using CPU.
3. Clear CMDFFF by writing a 1 to its location. If CMD FIFO is not full, this flag does not clear.

77.4.13.4 Transmit FIFO invalid write interrupt request

The transmit FIFO invalid write request is valid only when the value of MCR[XSPI] is 1. This request indicates that data exists in the TX FIFO while the CMD FIFO is empty. Because no command fields are associated with the data present in TX FIFO, this data is considered invalid until a command entry is available. The transmit FIFO invalid write request is generated for this condition when the value of RSER[TFIWF_RE] is 1.

77.4.13.5 Transfer complete interrupt request

The transfer complete request indicates the end of the transfer of a serial frame. This request is generated at the end of each frame transfer when the value of RSER[TCF_RE] is 1.

77.4.13.6 Command transfer complete interrupt request

The command transfer complete request indicates the end of transfer of the last SPI frame in a command cycle. This request is generated when the value of RSER[CMDTCF_RE] is 1.

77.4.13.7 SPI transfer complete interrupt request

The SPI Transfer Complete Request indicates the end of transfer of an DSPI frame in any Transmission Mode which uses DSPI in CSI Mode. The DSPI Transfer Complete Request is generated when SR[SPITCF] flag asserts and SPITCF_RE bit is set in the RSER.

77.4.13.8 DSI transfer complete interrupt request

The DSI Transfer Complete Request indicates the end of transfer of a DSI frame in any Transmission Mode which uses DSPI in CSI Mode. The DSI Transfer Complete Request is generated when SR[DSITCF] flag asserts and DSITCF_RE bit is set in the RSER.

77.4.13.9 Receive FIFO drain interrupt or DMA request

The receive FIFO drain request indicates that the RX FIFO is not empty. This request is generated when the number of entries in the RX FIFO is not 0, and the value of RSER[RFDF_RE] is 1.

RSER[RFDF_DIRS] selects whether a DMA request or an interrupt request is generated. You must configure the DMA to drain only one FIFO location per transfer.

77.4.13.10 Receive FIFO overflow interrupt request

The receive FIFO overflow request indicates that an overflow condition in the RX FIFO has occurred. This request is generated when RX FIFO and the Shift register are full, and a transfer is initiated. The value of RSER[RFOF_RE] must be equal to 1 for the interrupt request to be generated.

Depending on the state of MCR[ROOE], the data from the transfer that generated the overflow is either ignored or shifted to the Shift register. If the value of the ROOE field is 1, the incoming data is shifted in to the Shift register. If the value of the ROOE field is 0, the incoming data is ignored.

77.4.13.11 SPI frame parity error interrupt request

The DSPI Frame Parity Error Flag indicates that a DSPI frame with parity error had been received. The SPEF_RE bit in the RSER must be set for the interrupt request to be generated.

77.4.13.12 DSI frame parity error interrupt request

The DSI Frame Parity Error Flag indicates that a DSI frame with parity error has been received. The DPEF_RE bit in the DSPI_RSER must be set for the interrupt request to be generated.

77.4.13.13 Deserialized data match interrupt or DMA request

The DDIF indicates that a DSI frame matching the data in DPIR0–1, masked with DIMR0–1, had been received.The value of RSER[DDIF_RE] must be 1 for the request to be generated. RSER[DDIF_DIRS] selects whether a DMA request or an interrupt request is generated.

77.4.14 Power saving features

This module supports the following power-saving strategies:

- Module Disable mode: clock gating of non-memory mapped logic

All power-saving features require a logic external to DSPI.

77.4.14.1 Module Disable mode

This is a block-specific mode that the module can enter to save power. The host CPU can initiate the Module Disable mode by writing a 1 to MCR[MDIS]. The hardware can also initiate this mode.

When the value of the MDIS field is 1, the module negates the Clock Enable signal at the next frame boundary. After the Clock Enable signal is negated, it is said to have entered the Module Disable Mode. This also puts the module in the Stopped state. The value of SR[TXRXS] must be 0 to indicate the Stopped state. If implemented, the Clock Enable signal can stop the clock to the non-memory mapped logic. When Clock Enable is negated, the module is in a dormant state, but the memory mapped registers are still accessible. Certain read or write operations have a different effect when the module is in the Module Disable mode. Reading the POPR does not change the state of the RX FIFO. Similarly, writing to the PUSHR does not change the state of the TX FIFO or CMD FIFO. Clearing either of the FIFOs has no effect in the Module Disable mode. Also, changes to MCR[DIS_TXF]

and MCR[DIS_RXF] have no effect in the Module Disable mode. In this mode, all status bits and register flags in the module return the correct values when read, but writing to them has no effect. Also, writing to the TCR during the Module Disable mode has no effect. Interrupt and DMA request signals cannot be cleared in the Module Disable mode.

77.5 Initialization/application information

This section describes how to initialize the module.

77.5.1 How to manage queues

Queues are not a part of this module, but the module includes features to support queue management.

Queues are primarily supported in DSPI configuration, and here are the steps to manage them.

1. When the module executes the last command word from a queue, the EOQ bit in the command word indicates that it is the last entry in the queue.
2. At the end of the transfer, the value of SR[EOQF] is configured as 1.
3. If the value of SR[EOQF] is 1, the field disables serial transmission and reception of data, putting the module in the Stopped state. The value 0 is written to SR[TXRXS] indicating the Stopped state.
4. The DMA can continue to fill TX FIFO until it is full or step 5 occurs.
5. Disable DMA transfers by disabling the DMA enable request for the DMA channel assigned to TX FIFO, CMD FIFO, and RX FIFO. This is done by clearing the corresponding DMA enable request bits in the DMA controller.
6. Ensure that all the received data in RX FIFO has been transferred to the memory receive queue by reading SR[RXCNT] or by checking SR[RFDF] after each read operation of the POPR.
7. Modify the DMA descriptor of TX and RX channels for new queues.
8. Flush TX FIFO and CMD FIFO by writing a 1 to MCR[CLR_TXF] and flushing RX FIFO by writing a 1 to MCR[CLR_RXF].
9. Clear the transfer count either by setting the CTCNT bit in the command word of the first entry in the new queue or via the CPU writing directly to TCR[SPI_TCNT].
10. Enable the DMA channel through the DMA enable request. DMA channels are assigned to modules TX FIFO, CMD FIFO, and RX FIFO. For each module, a separate DMA enable request bit is available.
11. Enable serial transmission and serial reception of data by clearing the EOQF field.

77.5.2 Initializing module in Master mode

After the appropriate mode in MCR[MSTR] is configured, the module is enabled by writing a 0 to MCR[HALT]. The module's slave must be enabled before you enable its master. This ensures that the slave is ready to be communicated with, before the master initializes communication.

77.5.3 Baud rate settings

The following table shows the baud rate that is generated based on the combination of the baud rate prescaler, PBR, and the baud rate scaler, BR, in the CTARs. The values calculated assume a 100 MHz protocol frequency, and the value of the DBR field is 0..

NOTE

The clock frequency provided in this chapter is an example. See the Clocking chapter for details on the frequency used to drive this module in the chip.

Table 606. Baud rate values (bit/s)

		Baud rate divider prescaler values			
		2	3	5	7
Baud rate scaler values	2	25.0M	16.7M	10.0M	7.14M
	4	12.5M	8.33M	5.00M	3.57M
	6	8.33M	5.56M	3.33M	2.38M
	8	6.25M	4.17M	2.50M	1.79M
	16	3.12M	2.08M	1.25M	893k
	32	1.56M	1.04M	625k	446k
	64	781k	521k	312k	223k
	128	391k	260k	156k	112k
	256	195k	130k	78.1k	55.8k
	512	97.7k	65.1k	39.1k	27.9k
	1024	48.8k	32.6k	19.5k	14.0k
	2048	24.4k	16.3k	9.77k	6.98k
	4096	12.2k	8.14k	4.88k	3.49k
	8192	6.10k	4.07k	2.44k	1.74k
	16384	3.05k	2.04k	1.22k	872
	32768	1.53k	1.02k	610	436

77.5.4 Delay settings

The following table shows the values for the Delay after Transfer (t_{DT}) and CS to SCK Delay (T_{CSC}) that can be generated based on the prescaler values and the scaler values set in the CTARs. The values calculated assume a 100 MHz protocol frequency.

NOTE

The clock frequency mentioned in this section is only an example. See the clocking chapter for the frequency used to drive this module in the chip.

This table does not apply for TSB Continuous mode.

Table 607. Delay values

		Delay scaler values (CTAR[PDT])			
		1	3	5	7
Delay scaler values (CTAR[DT])	2	20.0 ns	60.0 ns	100.0 ns	140.0 ns
	4	40.0 ns	120.0 ns	200.0 ns	280.0 ns
	8	80.0 ns	240.0 ns	400.0 ns	560.0 ns
	16	160.0 ns	480.0 ns	800.0 ns	1.1 µs
	32	320.0 ns	960.0 ns	1.6 µs	2.2 µs
	64	640.0 ns	1.9 µs	3.2 µs	4.5 µs
	128	1.3 µs	3.8 µs	6.4 µs	9.0 µs
	256	2.6 µs	7.7 µs	12.8 µs	17.9 µs
	512	5.1 µs	15.4 µs	25.6 µs	35.8 µs
	1024	10.2 µs	30.7 µs	51.2 µs	71.7 µs
	2048	20.5 µs	61.4 µs	102.4 µs	143.4 µs
	4096	41.0 µs	122.9 µs	204.8 µs	286.7 µs
	8192	81.9 µs	245.8 µs	409.6 µs	573.4 µs
	16384	163.8 µs	491.5 µs	819.2 µs	1.1 ms
	32768	327.7 µs	983.0 µs	1.6 ms	2.3 ms
	65536	655.4 µs	2.0 ms	3.3 ms	4.6 ms

77.5.5 Calculation of FIFO pointer addresses

Complete visibility of the FIFO contents is available through the FIFO registers, and valid entries can be identified through a memory-mapped pointer and counter for each FIFO. The pointer to the first-in entry in each FIFO is memory mapped. For the TX FIFO, the first-in pointer is Transmit Next Pointer (TXNXTPTR), and for the CMD FIFO, the first-in pointer is the Command Next Pointer (CMDNXTPTR). For the RX FIFO, the first-in pointer is the Pop Next Pointer (POPNXTPTR). The following figure illustrates the concept of first-in and last-in FIFO entries along with the FIFO counter. The TX FIFO is chosen for illustration, but the concepts carry over. See TX FIFO buffering mechanism, CMD FIFO buffering mechanism, and RX FIFO buffering mechanism for details on the FIFO operation.

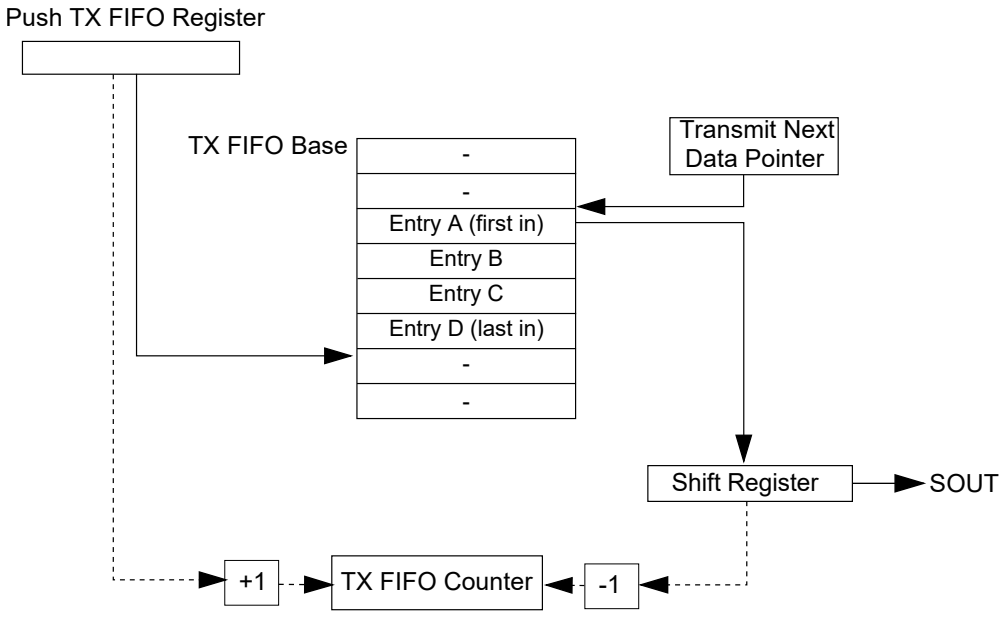

Figure 557. TX FIFO pointers and counter

77.5.5.1 Address calculation for the first-in entry and last-in entry in the TX FIFO

Use the following equation to compute the memory address of the first-in entry in the TX FIFO:

- First-in EntryAddress = TXFIFOBase+[4xTXNXTPTR]

Use the following equation to compute the memory address of the last-in entry in the TX FIFO:

- Last-in EntryAddress = TXFIFOBase+4x[TXCTR+TXNXTPTR - 1]mod[TXFIFOdepth]

Here is an explanation of the different components of these equations:

- TX FIFO base: Base address of TX FIFO
- TXCTR: TX FIFO Counter
- TXNXTPTR: Transmit Next Pointer
- TX FIFO Depth: Transmit FIFO depth, implementation specific

77.5.5.2 Address calculation for the first-in entry and last-in entry in the CMD FIFO

Use the following equation to compute the memory address of the first-in entry in the CMD FIFO:

- First-in EntryAddress = CMDFIFOBase+[4xCMDNXTPTR]

Use the following equation to compute the memory address of the last-in entry in the CMD FIFO:

- Last-in EntryAddress = CMDFIFOBase+4x[CMDCTR+CMDNXTPTR - 1]mod[CMDFIFOdepth]

Here is an explanation of the different components of these equations:

- CMD FIFO Base: Base address of CMD FIFO
- CMDCTR: CMD FIFO Counter
- CMDNXTPTR: Command Next Pointer
- CMD FIFO Depth: Command FIFO depth, implementation specific

77.5.5.3 Address calculation for the first-in entry and last-in entry in the RX FIFO

Use the following equation to compute the memory address of the first-in entry in the RX FIFO:

- First-in EntryAddress = RXFIFOBase+[4xPOPNXTPTR]

Use the following equation to compute the memory address of the last-in entry in the RX FIFO:

- Last-in EntryAddress = RXFIFOBase+4x[RXCTR+POPNXTPTR - 1]mod[RXFIFOdepth]

Here is an explanation of the different components of these equations:

- RX FIFO Base: Base address of RX FIFO
- RXCTR: TX FIFO Counter
- POPNXTPTR: Pop Next Pointer
- RX FIFO Depth: Receive FIFO depth, implementation specific

77.6 DSPI register descriptions

Register accesses to memory addresses that are reserved or undefined result in a transfer error. Any write access to the POPR and RXFR*n* also results in a transfer error. No transfer error will be generated when accessing offset 0x140.

NOTE

While the module is in the running state, do not write to:

- DIMR0, DPIR0, and SSR0
- DIMR1, DPIR1, and SSR1
- CTAREn
- TSL and TS_CONF

77.6.1 DSPI memory map

DSPI_MSC base address: 4050_8000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Module Configuration Register (MCR)	32	RW	8000_4001h
8h	Transfer Count Register (TCR)	32	RW	0000_0000h

77.6.2 Module Configuration Register (MCR)

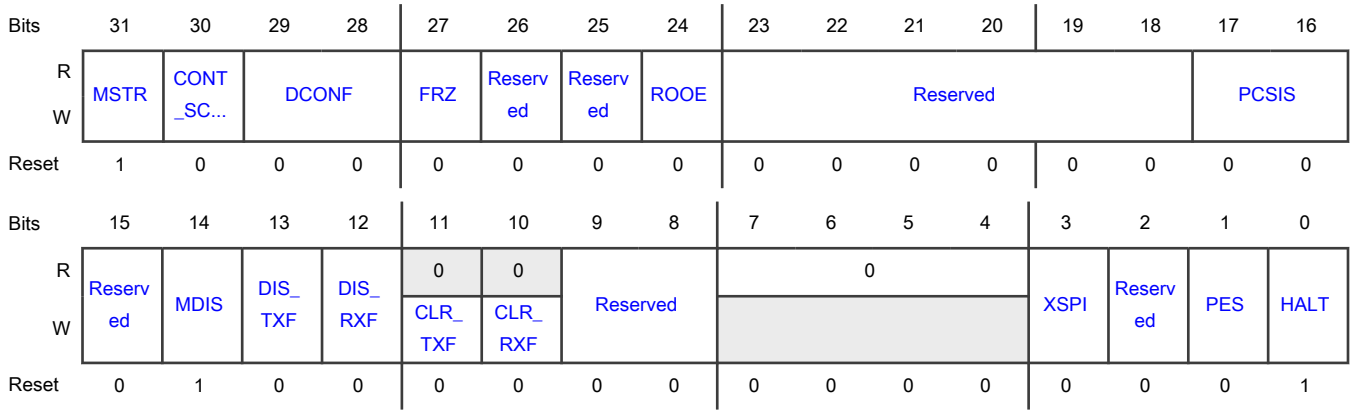
Offset

Register	Offset
MCR	0h

Function

This register includes fields to configure various attributes associated with module operations. The HALT and MDIS fields of this register can be changed any time, but the effect takes place only on the next frame boundary. Also, only these two fields can be changed when the module is in the Running state.

Diagram



Fields

Field	Function
31 MSTR	Master/Slave Mode Select Enables either Master mode (if supported) or Slave mode (if supported) operation 0b - Reserved 1b - Enables Master mode
30 CONT_SCKE	Continuous SCK Enable Enables the SCK to run continuously 0b - Continuous SCK disabled 1b - Continuous SCK enabled
29-28 DCONF	Interface Configuration Selects among the different interface configurations of the module 00b - DSPI 01b - DSI 10b - CSI 11b - Reserved
27 FRZ	Freeze Enables transfers to be stopped on the next frame boundary when the device enters Debug mode. 0b - Do not halt serial transfers in Debug mode. 1b - Halt serial transfers in Debug mode.
26 —	Reserved
25	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
24 ROOE	Receive FIFO Overflow Overwrite Enable In case of RX FIFO overflow, configures the module to ignore the incoming serial data or overwrite existing data. If the RX FIFO is full and new data is received, the data from the transfer, generating the overflow, is ignored or shifted to the Shift register. 0b - Incoming data is ignored. 1b - Incoming data is shifted to the Shift register.
23-18 —	Always write the reset value to this field.
17-16 PCSIS	Peripheral Chip Select x Inactive State Determines the inactive state of PCSx. **NOTE** The effect of this bit only takes place when module is enabled. Ensure that this bit is configured correctly before enabling the DSPI interface. 00b - The inactive state of PCSx is low. 01b - The inactive state of PCS0 is high and for rest of PCSx, it is low.
15 —	Reserved
14 MDIS	Module Disable Allows the clock to be stopped to the non-memory mapped logic in the module, effectively putting it in a software-controlled, power-saving state. The reset value of this field is parametrized with a default reset value of 1. 0b - Enables the module clocks 1b - Allows external logic to disable the module clocks
13 DIS_TXF	Disable Transmit FIFO When the TX FIFO is disabled, the transmit part of the module operates as a simplified, double-buffered DSPI. This field can be written to only when the value of the MDIS field is 0. 0b - TX FIFO is enabled. 1b - TX FIFO is disabled.
12 DIS_RXF	Disable Receive FIFO When the RX FIFO is disabled, the receive part of the module operates as a simplified, double-buffered DSPI. This field can only be written to when the MDIS field is cleared. 0b - RX FIFO is enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - RX FIFO is disabled.
11 CLR_TXF	Clear TX FIFO Flushes the TX FIFO. Writing a 1 to this field clears the TX FIFO counter. The value of this field is always read as 0. 0b - Do not clear the TX FIFO counter. 1b - Clear the TX FIFO counter.
10 CLR_RXF	Clear RX FIFO Flushes the RX FIFO. Writing a 1 to this field clears the RX counter. The value of this field is always read as 0. 0b - Do not clear the RX FIFO counter. 1b - Clear the RX FIFO counter.
9-8 —	Reserved
7-4 —	Reserved
3 XSPI	Extended SPI Mode Enables the usage of CTARE registers that allow you to send up to 32-bit SPI frames. Command cycling is also enabled, and that allows you to send multiple data frames using a single command frame. If MCR[DIS_TXF] is asserted, you cannot use the Extended SPI mode to transmit SPI frames, which are more than 16 bits in size. 0b - Normal SPI mode. Frame size can be up to 16 bits, and command cycling is unavailable in this mode. 1b - Extended SPI mode. Up to 32-bit SPI frames, along with command cycling, are enabled.
2 —	Reserved
1 PES	Parity Error Stop Controls DSPI operation when a parity error is detected in a received DSPI frame. 0b - DSPI frame transmission continues. 1b - DSPI frame transmission stops.
0 HALT	Halt Starts and stops frame transfers. See Start and Stop of Module transfers for details. 0b - Starts transfers. 1b - Stops transfers.

77.6.3 Transfer Count Register (TCR)

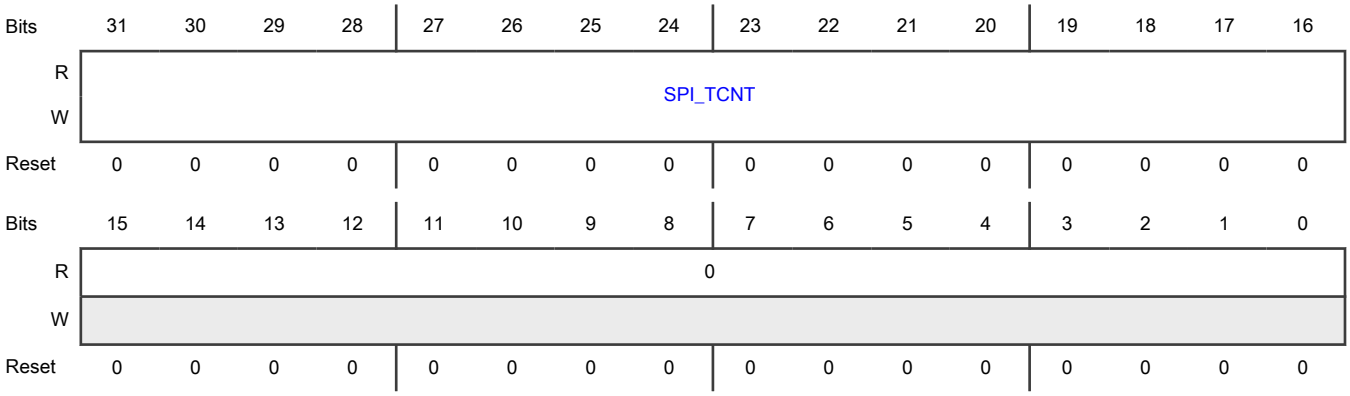
Offset

Register	Offset
TCR	8h

Function

This register includes a counter that indicates the number of DSPI transfers made. The purpose of the transfer counter is to assist with queue management. Do not write to the TCR when the module is in the Running state.

Diagram



Fields

Field	Function
31-16 SPI_TCNT	DSPI Transfer Counter Counts the number of DSPI transfers that the module performs This field increments every time the last bit of a DSPI frame is transmitted, and a value written to this field presets the counter to that value. The field is reset to 0 at the beginning of a frame if the value of PUSHR[CTCNT] is 1. If the counter is not overwritten or cleared, it eventually overflows at value 65535 to 0.
15-0 —	Reserved

77.6.4 Clock and Transfer Attributes Register (In Master Mode) (CTAR0 - CTAR5)

Offset

Register	Offset
CTAR0	Ch

Table continues on the next page...

Table continued from the previous page...

Register	Offset
CTAR1	10h
CTAR2	14h
CTAR3	18h
CTAR4	1Ch
CTAR5	20h

Function

CTARs are used to define different transfer attributes. Do not write to the CTARs when the module is in the Running state, except FMSZ and LSBFE in Continuous Selection Format.

In Master mode, the CTARs define combinations of transfer attributes such as frame size, clock phase and polarity, data bit ordering, baud rate, and various delays.

When the module is configured as a DSPI master, the CTAS field in the command portion of the TX FIFO entry selects which of the CTARs is used.

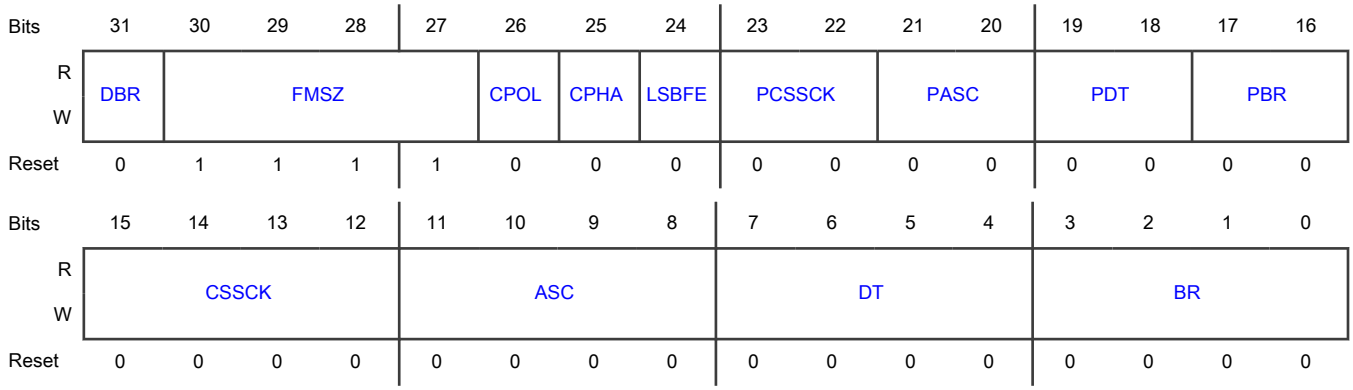
When the module is configured as a DSI master, the DSICTAS field in the DSI Configuration Register 0 (DSICR0), selects which of the CTAR register is used.

In CSI Configuration, the transfer attributes are selected based on whether the current frame is DSPI data or DSI data. DSPI transfers in CSI Configuration follow the protocol described for DSPI Configuration, and DSI transfers in CSI Configuration follow the protocol described for DSI Configuration.CSI Configuration is valid only in conjunction with master mode.

TSB mode sets some limitations on transfer attributes:

- Clock phase is forced to be CPHA = 1 and the CPHA bit setting has no effect.
- PCS lines are driven at the driving edge of the SCK clock together with SOUT, so PCS assertion and negation delays control is unavailable and PCSSCK, PASC, CSSCK and ASC fields have no effect.
- Delay after transfer can be set from 1 to 64 serial clocks with help of PDT and DT fields

Diagram



Fields

Field	Function
31 DBR	Double Baud Rate Doubles the effective baud rate of the Serial Communications Clock (SCK). This field is used only in master mode. It effectively halves the Baud Rate division ratio, supporting faster frequencies, and odd division ratios for the Serial Communications Clock (SCK). If the value of this field is 1, the duty cycle of the SCK depends on the value in the Baud Rate Prescaler and the Clock Phase bit as listed in the following table. See the BR field description for details on how to compute the baud rate.

Table 608. DSPI SCK Duty Cycle

DBR	CPHA	PBR	SCK Duty Cycle
0	any	any	50/50
1	0	00	50/50
1	0	01	33/66
1	0	10	40/60
1	0	11	43/57
1	1	00	50/50
1	1	01	66/33
1	1	10	60/40
1	1	11	57/43

0b - The baud rate is computed normally with a 50/50 duty cycle.

1b - The baud rate is doubled with the duty cycle depending on the Baud Rate Prescaler.

30-27 FMSZ	Frame Size The number of bits transferred per frame is equal to the FMSZ value plus 1. Regardless of the transmission mode, the minimum valid frame size value is 4. When the DSPI operates in TSB mode, the FMSZ field value plus 1 is equal to the data frame bit number, where control of the PCS assertion switches from the DSICR0 to the DSICR1 register. If TSB Mode is operated when DSI is in 64-bit mode, then DSICR0[FMSZ4] also affects the switching of PCS assertion control.
26 CPOL	Clock Polarity Selects the inactive state of the SCK. For successful communication between serial devices, the devices must have identical clock polarities. When the Continuous Selection Format is selected, switching between clock polarities without stopping the module can cause errors in the transfer due to the peripheral device interpreting the switch of clock polarity as a valid clock edge.

NOTE

In case of Continuous SCK mode, when the module goes in low power mode(disabled), inactive state of SCK is not guaranteed.

0b - The inactive state value of SCK is low.

1b - The inactive state value of SCK is high.

Table continues on the next page...

Field	Function
25 CPHA	Clock Phase Selects which edge of SCK causes data to change and which edge causes data to be captured. This field is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode or TSB mode, the field value is ignored and the transfers are done as if the value of this field is set to 1. 0b - Data is captured on the leading edge of SCK and changed on the following edge. 1b - Data is changed on the leading edge of SCK and captured on the following edge.
24 LSBFE	LSB First Specifies whether the LSB or MSB of the frame is transferred first. When the DSPI operates in TSB configuration, this field should be set to be compliant to the MSC specification. 0b - Data is transferred MSB first. 1b - Data is transferred LSB first.
23-22 PCSSCK	PCS to SCK Delay Prescaler Selects the prescaler value for the delay between assertion of PCS and the first edge of the SCK. See the CSSCK field description for information on how to compute the PCS to SCK Delay. See PCS to SCK Delay (t_{CSC}) for more details. In the TSB mode, the PCSSCK field has no effect. 00b - PCS to SCK Prescaler value is 1. 01b - PCS to SCK Prescaler value is 3. 10b - PCS to SCK Prescaler value is 5. 11b - PCS to SCK Prescaler value is 7.
21-20 PASC	After SCK Delay Prescaler Selects the prescaler value for the delay between the last edge of SCK and the negation of PCS. See the ASC field description for information on how to compute the "After SCK Delay". In the TSB mode, the PASC field has no effect. See After SCK Delay (t_{ASC}) for details. 00b - Delay after Transfer Prescaler value is 1. 01b - Delay after Transfer Prescaler value is 3. 10b - Delay after Transfer Prescaler value is 5. 11b - Delay after Transfer Prescaler value is 7.
19-18 PDT	Delay after Transfer Prescaler Selects the prescaler value for the delay between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. The PDT field is only used in master mode. In the TSB mode the PDT field defines two most-significant bits of the "Delay after Transfer". See the DT field description for details on how to compute the "Delay after Transfer". See Delay after Transfer (t_{DT}) for more details. 00b - Delay after Transfer Prescaler value is 1. 01b - Delay after Transfer Prescaler value is 3. 10b - Delay after Transfer Prescaler value is 5. 11b - Delay after Transfer Prescaler value is 7.

Table continues on the next page...

Field	Function
17-16 PBR	Baud Rate Prescaler Selects the prescaler value for the baud rate. This field is used only in master mode. The baud rate is the frequency of the SCK. The protocol clock is divided by the prescaler value before the baud rate selection takes place. See the BR field description for details on how to compute the baud rate. 00b - Baud Rate Prescaler value is 2. 01b - Baud Rate Prescaler value is 3. 10b - Baud Rate Prescaler value is 5. 11b - Baud Rate Prescaler value is 7.
15-12 CSSCK	PCS to SCK Delay Scaler Selects the scaler value for the PCS to SCK delay. This field is used only in Master mode. In the TSB mode, the field has no effect. The PCS to SCK Delay is the delay between the assertion of PCS and the first edge of the SCK. The delay is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{CSC} = (1/f_P) \times PCSSCK \times CSSCK$. The following table lists the delay scaler values.

Table 609. Delay scaler encoding

Field value	Delay scaler value
0000	2
0001	4
0010	8
0011	16
0100	32
0101	64
0110	128
0111	256
1000	512
1001	1024
1010	2048
1011	4096
1100	8192
1101	16384
1110	32768
1111	65536

See PCS to SCK Delay (t_{CSC}) for details.

Table continues on the next page...

Field	Function
11-8 ASC	After SCK Delay Scaler Selects the scaler value for the "After SCK Delay". This field is used only in master mode. The "After SCK Delay" is the delay between the last edge of SCK and the negation of PCS. The delay is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{ASC} = (1/f_P) \times PASC \times ASC$ See Delay Scaler Encoding table in CTARn[CSSCK] field description for scaler values. See After SCK Delay (t_{ASC}) for more details.
7-4 DT	Delay After Transfer Scaler Selects the "Delay after Transfer" Scaler. This field is used only in master mode. The "Delay after Transfer" is the time between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. In the Continuous Serial Communications Clock operation, the DT value is fixed to one SCK clock period, The "Delay after Transfer" is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{DT} = (1/f_P) \times PDT \times DT$ See Delay Scaler Encoding table in CTARn[CSSCK] field description for scaler values. In the TSB mode, the "Delay after Transfer" is equal to a number formed by concatenation of the PDT and DT fields plus 1 of the SCK clock periods. See Delay after Transfer (t_{DT}) for more details.
3-0 BR	Baud Rate Scaler Selects the scaler value for the baud rate. This field is used only in master mode. The prescaled protocol clock is divided by the baud rate scaler to generate the frequency of the SCK. The baud rate is computed according to the following equation: SCK baud rate = (f_P /PBR) x [(1+DBR)/BR] The following table lists the baud rate scaler values.

Table 610. Baud rate scaler

CTARn[BR]	Baud rate scaler value
0000	2
0001	4
0010	6
0011	8
0100	16
0101	32
0110	64
0111	128
1000	256
1001	512
1010	1024

Table continues on the next page...

1110	16384
1111	32768

77.6.5 Status Register (SR)

Offset

Register	Offset
SR	2Ch

Function

This register includes status and flag fields, which reflect the status of the module and indicate the occurrence of events that can generate interrupts or DMA requests. The software can clear the fields of this register by writing a 1, and writing a 0 does not effect the fields. The register may not be writeable in the Module Disable mode because of the use of power-saving mechanisms.

Diagram

Fields

Field	Function
31 TCF	Transfer Complete Flag Indicates that all bits in a frame are shifted out. This field remains set until it is cleared by writing a 1 to it.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Transfer is incomplete. 1b - Transfer is complete.
30 TXRXS	TX and RX Status Reflects the run status of the module 0b - Transmit and receive operations are disabled when the module is in the Stopped state. 1b - Transmit and receive operations are enabled when the module is in the Running state.
29 SPITCF	DSPI Frame Transfer Complete Flag. This bit functions similar to TCF except that this bit is asserted only on DSPI frame transmission completion in the following modes: • CSI • TSB in CSI • ITSB This flag will not be asserted when the module is used in DSPI or DSI Modes. 0b - DSPI frame transfer is not complete. 1b - DSPI frame transfer is complete.
28 EOQF	End of Queue Flag Indicates that the last entry in a queue has been transmitted when the module is in the Master mode. This field is set when the TX FIFO entry has the EOQ bit set in the command halfword and the end of the transfer is reached. The field remains set until cleared by writing a 1 to it, and when it is set, the TXRXS field is automatically cleared. 0b - EOQ is not set in the executing command. 1b - EOQ is set in the executing DSPI command.
27 —	Reserved
26 DSITCF	DSI Frame Transfer Complete Flag. This bit functions similar to TCF except that this bit is asserted only on DSI frame transmission completion in the following modes: • CSI • TSB in CSI • ITSB This flag will not be asserted when the module is in SPI or DSI mode. 0b - DSI frame transfer is not complete. 1b - DSI frame transfer is complete.

Table continues on the next page...

Table continued from the previous page...

Field	Function
25 TFFF	Transmit FIFO Fill Flag Indicates whether there is an available location to be filled in the FIFO. Either DMA or an interrupt can be used to add another entry to the FIFO. Note that this field is set if at least one location is free in the FIFO. The field can be cleared if the value 1 is written to it or by acknowledgement from the DMA controller to the TX FIFO full request, when the TX FIFO is full. If FIFO is filled manually, and not by DMA, see Transmit FIFO fill interrupt or DMA request. **NOTE** The reset value of this field is 0 when the module is disabled (MCR[MDIS] = 1). 0b - TX FIFO is full. 1b - TX FIFO is not full.
24 BSYF	Busy Flag Indicates that the current command frame is being used for transmitting multiple data frames. The value of this field is valid only when the value of MCR[XSPI] is 1, and the field is not set for the last data frame of a cyclic command transfer or when the value of CTARE[DTCP] is 1. See CMD FIFO buffering mechanism for details. 0b - No cyclic command transfer is in progress. 1b - Cyclic command transfer is in progress. Current data frame is not the last data frame for on-going cyclic command transfer.
23 CMDTCF	Command Transfer Complete Flag Indicates that the last data frame for the current cyclic command has been transmitted. Therefore, this field is set only for the last data frame of a cyclic command transfer or when the value of CTARE[DTCP] is 1. The field remains set until it is cleared by writing a 1 to it. 0b - Data transfer by current command is incomplete. 1b - Data transfer by current command is complete.
22 DPEF	DSI Parity Error Flag Indicates that a DSI frame with parity error had been received. The field remains set until it is cleared by writing a 1 to it. 0b - No parity error. 1b - Parity error has occurred.
21 SPEF	DSPI Parity Error Flag Indicates that a DSPI frame with parity error had been received. The field remains set until it is cleared by writing a 1 to it. 0b - No parity error. 1b - Parity error has occurred.
20	DSI Data Received with Active Fields

Table continues on the next page...

Table continued from the previous page...

Field	Function
DDIF	Indicates that a DSI frame had been received with bits selected by DIMR with active polarity, defined by DPIR. The field remains set until it is cleared by writing a 1 to it. 0b - No DSI data with active bits was received. 1b - DSI data with active bits was received.
19 RFOF	Receive FIFO Overflow Flag Indicates an overflow condition in the RX FIFO. The field is set when the RX FIFO and the Shift register are full and a transfer is initiated. The field remains set until it is cleared by writing a 1 to it. 0b - No RX FIFO overflow occurred. 1b - RX FIFO overflow has occurred.
18 TFIWF	Transmit FIFO Invalid Write Flag Indicates data write on TX FIFO when CMD FIFO is empty. Without a command, the data entries present in TX FIFO are invalid. This field remains set until it is cleared by writing a 1 to it. 0b - No invalid data is present in TX FIFO. 1b - Invalid data is present in TX FIFO because CMD FIFO is empty.
17 RFDF	Receive FIFO Drain Flag Indicates whether there is an available location to be drained from the FIFO. Either DMA or an interrupt can be used to read from the FIFO. Note that this field is set if at least one location can be read from the FIFO. The field can be cleared by writing a 1 to it or by acknowledgement from the DMA controller when the RX FIFO is empty. 0b - RX FIFO is empty. 1b - RX FIFO is not empty.
16 CMDFFF	Command FIFO Fill Flag Indicates whether there is an available location to be filled in the FIFO. Either a DMA request or an interrupt indication can be used to add another entry to the FIFO. Note that this bit is set if at least one location is free in the FIFO. The CMDFFF is cleared by writing a '1' to it or by acknowledgement from the DMA controller to the CMD FIFO full request. **NOTE** The reset value of this field is 0 when the module is disabled (MCR[MDIS] = 1). 0b - CMD FIFO is full. 1b - CMD FIFO is not full.
15-12 TXCTR	TX FIFO Counter Indicates the number of valid entries in the TX FIFO. This field increments every time the PUSHR is written and decrements every time DSPI command is executed and the DSPI data is transferred to the Shift register.
11-8	Transmit Next Pointer

Table continues on the next page...

Table continued from the previous page...

Field	Function
TXNXTPTR	Indicates which TX FIFO entry is transmitted during the next transfer. This field updates every time DSPI data is transferred from the TX FIFO to the Shift register. **NOTE** If TX FIFO is cleared by writing 1 to MCR[CLR_TXF], the value of the TXNXTPTR field does not change immediately to 0. Only when the next transfer starts, the field reflects the latest value, TXNXTPTR = 1.
7-4 RXCTR	RX FIFO Counter Indicates the number of entries in the RX FIFO. This field decrements every time the POPR is read and increments every time data is transferred from the Shift register to the RX FIFO.
3-0 POPNXTPTR	Pop Next Pointer Contains a pointer to the RX FIFO entry to be returned when the POPR is read. This field is updated when the POPR is read.

77.6.6 DMA/Interrupt Request Select and Enable Register (RSER)

Offset

Register	Offset
RSER	30h

Function

This register controls DMA and interrupt requests. Do not write to the register when the module is in the Running state.

Diagram

Fields

Field	Function
31 TCF_RE	Transmission Complete Request Enable Enables SR[TCF] to generate an interrupt request 0b - TCF interrupt requests are disabled. 1b - TCF interrupt requests are enabled.
30 CMDFFF_RE	Command FIFO Fill Flag Request Enable Enables SR[CMDFFF] to generate a request. The CMDFFF_DIRS field of this register selects between generating an interrupt request or a DMA request. 0b - CMDFFF interrupts or DMA requests are disabled. 1b - CMDFFF interrupts or DMA requests are enabled.
29 SPITCF_RE	DSPI Frame Transmission Complete Request Enable. The SPITCF_RE bit enables SPITCF flag in the SR to generate an interrupt request. 0b - SPITCF interrupt requests are disabled. 1b - SPITCF interrupt requests are enabled.
28 EOQF_RE	Finished Request Enable Enables SR[EOQF] to generate an interrupt request 0b - EOQF interrupt requests are disabled. 1b - EOQF interrupt requests are enabled.
27 —	Reserved
26 DSITCF_RE	DSI Frame Transmission Complete Request Enable. The DSITCF_RE bit enables DSITCF flag in the SR to generate an interrupt request. 0b - DSITCF interrupt requests are disabled. 1b - DSITCF interrupt requests are enabled.
25 TFFF_RE	Transmit FIFO Fill Request Enable Enables SR[TFFF] to generate a request. The TFFF_DIRS field of this register selects between generating an interrupt request or a DMA request. 0b - TFFF interrupts or DMA requests are disabled. 1b - TFFF interrupts or DMA requests are enabled.
24 TFFF_DIRS	Transmit FIFO Fill DMA or Interrupt Request Select Selects between generating a DMA request or an interrupt request. When SR[TFFF] and RSER[TFFF_RE] are set, this field selects between generating an interrupt request or a DMA request. 0b - TFFF flag generates interrupt requests.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - TFFF flag generates DMA requests.
23 CMDTCF_RE	Command Transmission Complete Request Enable Enables SR[CMDTCF] to generate an interrupt request 0b - CMDTCF interrupt requests are disabled. 1b - CMDTCF interrupt requests are enabled.
22 DPEF_RE	DSI Parity Error Request Enable Enables the DPEF flag in the SR to generate an interrupt request. 0b - DPEF interrupt requests are disabled. 1b - DPEF interrupt requests are enabled.
21 SPEF_RE	DSPI Parity Error Request Enable Enables the SPEF flag in the SR to generate an interrupt request. 0b - SPEF interrupt requests are disabled. 1b - SPEF interrupt requests are enabled.
20 DDIF_RE	DSI Data Received (with active bits request enable) Enables SR[DDIF] to generate an interrupt or DMA request. 0b - Disabled 1b - Enabled
19 RFOF_RE	Receive FIFO Overflow Request Enable Enables SR[RFOF] to generate an interrupt request 0b - RFOF interrupt requests are disabled. 1b - RFOF interrupt requests are enabled.
18 TFIWF_RE	Transmit FIFO Invalid Write Request Enable Enables SR[TFIWF] to generate an interrupt request 0b - TFIWF interrupt requests are disabled. 1b - TFIWF interrupt requests are enabled.
17 RFDF_RE	Receive FIFO Drain Request Enable Enables SR[RFDF] to generate a request. The RFDF_DIRS field of this register selects between generating an interrupt request or a DMA request. 0b - RFDF interrupt or DMA requests are disabled. 1b - RFDF interrupt or DMA requests are enabled.
16	Receive FIFO Drain DMA or Interrupt Request Select

Table continues on the next page...

Table continued from the previous page...

Field	Function
RFDF_DIRS	Selects between generating a DMA request or an interrupt request. If SR[RFDF] is set, and the value of the RFDF_RE field in this register is 1, the RFDF_DIRS field selects between generating an interrupt request or a DMA request. 0b - Interrupt request 1b - DMA request
15 CMDFFF_DIRS	Command FIFO Fill DMA or Interrupt Request Select Selects between generating a DMA request or an interrupt request. When SR[CMDFFF] is set, and the value of the CMDFFF_RE field in this register is 1, the CMDFFF_DIRS field selects between generating an interrupt request or a DMA request. 0b - CMDFFF flag generates interrupt requests. 1b - CMDFFF flag generates DMA requests.
14 DDIF_DIRS	DSI Data Received (with active bits, DMA, or interrupt request select) Selects between generating a DMA request or an interrupt request. When SR[DDIF] is set, and the value of the DDIF_RE field in this register is 1, the DDIF_DIRS field selects between generating an interrupt request or a DMA request. 0b - Interrupt request 1b - DMA request
13-0 —	Reserved

77.6.7 PUSH TX FIFO Register In Master Mode (PUSHR)

Offset

Register	Offset
PUSHR	34h

Function

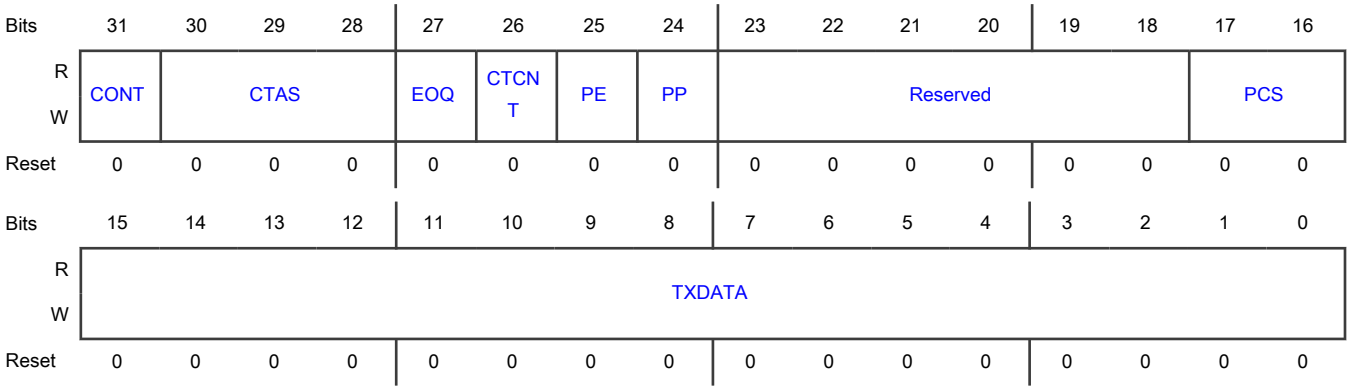
Specifies data to be transferred to the TX FIFO and CMD FIFO. You must write 16 bits of data into the TXDATA field. An 8- or 16-bit write access to the TXDATA field transfers 16 bits of data bus to the TX FIFO. A write access to the command fields transfers the 16 bits of command information to the CMD FIFO. In Master mode, the register transfers 16 bits of data to the TX FIFO and 16 bits of command information to the CMD FIFO.

If Extended SPI Mode is disabled (MCR[XSPI]), the TX FIFO and CMD FIFO must be filled simultaneously. In other words, you must perform write accesses to both the data and command fields for every PUSHR operation. With Extended SPI Mode disabled and both the TX FIFO and CMD FIFO are written to and read from simultaneously, they behave as a single 32 bit FIFO. When Extended SPI mode is enabled (MCR[XSPI]), the TX FIFO and CMD FIFO can be written to independently.

A read access of PUSHR returns the topmost TX FIFO and CMD FIFO entries concatenated.

When the module is disabled, writing to this register does not update the FIFO. Therefore, any reads performed while the module is disabled return the last PUSHR write performed while the module was still enabled.

Diagram



Fields

Field	Function
31 CONT	Continuous Peripheral Chip Select Enable Selects a continuous selection format. The bit is used in DSPI Master mode. The bit enables the selected PCS signals to remain asserted between transfers. 0b - Return PCSn signals to their inactive state between transfers. 1b - Keep PCSn signals asserted between transfers.
30-28 CTAS	Clock and Transfer Attributes Select Selects which CTAR to use in master mode to specify the transfer attributes for the associated DSPI frame. See the chip specific section for details to determine how many CTARs this device has. You should not program a value in this field for a register that is not present. 000b - CTAR0 001b - CTAR1 010b - CTAR2 011b - CTAR3 100b - CTAR4 101b - CTAR5 110b - Reserved 111b - Reserved
27 EOQ	End Of Queue Host software uses this bit to signal to the module that the current DSPI transfer is the last in a queue. At the end of the transfer, the EOQF bit in the SR is set. 0b - The DSPI data is not the last data to transfer. 1b - The DSPI data is the last data to transfer.
26	Clear Transfer Counter

Table continues on the next page...

Table continued from the previous page...

Field	Function
CTCNT	Clears the TCNT field in the TCR register. The TCNT field is cleared before the module starts transmitting the current DSPI frame. 0b - Do not clear the TCR[TCNT] field. 1b - Clear the TCR[TCNT] field.
25 PE	Parity Enable Enables parity bit transmission and parity reception check for the DSPI frame. 0b - No parity bit included/checked. 1b - Parity bit is transmitted instead of the last data bit in the frame; parity is checked for the received frame.
24 PP	Parity Polarity Controls the polarity of the parity bit transmitted and checked. 0b - Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. 1b - Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame.
23-18 —	Always write the reset value to this field.
17-16 PCS	PCS Select which PCS signals are to be asserted for the transfer. 00b - Negate the PCS[x] signal. 01b - Assert the PCS[x] signal.
15-0 TXDATA	Transmit Data Holds SPI data to be transferred according to the associated DSPI command.

77.6.8 POP RX FIFO Register (POPR)

Offset

Register	Offset
POPR	38h

Function

This register is used to read the RX FIFO. An 8- or 16-bit access to the register has the same effect on the RX FIFO as 32-bit read accesses. A write to this register generates a transfer error.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 RXDATA	Received Data Contains the DSPI data from the RX FIFO entry to which the pop next data pointer points

77.6.9 Transmit FIFO Registers (TXFR0 - TXFR15)

Offset

For a = 0 to 15:

Register	Offset
TXFRa	3Ch + (a × 4h)

Function

These registers provide visibility into the TX FIFO for debugging purposes. Each register is an entry in the TX FIFO. The registers can only be read and not modified. Reading the TXFR*x* registers does not alter the state of the TX FIFO. Also, reading these registers is invalid if the module is operating in the Extended SPI mode.

Diagram

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 TXCMD_TXDATA	Transmit Command or Transmit Data In Master mode the TXCMD field contains the command that sets the transfer attributes for the DSPI data.
15-0 TXDATA	Transmit Data Contains the DSPI data to be shifted out

77.6.10 Receive FIFO Registers (RXFR0 - RXFR15)

Offset

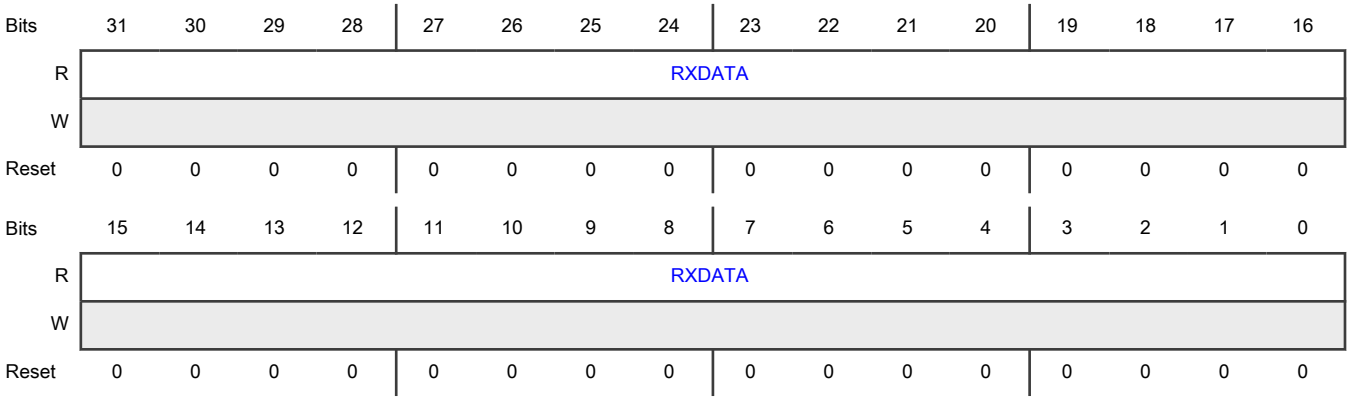
For a = 0 to 15:

Register	Offset
RXFRa	7Ch + (a × 4h)

Function

These read-only registers provide visibility into the RX FIFO for debugging purposes. Each register is an entry in the RX FIFO. Reading the RXFR*x* registers does not alter the state of the RX FIFO. However, the value of MCR[MDIS] must be 0 when RXFR is read.

Diagram



Fields

Field	Function
31-0 RXDATA	Receive Data Contains the received SPI data

77.6.11 DSI Configuration Register 0 (DSICR0)

Offset

Register	Offset
DSICR0	BCh

Function

This register selects various attributes associated with the following configurations:

- DSI
- TSB
- ITSB

NOTE

Do not write to this register while the module is in the Running state.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31 —	Reserved
30 FMSZ4	MSB of Frame Size in Master Mode If 1 is the value of this field, 16 is added to the frame size, as defined by CTAR*n*[FMSZ]. The DSICTAS field of this register selects the CTAR*n* register.
29-24 —	Reserved
23 FMSZ5	MSB of Frame Size in Master Mode (when DSI is used in 64-bit mode)

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If 1 is the value of this field, 32 is added to the frame size, as defined by the concatenation of {DSICR0[FMSZ[4]], CTARn[FMSZ]} fields. The DSICTAS field in this register selects the CTAR*n* register. Hence, the final concatenated frame size is {DSICR0[FMSZ[5]], DSICR0[FMSZ[4]] , CTARn[FMSZ]}. This field is only valid when the value of DSICR1[DSI64E] is 1.
22 TRG	Trigger Source for Interleaved TSB mode. This bit decides the source for trigger. 0b - Internal Trigger - Trigger is generated internal to IP. 1b - External Trigger - Trigger is generated external to IP at chip level.
21 ITSB	Interleaved TSB mode. This bit enables the Interleaved TSB mode of operation. When enabled, there is no priority among frames from the SPI/DSI. DSI frames are always sent when either the previous transmission was a DSPI frame or if the TX_FIFO is empty. Frames are transmitted on every trigger whose source is selected by the TRG bit setting. The ITSB mode requires the DSICR0[TSBC] bit to be set and should be written only when MCR[HALT] bit is asserted. If ITSB bit is set without setting DSICR0[TSBC], then the module operates in the Normal Mode depending on MCR[DCONF] bit. See Interleaved TSB (ITSB) Mode for more details. 0b - Interleaved mode is disabled. 1b - Interleaved mode is enabled.
20 TSBC	Timed Serial Bus Configuration. Enables the Timed Serial Bus interface configuration and allows t_{DT} to be programmable. 0b - Timed Serial Bus Configuration disabled. 1b - Timed Serial Bus Configuration enabled.
19 TXSS	Transmit Data Source Select Selects the source of data to be serialized. The source can be either data from the host software, written to the ASDR0/1, or parallel input pin states latched into the SDR0/1. 0b - Source of serialized data is the SDR. 1b - Source of serialized data is the ASDR.
18 TPOL	Trigger Polarity Selects the active edge of the hardware trigger input signal, initiating DSI frames transfer 0b - Falling edge initiates a transfer. 1b - Rising edge initiates a transfer.
17 TRRE	Trigger Reception Enable Enables the module to initiate a DSI frames transfer with an hardware trigger signal. 0b - Trigger signal reception is disabled. 1b - Trigger signal reception is enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
16 CID	Change In Data Transfer Enable Enables a change in serialization data to initiate a DSI frames transfer in DSI and CSI configurations. If the value of this field is 1, DSI frames are initiated when the current DSI data differs from the previous DSI data shifted out.
15 DCONT	DSI Continuous Peripheral Chip Select Enable Enables the PCS signals to remain asserted between transfers. This field affects PCS signals only in the DSI Master mode. When the TSBC bit is set, DCONT has no effect. 0b - Return PCS signals to their inactive state after the transfer is complete. 1b - Keep PCS signals asserted after the transfer is complete.
14-12 DSICTAS	DSI Clock and Transfer Attributes Select Selects the CTAR register to provide transfer attributes for DSI frames. This field is used in the DSI Master mode. In the DSI Slave mode, CTAR1 is always selected.
11 DMS	Data Match Stop If the value of this field is 1, it stops DSI frame transmissions when SR[DDIF] is set. 0b - DDIF flag does not have an effect on DSI frame transmissions. 1b - DDIF flag stops DSI frame transmissions.
10 PES	Parity Error Stop If set, stops DSI operation if the parity error happened in the received DSI frame. 0b - Parity error does not stop DSI frame transmissions. 1b - Parity error stops all DSI frame transmissions.
9 PE	Parity Enable Enables parity bit transmission and parity reception check for the DSI frames. 0b - No parity bit included/checked. 1b - Parity bit is transmitted instead of the last data bit in the frame; parity is checked for the received frame.
8 PP	Parity Polarity Controls the polarity of the parity bit transmitted and checked. 0b - Even Parity: the number of 1 bits in the transmitted frame is even. The SR[DPEF] bit is set if in the received frame number of 1 bits is odd. 1b - Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[DPEF] bit is set if in the received frame number of 1 bits is even.
7-0 DPCSx	DSI Peripheral Chip Select 0–7 Selects which of the PCS signals to assert during a DSI master mode transfer

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0000_0000b - Negate PCS[x] 0000_0001b - Assert PCS[x]

77.6.12 DSI Serialization Data Register 0 (SDR0)

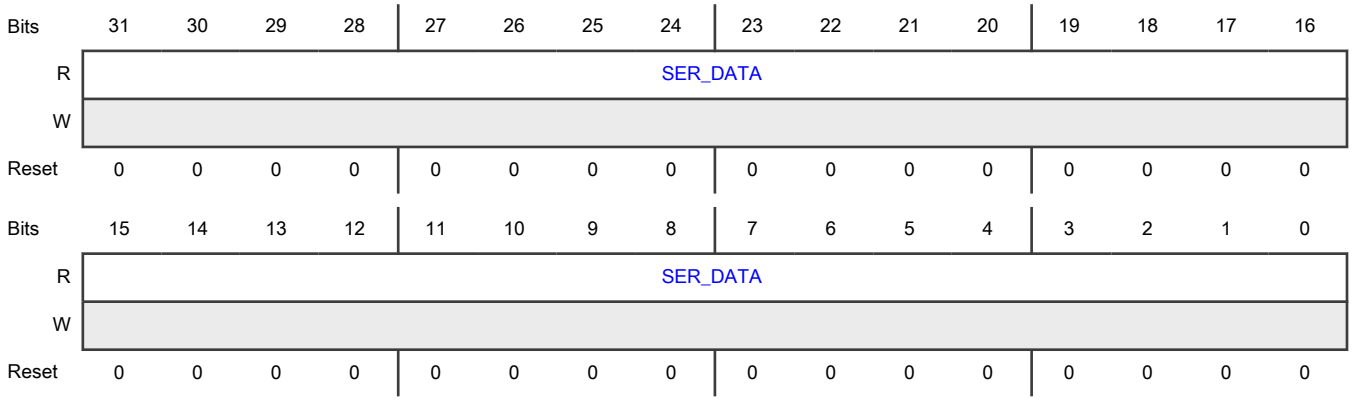
Offset

Register	Offset
SDR0	C0h

Function

This register includes the states of the 32 LSB parallel input signals. These states are latched into the SDR0, which is a read-only register, on the rising edge of every bus clock. If the value of DSICR0[TXSS] is 0, the data in the SDR0 is used as the source for DSI frames. If the value of DSICR1[DSI64E] is 1, the concatenation of {SDR1, SDR0} provides the 64-bit serialization data value.

Diagram



Fields

Field	Function
31-0 SER_DATA	Serialized Data Contains the signal states of the 32 LSB parallel input signals

77.6.13 DSI Alternate Serialization Data Register 0 (ASDR0)

Offset

Register	Offset
ASDR0	C4h

Function

The host software uses this register to write 32 LSB of the data to be serialized. If the value of DSICR0[TXSS] is 0, the data in the ASDR0 is the source for DSI frames. Writes to the ASDR0 take effect on the next frame boundary. If the value of DSICR1[DSI64E] is 1, the concatenation of {ASDR1, ASDR0} provides the 64-bit alternate serialization data value.

77.6.14 DSI Transmit Comparison Register 0 (COMPR0)

Offset

Register	Offset
COMPR0	C8h

Function

This register holds a copy of 32 LSB of the last transmitted DSI data, which is transferred to the COMPR0 as it is loaded into the TX Shift register. If the value of DSICR1[DSI64E] is 1, the concatenation of {COMPR1, COMPR0} provides the 64-bit transmit comparison value.

77.6.15 DSI Deserialization Data Register 0 (DDR0)

Offset

Register	Offset
DDR0	CCh

Function

This register holds the 32 LSB signal states for the parallel output signals. The host software can read data from incoming DSI frames. If the value of DSICR1[DSI64E] is 1, the concatenation of {DDR1, DDR0} provides the 64-bit deserialized data value.

77.6.16 DSI Configuration Register 1 (DSICR1)

Offset

Register	Offset
DSICR1	D0h

Function

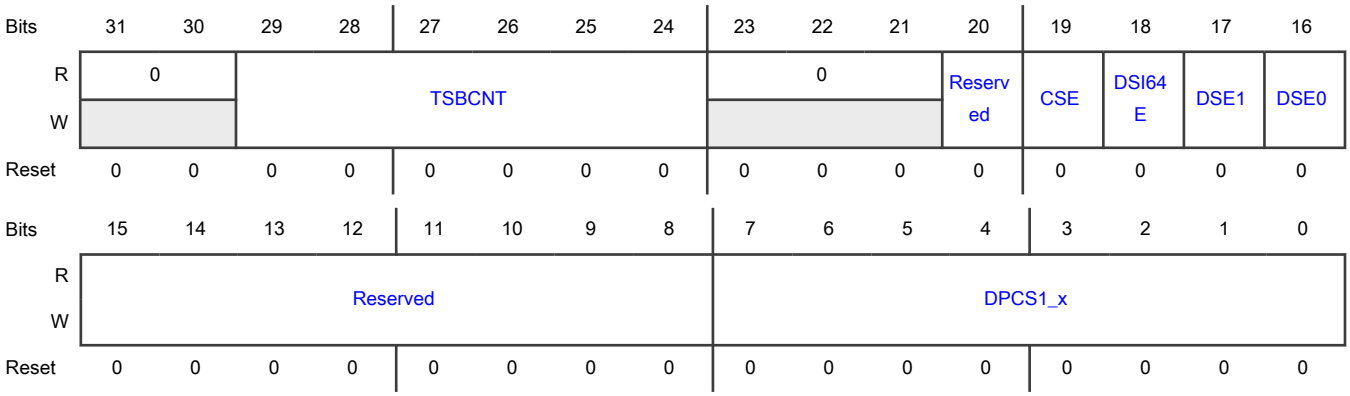
This register selects various attributes associated with the following configurations:

- DSI
- TSB
- ITSB

NOTE

You must not write to the DSICR1 when the module is in the Running state.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-24	Timed Serial Bus Operation Count

Table continues on the next page...

Table continued from the previous page...

Field	Function
TSBCNT	When TSB is enabled (DSICR0[TSBC]), TSBCNT defines the length of the data frame. When DSI 64-bit mode is enabled (DSI64E), the length value can vary from 3 to 63 (000011b to 111111b); otherwise, it can vary from 3 to 31 (000011b to 011111b). The length value specifies the number of data bits to be shifted out during a transfer in TSB mode. The number of data bits in the data frame is one more than the value in the TSBCNT field.
23-21 —	Reserved
20 —	Reserved
19 CSE	Command Select Enable When the DSICR0[ITSB] and DSICR0[TSBC] is set, the CSE bit controls insertion of command selection bit (Logic 1) in the beginning of the DSPI (command) frame. 0b - No selection bit is inserted in the beginning of the command frame. 1b - Command selection bit is inserted at the beginning of the command frame. Total number of bits in the command frame is increased by 1.
18 DSI64E	DSI 64-bit Mode Enable Enables DSI 64-bit mode, which allows the serialization and deserialization of data frames up to 64 bits in size. The following extended registers are valid only when this mode is enabled: SDR1, ASDR1, COMPR1, DDR1, SSR1, DIMR1, DPIR1. 0b - DSI 64-bit mode disabled. DSI mode operates according to the default 32-bit configuration. 1b - DSI 64-bit mode enabled. DSI mode operates according to the 64-bit configuration.
17 DSE1	Data Select Enable 1 When the TBSC bit is set, the DSE1 bit controls insertion of the zero bit (Data Select) in the middle of the data frame. The insertion bit position is defined by the FMSZ field of CTARn register, selected by the DSICR0[DSICTAS] field. If DSI 64-bit mode is enabled (DSICR1[DSI64]), then the insertion bit position is defined by the concatenation of {DSICR0[FMSZ4], CTAR[FMSZ]}. The TSBCNT field value must be greater than the position of insertion for proper operation of DSE1. 0b - No Zero bit is inserted in the middle of the data frame. 1b - Zero bit is inserted at the middle of the data frame. Total number of bits in the data frame is increased by 1.
16 DSE0	Data Select Enable 0 When the TBSC bit is set, the DSE0 bit controls insertion of the zero bit (Data Select) in the beginning of the DSI frame. 0b - No Zero bit is inserted in the beginning of the frame. 1b - Zero bit is inserted at the beginning of the data frame. Total number of bits in the data frame is increased by 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-8 —	Reserved
7-0 DPCS1_x	DSI Peripheral Chip Select 0–7 Specifies the PCSs to assert for the second part of the DSI frame when operating in TSB or ITSB configuration with dual receiver. DPCS1 selects the PCS signals to assert during the second part of the DSI frame. DPCS1 controls the assertions of PCS signals only in TSB and ITSB mode. 0000_0000b - Negate PCS[x]. 0000_0001b - Assert PCS[x].

77.6.17 DSI Serialization Source Select Register 0 (SSR0)

Offset

Register	Offset
SSR0	D4h

Function

This register is used to create a combined frame for transmission that contains fields from ASDR0 and SDR0. Each field in the SSR0 selects a corresponding field to be serialized. If the value of DSICR0[TXSS] is 1, SSR0 has no effect. If the value of DSICR1[DSI64E] is 1, the concatenation of {SSR1, SSR0} provides the 64-bit serialization source select value.

Diagram

Fields

Field	Function
31-0	Source Select

Table continues on the next page...

Field	Function
SS	Selects the serialization source for the 32 LSB of the DSI frame. Each bit of this field selects data for a corresponding bit in the transmitted frame. 0000_0000_0000_0000_0000_0000_0000_0000b - The bit in the transmitted frame is derived from the parallel input pin. 0000_0000_0000_0000_0000_0000_0000_0001b - The bit in the transmitted frame is derived from the ASDR0.

77.6.18 DSI Deserialized Data Interrupt Mask Register 0 (DIMR0)

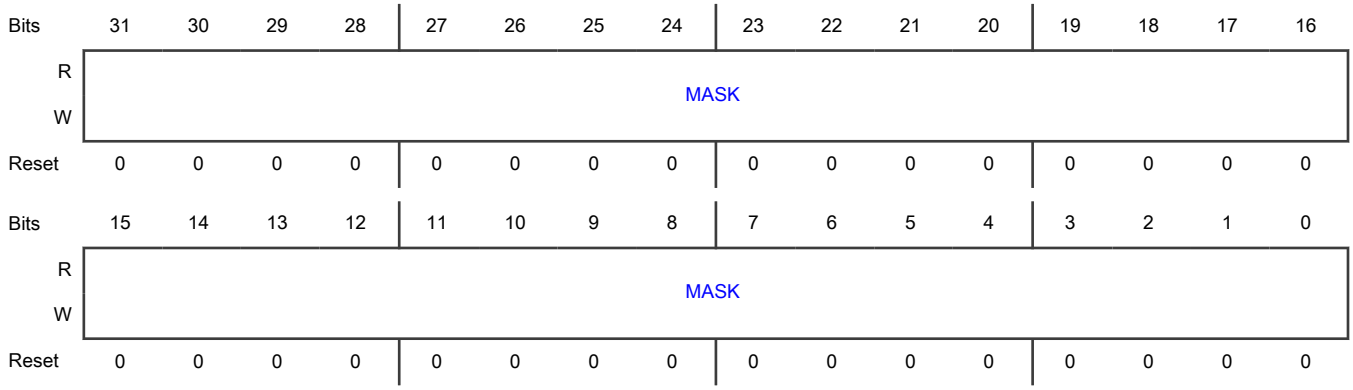
Offset

Register	Offset
DIMR0	E8h

Function

This register selects bits from the 32 LSB of the received DSI frame to be checked to generate the Deserialized Data Interrupt (DDI). If the value of DSICR1[DSI64E] is 1, the concatenation of {DIMR1, DIMR0} provides the 64-bit deserialized data interrupt mask value.

Diagram



Fields

Field	Function
31-0 MASK	Mask Defines which bits in the 32 LSB of received deserialized data should be checked to produce the DDI 0000_0000_0000_0000_0000_0000_0000_0000b - The bit in the received DSI frame does not produce a DDI interrupt. 0000_0000_0000_0000_0000_0000_0000_0001b - The bit in the received DSI frame can produce a DDI interrupt if the data bit matches the configured polarity.

77.6.19 DSI Deserialized Data Polarity Interrupt Register 0 (DPIR0)

Offset

Register	Offset
DPIR0	ECh

Function

This register defines which data bit value from the 32 LSB of received DSI frame generates the DDI. If the value of DSICR1[DSI64E] is 1, the concatenation of {DPIR1, DPIR0} provides the 64-bit deserialized data polarity interrupt value.

Field	Function
31-0 DP	Data Polarity Defines which value from the 32 LSB of the received deserialized data configures SR[DDIF] 0000_0000_0000_0000_0000_0000_0000_0000b - SR[DDIF] is configured if the received bit is 0. 0000_0000_0000_0000_0000_0000_0000_0001b - SR[DDIF] is configured if the received bit is 1.

77.6.20 DSI Serialization Data Register 1 (SDR1)

Offset

Register	Offset
SDR1	F0h

Function

This register contains the states of the 32 MSB signal states of the 64 parallel input signals. The states of these parallel input signals are latched into the SDR1 on the rising edge of every bus clock. If the value if DSICR0[TXSS] is 0, the data in the SDR1 and SDR0 is used as the source of the DSI frames. The concatenation of {SDR1, SDR0} provides the 64-bit data to be serialized. This register is valid only when the value of DSICR1[DSI64E] is 1.

77.6.21 DSI Alternate Serialization Data Register 1 (ASDR1)

Offset

Register	Offset
ASDR1	F4h

Function

The host software uses this register to write the 32 MSB of the 64-bit data to be serialized. When the value of DSICR0[TXSS] is 1, the data in the ASDR1 and ASDR0 is the source of the DSI frames. Writes to the ASDR1 take effect on the next frame boundary. The concatenation of {ASDR1, ASDR0} provides the 64-bit alternate serialization data. This register is valid only when the value of DSICR1[DSI64E] is 1.

77.6.22 DSI Transmit Comparison Register 1 (COMPR1)

Offset

Register	Offset
COMPR1	F8h

Function

This register holds a copy of the 32 MSB of the last transmitted 64-bit DSI data. The upper 32 bits of the 64-bit DSI data is transferred to this register as it is loaded into the TX Shift register. The concatenation of {COMPR1, COMPR0} provides the 64-bit transmit comparison data. This register is valid only when the value of DSICR1[DSI64E] is 1.

77.6.24 DSI Serialization Source Select Register 1 (SSR1)

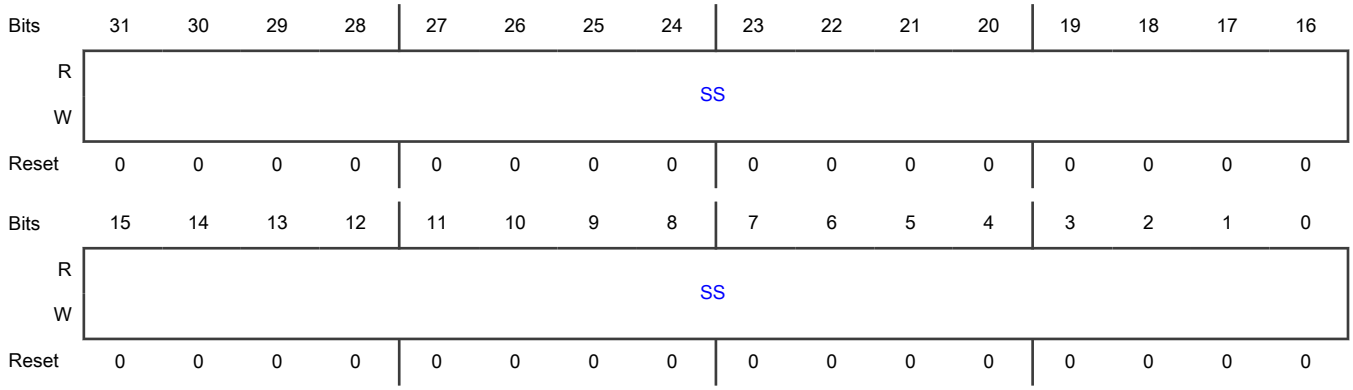
Offset

Register	Offset
SSR1	100h

Function

This register is used to create a combined frame for transmission that contains fields from ASDR1 and SDR1. Each field in the SSR1 selects a corresponding field to be serialized. If the value of DSICR0[TXSS] is 1, the SSR1 has no effect. The concatenation of {SSR1, SSR0} provides the 64-bit serialization source select value. The register is valid only when the value of DSICR1[DSI64E] is 1.

Diagram



Fields

Field	Function
31-0 SS	Source Select Selects the serialization source for the 32 MSB of the 64-bit DSI frame. Each bit of this field selects data for a corresponding bit in the transmitted frame. 0000_0000_0000_0000_0000_0000_0000_0000b - The bit in the transmitted frame is derived from the parallel input pin. 0000_0000_0000_0000_0000_0000_0000_0001b - The bit in the transmitted frame is derived from the ASDR0/1 registers.

77.6.25 DSI Deserialized Data Interrupt Mask Register 1 (DIMR1)

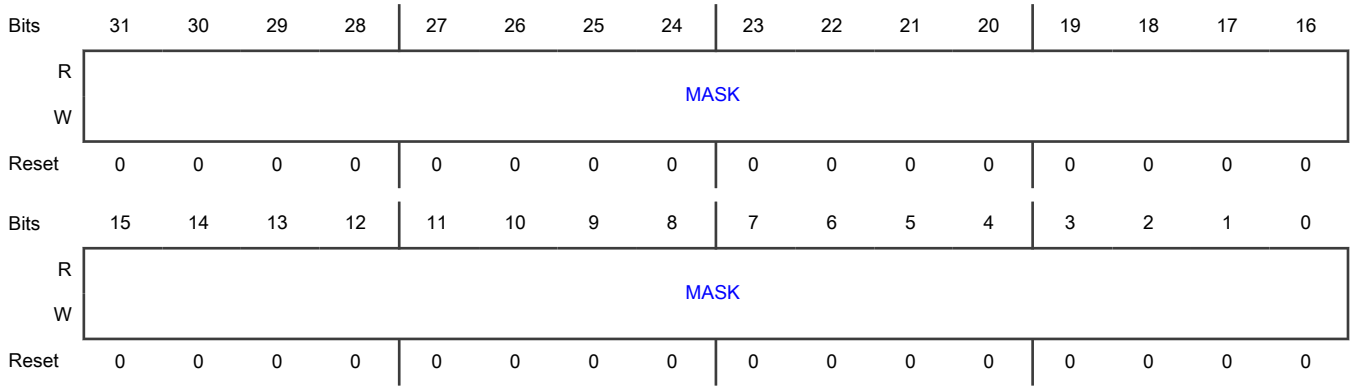
Offset

Register	Offset
DIMR1	114h

Function

This register selects bits from the 32 MSB of the received 64-bit DSI frame to be checked to generate the DDI. The concatenation of {DIMR1, DIMR0} provides the 64-bit deserialized data interrupt mask value. The register is valid only when the value of DSICR1[DSI64E] is 1.

Diagram



Fields

Field	Function
31-0 MASK	Mask Defines which of the 32 MSB in the received 64-bit deserialization data should be checked to produce the DDI 0000_0000_0000_0000_0000_0000_0000_0000b - The bit in the received DSI frame does not produce a DDI. 0000_0000_0000_0000_0000_0000_0000_0001b - The bit in the received DSI frame can produce a DDI if the data bit matches the configured polarity.

77.6.26 DSI Deserialized Data Polarity Interrupt Register 1 (DPIR1)

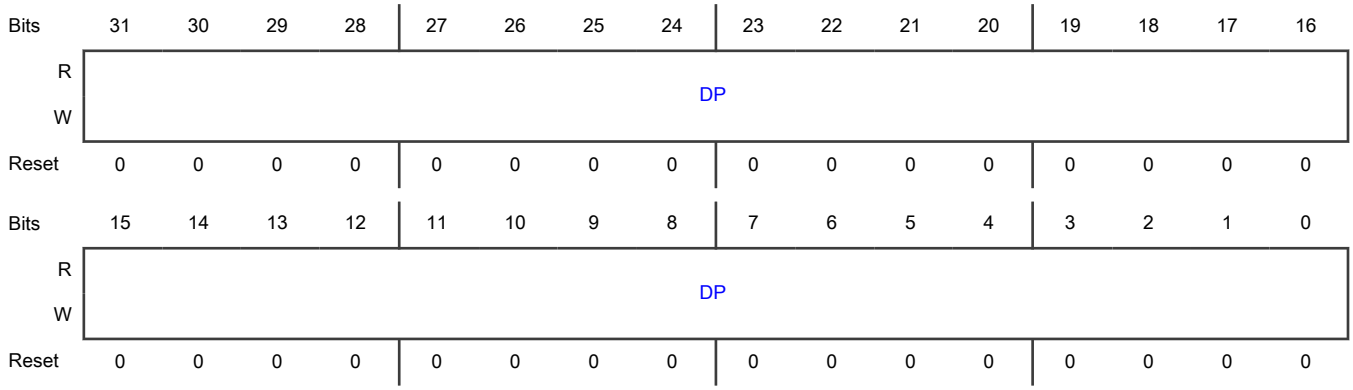
Offset

Register	Offset
DPIR1	118h

Function

This register defines which of the 32 MSB value in the received 64-bit DSI frame generates the DDI. The concatenation of {DPIR1, DPIR0} provides the 64-bit deserialized data polarity value. The register is valid only when the value of DSICR1[DSI64E] is 1.

Diagram



Fields

Field	Function
31-0 DP	Data Polarity Defines which of the 32 MSB of the received 64-bit deserialized data configures SR[DDIF] 0000_0000_0000_0000_0000_0000_0000_0000b - SR[DDIF] is configured if the received bit is 0. 0000_0000_0000_0000_0000_0000_0000_0001b - SR[DDIF] is configured if the received bit is 1.

77.6.27 Clock and Transfer Attributes Register Extended (CTARE0 - CTARE5)

Offset

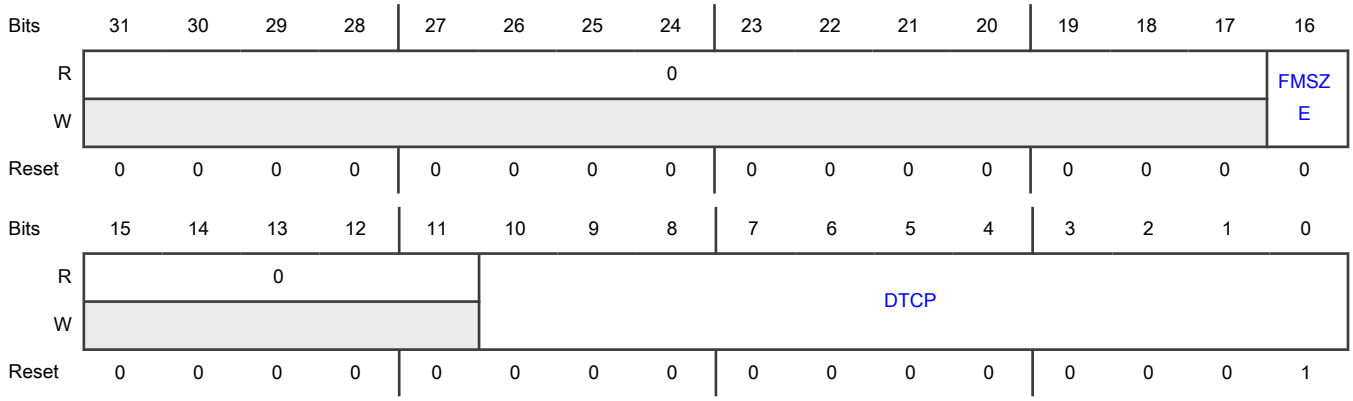
Register	Offset
CTARE0	11Ch
CTARE1	120h
CTARE2	124h
CTARE3	128h
CTARE4	12Ch
CTARE5	130h

Function

These registers are used to define the extended transfer attributes for DSPI frames. The registers are valid only when the value of MCR[XSPI] is 1.

When the module is configured as a DSPI master, the CTAS field in CMD FIFO entry selects which of the CTARE registers is used.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 FMSZE	Frame Size Extended This field is valid only when the value of MCR[XSPI] is 1. The field, concatenated with CTAR[FMSZ], defines the frame size of the DSPI frames to be transmitted. The effective frame size is the concatenation of {CTARE[FMSZE], CTAR[FMSZ]} plus 1. 0b - Default mode. Up to 16-bit DSPI frames can be transferred. 1b - Up to 32-bit DSPI frames can be transferred. Each frame transfer is a result of two simultaneous TX FIFO pop operations.
15-11 —	Reserved
10-0 DTCP	Data Transfer Count Preload This field is valid only when the value of MCR[XSPI] is 1. The field defines the number of data frames, the size of which is defined by CTARE[FMSZE] and CTAR[FMSZ], to be transmitted using the command frame that selected this register. The value 0 is reserved and should not be written to this field, and the default value of the field is 1.

77.6.28 Status Register Extended (SREX)

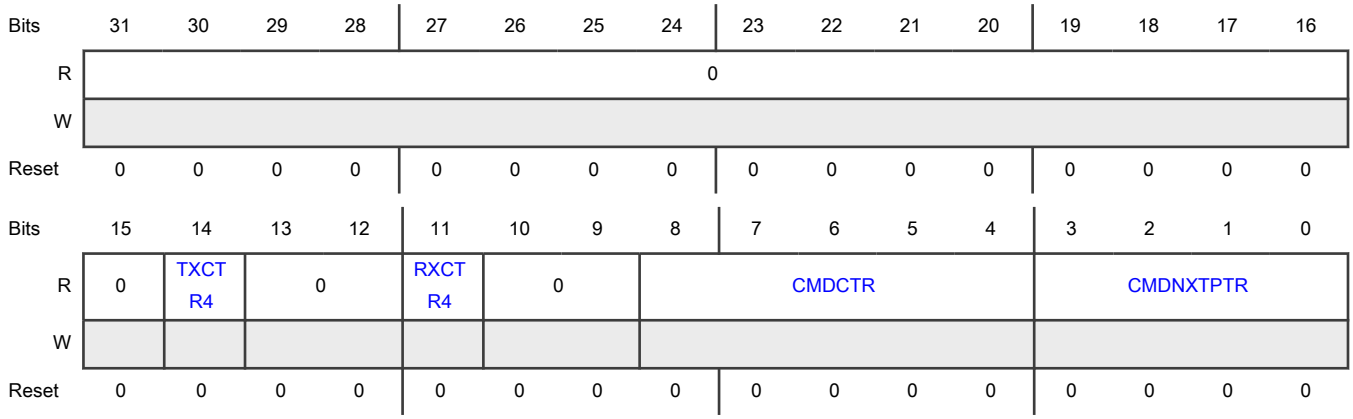
Offset

Register	Offset
SREX	13Ch

Function

The register contains status fields, which indicate the status of the module and the occurrence of events. The register is not writeable.

Diagram



Fields

Field	Function
31-15 —	Reserved
14 TXCTR4	TX FIFO Counter[4] This bit is an extension of SR[TXCTR]. The concatenated field {TXCTR4, TXCTR} indicates the number of valid entries in the TX FIFO. This field is incremented every time the PUSHR is written. And this field is decremented every time an DSPI command is executed and the DSPI data is transferred to the Shift register.
13-12 —	Reserved
11 RXCTR4	RX FIFO Counter[4] This bit is an extension of SR[RXCTR]. The concatenated field {RXCTR4, RXCTR} indicates the number of entries in the RX FIFO. This field is decremented every time the POPR is read. And this field is incremented every time data is transferred from the Shift register to the RX FIFO.
10-9 —	Reserved
8-4 CMDCTR	CMD FIFO Counter Indicates the number of entries in the CMD FIFO. This field increments every time the command part of the PUSHR is written, and decrements every time the DSPI command is executed (all data frames are transmitted because of current command frame).
3-0 CMDNXTPTR	Command Next Pointer Indicates which CMD FIFO entry is used during the next transfer. This field updates every time DSPI data is transmitted because of current command frame.

77.6.29 Time Slot Length Register (TSL)

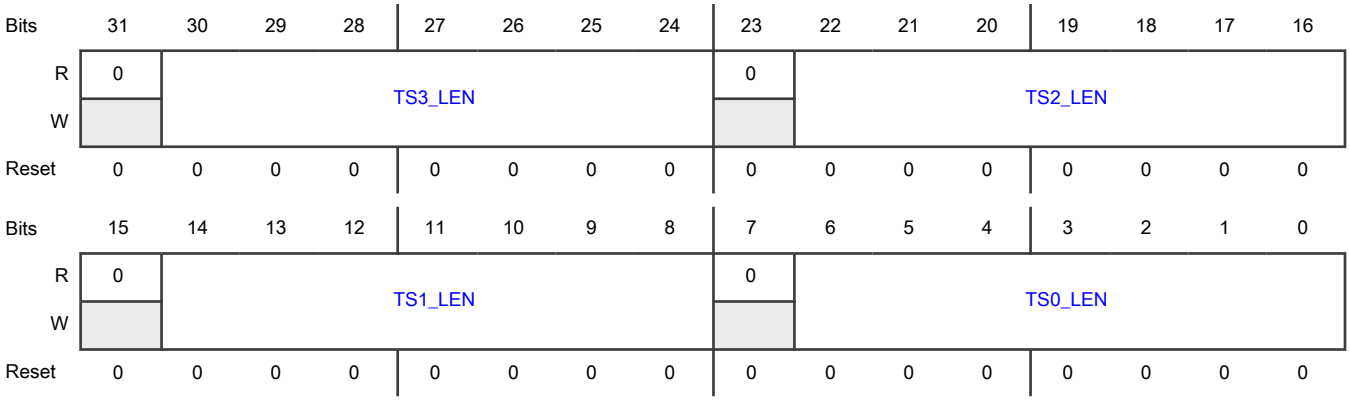
Offset

Register	Offset
TSL	150h

Function

The TSL register is only valid when DSICR0[ITSB] is enabled and internal triggering mechanism is used. It provides the length of every time slot in terms of baud cycles.

Diagram



Fields

Field	Function
31 —	Reserved
30-24 TS3_LEN	Time Slot 3 Length This field provides the length of TS3 in terms of baud cycles. It must be ensured that the programmed value is greater than or equal to the length of the frame to be transmitted during TS3. Time Slot3 Length = TS3_LEN+1.This time slot shall be skipped if programmed to 0.
23 —	Reserved
22-16 TS2_LEN	Time Slot 2 Length This field provides the length of TS2 in terms of baud cycles. It must be ensured that the programmed value is greater than or equal to the length of the frame to be transmitted during TS2. Time Slot 2 Length = TS2_LEN+1.This time slot shall be skipped if programmed to 0.
15 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
14-8 TS1_LEN	Time Slot 1 Length This field provides the length of TS1 in terms of baud cycles. It must be ensured that the programmed value is greater than or equal to the length of the frame to be transmitted during TS1. Time Slot 1 Length = TS1_LEN+1.This time slot shall be skipped if programmed to 0.
7 —	Reserved
6-0 TS0_LEN	Time Slot 0 Length This field provides the length of TS0 in terms of baud cycles. It must be ensured that the programmed value is greater than or equal to the length of the frame to be transmitted during TS0. Time Slot 0 Length = TS0_LEN+1.This time slot shall be skipped if programmed to 0.

77.6.30 Time Slot Configuration Register (TS_CONF)

Offset

Register	Offset
TS_CONF	154h

Function

This register provides the basic configuration options available for the triggered implementation of MSC protocol. This register is only valid when DSICR0[ITSB] is enabled. Some configurations in this register check for the validity of command frame. The following conditions must be true for a command frame to be valid : a) The previous transmitted frame should not be a command frame. b) Data required to transmit the command frame should be available.

Diagram

77.7 Glossary

Table 611. Glossary

Term	Definition
Asserted	A signal that is asserted is in its active state. An active low signal changes from logic level one to logic level zero when asserted, and an active high signal changes from logic level zero to logic level one.
Clear	To clear a bit or bits means to establish logic level zero on the bit or bits.
FIFO entry	FIFO entries and FIFO registers are used interchangeably.
Logic level one	The voltage that corresponds to Boolean true (1) state.
Logic level zero	The voltage that corresponds to Boolean false (0) state.
Negated	A signal that is negated is in its inactive state. An active low signal changes from logic level zero to logic level one when negated, and an active high signal changes from logic level one to logic level zero.
Set	To set a bit or bits means to establish logic level one on the bit or bits.
SPI/DSPI slave	Peripheral device which operates under the control of SPI master device.

Table continues on the next page...

Table 611. Glossary (continued)

Term	Definition
SS/SS_b	SS is slave select. Signal from the SPI master to the SPI slave indicating which SPI slave device the master want to communicate with.

Chapter 78
Ethernet Media Access Controller (EMAC)

78.1 Chip-specific EMAC information

78.1.1 EMAC instance and configuration

This chip supports up to 1 instance of EMAC IP.

NOTE

DWC_EQOS refer to the Synopsys Ethernet MAC IP.

NOTE

The description for some EMAC registers include references to configurations of the Synopsis Ethernet MAC IP. Refer to MAC_HW_Feature registers for the specific features available in this chip.

NOTE

EMAC operates only in Clock options A and B, since the module clock becomes lower than the protocol clock (RMII/MII clocks) in other modes.

NOTE

QuadSPI cannot be used along with Ethernet in 176LQFP-EP.

Following key features are supported:

- This chip supports only MII/RMII interfaces
- 4 bit MII interface operating at 2.5/25/50Mhz, MII can run at 10/100/200 Mbps.
- 2 bit RMII interface operating at 50Mhz, RMII can run at 10/100Mbps
- 4 bit MII-Lite interface operating at 2.5/25Mhz
- 4 PPS are supported using DMA trigger
- 200Mbps data rate is supported on Ethernet MII interface
- MTL Receive FIFO size 8192bytes
- MTL Transmit FIFO size 8192bytes

NOTE

The DMA referred within EMAC chapter refers to the internal EMAC DMA engine and not the device AXBS master DMA.

NOTE

Register access beyond 8k address space is not supported and will generate a transfer error.

NOTE

Always use store and forward mode if possible. In cut through mode, if multiple masters are active then there is chance (even in round robin arbitration mode) that EMAC DMA may starve for data resulting in insufficient data in TX FIFO leading to Tx underflow. To avoid this, increase MTL_TxQ0_Operation_Mode[TTC] value as needed.

The table below provides the information on the specific configuration utilized for the S32K396.

Table 612. Specific configuration information

Application Interface		
	Application interface configuration	EQOS-AHB
	Data width	32
	Endian mode	Little Endian
	Address width	32
	CSR interface	APB3 interface
General feature		
	Mode of operation	10/100
	Enable double VLAN processing	Yes
	Enable Que/channel based VLAN tag insertion on Tx	Yes
	Enable SA and VLAN insertion on Tx	Enabled by default
Buffer management		
	MTL Receive FIFO size in bytes	8192
	MTL Receive FIFO size in bytes	8192
	Enable debug memory access	Yes
	Use single port memory	Yes
PHY interface		
	Supported interfaces	MII, RMII
	Enabled signal phy interface	No
	Enable MDIO interface	Yes
Filtering		
	Enable Additional 1-31 MAC address registers	2
	Enable Address Filter Hash Table	Yes
	Hash Table Size	64
	Enable VLAN Hash table based filtering	Yes
	Extended Rx VLAN Filter Enable	Yes
	Number of VLAN tag Filters	4
	Enable Layer3 and Layer4 Packet Filter	Yes
	Number of layer3 and Layer 4 packet filters	4
	Enable Flexible Programmable Receive Parser	Yes

Table continues on the next page...

Table 612. Specific configuration information (continued)

	Maximum Packet Header Size for Parsing	128
	Maximum Entries of Parser Look up table	64
	Packet duplication support	Yes
IEEE 1588 timestamp		
	Enable IEEE 1588 Time stamp support	Enabled by default
	IEEE 1588 System Time Support	Both option
	Add IEEE 1588 Higher word register	Yes
	Enable IEEE 1588 sub nanoseconds time stamp support	Yes
	Add IEEE 1588 Auxiliary snapshot	No
	Enable Flexible Pulse Per Seconds Output	Yes
	Number of pulse per Second outputs	4
	Enable PTP Timestamp offload feature	No
	Enable One Step timestamp for PTP over UDP/IP feature	No
	Enable One Step timestamp feature	Yes
Multiple queue support		
	Number of transmit Queue	2
	Number of receive Queue	2
	Enable data center Bridging	No
	Enable Audio Video Bridging	Yes
	Enable support for AV in Tx queue 1	No
	Number of DMA Channel on the receive side	2
Time sensitive networking		
	Enable Enhancement to Schedule traffic(EST)	Yes
	Width of Time Interval Field in the Gate Control List	24
	Depth of Gate Control List	256
	Enable Frame Pre-emption support	Yes
Time based scheduling		
	Enable time based Scheduling	Yes
TCP/IP offloading features		

Table continues on the next page...

Table 612. Specific configuration information (continued)

	Enable receive TCP/IP Checksum Check	Enabled by default
	Enable transmit TCP/IP Checksum offload	Enabled by default
	Enable support for Tx COE in Tx queue 0	Yes
	Enable support for Tx COE in Tx queue 1	No
	Enable TCP Segmentation offloading for TCP/IP	No
	Enable Split Header Feature	No
	Enable IPv4 ARP offload	No
RMON counters		
	Enable MAC Management Counters(MMC)	Yes
	Enable the MAC Management Counters for Receiver TCP/IP Checksum offload	No
Automotive safety feature		
	Enable all automotive safety feature	Yes

78.2 Overview

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

EMAC:

- Supports the 10/100 Mbps application in compliance with IEEE802.3-2015 specifications
- Can support advanced applications such as time-sensitive networking and AVB
- Supports a MAC core that has prominent features such as a flexible receive parser, media clock recovery and generation, and safety

78.2.1 Features

EMAC supports these features in addition to the default feature defined in the IEEE802.3 specification:

- MII (10/100 Mbps), RMII (10/100 Mbps)
- Time-aware shaper (IEEE802.1bv), time synchronization (IEEE802.1AS-rev), and frame preemption (IEEE802.1Qbu) for time-sensitive networking
- Media clock recovery and generation for AVB
- AMBA 2.0 for AHB master and APB3 interface
- RMII specification version 1.2 from RMII consortium
- Separate interface for transmit, receive, and control paths
- Two-buffer ring
- Broadcast and multicast packet duplication
- Full-duplex flow control operations (IEEE 802.3x pause packet and priority flow control)
- Network statistics with MAC management (RMON) counters
- Flexibility to control the pulse per second (PPS) output signal

- MDIO clause 22 and clause 45 interface for configuration and management of the PHY device
- Preamble and SFD insertion and deletion

NOTE

Only byte-aligned preamble is supported.

- Automatic CRC and pad generation/stripping option
- Option to disable CRC checking
- Programmable insert packet gap
- Source address insertion or replacement
- VLAN insertion, replacement, and deletion in transmitted packets with per-packet or static-global control, insertion, replacement, and deletion of up to two VLAN tags, insertion, replacement, and deletion of queue or channel-based VLAN tags
- IEEE802.1Q VLAN tag detection and an option to delete the tags in the receive packets
- Programmable safety watchdog timeout limits
- Flexible address filtering modes that allow:
  - Up to two additional 48-bit perfect DA filters with masks for each byte
  - Up to two 48-bit SA comparison checks with masks for each byte
  - 64-bit hash filter for multicast and unicast DA addresses
  - Option to pass all multi-cast addressed packets
  - Promiscuous mode to pass all packets without any filtering for network monitoring
  - Passing of all incoming packets (according to filter) with a status report
- Additional packet filtering that is based on:
  - Virtual local area network (VLAN) tag—perfect match and hash-based filtering, which is based on either outer or inner VLAN tag, is possible
  - Layer 3 and layer 4—TCP or UDP over IPv4 or IPv6
  - Extended VLAN tag—filtering based on four filter selections

NOTE

The DCB feature discussed in the following section(s) is not supported.

78.2.2 Block diagram

This figure shows the EMAC block diagram. EMAC has four main blocks to perform all the functions.

- The AHB interface is connected to all DMA channels.
- The DMA arbiter helps in the arbitration of all paths (transmit and receive) in DMA channels.
- Each channel has a separate set of control and status registers (CSRs) for managing the transmit and receive functions, descriptor handling, and interrupt handling.

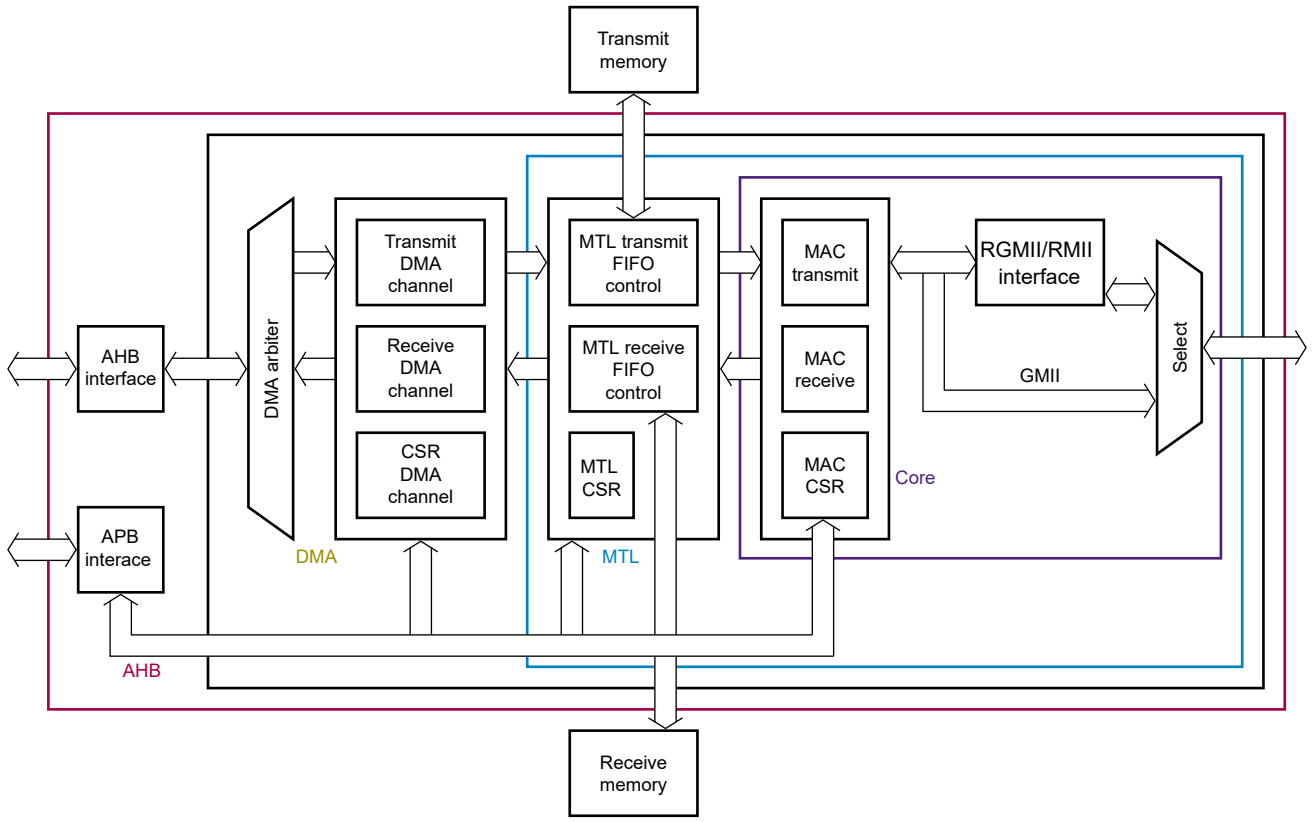

Figure 558. System-level block diagram

78.3 Architecture

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

The section describes EMAC interfaces, protocols, and functionality. These are its main blocks:

- AHB master and APB3 slave interface
- DMA controller
- MTL
- MAC
- Interrupts

78.3.1 AHB master and CSR slave (APB3) interface

The 32-bit APB3 slave interface:

- Provides access to DMA, MTL, and MAC control and status registers (CSRs)
- Supports the 32-bit write and read transfers to these CSRs
- Supports single- and all-burst transfers, and an OKAY response

The DMA block uses the AHB master interface to interact with the external world. The AHB master interface:

- Controls data transfer
- Is AMBA 2.0-compliant with no restrictions
- Supports 32-bit data transfer

- Supports single and INCR transfers
- Supports burst-length modes such as Fixed, Unspecified, and Mixed

78.3.2 DMA inclusions

DMA controller:

- Includes independent transmit (Tx) and receive (Rx) engines, and a CSR space. The transmit engine transfers data from the system memory to the MTL interface, whereas the receive engine transfers data from the MTL interface to the system memory.
- Is designed for packet-oriented data transfers such as packets in Ethernet.
- Communicates with the host through CSR, descriptor lists, and data buffers.

DMA descriptors

DMA supports up to two transmit and two receive descriptor lists (or DMA channels). The base address of each list is written to the respective transmit and receive descriptor list address registers. A descriptor list is forward linked and the next descriptor is always considered at a fixed offset to the current one, and DMA_CH0_Control[DSL] controls the offset. The number of descriptors in the list is programmed using the respective DMA Channel 0 Tx Descriptor Ring Length (DMA_CH0_TxDesc_Ring_Length) and DMA Channel 0 Rx Descriptor Ring Length (DMA_CH0_RxDesc_Ring_Length) registers. After the DMA processes the last descriptor in the list, it automatically jumps to the descriptor in the list address register to create a descriptor ring.

EMAC supports the ring structure for DMA descriptors. For more information, see Descriptors .

The DMA engine uses descriptors to efficiently move data from source to destination with minimal host intervention, and the DMA controller can be programmed to interrupt the host in certain situations. These situations may include packet transmit and receive transfer completion and other normal or error conditions.

The descriptor lists reside in the physical memory address space of the application. Each descriptor can point to a maximum of two buffers in the system memory, enabling two buffers to be used and physically addressed rather than contiguous buffers in the memory.

Data buffers

A data buffer resides in the application physical memory space and consists of an entire packet or part of a packet but cannot exceed a single packet. Buffers contain only data. The buffer status is maintained in the descriptor. Data chaining refers to packets that span multiple data buffers. However, a single descriptor cannot span multiple packets. The DMA skips to the data buffer of the next packet when an EOP is detected.

The next few sections discuss DMA controller.

78.3.2.1 DMA controller bus burst access

DMA engines attempt to transfer data in a burst of the maximum size programmed using DMA_CH0_Tx_Control[TxPBL] and DMA_CH0_Rx_Control[RxPBL] of the respective DMAs, which always access the receive and transmit descriptors in the maximum possible (limited by PBL or 16 * 8/bus width) burst length for 16 bytes to be read. The burst transfers that the DMA initiates can be split into multiple burst transfers according to the AHB requirements and settings specified in DMA System Bus Mode (DMA_SysBus_Mode).

The transmit DMA initiates a data transfer only when sufficient space is available in the MTL transmit queue to accommodate either of these:

- Bytes corresponding to the configured burst (PBL * bus_width/8)
- Remaining bytes in the transmit buffer without EOP
- Number of bytes till EOP

The receive DMA initiates a data transfer in these conditions:

- Sufficient data is available in the MTL receive queue to accommodate the configured burst
- EOP (when it is less than the configured burst length) is detected in the receive queue

DMA indicates the start address and the number of transfers required to the AHB master interface. When the interface is configured for fixed-length burst, it transfers data by using the best combination of the INCR4, INCR8, or INCR16 and SINGLE transactions. If EOP is reached before the fixed burst ends on the AHB interface, DMA performs dummy transfers to complete the fixed burst. Otherwise, DMA_SysBus_Mode[FB] becomes 0. The DMA transfers the data using undefined length (INCR) and SINGLE transactions.

When the AHB interface is configured for address-aligned beats, both DMA engines ensure that the first-burst transfer that AHB initiates is less than or equal to the size of the configured PBL value, and the subsequent beats start at an address aligned to this value. The DMA can only align the address for beats up to size 16 (for PBL > 16) for the AHB interface because it does not support more than INCR16.

78.3.2.2 DMA application data buffer alignment

The transmit and receive data buffers do not have any restrictions on start address alignment. For example, in systems with 32-bit memory, the start address for buffers can be aligned to any of the four bytes. However, the DMA always initiates write transfers with an address aligned to the bus width and dummy data (old data) in the invalid byte lanes. The process of write transfer typically happens during the beginning or end of an Ethernet packet transfer. The software driver must discard the dummy bytes based on the start address of the buffer and size of the packet.

Table 613. Data buffer alignment examples

Examples	
Buffer read	If the transmit buffer address is FF2h (for a 32-bit data bus) and 15 bytes need to be transferred, the DMA reads five full words from address FF0h. However, when DMA transfers data to the MTL transmit queue, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are also ignored. The DMA always ensures that it transfers a full 32-bit data to the MTL transmit queue, unless it is the end of the packet.
Buffer write	If the receive buffer address is FF2h (for a 64-bit data bus) and 16 bytes of a received packet need to be transferred, the DMA writes 3 full words from address FF0h. However, the first 2 bytes of the first transfer and the last 6 bytes of the third transfer have dummy data. The DMA considers the offset address only if it is the first receive buffer of the packet. It ignores the offset address and performs full-word writes for the middle and last receive buffers of the packet.

78.3.2.3 DMA buffer size calculations

DMA does not update the size fields in the transmit and receive descriptors. It updates only the status fields (RDES and TDES) of the descriptors. The driver performs the size calculations.

The transmit DMA transfers the exact number of bytes (as the buffer size field of TDES2 indicates) to MAC. If a descriptor is marked as first (TDES3[FD] = 1), the DMA marks the first transfer from the buffer as SOP, and if the descriptor is marked as last (TDES3[LD]), the DMA marks the last transfer from that data buffer as EOP to the MTL.

The receive DMA transfers data to a buffer until the buffer is full or MTL sends the end of packet. When TDES3[FD] = 1, the amount of valid data in a buffer is accurately indicated by the buffer size fields in DMA Channel Rx Control (DMA_CH0_Rx_Control) minus the data buffer pointer offset. The offset is 0 when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, the buffer may not be full (as indicated by DMA_CH0_Rx_Control[RBSZ_13_y] and DMA_CH0_Rx_Control[RBSZ_x_0]). To compute the amount of valid data in this final buffer, the driver must read the packet length (PL fields of RDES3[14:0]) and subtract the sum of the buffer sizes of the preceding buffers in this packet. The receive DMA always transfers the start of the next packet with a new descriptor.

78.3.2.4 DMA arbiter

The arbiter inside the DMA module performs the arbitration between the transmit and receive channel accesses to the AHB master interface. These two types of arbitrations are supported:

- Round-robin: If DMA_Mode[DA] = 0 and both transmit and receive DMAs simultaneously request access, the arbiter allocates the data bus in ratio sets defined in DMA_Mode[PR].
- Fixed-priority: If DMA_Mode[DA] = 1, receive DMA is always prioritized over transmit DMA for data access by default. If DMA_Mode[TXPR] = 1, transmit DMA is prioritized over receive DMA as explained in Table 630.

78.3.3 MTL

MTL provides the FIFO memory interface to buffer and regulate the packets between system memory and MAC. It also enables data to be transferred between the system clock and MAC clock domains. The MTL layer has two data paths: transmit path and receive path. MTL communicates with the host through ATI on the transmit path and through ARI on the receive path.

78.3.3.1 Transmit path

The internal DMA:

- Handles all transactions for the transmit path through ATI.
- Pushes the Ethernet packet reads from system memory to the corresponding queue.

The Ethernet packet, then, pops out and is transferred to MAC when the queue reaches its threshold (Threshold mode) or if the complete packet is in the queue (Store-and-Forward mode). When EOP is transferred, the status of the transmission is taken from MAC and transferred back to the internal DMA.

78.3.3.1.1 Transmit control word

This control information related to packet transmission is provided as part of the control word through the ATI interface:

- Packet length (if DCB is enabled with WFQ scheduling algorithm)
- CRC pad control
- Source address insertion control
- VLAN insertion and replacement control and VLAN tag for outer and inner VLAN tags
- TCP/IP checksum insertion control
- One-step timestamping control correction
- Transmit timestamp enable

78.3.3.1.2 Transmit operation

These two modes of operation trigger data read towards MAC:

- Threshold (or cut-through) mode: This is the default mode. In this mode, as soon as the number of bytes in the queue crosses the configured threshold level (or when the end of packet is written before the threshold is crossed), the data is ready to be popped out and forwarded to MAC. The threshold level is configured by using MTL_TxQ0_Operation_Mode[TTC].
- Store-and-Forward mode: In this mode, MTL pops the packet out to MAC only when one or more of the following conditions are true:
  - A complete packet is stored in the queue.
  - The transmit FIFO becomes almost full.
  - The ATI watermark becomes low.

  The watermark becomes low when the requested queue is not spacious enough to accommodate the requested burst length on ATI. Therefore, MTL, when operating in Store-and-Forward mode, allows packet transmission even if the packet length is bigger than the transmit queue size.

You can flush the complete content of the transmit queue by writing 1 to MTL_TxQ0_Operation_Mode[FTQ] or MTL_TxQ1_Operation_Mode[FTQ], depending on the queue. Doing so initializes the queue pointers to the default state. The FTQ

field returns to 0 by itself. If you write 1 to the FTQ field during a packet transfer from MTL to MAC, MTL stops further transfers because MTL considers the queue to be empty. Therefore, an underflow event occurs at the MAC transmitter.

78.3.3.1.3 Initialization flow

After reset, MTL is ready to manage the data flow between DMA and MAC.

- With single-transmit queue configurations, there are no initialization requirements for enabling MTL.
- With multiple-transmit queue configurations, initialize the queue size for each of the queues by programming MTL_TxQ0_Operation_Mode[TQS] corresponding to a transmit queue. Also, initialize the MAC block. Internal DMA controllers must be individually enabled through their respective CSRs.

78.3.3.2 Receive path

MAC sends packets to the MTL receive module and pushes them into the receive queue. MTL indicates the status (fill level) of the queue to the application or DMA when it crosses the configured receive threshold (MTL_RxQ0_Operation_Mode[RTC]), or when the MTL receive module receives the complete packet in Store-and-Forward mode. MTL also indicates the fill level of the queue so that DMA can initiate preconfigured burst transfers to the AHB interface.

78.3.3.2.1 Receive operation

During a receive operation, MTL is MAC's slave. This is the general sequence of events:

1. When MAC receives a packet, it indicates the availability of receive data.
2. MAC indicates the SOP and EOP delimiters.
3. MTL accepts the data and pushes it into the corresponding receive queue.
4. When MAC transfers EOP to the MTL receive module, MAC also drives the status word that MTL pushes into the corresponding receive queue.
5. MTL takes the data out of the queue and sends it to DMA depending on these modes:
   - Threshold mode
   - Store-and-Forward mode

   The sections that follow discuss these modes.

78.3.3.2.1.1 Threshold mode

In Threshold (default) mode, MTL reads the data and indicates its availability to the application or DMA when one of these occurs:

- Data bytes equal to the threshold amount are written to the receive queue (to MTL_RxQ0_Operation_Mode[RTC] and MTL_RxQ1_Operation_Mode[RTC]).
- A full packet of data is received into the queue.

78.3.3.2.1.2 Store-and-Forward mode

In this mode (when MTL_RxQ0_Operation_Mode[RSF] = 1), the initial receive queue locations are reserved for the status words before writing the SOP. A packet is read out only after it is completely written into the receive queue. In this mode, all error packets are dropped (if configured through MTL_RxQ0_Operation_Mode[FEP]) in such a way that only valid packets are read and forwarded to the application.

78.3.3.2.2 Multi-packet receive operation

In Threshold mode, the packet status is available immediately after the packet data. In Store-and-Forward mode, the packet data is available after the packet status. MTL is capable of storing any number of packets in the queue as long as it is not full.

If MAC receives a packet when the corresponding receive queue is full, MTL ignores that packet and overflow pulse generates on the corresponding receive queue. In addition, MTL increments the overflow counter in MTL Rx Queue Missed Packet Overflow Count (MTL_RxQ0_Missed_Packet_Overflow_Cnt) for the corresponding queue.

78.3.3.2.3 Error handling in receive operation

MTL performs these actions if the MTL receive queue is full before it receives the EOP data from MAC:

1. Declares an overflow
2. Drops the whole packet (including the status word)
3. Increments the overflow counter in DMA (MTL Rx Queue Missed Packet Overflow Count (MTL_RxQ0_Missed_Packet_Overflow_Cnt))

This is true even if MTL_RxQ0_Operation_Mode[FEP] is 1.

If the start address of such a packet is already transferred to the read controller, the rest of the packet is dropped and a dummy EOP is written to the queue along with the status word with overflow status. The status indicates a partial packet because of overflow. In such packets, the Packet Length field is invalid. If the MTL receive queue is configured to operate in the Store-and-Forward mode and the length of the received packet is more than the queue size, overflow occurs and all such packets are dropped.

The MTL receive control logic can filter errors and undersized packets, if enabled by using MTL_RxQ0_Operation_Mode[FEP] and MTL_RxQ0_Operation_Mode[FUP]. If the start address of one such packet is already transferred to the receive queue read controller, the packet is not filtered. The start address of the packet is transferred to the read controller after the packet crosses the receive threshold defined using MTL_RxQ0_Operation_Mode[RTC].

If the MTL receive queue is configured to operate in Store-and-Forward mode, all error packets can be filtered and dropped. For the application or DMA to flush the error packet being read from the queue, it must assert the flush signal. MTL then stops transferring data to the application (DMA). It internally reads the rest of the packet and drops it. MTL then starts transferring the next packet, if it's available.

78.3.4 MAC

MAC can support the MII and RMII PHY interface and it consists of:

- MTI
- MRI
- MCI

78.3.4.1 MAC transmission

The MAC transmission process is as follows:

1. The transmission initiates when MTL pushes in data with the SOP signal asserted.
2. After the SOP signal is detected, MAC accepts the data and begins transmitting to RMII or MII.
3. After the EOP signal is transferred to MAC, it performs one of these steps:
   - Completes normal packet transmission and sends the transmission status to MTL
   - Sends retry requests if a normal collision (in Half-Duplex mode) occurs during transmission, and until one of the following is true:
     - Packet is successfully transmitted.
     - Maximum retry requests have expired. When this happens, MAC aborts the packet transmission with "excessive collision transmit" status. MAC accepts and drops all further data until it receives the next SOP. The MTL block must retransmit the same packet from SOP on observing a retry request (in the status) from MAC.
   - If any one of the following happens, MAC aborts the packet transmission:

- No carrier (Half-Duplex mode)
- Loss of carrier (Half-Duplex mode)
- Excessive deferral (Half-Duplex mode)
- Late collisions (Half-Duplex mode)
- Jabber
- MAC accepts and drops all further data until it receives the next SOP

4. MAC issues an underflow status if MTL is not able to provide data continuously during transmission. Until the next SOP is received, MAC accepts and drops all further data.
5. During the normal transfer of a packet from MTL, if MAC receives an SOP without getting an EOP for the previous packet, it ignores the SOP and considers the new packet as a continuation of the previous packet.

78.3.4.2 MAC reception

The receive operation initiates as follows:

1. MAC detects a state-of-frame data on RMII or MII.
2. MAC strips the preamble and SFD before processing an Ethernet packet.
3. The MAC AFM:
   - Checks the header fields (SA and DA) of an incoming packet for filtering
   - Verifies the CRC contained in the packet's FCS field
4. MAC's AFM checks the header fields (SA and DA) of an incoming packet for filtering.
5. FCS verifies the CRC of the received packet.
6. MAC stores the received packet in a shallow buffer until address filtering is performed.
7. AFM drops the packet if it fails the address filter.

78.3.5 Interrupts

EMAC supports interrupt coalescing, which reduces the number of interrupts generated by the module and reduces the CPU load. MAC Interrupt Status (MAC_Interrupt_Status) captures various interrupt events. If the interrupt enable field of an interrupt is 1, the corresponding interrupt generates based on the event status in the Status registers. The Interrupt mode (INTM) field decides whether the interrupt signal is a level signal or pulse signal. See the following table and interrupt map file attached to this document for details.

Table 614. Interrupt request

Interrupt request	Interrupt Enable / Mask Register	Interrupt Flag Register
Common interrupt	MAC Interrupt Enable (MAC_Interrupt_Enable)	MAC Interrupt Status (MAC_Interrupt_Status)
	MMC Receive Interrupt Mask (MMC_Rx_Interrupt_Mask)	MMC Receive Interrupt (MMC_Rx_Interrupt)
	MMC Transmit Interrupt Mask (MMC_Tx_Interrupt_Mask)	MMC Transmit Interrupt (MMC_Tx_Interrupt)
	MMC FPE Transmit Interrupt Mask (MMC_FPE_Tx_Interrupt_Mask)	MMC Transmit FPE Fragment Counter Interrupt Status (MMC_FPE_Tx_Interrupt)

Table continues on the next page...

Table 614. Interrupt request (continued)

Interrupt request	Interrupt Enable / Mask Register	Interrupt Flag Register
	MMC FPE Receive Interrupt Mask (MMC_FPE_Rx_Interrupt_Mask)	MMC Receive Packet Assembly Error Counter Interrupt Status (MMC_FPE_Rx_Interrupt)
	MTL Debug Control (MTL_DBG_CTL)	MTL Debug Status (MTL_DBG_STS)
	MTL EST Interrupt Enable (MTL_EST_Intr_Enable)	MTL EST Status (MTL_EST_Status)
	MTL Rx Parser Interrupt Control Status (MTL_RXP_Interrupt_Control_Status)	MTL Rx Parser Interrupt Control Status (MTL_RXP_Interrupt_Control_Status)
	MTL Queue 0 Interrupt Control Status (MTL_Q0_Interrupt_Control_Status)	MTL Queue 0 Interrupt Control Status (MTL_Q0_Interrupt_Control_Status)
	MTL Queue 1 Interrupt Control Status (MTL_Q1_Interrupt_Control_Status)	MTL Queue 1 Interrupt Control Status (MTL_Q1_Interrupt_Control_Status)
	DMA Channel 0 Interrupt Enable (DMA_CH0_Interrupt_Enable)(transfer complete interrupts only)	DMA_CH0_Interrupt_Status
	DMA Channel 1 Interrupt Enable (DMA_CH1_Interrupt_Enable)(transfer complete interrupts only)	DMA_CH1_Interrupt_Status
		DMA Interrupt Status (DMA_Interrupt_Status) (First level status. Indicates major block event source: DMA channel, MTL or MAC)
		MTL Interrupt Status (MTL_Interrupt_Status) (Status summary for MTL block interrupts: Rx Parser, EST, FIFO Debug, Queue 1/Queue 0)
Tx interrupt 0/1	DMA Channel Tx Control (DMA_CH0_Tx_Control)	DMA Channel 0 Status (DMA_CH0_Status)
	DMA Channel 0 Interrupt Enable (DMA_CH0_Interrupt_Enable)	
	DMA Channel 1 Tx Control (DMA_CH1_Tx_Control)	DMA Channel 1 Status (DMA_CH1_Status)
	DMA Channel 1 Interrupt Enable (DMA_CH1_Interrupt_Enable)	
Rx interrupt 0/1	DMA Channel Rx Control (DMA_CH0_Rx_Control)	DMA Channel 0 Status (DMA_CH0_Status)
	DMA Channel 0 Interrupt Enable (DMA_CH0_Interrupt_Enable)	
	DMA Channel 1 Rx Control (DMA_CH1_Rx_Control)	DMA Channel 1 Status (DMA_CH1_Status)
	DMA Channel 1 Interrupt Enable (DMA_CH1_Interrupt_Enable)	

Table continues on the next page...

Table 614. Interrupt request (continued)

Interrupt request	Interrupt Enable / Mask Register	Interrupt Flag Register
Safety interrupt	MTL ECC Interrupt Enable (MTL_ECC_Interrupt_Enable)	MTL ECC Interrupt Status (MTL_ECC_Interrupt_Status)
		MTL Safety Interrupt Status (MTL_Safety_Interrupt_Status)
	MTL DPP Control (MTL_DPP_Control)	MAC DPP FSM Interrupt Status (MAC_DPP_FSM_Interrupt_Status)
	MAC FSM Control (MAC_FSM_Control)	

These are the interrupt output signals that are synchronous to the CSR clock.

- Sbd_intr_o – common interrupt
- Sbd_perch_tx_intr_o[max_dma_ch] – interrupt per transmit channel
- Sbd_perch_rx_intr_o [max_dma_ch] – interrupt per receive channel

NOTE

max_dma_ch = number of transmit/receive queues, which is 2

The sbd_intr_o common interrupt is a level signal. When it is asserted, a corresponding interrupt event source can be found in DMA Interrupt Status (DMA_Interrupt_Status), which is a read-only register that contains the event source fields corresponding to each DMA channel (transmit and receive queue pair), MAC transaction layer, and MAC blocks. You must then read the following registers and look for the fields that are 1:

- MAC Interrupt Status (MAC_Interrupt_Status)
- MTL Interrupt Status (MTL_Interrupt_Status)
- DMA Channel 0 Status (DMA_CH0_Status)

The sbd_intr_o interrupt deasserts only when all the enabled interrupt events are clear in their respective status registers, and correspondingly, all the fields in DMA Interrupt Status (DMA_Interrupt_Status) are 0. DMA Channel 0 Status (DMA_CH0_Status) captures all the interrupt events of that transmit DMA and receive DMA channel pair.

DMA Channel 0 Interrupt Enable (DMA_CH0_Interrupt_Enable) contains the corresponding enable fields for each of the interrupt events. These are the two groups of interrupts in the DMA channel:

- Normal—DMA_CH0_Status[NIS] indicates this interrupt, which is used for events that occur during the normal transfer of packets (TI, RI, TBU).
- Abnormal—DMA_CH0_Status[AIS] indicates this interrupt, which is used for error events.

Interrupts are not queued. If the same interrupt event occurs again before the driver responds to the previous one, no additional interrupts generate.

The common sbd_intr_o output signal asserts for the transfer complete interrupts only when the corresponding interrupts are enabled in DMA Channel 0 Interrupt Enable (DMA_CH0_Interrupt_Enable).

EMAC also supports these per-channel transfer-complete interrupt signals:

- sbd_perch_tx_intr_o[max_dma_ch] (transmit per channel interrupts)
- sbd_perch_rx_intr_o[max_dma_ch] (receive per channel interrupts)

The behavior of the RI/TI/sbd_perch_tx_intr_o[]/sbd_perch_rx_intr_o[] changes depends on the configuration specified in DMA_Mode[INTM]. This table explains the transfer complete interrupt behavior.

Table 615. Transfer complete interrupt behavior

Interrupt mode	Behavior of sbd_perch_tx_intr_o[] and sbd_perch_rx_intr_o[]	Behavior of the TI/RI interrupts and sbd_intr_o
INTM = 1	In this mode, these signals indicate the values of the corresponding DMA_CH0_Status[RI] and DMA_CH0_Status[TI] fields when DMA_CH0_Status[RI] and DMA_CH0_Status[TI] are 1, respectively. Therefore, they are level signals that you clear by writing 1 to these fields. The signals do not assert when DMA_CH0_Status[RI] or DMA_CH0_Status[TI] is 0.	DMA_CH0_Status[RI] and DMA_CH0_Status[TI] are configured as explained. For any RI/TI events: • The sbd_intr_o signal does not assert. • DMA_CH0_Status[NIS] remains 0.
INTM = 2	In this mode, RI/TI are queued and indicate the values of the corresponding DMA_CH0_Status[RI] and DMA_CH0_Status[TI] fields when any of these fields is 1. RI and TI are level signals that you clear by writing 1 to these fields. However, the fields become 1 again if another TI/RI event is detected before DMA_CH0_Status[RI] and DMA_CH0_Status[TI] become 1 for the previous event.	DMA_CH0_Status[RI] and DMA_CH0_Status[TI] become 1 whenever the transfer complete event is detected and are reset whenever the software driver changes them to 0 by writing 1. However, if another transfer complete event is detected before the software changes it to 0 (services it), EMAC automatically writes 1 to these fields again. The generation of the sbd_intr_o signal; however, is not based on DMA_CH0_Status[RI] or DMA_CH0_Status[TI].

78.4 External signals

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

78.4.1 Module signals

This table provides port/signal names and their descriptions. See the IOMUX file attached to this document for details.

Table 616. Module signals

Port name (clock/signal)	I/O	Description
MII_RMII_TXCLK (Clock)	I	MII: The external PHY provides this transmission clock, which operates at a frequency of 25 MHz in 100 Mbps mode and at 2.5 MHz in 10 Mbps mode. All transmission signals that MAC generates are synchronous to this clock, which is required for all PHY interfaces.

Table continues on the next page...

Table 616. Module signals (continued)

Port name (clock/signal)	I/O	Description
		RMII: The RMII interface uses this 50 MHz clock. If you select RMII mode, MII_RX_CLK (25 MHz or 2.5 MHz) must be derived from the RMII reference clock.
MII_RX_CLK (Clock)	I	The external PHY provides this receive clock for the MII and RMII interfaces. The clock operates at a frequency of 25 MHz in 100 Mbps mode and at 2.5 MHz in 10 Mbps mode. All MII receive signals that MAC receives are synchronous to MII_RX_CLK. The clock's input is required for all PHY interfaces.
EMAC_PPS[3:0] (Signals)	I/O	This group of signals is used as pulse per second in Output mode and as media clock generation trigger in Input mode. The signals trigger input to DUT to capture presentation time. Based on the presentation control value of MAC PPS Control (MAC_PPS_Control), the signals can be defined as pulse or level signals.
MII_RMII_TX_EN (Signal)	O	MAC drives this signal, which performs multiple functions depending on the selected PHY interface as described in this list: • MII: When high, indicates that valid data is being transmitted to the phy_txd_o bus. MII_RMII_TX_EN is synchronous to MII_RMII_TX_CLK. • RMII: When high, indicates that valid data is being transmitted to the phy_txd_o bus. MII_RMII_TX_EN is synchronous to MII_RMII_RX_CLK.
MII_RMII_TXD[3:0] (Signals)	O	This is a group of transmit data signals driven by MAC. These signals perform multiple functions depending on the selected PHY interface as described in this list: • MII: Bits[3:0] provide the MII transmit data nibble. The data is valid only when the MII_RMII_TX_EN signal is high. MII_RMII_TXD[3:0] is synchronous to MII_MII_TX_CLK. • RMII: Bits[1:0] provide the RMII transmit data. The data is valid

Table continues on the next page...

Table 616. Module signals (continued)

Port name (clock/signal)	I/O	Description
		only when the MII_RMII_TX_EN signal is high. MII_RMII_TXD[3:0] is synchronous to MII_RMII_TX_CLK.
MII_CRS (Signal)	I	This signal is valid only in MII mode. The PHY drives this signal high when the transmit or receive medium is not idle, and drives the signal low when both these mediums are idle. The signal is not synchronous to any clock.
MII_COL (Signal)	I	This signal is valid only in MII mode. The PHY drives this signal high when a collision is detected on the medium. The signal is not synchronous to any clock.
MII_RMII_RX_DV (Signal)	I	The PHY drives this signal. It performs multiple functions depending on the selected PHY interface as described in this list: • MII: Indicates that the data on the MII_RXD bus is valid. It remains high continuously from the first recovered byte or nibble of the packet through the final recovered byte or nibble of the packet. MII_RMII_RX_DV is synchronous to MII_RX_CLK. • RMII: Contains the CRS and data valid information of the receive interface. MII_RMII_RX_DV is synchronous to MII_RMII_TX_CLK.
MII_RMII_RX_ER (Signal)	I	The PHY drives this signal. It performs multiple functions depending on the selected PHY interface as described in this list: • MII: Indicates an error or carrier extension in the received packet of the MII_RXD[3:0] bus. MII_RMII_RX_ER is synchronous to MII_RX_CLK. • RMII: Is not used.
MII_RMII_RXD[3:0] (Signals)	I	This is a group of data signals received from the PHY. These signals perform multiple functions depending on the selected PHY interface as described in this list:

Table continues on the next page...

Table 616. Module signals (continued)

Port name (clock/signal)	I/O	Description
		• MII: Bits [3:0] provide the MII receive data nibble. The data is valid only when the MII_RMII_RX_DV signals are high. MII_RMII_RXD[3:0] is synchronous to MII_RX_CLK. • RMII: Bits [1:0] provide the RMII receive data. The data is valid only when the MII_RMII_RX_DV signal is high. MII_RMII_RXD[3:0] is synchronous to MII_RMII_TX_CLK.
MII_RMII_MDC	O	MAC provides timing reference for MII_RMII_MDIO or MII through this periodic clock. The application clock generates this clock through a clock divider that MAC_MDIO_Address[CR] controls.
MII_RMII_MDIO (Signal)	I/O	MDIO uses this signal to transfer control and data information to PHY.

78.5 Using PHY interfaces

This section is Synopsys Proprietary. Used with permission.

This module support the following modes:

- RMII 10/100 Mbps interface
- MII 10/100 Mbps interface

Phy_intf_sel input signal decides which mode is selected. Samples the Phy_intf_sel signal at reset. See External signals for more information. MAC_Configuration[PS] and MAC_Configuration[FES] selects the mode's speed.

The module supports the IEEE802.3-2015 specification for MII and RMII specification version 1.2 from RMII consortium.

NOTE

RMII reference clock (50 MHz) can be fed to IP from an external source or internally from PLL on SoC.

The module supports the access of the phy registers through SMA. It is a two wire Station management interface (MIM):

1. MDC
2. MDIO

According to IEEE 802.3 specification, maximum operating frequency of MDC is 2.5 Mhz which system clock derives using a divider. MAC_MDIO_Address[CR] programs to generate different MDC clock frequency.

SMA supports MDIO clause 45 and clause 22 frame structure per the IEEE802.3 specification. Writing 1 to MAC_MDIO_Address[C45E] enables the clause 45 frame structure.

The MII interface reduces the accuracy of the 1588 timestamp if it is overclocked to run at 200 Mbps. This happens because the MAC logic uses the MII interface speed,to adjust or compensate for the timestamps taken at MII, as compared to the time generated in the PTP clock domain as specified in MAC_Configuration[FES].

78.6 VLAN and double VLAN insertion, deletion, replacement and tagging

This section and all its sub-sections are Synopsys proprietary. These are used with permission.

The following sections describe the VLAN and double VLAN features.

78.6.1 Double VLAN processing

In the double VLAN tagging processing, the module supports the processing of two VLAN tags. The two VLAN tags are:

1. Inner VLAN tag (C-VLAN)
2. Outer VLAN tag (S-VLAN)

If there is only one tag in a packet then it is considered as an outer tag.

The module uses MAC_VLAN_Incl and MAC_Inner_VLAN_Incl and MAC_VLAN_Tag registers to support the following functions in a double VLAN processing feature.

- Insertion, replacement, or deletion of up to two VLAN tags in the transmit path.
- Packet filtering and stripping on the basis of any one of the two VLAN tags in the receive path. Stripping and providing up to two VLAN tags in the receive path as a part of the receive status.

78.6.1.1 Transmit path

Table 617. Double VLAN processing features in transmit path

Feature	Description
Support for C-VLAN and S-VLAN tag types	The inner or outer VLAN tag can be of C-VLAN and S-VLAN type. MAC_VLAN_Incl[CSVL] and MAC_Inner_VLAN_Incl[CSVL] specifies the VLAN type. The module supports the processing of any sequence of outer and inner VLAN tags. **NOTE** The module does not support the C-VLAN and S-VLAN sequence. MAC does not examine whether the packet, which the application provides has a valid sequence of the VLAN tag types or the insertion or replacement operation results in an invalid sequence of VLAN tag type. Therefore, the application must provide a correct sequence of VLAN tag types and program the MAC in such a way that it results in correct sequence of VLAN tag types in the transmitted packet. The application must ensure the following: • The inner tag should not be S-VLAN when outer C-VLAN Tag insertion is enabled. • The outer tag should not be C-VLAN when inner S-VLAN Tag insertion is enabled. • The inner tag should not be S-VLAN when C-VLAN replaces the outer tag. • The outer tag should not be C-VLAN when S-VLAN replaces the inner tag.
VLAN tag deletion	MAC_VLAN_Incl[VLC] or MAC_Inner_VLAN_Incl[VLC] respectively enables the VLAN tag deletion for an outer or inner tag. When you enable the VLAN deletion, MAC deletes the tag present at the corresponding position. When a packet has only one tag, it is considered as the outer tag. If you enable the inner tag deletion and if there is only one tag in the packet, then the MAC does not delete the tag.
VLAN tag insertion or replacement	MAC_VLAN_Incl[VLC] or MAC_Inner_VLAN_Incl[VLC] respectively enables the VLAN tag insertion or replacement for an outer or inner tag. When you enable the VLAN tag insertion or replacement, the MAC_VLAN_Incl[VLTI] or MAC_Inner_VLAN_Incl[VLTI] determines whether the VLAN tag must be fetched from the register or from the control word.

78.6.1.2 Receive path

Table 618. Double VLAN processing in receive path

Feature	Description
Outer or inner VLAN tag-based filtering	Mac can filter packets through the ERIVLT bit on the basis of the outer or inner VLAN tag.
C-VLAN or S-VLAN tag-based filtering	Mac can filter packets through the ERSVLM bit on the basis of the C-VLAN or S-VLAN type.
Outer and inner VLAN tag stripping	Mac can strip the outer and inner VLAN tags from received frame on the basis of the EVLS and EIVLS bits.
16-bit outer and inner VLAN tag and type in Rx status	Mac can provide the 16-bit outer and inner VLAN tag and type in the Rx status on the basis of the EVLRXS and EIVLRXS bits, respectively.
Disabling or skipping checking of outer VLAN tag type	Mac can disable or skip checking of an outer VLAN tag type to match C-VLAN or S-VLAN on the basis of the DOVLTC bit.

78.6.1.3 Source address and VLAN insertion, replacement, or deletion

This module supports the SA, and VLAN insertion, replacement and deletion feature. The SA and VLAN fields are Tx packet-related control information that interfaces provide as part of the control word. IP supports the feature to insert or replace the source address on the basis of the information in the MAC address registers, and it also supports the feature to insert, replace, or delete the VLAN fields (VLAN type and VLAN tag) on the basis of the setting of the MAC_VLAN_Incl[VLTI]. SA insertion or replacement feature is enabled for all the transmit packets or selective packets. Similarly, VLAN insertion, replacement, or deletion feature is enabled for all the Tx packets or selective packets.

78.6.1.4 Programming source address insertion or replacement

You can use the SA insertion or replacement feature to instruct MAC to perform the following actions for Tx packets:

- Insert the content of the MAC address registers in the SA field
- Replace the content of the SA field with the content of the MAC address registers

When SA insertion is enabled, the application must ensure that the packets sent to MAC do not have the SA field. The MAC does not check whether the SA field is present in the transmit packet and it inserts the content of MAC address registers in the SA field. Similarly, when the SA replacement is enabled, the application must ensure that the SA field is present in the packets sent to the MAC.

MAC replaces the six bytes following the DA field in the transmit packet with the content of the MAC address registers.

- Configure MAC_Configuration[SARC] to enable the SA insertion or replacement for all Tx packets.
- Enable the SA insertion for selective packet by configuring the SA insertion control field (bits [25:23] of TDES3) in the first transmit descriptor of the packet. When you write 1 to bit 25 of TDES3, the SA insertion control field indicates insertion or replacement by MAC Address1 registers. When bit 25 of TDES3 resets, it indicates insertion or replacement by MAC Address 0 registers.

If you do not enable the MAC Address1 registers, then the MAC Address0 registers are used for insertion or replacement irrespective of the value of the most-significant bit of the SA insertion control field.

78.6.1.5 Programming VLAN insertion, replacement, or deletion

You can use the VLAN insertion, replacement, or deletion feature to instruct MAC to perform the following actions for the Tx packets:

- Delete the VLAN type and VLAN tag fields.
- Insert or replace the VLAN type and VLAN tag fields.

Insertion or replacement is done on the basis of the setting of the MAC_VLAN_Incl[VLTI] as described in theTable 619:

Table 619. VLAN insertion or replacement based on VLTI bit

Condition	Description
VLTI bit=1	MAC inserts or replaces the following: • VLAN type field (C-VLAN or S-VLAN as indicated by the MAC_VLAN_Incl[CSVL]) • VLAN tag field depending on the content of the VT field of transmit context descriptor of the packet
VLTI bit resets	MAC inserts or replaces the following: • VLAN type field (C-VLAN or S-VLAN as indicated by the MAC_VLAN_Incl[CSVL]) • VLAN tag field with the MAC_VLAN_Incl[VLT]

When the VLAN replacement or deletion is enabled, MAC checks whether the VLAN type field (0x8100 or 0x88a8) is present after the DA and SA fields in the transmit packet. The replace or delete operation does not occur if the VLAN type field is not detected in two bytes following the DA and SA fields. However, when the VLAN insertion is enabled, MAC does not check the presence of VLAN type field in the transmit packet and just inserts the VLAN type and VLAN tag fields.

Configuring MAC_VLAN_Incl[VLC] and MAC_VLAN_Incl[VLP] enables the VLAN insertion, replacement, or deletion feature for all Tx packets.

Configuring the VTIR field of TDES2 normal descriptor enables the VLAN insertion, replacement, or deletion for selective packets.

In addition, the VLP (VLAN Priority control) field must reset in MAC_VLAN_Incl (for outer VLAN) and MAC_Inner_VLAN_Incl register (in inner VLAN) for MAC to take the control inputs from the host, depending on the configuration.

78.7 Packet Filtering

This section and all its sub-sections are Synopsys proprietary. Used with permission.

MAC receiver contains various packet filtering scheme. Figure 559 shows the filtering sequence in their precedence order of received packet.

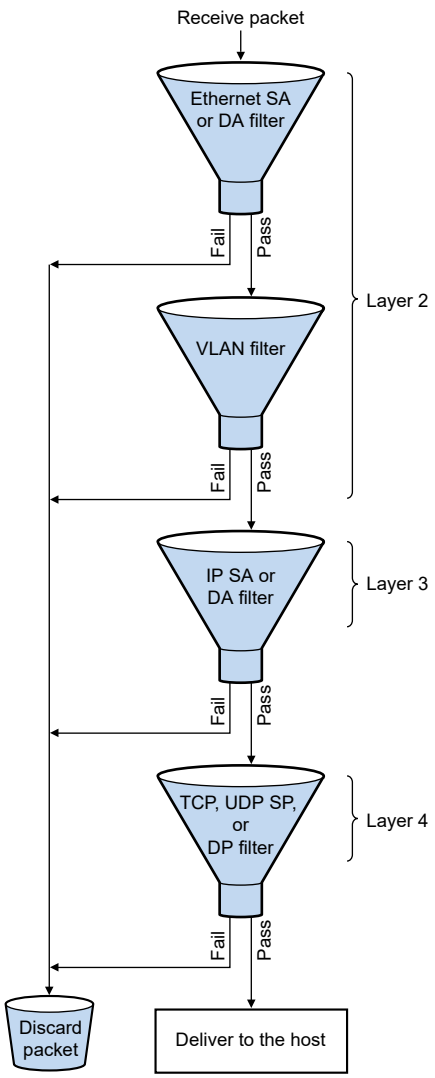

Figure 559. Packet filtering sequence

If you do not enable any of the layer filters, then that filter is bypassed and the subsequent filter is applied. Discard the packet that fails any of the filters. However, you can forward the discarded packet to the host on the basis of the register control.

78.7.1 Source address or destination address filtering

The address filtering module of MAC checks the SA and DA fields of each incoming packet. Programming of different types of address filtering is described in the sections that follows.

78.7.1.1 Unicast destination address filtering

MAC supports up to three MAC addresses for unicast perfect filtering. If perfect filtering is selected (MAC_Packet_Filter[HUC] resets), MAC compares all 48 bits of received unicast address with the programmed MAC address for any match. Default MacAddr0 is always enabled. MAC selects the MacAddr1 to MacAddr2 addresses with an individual enable field. Each byte of MacAddr1 to MacAddr2 can be masked when you compare them with corresponding received DA byte by writing 1 to the corresponding Mask byte control field in the register. This enables group address filtering for the DA.

In hash filtering mode (when you write 1 to HUC bit), MAC performs imperfect filtering by using a 64-bit hash table for unicast addresses . For hash filtering, MAC uses the upper 6 bits CRC of the received destination address to index the content of the hash table. A value of 00000 selects bit 0 of selected register, and a value of 11111 selects bit 63 of hash table register. If the value of

the corresponding bit (indicated by the 6-bit CRC) is 1, the unicast packet is considered to have passed the hash filter, otherwise, the packet is considered to have failed the hash filter.

78.7.1.2 Multicast destination address filtering

Enable MAC_Packet_Filter[PM] to pass all the multicast packets or disable to do multicast addresses filtering on the basis of MAC_Packet_Filter[HMC]. Compare the multicast address with the configured MAC destination address registers (1–2), also supports the group address filtering.

In Hash filtering mode, MAC performs imperfect filtering using a 64-bit hash table. MAC uses the upper 6-bits CRC of received multicast address to index the content of the hash table. A value of 000000 selects bit 0 of selected register and a value of 111111 selects bit 63 of the hash table register. The multicast packet is considered to have passed the hash filter if the value of the corresponding bit is equal to 1. Otherwise, the packet is considered to have failed the hash filter.

78.7.1.3 Hash or perfect address filtering

Configure MAC_Packet_Filter[HPF] to enable or disable the destination address filtering either by hash filter or perfect filter. Also configure MAC_Packet_Filter[HUC] and MAC_Packet_Filter[HMC] to select the hash filtering or perfect filtering for unicast or multicast packet.

78.7.1.4 Broadcast address filtering

MAC does not filter any broadcast packets by default. You must write 1 to MAC_Packet_Filter[DBF] to reject the broadcast packets.

78.7.1.5 Unicast source address filtering

MAC by default compares the source address field with the value configured in the source address registers. Configure bit 30 of MAC address register [1-2] to use it for source address instead of destination address comparison. MAC also supports group filtering with SA. You can filter a group of addresses by masking one or more bytes of the address. MAC drop the packets that fail the SA filter if you write 1 to MAC_Packet_Filter[SAF] field. Otherwise, the result of the SA filter is given as a status bit in the receive status word. When you write 1 to the SAF field, the SA filter and DA filter results ends to decide whether you can forward the packets. This means that the packet is dropped if either filter fails. The packet is forwarded to the application only if the packet passes both filters in-order.

78.7.1.6 Inverse filtering

For DA and SA filtering, you can invert the filter-match result at the final output by writing 1 to the DAIF and SAIF fields of MAC_Packet_Filter register. The DAIF field is applicable for both the unicast and multicast DA packets. The unicast or multicast destination address filter result is inverted in this mode. Similarly, writing 1 to the SAIF field reverses the result of unicast SA filter.

Table 620 and Table 621 summarize the DA and SA filtering on the basis of the type of packets received.

Table 620. Destination address filtering

Packet type	PR	HPF	HUC	DAIF	HMC	PM	DBF	DA filter operation
Broadcast	1	X	X	X	X	X	X	Pass
	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail
Unicast	1	X	X	X	X	X	X	All packets pass
	0	X	0	0	X	X	X	Pass on perfect or group filter match

Table continues on the next page...

Table 620. Destination address filtering (continued)

	0	X	0	1	X	X	X	Fail on perfect or group filter match
	0	0	1	0	X	X	X	Pass on hash filter match
	0	0	1	1	X	X	X	Fail on hash filter match
	0	1	1	0	X	X	X	Pass on hash or perfect or group filter match
	0	1	1	1	X	X	X	Fail on hash or perfect or group filter match
Multicast	1	X	X	X	X	X	X	Pass all packets
	X	X	X	X	X	1	X	Pass all packets
	0	X	X	0	0	0	X	Pass on perfect or group filter match and drop pause packets if PCF = 0x
	0	0	X	0	1	0	X	Pass on hash filter match and drop pause packets if PCF = 0x
	0	1	X	0	1	0	X	Pass on hash or perfect or group filter match and drop pause packets if PCF = 0x
	0	X	X	1	0	0	X	Fail on perfect or group filter match and drop pause packets if PCF = 0x
	0	0	X	1	1	0	X	Fail on hash filter match and drop pause packets if PCF = 0x
	0	1	X	1	1	0	X	Fail on hash or perfect/group filter match and drop pause packets if PCF = 0x

Table 621. Source address filtering

Packet type	PR	SAIF	SAF	SA filter operation
Unicast	1	X	X	Pass all packets.
	0	0	0	Pass status on perfect or group filter match but do not drop packets that fail
	0	1	0	Fail status on perfect or group filter match but do not drop packet
	0	0	1	Pass status on perfect or group filter match and drop packets that fail
	0	1	1	Fail status on perfect or group filter match and drop packets that fail

NOTE

When you write 1 to the MAC_Packet_Filter[RA] field, all packets are forwarded to the system along with the correct result of the address filtering in the Rx Status.

78.7.2 VLAN filtering

VLAN tag filter can be done either by perfect match or hash table. Depending upon the configuration, MAC can compare either lower 12 bits or all 16 bits of received VLAN tag for perfect match. MAC forward the VLAN tagged packet with match status when it drop all the packets which do not match.

MAC uses 16-bit VLAN hash table for group address filtering on the basis of the VLAN tag. If MAC enables the hash filtering then the most significant 4-bit of CRC-32 of VLAN tag are used to index the content of the MAC_VLAN_Hash_Table. A value of 1 in the VLAN hash table register, corresponding to the index indicates that the VLAN tag of the packet has matched and the packet should be forwarded. A value of 0 indicates that VLAN-tagged packet should be dropped.

MAC supports the inverse matching for VLAN packets. In the Inverse matching mode, the packet must be dropped when the VLAN tag of a packet matches the perfect or hash filter. If MAC enables the VLAN perfect and VLAN hash match, then a packet is considered as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, MAC forwards a packet only when both the perfect and hash filters indicate mismatch.

Table 622 specifies the different possibilities for VLAN matching and the final VLAN match status. When you write 1 to MAC_Packet_Filter[RA] all packets are received and it indicates the VLAN match status in the VF field of RDES2 normal descriptor (write-back format). When the RA field is not set and when you write 1 to MAC_Packet_Filter[VTFE] the packet drops if the final VLAN match status fails

When VLAN VID programs to 0 in the VL field of MAC_VLAN_Tag register, consider that all the VLAN-tagged packets are perfectly matched but the status of the VLAN hash match depends on the VTHM and VTIM fields in MAC_VLAN_Tag register.

Table 622. VLAN match status

VID	VLAN perfect filter match result	VTHM bit	VLAN hash filter match result	VTIM bit	Final VLAN match status
VID = 0	Pass	0	X	X	Pass
	Pass	1	X	0	Pass
	Pass	1	Fail	1	Pass
	Pass	1	Pass	1	Fail
VID1= 0	Pass	X	X	0	Pass
	Fail	0	X	0	Fail
	Fail	1	Fail	0	Fail
	Fail	1	Pass	0	Pass
	Fail	0	X	1	Pass
	Pass	X	X	1	Fail
	Fail	1	Pass	1	Fail
	Fail	1	Fail	1	Pass

In Table 622, X represents any value.

78.7.3 VLAN filter fail packets queue

When you enable VLAN filtering, route the VLAN filter fail packets to a programmable queue (VFFQ) when the value of MAC_Packet_Filter[RA] = 1 or MAC_Packet_Filter[VTFE] = 0 and write 1 to MAC_RxQ_Ctrl4[VFFQE] for the queue.

Route the packets that passes the VLAN filtering to Rx queues on the basis of the VLAN tag priority field by configuring the PSRQ field in the corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers. Discard the packets that fail the VLAN filter if RA=0 or VTFE=1. However, when RA=1 or VTFE=0, forward the VLAN filter fail packets to the application. In such case, when you write 1 to the VLAN filter fail queue enable (VFFQE) field, the VLAN filter fail packets forward to the Rx queue number programmed in the VFFQ field. If the value of VFFQE=0, the VLAN priority mapping determines the Rx queue number per the PSRQ fields.

Table 623 shows the Rx queue routing table for unicast tagged packets, with DA or SA filter enabled.

Table 623. Rx queue routing table for unicast tagged packets

RA	VFTE	SA or DA filter result	VLAN filter result	VFFQE	Queue routing
X	X	Pass	Pass	X	PSRQ
0	0	Pass	Fail	0	PSRQ
0	0	Pass	Fail	1	VFFQ
0	X	Fail	X	X	Dropped
0	1	Pass	Fail	X	Dropped
1	X	Fail	X	0	UFFQ*/PSRQ
1	X	Fail	X	1	UFFQ*/VFFQ
1	X	Pass	Fail	0	PSRQ
1	X	Pass	Fail	1	VFFQ

X : Don't care condition * : When UFFQE is enabled else PSRQ.

78.7.4 Extended receive VLAN filtering and routing

When the extended Rx VLAN filtering and routing is enabled then both the perfect filtering and hash filtering can be enabled. The overall VLAN filter result is based on the perfect filter result and hash filter result (if enabled). Filter result is passed to application as part of the status bit. Extended routing will take place only if VLAN filter has passed. Routing is only based on perfect filter result. Each perfect filter has a DMA channel enable and DMA channel number filed which must be programmed for routing.

See the extended VLAN based DMA selection in Dynamic (per packet) mapping for more information about routing.

78.7.4.1 Comparison mode

Application has these comparison option for each VLAN tag filter:

- Programs MAC to compare the inner or outer VLAN tag either with 12 bits or 16 bits programmed VID.
- Selects whether the VID comparison is for SVLAN or CVLAN type frames, if type check is enabled for a filter.

78.7.4.2 Filtering

Perfect filtering is done on the basis of the MAC_VLAN_Tag_Filter registers. MAC compares the relevant VLAN tag ID and gives a result for each VLAN tag filter.

The results for each VLAN tag filter are:

- Pass- If any one of the VLAN tag filters gives a match.
- Fail- If the frame mismatches all the filters.

This behavior is applicable only when the inverse filtering is not enabled in MAC_VLAN_Tag_Ctrl.

If inverse filtering is enabled and the frame mis-matches all the relevant filters then it is considered to have passed the VLAN filter. If the frame matches any one of the relevant filters then it is considered to have failed. The frame is bypassed to the application if none of the enabled filters can perform a comparison or if none of the filters are enabled.

The overall filter result and the programming on MAC_Packet_Filter[VTFE] and MAC_Packet_Filter[RA] determines if the frame will drop or it is forwarded to the application. If the value of RA = 1 or VTFE = 0, then the frame is always forwarded whether the filter result is a pass or fail, . If the value of RA = 0 and VTFE = 1, only then, if the VLAN tag filter result is a pass the MAC forwards the frame. If the frame is forwarded to the application, then the relevant filter result is indicated through the status bits.

78.7.4.3 Filter status

The extended receive VLAN filtering and routing feature provides two status fields to show the comparison result of the VLAN tags.

By default, MAC indicates the VLAN filter status through one bit in the status VF field in RDES2. When you enable the extended RX VLAN filtering and routing, two status fields will show the comparison result of the VLAN tags. The outer VLAN tag filter pass and inner VLAN tag filter pass bits are defined in the following positions. The status indicated through these fields depends on the programming as described below.

In RDES2:

- Bit 15 – Outer VLAN tag filter status
- Bit 14 – Inner VLAN tag filter status

In ARI status: MAC filter status:

- Bit 15 – Outer VLAN tag filter status
- Bit 14 – Inner VLAN tag filter status

In MRI status:

- Bit 47 – Outer VLAN tag filter status
- Bit 46 – Inner VLAN tag filter status

Outer VLAN tag filter status (OTS)

- In perfect filtering, without enabling inverse filtering, if you write 1 to this field, it indicates that the frame's outer VLAN tag has matched one of the VLAN tag filters.
- If this field resets, it indicates that the frame's outer VLAN tag has either failed the relevant outer VLAN tag filters or bypassed them.
- This field resets if none of the filters are enabled for outer VLAN tag comparison.
- If inverse filtering is enabled and if you write 1 to this field, then the frame's VLAN tag has passed all the relevant VLAN tag filters. If it is resets, then it has failed at least one filter or bypassed all the filters programmed for outer VLAN tag comparison.
- This bit is valid for both single and double VLAN tagged frames.

Inner VLAN tag filter status (ITS)

- In perfect Filtering, without enabling inverse filtering, if you write 1 to this field, it indicates that the frame's inner VLAN tag has matched one of the VLAN tag filters.
- If this field resets, it indicates that the frame's inner VLAN tag has either failed the relevant inner VLAN tag filters or bypassed them.
- This field resets if none of the filters are enabled for inner VLAN tag comparison.
- If Inverse Filtering is enabled and if you write 1 to this field, then the frame's VLAN tag has passed all the relevant VLAN tag filters. If it resets, then it has failed at least one filter or bypassed all the filters programmed for inner VLAN tag comparison.

- This bit is valid for only double VLAN tagged frames, when double VLAN processing is enabled.

The application must observe the status fields and the program to determine if the frame has passed or failed the VLAN filter.

Table 624 and Table 625 describes the possible filter combinations and the corresponding filter results and they also explain the scenarios when the double VLAN processing and the hash VLAN filter are enabled in the design.

Legend for the table OTS and ITS Bit Values with at least 1 perfect filter enabled

- VTIM: VLAN tag inverse match enable – bit 17 in VLAN_Tag_Ctrl register.
- HFO: Hash filter enabled for outer VLAN tag comparison - bit 25 and bit 27 in VLAN_Tag_Ctrl register.
- HFI: Hash filter enabled for inner VLAN tag comparison – bit 25 and bit 27 in VLAN_Tag_Ctrl register.
- PFO – Perfect filter comparison enabled for outer VLAN tag - Any of the MAC_VLAN_Tag_Filter registers is enabled (write 1 to bit 16) and programmed for outer VLAN tag comparison (write 0 to bit 20).
- PFI – Perfect filter comparison enabled for Inner VLAN Tag - Any of the MAC_VLAN_Tag_Filter registers is enabled (write 1 to bit 16) and programmed for inner VLAN tag comparison (write 1 to bit 20).
- OTS – Outer VLAN tag filter status
- ITS – Inner VLAN tag filter status

Table 624 shows the possible values of status bits (OTS and ITS) when at least one perfect filter is enabled.

Table 624. OTS and ITS bit values with at least 1 perfect filter enabled

VTIM	HFO	HFI	PFO	PFI	OTS	ITS
0	0	0	0	1	0	1/0
0	0	0	1	0	1/0	0
0	0	0	1	1	1/0	1/0
0	1	0	1	1	1/0	1/0
0	1	0	1	0	1/0	0
0	1	0	0	1	1/0	1/0
0	0	1	1	1	1/0	1/0
0	0	1	1	0	1/0	1/0
0	0	1	0	1	0	1/0
1	0	0	0	1	0	1/0
1	0	0	1	0	1/0	0
1	0	0	1	1	1/0	1/0
1	1	0	1	1	1/0	1/0
1	1	0	1	0	1/0	0
1	1	0	0	1	1/0	1/0

Table continues on the next page...

Table 624. OTS and ITS bit values with at least 1 perfect filter enabled (continued)

VTIM	HFO	HFI	PFO	PFI	OTS	ITS
1	0	1	1	1	1/0	1/0
1	0	1	1	0	1/0	1/0
1	0	1	0	1	0	1/0

Table 625 shows the possible values of status bits (OTS and ITS) when no perfect filters are enabled except the VLAN hash filter is enabled.

Table 625. OTS and ITS bit values with only VLAN hash filter enabled

VTIM	HFO	HFI	OTS	ITS
0	0	0	0	0
0	1	0	1/0	0
0	0	1	1/0	1/0
1	0	0	1/0	0
1	1	0	1/0	0
1	0	1	1/0	1/0

With no perfect filters enabled, any VLAN packet is considered to have bypassed the perfect filter. If Hash Filter is enabled for one of the Tags, then the respective Status bit depends on the Filter's result. The Status bits are set to 0 if VLAN Hash Filter is also not enabled.

If the value of ITS/OTS is shown as 1/0; then it indicates that the final result is dependent on the enabled relevant filter's result.

Example 1: The second row of OTS and ITS bit values with only VLAN hash filter enabled indicates that at least one Perfect Filter is enabled for Outer VLAN tag comparison and none of the filters are enabled for Inner VLAN tag comparison. Inverse VLAN Filtering is not enabled. The bit OTS is given as 1/0. If the received frame passes at least one of the enabled Outer VLAN Tag filters then the bit is set to 1. If the frame doesn't pass any of the enabled Outer VLAN Tag filters, then the bit is set to 0.

Example 2: The last row of table "OTS and ITS bit values with only VLAN hash filter enabled" indicates that the inverse filtering is enabled, hash filter and at least one perfect filter is enabled for Inner VLAN Tag comparison, then if the received frame's Inner VLAN tag mismatches with both the Hash Filter and all the enabled Perfect filters, then the frame will have the ITS bit set to 1 else it is set to 0. OTS will be set to 0 as no comparison is performed.

78.7.4.4 Stripping

Each VLAN tags has individual control over stripping. The programming options of always strip, never strip, strip on pass and strip on fail are available. Inner or outer VLAN tag stripping is based on the pass or fail results of the individual tag. If all the relevant filters bypasses a tag, stripping is not applicable for the tag.

- If strip on pass is enabled for the outer VLAN tag, then the stripping occurs only if the outer VLAN tag has passed the relevant filters. The outer VLAN tag filter result field will be 1.
- If strip on fail is enabled for the outer VLAN tag, then the stripping occurs only if the outer VLAN tag has failed relevant filters. The outer VLAN tag filter result field will reset.
- If the outer VLAN tag of the received frame is bypassed by the entire filter (no comparison has been made), then the tag is not stripped, though the status bit is 0.

- As multiple filters are enabled, it is possible that the received VLAN frame could have matched any one or more of the filters. The VLAN Tag's value is not always deterministic from the filter status bits.

If an application strips the VLAN tag on the basis of the filter result, it might lose the VID. You can use it, if stripping is enabled for any of the tags, place the tag in the status. For this the software or application will enable the respective VLAN tag in status bit - 24 or 31 in the MAC VLAN tag control register.

See section Programming guidelines for extended VLAN filtering and routing on receive for more information.

78.7.5 Layer 3 and layer 4 filtering

IP supports the layer 3 based packet filtering which is an IP source or destination address filtering in the IPv4 or IPv6 packets, and layer 4 based packet filtering which is a source or destination port number filtering in TCP or UDP. When you enable layer 3 and layer 4 packet filtering then packets are filtered in the following manner.

- Matched packets: MAC forward the packets that match all enabled fields to the application along with the status. It gives the matched field status only if MAC_Configuration[IPC] = 1 and if one of the following conditions is true:
  - All enabled layer 3 and layer 4 fields match
  - At least one enabled field matches and other fields are bypassed or disabled

When you enable multiple layer 3 and layer 4 filters, any filter match is considered as a match. If more than one filter matches, MAC provides the status of the lowest filter where filter 0 is the lowest filter and filter 3 is the highest filter.

- Unmatched packets: MAC drop the packets that do not match any enabled fields. You can use the inverse match feature to block or drop a packet with specific TCP or UDP over IP fields and forward all other packets.
- Non-TCP or UDP IP packets: By default, all the non-TCP or UDP IP packets bypasses the layer 3 and layer 4 filters. You can optionally program MAC to drop all the non-TCP or UDP packets over IP packets.
- IP has a control register MAC_L3_L4_Control to control the layer L3 and L4 packet filtering along with address registers to program the layer L3 and L4 fields to be matched.

78.7.6 Flexible receive parser

When you enable this function, all incoming packets are parsed per the programmable instruction stored in memory. It perform these functions:

- Packet filter (Accept or reject)
- DMA channel selection

Flexible receive parser block operates over the first 128 bytes data of receive packet on the basis of 64 bytes of instruction on each packet. Figure 560 shows the functional block diagram of flexible receive parser.

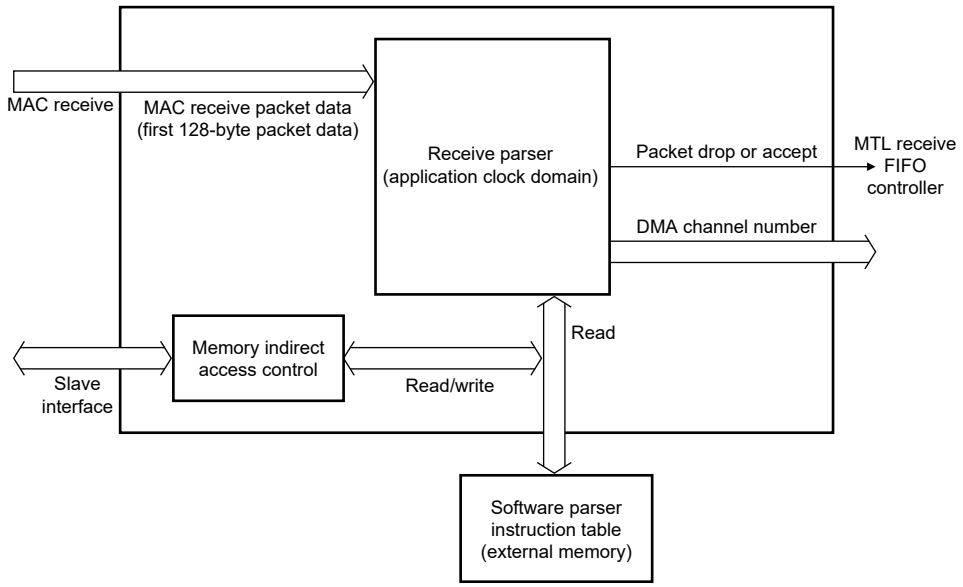

Figure 560. Functional block diagram of flexible receive parser

78.7.6.1 Instruction table format of the flexible receive parser

You must build the 96-bit wide instruction before enabling the receive parser feature and program each instruction as an entry in the instruction memory.

Table 626 shows the format of each entry in the instruction table .

Table 626. Rx parser instruction entry format

Field	Field Name	Description
31:0	MATCH_DATA	This is a 4-byte data. You can use it to compare with incoming packet data which starts at the frame offset as defined in [79:72] of the entry. The comparison is done only on those bits whose corresponding mask bits are 1 (MATCH_EN bits of [63:32]). See the notes (below this table) on the byte order relative to Ethernet arrival data and endianness which the QoS IP supports on the slave interface. The programming of this instruction table must adhere to the same.
62:32	MATCH_EN	When the MATCH_EN = 1, you can use the corresponding packet data bit for comparing. Otherwise, corresponding data bit is don’t care.
64	AF	Accept frame
65	RF	Reject frame
66	IM	Inverse match
67	NC	Next instruction control
71:68	Reserved	-

Table continues on the next page...

Table 626. Rx parser instruction entry format (continued)

Field	Field Name	Description
79:72	Frame offset	[77:72] indicates the frame offset in terms of 4 bytes. (Here [79:78] always 0) Compare the frame offset in the packet data for Match. This is in terms of 4 bytes. The value of actual frame offset in bytes are 0 01 42 8… ..63 252 The max value programmed in this instruction table is 128 B. The 'Actual frame offset' must not cross this limit.
87:80	OK index	If (NIC==0) the memory index you can use next when ENTRY_MATCH==1 and neither AF or RF = 1. If (NIC==1) the memory index you can use next when ENTRY_MATCH==0
95:88	DMA Ch No	Indicates the DMA channel number (1-bit for each). You can use this when ENTRY_MATCH ==1 and AF = 1 (Accept frame). The following bits give the encoding: bit[0]- DMA channel number o, bit[1]- DMA channel number , 1bit[2]- DMA channel number 2… bit[7]- DMA channel number 7. **NOTE** You can encode the DMA channel number using bit wise as QoS IP support multicasting or broadcast across DMA channels. See section 3.3.12 for more information and proper usage.
128:96	Reserved	0 (This field is only for software view and reserved for future enhancements. The memory width remains as 96-bits).

The parser begins parsing from the 0th entry, for each received packet. The subsequent parsing entry location (next entry or OK_INDEX[]) depends on the current entry parser result. Flexible receive parser flow chart shows the detailed flow.

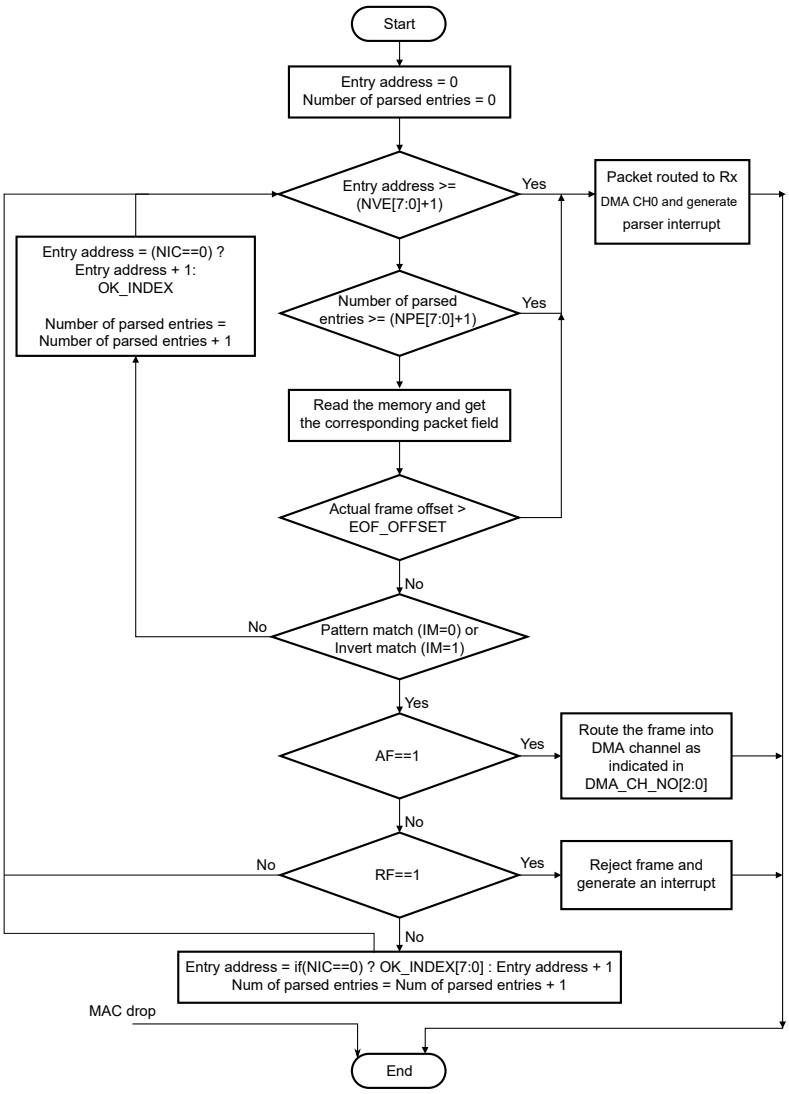

Figure 561. Flexible receive parser flow chart

The EOF_OFFSET shown in the figure is the least among the following:

- Actual packet size
- 128 Byte when frame pre-emption feature is not enabled or configured
- 128 Byte when frame pre-emption feature is enabled and packet is pre-emptive
- 64 Byte when frame pre-emption feature is enabled and packet is express packet

78.7.6.2 Number of valid entries (NVE)

NVE indicates the number of valid entries in the instruction table. The default value is 64. You can change this value by writing into MTL_RXP_Control_Status[NVE].

When parsing, an error is flagged in MTL_RXP_Interrupt_Control_Status[NVEOVIS], if the entry address is greater than MTL_RXP_Control_Status[NVE] + 1. IP generates an interrupt status (MTL_Interrupt_Status[MTLPIS]).

78.7.6.3 Number of parsable entries (NPE)

NPE indicates the number of entries that you can parse on an incoming packet. The default value is 64. Write into MTL_RXP_Control_Status[NPE] to change this value.

When parsing, an error is flagged in MTL_RXP_Interrupt_Control_Status[NPEOVIS], if the number of parsed of parsed entries is more than MTL_RXP_Control_Status[NPE] + 1. IP generates an interrupt status (MTL_Interrupt_Status[MTLPIS]).

NVE[] indicates the number of valid entries in the receive parser memory which you have built and NPE[] indicates the worstcase parsable entries considering the various possible paths that the parser can take. (NVE[] >= NPE[]).

78.7.6.4 Frame offset

It indicates the frame offset, in terms of 4 bytes which you use when comparing against the current table entry.

In an entry, an error is flagged in MTL_RXP_Interrupt_Control_Status[FOOVIS] in any of the following cases:

When frame offset is more than:

- Packet size
- 128B if pre-emption is disabled
- 128B if pre-emption is enabled and packet is pre-empitble
- 64B if pre-emption is enabled and packet is an express packet

IP generates an interrupt status (MTL_Interrupt_Status[MTLPIS]).

NOTE

If the frame ends after the (frame_offset *4) bytes but before ((frame_offset *4)+4) bytes, the receive parser declares a frame offset error if you enable comparison (via MASK bits) for the non-received bytes; from (frame_offset *4) to ((frame_offset *4)+4).

78.7.6.5 Frame reject

You can drop the frame in cases, where an entry matches (considering the inverse match, IM bit in the instruction table) and frame accept bit is not 1, and frame reject bit (RF) = 1.

When a frame drops because RF = 1, IP generates an interrupt status (MTL_Interrupt_Status[MTLPIS]).

78.7.6.6 Out of order processing

The Rx parser flow can be out of order. The decision tree is not based on the order in which packet arrives. This implies that the next entry and next frame offset (OK_INDEX[] and FRAME_OFFSET[]) can be less than the current entry address and current frame offset.

78.7.6.7 DMA channel selection

When you enables the receive parser (MTL_Operation_Mode[FRPE] = 1) it overrides the MAC DMA selection criteria.

When you disables the receive parser (MTL_Operation_Mode[FRPE] = 0) the MAC/MTL determines the DMA channel number.

78.7.6.8 Receive queue selection

The existing MAC functionality determines the receive queue, irrespective of whether the receive parser is enabled or disabled. This is because the receive parser is mainly designed to select the DMA channel and the MAC decides the receive queuing to enable the proper functioning of the pause or PFC feature.

NOTE

When there are multiple queues and multiple DMA Channels are enabled, a particular DMA channel might receive out of order packets because queue selection is based on MAC criteria (VLAN Priority and other criteria) and Rx DMA channel selection is based on receive parser.

78.7.6.9 MAC packet filtering/drop/error handling

Packet filtering is done on the basis of the received packet fields. You must disable the packet filtering features inside the MAC when the receive parser is enabled. Follow these steps to disable the packet filtering features inside the MAC :

1. Write 1 to the Promiscuous mode (MAC_Packet_Filter[PR]).
2. Write 1 to all other fields in MAC_Packet_Filter to its default values.

When MAC decides to drop the packet due to the receive MAC dependent error such as:

- GMII error
- Receive watchdog error
- CRC error
- Giant frame error

the packet drops irrespective of the receive parser decision.

78.7.6.10 Pad strip or CRC strip handling

Software controls the pad strip and CRC strip and it is applicable to all the received packets. Also,software must build the receive parser instructions accordingly, when you enable these features.

NOTE

Enable pad and CRC stripping in real use case.

78.7.6.11 VLAN strip handling

MAC supports stripping the outer VLAN as well as inner VLAN. When you program MAC to strip the VLAN, the receive parser considers those VLAN tags to be part of the incoming packet.

78.7.6.12 Multicast and broadcast support

IP supports multicast and broadcast packet and the packet route to the highest queue number.

When you enables the receive parser, the DMA channel numbers (DMA CH NO, Bits [95:88]) in the instruction table, decide the packet routing.

When you disables the receive parser, DCS (DMA Channel Select) field of the MAC_AddressX_High register determines the packet routing. See the Broadcast/multicast packet duplication.

NOTE

You can select multiple DMA channels for the packet routing because the DCS/DMA CH NO field is per the DMA channel control.

78.7.6.13 Pre-emption support

IP supports the frame preemption feature when the flexible receive parser feature is enabled. It has the following limitations:

- Number of bytes would be 64, so that the receive parser can operate on an express traffic
- Number of bytes would be 128, so that receive parser can operate on a pre-emptive traffic.

78.7.6.14 Software access to the flexible receive parser memory

Software can read and write into the receive parser memory. It uses the following registers via indirect addressing.

- MTL_RXP_Indirect_Acc_Control_Status
- MTL_RXP_Indirect_Acc_Data

For more details, see EMAC register descriptions.

78.7.6.15 Statistical counters

IP supports these statistics counters for flexible receive parser.

1. MTL_RXP_Drop_Cnt
2. DMA_RXP_Error_Cnt

DMA_CH(#i)_Rxp_Accept_cnt (i=0; i<2)

For more details, see EMAC register descriptions.

78.7.6.16 Changing the instruction table by software

Software can update the instruction table in the memory in the following ways:

- Disables the MAC receiver and receive parser by writing 0 to MAC_Configuration[RE] and MTL_Operation_Mode[FRPE]. It waits for receive parser to become inactive (RXPIA, MTL_RXP_Control_Status register bit[31]).
- (Optional) Programs in the entry address 0 to unconditionally (all MATCH_EN bit 0) skip to OK_INDEX[] (to certain location in the memory), where you can program it to reject or accept all the packets.

78.7.6.17 Receive cut-through functionality

In the Cut-Through mode, the receive controller transfer the received packets to DMA just after it receives the cut-through threshold amount of packet data (RTC field in the MTL_RxQx_Operation_Mode register).

However due to Rx parser's result worst case arrival time can be more than the programmed cut-through threshold. So, the receive controller delays the packet transfer to DMA accordingly, and the cut-through functionality is re-defined as follows:

The receive controller transfers packet to DMA after at least RTC number of bytes have been received and receive parser results are available.

78.7.6.18 Receive packet drop indication

In most cases, the packet drops internally in the receive queue. However, back-to-back packets can arrive for the same queue and the first packet's receive parser result is not available when the second packet arrives. In such cases, the packet cannot be flushed internally and forwarded to DMA or the application interface and indicates the status accordingly. See RDES2, bit 16(RXPD) in Receive normal descriptor (write-back format) for more information.

78.7.6.19 Runt packet handling

The receive parser can performs the operation with 64B minimum size packet. If the runt packet is received (MAC must indicate it), the receive parser assumes that it is dropped in the MAC, this is because, the back-to-back runt packets (< 64B) cannot be handled in the receive parser.

78.7.6.20 Uncorrectable ECC error handling

The packet does not drops when the parser detects an uncorrectable ECC error while parsing the parser memory. The packet is sent to the application with an error indication. The RXPI (RX parser incomplete) sets in the packet status along with error summary (ES) bit.

See the Receive normal descriptor (write-back format) for more information.

78.8 IEEE 1588 timestamp support

This section and all its sub-sections are Synopsys proprietary. Used with permission.

IP supports the IEEE 1588 precision time protocol (PTP). It is also able to do precise time stamping and captures incoming and outgoing frame because of the PTP protocol implementation in the IP. It supports all the clock types defined in IEEE 1588-2008. The typical frequency of PTP timestamp clock is 125 MHz.

IP supports these features:

- Provides an option to take snapshot of all packets or only PTP type packets
- Provides an option to take snapshot of only event messages
- Identifies the PTP message type, version, and PTP payload in packets sent directly over Ethernet and sends the status
- Provides an option to measure sub-second time in digital or binary format

78.8.1 Delay request-response mechanism

The system or network is classified into the master and slave nodes for distributing the timing and clock information. Figure 562 shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

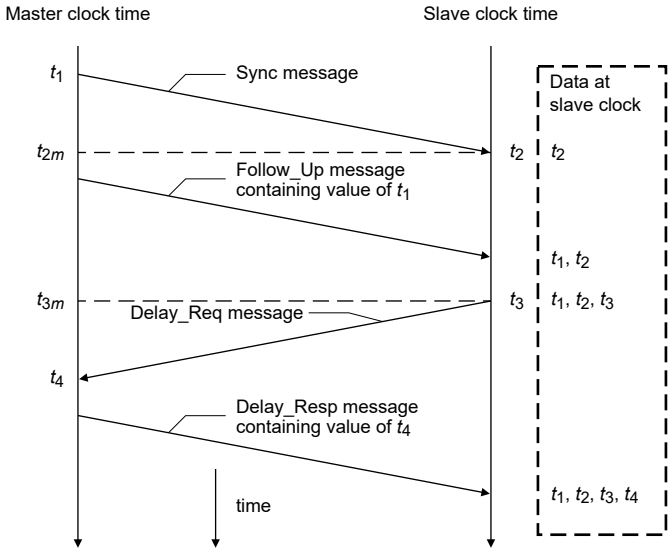

Figure 562. Networked time synchronization

As shown in the figure, PTP uses this process:

1. The master broadcast the PTP sync messages to all its nodes. The sync message contains the reference time information of the master. This message leaves the system of the master at t1. You must capture this time for Ethernet ports at GMII or MII.
2. The slave receives the sync message and it also captures the exact time, t2, using its timing reference.
3. The master sends a Follow_Up message to the slave, which contains t1 information for later use.
4. The slave sends a Delay_Req message to the master and note the exact time, t3, at which this packet leaves the GMII or MII interface.
5. The master receives the message, capturing the exact time t4, at which the message enters its system.
6. The master sends the t4 information to the slave in the Delay_Resp message.
7. The slave use the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the master's timing reference.

Most of the PTP implementation is done in the software above the Ethernet layer. However, the hardware captures the exact time when specific PTP packets enter into or leave the Ethernet port at the MII interface. This timing information must be captured and returned to the software for proper implementation of PTP with high accuracy.

78.8.2 Peer-to-peer PTP transparent clock (P2P TC) message support

The IEEE 1588-2008 supports the peer-to-peer PTP (Pdelay) message in addition to the sync, delay request, follow-up, and delay response messages. Figure 563 shows the method to calculate the propagation delay in clocks supporting the peer-to-peer path correction.

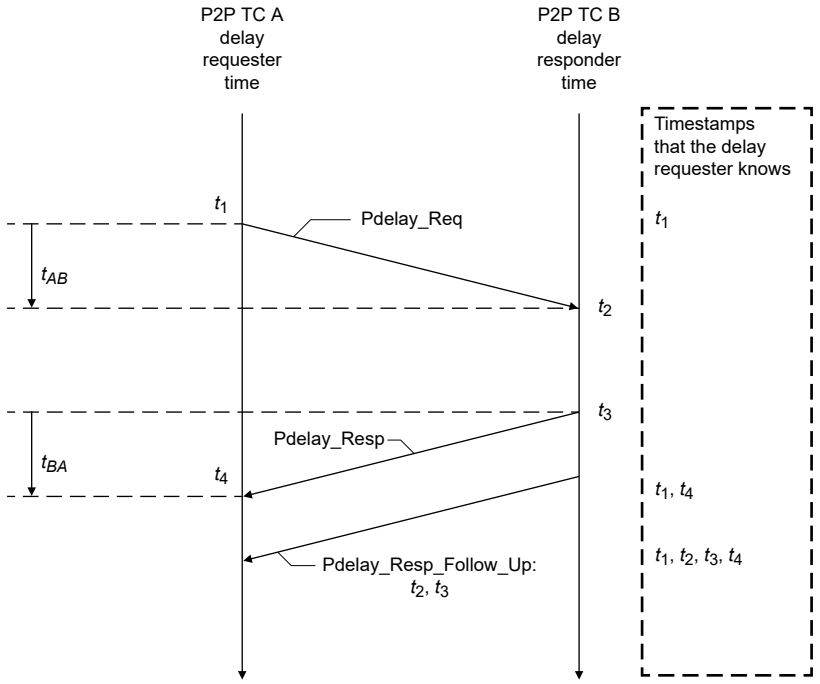

Figure 563. Propagation delay calculation in clocks supporting peer-to-peer path correction

As shown in the above figure, the propagation delay is calculated in the following way:

1. Port 1 issues a Pdelay_Req message and generates a timestamp (t1) for the Pdelay_Req message.
2. Port 2 receives a Pdelay_Req message and generates a timestamp (t2) for this message.
3. Port 2 returns a Pdelay_Resp message and generates a timestamp (t3) for this message. Port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message, to minimize the errors because of any frequency offset between the two ports. Port 2 returns any one of the following:
   - Difference between the timestamps t2 and t3 in the Pdelay_Resp message
   - Difference between the timestamps t2 and t3 in the Pdelay_Resp_Follow_Up message
   - Timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages, respectively
4. Port 1 generates a timestamp (t4) after receiving the Pdelay_Resp message.
5. Port 1 uses all the four timestamps t1, t2, t3, and t4 to compute the mean link delay.

78.8.3 Timestamp correction

According to the IEEE 1588 specification, you must capture a timestamp when the PTP message timestamp point (leading edge of the first bit of the octet immediately following the start frame delimiter octet) crosses the boundary between the node and the network. As MAC takes the timestamp at an internal point far from the actual boundary of the node and network, you must correct or update the captured timestamp for the ingress or egress path latency (including the delay in the PHY layers). Further

correction is done for the inaccuracies or errors introduced because the clock (MII Tx, Rx clock) is different at the capture point as compared to the PTP clock (clk_ptp_ref_i) that generates the time. The resultant CDC (Clock domain crossing) circuits add an error depending on the clock period of the MII and PTP clocks.

78.8.3.1 Ingress correction

The timestamp captured at the internal snapshot point In the receive side is delayed (later in time) as compared to the time at which the packet's SFD bit is received at the port's boundary. Therefore, the ingress latency and the errors in CDC sampling reduces the captured timestamp. You must determine or calculate the correction value and write into the MAC_Timestamp_Ingress_Corr_* registers.

The correction value consists of these three components:

1. External latency in the PHY layer between boundary point and the input of the core.

   If the PHY is compliant with the IEEE 802.3 Clause 45 MMD registers, it has a register which indicates the maximum and minimum ingress latency. You can read these registers and determines the average ingress latency in the PHY. Alternatively (if the PHY does not support these registers), you must determine the ingress latency from its datasheet or timing characteristics.

2. Internal latency from the core's input to the internal capture point.

   You can read the internal ingress latency from MAC_Timestamp_Ingress_Latency. This is a read-only register and provides the latency in scaled nanoseconds format as defined in IEEE 1588 Clause 5.3.2. The latency differs on the basis of the active PHY interface (MII, RMII, so on) and the operating speed. Therefore, you must read this register after any speed change in MAC, to determine the current internal latency.

3. CDC synchronization

   The CDC synchronization error is almost equal to twice the clock-period of the PTP clock (clk_pt-p_ref_i).

You must add the values that these three components determine and must write into the TSIC and TSICSNS fields of the MAC_Timestamp_Ingress_Corr_* registers.

NOTE

The value written into the register must be negative (two's complement as explained below), because it is subtracted from the captured timestamp. The MAC receiver adds the value in this register to the captured timestamp and then gives the resultant value as the timestamp of the received packet.

When MAC_Timestamp_Control[TSCTRLSSR] is 1, it indicates that the nanoseconds field of the captured timestamp is in decimal format with a granularity of 1ns. So the Bit31 of TSIC must be 1 (for negative value) and bits[30:0] must write with "10^9 - total ingress_correction_value[nanosecond part]" represented in binary. For example, if the required correction value is -5 ns, then the value is 0xBB9A_C9FB.

When MAC_Timestamp_Control[TSCTRLSSR] becomes 0, it indicates that the nanoseconds field of the captured timestamp is in binary format with a granularity of ~0.466ns. Therefore, bits[30:0] must write with "2^31 - total ingress_correction_value" represented in binary with bit[31] = 1.

78.8.3.2 Egress correction

The timestamp captured at the internal snapshot point in the transmit side is earlier (advanced in time) as compared to the time at which the packet's SFD bit is output at the port's boundary. Therefore, the egress latency and the errors in CDC sampling must compensate the captured timestamp. You must determine or calculate this correction value and write into the MAC_Timestamp_Egress_Corr_* registers.

The correction value consists of these three components:

1. External latency in the PHY layer between the core output and the port and the network boundary

   If the PHY is compliant with the IEEE 802.3 Clause 45 MMD registers, it has a register which indicates the maximum and minimum egress latency. You can read these registers and determine the average egress latency in the PHY. Alternatively (if the PHY does not support these registers), you must determine the egress latency from its datasheet or timing characteristics.

2. Internal latency from the internal capture point and the core output of the c

   You can read this internal egress latency from MAC_Timestamp_Egress_Latency. This is a read-only register and gives the latency in scaled nanoseconds format as defined in IEEE 1588 Clause 5.3.2. The latency differs on the basis of the active PHY interface (MII, RMII, so on) and the operating speed. Therefore, you must read this register after any speed change in MAC to determine the current internal latency.

3. CDC synchronization error

   The CDC synchronization error value for one-step timestamping = (1 * period of clk_ptp_ref_i + 4 * period of clk_tx_i). Otherwise (Two-step timestamping mode), the value = -(2 * period of clk_ptp_ref_i).

78.8.3.3 Frequency range of reference timing clock

The timestamp information is transferred across asynchronous clock domains that is from the MAC clock domain to the application/system clock domain. Therefore, a minimum delay is required between the two consecutive timestamp captures. This delay is 4 clock cycles of MII and 3 clock cycles of PTP clocks. If the delay between the two captured timestamp is less than this delay, MAC does not take a timestamp snapshot for the second packet.

78.8.3.4 PTP processing and control

Table 627 shows the common message header for the PTP messages. This format is defined in the IEEE 1588-2008.

Table 627. Message format defined in IEEE 1588-2008

Bits								Octet	Offset
7	6	5	4	3	2	1	0		
transportSpecific				messageType				1	0
Reserved				versionPTP				1	1
messageLength								2	2
domainNumber								1	4
Reserved								1	5
flagField								2	6
correctionField								8	8
Reserved								4	16
sourcePortIdentity								10	20
sequenceId								2	30
controlField (*)								1	32
logMessageInterval								1	33

(*) – control Field is used in version 1. In version 2 message type field is used for detecting different message types.

There are some fields in the Ethernet payload that detects the PTP packet type and controls the snapshot to be taken. These fields are specified in Table 628 for PTP packets over Ethernet.

Following table provides the information about the fields that match to control the snapshots for the PTP packets sent over Ethernet for IEEE 1588 version 1 and version 2. The octet positions are offset by 4 for the tagged packets. This is based on the IEEE 1588-2008, Annex D, and the message format.

Table 628. Ethernet PTP packet fields required for control And status

Field matched	Octet position	Matched value	Description
MAC destination multicast address[1]	0–5	01-1B-19-00-00-00 01-80-C2-00-00-0E	All PTP messages can use any of the following multicast addresses[2]: • 01-1B-19-00-00-00 • 01-80-C2-00-00-0E[3]
MAC packet type	12, 13	0x88F7	PTP Ethernet packet
PTP control field (IEEE 1588 version 1)	46	0x00, 0x01, 0x02, 0x03, or 0x04	• 0x00: SYNC • 0x01: Delay_Req • 0x02: Follow_Up • 0x03: Delay_Resp • 0x04: Management
PTP message type field (IEEE 1588 version 2)	14 (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, or 0xD	• 0x0: SYNC • 0x1: Delay_Req • 0x2: Pdelay_Req • 0x3: Pdelay_Resp • 0x8: Follow_Up • 0x9: Delay_Resp • 0xA: Pdelay_Resp_Follow_Up • 0xB: Announce • 0xC: Signaling • 0xD: Management
PTP version	15 (nibble)	0x1 or 0x2	• 0x1: Supports PTP version 1 • 0x2: Supports PTP version 2

1. The unicast address match of destination addresses (DA), which is programmed in MAC address 0 to 31, is used if MAC_Timestamp_Control[TSENMACADDR] = 1.
2. IEEE 1588-2008, Annex F
3. MAC does not consider the PTP version 1 messages with peer delay multicast address (01-80-C2-00-00-0E) as valid PTP messages.

78.8.4 Transmit path functions

MAC captures a timestamp when the start packet delimiter (SFD) of a packet is sent on the MII interface. You can control the packets, for which the timestamps are captured on a per-packet basis and mark each transmit packet to indicate whether to capture a timestamp for it. MAC does not process the transmitted packets to identify the PTP packets. You can use the control bits in the transmit descriptor to specify the packets. MAC returns the timestamp to the software inside the corresponding transmit descriptor and therefore connects the timestamp automatically to the specific PTP packet. You must write the 64-bit timestamp information to TDES0 and TDES1 fields. The TDES0 field holds the 32 least significant bits of the timestamp.

78.8.5 Receive path functions

You can program MAC to capture the timestamp of all packets received on the MII interface or to process the packets to identify the valid PTP messages.

You can use these options of MAC_Timestamp_Control to control the snapshot of the time sent to the application:

- Enable snapshot for all packets
- Enable snapshot for IEEE 1588 version 1 or version 2 timestamp
- Enable snapshot for PTP packets transmitted directly over Ethernet
- Enable timestamp snapshot for the received packet for IPv4 or IPv6
- Enable timestamp snapshot only for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP)
- Enable the node to be a master or slave and select the snapshot type

Table 629. Timestamp snapshot dependency on register bits

SNAPTYPSEL	TSMSTRENA	TSEVNTENA	PTP messages
00	x	0	SYNC, Follow_Up, Delay_Req, Delay_Resp
00	0	1	SYNC
00	1	1	Delay_Req
01	x	0	SYNC, Follow_Up, Delay_Req, Delay_Resp, Pdelay_Req, Pdelay_Resp, Pdelay_Resp_Follow_Up
01	0	1	SYNC, Pdelay_Req, Pdelay_Resp
01	1	1	Delay_Req, Pdelay_Req, Pdelay_Resp
10	x	x	SYNC, Delay_Req
11	x	x	Pdelay_Req, Pdelay_Resp

DMA returns the timestamp to the software inside the corresponding receive descriptor. The extended status, contains the timestamp message status and the IPC status. You must write the extended status in the normal descriptor RDES1 and the snapshot of the timestamp in RDES0 and RDES1 fields of context descriptor. The RDES0 field holds the 32 least significant bits of the timestamp.

See the System time correction for programming guidelines for IEEE 1588 timestamping (System time correction).

78.8.6 IEEE 1588 system time source

IP supports both the external and internal time source for reference timestamping.

- External time source uses the 64-bit external time reference and clock as an input in IP. The clock input synchronizes the external timing reference into the MAC clock domain. Upper 32-bit indicates the time in seconds and the lower 32-bit indicates the time in nanoseconds.
- Internal time source uses the only clock input to generate timing reference internally for snapshot and capture timestamps. Internal time reference has two fields.
  - UInteger48 seconds field: The seconds field is the integer portion of the timestamp in seconds units. It is 48-bit wide.

    For example, 2.000000001 seconds are represented as seconds field = 0x0000_0000_0002.

— UInteger32 nanoseconds field The nanoseconds field is the fractional portion of the timestamp in nanoseconds units.

For example, 2.000000001 seconds are represented as nanoseconds field = 0x0000_0001. The nanoseconds field supports the following two modes:

- Digital rollover mode: In this mode, the maximum value in the nanoseconds field is 0x3B9A_C9FF, that is, (10e9-1) nanoseconds.
- Binary rollover mode: In this mode, the nanoseconds field rolls over and increments the seconds field after 0x7FFF_FFFF value . Accuracy is ~0.466 ns per bit.

There is a system time register module, it is used when you use an internal time reference. The 80-bit time is maintained in this module and updated using the input reference clock (clk_ptp_ref_i). This time is the source for taking snapshots (timestamps) of Ethernet packets which is transmitted or received at the MII interface.

Initialize or correct the system time counter using the coarse correction method. In this method, write the initial value or the offset value to the timestamp update register. For initialization, write the system time counter with the value in the timestamp update register. For system time correction, the offset value is added to or subtracted from the system time.

In the fine correction method, correct the frequency offset and/or frequency drift of a slave clock (clk_ptp_ref_i) with respect to the master clock (as defined in IEEE 1588-2002) over a period of time instead of in one clock, as in coarse correction. This maintains linear time and does not introduce drastic changes (or a large jitter) in the reference time between the PTP sync message intervals.

See Initialization guidelines for system time generation for programming guidelines for IEEE 1588 timestamping (For internal timestamp source configuration).

78.8.7 IEEE 1588 higher word register

You can invoke the higher word register if system time source is internal. MAC timestamp is 64-bit wide. The values of the upper 16-bits of the seconds field are read from the CSR register.

78.8.8 Flexible pulse-per-second output

IP supports the flexibility of programming the start or stop time, generates pulse width and interval on pulse-per-second output. It also support four such output signals. By default, IP is in fixed pulse-per-second output mode with interval of 1 second.

Initially you must program the start time in target time registers "MAC_PPSx_Target_Time_Seconds and MAC_PPSx_Target_Time_Nanoseconds" for all desired or enabled pps output. If you re-programs start or stop time then you must do it after the synchronization of earlier programmed value. Bit 31 of MAC_PPS#_Target_Time_Nanoseconds register indicates that the synchronization is complete. If the application programs a start or stop time that has already elapsed, MAC sets an error status bit which indicates the programming error. If enabled, MAC also sets the target time reached interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

Program the PPS width and interval in terms of granularity of system time, that is, the number of units of sub-second increment value.

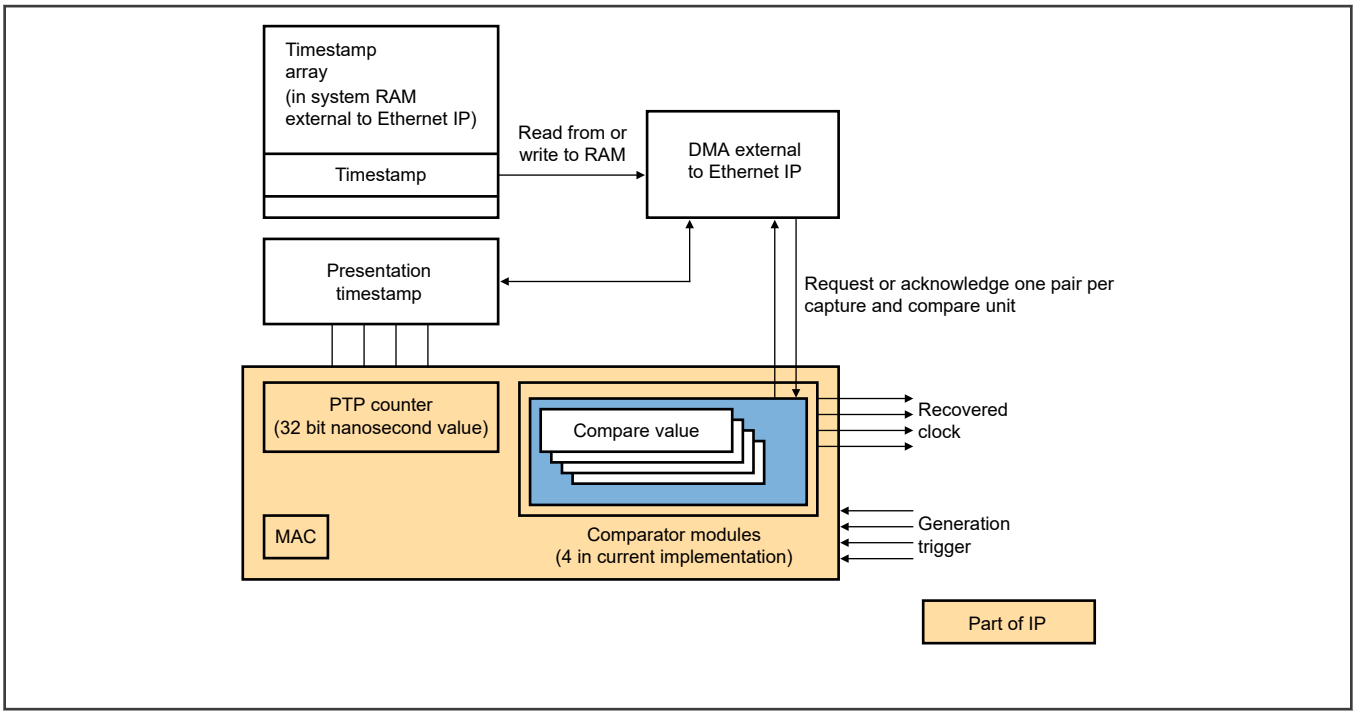
See Programming guidelines for flexible pulse-per-second output for more information.

78.8.9 Media clock generation and recovery

Media clock recovery and generation requires a dedicated hardware and software to complete the operation. IP generates a reference clock with the help of a dedicated hardware which multiplies to get the desired media clock. Software extracts the presentation time from the incoming PTP 1722 frames and program these values into CSR registers so that IP can read them for media clock recovery.

Figure 564 shows that the timestamp array and the DMA module are external to IP. IP supports a 32-bit presentation time counter in nanoseconds that completes at the full 32-bit value to match with 1722 presentation time format and an handshake mechanism with an external application (such as DMA) to program the presentation time into CSR register.

Figure 564. Media clock generation and recovery block diagram



78.8.9.1 Presentation time counter

Presentation time counter provides an another perspective of the PTP system time (1588 timer). For a given PTP system time (PTP[63:32] represents time in seconds Comparator modules and PTP[31:0] represents time in nanoseconds), there exists a corresponding presentation time (32-bit value in nanosecond). The presentation time computed is referred to as current presentation time (CPT).

CPT derives from 64-bit PTP system time. PTPNS[63:0] = (PTP[63:32] * 32'd1,000,000,000) + PTP[31:0] where, PTPNS is the PTP system time converted into a 64-bit nanosecond value.

Current presentation time[31:0] = PTPNS[31:0]

Media clock recovery is possible when the system time is internally generated in IP and compute the CPT in the same way as the internal PTP system time generation. The increment cycle of CPT and system time are same because the values of both the timers are in nanoseconds and they are synchronous. The timer updates at the same instance, but the updated value could be different. You must compute a separate 32-bit update value in nanoseconds for the CPT update. CPT sampled at different edges of a triggering input generates media clock timestamps that are inserted in 1722 based AVBTP packets, to recover the clock at the destination.

78.8.9.2 Comparator modules

Figure 564 shows that the module supports four comparator modules to handle multiple media clocks that it may require. When MAC_Timestamp_Control[PTGE] is 1, it indicates that the comparator modules handshake with the application to program the timestamps into the MAC_PPS(#i)_Target_Time_Seconds register.

Write 1 to presentation time control fields of the particular instance for recovery mode.

The timestamps received from the application are referred as target presentation time (TPT).

When MCGREN#i field of MAC_PPS_Control is 1, it indicates that the IP operates in MCGR mode. The comparator module sends up to two requests to the application for TPT write, when MAC_Timestamp_Control[PTGE] and the presentation time control bits of the particular instance are 1 for MCGR mode. Subsequent requests are generated each time a presentation time match occurs. CPT transitions from a value less than TPT, to a value greater than or equal to CPT. The first request asserts when a specific comparator instance sets to MCGR mode with a non-zero presentation time control and an additional request is made when the comparator receives the first data. This allows the application to write the next TPT value when IP processes the previous TPT value for a match.

TPT read from the MAC_PPS(#i)_Target_Time_Second is considered as a future time. A toggle or pulse is generated in the next cycle when a match is detected. Also,the mcgr_dma_req_o#i request for that comparator asserts (to obtain next TPT) until the corresponding application acknowledgment is set, when a match is detected.

The presentation control fields (PPSCMD#i field of MAC_PPS_Control) determine the shape of the generated waveform. You can program these fields to either toggle or generate a high/low pulse for one PTP clock cycle, when matched.

Media clock recovery: A match occurs, when the free-running CPT value matches the received TPT value. An output signal, EMAC_TMR signal as shown in the IO mux sheet asserts (toggle, low pulse, or high pulse) on the basis of the programmed presentation control value.

Media clock generation: On the basis of the presentation control value programmed in MAC_PPS_Control, the particular comparator captures the presentation time and programs it into MAC_PPS(#i)_Target_Time_Second register. The captured timestamp is read when a request is raised to the application. No new timestamps are captured, until the read operation is complete acknowledgment is received from the application.

78.8.9.3 Media clock generation and recovery flow

Figure 565 shows the media clock generation and recovery flow. Write 1 to MAC_Timestamp_Control[PTGE] for CPT generation and write 1 to MAC_PPS_Control MCGREN#i field to enable the corresponding instance in the MCGR mode, for both media clock generation and recovery.

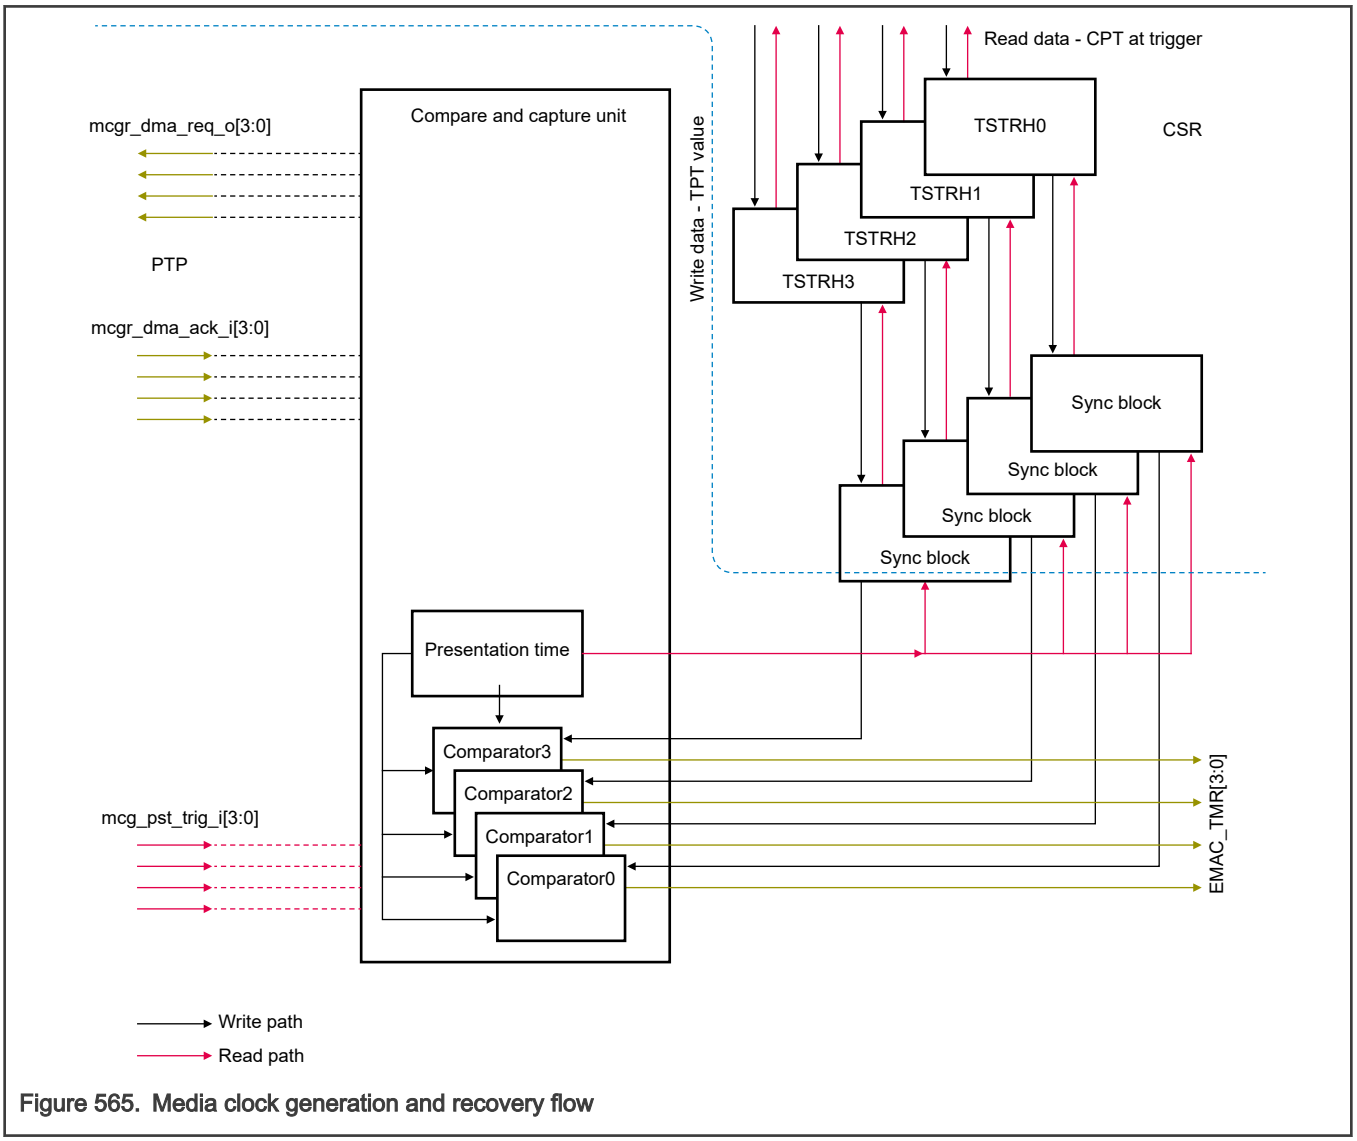


Figure 565. Media clock generation and recovery flow

NOTE

1. The consecutive triggers to sample the presentation time must assert after a few PTP clock cycles so as to allow synchronization delays. (There is no such issue when the input trigger maximum frequency is 8 KHz and the PTP clock runs at least at 1MHz)
2. In the Media Clock Recovery mode, the DMA acknowledgment is both posted as well as non-posted.

See Programming guidelines for media clock generation and recovery for more information.

78.8.10 One step timestamp

IP supports the one step timestamp feature. Writing 1 to bit 20 (OSTC) in the control word, enables the one step timestamp feature for a packet.

See the Programming guidelines for IEEE 1588 timestamping for more information.

78.8.11 IEEE 1588 sub nanoseconds timestamp

IP supports the ingress and egress correction accuracy in sub nanoseconds. It is programmed in MAC_Timestamp_Ingress_Corr_Subnanosec[TSICSNS] and MAC_Timestamp_Egress_Corr_Subnanosec[TSECSNS], respectively. In this case, the correction has an unit of nanosecond, multiplied by 2^8. You must program the least significant 8 bits of the value in the sub-nanoseconds register.

For example, if the required egress correction is 3.6 nS and MAC_Timestamp_Control[TSCTRLSSR] is 1, then MAC_Timestamp_Egress_Corr_Nanosecond[TSEC] must be 0x3 and MAC_Timestamp_Egress_Corr_Subnanosec[TSECSNS] must be 0x99 (0.6 * 256). Similarly, if the required ingress correction is -3.6 nS and MAC_Timestamp_Control[TSCTRLSSR] is 1, then MAC_Timestamp_Ingress_Corr_Nanosecond[TSIC] must be 0xBB9A_C9FC and MAC_Timestamp_Ingress_Corr_Subnanosec[TSICSNS] must be 0x66 (fractional part of (10^9 - 3.6) * 256).

78.9 Multiple channels and queues support

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

IP support two queues and channel on Tx and Rx paths. Figure 566 shows the architecture of IP with two queues and channel.

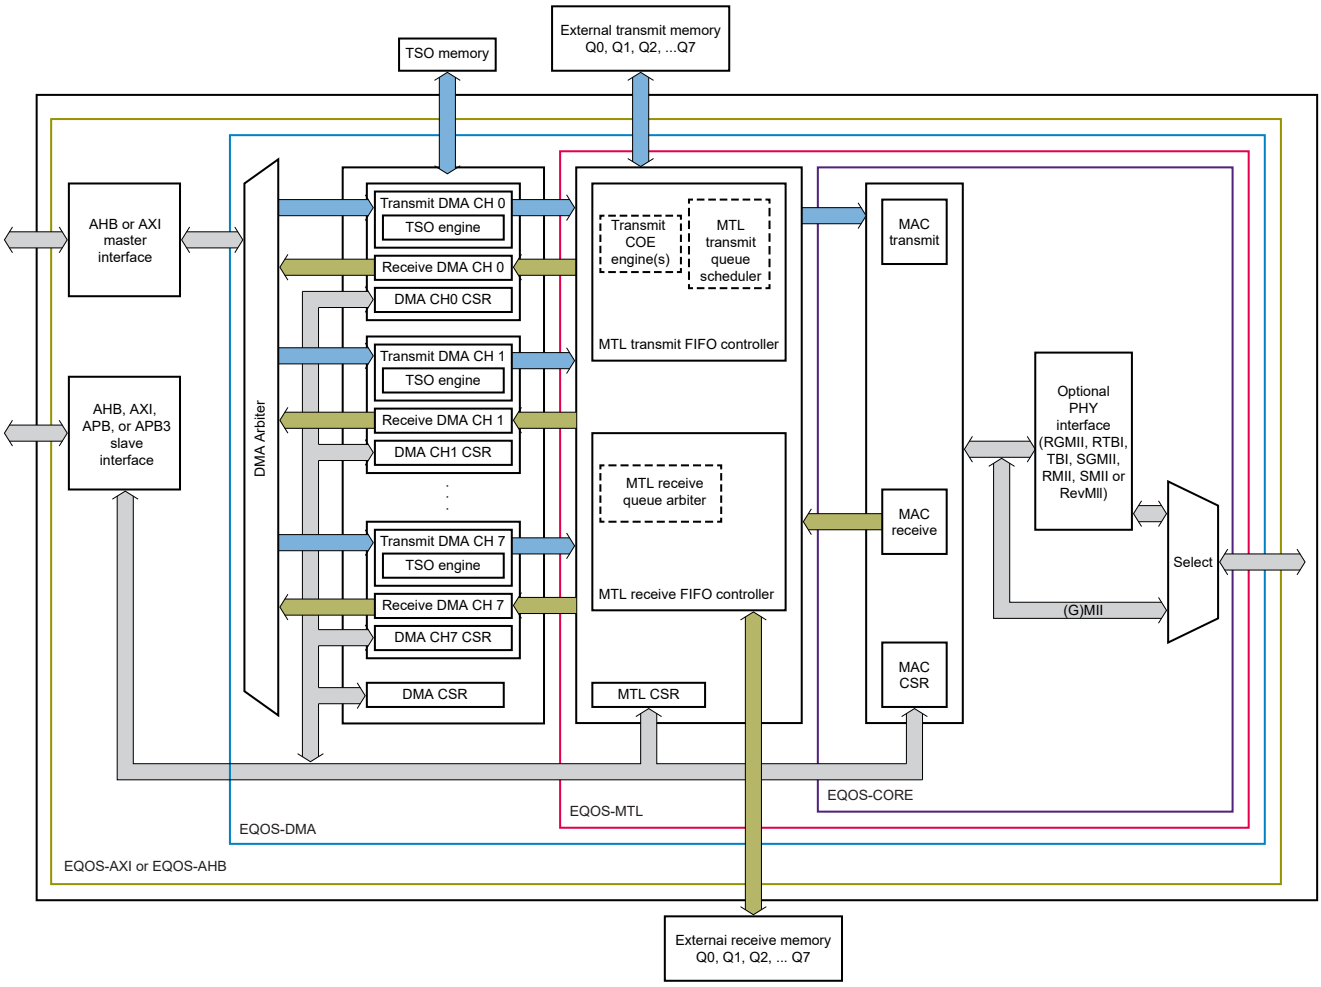

Figure 566. Module with multiple channels and queues block diagram

The above block diagram, support only two queues.

IP DMA arbiter support two types of arbitration scheme, fixed priority and weighted round-robin. The DMA arbiter performs the arbitration between the Tx and Rx paths of DMA channels to access descriptors and data buffers. DMA_Mode[DA] specifies the arbitration scheme (fixed or weighted round-robin) between the channel Tx and Rx DMA.

DMA_Mode[TXPR] sets the priority between the corresponding Tx DMA and Rx DMA. Writing 1 to DMA_Mode[PR] specifies the weighted priority between the Tx DMA and Rx DMA in round robin arbitration scheme.

Table 630 provides an information about the priority scheme between Tx DMA and Rx DMA.

Table 630. Priority scheme for Tx DMA and Rx DMA

Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Priority schemes
x	x	x	0	1	Rx always has priority over Tx
0	0	0	0	0	Tx and Rx have equal priority. Rx gets the access first on simultaneous requests
0	0	1	0	0	Rx has priority over Tx in ratio 2:1

Table continues on the next page...

Table 630. Priority scheme for Tx DMA and Rx DMA (continued)

Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Priority schemes
0	1	0	0	0	Rx has priority over Tx in ratio 3:1
0	1	1	0	0	Rx has priority over Tx in ratio 4:1
1	0	0	0	0	Rx has priority over Tx in ratio 5:1
1	0	1	0	0	Rx has priority over Tx in ratio 6:1
1	1	0	0	0	Rx has priority over Tx in ratio 7:1
1	1	1	0	0	Rx has priority over Tx in ratio 8:1
x	x	x	1	1	Tx always has priority over Rx
0	0	0	1	0	Tx and Rx have equal priority. Tx gets the access first on simultaneous requests
0	0	1	1	0	Tx has priority over Rx in ratio 2:1
0	1	0	1	0	Tx has priority over Rx in ratio 3:1
0	1	1	1	0	Tx has priority over Rx in ratio 4:1
1	0	0	1	0	Tx has priority over Rx in ratio 5:1
1	0	1	1	0	Tx has priority over Rx in ratio 6:1
1	1	0	1	0	Tx has priority over Rx in ratio 7:1
1	1	1	1	0	Tx has priority over Rx in ratio 8:1

78.9.1 Multiple queues and channels support in the transmit path

IP support two transmit queues and two channels.

Fixed priority scheme is the default priority scheme for the DMA channels and channel with highest priority always wins the arbitration when it requests for the bus. Channel 0 is always of lowest priority and channel 1 is always of highest priority.

In weighted strict priority (WSP), the weight corresponds to the number of burst transfers given to a channel in one arbitration cycle. Reallocate the unused burst transfers of one or more channels on the basis of the priority. The channel with highest priority receives the unused burst transfer time before it is allocated to a channel with the next highest priority. You can process the next lower priority, when a channel uses the allocated burst transfers. After processing the allocated bandwidth of all the channels that have packets to transmit, allocate any unused burst transfer time to the channel of the highest priority (if required), and then next highest priority (if required), and so on.

In weighted round robin (WRR) priority scheme, program the weight through TCW field of DMA_CH#_Tx_Control register. IN WRR scheme, service all channels in round-robin order according to the weights settings. Table 631 shows that the TCW field of DMA_CH#_Tx_Control register provides the weight for each transmit channel.

Table 631. Weight for DMA channels

TCW Field	Transmit Channel Weight
000	1
001	2
010	3
011	4
100	5
101	6
110	7
111	8

The configured weights correspond to the number of burst transfers given to a channel in one arbitration cycle. The unused or excess burst transfers are distributed equally to all channels.

See Programming guidelines for multi-channel multi-queuing for more information.

78.9.2 Multiple queues and channels support in the receive path

IP support two receive channels and two queues.

In the receive direction, the MTL Rx controller selects the Rx DMA for which it transfers or reads the data from the receive FIFO memory. This scheduling is based on the programming done in the respective MTL_RxQ[x]_Control register.

Each Rx DMA indicates when it is ready to transfer data and the size of the burst-length (number of beats) that it will transfer. The scheduler checks whether sufficient data (of requested burst length) is available to transfer to these DMAs and then selects the receive DMA that is serviced using the programmed priorities.

See Programming guidelines for multi-channel multi-queuing for more information.

78.9.3 Rx queue to DMA mapping

You can program MTL_RxQ_DMA_Map0 (for queues 0 and 1) to route the packets in the MTL receive queues to any one of the multiple DMA channels.

The following types of receive queue to DMA mapping is possible through programming.

78.9.3.1 Static mapping

In this mode, you can connect all the packets of the receive queue to a specific DMA channel. For example, all the packets from the receive queue 0 program MTL_RxQ_DMA_Map0[Q0MDMACH] (bit[3:0]) and MTL_RxQ_DMA_Map0[Q0DDMACH] (bit[7] = 0) to route to a DMA channel.

Similarly, packets from other receive queues program register fields corresponding to each queue to route to any DMA channel.

78.9.3.2 Dynamic (per packet) mapping

In this mode, the destination DMA channel of a packet read from a Rx queue is not constant but it is decided independently for each packet. For example, if you write 1 to MTL_RxQ_DMA_Map0[Q1DDMACH], it indicates that the static mapping disables for receive queue 1 and ignores the value in MTL_RxQ_DMA_Map0[Q1MDMACH]. The MAC receiver decides the destination DMA channel for each packet, depending on the following in decreasing order of priority:

1. **L3-L4 filter based DMA selection**: The TCP/UDP and IP header fields of the received packet are matched against the corresponding values programmed and enabled for comparison in the MAC_L3_L4_Address_Control register. If the match is successful, the DMA channel number programmed in the DMCHN field of the MAC_L3_L4_Address_Control register is selected as the destination DMA channel number, if DMCHEN field of the same register is 1. If none of the L3-L4 registers give a comparison match, then the module proceeds to the next step below.
2. **Extended VLAN based DMA selection**: Extended routing is applicable only if the VLAN filter has passed. Routing is done only on the basis of the perfect filter result. Each perfect filter has a DMA channel enable and a DMA channel number field which you can program. Routing is applicable for a filter, only if the DMA channel enable field is 1. The frame routes to the smallest matching filter's DMA channel, if it is enabled. If the filter's DMA channel number is not enabled, the frame route to channel 0. For example, if a frame's VLAN tag matches filters 7, 3, and 1, then the MAC checks if DMA channel number of filter 1 is enabled through programming. If yes, the frame route to the programmed value; otherwise it route to DMA. When the inverse filter is enabled; is routed to the least mismatched filter's DMA channel number provided it is enabled. If the DMA Channel enable bit is not set, then the frame routes on the basis of the DA based addressing or to channel 0.

   If hash filter is also enabled, it is determines the filter result only. Routing will still depends on the enabled perfect filters. Routing based on the VLAN filter will not occur if none of the perfect filters are enabled or if all of them are bypassed. The frame will route via DA based addressing or to channel 0. If all the perfect filters fails and the hash filter has passed, then the VLAN filter result is a pass but routing will be based on DA based addressing or to channel 0. Similar behavior is seen when you enables inverse filtering as well.
3. **Ethernet DA-based DMA selection**: The DA address of the received packet is compared against the programmed DA values in MAC address registers. If the address matches any of the programmed values, the corresponding DCS field (when enabled) determines the destination DMA channel number.

If none of the above operations make a successful match or decision, then the packet routes to the DMA channel 0 by default.

78.9.3.2.1 Broadcast/multicast packet duplication

This feature provides a mechanism to send the received broadcast or multicast packets to multiple DMA channels.

MAC_Address0_High[DCS] and other optional MAC_Address(#i)_High (i=1 to 2) registers determines the DMA channel number to which the received packet (that matches the MAC address present in that register) must route.

DMA channel routing mechanisms such as extended VLAN, or L3-L4 based routing does not support the packet duplication.

The packet duplication feature is supported only on the highest MTL queue configured. Therefore, you must program MAC_RxQ_Ctrl1[MCBCQ] to the highest RxQ present in the configuration for the packet duplication for broadcast or multicast packets.

78.9.4 Selection of tag priorities assigned to receive queues

Program the PSRQ field in the corresponding MAC_RxQ_Ctrl2 to assign the VLAN tag priorities to receive queues. The bit corresponding to the VLAN tag priority can be set in the PSRQ field for assigning that priority to the receive queue. For example, if you want to assign VLAN tag priority of 3 to receive queue 0, write 1 to bit [3] in PSRQ field of MAC_RxQ_Ctrl2. The VLAN tag priority assigned to particular receive queue must be unique, that is, you cannot assign more than one receive queue to the same VLAN tag priority. However, more than one VLAN tag priorities can be assigned to same receive queue.

The settings in the PSRQ field is used for VLAN tagged receive packet routing to receive queues as well as for PFC based transit flow control. The received VLAN tagged receive packet route to receive queue that has the VLAN tag priority match. In PFC based transit flow control, PSRQ field corresponding to a particular receive queue enables VLAN tag priorities in the PFC packet transmitted when corresponding receive queue reach the threshold level.

78.9.5 Receive side routing from MAC to queues

IP supports receive side routing from MAC to queues. MAC route the receive packets to the receive queues on the basis of the these packet types in that order

- Unicast/Multicast destination address packets that fail the destination address filter

- Multicast/Broadcast destination address packets that pass the destination address filter
- VLAN tag priority field in VLAN tagged AV data packets
- AV control packets
- VLAN tagged IEEE 1588 PTP over Ethernet packets
- Untagged IEEE1588 PTP over Ethernet packets
- VLAN tag priority field in VLAN tagged packets
- Untagged packets

You can route the outer C-VLAN tagged AV data receive packets on the basis of the priorities assigned to receive queues through PSRQ field in the corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 and the corresponding receive queue is enabled for AV through RXQ#EN field in MAC_RxQ_Ctrl0. These packets may be single VLAN tagged with C-VLAN type or double VLAN tagged with outer VLAN tag of C-VLAN type when double VLAN feature enables (MAC_VLAN_Tag_Ctrl[EDVLP] = 1) with an inner C-VLAN tagged or inner S-VLAN tagged when SVLAN processing is enabled (MAC_VLAN_Tag_Ctrl[ESVL] = 1). This type of Rx packet routing is available when you select the AV feature and multiple receive queues in the configuration.

You can route the AV control receive packets on the basis of the receive queue number specified in MAC_RxQ_Ctrl1[AVCPQ] and the corresponding receive queue is enabled for AV through RXQ#EN field in MAC_RxQ_Ctrl0. These packets may be single VLAN tagged with C-VLAN type or double VLAN tagged with outer VLAN tag of C-VLAN type when double VLAN feature is enabled (MAC_VLAN_Tag_Ctrl[EDVLP] = 1) with inner C-VLAN tagged or inner S-VLAN tagged when SVLAN processing is enabled (MAC_VLAN_Tag_Ctrl[ESVL] = 1). This type of receive packet routing is available when you select the AV feature and multiple receive queues in the configuration.

You can route the VLAN tagged receive packets on the basis of the priorities assigned to receive queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 and RXQ#EN field in MAC_RxQ_Ctrl0 enables the corresponding receive queue for DCB/generic. This type of receive packet routing is available when you select the multiple receive queues in the configuration.

You can route the untagged IEEE 1588 PTP over Ethernet receive packets on the basis of the receive queue number specified in MAC_RxQ_Ctrl1[PTPQ] and the corresponding receive queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0. Also, you can route the VLAN tagged IEEE 1588 PTP over Ethernet receive packets on the basis of the priorities assigned to receive queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 or the receive queue number specified in the MAC_RxQ_Ctrl1[PTPQ] and RXQ#EN field in MAC_RxQ_Ctrl0 register enables the corresponding Rx queue. Programming MAC_RxQ_Ctrl1[TPQC] determines this. This type of receive packet routing is available when IEEE 1588 timestamp feature supports and the multiple receive queues are selected in the configuration. The VLAN tagged IEEE 1588 PTP over Ethernet receive packets are detected only when you disables 802.1AS mode (MAC_Timestamp_Control[AV8021ASMEN] = 0), otherwise this type of receive packets are routed as generic VLAN tagged Rx packets.

You can route the multicast or broadcast destination address receive packets that passes the destination address filter on the basis of the receive queue number specified in MAC_RxQ_Ctrl1[MCBCQ]the MCBCQ field of MAC_RxQ_Ctrl1 register when enabled through MAC_RxQ_Ctrl1[MCBCQEN] and the corresponding receive queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0. This type of Rx packet routing is available when you select the multiple receive queues in the configuration.

You can route the untagged receive packets on the basis of the receive queue number specified in MAC_RxQ_Ctrl1[UPQ] and RXQ#EN field in MAC_RxQ_Ctrl0 enables the corresponding receive queue. This type of receive packet routing is available when you select the multiple receive queues in the configuration.

The unicast destination address receive packets that fail the destination address filter can be routed based on the receive queue number specified in MAC_RxQ_Ctrl4[UFFQ] when enabled through MAC_RxQ_Ctrl4[UFFQE]UFFQE, MAC_Packet_Filter[RA] = 1 and the corresponding receive queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0. This type of receive packet routing is available when you select the multiple receive queues in the configuration.

You can route the multicast destination address receive packets that fails the destination address filter on the basis of the receive queue number specified in MAC_RxQ_Ctrl4[MFFQ] when MAC_RxQ_Ctrl4[MFFQE] enables it. MAC_Packet_Filter[RA] = 1 and RXQ#EN field in MAC_RxQ_Ctrl0 enables the corresponding receive queue. This type of receive packet routing is available when you select the multiple receive queues in the configuration.

The receive packet will route through the receive queue 0, if it is not classified in any of the defined packet type for routing.

78.9.6 Receive side arbitration between DMA and MTL

IP controller supports receive side arbitration between DMA and MTL.

After the current packet processing completes, the DMA channel controller fetches the next descriptor and after the descriptor fetching completes, the DMA channel controller evaluates the amount of data to transfer to the Rx buffer on the basis of the programmed PBL and receive buffer length. Accordingly, it requests the MTL to transfer the data.

After servicing the current request, the MTL receive queue arbitration scheme selects receive queue on the basis of the arbitration scheme (MTL_Operation_Mode[RAA]) and the weights programmed in queue <n> receive control register. The arbitration is done among queues for which DMA is ready to service. After the receive queue is selected, PBL amount of data is read out from that queue and route to the receive DMA channel on the basis of the receive channel selection criteria.

The arbitration occur after every PBL data transfer completes and descriptors are ready for processing from at least one DMA channel.

78.9.7 Transit side arbitration between DMA and MTL

IP supports transit side arbitration between DMA and MTL. Transit DMA channels and transit queues are always mapped directly because the number of transit DMA channels are always equal to the number of transit queues in MTL. For instance, each transit DMA pushes data into its respective transit queue assigned to it.

The data inside each transit queue is stored in packets. Therefore, if two DMAs are allowed to transfer data into the same queue, when a transit DMA starts a packet transfer, the other DMA cannot transfer data unless the previous packet is completely pushed-in. This means that the second DMA remains idle until the first packet is transferred. Hence, each DMA is always connected directly to its corresponding transit queue.

78.9.8 Audio video bridging

IP supports the audio video bridging in 100 Mbps mode only, which allows the transmission of time sensitive traffic over network. IP implements these protocol for supporting the AVB feature:

- IEEE 802.1Qbv-2015 (Enhancements to scheduling traffic)
- IEEE 802.3br (Interspersing traffic)
- IEEE 802.1Qbu (Frame preemption)

The queue 0 transmit path supports the strict priority algorithm, and it is used for best-effort traffic when transmit paths of additional queues use the credit-based shaper algorithm to support traffic management. For a queue, the credit-based shaper algorithm determines that a queue is available for transmission if these conditions are true:

- The queue contains one or more packets.
- The credit for the queue is positive per the algorithm
- AV traffic is received on all queues. IP can also receive untagged PTP packets in addition to AV traffic on any queue.

78.9.9 Queue modes

Transit and receive queues both handles the AV traffic.

Queueing is based on WRR (Weighted round robin) or WSP (Weighted strict priority) algorithm for generic traffic. It is based on CBS (Credit Base Shaper) and SP (Strict Priority) algorithm for AV traffic.

The receive queue is configured for generic or AV based routing, which depends on the RXQ#EN field of corresponding queue. Queueing is done on the basis of the VLAN tag priority. The VLAN tag priority must match the PSRQ field of MAC_RxQ_Ctrl2. The receive packets can route to a particular DMA channel on the basis of the DCS field of perfectly-matched MAC address register.

By default, the untagged packets in a generic traffic route to the receive queue specified in MAC_RxQ_Ctrl1[UPQ]. Queue 0 is the default value of MAC_RxQ_Ctrl1[UPQ]. You can override the default value with any other value, for the MAC_RxQ_Ctrl1[UPQ].

The AV control packets (tagged or untagged) route on the basis of MAC_RxQ_Ctrl1[AVCPQ]. The PTP over Ethernet packets route on the basis of MAC_RxQ_Ctrl1[PTPQ].

78.9.10 Queue priorities

You can program the priority of an receive queue in the corresponding field of MAC_RxQ_Ctrl2. Also, you must program the AV queue (high priority) as an higher priority than the best-effort queue (low priority).

78.9.11 Enhancements to scheduled traffic (EST)

The IEEE 802.1Qbv-2015 defines the schedule for each queues on every egress port which makes the implementation aware of traffic arrival schedule. This information blocks the lower priority traffic from transmission in this time window or slot. This ensures that the sender forward the scheduled traffic to receiver through all the network nodes with a deterministic delay.

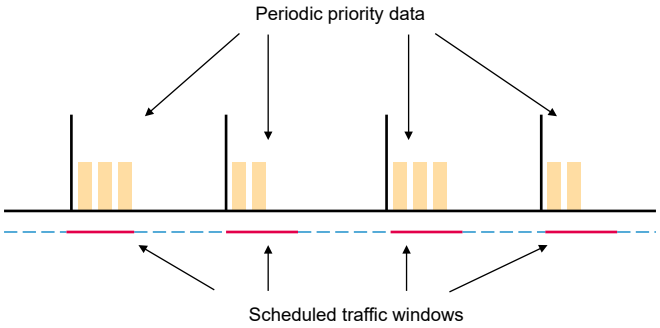

Figure 567. Time aware shaper implementation for traffic scheduling

An important requirement to achieve a low latency is to ensure that there are no interfering frames during the scheduled windows that are reserved for high priority traffic. The use of scheduled traffic imposes limitations when a transmission starts.

As shown in Figure 568 , if an interfering frame begins transmission just before the reserved time period starts, it can extend transmission into the reserved window, and potentially interfere with higher priority traffic. Therefore, a guard band whose size is equal to the largest possible interfering frame is required before the window starts.

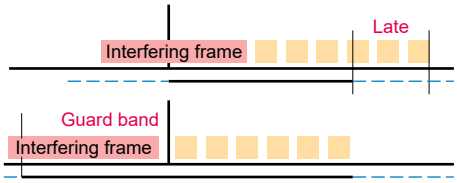

Figure 568. Implementing a guard band to avoid delays due to interfering frames

A larger guard band equates to a less efficient use of network bandwidth. However, this issue is addressed with the implementation of IEEE802.1Qbu (frame preemption). Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band must be as large as the largest possible interfering fragment instead of the largest possible interfering frame.

During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

78.9.11.1 Frequently used terms in EST

These are some of the frequently used terms in the EST support and their definitions.

- Gate control list: The list in the hardware memory that hold the gate controls and the associated time intervals.
- Gate controls: For a given schedule (row in gate control list) there is a gate open (O) and gate close (C) state associated with each TC. The set of O or C values, whose width is same as configured TCs is called the gate controls. Example: CCOCOOCO means TC7=C, TC6=C, TC5=O and so on.

- Time interval: Time interval (in nanoseconds) is a 16, 20, or 24-bit configurable field in the gate control list that indicates the time for which the associated gate controls are valid.
- Base time register: Each gate control list is associated with a 64-bit base time register that holds the start time (in PTP format) for the list.

78.9.11.2 Updates to the transmit scheduling to support EST

To support EST, these updates are required to transmit scheduling:

- Implementation of gate control list (GCL)
- Enforcing gate controls in the scheduler
- Utilizing gate open (O) duty cycle in the computation of idleSlope (CBS)

78.9.11.2.1 Implementation of gate control list (GCL)

Figure 569 shows how the gate control list governs the gate close(C) and open(O) events on the basis of the schedule provided for each event. GCL has two parts:

- Time interval: Defines the time in nanoseconds for which the gate controls are valid and must apply before reading the next gate controls from the list. The configurable width of 16, 20 or 24-bit represents a maximum of 64us, 1ms, or 16ms schedule interval respectively. It supports left shift of the time interval up to 7 bits to be able to apply a multiplication factor from 1 to 128ns (in steps of 2(power)n). The maximum value (post shifting) of this field must be 999,999,999 ns.
- Gate control: Defines the open (O) represented by logic 1 or close (C) represented by logic 0 state for the gate of each TC.

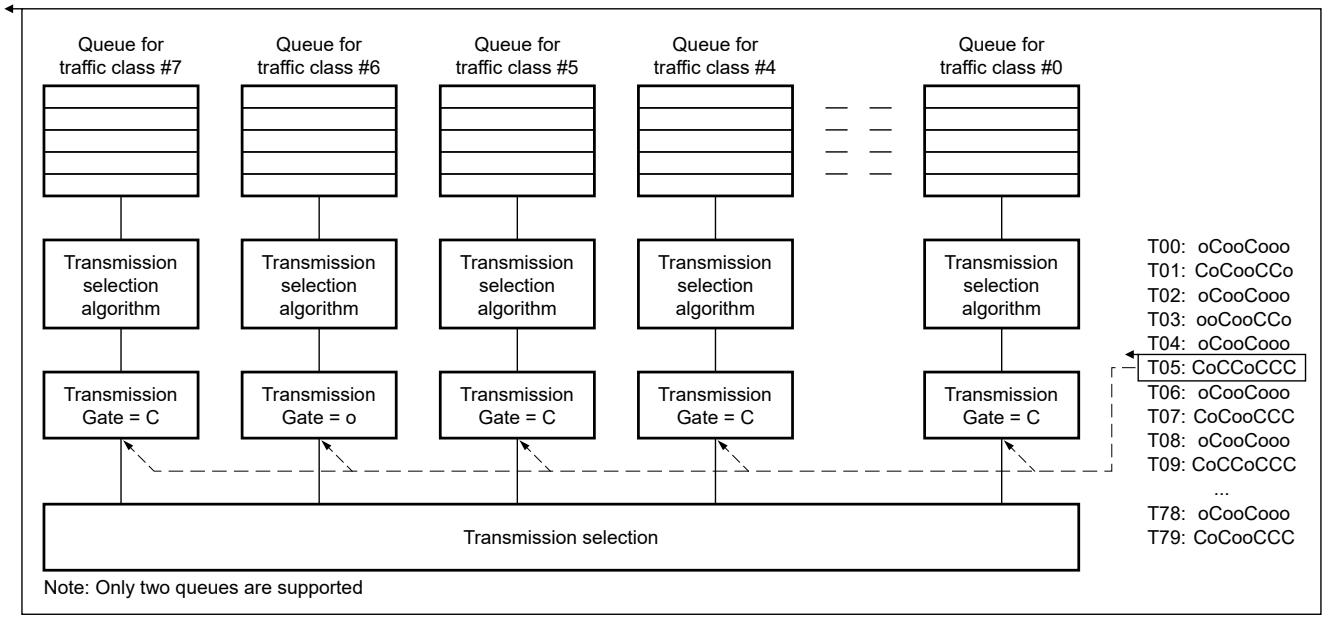

Figure 569. Block diagram from IEEE 802.1 Qbv specification - GCL governing gate close and open events

The implementation of GCL consists of these two gate control lists:

- HWOL - Hardware owned list which is a list for hardware access.
- SWOL - Software owned list which is a list for software access.

The access to these lists is mutually exclusive. Hardware sets the ownership to the list in MTL_EST_Status[SWOL]. Table 632 provides the implementation details of GCL.

Table 632. External memory used for holding the two gate-control lists

Gate control (up to 8 bits)	Time interval (ns) 16, 20, or 24 bits	
OOCCCCCC	T0	HWOL or SWOL
OOOOCCCC	T1	
CCCCOOCC	T2	
CCCCCCOO	T3	
I	I	
I	I	
OCOCOCOO		
OOOOCCCC	T last	
OOOOCCCC	T0	SWOL or HWOL
OOOOCCCC	T1	
OOCCCCCC	T2	
OOOOCCCC	T3	
I	I	
I	I	
OCOCCCCC		
OOCCCCCC	T last	

78.9.11.2.2 Registers related to gate control list

The following are the set of four registers (one for each GCL) related to GCL. These registers are implemented through Indirect addressing using MTL_EST_GCL_Control and MTL_EST_GCL_Data registers.

1. 64-bit Base time register (BTR)

2. 40-bit Cycle time register (CTR)

3. m-bit Time extension register (TER)

4. n-bit [Gate control] List length register (LLR) (n depends of the configured GCL depth)

78.9.11.2.2.1 Base time register (BTR)

This is a 64-bit register that specifies the start time to execute the GCL. The format of the BTR is same as the PTP format (upper 32-bits holds time in seconds and lower 32 bits hold time in nanoseconds). After the execution of a given list starts, the implementation can update the value in BTR to indicate the next list execution start time.

78.9.11.2.2.2 Cycle time register (CTR)

This is a 40-bit register that specifies the time at which the execution of the GCL must repeat. This register consists of an 8-bit value in seconds, and a 32-bit value in nanoseconds (similar to the PTP time format with truncated seconds register). For a given GCL, the start time is "Base Time" + N * "Cycle Time" where N is an integer value that represents the iteration number starting with 0 for first iteration. If the GCL execution takes longer than the cycle time, then the list is truncated at the cycle time and the subsequent loop begins at cycle time.

78.9.11.2.2.3 Time extension register (TER)

This is a m-bit (where m = Configured time interval width + 7) register that specifies the amount of time (in nano seconds) the current GCL can extend before switching to the new GCL. This helps to avoid the execution of the small fragments of the current list before switching to a new list.

78.9.11.2.2.4 List length register (LLR)

This is an n-bit register (when n is 7, 8, 9, 10, or 11 for a GCL configured depth of 64, 128, 256, 512, or 1024 respectively) that specifies the integer value of the length of the GCL (that is the number of valid rows in each GCL). The processing of the GCL stops after the number of rows read equals to the LLR value.

78.9.11.2.3 Transmission gating implementation

A bridge or an end station can enhance to allow transmission from each TC that is yet to be scheduled relative to a known timescale. To achieve this, a transmission gate is associated with each TC; the state of the transmission gate determines if you can select the queued frames for transmission.

For a TC, the transmission gate can be in one of these two states:

1. Open: Select queued frames for transmission, in accordance with the definition of the transmission selection algorithm associated with the TC.
2. Closed: Does not select queued frames for transmission.

A frame on a traffic class queue is not available for transmission if the transmission gate is in the closed state or if there is insufficient time available to transmit the entirety of that frame before the next gate-close event associated with that queue.

The implementation has visibility to the current schedule of gate controls and the immediate next schedule of the gate controls. So the maximum Gate Open period does not exceed the sum of the two Time Intervals. This is because, a frame is selected for transmission only if the gate is currently Open and the duration of gate open interval is greater than the time taken to transfer the entire frame.

The implementation must know the frame size before the transmission, so that you can avoid the transmission overruns and only the frames that can complete are scheduled at all times.

The implementation adequately compensates for the implementation delays in the data transfer from the buffer to the line by offsetting the current time with all the relevant delays (provided by MTL_EST_Control[CTOV]). This ensures that the schedule provided is always accurately implemented at the line.

You must ensure that the GCL slot interval is always greater than the expected packet size and overhead (scheduler delay, inter frame gap (IFG), and preamble, all combined).

78.9.11.3 Idle slope computation updates

When EST is enabled, credit accumulates only when the gate is open therefore, the effective data rate of the idleSlope must increase to reflect the duty cycle for the transmission gate associated with the queue.

The idleSlope is computed on the basis of the gate open time and oper cycle time values. Program the idleSlope registers (implemented one per CBS enabled TC) based on the following equation. The existing MTL register has sufficient field width to accommodate the new values for idleSlope.

idleSlope = (operIdleSlope(N) * OperCycle/GateOpenTime)

78.9.11.3.1 Operational details of GCL

Write 1 to MTL_EST_Control[SSWL], so that the hardware can access the programmed gate control list. The first set of gate controls are applied when the current time is equal to the value in the base time register (BTR) and is held until the programmed "time interval" value.

One additional gate control event is always read ahead from the list, to avoid the transmission overruns. This enables the GCL to determine the next gate close events (if any) for the open TCs.

The scheduling is done on the basis of the gate open state and time interval of only the current and subsequent schedule. An internal accumulator adds the time intervals when gate controls are applied. BTR + Accumulator specifies the time at which the next set of gate controls are applied.

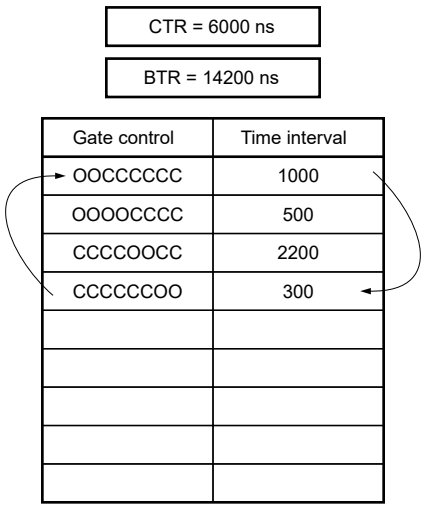

Figure 570. GCL and associated registers - basetime and cycletime

GCL is read progressively from the first row adhering to the schedule. The read operations continue until the list length (from LLR register) is reached and the execution of the list restarts at BTR + CTR time. At this point the value in CTR increments BTR to mark the beginning of a new cycle. In the absence of any gate controls, all the gates are in open state, during the execution of the list.

In cases where the execution time of the list is greater than the cycletime, the list is truncated and the next iteration starts when the current time equals BTR + CTR.

Table 633. GCL and associated registers - BTR and CTR

Current time	Gate control applied	Accumulator value	BTR (with updates)
14200	OOCCCCCC	1000	14200
15200	OOOOCCCC	1500	14200
15700	CCCCOOCC	3700	14200
17900	CCCCCCOO	4000	14200
18200	OOOOOOOO	0	20200
20200	OOCCCCCC	1000	20200
21200	OOOOCCCC	1500	20200

Table 633 describes an example in which the execution starts at 14200 and the first set of gate controls "OOCCCCCC" are applied immediately. The time interval is 1000 ns, so the next set of gate controls are applied at 14200 (BTR) + 1000 (Accumulator) = 15200 ns . The above table shows that there are no gate controls available after the execution of the last gate control and before the next iteration of the loop. The gates are deemed in open state during that time period as depicted at 18200 current time.

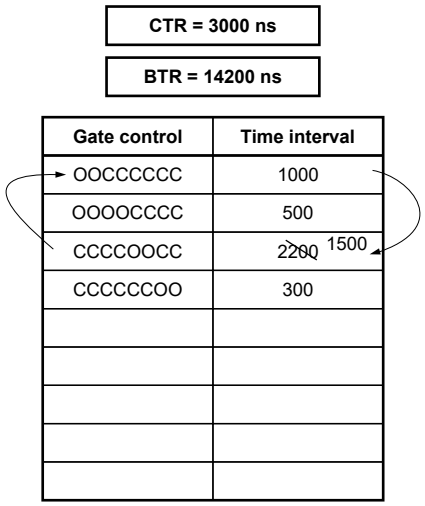

Figure 571. GCL and associated registers - BaseTime and CycleTime list execution time > CycleTime

Table 634 indicates that the list execution takes longer than the allocated CycleTime, so the list is truncated and the list starts from the BTR+CTR.

Table 634. GCL and associated registers - BTR and CTR, execution time > Cycle Time

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
14200	OOCCCCCC	1000	14200
15200	OOOOCCCC	1500	14200
15700	CCCCOOCC	3700	14200
17200	OOCCCCCC	1000	17200
18200	OOOOCCCC	1500	17200
18700	CCCCOOCC	3700	17200

When you apply the third set of gate controls, BTR + CycleTime (17200) < BTR + Accumulator (17900), so the list is truncated and execution switches to a new iteration at 17200.

78.9.11.3.2 Installing a new GCL

The switch to the new GCL can happen in one of the following ways when a new software programmed GCL is available and executed at the new BTR value:

- New base time aligned with current schedule
- New base time unaligned with current schedule

78.9.11.3.2.1 New base time aligned with current schedule

If the choice of cycle time for the new gating cycle is unchanged from the cycle time for the current gating cycle, and if the BTR chosen for the new gating cycle (new BTR) is an integer multiple of the current cycle time (+ current BTR), then the new gating cycle exactly lines up with the old gating cycle, that is, the cycle start times for the new gating cycle is same as they would have been for the old configuration. This could be considered to be the ideal case and allows the new gating cycle to be installed and executed with no timing issues. The implementation completes the execution of an iteration of the current list and switches to the new list at the beginning of the BaseTime listed in the new list.

If (New base time > = Current time)

ConfigChangeTime = New BaseTime

Else If (New base time < Current time)

1. Set the BTRError

2. ConfigChangeTime = (New BaseTime + N* New CycleTime)

where N is the smallest integer for which the relation ConfigChangeTime >= CurrentTime and (N =< 8) is true.

When N > 8 the hardware cannot auto recover and the loop count value in BTRError reporting is set to 1111 requires the software to reprogram the new base time.

Figure 572 illustrates the installation of the new GCL along with the timelines.

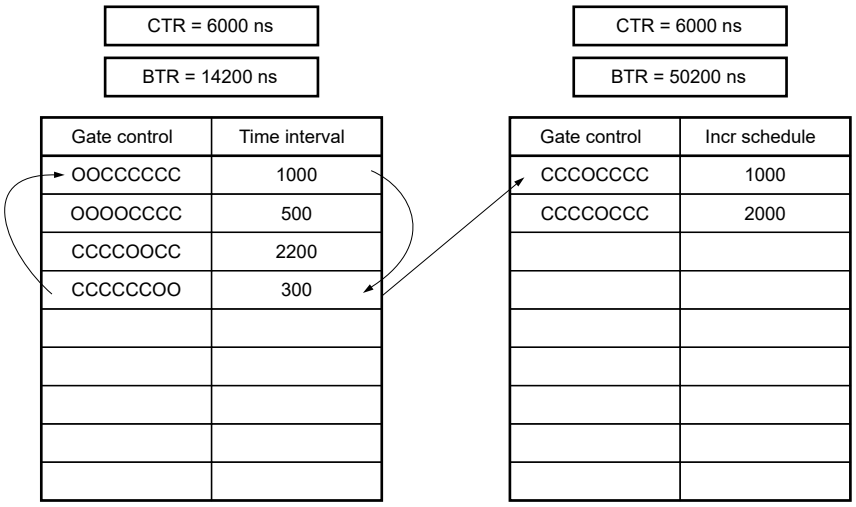

Figure 572. Switching to a new configuration that is aligned with the existing configuration

In the above example, after the sixth iteration of the first GCL, the BTR values of the old and new GCL are equal. At that point the new GCL is processed as a natural extension to the existing GCL.

Table 635. GCL and associated registers - BTR and CTR

Current time	Gate control applied	Accumulator value	BTR (with updates)
44200	OOCCCCCC	1000	44200
45200	OOOOCCCC	1500	44200
45700	CCCCOOCC	3700	44200

Table continues on the next page...

Table 635. GCL and associated registers - BTR and CTR (continued)

Current time	Gate control applied	Accumulator value	BTR (with updates)
47900	CCCCCCOO	4000	44200
48200	OOOOOOOO	0	50200
50200	CCCOCCCC	1000	50200
51200	CCCCOCCC	3000	50200
53200	OOOOOOOO	0	56200

78.9.11.3.2.2 New base time unaligned with current schedule

If the new cycletime differs from the current cycletime or new basetime in the future and is not an integer multiple of current cycletime, then the old and new cycles do not line up. When new basetime is reached (when the new configuration is installed and starts to execute), the last old cycle is normally truncated to start the first new cycle. This could be undesirable if it results in a very short last old cycle; arguably it would be better to simply extend the penultimate old cycle by that small amount, rather than starting a very short cycle. The Cycle Time Extension Register (related to the current config list) allows this extension of the last old cycle to be done in a defined way; if the last complete old cycle ends normally in less than current Cycle Time Extension (TER) ns before the new base time, then the last complete cycle before new BaseTime is reached is extended so that it ends at new BaseTime.

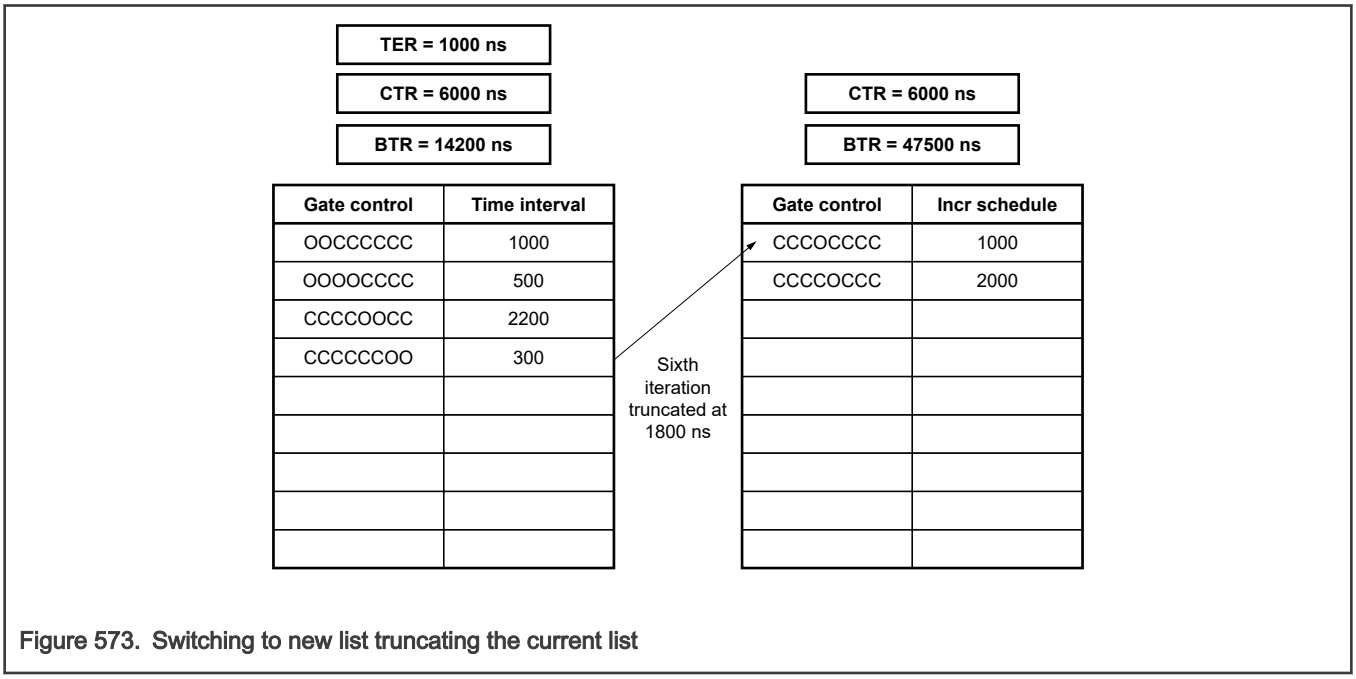

Figure 573. Switching to new list truncating the current list

At the end of the fifth iteration the Current time + Cycle time extension (TER) < New BTR so the sixth iteration of current configuration is started. During the sixth iteration of the current list when the new BTR value is smaller than the next schedule in the current list, it switches to the new list.

Table 636. Extending to new list by truncating the current list

Current time	Gate control applied	Accumulator value	BTR (with updates)
44200	OOCCCCCC	1000	44200

Table continues on the next page...

Table 636. Extending to new list by truncating the current list (continued)

Current time	Gate control applied	Accumulator value	BTR (with updates)
45200	OOOOCCCC	1500	44200
45700	CCCCOOCC	3700	44200
47500	CCCOCCCC	4000	44200
48500	CCCCOCCC	0	50200
50500	OOOOOOOO	1000	50200

Below is an example where the current config list is extended instead of starting a new iteration as the extension time of 800 ns is less than the allowed cycle extension time (TER) of 1000 ns.

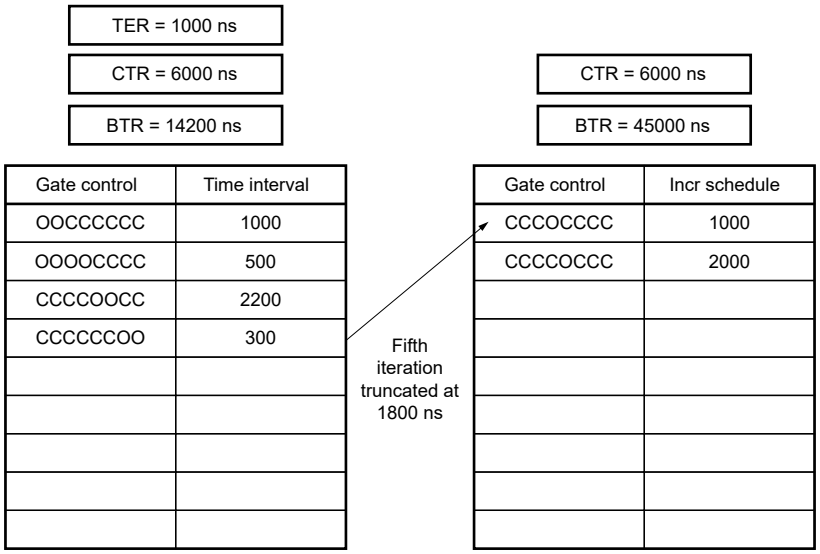

Figure 574. Switching to new list by extending the current list

Table 637. Switching to new list by extending the current list

Current time	Gate control applied	Accumulator value	BTR (with updates)
38200	OOCCCCCC	1000	38200
39200	OOOOCCCC	1500	38200
39700	CCCCOOCC	3700	38200
41900	CCCCCCOO	4000	38200
42200	OOOOOOOO	0	44200
45000	CCCOCCCC	1000	45000

Table continues on the next page...

Table 637. Switching to new list by extending the current list (continued)

Current time	Gate control applied	Accumulator value	BTR (with updates)
46000	CCCCOCCC	3000	45000
48000	OOOOOOOO	0	51000

78.9.11.4 Impact of Transmit Scheduling Algorithms on EST

When EST is used in isolation, the Gate Control List manages the final open/close state of the Queues along with the checks carried out by the Transmission Selection Algorithm in MTL. As the Gate Controls operate on a predefined repetitive schedule, it is recommended to use Strict Priority or Credit Based Shaper (CBS) scheduling algorithms.

Other algorithms such as the Weighted Round Robin (WRR), Deficit Weighted Round Robin (DWRR) and Weighted Fair Queuing (WFQ) implement masking of the queues based on the current winning queue. The algorithm is applied only among the group of queues that open simultaneously. To ensure Queues whose gates are "Open" get priority, these algorithms are modified to treat "gate open" queues and "gate closed" queues as separate groups giving priority to gate open queues.

For example, consider 4 queues (Q3, Q2, Q1, Q0) with weights 4:3:2:1; Q3 and Q2 are in Open state in slot one slot, while Q1 and Q0 are in Open state in another slot. In this case, the scheduler works as follows:

1. In the first slot, the Q3 and Q2 are serviced in the ratio of 4:3 for the duration the slot is open.
2. In the second slot, the queues Q1 and Q0 are serviced in the ratio of 2:1.
3. Fresh arbitration is started every time a slot is opened.

In other words, the traffic does not get distributed in the intended ratio of 4:3:2:1; but as two groups with different ratios and only for the duration of the slot when the gates are open continuously

NOTE

See Programming guidelines for EST

78.9.12 Frame preemption (FPE)

Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band needs to be only as large as the largest possible interfering fragment instead of the largest possible interfering frame. During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

Preemption allows one or more higher priority (express) frames to interrupt the transmission of a lower priority (preemptable) frame; the preemptable frame transmission is resumed and completed after the express frame transmission is complete. To support frame preemption, the following two abstractions of the MAC are used:

- A preemptable MAC, called pMAC, which carries the preemptable traffic.
- An express MAC, called eMAC, which carries the express traffic.

In the implementation, only parts of the MAC that holds the state during preemption is replicated and represented as pMAC and eMAC. The MAC uses the following two ways to puts on hold, the transmission of the preemtable traffic, in the presence of express traffic:

- The MTL scheduler interrupts the preemptable traffic that is currently being transmitted. When the preemption capability is active, the MAC interrupts the transmission and reception of preemptable frames. A preempted fragment can be followed by zero or more express frames, before the continuation fragments. The preemptable frame can be fragmented any number of times, however, the minimum final and non-final fragment length criterion must be is met. However, interleaving of more than 1 preemptable packet is not permitted. This implies that if a preemptable packet is fragmented by an express packet, another preemptable packet cannot be transferred until all the remaining fragments of the first preempted packet are transferred.

- The MTL scheduler prevents starting the transmission of preemptable traffic. When the preemption capability is inactive, the pMAC entity is disabled and only express traffic is transmitted or received. Frame preemption feature can be enabled by setting EFPE field of the MAC_FPE_CTRL_STS register.

If you are unable to schedule fragmented packets after a certain number of attempts because of some reason, there is a possibility that the remaining fragmented packets are dropped. For this, software can program MTL_EST_Control[LCSE] to increase number of iterations or MTL_EST_Control[DFBS] to disable dropping of packet.

NOTE

EST and FPE cannot be used at the same time.

78.9.12.1 GCL Modification to Support FPE

In the EST-only configuration, the GCL entry has up to 24 bits of Time Interval and up to 8 high order bits representing the Gate Open/Close state requirements as shown in the following figure.

Gate control (up to 8 bits)	Time interval (ns) 16, 20 or 24 bits
OOCCCCCC	T0
OOOOCCCC	T1
CCCCOOCC	T2
CCCCCCOO	T3
|	|
|	|
OCOCOCOO	T126
OOOOCCCC	T127

Figure 575. Gate Control List When FPE is Disabled

EST only supports SetGate operation, which implies that the gates are set to either open or close at a given time interval. However, when both Frame Preemption (FPE) and EST are enabled, the GCL also supports Set-and-Hold-MAC and Set-and-Release-MAC operations, in addition to the SetGate operation. To enable the support of hold and release operations, the format of the GCL is slightly changed while configuring and enabling the FPE. The first Queue (Q0) is always programmed to carry preemption traffic and therefore it is always Open. The bit corresponding to Q0 is renamed as Release/Hold MAC control. The TX Queues whose packets are preemptable are indicated by setting the PEC field of the MTL_FPE_CTRL_STS register. The GCL bit of the corresponding Queue are ignored and considered as always "Open". So, even if the software writes a "0" ("C"), it is ignored for such queues.

Gate control (up to 7 bits)	Release or hold indication	Time interval (ns) 16, 20 or 24 bits
CCCOOOO	0	T0
CCCCOOO	0	T1
OCCCOOO	1	T2
COCCOOO	1	T3
CCOCOOO	1	T4
CCCOOOO	0	T5
CCCCOOO	0	T6

Figure 576. Gate Control List When FPE is Enabled

When the Release/Hold bit transitions from a '0' to '1', a Set-and-Hold-MAC operation is performed. This marks the cease of the preemptable traffic. This is achieved by sending a Hold request to MTL "ha" ns in advance (where ha is the time interval mentioned in the Hold Advance (HADV) field of the MTL_FPE_Advance register). When the Release/Hold bit transitions from a '1' to '0' a Set-and-Release-MAC operation is performed. This marks the resuming of the preemptable traffic. This is achieved by sending a Release request to MTL "ra" ns in advance (where ra is the time interval mentioned in the Release Advance (RADV) field of the MTL_FPE_Advance register). The preemptable traffic is blocked for the time duration the Release/Hold bit is set to a '1' in the Gate Control List.

78.9.12.2 Impact of Preemption on CBS

In Credit Base Shaper(CBS), the definition of "Transmit" is as follows:

- TRUE for the duration of frame transmission from the queue.
- FALSE when frame transmission from the queue is complete.
- When CBS algorithm is used along with frame preemption, the value of "Transmit" is TRUE only while the frame is being transmitted by the MAC. If the frame transmission is delayed or interrupted (for instance, a preemptable frame transmission is interrupted to allow the transmission of an express frame from a different queue, or the start of express frame is delayed because a preemptable frame is being transmitted) the value of "Transmit" is FALSE until transmission of the frame commences or is resumed.

Also, the value of "Transmit" is FALSE during the transmission of any overhead that is a consequence of frame preemption. For example, additional frame overhead (mCRC, Fragment Count) that is added to the preemptable frame.

At any given time, if there are no frames in the queue, and the value of Transmit is FALSE, and credit is positive value, the credit value is set to zero if here is no preemptable frame from the queue for which transmission is in progress but has been interrupted.

78.9.12.3 mPacket Format

When the preemption capability is active, MAC sends mPackets to the PHY. An mPacket can be one of the following:

1. A express packet
2. A preemptable packet
3. An initial fragment of a preemptable packet
4. A continuation fragment of a preemptable packet

Start mPacket Delimiter (SMD)

The value of the SMD indicates whether the mPacket contains an express packet, the start of a preemptable packet (initial fragment or complete packet), or any of continuation fragments of a preemptable packet. Following table shows the valid SMD values.

Table 638. Possible SMD Values of mPacket

mPacket Type	Notation	Frame Count	Value
verify packet	SMD-V	-	0x07
respond packet	SMD-R	-	0x19
express packet	SMD-E	-	0xD5
preemptable packet start	SMD-S0	0	0xE6
	SMD-S1	1	0x4C

Table continues on the next page...

Table 638. Possible SMD Values of mPacket (continued)

mPacket Type	Notation	Frame Count	Value
	SMD-S2	2	0x7F
	SMD-S3	3	0xB3
continuation fragment	SMD-C0	0	0x61
	SMD-C1	1	0x52
	SMD-C2	2	0x9E
	SMD-C3	3	0x2A

frag_count

A frag_count is a modulo-4 counter that increments for each continuation fragment of the preemptable packet. The frag_count protects against mPacket reassembly errors by enabling detection of the loss of up to 3 packet fragments.

The frag_count field is present only in mPackets with SMD-C notation (continuation fragment). The frag_count is zero in the first continuation fragment of each preemptable packet.

Table 639. Possible frag_count Values

frag_count	Value
0	0xE6
1	0x4C
2	0x7F
3	0xB3

mData

The contents of the packet from the MAC, starting with the first byte after the SFD to the last byte before the FCS are sent in the mData fields of one or more mPackets for that frame. The minimum size of the mData field is 60 bytes.

CRC The CRC field contains a cyclic redundancy check (CRC) and has an indication of the final mPacket of a frame. In the final mPacket of a frame, the CRC field contains the last 4 octets of the MAC frame (the FCS field).

For other mPackets, the CRC field contains an mCRC value. The mCRC is calculated on the octets of the packet from the first octet of the frame (the octet following the SFD of preemption frames) to the last octet of the packet transmitted in that mPacket by performing an XOR of the calculated 32 bit CRC value of the fragment and a value of 0x0000FFFF.

Summary of Packet Formats

- Express Packet: 7bytes of PREAMBLE, SMD-E, Data, and CRC
- Complete Preemptable Packet: 7 bytes of PREAMBLE, <Current Preemptable packet SMD>, Data, CRC
- Initial Fragment (non-final) of Preemptable Packet: 7 bytes of PREAMBLE, <Current Preemptable packet SMD>, Data, mCRC
- Continuation fragments (non-final) of Preemptable packet: 6 bytes of PREAMBLE, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, mCRC

- Final fragment of Preemptable packet: 6 bytes of PREAMBLE, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, CRC

78.9.12.4 Transmit Preemption

When FPE is enabled (setting EFPE=1 in MAC_FPE_CTRL_STS register), the MTL preempts a preemptable frame, when a "hold" request is asserted (EST/Qbv configured and enabled) express frames are available for transmission, that is, frame is present in MTL FIFO and is qualified for arbitration, after ensuring that the minimum mPacket mData field size is met. Therefore, preemption occurs only if at least 60 bytes of the preemptable frame have been transmitted and at least 64 bytes (including the frame CRC) remain to be transmitted.

The earliest starting position of preemption is controlled by the AFSZ field of the MTL_ FPE_CTRL_STS Register. Preemption does not occur until at least 64 * (1+ AFSZ) - 4 bytes of the preemptable frame have been sent.

When preemption occurs, all the preemptable queues are blocked and only the express queues are allowed to arbitrate (if more than one express queue has traffic) and transmit.

Continuation fragment of the preempted frame is the first frame to be transmitted after "release" request is asserted (EST/Qbv configured and enabled) and all the express traffic transmission completes.

NOTE

All the PTP packets should be transmitted as express packets

MTL communicates the following frame-type information to the MAC using a 2-bit preemption control signal on the MTI interface qualified by SoF and EoF.

- Express Frame
- Preemption Frame (Full or Fragment)
- Continuation Fragment (non-Final or Final)

Table 642. Preemption Control Values on MTI Interface for Various Frame Types

Qualifier	Preemption Control Value	Frame Type
SoF	00	Start Express
SoF	01	Start Preemption
SoF	10	Continuation Fragment
SoF	11	Reserved
EoF	00	End of Frame
EoF	01	End of Fragment

MTL should wait for the previous fragment status to be received before resuming the continuation fragments of a preempted frame. Fragment status is described in detail in the Tx Fragment Status section.

78.9.12.4.1 MAC Tx Preemption

MAC supports preemption by implementing the functionality needed to generate the mPackets as described in “mPacket Format”.

Based on the Preemption Control value received on the MTI interface (qualified with SoF and EoF), MAC determines the frame type (shown in the above table 'Preemption Control Values on MTI Interface for Various Frame Types') and generates mPackets accordingly.

When the preemption capability is active, MAC replaces the SFD of a preemption packet with an SMD-S value. A 2-bit rolling frame count is encoded in the SMD-S value.

The SMD-E value is the same as the SFD value so the SFD of an express packet does not need to be replaced.

78.9.12.4.1.1 Tx Fragment Status

MAC sends Tx fragment status to indicate successful transmission of fragmented mPackets.

In case of a transmission error (underflow, jabber, and so on) the frame status is sent (and not a fragment status) with an error indication along with all other relevant status fields. In case of receiving an error status for a transmitted fragment, the MTL drops the remaining fragments and does not send any more continuation fragments.

78.9.12.5 Receive Preemption

78.9.12.5.1 MAC Receive Preemption

When FPE is enabled, the MAC Receiver passes the incoming packets and differentiates between Express packets and preemptable packets. An SMD containing an SMD-E indicates express packet, and SMD containing an SMD-S indicates the first mPacket of a preemptable packet.

If an mPacket containing an SMD-S is received when MAC has not completed receiving the previous preempted packet, MAC sets a CRC Error status for the previously received partial packet.

When an SMD-S is detected, MAC records the frame count indicated by the SMD and then begins sending data on the MRI interface.

The MAC checks the last four bytes of the mPacket . If the last four bytes of the mPacket do not match CRC, that indicates the end of the packet with or without a CRC error as per the CRC check result. If the last four octets of the mPacket match, that indicates that the packet was preempted.

An SMD containing an SMD-C indicates an mPacket that continues the data for a preempted packet. Upon receiving an SMD value of SMD-C, MAC checks the following:

1. A preempted packet is in progress
2. The frame count indicated by the SMD matches the frame count of the packet in progress
3. The frag_count value indicates the next fragment count.

If any of the above check fails, the mPacket is discarded and MAC sets a CRC Error status for the partially received packet.

If all the checks pass, the next fragment count is incremented modulo 4.

When a packet is preempted, the MAC saves the state of the partially received packet (filter check status, timestamp, length fields etc.) and will be able to process any received Express packets before the continuation fragment is received.

The MAC Receiver sends a "dummy status" for all the mPacket fragments successfully received and sends the Rx status with the final fragment. If an error is detected during any of the fragments the Rx status is sent and the fragment is marked as final fragment. All subsequent continuation fragments received for this packet are dropped in the MAC.

The MAC communicates the following frame type information to the MTL using a 2-bit preemption control signal.

1. Express Frame
2. Preemption Frame (Full or Fragment)
3. Continuation Fragment (non-Final or Final)

Table 643. Preemption Control Values on MRI Interface for Various Frame Types

Qualifier	Preemption Control Value	Frame Type
SoF	00	Start Express
SoF	01	Start Preemption
SoF	10	Continuation Fragment
SoF	11	Reserved
EoF	00	End of Frame
EoF	01	End of Fragment

78.9.12.5.1.1 Data Alignment

When a received frame cannot be fragmented on any byte boundary, MAC retains the unaligned bytes of data in the previous fragment and resends them with the next fragment as shown in the following figure.

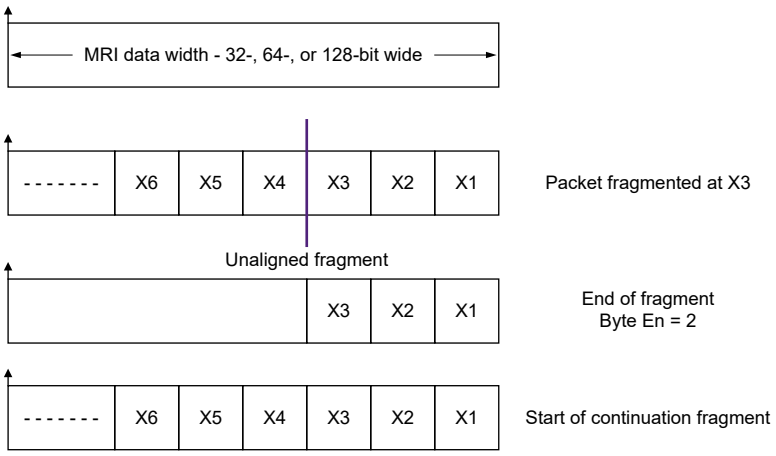

Figure 577. Data Alignment Feature of MAC

78.9.12.5.1.2 MTL Receive Preemption

The MTL Rx must have at least 2 Rx queues to support FPE function as the preemptable packets and the express packets must be routed to separate Rx queues. The destination Rx queue of a received packet is controlled by MAC_RxQ_Ctrl[n] registers. Program these registers such that Preemptable traffic and express traffic are not routed to the same Rx queue. As the queue mapping for tagged packets is based on VLAN user-priority field, this implies that priority of preemptable and express packets are mutually exclusive. In other words, packets of a certain priority (traffic class) are either express or preemptable but cannot be both.

For the preemptable frames, in addition to the PSRQ (Priority Selected in Rx queue) based queue routing, a programmable "Frame Preemption Residue Queue" (FPRQ) is supported to route all other Preemption Packets received (Untagged, SA/ DA or VLAN Filter Fails forwarded due to RA being set or VTFE being reset).

Table 644. Preemption Control Values on MRI Interface for Various Frame Types

Preemption Packet Type	Queue Routing
AV Tagged Packets passing the SA/DA and VLAN filters	PSRQ*
DCB/Generic Tagged Packets passing the SA/DA and VLAN filters	PSRQ**
Tagged Packets failing the SA/DA and VLAN filters without setting the Receive All (RA = 0) or setting VTFE = 1	Dropped
All other packets OR when RA = 1	FPRQ

78.9.12.5.1.3 MTL Receive Arbitration

On the ARI Interface, data is fetched from the MTL Rx FIFO based on the arbitration selected in the MTL_Operation_Mode register. Frame based arbitration can be used only when all the MTL Preemption Queues are operating in Store and Forward mode, else there will be loss of bandwidth on the ARI interface because all the fragments of a preemptable packet is not available. Therefore, any express packets received between the fragments are blocked until all the fragments are received and transferred; this defeats the purpose of express traffic.

When operating in either Threshold (cut through) or Store and forward modes of operation, PBL based arbitration is recommended over Frame based arbitration. In case of PBL based arbitration, the watermark check is always performed and the arbitration/ transfer of data in terms of chunks of "PBL" size of data which is almost similar to the concepts of "fragments". Therefore the express queue packets get blocked for less time as well as the ARI interface transfers the data without loss of efficiency.

78.9.12.6 Verify and Respond mPackets

When FPE function is present, the MAC can receive and detect the Verify and Respond mPackets, even when FPE is not enabled by software. When MAC detects valid Verify/Respond mPackets, it notifies the software by setting the RVER and RRSP fields of MAC_FPE_CTRL_STS register respectively. Optionally an interrupt can be generated. As such packets have empty (all-zero) data payload, they are dropped inside the MAC and not forwarded to the MRI.

Software can set the SVER and SRSP fields of MAC_FPE_CTRL_STS register to request MAC to transmit Verify and Respond mPackets respectively. Upon successful transmission of these frames, MAC clears the SVER/SRSP bits and sets the TVER & TRSP fields of MAC_FPE_CTRL_STS register. Optionally an interrupt can be generated when these events occur.

Software must ensure that frame preemption verify and response packet are not triggered at the same time. Trigger either of the packets and then wait for its completion before triggering another packet.

78.9.12.7 Frame Preemption and MMC Counter and Interrupt Registers

The following MMC counters and associated Interrupt registers are instantiated/present in the MAC when Frame Preemption feature is enabled.

Table 645. MMC Counters and Associated Interrupt Registers

Frame Assembly Error Counter	Description	Associated MMC Counter
Frame Assembly Error Counter	A 32-bit counter that provides the number of MAC frames with reassembly errors on the Receiver, due to mismatch in the Fragment Count value.	MMC_Rx_Packet_Assembly_Err_Cntr

Table continues on the next page...

Table 645. MMC Counters and Associated Interrupt Registers (continued)

Frame Assembly Error Counter	Description	Associated MMC Counter
Frame SMD Error Counter	A 32-bit counter that provides the number of received MAC frames rejected due to arriving with an SMD-C when there was no preceding preempted frame.	MMC_Rx_Packet_SMD_Err_Cntr
Frame Assembly OK Counter	A 32-bit counter that provides the number of MAC frames that were successfully reassembled.	MMC_Rx_Packet_Assembly_Ok_Cntr
MAC Rx Fragment Counter	A 32-bit counter that provides the number of additional mPackets received due to preemption.	MMC_Rx_FPE_Fragment_Cntr
MAC Tx Fragment Counter	A 32-bit counter that provides the number of additional mPackets transmitted due to preemption.	MMC_Tx_FPE_Fragment_Cntr
Hold Request Counter	A 32-bit counter that maintains the count of number of times a hold request is given to MAC.	MMC_Tx_Hold_Req_Cntr

78.9.12.7.1 Additional Registers Associated With MMC Interrupts

Following are the additional registers associated with MMC interrupts for the MMC error counters:

- MMC_FPE_Tx_Interrupt
- MMC_FPE_Tx_Interrupt_Mask
- MMC_Rx_Interrupt
- MMC_FPE_Rx_Interrupt_Mask

78.9.13 Time-Based Scheduling

Time-based scheduling feature is suitable for traffic whose periodicity and rate are predictable. To improve the quality-of-service of such traffic,

- The transmit DMA fetches the packet from the host memory for transmission at designated time. This helps the software to setup the Transmit descriptors in advance even before packet is ready/available. It reduces the overhead on the software and avoids constant monitoring of the time and preparing descriptors just in time when the packet is targeted to be transmitted.
- The MAC transmits the packet only at the designated/pre-determined time even if the packets are fetched in advance. This helps in maintaining a constant transmission rate that can be consumed by the receiver station; therefore avoiding congestion and excessive buffering in the network.

The time-based scheduling feature supports fetching and launching an Ethernet packet at (or after) a pre-determined time. The time-based scheduling is supported only in the following modes/configurations:

- Full duplex mode
- Link speed is 100Mbps or higher

The following figure shows the time-based scheduling flow.

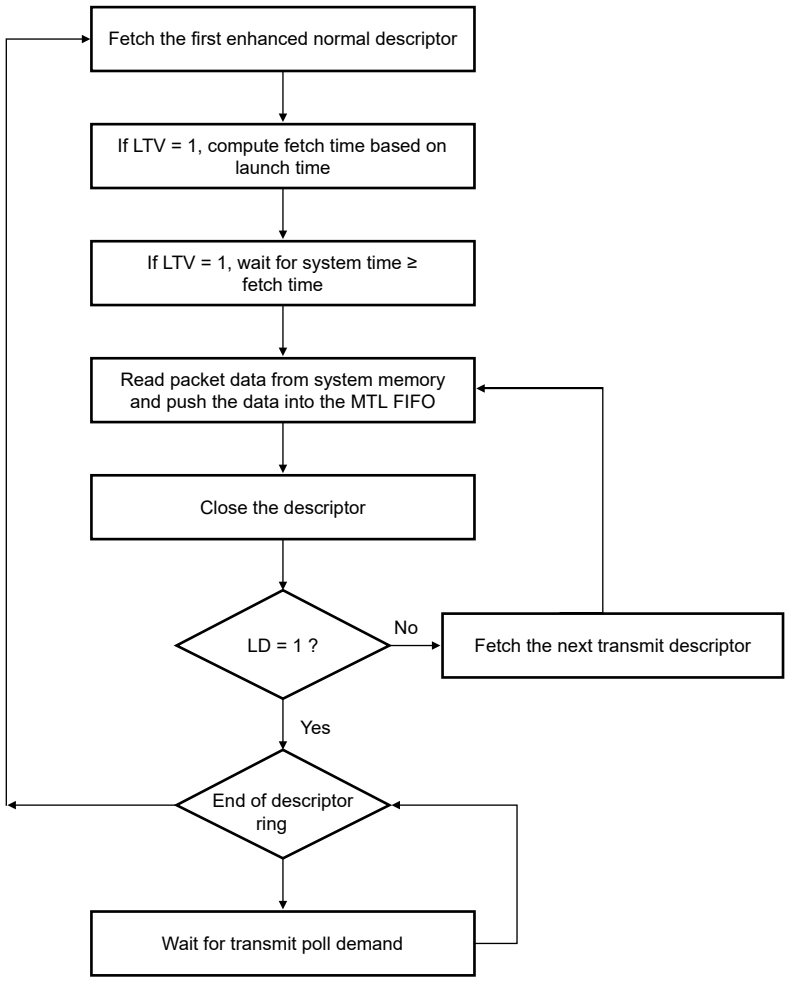

Figure 578. Time-Based Scheduling Flow

Following are the definitions specific to the time-based scheduling feature:

78.9.13.1 Launch time

The time beyond which MTL can schedule the packet for transmission. The launch time resets after the transmission of one frame. These are the two formats of the launch time.

Normal or absolute format:

In this format, the launch time is interpreted in the normal or absolute format if the ESTM bit of the MTL_TBS_CTRL register is set to 0.

The launch time is a 32-bit value, where most-significant 8-bits represent the time in seconds and the rest 24-bits represent the time in 256 ns. The launch time is compared against the IEEE 1588 based system or PTP time (bits[39:8]) and rolls over after 256 seconds.

The maximum value of the lower 32-bits of system time is 999,999,999 decimal (0x3B9AC9FF) and it wraps to 0 when reaching this value (representing a full second). Therefore, the maximum value of the lower 24-bits of the launch time (after multiplying by 256) must be 0x3B9AC9.

As the maximum value of launch time is 256 seconds,

- Launch time is greater than current system time when its value is between system time[39:8] and System time[39:8] + 128 sec.

- Launch time is less than current system time when its value is between System Time[39:8] + 128sec and System Time[39:8] + 256 sec, because this is a modulo 256 computation.

EST or offset format

In this format, the launch time is a offset value relative to the time which the BTR of the GCL list provided in the GCL slot number (GSN) indicates. The value in the BTR is always updated to the start time of the current loop of the GCL.

For each packet, the GSN value and the launch time value are specified in the enhanced transmit descriptor in the DMA configurations, or as control word in the MTL configurations.

The launch time offset is a 32-bit value; the upper 8-bits represent the time in seconds and the rest 24 bits represent the time in 256 ns, which is added to the BTR value corresponding to GCL slot number. The value of the launch time offset must be smaller than the value of the cycle time (specified in the CTR register that is implemented when EST is enabled). If the CTR is greater than or equal to 1s, the maximum value of the lower-24 bits of launch time offset must be 999,999,999 decimal (0x3B9AC9FF).

In this format, the launch time is a 64-bit value, which is interpreted as, Launch time = Launch GSN BTR[63:0] + (Launch time offset[31:0] << 8), which is compared with the system time [63:0].

GSN BTR is the Base Time value at which the Launch GSN loop started execution.

GCL slot number (GSN) A modulo 16 count of the GCL loop count is implemented and it is known as GSN. The count is incremented for every new GCL loop. Installation of new GCL list does not impact the count. Read MTL_EST_Status[CGSN] to obtain the current GCL slot number.

The maximum value of GSN is 15. Therefore the GSN values between MTL_EST_Status[CGSN] and MTL_EST_Status[CGSN]+8 represent current or future slots and all other GSN values are interpreted as elapsed slots or past slots. So, for the correct interpretation of time, GSN value must be between MTL_EST_Status[CGSN] and MTL_EST_Status[CGSN]+8.

78.9.13.2 Launch expiry time

Normal or Absolute Mode

In this mode, when MTL_TBS_CTRL[LEOV] = 1, MTL_TBS_CTRL[LEOS] determines the maximum amount of time a frame is eligible for launch, starting from the time the frame becomes eligible for launch.

The launch expiry offset is a 24-bit value defined in 256 ns units, with a maximum possible value of 999,999,999 ns (0x3B9AC9FF).

Launch expiry time = (Launch time[39:8] + LEOS[32:8]) * 256 ns

The packet with a specific launch time is considered as eligible for transmission when the launch time is less than the system time and (if MTL_TBS_CTRL[LEOV] = 1) the system time is less than the launch expiry time.

When the system time is greater than the launch expiry time, the frame is categorized as expired and it drops from the MTL FIFO.

NOTE

- For correct interpretation and meaningful operation, the fetch, launch, and launch expiry time must never set to a value larger than the Current system time + 128 sec; such a value is interpreted as time that has already elapsed.
- In Full Duplex mode, the frames dropped from the MTL FIFO have error summary (Bit 15) and excessive deferral (bit 3) of TxStatus set.

EST/Offset Mode

In EST mode, when MTL_TBS_CTRL[LEOV] = 1, MTL_TBS_CTRL[LEGOS] and MTL_TBS_CTRL[LEOS] determines the maximum amount of time a frame remains eligible for launch, starting from the time the frame becomes eligible for launch.

Launch Expiry Offset = (LEGOS: LEOS)

LEGOS holds the GSN offset (multiples of CTR time) and LEOS holds maximum value of CTR (sub CTR values) in ns.

Launch expiry offset is a 24-bit value defined in the units of 256 ns, with a maximum possible value of the smaller of 999,999,999 ns or CTR-1 ns.

The Launch expiry GSN is computed as follows:

Launch expiry GSN = (Launch GSN + LEGOS + CCMA) where, CCMA is the CTR carry due to modulo addition. This value is 1 if ((Launch time offset + LEOS) << 8) is equal to or greater than CTR.

When CCMA = 1, Launch expiry offset = (Launch time offset+ LEOS) - CTR

When CCMA = 0,

Launch expiry offset = (Launch time offset + LEOS).

Launch expiry time = Launch expiry GSN BTR [63:0] + Launch expiry time offset.

When MTL_TBS_CTRL[LEOV] is not 1, the launch expiry time is not checked.

When MTL_TBS_CTRL[LEOV] = 1, and

- the system time is greater than the launch expiry time, the frame drops from MTL FIFO. Then the frame is considered as expired.
- the launch time is smaller than the system time and the launch expiry time is greater than the system time, then the frame is considered eligible for launch.

NOTE

- Max value of MTL_TBS_CTRL[LEGOS] is 7. This indicates that when MTL_TBS_CTRL[LEOV] = 1, the frame has a maximum life time of <8 GCL loop iterations after it becomes eligible for launch.
- The slot number of the first GCL list that executes each time after EST is enabled, is zero.

78.9.13.3 Fetch time

This accounts for all possible delays in the DMA fetch operation and ensures that the frame is present in the MTL FIFO before the launch time.

If DMA_TBS_CTRL[FTOV] is 1, it indicates the fetch time for each packet. If DMA_TBS_CTRL[FTOV] is not 1, it indicates that the fetch time offset is not valid and DMA fetches packets without any time constraints.

Normal/Absolute mode

In this mode fetch time is derived or calculated by reducing the time specified in DMA_TBS_CTRL[FTOS] from the given launch time.

In Normal mode, the fetch launch time is computed as:

Fetch Time[39:8] = (Launch Time[39:8] - FTOS[31:8])

The fetch time is 32-bits and is compared against the system time[39:8] to determine whether it is eligible for fetching the frame:

- The fetch time is defined as greater than system time if the fetch time is in the range of system time[39:8]" and system time[39:8] + 128 sec. The frame is considered as not-eligible for fetch.
- The fetch time is defined as smaller than the system time if the fetch time is in the range of system time[39:8] + 128 sec and system time[39:8] + 256 sec. The frame is considered as eligible for fetch.

This is a modulo 256 computation.

EST/Offset mode

In this mode, the fetch GSN offset (DMA_TBS_CTRL[FGOS]) provides the slot number offset to deduct from the launch GSN. In this case the FTOS value must be smaller than 999,999,999 ns or CTR-1 ns.

If (Launch time offset >= FTOS):

Fetch time offset = ((Launch time offset - FTOS) * 256ns)

CBFS(CTR borrow for fetch subtraction) = 0

If (Launch time offset < FTOS) Fetch time offset = CTR + ((Launch time offset - FTOS) * 256ns)

CBFS (CTR borrow for fetch subtraction) = 1

The fetch GSN is computed as follows:

Fetch GSN = Launch GSN - FGOS - CBFS

Fetch time = Fetch GSN BTR[63:0] + Fetch time offset

The frame is eligible for DMA fetch when the fetch time is smaller than the system time.

DMA operations sequence

This is the sequence of operation when FTOV = 1:

1. Fetch the first enhanced normal descriptor (FD = 1).
2. Compute the fetch time on the basis of the launch time and wait for the system time to be greater than fetch time, if LTV = 1 and fetch is enabled.
3. Read the frame (data) from the host memory and transfer to MTL FIFO.
4. Close the normal descriptor.
5. Fetch the next normal descriptor (if the previous descriptor was not the last).
6. Repeat steps 4 to 6, until the last descriptor of the frame (LD = 1).

After the last descriptor of a frame, program the next enhanced normal descriptor with a new launch time and with LTV = 1. Otherwise, process the subsequent frames without any time restrictions.

See Programming the launch time in time-based scheduling for more information.

78.10 TCP/IP Offloading Features

This section and all other sections, along with respective sub-sections are Synopsys Proprietary. Used with permission.

78.10.1 Transmit Checksum Offload Engine

The MAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the Transmit path, using which, the software can offload the task of checksum insertion to the hardware. In the transmit path MAC calculates the checksum and inserts it in the Tx packet. This feature helps in reducing the load on the software and can improve the overall throughput of the system. This feature is supported for only Q0 queue.

The checksum offload engine module supports two types of checksum calculation and insertion. The checksum engine can be controlled for each packet by setting the CIC bits (TDES3 Bits[17:16]).

Note: The checksum for TCP, UDP, or ICMP is calculated over a complete packet, and then inserted into its corresponding header field. Because of this requirement, when this function is enabled, the Tx FIFO automatically operates in the store-and-forward mode even if IP is configured for Threshold (cut-through) mode.

78.10.1.1 IP Header Checksum Engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Type field of Ethernet packet has the value 0x0800 and the Version field of IP datagram has the value 0x4. The checksum field of the input packet is ignored during calculation and replaced with the calculated value.

NOTE

IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (Bit 0 in Table 19-12 on page 1330). This status bit is set whenever the values of the Ethernet Type field and the Version field of IP header are not consistent, or when the Ethernet packet does not have enough data, as indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- For IPv4 datagrams:
  - The received Ethernet type is 0x0800, but the Version field of IP header is not equal to 0x4.
  - The IPv4 Header Length field indicates a value less than 0x5 (20 bytes).
  - The total packet length is less than the value given in the IPv4 Header Length field.
- For IPv6 datagrams:
  - The Ethernet type is 0x86dd but the IP header Version field is not equal to 0x6.
  - The packet ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received.

78.10.1.2 TCP/UDP/ICMP Checksum Engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP. The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. The Tx COE can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the Checksum field of the input packet. This engine includes the Checksum field in the checksum calculation, and then replaces the Checksum field with the final calculated checksum.
- The engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

NOTE

For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 16'h0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 16'h0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector (Bit 12 in Table 19-3 on page 1324). This engine sets the Payload Checksum Error status bit when it detects that the packet has been forwarded to the MAC Transmitter engine in the store-and-forward mode without the end of packet (EOP) being written to the FIFO, or when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field. Following table describes the functions supported by Transmit Checksum Offload engine based on the packet type. When the MAC does not insert the checksum, it is indicated as "No" in the table.

NOTE

You should not enable checksum insertion for IPv4 or IPv6 packets that are greater than the frame size constraint specified in Description of Transmit Checksum Offload Engine because it may result in incorrect checksum insertion or unexpected behavior.

Table 646. Transmit Checksum Offload Engine Functions for Different Packet Types

Packet Type	Hardware IP headerchecksum insertion	Hardware TCP/ UDPchecksum insertion
Non-IPv4 or IPv6 packet	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Yes	Yes

Table continues on the next page...

Table 646. Transmit Checksum Offload Engine Functions for Different Packet Types (continued)

Packet Type	Hardware IP headerchecksum insertion	Hardware TCP/ UDPchecksum insertion
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers: • Hop-by-hop options (in IPv6 main header) • Hop-by-hop options (in IPv6 extension header) • Destinations options • Routing (with segment left 0) • Routing (with segment left > 0) • TCP, UDP, or ICMP • Authentication • Any other next header field in main or extension headers	• Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable	• Yes • No • Yes • No • No • Yes • No • No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels: • IPv4 packet in an IPv4 tunnel • IPv6 packet in an IPv4 tunnel	• Yes (IPv4 tunnel header) • Yes (IPv4 tunnel header)	• No • No
IPv6 Tunnels: • IPv4 packet in an IPv6 tunnel • IPv6 packet in an IPv6 tunnel	• Not applicable • Not applicable	• No • No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Not applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not applicable	No

78.10.2 Receive Checksum Offload Engine

IP provides the Checksum Offload Engine that is used to detect any error in an IPv4 or IPv6 packet in the receive path. The MAC verifies the checksum field of the received packet with the internally calculated checksum and provides the status.

The Receive Checksum Offload engine is used to detect errors in IP packets by calculating the header checksum and further matching it with the received header checksum. This engine also identifies a TCP, UDP, or ICMP payload in received IP packets and calculates the checksum of such payloads appropriately.

Here, both IPv4 and IPv6 packet in the received Ethernet packets are detected and processed for data integrity. The MAC receiver identifies IPv4 or IPv6 packets by checking for value 0x0800 or 0x86DD, respectively, in the Type field of the received Ethernet packet. This identification is applicable to single VLAN-tagged packets. It is also applicable to double VLAN-tagged packets when the Enable Double VLAN Processing option is selected and the EDVLP bit of the MAC_VLAN_Tag register is set.

The Rx COE calculates the IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is given to the RFC module for insertion into the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received packet does not have enough bytes, as indicated by the Length field of the IPv4 header (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

Following table describes the functions supported by the Rx COE based on the packet type. When the payload of an IP packet is not processed (indicated as "No" in the table), the information (whether the checksum engine is bypassed or not) is given in the receive status.

NOTE

The MAC does not append any payload checksum bytes to the received Ethernet packets.

Table 647. Receive Checksum Offload Engine Functions for Different Packet Types

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
Non-IPv4 or IPv6	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 header's protocol field contains a protocol other than TCP, UDP, or ICMP	Yes	No

Table continues on the next page...

Table 647. Receive Checksum Offload Engine Functions for Different Packet Types (continued)

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers: • Hop-by-hop options (in IPv6 main header) • Hop-by-hop options (in IPv6 extension header) • Destinations options • Routing (with segment left 0) • Routing (with segment left > 0) • TCP, UDP, or ICMP • Any other next header field in main or extension headers	• Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable	• Yes • No • Yes • Yes • No • Yes • No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels: • IPv4 packet in an IPv4 tunnel • IPv6 packet in an IPv4 tunnel	• Yes (IPv4 tunnel header) • Yes (IPv4 tunnel header)	• No • No
IPv4 Tunnels: • IPv4 packet in an IPv6 tunnel • IPv6 packet in an IPv6 tunnel	• Not Applicable • Not Applicable	• No • No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled)	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled)	Not Applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No

Table continues on the next page...

Table 647. Receive Checksum Offload Engine Functions for Different Packet Types (continued)

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
IPv6 frames with security features (such as encapsulated security payload)	Not Applicable	No

Set the IPC bit of the MAC_Configuration register for enabling Receive Checksum offload.

78.11 MAC Management Counters

This section is Synopsys Proprietary. Used with permission.

IP supports storing the statistics about the received and transmitted packets in registers that are accessible through the application/software. The MMC module maintains a set of registers for gathering statistics on the received and transmitted packets. The MMC counters are free running.

For MMC register details, see registers "MMC_Control" to "MMC_Rx_FPE_Fragment_Cntr" in EMAC register descriptions.

78.12 Flow Control

This section and its sub-sections are Synopsys Proprietary. Used with permission.

78.12.1 Transmit Flow Control

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end.

78.12.1.1 Flow control in Full duplex mode

IP supports the IEEE802.3x Pause Packets.

Pause packet structure is shown in the following table.

Table 648. Pause Packet Fields

Field	Description
DA	Contains the special multicast address
SA	Contains the MAC address 0
Type	Contains 8808
MAC Control opcode	Contains 0001 for IEEE 802.3x Pause Control packets; 0101 for PFC packets
PT	Contains Pause time specified in the PT field of the MAC_Q#_Tx_Flow_Ctrl register

78.12.1.2 Pause Packet Control

When the FCB bit is set, the MAC generates and transmits a single Pause packet. If the FCB bit is set again after the Pause packet transmission is complete, the MAC sends another Pause packet irrespective of whether the pause time is complete or not. To extend the pause or terminate the pause prior to the time specified in the previously-transmitted Pause packet, the application should program the Pause Time register with appropriate value and then again set the FCB bit.

78.12.1.3 Flow Control in Half-Duplex Mode

In half-duplex mode, the MAC uses the deferral mechanism for the flow control (backpressure). When the application requests to stop receiving packets, the MAC sends a JAM pattern of 32 bytes when it senses a packet reception, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort the transmission because of excessive collisions.

Following table describes the flow control in the Tx path for Queue 0 based on the setting of the following bits:

- EHFC bit of MTL_RxQ0_Operation_Mode register
- TFE bit of MAC_Q0_Tx_Flow_Ctrl register
- DM bit of MAC_Configuration register

Flow control is similar for all queues.

Table 649. Tx MAC Flow Control

EHFC	TFE	DM	Description
x	0	x	The MAC transmitter does not perform the flow control or backpressure operation.
0	1	0	The MAC transmitter performs back-pressure when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1.
1	1	0	The MAC transmitter performs back-pressure when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. In addition, the MAC Tx performs back-pressure when Rx Queue level crosses the threshold set by Bits[10:8] of MTL_RxQ0_Operation_Mode register.
0	1	1	The MAC transmitter sends the Pause packet when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1.
1	1	1	The MAC transmitter sends the Pause packet when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. In addition, the MAC Tx sends a Pause packet when Rx Queue level crosses the threshold set by Bits[10:8] of MTL_RxQ0_Operation_Mode register.

78.12.1.4 Enabling Transmit Flow Control

To independently enable Transmit Flow Control for each Tx queue, set the TFE bit in the MAC_Q#_Tx_Flow_Ctrl register.

78.12.2 Receive Flow Control

In the Receive path, the Flow Control is functional only in the full-duplex mode. If any Pause packet is received in the half-duplex mode, the packet is considered as a normal control packet.

NOTE

Receive pause packets should have a frame size of 64 bytes.

The Receive Flow Control is implemented by the MAC based on the bit value of the respective register, and the destination address and different fields of the received packet.

Following table describes the flow control in the Rx path based on the setting of the following bits:

- RFE bit of MAC_Rx_Flow_Ctrl register
- DM bit of MAC_Configuration register

Table 650. Rx MAC Flow Control

RFE	DM	Description
0	x	The MAC receiver does not detect the received Pause packets.
1	0	The MAC receiver does not detect the received Pause packets but recognizes such packets as Control packets.
1	1	The MAC receiver detects or processes the Pause packets and responds to such packets by stopping the MAC transmitter.

78.12.2.1 Enabling Receive Flow Control

To enable Pause Flow Control, set the RFE bit in the MAC_Rx_Flow_Ctrl register.

78.13 Loopback Mode

This section is Synopsys Proprietary. Used with permission.

The MAC supports Loopback of transmitted packets to its receiver.

The following are some guidelines for using the loopback mode:

- Enable loopback only with the full-duplex mode. In half-duplex mode, the carrier sense signal (crs) or collision (col) signal inputs get sampled which may result into issues such as packet dropping.
- If the loopback mode is enabled without connecting a PHY chip (for example, in FPGA setup), you should externally generate the Tx and Rx clocks and provide these clocks to the MAC.
- Do not loop back big packets. Big packets (>1522 bytes) may get corrupted in the loopback FIFO.

To enable this feature, program the LM bit of the MAC_Configuration register.

You can enable loopback for all PHY interfaces. The data is always looped back through internal asynchronous FIFO on to the internal Receive MII or GMII interface, irrespective of which PHY interface is selected. The loopback data is also passed through the corresponding transmit PHY interface block, on to the Ethernet line.

78.14 Automotive Safety Features

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

IP supports the automotive safety feature.

78.14.1 Error Correction Code (ECC) Protection for Memories

The Error Correction Code (ECC) block can correct single-bit error and detect double-bit error.

At the write interface, ECC checkbits are generated by computing ECC on the contents of the data bus and respective address is appended with the data that is written to the memory.

At the read interface, ECC checkbits are recomputed on the content of the read data and the respective address is compared with the received checkbits in the memory.

Following figure shows the block diagram of ECC protection for memories

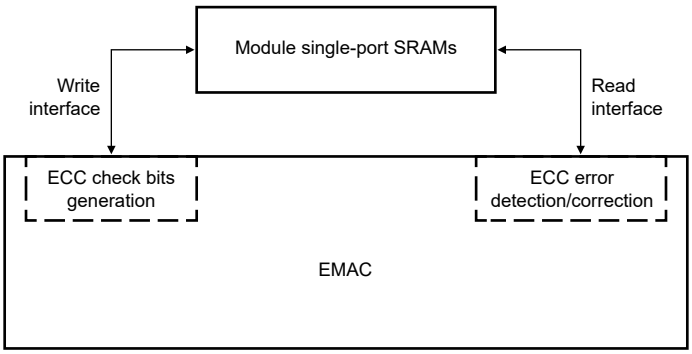

Figure 579. Block Diagram of ECC Protection for Memories

78.14.1.1 Handling the Address Mismatch

The ECC is calculated over the sum of memory data and memory location address. However only data is written in the memory along with the ECC(address is excluded).

On the read interface, the ECC is checked over the sum of memory DATA, memory ECC, and Internally generated address. When an ECC correctable error is detected over the range of the address bit position, it is treated as an uncorrectable error. This is because data might have been read from a different location.

78.14.1.2 Diagnostic Support for the Error Management

Following statistics are provided for monitoring the error behavior on each of the memory blocks.

- Error status provided to management
  - A separate status for correctable, uncorrectable, and address mismatch is specified in the MTL_ECC_Interrupt_Status register.
  - Memory locations at which correctable and uncorrectable errors are detected is specified in the MTL_ECC_Err_Addr_Status register. In addition, a control bit (MEEAO field of MTL_ECC_Control register) decides, whether the first errored memory address is reported or the latest errored memory address is reported.
  - MTL_ECC_Err_Cntr_Status register has separate counters to count the number of correctable and uncorrectable errors
- Interrupts provided to management
  - Separate interrupts are generated for correctable and uncorrectable errors.
  - sbd_sfty_ue_intr_o interrupt is generated when uncorrectable errors are detected and these errors cannot be masked.
  - sbd_sfty_ce_intr_o interrupt is generated when correctable errors are detected. The module sets the respective interrupt enable bits (in the DMA/MTL_ECC_Interrupt_enable register).
  - To find the root cause of the error, read the DMA/MTL_Safety_Interrupt_Status and DMA/MTL_ECC_Interrupt_Status registers.
  - To clear the interrupt, write 1 in the respective interrupt status bit in DMA/MTL_ECC_Interrupt_Status registers.

NOTE

- The status/counters/interrupts are generated per memory.
- MTL Tx and Rx memory is logically divided into multiple queues. But, ECC diagnostics (status/counter/interrupts) are common to all queues.

78.14.1.3 ECC Error Injection Capabilities

IP supports error injection capabilities for each memory as a static configuration. The position where the errors are injected in the data word is random. For each memory, 3 control bits are provided to inject errors. The 3 bits are:

- A single bit to enable error injection
- Two bits to indicate the type of error to be injected ❑ 00: 1 bit error
  - 01: 2 bit error
  - 10: 3 bit error
  - 11: 1 bit error in address field

The control bit descriptions for

- MTL Tx/Rx and DMA TSO memory are specified in the MTL_DBG_CTL register, for and for R.
- MTL EST memory are specified in the MTL_EST_GCL_Control register
- Rx parser memory are specified in the MTL_RXP_Indirect_Acc_Control_Status register

NOTE

While using debug mode for ECC error injection:

- There should be no traffic in the module
- When multiple CSR writes are required for writing single data word into the memory, the application should ensure that all the CSR writes corresponding to one memory write maintains the same value for the error injection control word.
- See Programming guidelines for ECC protection for memories

78.14.2 Finite State Machine(FSM) Parity and Timeout Protection

The FSM protection feature supports FSM parity and time out protection.

78.14.2.1 FSM State Parity Protection

Odd parity is implemented on all the FSM state register bits. Parity is monitored for every clock, after the reset is de-asserted. When a bit flips due to transient errors or permanent faults, the erroneous FSM is set to its default state and an uncorrectable error is indicated.

When the FSM state parity protection is enabled, by setting PRTYEN field of MAC_FSM_Control Register, the FSM state error is indicated by setting the FSMPES field of the MAC_DPP_FSM_Interrupt_Status register. Also, the Safety Interrupt (sbd_sfty_ue_intr_o) is asserted when an FSM Error is detected.

Error Injection mode is also supported for FSM parity error check. Program the Error Injection enable for the respective clock domain denoted by [23:16] bits of MAC_FSM_Control Register.

78.14.2.2 FSM Timeout Protection

The FSM Timeout feature provides a mechanism to ensure that all FSMs in the module can complete a transaction and return to a known completion state (IDLE or any other state that indicates completion of a transaction/transfer) within the programmed timeout value.

Program the TMR field of MAC_FSM_ACT_Timer register with a value that indicates the number of CSR cycles required to generate a 1 microsecond tic. This microsecond tic is internally used to generate the programmed timeout duration. Two timeout tics (normal mode timeout and large mode timeouts) are generated to provide flexibility to choose one per clock domain, by using the bits [31:24] of MAC_FSM_Control Register. Supported values for Timeout duration are 1us, 1.024ms, 16.384ms, 65.5536ms, 262.144ms, 1048.576ms (~1sec), 4194.304ms (~4s), 8.388s, 16.777s, and 33.554s which is based on the programmable bits NTMRMD, LTMRMD fields of MAC_FSM_ACT_Timer register. Interface timeouts are based on the normal mode tic generation; only the FSM timeouts depend on either normal or large tick selection.

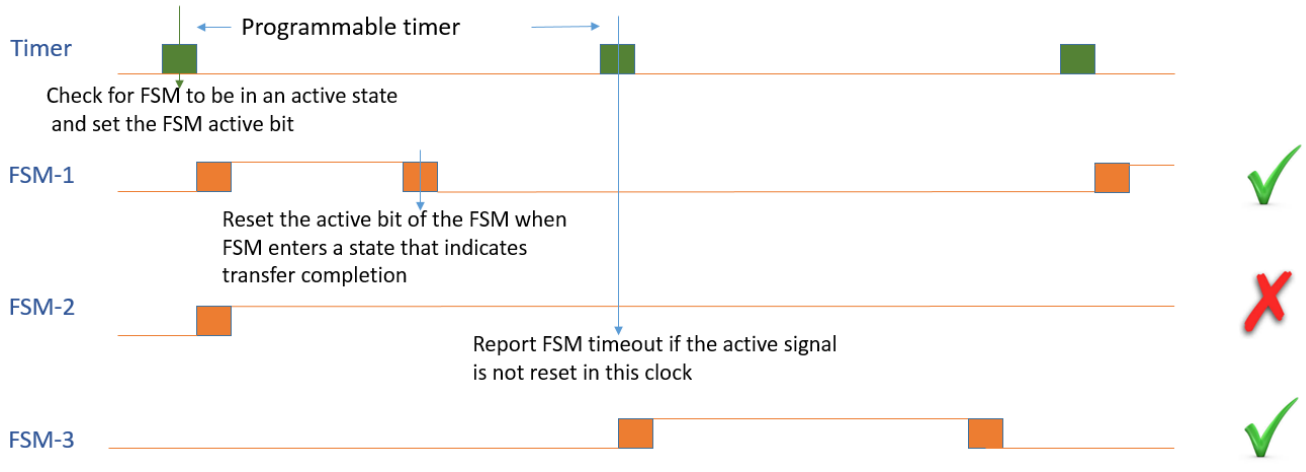

Figure 580. FSM Timeout Timing Diagram

In the above figure, the timer ticks are generated based on the programmable timeout value. The timer ticks are synchronized and made available in all the clock domains that have the FSMs.

At every timer tick, all the FSMs are monitored for being in active state (non-IDLE state, which indicates the FSM is actively processing transactions or hand-shakes) and an FSM active flag bit is set. The active flag bit is implemented for every FSM that is monitored for timeout. When the FSM reaches an IDLE or transaction completion state, the active flag bit of that FSM is reset. At the subsequent timer tick, all the FSMs' active flag bits are monitored and any flag that is set indicates a timeout for that FSM. This process of setting the flag and checking at subsequent timer tick is repeated at every tick.

Timeout Error Injection per clock domain is enabled by programming [15:8] fields of MAC_FSM_Control register. When Timeout error injection enable is set for a clock domain, the FSMs in that clock domain automatically timeout and generate an interrupt even without traffic. As error injection is a debug mode, TMR value need not indicate 1us, but can be programmed to a smaller value at which debug mode ticks are needed. FSM Timeout and Parity Error Injection modes can be used for testing at key-on/key-off.

The FSM timeout status is specified in the [15:8] field of MAC_DPP_FSM_Interrupt_Status register as per the respective clock domains. One FSM timeout status bit is made available per clock domain. The safety interrupt (sbd_sfty_ue_intr_o) is asserted when the timeout error is set for any of the clock domains. IP does not attempt to recover from a FSM timeout condition and relies on the application to take the corrective action (resetting IP).

78.14.2.3 Enabling FSM Parity and Timeout Protection

FSM timeout feature is enabled by setting the TMOUTEN field of MAC_FSM_Control register.

NOTE

See Programming guidelines for FSM parity and timeout

78.14.3 Application/CSR Interface Timeout Protection

This feature provides timeout protection to the application/CSR Interface. All the interfaces which has the handshake mechanism monitored for potential hangs due to the external agent (Master/Slave/Interconnect/Application client) not responding to the requests/transfers initiated by the QoS. After the request is initiated the response arrival interval is monitored. If the response does not arrive within a programmed time (TMR field of MAC_FSM_ACT_Timer) the timeout is triggered, using similar trigger generation as explained in the Section FSM protection.

The timeout is triggered when IP initiates SEQ, NON-SEQ and BUSY transfers on HTRANS[1:0]; and HREADY is not asserted by Slave within the programmed time.

The Timeout status for the AHB master interface is set in the MSTTES field of the MAC_DPP_FSM_Interrupt_Status register. The Safety interrupt (sbd_sfty_ue_intr_o) is asserted when application timeout status is set.

The hardware does not attempt to recover from Application/CSR Interface hangs and relies on software to take appropriate corrective action.

NOTE

- Protection is not needed for APB3 Slave interfaces because potential hangs can be only when IP does not respond to the requests. In such cases the IP internal protection logic (FSM timeout) detects such defects.
- Based on the time at which the transfer is initiated relative to the timer ticks, the timeout period could be any value between the programmed timeout and 2x times the programmed timeout.
- When an uncorrectable safety interrupt is issued and the read of the Interrupt status register returns all zeros, it implies that the CSR read is not functional. As soft reset of IP is not possible without the CSR access, and therefore, a hard reset of IP is recommended.
- See Programming guidelines for FSM parity and timeout .

78.15 Descriptors

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

78.15.1 Overview

The DMA in the Ethernet subsystem transfers data based on a linked list of descriptors. The application creates the descriptors in the system memory. The module supports the following two types of descriptors:

- Normal Descriptor: Normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted.
- Context Descriptor: Context descriptors are used to provide control information applicable to the packet to be transmitted.

Each normal descriptor contains two buffers and two address pointers. These buffers enable the adapter port to be compatible with various types of memory management schemes.

NOTE

There is no limit for the number of descriptors that can be used for a single packet.

78.15.2 Descriptor Structure

The module supports the ring structure for DMA descriptor as shown in the following figure.

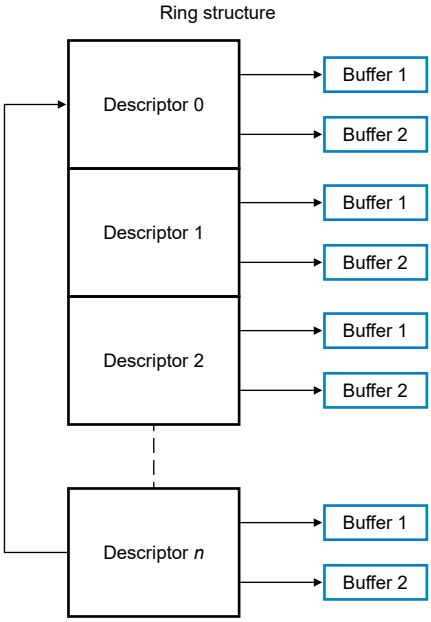

Figure 581. Descriptor Ring Structure

In Ring structure, descriptors are separated by the Word, DWord, or LWord number programmed in the DSL field of the DMA_CH#_Control register. The application needs to program the total ring length, that is, the total number of descriptors in ring span in the following registers of a DMA channel:

- Transmit Descriptor Ring Length Register (DMA_CH#_TxDesc_Ring_Length)
- Receive Descriptor Ring Length Register (DMA_CH#_RxDesc_Ring_Length)

The Descriptor Tail Pointer Register contains the pointer to the descriptor address (N). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process. The descriptors up to one location less than the one indicated by the descriptor tail pointer (N – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:

Current Descriptor Pointer == Descriptor Tail Pointer;

The DMA goes into the Suspend mode when this condition occurs. The application must perform a write to the Descriptor Tail pointer register and update the tail pointer so that the following condition is true:

Current Descriptor Pointer < Descriptor Tail Pointer;

The DMA automatically wraps around the base address when the end of ring is reached, as shown in the following figure.

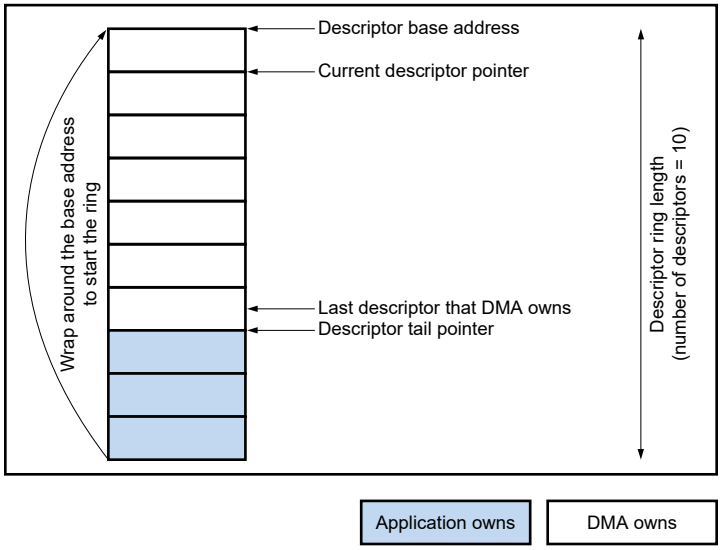

Figure 582. DMA Descriptor Ring

For descriptors owned by the application, the OWN bit of DES3 is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1. If the application has only one descriptor in the beginning, the application sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA processes the first descriptor and then waits for the application to advance the tail pointer.

78.15.3 Transmit Descriptor

The DMA in the module requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor has control fields which can be used to control the MAC operation on per-transmit packet basis. The Transmit Normal descriptor has two formats: Read format and Write-Back format

NOTE

TSO Split header is not supported.

Software must not write same tail pointer addresses when DMA is in Suspended state before setting new descriptor(s) for further processing.

78.15.3.1 Transmit Normal Descriptor (Read Format)

Following figure shows the Read Format for a Transmit normal descriptor. Table: 'TDES0 Normal Descriptor (Read Format)' through Table: 'TDES3 Normal Descriptor (Read Format)' describe the read format for the Transmit Normal Descriptors: TDES0, TDES1, TDES2, and TDES3.

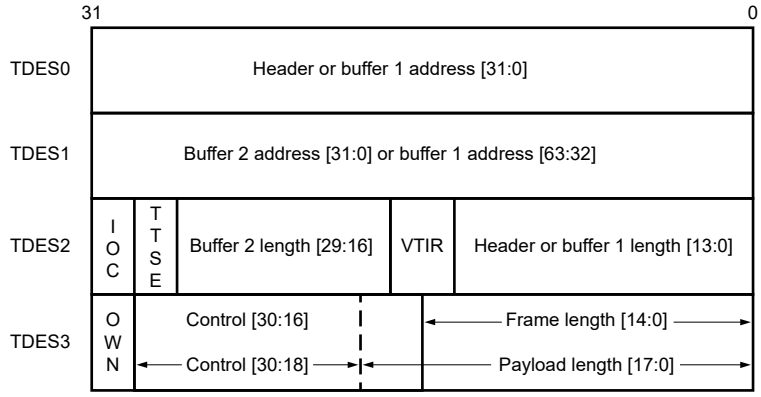

Figure 583. Transmit Descriptor Read Format

78.15.3.1.1 TDES0 Normal Descriptor (Read Format)

Table 651. TDES0 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF1AP	Buffer 1 Address Pointer or TSO Header Address Pointer These bits indicate the physical address of Buffer 1. These bits indicate the TSO Header Address pointer when the following bits are set: • TSE bit of TDES3 • FD bit of TDES3

78.15.3.1.2 TDES1 Normal Descriptor (Read Format)

Table 652. TDES1 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF2AP	Buffer 2 or Buffer 1 Address Pointer This bit indicates the physical address of Buffer 2 when a descriptor ring structure is used. There is no limitation for the buffer address alignment. In 40- or 48-bit addressing mode, these bits indicate the most-significant 8- or 16- bits of the Buffer 1 Address Pointer.

78.15.3.1.3 TDES2 Normal Descriptor (Read Format)

Table 653. TDES2 Normal Descriptor (Read Format)

31	30	29-16	15:14	13:0
IOC	TTSE/ TMWD	B2L	VTIR	HL or B1L

Table 654. TDES2 Normal Descriptor (Read Format)

Bits	Name	Description
31	IOC	Interrupt on Completion This bit controls the setting of TI and ETI status bits in the DMA_CH#_Status register. When ETIC = 1 and TDES2[LD] = 0, this bit sets the ETI bit. When TDES3[LD] = 1, this bit sets the TI status bit.
30	TTSE/ TMWD	Transmit Timestamp Enable or External TSO Memory Write Enable This bit enables the IEEE1588 time stamping for Transmit packet referenced by the descriptor, if TSE bit is not set. If TSE bit is set and external TSO memory is enabled, setting this bit disables external TSO memory writing for this packet.
29:16	B2L	Buffer 2 Length The driver sets this field. When set, this field indicates Buffer 2 length.
15:14	VTIR	VLAN Tag Insertion or Replacement These bits request the MAC to perform VLAN tagging or untagging before transmitting the packets. The application must set the CRC Pad Control bits appropriately when VLAN Tag Insertion, Replacement, or Deletion is enabled for the packet. The following list describes the values of these bits: • 2'b00: Do not add a VLAN tag. • 2'b01: Remove the VLAN tag from the packets before transmission. This option should be used only with the VLAN packets. • 2'b10: Insert a VLAN tag with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. • 2'b11: Replace the VLAN tag in packets with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. This option should be used only with the VLAN packets. These bits are valid when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core.
13:0	HL or B1L	Header Length or Buffer 1 Length For Header length only bits [9:0] are taken. The size 13:0 is applicable only when interpreting buffer 1 length. If the TCP Segmentation Offload feature is enabled through the TSE bit of TDES3, this field is equal to the header length. When the TSE bit is set in TDES3, the header length includes the length in bytes from Ethernet Source address till the end of the TCP header. The maximum header length supported for TSO feature is 1023 bytes. The maximum header length supported for TSO feature is 1023 bytes. If the TCP Segmentation Offload feature is not enabled, this field is equal to Buffer 1 length.

78.15.3.1.4 TDES3 Normal Descriptor (Read Format)

Table 655. TDES2 Normal Descriptor (Read Format)

31	30	29	28	27:26	25:23	22:19	18	17:16	15	14:0
OWN	CTXT	FD	LD	CPC	SAIC	SLOTNUM or THL	TSE	CIC/TPL	TPL	FL/TPL

Table 656. TDES3 Normal Descriptor (Read Format)

Bits	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffer(s).
30	CTXT	Context Type This bit should be set to 1'b0 for normal descriptor.
29	FD	First Descriptor When this bit is set, it indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor When this bit is set, it indicates that the buffer contains the last segment of the packet. When this bit is set, the B1L or B2L field should have a non-zero value.
27:26	CPC	CRC Pad Control This field controls the CRC and Pad Insertion for Tx packet. This field is valid only when the first descriptor bit (TDES3[29]) is set. The following list describes the values of Bits[27:26]: • 2'b00: CRC and Pad Insertion The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packet of length greater than or equal to 60 bytes. The MAC automatically appends padding and CRC to a packet with length less than 60 bytes. • 2'b01: CRC Insertion (Disable Pad Insertion) The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the Transmit Buffer, that is, the packet being transferred from the Transmit Buffer is of length greater than or equal to 60 bytes. • 2'b10: Disable CRC Insertion The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. • 2'b11: CRC Replacement The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. This field is valid only for the first descriptor. Note: When the TSE bit is set, the MAC ignores this field because the CRC and pad insertion is always done for segmentation.
25:23	SAIC	SA Insertion Control These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 register. The application must set the CRC Pad Control bits appropriately when SA Insertion Control is enabled for the packet.

Table continues on the next page...

Table 656. TDES3 Normal Descriptor (Read Format) (continued)

Bits	Name	Description
		Bit 25 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement. The following list describes the values of Bits[24:23]: • 2'b00: Do not include the source address • 2'b01: Include or insert the source address. For reliable transmission, the application must provide frames without source addresses. • 2'b10: Replace the source address. For reliable transmission, the application must provide frames with source addresses. • 2'b11: Reserved These bits are valid in the EQOS-DMA, EQOS-AXI, and EQOS-AHB configurations when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core and when the First Segment control bit (TDES3 [29]) is set. This field is valid only for the first descriptor.
22:19	SLOTNUM or THL	SLOTNUM: Slot Number Control Bits in AV Mode These bits indicate the slot interval in which the data should be fetched from the corresponding buffers addressed by TDES0 or TDES1. When the Transmit descriptor is fetched, the DMA compares the slot number value in this field with the slot interval maintained in the RSN field DMA_CH#_Slot_Function_Control_Status. It fetches the data from the buffers only if a value matches. These bits are valid only for the AV channels. THL: TCP/UDP Header Length If the TSE bit is set, this field contains the length of the TCP/UDP header. The minimum value of this field must be 5 for TCP header. The value must be equal to 2 for UDP header. This field is valid only for the first descriptor.
18	TSE	TSO Split header is not supported. The value of this bit is always zero.
17:16	CIC/TPL	Checksum Insertion Control or TCP Payload Length These bits control the checksum calculation and insertion. The following list describes the bit encoding: • 2'b00: Checksum Insertion Disabled. • 2'b01: Only IP header checksum calculation and insertion are enabled. • 2'b10: IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware. • 2'b11: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware. This field is valid when the Enable Transmit TCP/IP Checksum Offload option is selected and the TSE bit is reset. When the TSE bit is set, this field contains the upper bits [17:16] of the TCP Payload (or IP Payload for UDP fragmentation). This allows the TCP/UDP packet length field to be spanned across TDES3[17:0] to provide 256 KB packet length support.

Table continues on the next page...

Table 656. TDES3 Normal Descriptor (Read Format) (continued)

Bits	Name	Description
		This field is valid only for the first descriptor.
15	TPL	Reserved or TCP Payload Length When the TSE bit is reset, this bit is reserved. When the TSE bit is set, this is Bit 15 of the TCP payload length [17:0]. This field is valid only when the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected while configuring the core.
14:0	FL/TPL	Frame Length or TCP Payload Length This field is equal to the length of the packet to be transmitted in bytes. When the TSE bit is not set, this field is equal to the total length of the packet to be transmitted: Ethernet Header Length + TCP /IP Header Length – Preamble Length – SFD Length + Ethernet Payload Length When the TSE bit is set, this field is equal to the lower 15 bits of the TCP payload length in case of segmentation and IP payload in case of UDP fragmentation. In case of segmentation, this length does not include Ethernet header or TCP/UDP/IP header length. In case of fragmentation, this length does not include Ethernet header and IP header. When DWRR/WFQ algorithm is NOT enabled, value written into this field is not used when TSE = 0.

78.15.3.1.5 Transmit normal descriptor (write-back format)

The transmit descriptor write-back format includes timestamp low, timestamp high, OWN, and Status bits.

The write-back format is applicable only for the last descriptor of the corresponding packet. Write 1 to the LD bit (TDES3[28]) in the descriptor where DMA writes back the status and timestamp information for the corresponding transmit packet.

Figure 584 shows the transmit descriptor write-back format.

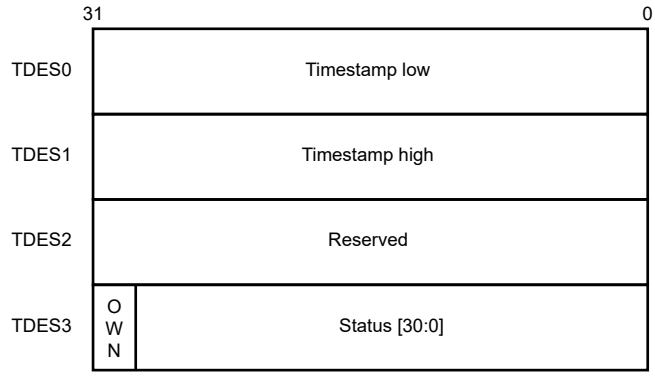

Figure 584. Transmit descriptor write-back format

TDES0 normal descriptor (write-back format)

Table 657 shows that this format is only applicable to the last descriptor of a packet.

Table 657. TDES0 normal descriptor (write-back format)TDES0 normal descriptor (write-back format)

Bit	Name	Description
31:0	TTSL	Transmit Packet Timestamp Low DMA updates this field with least significant 32 bits of the timestamp captured for the corresponding transmit packet. DMA writes the timestamp only if TTSE bit of TDES2 is 1 in the first descriptor of the packet. This field has the timestamp only if you write 1 to the Last Segment bit (LS) in the descriptor and the Timestamp status (TTSS) bit.

TDES1 normal descriptor (write-back format)

Table 658 shows that this format is only applicable to the last descriptor of a packet.

Table 658. TDES1 normal descriptor (write-back format)

Bit	Name	Description
31:0	TTSH	Transmit Packet Timestamp High DMA updates this field with the most significant 32 bits of the timestamp captured for a corresponding transmit packet. DMA writes the timestamp only if the TTSE bit of TDES2 is 1 in the first descriptor of the packet. This field has the timestamp only if you write 1 to the Last Segment bit (LS) in the descriptor and Timestamp status (TTSS) bit.

TDES2 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

Table 659. TDES2 normal descriptor (write-back format)

Bit	Description
31:0	Reserved

TDES3 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

Table 660. TDES3 normal descriptor (write-back format)

31	30	29	28	27:18	17	16	15	14	13	12	11	10	9	8	7:4	3	2	1	0
OWN	CTXT	FD	LD	Rsvd	TTSS	EUE	ES	JT	FF	PCE	LoC	NC	LC	EC	CC	ED	UF	DB	IHE

Table 661. TDES3 normal descriptor (write-back format)

Bit	Name	Description
31	OWN	Own Bit When this field is 1, it indicates that the module DMA owns the descriptor. DMA write 0 to this field when it completes the packet transmission. After the write-back is complete, this field is set to 'b0.
30	CTXT	Context Type

Table continues on the next page...

Table 661. TDES3 normal descriptor (write-back format) (continued)

Bit	Name	Description
		This field must be set to 'b0 for normal descriptor.
29	FD	First Descriptor This field indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor This field is set to 'b1 for last descriptor of a packet. DMA writes the status fields only in the last descriptor of the packet.
27:24	Rsvd	Reserved
23	DE	Descriptor Error When this field is 1, it indicates that the descriptor content is incorrect. DMA writes 1 to this field during write-back when the descriptor is closed. Descriptor errors can be: • Incorrect sequence from the context descriptor. For example, a location after the first descriptor for a packet. • All 1s • CTXT is 1 along with LD or FD bits as 1. **NOTE** When a descriptor error occurs due to all ones or CTXT, LD, and FD bits are 1, the transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When you write 1 to IOC bit in TDES2 of corresponding first descriptor, the transmit DMA write 1 to TI bit in the DMA_CH#_Status register **NOTE** Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might consider as the first descriptor (even if FD bit is not 1) and partial packet is sent.
22:18	Rsvd	Reserved
17	TTSS	Tx Timestamp Status This field indicates that a timestamp has been captured for the corresponding transmit packet. When this field is 1, it indicates that TDES0 and TDES1 have timestamp values that were captured for the transmit packet. This field is valid only when the Last Segment control bit (TDES3 [28]) in a descriptor is 1. This field is valid only when IEEE1588 timestamping feature is enabled; otherwise, it is reserved.
16	EUE	ECC Uncorrectable Error Status Indicates the ECC uncorrectable error in the TSO memory. **NOTE** An uncorrectable error in the transmit FIFO memory is reported with (Bit 13) FF = 1. This is because the module flushes all such packets.

Table continues on the next page...

Table 661. TDES3 normal descriptor (write-back format) (continued)

Bit	Name	Description
15	ES	Error Summary This field indicates the logical OR of the following bits: • TDES3[0]: IP header error • TDES3[14]: Jabber timeout • TDES3[13]: Packet flush • TDES3[12]: Payload checksum error • TDES3[11]: Loss of carrier • TDES3[10]: No carrier • TDES3[9]: Late collision • TDES3[8]: Excessive collision • TDES3[3]: Excessive deferral • TDES3[2]: Underflow error This field is 1 when EUE (bit 16) = 1.
14	JT	Jabber Timeout This field indicates that the MAC transmitter experiences a jabber time-out. This field is 1 only when MAC_Configuration[JD] is not 1.
13	FF	Packet Flushed This field indicates that DMA or MTL flushes the packet because the CPU gives a software flush command.
12	PCE	Payload Checksum Error This field indicates that the checksum offload engine had a failure and does not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can either because of insufficient bytes, as the payload length field of the IP header indicates or the MTL starting to forward the packet to the MAC transmitter in Store-and-forward mode without calculating the checksum. This second error condition only occurs when the transmit FIFO depth is less than the length of the Ethernet packet that is transmitted to avoid deadlock. The MTL starts forwarding the packet when the FIFO is full, even in the Store-and-forward mode. This error can also occur when you detects a bus error during packet transfer. When the full checksum offload engine is not enabled, this bit is reserved.
11	LoC	Loss of Carrier This field indicates that a loss of carrier occurred during packet transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during packet transmission). This field is valid only for the packets transmitted without collision and when MAC operates in the Half-duplex mode.
10	NC	No Carrier This field indicates that the carrier sense signal from the PHY was not asserted during transmission.

Table continues on the next page...

Table 661. TDES3 normal descriptor (write-back format) (continued)

Bit	Name	Description
9	LC	Late Collision This bit indicates that packet transmission was aborted because a collision occurred after the collision window (64 byte times including Preamble in MII mode and 512 byte times including Preamble and Carrier Extension in GMII mode). This bit is not valid if Underflow Error is set.
8	EC	Excessive Collision This field indicates that the transmission was aborted after 16 successive collisions when you transmits the current packet. If MAC_Configuration[DR] = 1, this field is 1 after first collision and abort the packet transmission.
7:4	CC	Collision Count This 4-bit counter value indicates the number of collisions occurred before transmitting the packet. The count is not valid when the EC bit = 1.
3	ED	Excessive Deferral This field indicates that the transmission ends because of an excessive deferral of over 24,288 bit times (155,680 bits times in 1000 Mbit/s mode or Jumbo packet enabled mode) if MAC_Configuration[DC] = 1. When TBS is enabled in Full duplex mode and this field is 1, it indicates that the frame drops after the expiry time is reached.
2	UF	Underflow Error This field indicates that MAC aborts the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions: • DMA encounters an empty transmit buffer when it transmits the packet • The application filled the MTL Tx FIFO slower than the MAC transmit rate The transmission process enters the Suspended state and sets the underflow bit corresponding to a queue in MTL_Interrupt_Status.
1	DB	Deferred Bit This field indicates that MAC defers before transmitting because of presence of carrier. This field is valid only in the Half-Duplex mode.
0	IHE	IP Header Error When IP Header Error is 1, this field indicates that the checksum offload engine detects an IP header error. This field is valid only when transit checksum offload is enabled. Otherwise, it is reserved. If COE detects an IP header error, it inserts an IPv4 header checksum if the Ethernet type field indicates an IPv4 payload. In Full-Duplex mode, when EST/Qbv is enabled and this field is 1, it indicates the frame drop status due to the frame size error or schedule error.

78.15.3.2 Transmit context descriptor

The transmit context descriptor can provide any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor provide the timestamps for one-step timestamp correction and VLAN tag ID for VLAN insertion feature. Write back is done on a context descriptor only to write 0 to OWN bit.

NOTE

DMA internally store the VLAN tag IDs and MSS values which the application provides in a context descriptor with their corresponding valid bits set. DMA always passes the last valid VLAN tag to the MTL, when the outer or inner VLAN tag is provided with the valid bit set. The application cannot invalidate the valid VLAN tag which DMA stores. The VLAN tag is inserted or replaced based on the control inputs provided for the packet.

The inner VLAN tag control input is used only for the next packet that immediately follows the context descriptor. The application must provide a context descriptor before the normal descriptor of each packet for which DMA must use the inner VLAN tag control input.

Figure 585 shows the transmit context descriptor format.

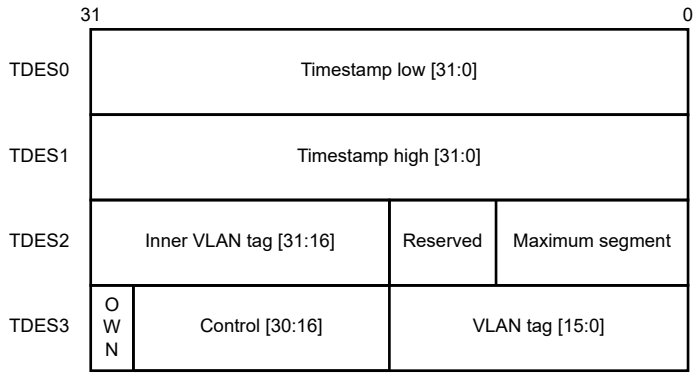

Figure 585. Transmit context descriptor format

78.15.3.2.1 TDES0 context descriptor

Table 662 describes the TDES0 context descriptor format.

Table 662. TDES0 context descriptor

Bit	Name	Description
31:0	TTSL	Transmit Packet Timestamp Low For one-step correction, the driver can provide the lower 32 bits of timestamp in this descriptor word. DMA uses this value as the low word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are 1.

78.15.3.2.2 TDES1 context descriptor

Table 663 describes the TDES1 context descriptor format.

Table 663. TDES1 context descriptor

Bit	Name	Description
31:0	TTSH	Transmit Packet Timestamp High For one-step correction, the driver can provide the upper 32 bits of timestamp in this descriptor. DMA uses this value as the high word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are 1.

78.15.3.2.3 TDES2 context descriptor

Table 664 shows the TDES2 context descriptor format.

Table 664. TDES2 context descriptor

Bit	Name	Description
31:16	IVT	Inner VLAN Tag When the IVLTV bit of TDES3 context descriptor is 1 and the TCMSSV and OSTC bits of TDES3 context descriptor becomes 0, it indicates that the TDES2[31:16] contains the inner VLAN tag to insert in the subsequent transmit packets.
15:14	Rsvd	Reserved
13:0	MSS	TSO split header is not supported. The value of this bit is always zero.

78.15.3.2.4 TDES3 context descriptor

Table 665. TDES3 context descriptor

31	30	29:28	27	26	25:24	23	22:18	17	16	15:0
OWN	CTXT	Rsvd	OSTC	TCMSSV	Rsvd	CDE	Rsvd	IVLTV	VLTV	VT

Table 666 shows the TDES3 context descriptor format.

Table 666. TDES3 context descriptor

Bit	Name	Description
31	OWN	Own Bit When this field is 1, it indicates that the module DMA owns the descriptor. When this field becomes 0, it indicates that the application owns the descriptor. DMA writes 0 to this field immediately after the read.
30	CTXT	Context Type This field must set to 1'b1 for context descriptor.
29:28	Rsvd	Reserved
27	OSTC	One-Step Timestamp Correction Enable When this field is 1, it indicates that DMA performs a one-step timestamp correction with reference to the timestamp values provided in TDES0 and TDES1.
26	TCMSSV	One-Step Timestamp Correction Input or MSS Valid When this field and the OSTC field are 1, it indicates that the timestamp correction input provided in TDES0 and TDES1 is valid. When the OSTC field becomes 0 and this field and the TSE bit of TDES3 are 1 in subsequent normal descriptor, it indicates that the MSS input in TDES2 is valid.
25:24	Rsvd	Reserved

Table continues on the next page...

Table 666. TDES3 context descriptor (continued)

Bit	Name	Description
23	DE	Descriptor Error When this field is 1, it indicates that the descriptor content is incorrect. DMA writes 1 to this field during write-back when it closes the context descriptor. Descriptor errors can be: • Incorrect sequence from the context descriptor. For example, a location before the first descriptor for a packet. • All ones. • CD, LD, and FD bits = 1. **NOTE** When a descriptor error occurs due to all ones or CTXT, LD, and FD bits are 1, the transmit DMA closes the transmit descriptor with DE and LD bits are 1. When you write 1 to IOC bit in TDES2 of corresponding first descriptor, the transmit DMA writes 1 to TI bit in the DMA_CH#_Status register **NOTE** On the basis of CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might considered as the first descriptor (even if FD bit is not 1) and partial packet is sent. **NOTE** This error is categorized as an abnormal event. Recovery from this event is possible by issuing a software reset only. DMA stopping, reconfiguring, and restarting recovery mechanism is not supported.
22:20	Rsvd	Reserved
19:18	IVTIR	Inner VLAN Tag Insert or Replace When this field is 1, it requests MAC to perform inner VLAN tagging or un-tagging before transmitting the packets. If the packet is modified for VLAN tags, MAC automatically recalculates and replaces the CRC bytes. The following list describes the values of these bits: • 2'b00: Do not add the inner VLAN tag. • 2'b01: Remove the inner VLAN tag from the packets before transmission. You must use this option only with the VLAN frames. • 2'b10: Insert an inner VLAN tag with the tag value programmed in MAC_Inner_VLAN_Incl or context descriptor. • 2'b11: Replace the inner VLAN tag in packets with the tag value programmed in MAC_Inner_VLAN_Incl or context descriptor. You must use this option only with the VLAN frames.. These fields are valid when you select the enable SA and VLAN insertion on transit and enable double VLAN processing options.
17	IVLTV	Inner VLAN Tag Valid When this field is 1, it indicates that IVT field of TDES2 is valid.

Table continues on the next page...

Table 666. TDES3 context descriptor (continued)

Bit	Name	Description
16	VLTV	VLAN Tag Valid When this field is 1, it indicates that VT field of TDES3 is valid.
15:0	VT	VLAN Tag Contains the VLAN tag to insert or replace in the packet. This field is used as VLAN tag only when MAC_VLAN_Incl[VLTI] becomes 0.

78.15.4 Receive descriptor

DMA in the module reads a descriptor only if the tail pointer is different from the base pointer or current pointer. It is recommended to have a descriptor ring with a length that accommodates at least two complete packets which MAC receives. Otherwise, the performance of DMA is impacted because of the unavailability of the descriptors. In such situations, the RxFIFO in MTL becomes full and starts dropping packets.

The following receive descriptors are present:

- Normal descriptors
- Context descriptors

You can prepare all the receive descriptors and give to DMA as normal descriptors with the content as shown in receive normal descriptor (read format). DMA reads this descriptor and the receive DMA closes the descriptor with the corresponding packet status after transferring a received packet (or part of) to the buffers indicated by the descriptor. The receive normal descriptor (write-back format) describes the format of this status.

For some packets, only the normal descriptor bits cannot write the complete status. For such packets, the receive DMA writes the extended status to the next descriptor (without processing or using the buffers or pointers embedded in that descriptor). Receive context descriptor describes the descriptor write back format and content.

78.15.4.1 Receive normal descriptor (read format)

The read format for a receive normal descriptor is made up of the following:

- A header or buffer 1 address
- Reserved field
- Payload or buffer 2 or next descriptor address
- A 30-bit reserved field
- OWN bit
- An interrupt field

Figure 586 shows the read format for a receive normal descriptor.

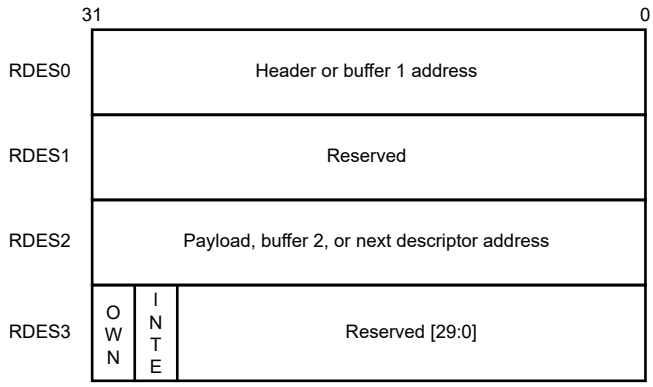

Figure 586. Receive normal descriptor read format

NOTE

In the receive descriptor (read format), if the buffer address field is all zeros, the module does not transfer data to that buffer and skips to the next buffer or next descriptor.

78.15.4.1.1 RDES0 normal descriptor (read format)

Table 667 shows the RDES0 normal descriptor read format.

Table 667. RDES0 normal descriptor (read format)

Bit	Name	Description
31:0	BUF1AP	Header or Buffer 1 Address Pointer When the SPH field of control register of a channel becomes 0, these field indicates the physical address of buffer 1. When the SPH field is 1, these field indicates the physical address of header buffer where the receive DMA writes the L2/L3/L4 header bytes of the received packet. The application can program a byte-aligned address for this buffer which means that the LS bits of this field can be non-zero. However, DMA performs a write operation with RDES0[1:0] (or RDES0[2:0]/[3:0] in case of 64-/128-bit configuration) as zero, when the start of packet is transferred. However, the packet data shifts per the actual offset which the buffer address pointer provides. If the address pointer points to a buffer where the middle or last part of the packet is stored, DMA ignores the offset address and writes to the full location which the data-width indicates .

78.15.4.1.2 RDES1 normal descriptor (read format)

Table 668 shows the RDES1 normal descriptor read format.

Table 668. RDES1 normal descriptor (read format)

Bit	Name	Description
31:0	Reserved or BUF1AP	Contains the most-significant 32 bits of the buffer 1 address pointer in 64-bit Addressing mode. Otherwise, this field is reserved.

78.15.4.1.3 RDES2 normal descriptor (read format)

Table 669 shows the RDES2 normal descriptor read format.

Table 669. RDES2 normal descriptor (read format)

Bit	Name	Description
31:0	BUF2AP	Buffer 2 Address Pointer Indicates the physical address of buffer 2. When the SPH bit of the DMA_CH#_Control register = 1, it indicates that the buffer address pointer must be bus width-aligned, that is, RDES2[3:0, 2:0, or 1:0] = 0 corresponding to 128, 64, or 32 bus width. LSBs are ignored internally. When the SPH bit of the DMA_CH#_Control register becomes 0, it indicates that there is no limitations on the RDES2 value. However, the RxDMA uses the LS fields of the pointer address only when it transfers the start bytes of a packet. If the BUF2AP provides the address of a buffer in which the middle or last part of a packet is stored, DMA ignores BUF2AP[3:0 or 2:0 or 1:0] (corresponding to 128- or 64- or 32-bit data-bus) and writes to the complete location.

78.15.4.1.4 RDES3 normal descriptor (read format)

Following table describes the RDES3 normal descriptor read format.

31	30	19-26	25	24	23:0
OWN	IOC	Rsvd	BUF2V	BUF1V	Rsvd

Table 670. RDES3 normal descriptor (read format)

Bit	Name	Description
31	OWN	Own Bit When this field is 1, it indicates that the module DMA owns the descriptor. When this field becomes 0, it indicates that the application owns the descriptor. DMA write 0 this field when either of the following conditions is true: • DMA completes the packet reception. • The buffers associated with the descriptor are full.
30	IOC	Interrupt Enabled on Completion When this field is 1, it indicates that an interrupt is issued to the application when DMA closes this descriptor.
29:26	Rsvd	Reserved
25	BUF2V	Buffer 2 Address Valid When this field is 1, it indicates to the DMA that the buffer 2 address specified in RDES2 is valid. The application must write 1 to this field so that DMA can use the address, to which the buffer 2 address in RDES2 points to write received packet data.
24	BUF1V	Buffer 1 Address Valid When this field is 1, it indicates to the DMA that the buffer 1 address specified in RDES1 is valid.

Table continues on the next page...

Table 670. RDES3 normal descriptor (read format) (continued)

Bit	Name	Description
		The application must write 1 to this field, if DMA uses the address to which the buffer 1 address in RDES1 points to write the received packet data.
23:0	Rsvd	Reserved

78.15.4.1.5 Receive normal descriptor (write-back format)

Following figure shows the write-back format for a receive normal descriptor.

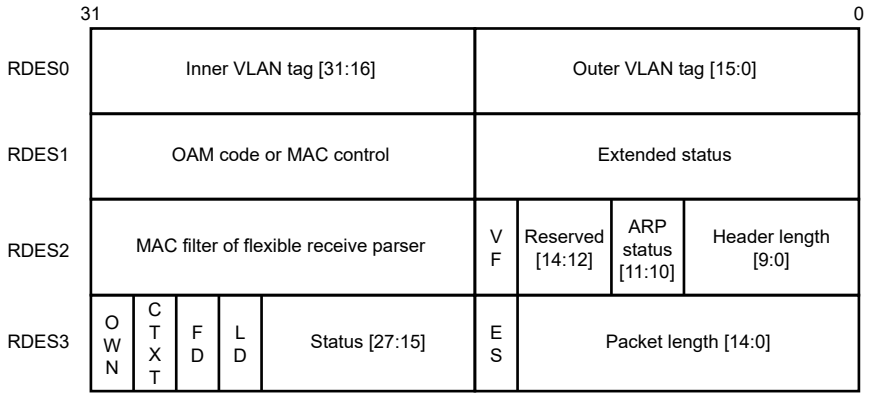

Figure 587. Receive normal descriptor (write-back format)

NOTE

When you enables the flexible receive parser, RDES2[31:16] indicates the parser status, and not the MAC filter status. The MAC filter status is not available when flexible receive parser is enabled.

78.15.4.1.5.1 RDES0 normal descriptor (write-back format)

Table 671 shows the write-back format for the RDES0 normal descriptor.

Table 671. RDES0 normal descriptor (write-back format)

Bit	Name	Description
31:16	IVT	Inner VLAN Tag Contains the inner VLAN tag of the received packet if the RS0V bit of RDES3 = 1. This field is valid only when you enables the double VLAN tag processing and VLAN tag stripping.
15:0	OVT	Outer VLAN Tag Contains the outer VLAN tag of the received packet if the RS0V bit of RDES3 = 1.

78.15.4.1.5.2 RDES1 normal descriptor (write-back format)

The status fields in the write-back format are valid only for the last descriptor (RDES3[28] = 1). Following table provide the details of the write-back format for RDES1 normal descriptor.

31:16	15	14	13	12	11:8	7	6	5	4	3	2:0
OPC	TD	TSA	PV	PFT	PMT	IPCE	IPCB	IPV6	IPV4	IPHE	PT

Table 672. RDES1 normal descriptor (write-back format)

Bit	Name	Description
31:16	OPC	Indicates any one of the following: • OAM sub-type code: If bits [18:16] of RDES3 as described in RDES3 normal descriptor (read format) are 111b, this field contains the OAM sub-type and code fields. • MAC control packet opcode: Bits 15:8 of RDES3 as described in RDES3 normal descriptor (read format) contain the subtype and bits 7:0 contain the code.
15	TD	Timestamp Dropped Indicates that the timestamp was captured for this packet but it dropped in the MTL Rx FIFO because of overflow. This field is available only when you select the timestamp feature. Otherwise, this field is reserved.
14	TSA	Timestamp Available Indicates that the timestamp value is available in a context descriptor word 2 (RDES2) and word 1(RDES1) when timestamp is present. This is valid only when the last descriptor field (RDES3 [28]) = 1 You can write the context descriptor in the next descriptor just after the last normal descriptor for a packet.
13	PV	PTP Version Indicates that the received PTP message has the IEEE 1588 version 2 format. When this field becomes 0, it indicates the IEEE 1588 version 1 format. This field is available only when you select the timestamp feature. Otherwise, this field is reserved.
12	PFT	PTP Packet Type Indicates that the PTP message is sent directly over Ethernet. This field is available only when you select the timestamp feature. Otherwise, this field is reserved.
11:8	PMT	PTP Message Type Encodes to give the type of the message received: • 0000: No PTP message received • 0001: SYNC (all clock types) • 0010: Follow_Up (all clock types) • 0011: Delay_Req (all clock types) • 0100: Delay_Resp (all clock types) • 0101: Pdelay_Req (in peer-to-peer transparent clock) • 0110: Pdelay_Resp (in peer-to-peer transparent clock) • 0111: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock)

Table continues on the next page...

Table 672. RDES1 normal descriptor (write-back format) (continued)

Bit	Name	Description
		• 1000: Announce • 1001: Management • 1010: Signaling • 1011–1110: Reserved • 1111: PTP packet with reserved message type These fields are available only when you select the timestamp feature.
7	IPCE	IP Payload Error When this field is 1, it indicates either of the following: • The 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) which MAC calculates does not match the corresponding checksum field in the received segment. • The TCP, UDP, or ICMP segment length does not match the payload length value in the IP header field. • The TCP, UDP, or ICMP segment length is less than minimum allowed segment length for TCP, UDP, or ICMP. Bit 15 (ES) of RDES3 is not set when this field is 1.
6	IPCB	IP Checksum Bypassed Indicates that the checksum offload engine is bypassed. This field is available when you select the enable receive TCP/IP checksum check feature.
5	IPV6	IPv6 header Present Indicates that an IPV6 header is detected. When you select the enable split header feature option and the SPH bit of control register of a channel is 1, the IPV6 header is available in the header buffer area to which RDES0 points.
4	IPV4	IPV4 Header Present Indicates that an IPV4 header is detected. When the SPH bit of RDES3 is 1, the IPV4 header is available in the header buffer area to which RDES0 points.
3	IPHE	IP Header Error When this field is 1, it indicates either of the following: • The 16-bit IPv4 header checksum which MAC calculates does not match the received checksum bytes. • The IP datagram version is not consistent with the Ethernet type value. • Ethernet packet does not have the expected number of IP header bytes. This field is valid when either bit 5 or bit 4 is 1. This field is available when you select the enable receive TCP/IP checksum check feature.
2:0	PT	Payload Type Indicates the type of payload encapsulated in the IP datagram that the receive checksum offload engine (COE) process.

Table continues on the next page...

Table 672. RDES1 normal descriptor (write-back format) (continued)

Bit	Name	Description
		• 3'b000: Unknown type or IP/AV payload not processed • 3'b001: UDP • 3'b010: TCP • 3'b011: ICMP • 3'b110: AV tagged data packet • 3'b111: AV tagged control packet • 3'b101: AV untagged control packet • 3'b100: IGMP, if IPV4 header present field = 1, else DCB (LLDP) control packet If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, it sets these fields to 3'b000.

78.15.4.1.5.3 RDES2 normal descriptor (Write-back format)

31:29	28	27	26:19	18	17	16	15	14	13:11	10	9:0
L3L4FM	L4FM	L3FM	MADRM	HF	DAF	SAF	OTS	ITS	Rsvd	ARPNR	HL

Table 673. RDES2 normal descriptor (Write-back format)

Bit	Name	Description
31:29	L3L4FM	Layer 3 and Layer 4 Filter Number Matched Indicates the number of the layer 3 and layer 4 filter that matches the received packet: • 000: Filter 0 • 001: Filter 1 • 010: Filter 2 • 011: Filter 3 • 100: Filter 4 • 101: Filter 5 • 110: Filter 6 • 111: Filter 7 This field is valid only when bit 28 or bit 27 = 1. When more than one filter matches, these fields provide the number of lowest filter. **NOTE** This status is not available when Flexible RX Parser is enabled.
28	L4FM	Layer 4 Filter Match

Table continues on the next page...

Table 673. RDES2 normal descriptor (Write-back format) (continued)

Bit	Name	Description
		When this field is 1, it indicates that the received packet matches one of the enabled layer 4 port number fields. This status is given only when one of these conditions is true: • Layer 3 fields are not enabled and all enabled layer 4 fields match • All enabled layer 3 and layer 4 filter fields match When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by Bits[31:29]. **NOTE** This status is not available when the flexible receive parser is enabled.
27	L3FM	Layer 3 Filter Match When this field is 1, it indicates that the received packet matches one of the enabled layer 3 IP address fields. This status is given only when one of these conditions is true: • All enabled layer 3 fields match and bypasses all enabled layer 4 fields. • All enabled filter fields match. When more than one filter matches, this field gives the layer 3 filter status of filter which bits[31:29] indicate. **NOTE** This status is not available when the flexible receive parser is enabled.
26:19	MADRM	MAC Address Match or Hash Value When HF becomes 0, it indicates that this field contains the MAC address register number that matches the received packet destination address. This field is valid only if the DAF field becomes 0. When HF = 1, it indicates that this field contains the hash value that MAC computes. A packet passes the hash filter when the field corresponding to the hash value is 1 in the hash filter register. **NOTE** This status is not available when the flexible receive parser is enabled.
18	HF	Hash Filter Status When this field is 1, it indicates that the packet passes the MAC address hash filter. Bits[26:19] indicate the hash value. **NOTE** This status is not available when the flexible receive parser is enabled.
17	DAF/RXPI	Destination Address Filter Fail When flexible receive parser is disabled, and this field is 1, it indicates that the packet fails the DA filter in MAC. When flexible receive parser is enabled, and this field is 1, it indicates that the packet parsing is incomplete (RXPI) due to ECC error.

Table continues on the next page...

Table 673. RDES2 normal descriptor (Write-back format) (continued)

Bit	Name	Description
		NOTE When this field is 1, RDES3 ES field is also 1.
16	SAF/RXPD	SA Address Filter Fail When flexible receive parser is disabled, and this field is 1, it indicates that the packet fails the SA filter in MAC. When flexible receive parser is enabled and this field is 1, it indicates that the parser drops the RXPD packet. **NOTE** When this field is 1, RDES3 ES field is also 1.
15	OTS	VLAN Filter Status When this field is 1, it indicates that the received packet VLAN tag passes the VLAN filter. This field redefines as an outer VLAN tag filter status (OTS). This field is valid for both single and double VLAN tagged frames.
14	ITS	Inner VLAN Tag Filter Status (ITS) This field is valid only for double VLAN tagged frames, when double VLAN processing is enabled. See Filter status for more information.
13:11	Rsvd	Reserved
10	ARPNR	ARP Reply Not Generated When this field is 1, it indicates that MAC did not generate the ARP reply for the ARP request packet it receives.. This field is 1 when MAC is busy transmitting ARP reply to earlier ARP request (only one ARP request is processed at a time). This field is reserved when you do not select the enable IPv4 ARP offload option.
9:0	HL	L3/L4 Header Length Contains the length of the packet header which MAC splits at L3 or L4 header boundary which the MAC receiver identifies. This field is valid only when the first descriptor bit = 1 (FD = 1). You can write the header data to the buffer 1 address of corresponding descriptor. If the header length is zero, this field is not valid. It implies that MAC does not identify and split the header. This field is valid when you select the enable split header feature option.

78.15.4.1.5.4 RDES3 normal descriptor (Write-back format)

Following table describes the write-back format for the RDES3 normal descriptor.

31	30	29	28	27	26	25	24	23	22	21	20	19	18:16	15	14:0
OWN	CTXT	FD	LD	RS2V	RS1V	RS0V	CE	GP	RWT	OE	RE	DE	LT	ES	PL

Table 674. RDES3 normal descriptor (Write-back format)

Bit	Name	Description
31	OWN	Own Bit When this field is 1, it indicates that the module DMA owns the descriptor. If this field becomes 0, it indicates that the application owns the descriptor. DMA writes 0 to this field when either of these conditions is true: • DMA completes the packet reception. • The buffers associated with the descriptor are full.
30	CTXT	Receive Context Descriptor When this field is 1, it indicates that the current descriptor is a context type descriptor. DMA writes 1'b0 to this field for a normal receive descriptor. When CTXT and FD bits are used together, {CTXT, FD} • 2’b00: Intermediate descriptor • 2’b01: First descriptor • 2’b10: Reserved • 2’b11: Descriptor error (due to all 1s) **NOTE** When descriptor error occurs, the receive DMA closes the receive descriptor indicating a descriptor error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data. Receive DMA will write 1 to the CDE bit in DMA_CH#_Status register but not to the RI bit even when IOC = 1, as this is not marked as the last receive descriptor for the packet. The subsequent valid receive descriptor writes the packet data.
29	FD	First Descriptor When this field is 1, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet and if the size of the second buffer is also 0, the next descriptor will contain the beginning of the packet. See the CTXT bit description for more information on how to use the CTXT bit and FD bit together.
28	LD	Last Descriptor When this field is 1, it indicates that this descriptor buffers points to the last buffers of the packet.
27	RS2V	Receive Status RDES2 Valid When this field is 1, it indicates that the status in RDES2 is valid and DMA writes it. This field is valid only when the LD bit of RDES3 = 1.
26	RS1V	Receive Status RDES1 Valid When this field is 1, it indicates that the status in RDES1 is valid and DMA writes it. This field is valid only when the LD bit of RDES3 = 1.
25	RS0V	Receive Status RDES0 Valid When this field is 1, it indicates that the status in RDES0 is valid and DMA writes it. This field is valid only when the LD bit of RDES3 = 1.

Table continues on the next page...

Table 674. RDES3 normal descriptor (Write-back format) (continued)

Bit	Name	Description
24	CE	CRC Error When this field is 1, it indicates that a cyclic redundancy check (CRC) error occurs on the received packet. This field is valid only when the LD bit of RDES3 = 1.
23	GP	Giant Packet When this field is 1, it indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9018 or 9022 bytes if jumbo packet enable = 1). **NOTE** Giant packet indicates only the packet length. It does not cause any packet truncation.
22	RWT	Receive Watchdog Timeout When this field is 1, it indicates that the receive watchdog timer expires when it receives the current packet. The current packet truncates after watchdog timeout.
21	OE	Overflow Error When this field is 1, it indicates that the received packet is damaged because of buffer overflow in receive FIFO. **NOTE** This field is 1 only when DMA transfers a partial packet to the application. This happens only when the receive FIFO operates in the Threshold mode. In the Store-and-Forward mode, all the partial packets drops completely in the receive FIFO.
20	RE	Receive Error When this field is 1, it indicates that the gmii_rxer_i signal asserts when the gmii_rxdv_i signal asserts during the packet reception. This error also includes carrier extension error in the GMII and Half-duplex mode. Error can be of less or no extension, or error (rxd!= 0f) during extension.
19	DE	Dribble Bit Error When this field is 1, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This field is valid only in the MII mode.
18:16	LT	Length/Type Field Indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is as follows: • 3'b000: The packet is a length packet. • 3'b001: The packet is a type packet. • 3'b011: The packet is a ARP request packet type • 3'b100: The packet is a type packet with VLAN tag • 3'b101: The packet is a type packet with double VLAN tag • 3'b110: The packet is a MAC control packet type • 3'b111: The packet is a OAM packet type

Table continues on the next page...

Table 674. RDES3 normal descriptor (Write-back format) (continued)

Bit	Name	Description
		• 3'b010: Reserved
15	ES	Error Summary When this field is 1, it indicates the logical OR of these bits, : • RDES3[24]: CRC error • RDES3[19]: Dribble error • RDES3[20]: Receive error • RDES3[22]: Watchdog timeout • RDES3[21]: Overflow error • RDES3[23]: Giant packet • RDES2[17]: Destination address filter fail, when the flexible receive parser is enabled • RDES2[16]: SA address filter fail, when flexible receive parser is enabled This field is valid only when the LD bit of RDES3 = 1.
14:0	PL	Packet Length Indicates the byte length of the received packet that was transferred to system memory (including CRC). This field is valid when the LD bit of RDES3 = 1 and overflow error bits becomes 0. The packet length also includes the two bytes that appends to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet. This field is valid when the LD bit of RDES3 = 1. When the last descriptor and error summary bits are not 1, this field indicates the accumulated number of bytes that are transferred for the current packet.

78.15.4.1.6 Receive context descriptor

This descriptor is read-only for the application. Only DMA can write to this descriptor. The context descriptor provides information about the extended status related to the last received packet. Bit 30 of RDES3 indicates the context type descriptor.

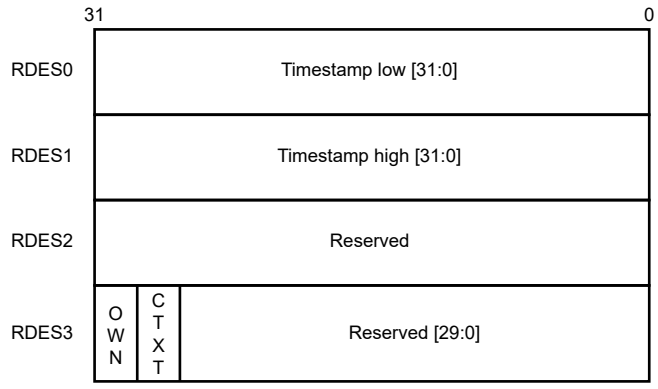

Figure 588. Receive context descriptor format

78.15.4.1.6.1 RDES0 context descriptor

Table 675. RDES0 context descriptor

Bit	Name	Description
31:0	RTSL	Receive Packet Timestamp Low DMA updates this field with least significant 32-bits of the timestamp captured for the corresponding receive packet. When this field and the RTSH field of RDES1 show all-ones value, you must consider the timestamp as corrupt.

78.15.4.1.6.2 RDES1 context descriptor

Table 676. RDES1 context descriptor

Bit	Field	Description
31:0	RTSH	Receive Packet Timestamp High DMA updates this field with the most significant 32-bits of the timestamp captured for the corresponding receive packet. When this field and the RTSL field of RDES0 show all-ones value, you must consider the timestamp as corrupt.

78.15.4.1.6.3 RDES2 context descriptor

Table 678. RDES3 context descriptor

Bit	Name	Description
31	OWN	Own Bit When this field is 1, it indicates that DMA owns the descriptor. When this field becomes 0, it indicates that the application owns the descriptor. DMA clears this field when either of these conditions is true: • DMA completes the packet reception. • The buffers associated with the descriptor are full.
30	CTXT	Receive Context Descriptor

Table continues on the next page...

Table 678. RDES3 context descriptor (continued)

Bit	Name	Description
		When this field is 1, it indicates that the current descriptor is a context descriptor. DMA writes 1'b1 to this field for context descriptor. DMA writes 2'b11 to indicate a descriptor error due to all = 1. When CTXT and DE bits are used together {CTXT, DE} • 2'b00: Reserved • 2'b01: Reserved • 2'b10: Context descriptor • 2'b11: Descriptor error Note: When descriptor error occurs, the receive DMA closes the receive descriptor indicating descriptor error. This receive descriptor is skipped and the buffer addresses does not write the packet data. The receive DMA writes 1 to the CDE bit in DMA_CH#_Status register but not to the RI bit even when IOC = 1, because this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor writes the packet data.
29	DE	Descriptor Error See the CTXT bit description for more information about how to use the DE bit along with CTXT bit.
28:0	Rsvd	Reserved

78.15.5 Enhanced descriptor for time-based scheduling

This feature needs 32 bytes enhanced descriptors to enable on all the DMA channels that uses this feature (write 1 to EDSE bit of DMA_CH(#i)_TX_Control register).

The structure of 32-byte descriptor for the context and the normal descriptor in read and write formats are described in the upcoming sections.

78.15.5.1 Enhanced normal descriptor - Read (32-bit mode)

These fields are present in the first 16 bytes of the enhanced descriptor format of normal descriptor:

- LTV- Indicates that the launch time (LT) and GSN fields present in the descriptor are valid. The LTV must be = 1 only if the FD bit of the descriptor is not.
- GSN- Indicates the GCL slot number associated with the packet.
- LT- Indicates the launch time associated with the packet.

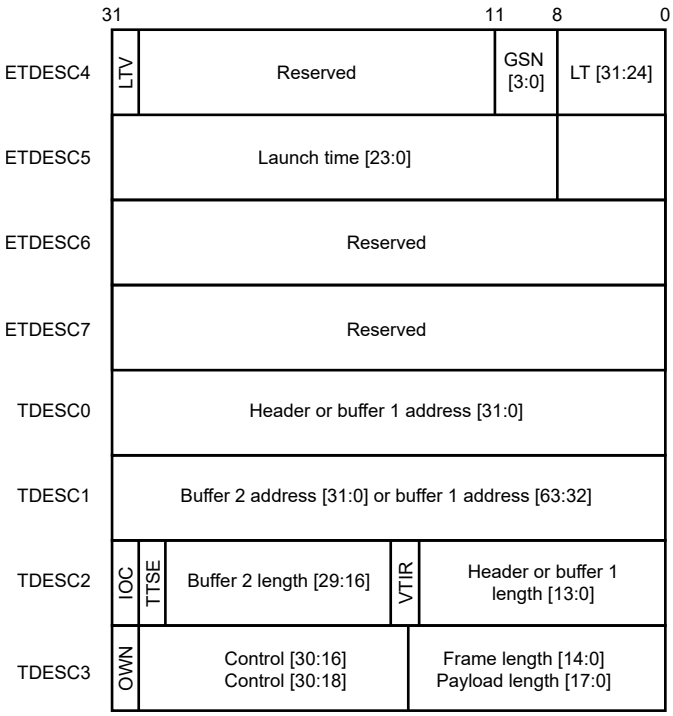

Figure 589. Enhanced normal descriptor - Read (32-bit mode)

78.15.5.2 Enhanced normal descriptor (Write, 32-bit mode)

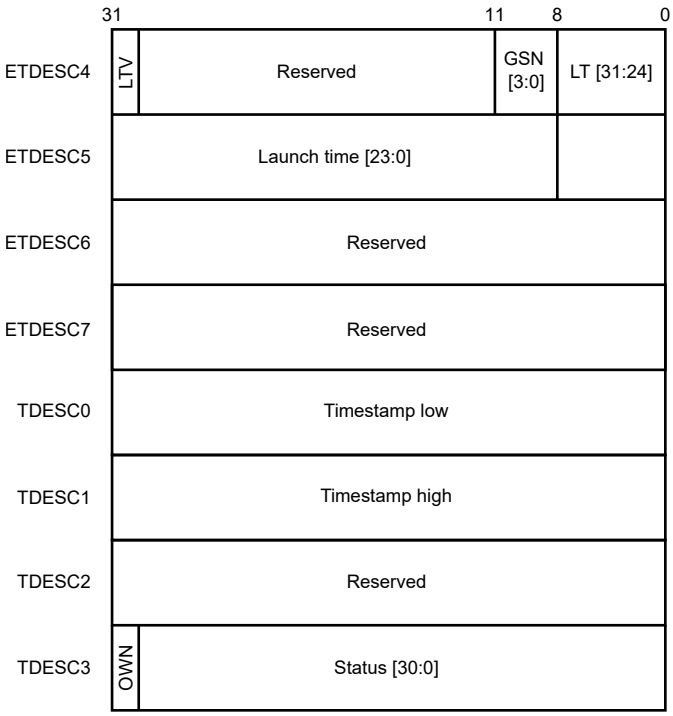

Figure 590. Enhanced normal descriptor write (32-bit mode)

NOTE

- All the enhanced descriptors, example, assumes a 32-bit data width configurations. However, the same definitions are valid in 64-bit and 128-bit configurations.
- In both the write back formats, you cannot modify the extended 16 bytes. The remaining 16 bytes (TDESC0 to TDESC3) are written back per the previous 16 bytes descriptor format.
- When you enable the fetch time it overrides the AV slot function
- When an unaligned new GCL list (with a different CTR) is installed it is recommended not to have traffic during the installation of the new list. Any traffic during the switching of the lists might have unpredictable behavior regarding fetch, launch, and launch expiry because the CTR and BTR values get updated when the frame is processed

78.15.5.3 Enhanced context descriptor (Read, 32-bit mode)

The first 16 bytes of the enhanced context descriptor (ETDESC4 to ETDESC7) are reserved and must be = 0. The fields present in the last bytes of the descriptor (TDESC0 to TDESC3) are same as the context descriptor (TDESC0 to TDESC3) in 16 byte format.

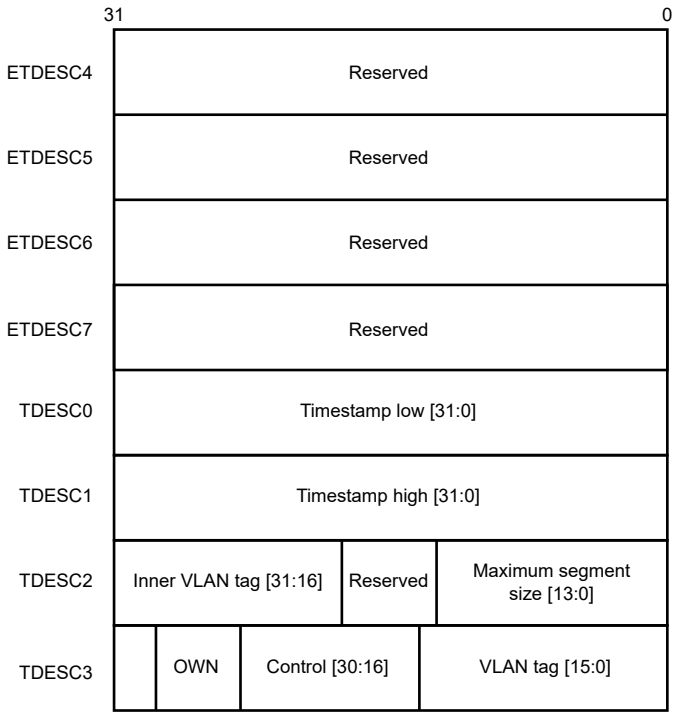

Figure 591. Enhanced context descriptor - Read

78.15.5.4 Enhanced context descriptor (Write, 32-bit mode)

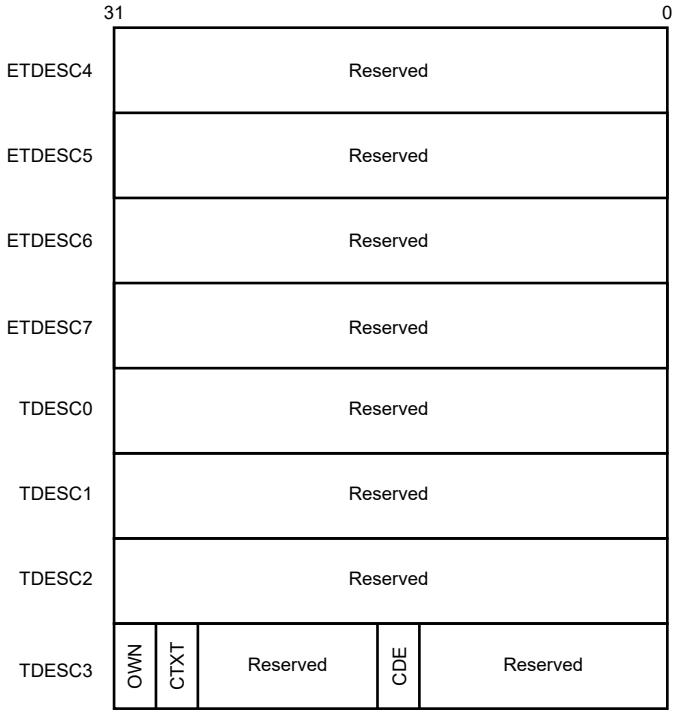

Figure 592. Enhanced context descriptor - Write

78.16 Programming

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

This section provides the instructions for initializing the DMA or MAC registers in the proper sequence.

78.16.1 Initializing DMA

Perform these steps to initialize DMA:

1. Provide a software reset. This resets all the MAC internal registers and logic (bit-0 of DMA_Mode).
2. Wait for the reset process (poll bit 0 of DMA_Mode which is only clears after the reset operation completes) to complete.
3. Program these fields to initialize DMA_SysBus_Mode:
    a. DMA_SysBus_Mode[AAL]
    b. Fixed burst or undefined burst
    c. Burst mode values in case of AHB bus interface, OSR_LMT in case of AXI bus interface.
    d. Select the maximum burst length possible on the AXI bus (bits [7:1]), if fixed length value is enabled.
4. Create a descriptor list for a transmit and receive. Also, ensure that DMA (write 1 to bit 31 of descriptor TDES3/RDES3) owns the descriptors. See Descriptors for more information about descriptors.
5. Program the transmit and receive ring length registers (DMA_CH(#i)_TxDesc_Ring_Length (for i = 0; i <= 1) and DMA_CH(#i)_RxDesc_Ring_Length (for i = 0; i <= 1)). The programmed ring length must be at least 4.

NOTE

The descriptor address from the start to the end of the ring must not cross the 4 GB boundary.

6. Initialize the receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH(#i)_TxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1), DMA_CH(#i)_RxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)). Also, program the transmit and receive tail pointer registers that indicates DMA about the available descriptors (DMA_CH(#i)_TxDesc_Tail_Pointer (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RxDesc_Tail_Pointer (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)).

   NOTE

   For 40-bit or 48-bit addressing mode, program the higher address List registers (DMA_CH[n]_TxDesc_List_HAddress, DMA_CH[n]_RxDesc_List_HAddress).

   The tailpointer registers must advance to the location immediately after the descriptors that are set so that DMA is aware that the additional descriptors are available.

7. Program the settings of these registers for the parameters like maximum burst-length (PBL) which DMA initiates, descriptor skip lengths, OSP in case of TxDMA, RBSZ in case of RxDMA, and so on:
   - DMA_CH(#i)_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)
   - DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)
   - DMA_CH(#i)_RX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)
8. Program the DMA_CH(#i)_Interrupt_Enable (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register to enable the interrupts.
9. Write 1 to SR (bit 0) of the DMA_CH(#i)_RX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1) and ST (bit 0) of the DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register to start the receive and transmit DMAs.
10. Repeat steps 4 to 9 for all the transit DMA and receive DMA channels selected in the hardware.

78.16.2 Initializing MTL registers

The transaction layer (MTL) registers must initialize to establish the transmit and receive operating modes and commands.

Perform these steps to initialize the MTL registers:

1. Program MTL_Operation_Mode[SCHALG] and MTL_Operation_Mode[RAA] to initialize the MTL operation in case of multiple transit and receive queues.
2. Program the receive queue to DMA mapping in MTL_RxQ_DMA_Map0.
3. Program these fields to initialize the mode of operation in MTL_TxQ0_Operation_Mode.
   a. MTL_TxQ0_Operation_Mode[TSF] or MTL_TxQ0_Operation_Mode[TTC] in case of Threshold mode.
   b. MTL_TxQ0_Operation_Mode[TXQEN] to value 2'b10 to enable transmit queue0.
   c. MTL_TxQ0_Operation_Mode[TQS]
4. Program these fields to initialize the mode of operation in MTL_RxQ0_Operation_Mode:
   a. MTL_RxQ0_Operation_Mode[RSF] or MTL_RxQ0_Operation_Mode[RTC] in case of Threshold mode.
   b. Flow control activation and de-activation thresholds for MTL receive FIFO (MTL_RxQ0_Operation_Mode[RFA] and MTL_RxQ0_Operation_Mode[RFD]).
   c. Error Packet and undersized good Packet forwarding enable (MTL_RxQ0_Operation_Mode[FEP] and MTL_RxQ0_Operation_Mode[FUP]).
   d. MTL_RxQ0_Operation_Mode[RQS]
5. Repeat previous two steps for all MTL transit and receive queues selected in the configuration.

78.16.3 Initializing MAC

The MAC configuration registers establish the operating mode of MAC. These registers must initialize before initializing DMA.

You can perform these MAC initialization operations after DMA initialization. If the MAC initialization completes before DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, the received frames fill the receive FIFO and overflow.

1. Provide the MAC address registers: MAC_Address0_High and MAC_Address0_Low. If more than one MAC address is enabled, , program the MAC addresses appropriately.

2. Program these fields to set the appropriate filters for the incoming frames in MAC_Packet_Filter:

a. Receive all

b. Promiscuous mode

c. Hash or perfect filter

d. Unicast, multicast, broadcast, and control frames filter settings

3. Program these fields for proper flow control in MAC_Q0_Tx_Flow_Ctrl:

a. Pause time and other Pause frame control bits

b. Transmit flow control bits

c. Flow control busy

4. Program MAC_Interrupt_Enable as required, and if applicable, for your configuration.

5. Program the appropriate fields in MAC_Configuration. For example Inter-packet gap when transmission and jabber disable.

6. Write 1 to MAC_Configuration[RE] and MAC_Configuration[TE] to start the MAC transmitter and receiver.

78.16.4 Performing normal receive and transmit operation

During normal operation of the module, read the normal and transmit interrupts, poll the descriptors, suspend the DMA (if it does not own descriptors), and read the values of the current host transmitter or receiver descriptor pointers for debugging.

For normal operation, perform these steps:

1. Read the interrupt status for normal transmit and receive interrupts. Then poll the descriptors, read the status of the descriptor which the host owns (either transmit or receive).

2. Set appropriate values for the descriptors, ensure that the DMA owns the transmit and receive descriptors to resume the data transmission and reception.

3. If DMA does not own the descriptors (or no descriptor is available), DMA enters into SUSPEND state. The transmission or reception can resume by freeing the descriptors and writing the descriptor tail pointer to Tx/Rx tail pointer register (DMA_CH[n]_TxDesc_Tail_Pointer and DMA_CH[n]_RxDesc_Tail_Pointer).

4. Read the current host transmitter or receiver descriptor address pointer values for the debug process (DMA_CH[n]_Current_App_TxDesc and DMA_CH[n]_Current_App_RxDesc register).

5. Read the current host transmit buffer address pointer and receive buffer address pointer values for the debug process (Register DMA_CH[n]_Current_App_TxBuffer and DMA_CH[n]_Cur-rent_App_RxBuffer).

78.16.5 Stopping and starting transmission

Perform these steps to pause the transmission for some time. The steps are provided for channel 0.

1. Write 0 to bit 0 (ST) of DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register to disable the transmit DMA (if applicable) .

2. Wait for any previous frame transmissions to complete. Read the appropriate fields of MTL_TxQ0_Debug (MTL_TxQ0_Debug[TRCSTS] is not 01 and MTL_TxQ0_Debug[TXQSTS] = 0) to check this.

3. Write 0 to MAC_Configuration[RE] and MAC_Configuration[TE] to disable the MAC transmitter and MAC receiver.

4. Disable the receive DMA (if applicable), after you ensure that the data in the receive FIFO transfers to the system memory (read the appropriate fields MTL_RxQ0_Debug[PRXQ] = 0 and MTL_RxQ0_Debug[RXQSTS] = 00).

5. Ensure that both the transit queue and receive queue are empty (MTL_TxQ0_Debug[TXQSTS] = 0 and MTL_RxQ0_Debug[RXQSTS] = 0).

6. Restart the operation by first starting the DMAs, and then enable the MAC transmitter and receiver.

NOTE

- Do not change the configuration (such as duplex mode, speed, port, or loop back) when the MAC is actively transmitting or receiving. You can change these parameters only when the MAC transmitter and receiver are not active.
- Similarly, do not change the DMA related configuration when transmit and receive DMA are active.

78.16.6 Programming guidelines for switching to new descriptor list in RxDMA

Switching to a new descriptor list is different in the receive DMA as compared to the transit DMA. It is permitted when the RxDMA is in SUSPEND state as described below:

- RxDMA prepares the descriptors in advance.
- If the RxDMA goes to SUSPEND state because the descriptors are not available, a major failure occurs (you are not able to free the filled-up descriptors or buffers). If this issue does not rectify immediately, frames will be lost because of an RxFIFO overflow. Therefore, you can create a new descriptor list and program the RxDMA to start using it immediately, without going into STOP state.

78.16.7 Programming guidelines for multi-channel multi-queuing

78.16.7.1 Transmit

1. Program the transmit queue size in TQS field of MTL_TxQ[n]_Operation_Mode register. Based on the value programmed in TQS field, you can determine the queue size.

In the transmit operation, the number of channels is equal to the number of the queues, because of this reason, the channel-to-queue mapping is fixed.

2. Enable the queue in TXQEN in the corresponding MTL_TxQ[n]_Operation_Mode register to use the queue. In DMA configurations, enable the ST field of DMA_CH[n]_Tx_Con-trol register and corresponding TXQEN in MTL_TxQ[n]_Operation Mode register.

3. Program the scheduling method in MTL_Operation_Mode[SCHALG].

4. Program MTL_TxQ[n]_Quantum_Weight register for DCB queue per the selected algorithm. In case of CBS algorithm in AVB queues program the MTL_TxQ[n]_ETS_Control, MTL_TxQ[n]_SendSlopeCredit, MTL_TxQ[n]_HiCredit, and MTL_TxQ[n]_LoCredit registers as required.

5. Program the MAC_TxQ_Prty_Map0 register to assign a fixed priority to the queue, if DCB is enabled and PFC function is required. You can use this assigned priority to determine if the corresponding queue must stop transmitting packet on the basis of the received PFC packet.

78.16.7.2 Receive

1. Program the receive queue size in RQS field of MTL_RxQ[n]_Operation_Mode register. Determine the size of the queue, based on the value programmed in RQS field.
2. Enable the receive queues 0 to 7 in the fields RXQ0EN to RXQ7EN in MAC_RxQ_Ctrl0 for AV or DCB. In DMA configurations, SR bit of statically or dynamically map DMA_CH[n]_Rx_Control register and the corresponding RXQ[n]_EN in MAC_RxQ_Ctrl0 is enabled.

3. Based on these packet types MAC routes the receive packets to the receive queues :
    a. AV PTP packets: Based on the programming of MAC_RxQ_Ctrl1[PTPQ].
    b. AV untagged control packets: Based on the programming of MAC_RxQ_Ctrl1[AVCPQ].
    c. Data center bridging (DCB) related link layer discovery protocol (LLDP) packets. Program DCBCPQ in MAC_RxQ_Ctrl1 to indicate MAC which queue should get the DCB packets.
    d. VLAN tag priority field in VLAN tagged packets: Program PSRQ7-0 of the MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 register for routing the tagged packets based on the received packets USP (user priority) field to the receive queues 0 to 7.
    e. Route the AV tagged control and data packets based on PSRQ field of MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers.

NOTE

The priorities set in PSRQ7-0 must be unique.

4. If multiple receive DMA channels are enabled, you must perform the following programming for proper arbitration and mapping:
    a. Program MTL_Operation_Mode[RAA] to select the arbitration algorithm to decide which RxQ is read out from the RxFIFO memory.
    b. Program the MTL_RxQ[n]_Control register to decide the weights and the packet arbitration for each RxQ.
    c. If you program the static mapping in MTL_RxQ_DMA_Map[n] register (RXQ[n]DADMACH becomes 0), fields RXQx2DMA and others are programmed to select the channel to map each queue.
    d. Write 1 to RXQ[n]DADMACH field in MTL_RxQ_DMA_Map0 to select the dynamic mapping of packets in each receive queue.
    e. In dynamic channel mapping, the value of DCS field in the lowest MAC address register the decides the routing of a packet to a specific RxDMA channel.

78.16.7.2.1 Programming guidelines for recovering from DMA channel failure

When the DMA channel issues a bus error, follow these steps to recover from the failure.

Recovering from the receive DMA channel failure.

Perform these steps if you get bus error in the receive DMA channel:

1. Write 1 to DMA_CH0_Rx_Control[RPF]. This flushes all the packets one after the other.

This step is optional. However, writing 1 to this field prevents head-of-line blocking in the receive queues when packets sent to the RXDMA are stopped due to the bus error.

2. Re-program the specific registers of the DMA channel.

3. Start the DMA channel.

Recovering from the transmit DMA channel failure.

1. Stop the specific DMA channel, even if it is in active state.

2. Flush the corresponding MTL queue.

3. Re-program the specific registers of the DMA channel.

4. Start the DMA channel.

NOTE

Due to the known limitations in the design, reprogramming the DMA channel registers might not be always successful in recovering from a bus error. If the module is not fully functional after reprogramming the DMA, you can issue a soft reset to recover from the bus error.

78.16.8 Programming guidelines for GMII link state transitions

78.16.8.1 Transmit and receive clocks running when link down

Perform these steps when the link is down but the transmit and receive clocks are running:

NOTE

The steps are provided for channel 0.

1. Write 0 to bit 0 (ST) of DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register to disable the transmit DMA (if applicable).

2. Write 0 to MAC_Configuration[RE] to disable the MAC receiver.

3. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate fields of MTL_TxQ0_Debug (MTL_TxQ0_Debug[TRCSTS] is not 01) or, flush the Tx FIFO for faster empty operation.

4. Write 0 to MAC_Configuration[TE] to disable the MAC transmitter.

5. Make sure that both the transit queue and receive queue are empty (MTL_TxQ0_Debug[TXQSTS] and MTL_RxQ0_Debug[RXQSTS] are 0).

6. Read the PHY registers to know the latest configuration and accordingly program the MAC registers, after the link is up.

7. Start the transit DMA to restart the operation, and then enable the MAC transmitter and receiver.

You do not disable the receive DMA because the receiver is disabled and the FIFO does not get any data in the receive FIFO.

78.16.8.2 Transmit and receive clocks stopped when link down

Perform these steps when the link is down and the transmit and receive clocks are stopped:

NOTE

The steps are provided for channel 0.

1. Write 0 to MAC_Configuration[RE] and MAC_Configuration[TE] to disable the MAC transmitter and receiver. This does not take effect immediately as the clocks are absent.

2. Wait until the link is up and the clocks are restored.

3. Wait for the transfer of any partial frame, if any to complete at time of stopping of the transmit or receive clock. To check this, read MAC_Debug (should be all-zero). Some old packets may still remain in the TXFIFO because the MAC transmitter is stopped.

4. Read the PHY registers to know the latest operating mode and accordingly program the MAC registers.

5. Write 1 to MAC_Configuration[RE] and MAC_Configuration[TE] to restart the MAC transmitter and receiver.

78.16.9 Programming guidelines for IEEE 1588 timestamping

78.16.9.1 Initialization guidelines for system time generation

Write 1 MAC_Timestamp_Control[TSENA] to enable the timestamp feature. However, it is essential to initialize the timestamp counter after MAC_Timestamp_Control[TSENA] = 1. Perform these steps during the module initialization:

1. Write 0 to the bit 16 of MAC_Interrupt_Enable to mask the timestamp trigger interrupt.
2. Write 1 to MAC_Timestamp_Control[TSENA] to enable timestamping.
3. Program MAC_Sub_Second_Increment based on the PTP clock frequency.
4. Program MAC_Timestamp_Addend and write 1 to MAC_Timestamp_Control[TSADDREG], if you are using the fine correction approach.
5. Poll MAC_Timestamp_Control until MAC_Timestamp_Control[TSADDREG] = 0.
6. Program MAC_Timestamp_Control[TSCFUPDT] to select the fine update method (if required).

7. Program MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update with the appropriate time value.
8. Write 1 to MAC_Timestamp_Control[TSINIT].
9. Initialize the timestamp counter with the value written in the timestamp update registers so that the timestamp counter can start operation. If one-step timestamping is enabled
    a. Program Bit 27 of the TDES3 context descriptor, to enable one-step timestamping.
    b. Program MAC_Timestamp_Ingress_Asym_Corr and MAC_Timestamp_Egress_Asym_Corr to update the correction field in PDelay_Req PTP messages.
10. Enable the MAC receiver and transmitter for proper timestamping.

NOTE

If the timestamp operation is disabled by writing 0 to MAC_Timestamp_Control[TSENA], repeat all these steps to restart the timestamp operation.

78.16.9.2 System time correction

78.16.9.2.1 Coarse correction method

Perform these steps to synchronize or update the system time in one process (coarse correction method):

1. Set the offset (positive or negative) in the timestamp registers that is MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update.

2. Write 1 to MAC_Timestamp_Control[TSUPDT].

The value in the timestamp update registers is added to or subtracted from the system time when MAC_Timestamp_Control[TSUPDT] = 0.

78.16.9.2.2 Fine correction method

Perform these steps to synchronize or update the system time to reduce system-time jitter (fine correction method):

1. Calculate the rate by which you want to increment the system time slower or faster, with the help of the algorithm.

2. Update MAC_Timestamp_Addend with the new value and write 1 to MAC_Timestamp_Control[TSADDREG].

3. Wait for the time for which you want the new value of the addend register to be active. You can do this by enabling the timestamp trigger interrupt after the system time reaches the target value.

4. Program the required target time in MAC_PPS[n]_Target_Time_Seconds register and MAC_PPS[n]_Target_Time_Nanoseconds register.

5. Enable the timestamp interrupt in MAC_Interrupt_Enable[TSIE].

6. Write 1 to bit 4 in MAC_Timestamp_Control.

7. Read MAC_Interrupt_Status when this trigger causes an interrupt.

8. Reprogram MAC_Timestamp_Addend with the old value and write 1 to MAC_Timestamp_Control[TSADDREG] again.

78.16.10 Programming guidelines for AV feature

After you enable the AV feature in the module controller, follow these programming tasks:

- Initializing the DMA for QOS-AHB configurations only
- Enabling slot number checking
- Enabling average bits per slot reporting
- Disabling flow control for AV-enabled queues (transmit and receive flow control)

78.16.10.1 Initializing the DMA in audio video feature

The first step to program the AV feature in a QOS-AHB configuration is to initialize the DMA.

Use this initialization sequence for QOS-AHB/QOS-AXI/QOS-AXI4 configurations with AV feature.

1. Provide a software reset to reset all the QOS internal registers and logic (DMA_Mode[SWR]).

2. Wait for the reset process to complete. Poll DMA_Mode[SWR], which clears only after the reset operation completes.

3. Set the values in DMA_Mode to program the fields to initialize the DMA register.

4. Create a descriptor list for transmit and receive. In addition, ensure that the DMA owns the transmit and receive descriptors. When you use OSF mode, at least two transmit descriptors are required.

See Descriptors for more information about descriptors.

5. Ensure that you create three or more different transmit or receive descriptors in the list before reusing any descriptors.

6. Program the transmit and receive ring length registers (DMA_CH(#i)_TxDesc_Ring_Length (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RxDesc_Ring_Length (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)). The ring length programmed must be at least 4.

7. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH(#i)_TxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1), DMA_CH(#i)_TxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)). In addition, you must program the transmit and receive tail pointer registers to indicate the DMA about the available descriptors (DMA_CH(#i)_TxDesc_Tail_Pointer (for i = 0; i <= DWC_EQOS_NUM_D-MA_TX_CH-1) and DMA_CH(#i)_RxDesc_Tail_Pointer (for i = 0; i <= DWC_EQOS_NUM_D-MA_RX_CH-1)).

8. Program these fields to initialize the mode of operation in MTL_TxQ0_Operation_Mode:

a. MTL_TxQ0_Operation_Mode[TSF]

b. MTL_TxQ0_Operation_Mode[TTC]

c. MTL_TxQ0_Operation_Mode[TXQEN] to value 2'b10 to enable transmit queue0

d. MTL_TxQ0_Operation_Mode[TQS]

9. Enable the interrupts by programming DMA_CH(#i)_Interrupt_Enable (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.

10. Repeat steps 4 through 9 for all the additional channels of AV feature.

11. Program the AV queues CBS control register, idleSlope, sendSlope, hiCredit, and loCredit registers.

12. Write 1 to bit 0 of DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1) register to start the receive and transmit DMA.

78.16.10.2 Enabling slot number checking

You can enable slot number checking feature if you specifies the intervals at which the DMA channels map to AV queues fetch the frames from the AHB/AXI system bus.

You must complete these steps after step 11 and before step 12 of Initializing the DMA in audio video feature .

You can use the slot number check feature to specify the intervals at which the DMA channels map to AV queues fetch the frames from the AHB/AXI system bus. This feature is useful for an uniform and periodic transfer of the AV traffic from the host memory and it is available only when you enable timestamping and programs MAC_Sub_Second_Increment. Perform these steps to enable the slot number checking:

1. Follow the steps described in Initialization guidelines for system time generation to enable timestamping.

2. Ensure that the SLOTNUM field (bits 22:19) of TDES3 normal descriptor (Read format) contains a valid slot number. You can read the current reference slot number from the DMA_CH(#i)_Slot_Func-tion_Control_Status (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.

3. Write 1 to bit 0 (ESC) of the slot function control and status register of a channel to enable the slot number checking.

78.16.10.3 Enabling average bits per slot reporting

You can enable the reporting of average bits transmitted in a slot.

The CBS status register of the additional AV channels provide information about the average bits that are transmitted in a slot. You can asynchronously read this register to retrieve information about the average bits transmitted per slot. Perform these steps to enable average bits per slot reporting:

1. Follow the steps as described in the Initialization guidelines for system time generation to enable timestamping.

2. Program SLC bits [6:4], of the MTL_TxQ[n]_ETS_Control register of a channel with the number of slots over which the average transmitted bits per slot are computed.

3. Enable bit 9(ABPSSIE) of the MTL_Q[n]_Interrupt_Control_Status register of a channel to generate the average bits per slot interrupt.

NOTE

- The frequency of this interrupt depends on the value programmed in step 2. For example, when you program value 0 in the SLC field, the interrupt generates at every 125 microsecond.
- You can disable this interrupt to stop the interrupt flooding, when it is not required.

4. Read ABS bits [16:0], of the MTL_TxQ[n]_ETS_Status register of a channel on each interrupt.

NOTE

You can read the ABS fields in the polling mode even if ABPSIE bit is not enabled. When bit 1 (ABPSIS) of the MTL_TxQ[n]_ETS_Status register is 1, it indicates that a new value is updated in the ABS field.

78.16.10.4 Disabling flow control for AV enabled queues

78.16.10.4.1 Transmit flow

Program the EHFC (Enable Hardware Flow Control) field of the corresponding receive queue's MTL_RxQ[n]_Operation_Mode register to 0.

78.16.10.4.2 Receive flow control

Program PSTQ[n] field, corresponding to AV enabled transit queue in MAC_TxQ_Prty_Map0/1 register to 0.

78.16.10.5 Programming guidelines for flexible pulse-per-second output

After you enable the flexible pulse-per-second output feature in the module controller, you can perform these tasks:

- Generating single pulse on PPS
- Generating next pulse on PPS
- Generating a pulse train on PPS
- Generating an interrupt without affecting the PPS

78.16.10.5.1 Generating single pulse on PPS

Perform these steps to generate single pulse on PPS:

1. Program 11 or 10 (for interrupt) in TRGTMODSEL bits [6:5], of MAC_PPS_Control. This instructs MAC to use the target time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds) for a start time of the PPS signal output.
2. Program the start time value in the target time registers (MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds).
3. Program the PPS signal output width in MAC_PPS(#i)_Width (for i = 0; i <= 3) register.

4. Program PPSCMD bits [3:0], of MAC_PPS_Control to 0001. This instructs MAC to generate single pulse on the PPS signal output at the time programmed in the target time registers.

78.16.10.5.2 Generating next pulse on PPS

When the PPSCMD is executed (PPSCMD bits = 0), you can give the cancel start command (PPSCMD=0011) before the programmed start time elapses to cancel the pulse generation. You can also program the behavior of the next pulse in advance.

Follow these steps to program the next pulse:

1. Program the start time for the next pulse in the target time registers. This time must be more than the time at which the falling edge occurs for the previous pulse.

2. Program the next PPS signal output width in MAC_PPS(#i)_Width (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) register.

3. Program PPSCMD bits [3:0], of MAC_PPS_Control to generate a single pulse after the time at which the previous pulse is de-asserted. This instructs MAC to generate single pulse on the PPS signal output, at the time programmed in target time registers.

If you give this command before the previous pulse becomes low, then the new command overwrites the previous command and the QOS may generate only 1 extended pulse.

78.16.10.5.3 Generating a pulse train on PPS

Perform these steps to generate a pulse train on PPS:

1. Program 11 or 10 (for interrupt) in TRGTMODSEL bits [6:5] , of MAC_PPS_Control. This instructs MAC to use the target time registers for the start time of the PPS signal output.

2. Program the start time value in the target time registers.

3. Program the interval value between the train of pulses on the PPS signal output in MAC_PPS(#i)_Interval (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) register.

4. Program the PPS signal output width in MAC_PPS(#i)_Width (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) register.

5. Program PPSCMD bits [3:0], of MAC_PPS_Control to 0010. This instructs MAC to generate train of pulses on the PPS signal output with start time programmed in target time registers.

By default, the PPS pulse train is free-running unless the STOP pulse train at time or STOP pulse train immediately commands stop it.

6. Program the stop value in the target time registers. Ensure that bit 31 (TSTRBUSY) of MAC_PPS(#i)_Target_Time_Nanoseconds (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) register becomes 0 before programming the target time registers again.

7. Program PPSCMD field [bit 3:0] of MAC_PPS_Control to 0100. This stops the train of pulses on the PPS signal output after the programmed stop time specified in step 6 elapses.

You can program 0101 in PPSCMD field [bit 3:0] of MAC_PPS_Control to stop the pulse train at any time. Similarly, you can program 0110 in PPSCMD field [bit 3:0] of MAC_PPS_Control before the time (programmed in step 6) elapses to cancel the stop pulse train command (given in Step 7). Also, program 0011 in PPSCMD field [bit 3:0] of MAC_PPS_Control before the programmed start time (in Step 2) elapses to cancel the pulse train generation.

78.16.10.5.4 Generating an interrupt without affecting the PPS

MAC_PPS_Control TRGTMODSEL bits [6:5] enables you to program the target time registers to perform any one of these actions:

- Generate only interrupts.
- Generate interrupts and the PPS start and stop time.
- Generate only PPS start and stop time.

Perform these steps to program the target time registers to generate only interrupt event:

1. Program 00 (for interrupt) in MAC_PPS_Control TRGTMODSEL bits [6:5]. This instructs the MAC to use the target time registers for target time interrupt.

2. Program a target time value in the target time registers. This instructs the MAC to generate an interrupt when the target time elapses.

If TRGTMODSEL bits [6:5], are changed (for example, to control the PPS) then over-write the interrupt generation with the new mode and new programmed target time register value.

78.16.10.6 Programming guidelines for VLAN filtering on receive

Perform these steps to program VLAN filtering on receive:

1. Program MAC_VLAN_Tag register for the following fields to select the filtering method:

a. ETV: Enables 12-Bit VLAN tag comparison or 16-bit VLAN tag comparison.

b. VTHM: VLAN tag hash table match enable.

c. ERIVLT: Enables inner VLAN tag or outer VLAN Tag (to enable the inner or outer VLAN tag filtering, writing 1 to MAC_VLAN_Tag_Ctrl[EDVLP] enables the double VLAN processing).

d. ERSVLM: Enables receive S-VLAN match or C-VLAN match (write 1 to MAC_VLAN_Tag_Ctrl[ESVL] to enable S-VLAN processing).

e. DOVLTC: Ignores VLAN type for tag match

f. VTIM: Enables VLAN tag inverse match instead of the normal VLAN tag matching

2. Program VL of MAC_VLAN_Tag register for the 12-bit or 16-bit VLAN tag.

3. Program MAC_VLAN_Hash_Table, if hash filtering of VLAN tag is enabled. When MAC_VLAN_Tag_Ctrl[ETV] becomes 0, it indicates that the upper 4 bits of the calculated CRC-32 of VLAN tag are inverted and index the content of MAC_VLAN_Hash_Table. When MAC_VLAN_Tag_Ctrl[ETV] is 1, it indicates that the upper 4 bits of calculated CRC-32 of VLAN Tag index the content of MAC_VLAN_Hash_Table. For example, when MAC_VLAN_Tag_Ctrl[ETV] is 1, a hash value of 4b'1000 selects bit 8 of MAC_VLAN_Hash_Table. When MAC_VLAN_Tag_Ctrl[ETV] becomes 0 a hash value of 4'b1000 selects bit 7 of MAC_VLAN_Hash_Table.

78.16.10.7 Programming guidelines for extended VLAN filtering and routing on receive

Perform these steps, for the indirect access of the per VLAN tag registers:

- Write
  - Write the required data into MAC_VLAN_Tag_Data.
  - Program MAC_VLAN_Tag_Ctrl[OFS] with the required filter register's offset and command type to MAC_VLAN_Tag_Ctrl[CT]. For a write command, set this field to 0.
  - Write 1 to MAC_VLAN_Tag_Ctrl[OB] and wait till it becomes 0 to do the next write. This will guarantee that you have programmed the appropriate VLAN Tag Filter register.
- Read
  - Program MAC_VLAN_Tag_Ctrl[OFS] with the required register's offset and command type to MAC_VLAN_Tag_Ctrl[CT]. For a read command, set this field to 1.
  - Write 1 to MAC_VLAN_Tag_Ctrl[OB] and wait till it becomes 0. The appropriate value of the VLAN Tag Filter register is available in MAC_VLAN_Tag_Data.

78.16.10.8 Programming sequence for queue/channel based VLAN inclusion register

Perform these steps to program the queue/channel-based VLAN inclusion register:

NOTE

When MAC_VLAN_Incl[CBTI] = 1 you cannot access the indirect VLAN include registers.

1. Write 1 to MAC_VLAN_Incl[CBTI], to enable queue or channel based VLAN tag insertion on all the transmitted packets. This field must be 1 before any indirect access to the queue or channel specific MAC_VLAN_Incl(#i) register.

2. Program the VLAN tag and VLAN type to insert in packets from a particular queue or channel in MAC_VLAN_Incl[VLT] and MAC_VLAN_Incl[CSVL], corresponding offset address in ADDR field (0 for queue/channel 0, 1 for queue/channel 1, and so on) must be set. Write 0 to MAC_VLAN_Incl[RDWR] to indicate write access. The write to byte 0 (byte 3 in Big Endian mode) of MAC_VLAN_Incl initiates access to indirect access MAC_VLAN_Incl(#i) register.

3. Write 1 to MAC_VLAN_Incl[BUSY] via the module to indicate the progress of access to indirect access MAC_VLAN_Incl(#i) register. After the access completes, MAC_VLAN_Incl[BUSY] = 0. The application must not attempt subsequent access to MAC_VLAN_Incl(#i) register when the MAC_VLAN_Incl[BUSY] is 1.

4. Repeat step 2 and step 3 to program VLAN tag and VLAN type to insert in packets from the remaining queues or channels. The application must ensure that the required VLAN tag and VLAN type for all the queues or channels are programmed, otherwise an unintended VLAN tag and VLAN type might be inserted.

78.16.11 Programming guidelines for EST

Program the gate control values and time intervals in MTL_EST_Status[SWOL] along with the other EST related registers that are described in EMAC register descriptions to appropriate values. The upcoming sub-sections provide step by step details for programming the GCL and the other EST related registers.

78.16.11.1 Programming the GCL and GCL linked registers

Perform these steps to program the GCL and the four other registers implemented per GCL:

1. Access the GCL and the four other GCL-linked registers via indirect addressing using MTL_EST_GCL_Control and MTL_EST_GCL_Data. MTL_EST_Status[SWOL] indicates whether the software owns GCL0 or GCL1.
2. Write the 32-bit write data to MTL_EST_GCL_Data, to program the GCL. Then program MTL_EST_GCL_Control to write the write address and other control information.
3. In MTL_EST_GCL_Data, write data consists of up to 8 bits (configurable) of gate controls and up to 24 bits (configurable) of time interval. Programming a 0 indicates gate close and programming a 1 indicates gate open. For a 4-TC and 20-bit time interval configuration, the data width is 24-bits and the remaining 8-bits are reserved/read-only. You must write the data in the following format.

   {8'h0, TC3, TC2, TC1, TC0, 20-bit Time Interval} where TCx = 0 or 1.
4. Program MTL_EST_GCL_Control[SRWO] to 1 (to start a Write Op) and program the address and R/W fields appropriately.
5. Poll and check that the hardware clears MTL_EST_GCL_Control[SRWO] to indicate that the previous operation completes before initiating a new read-write operation via the same indirect addressing mode.
6. Repeat steps 3, 4, 5 until the programming of the GCL completes.
7. Program the BTR, CTR, TER and LLR registers, using the same indirect addressing method as described above. Write 1 to MTL_EST_GCL_Control[GCRR] appropriately. MTL_EST_GCL_Control[GCRR] interprets the address field as belonging to these registers (instead of the GCL).

After the GCL and the related registers are programmed, program MTL_EST_GCL_Control to allow hardware to own and process the GCL. When the list length (as indicated in LLR) is 1, the associated time interval must be smaller than the cycle time register value. Otherwise, an error is reported (as described in the Error handling section) as a single set of gate controls add no value in the TSN context.

NOTE

The time unit in all the GCL related registers is seconds and nanoseconds. In cases where internally generated PTP system time is used, you must program the nanoseconds field to use the Digital Rollover mode. (The value of MAC_Timestamp_Control[TSCTRLSSR]must be 1)

78.16.11.2 Programming the EST registers

After the steps mentioned in "Programming the GCL and GCL Linked Registers" completes, program MTL_EST_Control

1. Write 1 to MTL_EST_Control[CTOV] and MTL_EST_Control[TILS]. Also, write 1 to MTL_EST_Control[EEST] and MTL_EST_Control[SWOL].

NOTE

The CTOV recommendations for GMII for SPRAM configurations are:

- 96 * Tx clock period, for 32 and 64 bit data width configurations.
- 128 * Tx clock period for 128 bit data width configurations.

The CTOV recommendations for GMII for non-SPRAM configurations are:

- 30 * Tx clock period, when SA/VLAN insertion is enabled.
- 22 * Tx clock period, when SA/VLAN insertion is not enabled.

2. Enables the hardware to own and process the new GCL and make a switch to the new GCL at the BTR value. The hardware provides an interrupt (if enabled) when the switch to the new list happens.
3. Performs an appropriate action to address any other interrupts (explained in the Interrupts section) received during the hardware execution of the GCL.

Write 1 to MTL_EST_Control[SSWL] to handoff to hardware. Software is not allowed to write to the GCL and GCL linked registers when MTL_EST_Control[SSWL] = 1, because the hardware might be using the new GCL.

The hardware resets or clears MTL_EST_Control[SSWL] when it successfully switches to the new list. The hardware also flips MTL_EST_Status[SWOL] to indicate the new GCL that the software owns.

Program the GCL that software owns (MTL_EST_Status[SWOL] indicates) as described in "Programming the GCL and GCL Linked Registers" and then program MTL_EST_Control as described above, to install a new GCL. Ensure that the new BTR is set to an appropriate value to avoid BTR Error that may require software intervention in some cases.

The packet length (frame size) information must be available at all times, to avoid transmission overruns. Therefore, in the DMA configurations, program the packet length in the first descriptor of every transmit frame. Similarly, in the MTL configuration, provide the packet length in the control word.

NOTE

The packet length provided in the transmit descriptor must account for the SA and VLAN insertion, to avoid transmission overruns, if applicable, that is, packet length must represent the actual packet length on the Ethernet line.

78.16.12 Programming the launch time in time-based scheduling

Configure the launch time in the enhanced normal transmit descriptors in DMA configurations and is driven as a control word in MTL configurations as follows:

The OSTC and launch time features are mutually exclusive and must not be used together. In case of a conflict (if OSTC = LTV = 1 in MTL configuration), give priority to OSTC and ignore the launch time.

In DMA configuration, if a context descriptor is received with a valid OSTC values immediately before receiving a first normal descriptor with LTV = 1, then the LTV is ignored.

78.16.13 Programming guidelines for media clock generation and recovery

78.16.13.1 Programming guidelines for media clock generation

These are the guidelines for the media clock generation:

1. Program the appropriate presentation time control (supported generation modes "1001-1011") to PPSCTRL_PPSCMD (for 0th instance)/PPSCMD#i (for 1,2,3 instances) of MAC_PPS_Control, to define the PPS instance in Media clock generation mode.

2. Based on the selected PPS instance, application must drive the appropriate trigger signal to the corresponding mcg_pst_trig_i[#i].

3. Based on the programmed mode, DUT captures the timestamp and programs it in the MAC_PPS(#i)_Target_Time_Seconds register. Then, mcgr_dma_req_o[#i] is set.

4. For every request which DUT generates, the module reads the corresponding MAC_PPS(#i)_Target_Time_Seconds register and asserts the corresponding mcgr_d-ma_ack_i[#i] to acknowledge the read request.

78.16.13.2 Programming guidelines for media clock recovery

These are the guidelines for the media clock recovery:

- Writing 1 to MAC_Timestamp_Control[PTGE] enables the CPT counter. In addition to configuring the initialization values for the system time, update MAC_Presn_Time_Updt with the equivalent presentation time initialization value, then MAC_Timestamp_Control[TSINIT] = 1.
- Use the increment values for the system time and also for the CPT because the increment value is in sub-seconds and sub-nanoseconds.
- Update MAC_Presn_Time_Updt with the equivalent presentation time update value (32 bit ns), when an update is required, and also configure the updated values for the system time. Finally, MAC_Timestamp_Control[TSUPDT] must be 1 for the update.
- Program the MCGREN#i field of MAC_PPS_Control to enable the PPS instance to operate in MCGR mode.
- Program the appropriate presentation time control (supported recovery modes "0001 - 0011") to PPSCTRL_PPSCMD (for 0th instance) or PPSCMD#i (for 1,2,3 instances) of MAC_PPS_Control register, to set the PPS instance in Media clock recovery mode.
- After the PPS instance is set in Recovery mode, DUT sets the corresponding mcgr_dma_req_o[#i]. For every request which DUT generates, program the target presentation time into the MAC_PPS(#i)_Target_Time_Seconds register and assert the corresponding mcgr_dma_ack_i[#i] to acknowledge the request. Acknowledgment can be given before/after programming the Target presentation time.
- Observe the recovered media clock on the corresponding ptp_pps_o[#i].

78.16.14 Programming guidelines for ECC protection for memories

These are the guidelines for the ECC protection for memories:

- Write 1 to the appropriate field of MTL_ECC_Control to enable the ECC features for the respective memory.
- Generate a correctable interrupt (sbd_sfty_ce_intr_o) or an uncorrectable interrupt (sbd_sfty_ue_intr_o) to indicate the application, if any correctable, uncorrectable, or address errors are detected. DMA_Interrupt_Status or MTL_ECC_Interrupt_Status indicates an appropriate status.
- Provide debug mode for each memory to specify errors.

NOTE

Enable the ECC feature before the traffic is online (or after the reset), otherwise the false interrupts may trigger.

78.16.14.1 Programming guidelines for ECC hardware error injection (Debug mode)

Follow these steps for ECC hardware error injection:

- Write 1 to the appropriate field in MTL_DBG_CTL to enable the ECC error injection feature for MTL TX/RX and DMA TSO.
- Write 1 to the appropriate field in MTL_EST_GCL_Control to enable the ECC error injection feature for the EST memory.
- Write 1 to the appropriate field in MTL_RXP_Indirect_Acc_Control_Status to enable the ECC error injection for the receive parser memory. To access the receive parser memory in Debug mode, write 0 to MTL_RXP_Indirect_Acc_Control_Status[FRPE] to disable the receive parser feature.
- Ensure that all the CSR writes corresponding to one memory write must have the same value for the error injection control word, where multiple CSR writes are required for writing single data word into the memory.

78.16.15 Programming guidelines for on-chip datapath parity protection

Follow these steps for on-chip datapath parity protection:

- Writing 1 to MTL_DPP_Control[EDPP] enables the parity generation and parity detection mismatch on datapath.
- Generates an uncorrectable interrupt (sbd_sfty_ue_intr_o) to indicate the application if any parity mismatch is detected. DMA_Safety_Interrupt_Status or MTL_Safety_Interrupt_Status and MAC_DPP_FSM_Interrupt_Status indicates the appropriate status.
- Supports Debug mode for each parity generator to insert an error.

NOTE

Enable the datapath parity protection before the receive or transit traffic starts, to avoid the false safety interrupts.

78.16.16 Programming guidelines for FSM parity and timeout

Follow these steps to configure the FSM parity and timeout:

- Write 1 to MAC_FSM_Control[PRTYEN] and MAC_FSM_Control[TMOUTEN] to enable the FSM parity and timeout feature respectively.
- Force the FSMs to enter into a state with even number of 1s and wait for the safety uncorrectable interrupt to define with MAC_DPP_FSM_Interrupt_Status[FSMPES] for a parity error detection.
- Write 1 to the parity error injection using the [23:16] bits of MAC_FSM_Control to select the appropriate clock domain, for Error injection mode in FSM parity. Wait for the safety uncorrectable interrupt to be defined with MAC_DPP_FSM_Interrupt_Status[FSMPES].
- Configure the large and normal mode values which MAC_FSM_ACT_Timer[LTMRMD] and MAC_FSM_ACT_Timer[NTMRMD] indicates , for FSM timeouts.
- Use the [31:24] bits of MAC_FSM_Control to select the large or normal mode tic generation per clock domain.
- Write 1 to MAC_FSM_ACT_Timer[TMR] with the appropriate number of CSR clock cycles to generate 1us tic.
- Force the FSM in a particular clock domain to remain in an active state for timeout duration (for example, T-2T). You can check the safety interrupt and the status field for the corresponding clock domain that sets in the [15:8] bits of the MAC_DPP_FSM_Interrupt_Status .
- Select the appropriate clock domain for which timeout error injection must be set using the [15:8] bits of MAC_FSM_Control, for Error injection mode in FSM timeout. Wait for the safety uncorrectable interrupt to define with the corresponding error status in the MAC_DPP_FSM_Interrupt_Status .
- Use only normal mode tic generation, for application or CSR interface timeout. On the basis of the time-outs of configured interface, appropriate fields (MSTTES, SLVTES) of MAC_DPP_FSM_Interrupt_Status is defined with the safety interrupt.

78.17 EMAC register descriptions

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

NOTE

This chip has 16 KB allocated per Ethernet controller for configuration space. EMAC uses only 8 KB of this memory and the remaining 8 KB is reserved for future use. Writing to the reserved memory may lead to unintended behavior.

78.17.1 EMAC memory map

Fields

Field	Function
31 —	Reserved
30-28 SARC	Source Address Insertion Or Replacement Control Controls the source address insertion or replacement for all the transmitted packets. Bit 30 of this field specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of bits [29:28]: • 2'b0x: The mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation. • 2'b10: If bit 30 = 0, MAC inserts the content of the MAC Address 0 registers in the SA field of all the transmitted packets. If bit 30 = 1 and the Enable MAC Address Register 1 option is selected while configuring the core, MAC inserts the content of the MAC Address 1 registers in the SA field of all the transmitted packets. • 2'b11: If bit 30 = 0, MAC replaces the content of the MAC Address 0 registers in the SA field of all the transmitted packets. If bit 30 = 1 and the MAC Address Register 1 is enabled, MAC replaces the content of the MAC Address 1 registers in the SA field of all the transmitted packets. **NOTE** Changes to this field take effect only on the start of a packet. If you write to the field when a packet is being transmitted, only the subsequent packet can use the updated value. This means that the current packet does not use the updated value. 000b - mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation 010b - Contents of are inserted in the SA field 011b - Contents of replace the SA field 110b - Contents of are inserted in the SA field 111b - Contents of replace the SA field
27 IPC	Checksum Offload Indicates the status of IP header or payload checksum checking. If this field is 1, the field enables IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When the field becomes 0, the COE function in the receiver is disabled. The Layer 3 and Layer 4 packet filter and enable split header features automatically select the IPC full checksum offload engine on the receive side. When any of these features are enabled, you must write 1 to this field. 0b - Disabled 1b - Enabled
26-24 IPG	Inter-Packet Gap Controls the minimum IPG between packets during transmission. The range of minimum IPG is valid in Full-Duplex mode, and in this mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When a JAM pattern is being transmitted because of backpressure activation, MAC does not consider the minimum IPG. This function (IPG less than 96-bit times) is valid only when MAC_Ext_Configuration[EIPGEN] is 0. If this field is 1, the minimum IPG (greater than 96-bit times) is controlled according to the field's description. 000b - 96-bit times IPG 001b - 88-bit times IPG 010b - 80-bit times IPG 011b - 72-bit times IPG 100b - 64-bit times IPG 101b - 56-bit times IPG 110b - 48-bit times IPG 111b - 40-bit times IPG
23 GPSLCE	Giant Packet Size Limit Control Enable Enables and disables giant packet size limit control. If this field = 1, MAC considers the value of MAC_Ext_Configuration[GPSL] to declare a received packet as a giant packet. This field must be programmed to have a size of more than 1,518 bytes. Otherwise, MAC considers 1,518 bytes as the giant packet limit. When this field becomes 0, MAC considers the received packet as a giant packet if its size is greater than 1,518 bytes (1522 bytes for a tagged packet). The WD, JE, and S2KP fields have a higher precedence over this field, which means MAC considers a received packet as a giant packet when its size is greater than 9,018 bytes (9,022 bytes for a tagged packet) with JE = 1 and the size of the jumbo packet greater than 2,000 bytes and S2KP = 1. If the WD field is 1, the field terminates the received packet if it reaches the watchdog limit. Therefore, the programmed giant packet limit must be less than the watchdog limit to get the giant packet status. 0b - Disabled 1b - Enabled
22 S2KP	IEEE 802.3 Support For 2K Packets Indicates the status of IEEE 802.3 support for 2K packets. If this field is 1, MAC considers all the packets with up to 2,000-byte length as normal. When the JE field is not 1, MAC considers all the received packets of size more than 2K bytes as giant packets. When this field becomes 0 and the JE field is not 1, MAC considers all the received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. For more information about how the setting of this field and the JE field impacts the giant packet status, see this status based on the S2KP and JE fields. If the JE field is 1, writing 1 to the S2KP field has no effect on the giant packet status. 0b - Disabled 1b - Enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
21 CST	CRC Stripping For Type Packets Indicates the status of CRC stripping for Type packets. If this field is 1, the last four bytes (FCS) of all the Ether-type packets are stripped and dropped before forwarding the packet to the application. This field is valid only when the receive packet size is more than or equal to 1536 bytes. For information about how the settings of this field and the ACS field impact the packet length, see MAC Configuration (MAC_Configuration). 0b - Disabled 1b - Enabled
20 ACS	Automatic Pad Or CRC Stripping Indicates the status of automatic pad or CRC stripping. If this field is 1, MAC strips the pad or the FCS field on the incoming packets only if the size of the packets is less than 1,536 bytes. All the received packets with a size greater than or equal to 1,536 bytes are passed to the application without stripping the pad or the FCS field. When this field becomes 0, MAC passes all the incoming packets to the application, without any modification. For information about how the settings of this field and the CST field impact the packet length, see MAC Configuration (MAC_Configuration). 0b - Disabled 1b - Enabled
19 WD	Watchdog Disable Indicates the status of watchdog. If this field is 1, MAC disables the watchdog timer on the receiver. MAC can receive packets of up to 16,383 bytes. When this field becomes 0, MAC does not allow more than 2,048 bytes (10,240 if the JE field = 1) of the packet being received. MAC cuts off bytes received after 2,048. 0b - Enabled 1b - Disabled
18 —	Reserved
17 JD	Jabber Disable Indicates the status of jabber. If this field is 1, MAC disables the jabber timer on the transmitter. It can transfer packets of up to 16,383 bytes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 0 and the application sends more than 2,048 bytes of data (10,240 if the JE field = 1) during transmission, MAC does not send the rest of the bytes in that packet. 0b - Enabled 1b - Disabled
16 JE	Jumbo Packet Enable Indicates the status of jumbo packets. If this field is 1, MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN-tagged packets) without reporting a giant packet error in the receive packet status. 0b - Disabled 1b - Enabled
15 PS	Port Select Selects the Ethernet line speed. This field, along with the FES field, selects the exact line speed. In the 10/100 Mbit/s-only (always 1) or 1000 Mbit/s-only (always 0) configurations, this field is read-only (RO) with an appropriate value. By default, with 10/100/1000 Mbit/s configurations, this field is read-write (R/W). The mac_speed_o[1] signal reflects the value of this field. 0b - For 1000 or 2500 Mbit/s operations 1b - For 10 or 100 Mbit/s operations
14 FES	Speed Indicates the speed. This field selects the speed mode. The mac_speed_o[0] signal indicates the value of this field. 0b - 10 Mbit/s if PS = 1 and 1 Gbps if PS = 0 1b - 100 Mbit/s if PS = 1 and 2.5 Gbps if PS = 0
13 DM	Duplex Mode Indicates the mode in which MAC operates. If this field is 1, MAC operates in Full-Duplex mode in which it can transmit and receive simultaneously. The field can only be read, with 1 as its default value, in full-duplex-only configurations. 0b - Half-duplex mode 1b - Full-duplex mode
12 LM	Loopback Mode Indicates the status of Loopback mode If this field is 1, MAC operates in Loopback mode at GMII or MII. This mode requires the (G)MII Rx clock input (clk_rx_i) signal to function properly because the transmit clock is not internally looped back.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
11 ECRSFD	Enable Carrier Sense In Full-Duplex Mode Indicates whether ECRSFD is enabled or disabled. If this field is 1, the MAC transmitter checks the CRS signal before packet transmission in Full-Duplex mode. MAC starts transmitting only when the CRS signal is low. If this field becomes 0, the MAC transmitter ignores the status of the CRS signal. 0b - Disabled 1b - Enabled
10 DO	Disable Receive Own Enables or disables receive own. If this field is 1, MAC disables the reception of packets when the gmii_txen_o signal asserts in Half-Duplex mode. When the field is 0, MAC receives all the packets that PHY sent. This field is not applicable in Full-Duplex mode. 0b - Enabled 1b - Disabled
9 DCRS	Disable Carrier Sense During Transmission Enables or disables carrier sense during transmission. If this field is 1, the MAC transmitter ignores the (G)MII CRS signal during packet transmission in Half-Duplex mode. As a result, no errors generate because of loss of carrier or no carrier during transmission. When this field becomes 0, the MAC transmitter generates errors because of carrier sense. MAC can even abort the transmission. 0b - Enabled 1b - Disabled
8 DR	Disable Retry Enables or disables retry attempts. If this field is 1, MAC attempts only one transmission. When a collision occurs on GMII or MII, MAC ignores the current packet transmission and reports a packet abort with excessive collision errors in the transmit packet status. If this field becomes 0, MAC retries based on the settings of the BL field of this register. The settings of this field apply only in Half-Duplex mode. 0b - Enabled 1b - Disabled
7	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
6-5 BL	Back-Off Limit Determines the random integer number (r) of slot time delays (4,096 bit times for 1000/2500 Mbit/s; 512 bit times for 10/100 Mbit/s) for which MAC waits before rescheduling a transmission attempt during retry attempts after a collision. • *n* = retransmission attempt • *r* = random integer that takes the value in the range 0 <= r < 2^k This field is applicable only in Half-Duplex mode. 00b - k = min(n,10) 01b - k = min(n,8) 10b - k = min(n,4) 11b - k = min(n,1)
4 DC	Deferral Check Indicates the status of the deferral check function. If this field is 1, the deferral check function is enabled in MAC, which issues a packet abort status, with Tx_Excessive_Deferral_Error[TXEXSDEF] = 1 in the transmit packet status, when the transmit state machine is deferred for more than 24,288 bit times in 10 Mbit/s or 100 Mbit/s mode. If MAC is configured for a 1000/2500 Mbit/s operation, the threshold for deferral is 155,680 bit times. Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on GMII or MII. The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active, and then the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of this collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer resets to 0 and restarts. When this field becomes 0, the deferral check function disables and MAC defers until the CRS signal becomes inactive. This field is applicable only in Half-Duplex mode. 0b - Disabled 1b - Enabled
3-2 PRELEN	Preamble Length for Transmit Packets Controls the number of preamble bytes that are added to the beginning of every transmit packet. Preamble reduction occurs only when MAC operates in Full-Duplex mode. 00b - 7 bytes 01b - 5 bytes 10b - 3 bytes 11b - Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 TE	Transmitter Enable Indicates the status of the transmitter. • If this field is 1, the MAC transmit state machine is enabled for transmission on GMII or MII. • When the field becomes 0, the MAC transmit state machine is disabled after it completes the transmission of the current packet. The transmit state machine does not transmit any more packets. 0b - Disabled 1b - Enabled
0 RE	Receiver Enable Indicates the status of the receiver. If this field is 1, MAC's receive state machine is enabled for receiving packets from GMII or MII. When this field becomes 0, the MAC receive state machine is disabled after it completes the reception of the current packet. The receive state machine does not receive any more packets from GMII or MII. 0b - Disabled 1b - Enabled

78.17.3 MAC Extended Configuration (MAC_Ext_Configuration)

Offset

Register	Offset
MAC_Ext_Configuration	4h

Function
Establishes MAC's operating mode.

Diagram

Fields

Field	Function
31 —	Reserved
30 —	Reserved
29-25 EIPG	Extended Inter-Packet Gap Indicates the value of the extended inter-packet gap. The value of this field is applicable when EIPGEN = 1. The most-significant bits of this field, along with those of MAC_Configuration[IPG], render the minimum IPG greater than 96-bit times in steps of 8-bit times. 8'h00: 104-bit times 8'h01: 112-bit times 8'h02: 120-bit times ---------- 8'hFF: 2144-bit times
24 EIPGEN	Extended Inter-Packet Gap Enable Indicates the status of the extended inter-packet gap. • If this field is 1, MAC interprets the EIPG field of this register and the IPG field of MAC Configuration (MAC_Configuration) together as minimum IPG greater than 96-bit times in steps of 8-bit times. • If this field is 0, MAC ignores the EIPG field of this register and interprets the IPG field of MAC Configuration (MAC_Configuration) as minimum IPG less than or equal to 96-bit times in steps of 8-bit times. **NOTE** You must enable the extended inter-packet gap feature when operating in Full-Duplex mode only. There could be undesirable effects on the back-pressure function and frame transmission if the feature is enabled in Half-Duplex mode. 0b - Disabled 1b - Enabled
23 —	Reserved
22-20 —	Reserved
19 PDC	Packet Duplication Control Indicates the packet duplication control status.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If this field is 1, the received packet with multicast or broadcast destination address is routed to multiple receive DMA channels. MAC_Address0_High[DCS] identifies the receive DMA channels (corresponding to the MAC Address register) that match the multicast or broadcast destination addresses in the received packet. The DCS field is interpreted to be a one-hot value, each bit corresponding to the receive DMA channel. • If this field is 0, the received packet routes to a single receive DMA channel. MAC_Address0_High[DCS] identifies the receive DMA channel corresponding to the MAC Address register that matches the destination address in the received packet. The DCS field is interpreted as a binary value. 0b - Disabled 1b - Enabled
18 USP	Unicast Slow Protocol Packet Detect Indicates the status of unicast slow-protocol packet detection. • If this field is 1, MAC detects the slow-protocol packets with unicast address of the station specified in MAC Address 0 High (MAC_Address0_High) and MAC Address 0 Low (MAC_Address0_Low). MAC also detects the slow-protocol packets with the slow-protocol multicast address (01-80-C2-00-00-02). • If this field is 0, MAC detects only slow-protocol packets with the slow protocol multicast address specified in IEEE 802.3-2015, section 5. 0b - Disabled 1b - Enabled
17 SPEN	Slow Protocol Detection Enable Enables or disables slow protocol detection. • If this field is 0, EMAC forwards all error-free, slow-protocol packets to the application. EMAC considers such packets as normal-type packets. • If this field is 1, EMAC processes the slow-protocol packets (Ether type 8809h) and provides the slow protocol sub-type and code fields in receive status. 0b - Disabled 1b - Enabled
16 DCRCC	Disable CRC Checking For Received Packets Indicates the status of CRC checking. If this field is 1, MAC receiver does not check the CRC field in the received packets. When this field becomes 0, the MAC receiver always checks the CRC field in the received packets. 0b - Enabled 1b - Disabled
15-14	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
13-0 GPSL	Giant Packet Size Limit Declares the status of a packet based on its size. If the received packet size (in bytes) is greater than the value programmed in this field, MAC declares the received packet as a giant packet. The value programmed in this field must be greater than or equal to 1,518 bytes. Also, any other programmed value is considered as 1,518 bytes. For VLAN-tagged packets, MAC adds 4 bytes to the programmed value. If MAC_VLAN_Tag_Ctrl[EDVLP] = 1, MAC adds 8 bytes to the programmed value for double VLAN-tagged packets. The value of GPSL is valid if MAC_Configuration[GPSLCE] = 1.

78.17.4 MAC Packet Filter (MAC_Packet_Filter)

Offset

Register	Offset
MAC_Packet_Filter	8h

Function

Contains the filter controls for receiving packets.

Some of the controls from this register go to MAC's address check block that performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as pass bad packets and pass control packets.

Diagram

Fields

Field	Function
31 RA	Receive All Indicates whether the received packets are enabled or disabled. • If this field is 1, the MAC Receiver module passes all the received packets to the application, irrespective of their passing the address filter. The result (pass or fail) of the SA or DA filtering is updated in the corresponding field of the receive status word. • If this field is 0, the module passes only those packets to the application that pass the SA or DA address filter. 0b - Receive All is disabled 1b - Receive All is enabled
30-22 —	Reserved
21 DNTU	Drop Non-TCP/UDP Over IP Packets Indicates whether MAC drops or forwards non-TCP/UDP protocols over IP packets. • If this field is 1, MAC drops these protocols over IP packets. MAC forwards only those packets that the layer 4 filter processes. • If this field is 0, MAC forwards all these protocols over IP packets. 0b - Forwards 1b - Drops
20 IPFE	Layer 3 and Layer 4 Filter Enable Indicates the status of layer 3 and layer 4 filters. • If this field is 1, MAC drops packets that do not match the enabled layer 3 and layer 4 filters. If these two filters are not enabled for matching, this field does not have any effect. • If this field is 0, MAC forwards all the packets irrespective of the match status of the layer 3 and layer 4 fields. 0b - Disabled 1b - Enabled
19-17 —	Reserved
16 VTFE	VLAN Tag Filter Enable Indicates the status of VLAN tag filter. • If this field is 1, MAC drops the VLAN-tagged packets that do not match the VLAN tag. • If this field is 0, MAC forwards all the packets irrespective of the match status of the VLAN tag. 0b - Disabled 1b - Enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-11 —	Reserved
10 HPF	Hash Or Perfect Filter Indicates the status of hash or perfect filter. • If this field is 1, the address filter passes a packet if it matches either perfect filtering or hash filtering as defined by the HMC or HUC fields of this register. • If this field is 0 and HUC = 1 or HMC = 1, the packet passes only if it matches the hash filter. 0b - Disabled 1b - Enabled
9 SAF	Source Address Filter Enable Indicates the status of SA filtering. • If this field is 1, MAC compares the SA field of the received packets with the values programmed in the enabled SA registers. If the comparison fails, MAC drops the packet. • When this field becomes 0, MAC forwards the received packet to the application with an updated field value, depending on the SA address comparison. **NOTE** According to the IEEE specification, bit 47 of the SA field is reserved. However, MAC compares all the 48 bits. You must consider this when programming the MAC address registers for SA. 0b - Disabled 1b - Enabled
8 SAIF	SA Inverse Filtering Indicates the status of SA inverse filtering. • If this field is 1, the address check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programmed in the SA registers, it is marked as failing the SA address filter. • If this field becomes 0 and the SA of a packet does not match the values programmed in the SA registers, the SA is marked as failing the SA address filter. 0b - Disabled 1b - Enabled
7-6 PCF	Pass Control Packets Controls the forwarding of all the control packets (including unicast and multicast pause packets). 00b - MAC filters all the control packets from reaching the application 01b - MAC forwards all the control packets, except pause packets, to the application even if they fail the address filter

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - MAC forwards all the control packets to the application even if they fail the address filter 11b - MAC forwards all the control packets that pass the address filter
5 DBF	Disable Broadcast Packets Enables or disables broadcast packets. • If this field is 1, AFM blocks all the incoming broadcast packets. In addition, it overrides all the other filter settings. • If this field is 0, AFM passes all the received broadcast packets. 0b - Enabled 1b - Disabled
4 PM	Pass All Multicast Enables or disables the passing of received packets. • If this field is 1, it indicates that all the received packets with a multicast destination address (first bit in the destination address field is 1) are passed. • If this field is 0, filtering of multicast packets depends on the settings of the HMC field. 0b - Disabled 1b - Enabled
3 DAIF	DA Inverse Filtering Indicates the status of DA inverse filtering. • If this field is 1, the Address Check block operates in Inverse Filtering mode for the DA address comparison of both unicast and multicast packets. • If this field is 0, normal filtering of packets is performed. 0b - Disabled 1b - Enabled
2 HMC	Hash Multicast Indicates the status of hast multicast. • If this field is 1, MAC performs the destination address filtering of received multicast packets according to the hash table. • If this field is 0, MAC performs the perfect destination address filtering for multicast packets, that is, it compares the DA field with the values programmed in DA registers. 0b - Disabled 1b - Enabled
1 HUC	Hash Unicast Indicates the status of hash unicast.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If this field is 1, MAC performs the destination address filtering of unicast packets according to the hash table. • When this field becomes 0, MAC performs a perfect destination address filtering for unicast packets, that is, it compares the DA field with the values you program in the MAC Address registers. 0b - Disabled 1b - Enabled
0 PR	Promiscuous Mode Indicates the status of Promiscuous mode. If this field is 1, the address filtering module passes all the incoming packets irrespective of the destination or source address. MAC clears the SA or DA filter fail status fields of the receive status word when PR = 1. 0b - Disabled 1b - Enabled

78.17.5 MAC Watchdog Timeout (MAC_Watchdog_Timeout)

Offset

Register	Offset
MAC_Watchdog_Timeout	Ch

Function
Controls the watchdog timeout for received packets.

Diagram

78.17.6 MAC Hash Table First 32 Bits (MAC_Hash_Table_Reg0)

Offset

Register	Offset
MAC_Hash_Table_Reg0	10h

Function

Contains the first 32 bits of the hash table, when the total width of the hash table is 128 bits or 256 bits.

The hash table is used for group address filtering, for which the content of the destination address in the incoming packet is passed through the CRC logic and the bits of Receive CRC Error Packets (Rx_CRC_Error_Packets) are used to index the contents of the hash table as follows:

- 6 bits when you have a 64-bit hash
- 7 bits when you have a 128-bit hash
- 8 bits when you have a 256-bit hash

The most-significant bits determine the Hash Table register to be used, and the least-significant 5 bits determine the bit within the register. For example, a hash value of 10_0000b (in 64-bit hash) selects bit 0 of MAC Hash Table Second 32 Bits (MAC_Hash_Table_Reg1).

Perform these steps to calculate the hash value of the destination address:

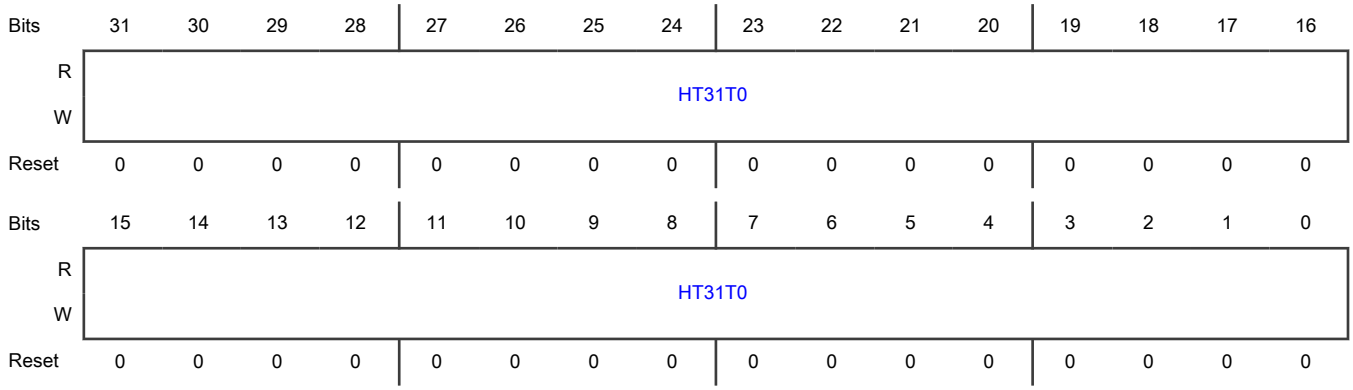
1. Calculate the 32-bit CRC for DA (see section 3.2.8 in IEEE 802.3 for the steps to calculate CRC32).
2. Perform bit-wise reversal for the value obtained in step 1.
3. Use the upper 6, 7, or 8 bits from the value obtained in step 2.

If this field is 1, the packet is accepted. Otherwise, it is rejected. If MAC_Packet_Filter[PM] = 1, all multicast packets are accepted regardless of the multicast hash values.

If this register is configured to be double-synchronized with the (G)MII clock domain, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the Hash Table registers are written to.

If double-synchronization is enabled, consecutive writes to this register must be performed after at least four clock cycles in the destination clock domain.

Diagram



Fields

Field	Function
31-0 HT31T0	MAC Hash Table First 32 Bits Contains the first 32 bits [31:0] of the hash table.

78.17.7 MAC Hash Table Second 32 Bits (MAC_Hash_Table_Reg1)

Offset

Register	Offset
MAC_Hash_Table_Reg1	14h

Function

Contains the second 32 bits of the hash table, when the width of the hash table is 128 or 256 bits.

The hash table is used for group address filtering, for which the content of the destination address in the incoming packet is passed through the CRC logic and the bits of Receive CRC Error Packets (Rx_CRC_Error_Packets) are used to index the contents of the hash table as follows:

- 6 bits when you have a 64-bit hash
- 7 bits when you have a 128-bit hash
- 8 bits when you have a 256-bit hash

The most-significant bits determine the Hash Table register to be used, and the least-significant 5 bits determine the bit within the register. For example, a hash value of 10_0000b (in 64-bit hash) selects bit 0 of MAC Hash Table Second 32 Bits (MAC_Hash_Table_Reg1).

Perform these steps to calculate the hash value of the destination address:

1. Calculate the 32-bit CRC for DA (see section 3.2.8 in IEEE 802.3 for the steps to calculate CRC32).
2. Perform bit-wise reversal for the value obtained in step 1.
3. Take the upper 6, 7, or 8 bits from the value obtained in step 2.

If the corresponding bit value of this register is 1'b1, the packet is accepted. Otherwise, it is rejected. If MAC_Packet_Filter[PM] = 1, all multicast packets are accepted regardless of the multicast hash values.

If this register is configured to be double-synchronized with the (G)MII clock domain, the synchronization is triggered only when bits [31:24] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the Hash Table registers are written to.

If double-synchronization is enabled, consecutive writes to this register must be performed after at least four clock cycles in the destination clock domain.

Fields

Field	Function
31 EIVLRXS	Enable Inner VLAN Tag In Receive Status Indicates whether the inner VLAN tag in receive status is enabled or disabled. • If this field is 1, MAC provides the inner VLAN tag in the receive status. • If this field is 0, MAC does not provide the inner VLAN tag in the receive status. 0b - Disabled 1b - Enabled
30 —	Reserved
29-28 EIVLS	Enable Inner VLAN Tag Stripping Indicates the stripping operation on the inner VLAN tag in a received packet. The field enables or disables inner VLAN tag stripping on receive. 00b - Do not strip 01b - Strip if VLAN filter passes 10b - Strip if VLAN filter fails 11b - Always strip
27 ERIVLT	Enable Inner VLAN Tag Comparison Enables or disables the inner VLAN tag. • If ERIVLT = VTHM = EDVLP = 1, the EMAC receiver enables the VLAN hash filtering operation on the inner VLAN tag (if present). • If ERIVLT = 0 and VTHM = 1, the EMAC receiver enables the VLAN hash filtering operation on the outer VLAN tag (if present). ERSVLM and DOVLTC determine which VLAN type is enabled for filtering. 0b - Disabled 1b - Enabled
26 EDVLP	Enable Double VLAN Processing Enables or disables double VLAN processing. • If this field is 1, MAC enables processing of up to two VLAN tags on transmit and receive (if present). • If this field is 0, MAC enables processing of up to one VLAN tag on transmit and receive (if present). 0b - Disabled 1b - Enabled
25 VTHM	VLAN Tag Hash Table Match Indicates the status of VLAN tag hash table match.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If this field is 1, the most-significant four bits of CRC-32 of VLAN tag are used to index the content of MAC VLAN Hash Table (MAC_VLAN_Hash_Table). See VLAN filtering for details. • If MAC_VLAN_Hash_Table[VLHT] = 1, corresponding to the index, it indicates that the Ethernet packet matches the VLAN hash table. See VLAN filtering for details. • If ETV = 1, the CRC of the 12-bit VLAN identifier (VID) is used for comparison. When the ETV field becomes 0, the CRC of the 16-bit VLAN tag is used for comparison. • If VTHM = 1, the VLAN hash match operation is not performed. 0b - Disabled 1b - Enabled
24 EVLRXS	Enable VLAN Tag In Receive Status Indicates whether the VLAN tag in receive status is enabled. • If this field is 1, MAC provides the outer VLAN tag in the receive status. • If this field is 0, MAC does not provide the outer VLAN tag in receive status. 0b - Disabled 1b - Enabled
23 —	Reserved
22-21 EVLS	Enable VLAN Tag Stripping Indicates the stripping operation on the outer VLAN tag in received packets. The field enables or disables VLAN tag stripping on receive. 00b - Do not strip 01b - Strip if VLAN filter passes 10b - Strip if VLAN filter fails 11b - Always strip
20 DOVLTC	Disable VLAN Type Check Enables or disables VLAN type check for VLAN hash filtering. • If this field is 1, the MAC VLAN hash filter matches or filters the VLAN tag that the ERIVLT field specifies only when the VLAN tag type is similar to the one that the ERSVLM field specifies. • If this field is 0, the MAC VLAN hash filter does not check whether the VLAN tag that the ERIVLT field specifies is of type S-VLAN or C-VLAN. • The VLAN filter is bypassed when VLAN type of received packet do not match the programmed VLAN type in the VLAN filter. 0b - Enabled 1b - Disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
19 ERSVLM	Enable Receive S-VLAN Match Enables or disables receive S-VLAN match for VLAN hash filtering. • If this field is 1, the MAC receiver enables VLAN hash filtering or S-VLAN matching (type = 88A8h) packets. • If this field is 0, the MAC receiver enables VLAN hash filtering or matching for C-VLAN (type = 8100h) packets. The ERIVLT field determines the VLAN tag position considered for VLAN hash filtering or matching. 0b - Disabled 1b - Enabled
18 ESVL	Enable S-VLAN Enables or disables S-VLAN. If this field is 1, the MAC transmitter and receiver consider the S-VLAN packets (type = 88A8h) as valid VLAN-tagged packets. 0b - Disabled 1b - Enabled
17 VTIM	VLAN Tag Inverse Match Enable Enables or disables VLAN tag inverse matching. • If this field is 1, it enables the VLAN tag inverse matching. The packets without matching VLAN tag are marked as matched. • If this field is 0, it enables the VLAN tag perfect matching. The packets with matched VLAN tag are marked as matched. 0b - Disabled 1b - Enabled
16 ETV	Enable Tag For VLAN Enables or disables 12-bit VLAN tag comparison for VLAN hash filtering. • If this field is 1, a 12-bit VLAN identifier is used for VLAN hash filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of the VLAN tag in the received VLAN-tagged packet are used for hash-based VLAN filtering. • When this field becomes 0, all 16 bits of the 15th and 16th bytes of the received VLAN packet are used for VLAN hash filtering. 0b - Disabled 1b - Enabled
15-0 VL	VLAN Tag Identifier for Receive Packets Contains the 802.1Q VLAN tag to identify the VLAN packets.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This VLAN tag identifier is compared to the 15th and 16th bytes of the packets being received for VLAN packets. The following list describes the bits of this field: • 15:13 — User priority • 12 — Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) • 11:0 — VID field of VLAN tag When ETV = 1, only the VID is used for comparison. When VL = 0, and ETV = 1, MAC does not check the 15th and 16th bytes for VLAN tag comparison and declares all packets with Type field value of 8100h or 88a8h as VLAN packets.

78.17.9 MAC VLAN Tag Control (MAC_VLAN_Tag_Ctrl)

Offset

Register	Offset
MAC_VLAN_Tag_Ctrl	50h

Function

Is the redefined version of the MAC_VLAN_Tag register.

This register provides the control and addressing fields required for indirect access to the MAC_VLAN_Tag_Filter registers. It also contains the address offset, command type, and busy bit for CSR access of the MAC VLAN Hash Filter registers.

Fields

Field	Function
31	Enable Inner VLAN Tag In Receive Status

Table continues on the next page...

Table continued from the previous page...

Field	Function
EIVLRXS	Indicates whether the inner VLAN tag in receive status is enabled or disabled. • If this field is 1, MAC provides the inner VLAN tag in the receive status. • If this field is 0, MAC does not provide the inner VLAN tag in the receive status. 0b - Disabled 1b - Enabled
30 —	Reserved
29-28 EIVLS	Enable Inner VLAN Tag Stripping Indicates the stripping operation on the inner VLAN tag in a received packet. The field enables or disables inner VLAN tag stripping on receive. 00b - Do not strip 01b - Strip if VLAN filter passes 10b - Strip if VLAN filter fails 11b - Always strip
27 ERIVLT	Enable Inner VLAN Tag Comparison Enables or disables the inner VLAN tag. • If ERIVLT = VTHM = EDVLP = 1, the EMAC receiver enables the VLAN hash filtering operation on the inner VLAN tag (if present). • If ERIVLT = 0 and VTHM = 1, the EMAC receiver enables the VLAN hash filtering operation on the outer VLAN tag (if present). ERSVLM and DOVLTC determine which VLAN type is enabled for filtering. 0b - Disabled 1b - Enabled
26 EDVLP	Enable Double VLAN Processing Enables or disables double VLAN processing. • If this field is 1, MAC enables processing of up to two VLAN tags on transmit and receive (if present). • If this field is 0, MAC enables processing of up to one VLAN tag on transmit and receive (if present). 0b - Disabled 1b - Enabled
25 VTHM	VLAN Tag Hash Table Match Indicates the status of VLAN tag hash table match. • If this field is 1, the most-significant four bits of CRC-32 of VLAN tag are used to index the content of MAC VLAN Hash Table (MAC_VLAN_Hash_Table). See VLAN filtering for details.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If MAC_VLAN_Hash_Table[VLHT] = 1, corresponding to the index, it indicates that the Ethernet packet matches the VLAN hash table. See VLAN filtering for details. • If ETV = 1, the CRC of the 12-bit VLAN identifier (VID) is used for comparison. When the ETV field becomes 0, the CRC of the 16-bit VLAN tag is used for comparison. • If VTHM = 1, the VLAN hash match operation is not performed. 0b - Disabled 1b - Enabled
24 EVLRXS	Enable VLAN Tag In Receive Status Indicates whether the VLAN tag in receive status is enabled. • If this field is 1, MAC provides the outer VLAN tag in the receive status. • If this field is 0, MAC does not provide the outer VLAN tag in receive status. 0b - Disabled 1b - Enabled
23 —	Reserved
22-21 EVLS	Enable VLAN Tag Stripping Indicates the stripping operation on the outer VLAN tag in received packets. The field enables or disables VLAN tag stripping on receive. 00b - Do not strip 01b - Strip if VLAN filter passes 10b - Strip if VLAN filter fails 11b - Always strip
20 DOVLTC	Disable VLAN Type Check Enables or disables VLAN type check for VLAN hash filtering. • If this field is 1, the MAC VLAN hash filter matches or filters the VLAN tag that the ERIVLT field specifies only when the VLAN tag type is similar to the one that the ERSVLM field specifies. • If this field is 0, the MAC VLAN hash filter does not check whether the VLAN tag that the ERIVLT field specifies is of type S-VLAN or C-VLAN. 0b - Enabled 1b - Disabled
19 ERSVLM	Enable Receive S-VLAN Match Enables or disables receive S-VLAN match for VLAN hash filtering. • If this field is 1, the MAC receiver enables VLAN hash filtering or S-VLAN matching (type = 88A8h) packets.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If this field is 0, the MAC receiver enables VLAN hash filtering or matching for C-VLAN (type = 8100h) packets. The ERIVLT field determines the VLAN tag position considered for VLAN hash filtering or matching. 0b - Disabled 1b - Enabled
18 ESVL	Enable S-VLAN Enables or disables S-VLAN. If this field is 1, the MAC transmitter and receiver consider the S-VLAN packets (type = 88A8h) as valid VLAN-tagged packets. 0b - Disabled 1b - Enabled
17 VTIM	VLAN Tag Inverse Match Enable Enables or disables VLAN tag inverse matching. • If this field is 1, it enables the VLAN tag inverse matching. The packets without matching VLAN tag are marked as matched. • If this field is 0, it enables the VLAN tag perfect matching. The packets with matched VLAN tag are marked as matched. 0b - Disabled 1b - Enabled
16 ETV	Enable Tag For VLAN Enables or disables 12-bit VLAN tag comparison for VLAN hash filtering. • If this field is 1, a 12-bit VLAN identifier is used for VLAN hash filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of the VLAN tag in the received VLAN-tagged packet are used for hash-based VLAN filtering. • When this field becomes 0, all 16 bits of the 15th and 16th bytes of the received VLAN packet are used for VLAN hash filtering. 0b - Disabled 1b - Enabled
15-4 —	Reserved
3-2 OFS	Offset Holds the address offset of the MAC VLAN Tag Filter register that the application tries to access. The width of this field depends on the number of enabled MAC VLAN Tag registers.
1	Command Type

Table continues on the next page...

Table continued from the previous page...

Field	Function
CT	Specifies whether the current register access indicates a read or a write operation. It indicates a read operation if this field is 1 and a write operation when the field is 0. 0b - Write operation 1b - Read operation
0 OB	Operation Busy Indicates the operation busy status. • This field becomes 1 to initiate a read or write command for an indirect access to the Per VLAN Tag Filter register. • The field becomes 0 when the read or write command to Per VLAN Tag Filter indirect access register completes. The next indirect register access can be initiated only after the field resets. During a write operation, the field becomes 0 only after the data is written into a MAC_VLAN_Tag_Filter register. During a read operation, the data must be read from MAC VLAN Tag Data (MAC_VLAN_Tag_Data) only after this field becomes 0. 0b - Disabled 1b - Enabled

78.17.10 MAC VLAN Tag Data (MAC_VLAN_Tag_Data)

Offset

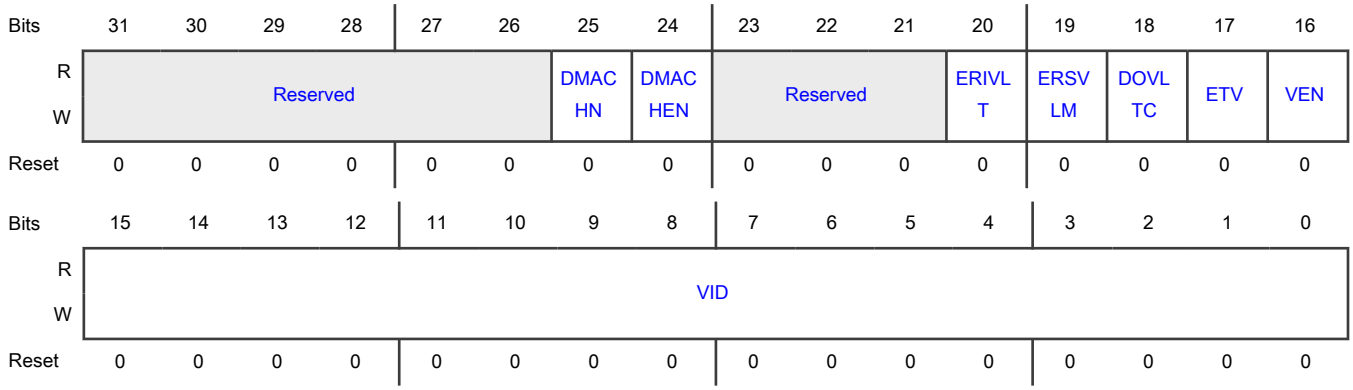
Register	Offset
MAC_VLAN_Tag_Data	54h

Function

Holds the read and write data for indirect access to the Per VLAN Tag registers.

- During read access, this register contains valid read data only after MAC_VLAN_Tag_Ctrl[OB] becomes 0.
- During write access, this register must become valid before you write 1 to MAC_VLAN_Tag_Ctrl[OB].

Diagram



Fields

Field	Function
31-26 —	Reserved
25 DMACHN	DMA Channel Number Indicates the DMA channel number to which the VLAN-tagged frame is to be routed if it passes the VLAN tag filter programmed using this field. If the routing based on VLAN tag filter is not necessary, this field does not need to be programmed.
24 DMACHEN	DMA Channel Number Enable Enables or disables the DMA channel number value programmed using the DMACHN field. If this field is 0, the routing does not occur based on the VLAN filter result. The frame is routed on the basis of DA-based DMA channel routing. 0b - Disabled 1b - Enabled
23-21 —	Reserved
20 ERIVLT	Enable Inner VLAN Tag Enables or disables inner VLAN tag comparison. • This field is valid only when the double VLAN tag enable of the filter is set. • If this field and the EDVLP field is 1, the MAC receiver enables operation on the inner VLAN tag (if present). • If this field is 0, the MAC receiver enables operation on the outer VLAN tag (if present). 0b - Disabled 1b - Enabled
19	Enable S-VLAN Match

Table continues on the next page...

Table continued from the previous page...

Field	Function
ERSVLM	Enables or disables S-VLAN match for received frames. This field is valid only when the VLAN tag enable of the filter is set. • If this field is 1, the MAC receiver enables filtering or matching for S-VLAN (type = 88A8h) packets. • If this field is 0, the MAC receiver enables filtering or matching for C-VLAN (type = 8100h) packets. 0b - Disabled 1b - Enabled
18 DOVLTC	Disable VLAN Type Comparison Enables or disables VLAN type comparison. This field is valid only when the VEN field is 1. • If this field is 1, MAC does not check whether the VLAN tag that ERIVLT specifies is of type S-VLAN or C-VLAN. • If this field is 0, MAC filters or matches the VLAN tag that the ERIVLT field specifies only when the VLAN tag type is similar to the one that the ERSVLM field specifies. 0b - Enabled 1b - Disabled
17 ETV	VLAN Comparison Indicates 12-bit or 16-bit VLAN comparison. • This field is valid only when the VEN field is 1. • When the value of this field is 1, a 12-bit VLAN identifier is used for filter and comparison instead of the complete 16-bit VLAN tag. Bits [11:0] of the VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. 0b - 16-bit VLAN comparison 1b - 12-bit VLAN comparison
16 VEN	VLAN Tag Enable Enables or disables the VLAN tag. • If this field is 1, MAC compares the VLAN tag of the received packet with the VLAN tag ID. • If this field is 0, no comparison is performed irrespective of the programming of the other fields. 0b - Disabled 1b - Enabled
15-0 VID	VLAN Tag ID Holds the VLAN tag value that MAC uses for perfect comparison. The field is valid when VEN = 1.

78.17.11 MAC VLAN Tag Filter 0 (MAC_VLAN_Tag_Filter0)

Offset

Register	Offset
MAC_VLAN_Tag_Filter0	54h

Function

Contains VLAN tag filter 0 control information.

78.17.15 MAC VLAN Hash Table (MAC_VLAN_Hash_Table)

Offset

Register	Offset
MAC_VLAN_Hash_Table	58h

Function

If MAC_VLAN_Tag_Ctrl[VTHM] = 1, the 16-bit VLAN hash table register is used for group address filtering based on the VLAN tag. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on MAC_VLAN_Tag_Ctrl[ETV]) in the incoming packet is passed through the CRC logic. The upper four bits of the calculated CRC value are used to index the contents of the VLAN hash table. For example, hash value of 1000b selects bit 8 of the VLAN hash table.

Perform these steps to calculate the hash value of the destination address:

1. Calculate the 32-bit CRC for DA (see section 3.2.8 of IEEE 802.3 for steps to calculate CRC32).
2. Perform bit-wise reversal for the value obtained in step 1.
3. Take the upper 4 bits from the value obtained in step 2.

If this register is configured to be double-synchronized with the (G)MII clock domain, the synchronization is triggered only when bits [15:8] (in Little-Endian mode) or bits [7:0] (in Big-Endian mode) of the register are written to.

If double-synchronization is enabled, consecutive writes to this register must be performed after at least four clock cycles in the destination clock domain.

78.17.16 MAC VLAN Inclusion Or Replacement (MAC_VLAN_Incl)

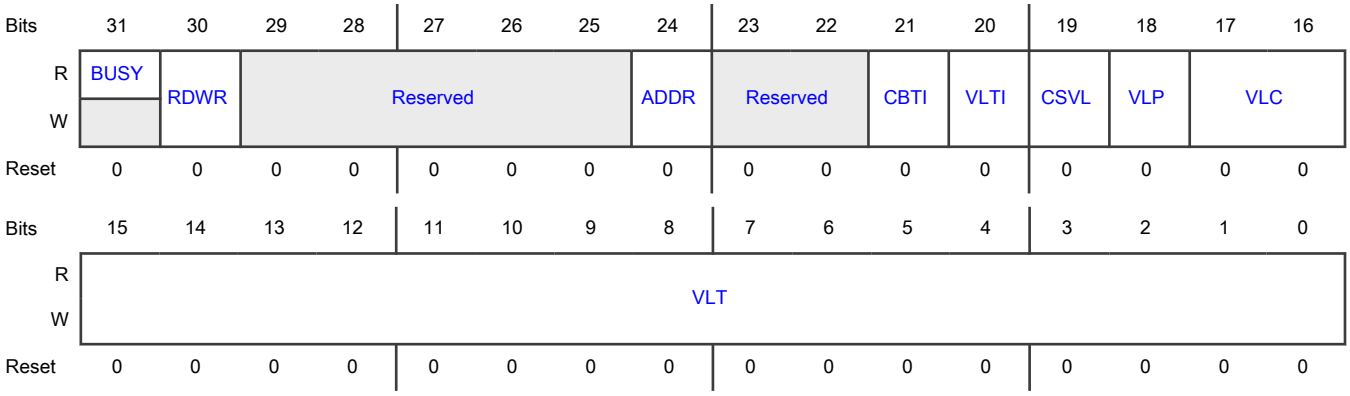
Offset

Register	Offset
MAC_VLAN_Incl	60h

Function

Contains the VLAN tag for insertion or replacement in the transmit packets and the VLAN tag insertion controls.

Diagram



Fields

Field	Function
31 BUSY	Busy Indicates the status of the read or write operation of indirect access to the queue- or channel-specific VLAN inclusion register. The write operation to a register completes when this field becomes 0. For a read operation, the read data is valid when the field becomes 0. The application must make sure that this field becomes 0 before attempting subsequent accesses to this register. 0b - Busy status not detected 1b - Busy status detected
30 RDWR	Read Write Control Controls the read or write operation for indirectly accessing the queue- or channel-specific VLAN inclusion register. • If this field is 1, it indicates the write operation. • If this field is 0, it indicates the read operation. The value of this field is not impacted when the CBTI field becomes 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Read operation of indirect access 1b - Write operation of indirect access
29-25 —	Reserved
24 ADDR	Address Selects one of the queue- or channel-specific VLAN inclusion registers for read or write access. The value of this field is not impacted when the CBTI field is 0.
23-22 —	Reserved
21 CBTI	Channel-Based Tag Insertion Indicates the status of channel-based tag insertion. If this field is 1: • The outer VLAN tag is inserted for all the packets that MAC transmits. • The tag value is taken from the queue- or channel-specific VLAN tag register. Also, the VLTI, VLP, VLC, and VLT fields of the register are ignored. • A write operation to byte 3 of this register initiates the read or write access to the indirect register. If this field is 0, the outer VLAN operation is based on the settings of the VLTI, VLP, VLC, and VLT fields of this register. 0b - Disabled 1b - Enabled
20 VLTI	VLAN Tag Input Indicates the status of the VLAN tag input. The value of this field being 1 indicates that the VLAN tag to be inserted or replaced in the transmit packet must be taken from the transmit descriptor. 0b - Disabled 1b - Enabled
19 CSVL	C-VLAN Or S-VLAN Indicates whether C-VLAN or S-VLAN is inserted or replaced in the transmitted packets. • If this field is 1, S-VLAN type (88A8h) is inserted or replaced in the 13th and 14th bytes of the transmitted packets. • If this field is 0, C-VLAN type (8100h) is inserted or replaced in the 13th and 14th bytes of the transmitted packets. 0b - C-VLAN

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - S-VLAN
18 VLP	VLAN Priority Control Indicates the status of VLAN priority control. • If this field is 1, the control bits [17:16] are used for VLAN deletion, insertion, or replacement. • If this field is 0, the mti_vlan_ctrl_i control input is used and bits [17:16] are ignored. 0b - Disabled 1b - Enabled
17-16 VLC	VLAN Tag Control Contains values for VLAN tag control in transmit packets. MAC: • Removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all the transmitted packets with VLAN tags. • Replaces VLT in bytes 15 and 16 of all the VLAN-type transmitted packets (bytes 13 and 14 are 8100h or 88a8h). MAC inserts the following into the packet in the order shown: 1. Type value (8100h or 88A8h) into bytes 13 and 14 2. MAC_VLAN_Tag_Data[VLT] into bytes 15 and 16 This operation is performed on all the transmitted packets, irrespective of whether they already have a VLAN tag. **NOTE** Changes to this field take effect only on the start of a packet. If you write to this field when a packet is being transmitted, only the subsequent packets can use the updated value. That is, the current packet does not use the updated value. 00b - No VLAN tag deletion, insertion, or replacement 01b - VLAN tag deletion 10b - VLAN tag insertion 11b - VLAN tag replacement
15-0 VLT	VLAN Tag For Transmit Packets Contains the value of the VLAN tag to be inserted or replaced. This value must only be changed during the initialization phase or when the transmit lines are inactive. The following list describes the bits of this field: • Bits [15:13]: User priority • Bit 12: Canonical format indicator (CFI) or drop eligible indicator (DEI) • Bits [11:0]: MAC_VLAN_Tag_Data[VID]

78.17.17 MAC VLAN Inclusion 0 (MAC_VLAN_Incl0)

Offset

Register	Offset
MAC_VLAN_Incl0	60h

Function

Contains the VLAN tag for insertion in the transmit packets from transmit queue 0. The register also contains the VLAN tag insertion controls.

78.17.25 Inner VLAN Tag Inclusion Or Replacement (MAC_Inner_VLAN_Incl)

Offset

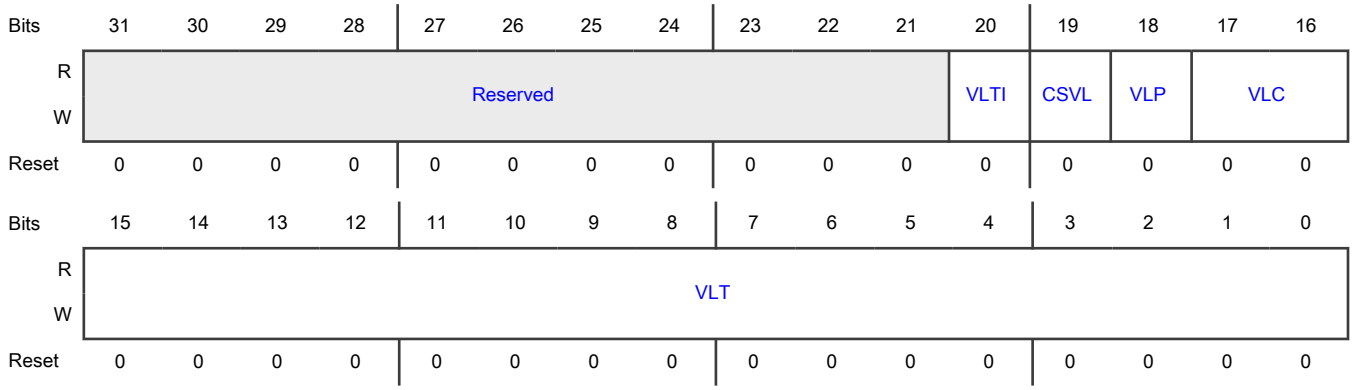
Register	Offset
MAC_Inner_VLAN_Incl	64h

Function

Contains:

- The inner VLAN tag to be inserted or replaced in the transmit packet
- The inner VLAN tag insertion controls

Diagram



Fields

Field	Function
31-21 —	Reserved
20 VLTI	VLAN Tag Input Indicates the status of VLAN tag input. If this field is 1, it indicates that the VLAN tag to be inserted or replaced in the transmit packet must be taken from the transmit descriptor. 0b - Disabled 1b - Enabled
19 CSVL	C-VLAN Or S-VLAN Controls the insertion or replacement type in the 17th and 18th bytes of the transmitted packets. 0b - C-VLAN type (8100h) 1b - S-VLAN type (88A8h)
18 VLP	VLAN Priority Control Indicates the status of VLAN priority control. • If this field is 1, it's used for VLAN deletion, insertion, or replacement. • If this field is 0, the mti_vlan_ctrl_i control input is used and MAC_VLAN_Incl[VLC] is ignored. 0b - Disabled 1b - Enabled
17-16 VLC	VLAN Tag Control in Transmit Packets Indicates the value of VLAN tag control in transmit packets. The following list specifies these values: • 2'b00: No VLAN tag deletion, insertion, or replacement

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• 2'b01: VLAN tag deletion • 2'b10: VLAN tag insertion • 2'b11: VLAN tag replacement MAC: • Removes the VLAN type (bytes 17 and 18) and VLAN tag (bytes 19 and 20) of all the transmitted packets with VLAN tags • Inserts VLT in bytes 19 and 20 of the packet after inserting the Type value (8100h or 88a8h) in bytes 17 and 18. This operation is performed on all the transmitted packets, irrespective of whether they already have a VLAN tag. • Replaces VLT in bytes 19 and 20 for all the VLAN-type transmitted packets (bytes 17 and 18 are 8100h or 88a8h). **NOTE** Changes to this field take effect only on the start of a packet. If you write to the field when a packet is being transmitted, only the subsequent packets can use the updated value. That is, the current packet does not use the updated value. 00b - No VLAN tag deletion, insertion, or replacement 01b - VLAN tag deletion 10b - VLAN tag insertion 11b - VLAN tag replacement
15-0 VLT	VLAN Tag For Transmit Packets Contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. The following list describes the bits of this field: • Bits [15:13]: User priority • Bit 12: CFI or DEI • Bits [11:0]: MAC_VLAN_Tag_Data[VID]

78.17.26 MAC Q0 Tx Flow Control (MAC_Q0_Tx_Flow_Ctrl)

Offset

Register	Offset
MAC_Q0_Tx_Flow_Ctrl	70h

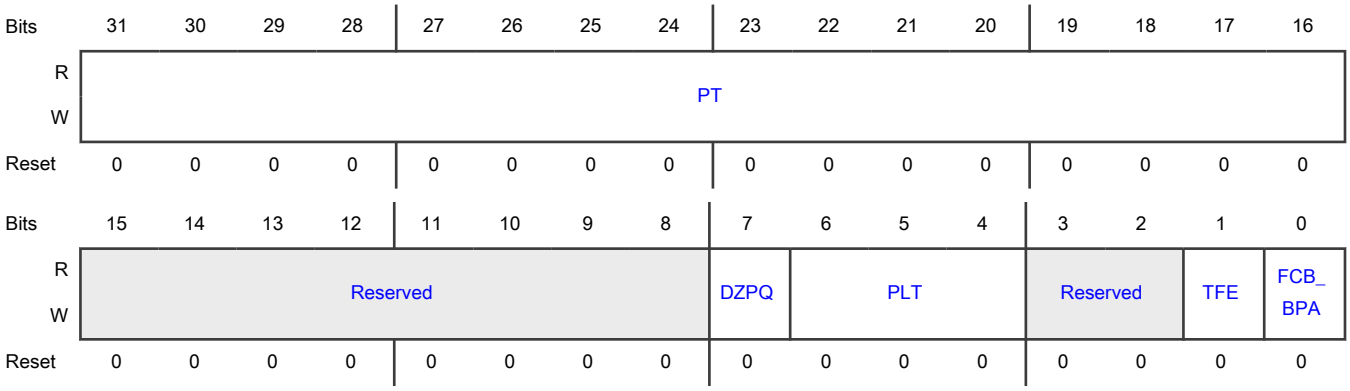
Function

Controls the generation and reception of the control (pause command) packets by MAC's flow control module. A write to the register with the Busy field = 1 triggers the flow control block to generate a pause packet. The 802.3x specification indicates the way the fields of the control packet are selected, and the pause time value from this register is used in the PT field of the control

packet. The Busy field remains 1 until the control packet is transferred onto the cable. You must make sure that the Busy field is 0 before writing to this register.

If the value of the PFCE field in the MAC_Rx_Flow_Ctrl register is 1, this register controls the generation of priority flow control (PFC) frames with priorities mapped according to MAC_RxQ_Ctrl2[PSRQ0].

Diagram



Fields

Field	Function
31-16 PT	Pause Time Holds the value to be used in this field in the transmit control packet. If the bits of this field are configured to be double-synchronized with the (G)MII clock domain, consecutive writes to this register must be performed only after at least four clock cycles in the destination clock domain.
15-8 —	Reserved
7 DZPQ	Disable Zero-Quanta Pause Enables or disables zero-quanta pause packet generation. • If this field is 1, it disables the automatic generation of the zero-quanta pause packets that the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i or mti_flowctrl_i) deasserts. • If this field is 0, normal operations with automatic zero-quanta pause packet generation are enabled. 0b - Enabled 1b - Disabled
6-4 PLT	Pause Low Threshold Configures the threshold of the pause timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of the pause packet. The threshold values must always be less than the pause time configured in bits [31:16]. For example, if the PT field = 100H (256 slot times), and the PLT field = 001, a second pause packet automatically transmits if the mti_flowctrl_i signal is asserted at 228 (256-28) slot times after the first pause packet transmits. This list provides the threshold values for different values:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• The slot time is defined as the time taken to transmit 512 bits (64 bytes) on GMII or MII. • This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + two pause packet sizes + IPG in slot times. 000b - Pause time minus 4 slot times (PT is 4 slot times) 001b - Pause time minus 28 slot times (PT is 28 slot times) 010b - Pause time minus 36 slot times (PT is 36 slot times) 011b - Pause time minus 144 slot times (PT is 144 slot times) 100b - Pause time minus 256 slot times (PT is 256 slot times) 101b - Pause time minus 512 slot times (PT is 512 slot times) 110b - Reserved
3-2 —	Reserved
1 TFE	Transmit Flow Control Enable Indicates whether transmit flow control is enabled or disabled. • Full-Duplex mode: If this field is 1, MAC enables the flow control operation to the transmit pause packets. When the field becomes 0, MAC's flow control operation disables and MAC does not transmit any pause packets. • Half-Duplex mode: If this field is 1, MAC enables the backpressure operation. When the field becomes 0, the backpressure operation disables. 0b - Disabled 1b - Enabled
0 FCB_BPA	Flow Control Busy Or Backpressure Activate Initiates if a pause packet is in Full-Duplex mode and activates the backpressure function in Half-Duplex mode if the TFE field is 1. • Full-Duplex mode: In this mode, FCB_BPA must be read as 1'b0 before writing to this register. To initiate a pause packet, the application must set this field to 1'b1. During control packet transfer, the field's value continues to be 1 to indicate that a packet transmission is in progress. When pause packet transmission is complete, MAC resets this field to 1'b0. You must not write to this register until this field becomes 0. • Half-Duplex mode: If FCB_BPA = 1 and TFE = 1 too, MAC asserts backpressure in this mode. During the backpressure function, when MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. This control register field is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When you configure MAC using Full-Duplex mode, this field automatically becomes 0. Access restrictions apply to this field: writing 1 sets it, writing 0 has no effect, and the field is self-clearing. 0b - Flow control busy or backpressure activate is disabled 1b - Flow control busy or backpressure activate is enabled

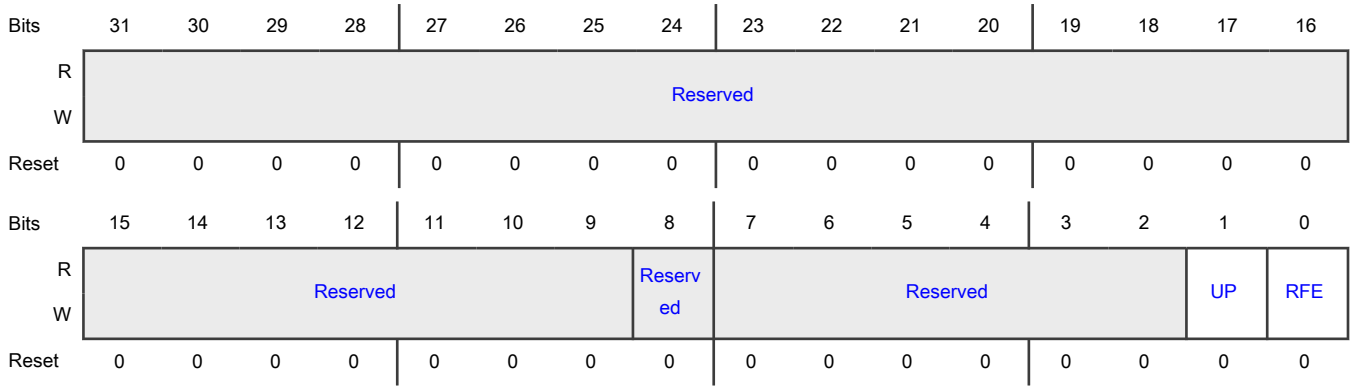
78.17.27 MAC Receive Flow Control (MAC_Rx_Flow_Ctrl)

Offset

Register	Offset
MAC_Rx_Flow_Ctrl	90h

Function
Controls the pausing of MAC transmit based on the received pause packet.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 —	Reserved
7-2 —	Reserved
1 UP	Unicast Pause Packet Detect Indicates whether the unicast pause packet is enabled or disabled. A pause packet is processed when it has the unique multicast address specified in IEEE 802.3. • If this field is 1, MAC can detect pause packets with a unicast address of the station. This address must comply with the specifications in MAC Address 0 High (MAC_Address0_High) and MAC Address 0 Low (MAC_Address0_Low). • If this field is 0, MAC only detects pause packets with a unique multicast address.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE MAC does not process a pause packet if the multicast address is different from the unique multicast address. This applies to the received PFC packet if PFC is enabled. The unique multicast address (01_80_C2_00_00_01h) complies with the IEEE 802.1 Qbb-2011 specifications. 0b - Disabled 1b - Enabled
0 RFE	Receive Flow Control Enable Indicates whether the receive flow control is enabled or disabled. • If this field is 1 and MAC is operating in Full-Duplex mode, MAC decodes the received pause packet and disables its transmitter for a specified (pause) time. • If this field is 0 or if MAC is operating in Half-Duplex mode, the decode function of the pause packet disables. When PFC is enabled, the flow control for PFC packets is enabled too. MAC decodes the received PFC packet and disables the transmit queue, with matching priorities, for a duration of the received pause time. 0b - Disabled 1b - Enabled

78.17.28 MAC RxQ Control 4 (MAC_RxQ_Ctrl4)

Offset

Register	Offset
MAC_RxQ_Ctrl4	94h

Function
